`numlib::phi` returns the function call with evaluated arguments if the argument is not a number. Cf. “Example 2” on page 20-64.

Examples

Example 1

`numlib::phi` works on integers unequal zero:
numlib::phi(-7), numlib::phi(10)6, 4

```
6, 4
```

Example 2

`numlib::phi` is returned as a function call with evaluated argument:
x := a: numlib::phi(x)numlib::phi(a)

```
numlib::phi(a)
```

Parameters

`n`

Integer not equal to zero

Return Values

`numlib::phi` returns a positive integer, if the argument evaluates to an integer unequal zero. If the argument cannot be evaluate to a number, the function call with evaluated arguments is returned .

Overloaded By n

See Also numlib::invphi

numlib::pi

Purpose

Number of primes up to a given bound

Syntax

```
numlib::pi(x)
```

Description

`numlib::pi(x)` returns the number of primes not exceeding *x*.

If the argument `x` is a real number (an integer, rational, or floating-point number), then the number of primes below `x` is returned. If `x` is a complex number, `numlib::pi` stops with an error. For every other kind of arithmetical expression `x`, an unevaluated call is returned.

`numlib::pi` becomes slightly faster if the internal prime number table is large. `ifactor(PrimeLimit)` displays the limit of the internal prime number table; it can be set by the user via the command line flag `-L`.

Internally, a fast kernel function with constant memory consumption is used for the computation.

Examples

Example 1

There are two primes less or equal 3:
numlib::pi(3)2

```
2
```

Example 2

Also larger inputs can be handled fast:
numlib::pi(150000000)8444396

```
8444396
```

Example 3

Floating point arguments are allowed, too.
numlib::pi(28.72)9

```
9
```

Parameters

x

An arithmetical expression

Return Values

Non-negative integer or an unevaluated call to `numlib::pi`

Algorithms

A Lehmer-type algorithm is used, with no precomputed sieve array and no remember tables. In contrast to the algorithm in "Computing π: The Meissel-Lehmer method", this means constant memory consumption, at the price of slowness.

References

[1] Lagarias, J.C., V.S. Miller, and A.M. Odlyzko. "Computing π: The Meissel-Lehmer method", Math. Comp., Vol. 44, No. 170 (1985), pp. 537-560

isprimeithprimenextprimeprevprime

numlib::pollard

Purpose

Pollard's rho factorization algorithm

Syntax

```
numlib::pollard(n, <m>)
```

Description

`numlib::pollard` returns either `n` if `n` is said to be prime by `isprime`, or `g,n/g` if a factor `g` was found. If after `m` iterations still no factor has been found, `FAIL` is returned.

Please note that the algorithm is not deterministic, thus two calls with the same arguments may give different results.

Examples

Example 1

10000000019 is a prime number, so `numlib::pollard` simply returns it:
numlib::pollard(10000000019)10000000019

```
10000000019
```

The default of 10000 iterations is insufficient to factor the following number:
numlib::pollard(27821843008528973480664295 3)FAIL

```
FAIL
```

Using 100000 iterations, `numlib::pollard` does find a factorisation:
numlib::pollard(27821843008528973480664295 3,10^5)3486784409, 79792266297612017

```
3486784409, 79792266297612017
```

Parameters

n

m

Positive integers

Return Values `numlib::pollard` returns `n`, a sequence of two factors, or `FAIL`.

See Also ifactornumlib::ecmnumlib::mpqs

numlib::proveprime

Purpose

Primality proving using elliptic curves

Syntax

```
numlib::proveprime(n)
```

Description

`numlib::proveprime(n)` tests whether `n` is a prime. Unlike isprime, `numlib::proveprime` always returns a correct answer.

`numlib::proveprime` may simply return `TRUE` or `FALSE`.

`numlib::proveprime` may return `FAIL` to indicate that the input is prime with high probability, but no proof could be found.

`numlib::proveprime` may also return a list or a sequence of lists containing a proof for the primality of `n`.

If `numlib::proveprime` manages to prove that `n` is a prime, it returns a primality certificate. A primality certificate is a sequence of lists of the form $[N, D, l_m, a, b, x, y, l_s]$ where N is a pseudo-prime, D is an integer (fundamental discriminant), l_m is a list of prime factors, a, b, x, y are integers modulo N, and l_s is another list of prime factors (subset of the factors in l_m).

Each primality certificate produced by `numlib::proveprime` can be checked by the function numlib::checkPrimalityCertificate.

Some information about the steps of the proof and checking can be obtained by using the function setuserinfo (see “Example 3” on page 20-72).

A particular domain `numlib::Ecpp` contains three parameters that control the algorithm:

- `Ecpp::maxit` (default 10000) is the maximal number of iterations in Pollard’s rho factorization method.
- `Ecpp::maxh` (default 17) is an integer that controls the number of possibilities tried at each level of the algorithm [in technical words, it is the maximum value of the order $h(-D)$].

- `Ecpp::B` (default 1000) controls the size of the numbers to check. If `n<=Ecpp::B`, the program simply calls isprime to check if `n` is prime. In this case the program returns either `TRUE` or `FALSE`. The integer `Ecpp::B` should be at least 11, because the algorithm used does not work for n=2, 3, 5, 7 or 11.

Increasing `Ecpp::maxit` or `Ecpp::maxh` will make the algorithm more powerful, but slower.

Environment Interactions

`numlib::proveprime` depends on the current settings in `numlib::Ecpp`, see below.

Examples

Example 1

Proving that 10007 is prime can be reduced to proving that 317 is prime. The primality of 317 is known because 317 is sufficiently small.
numlib::proveprime(10007)[10007, 7, [2, 2, 2, 2, 613], 3016, 8682, 1, 1234, [613]]

[10007, 7, [2, 2, 2, 2, 613], 3016, 8682, 1, 1234, [613]]

Example 2

Normally, the primality of the input is reduced to the primality of a smaller integer, the primality of that integer is reduced to the primality of an even smaller integer, and so on.
numlib::proveprime(1048583)[1048583, 7, [2, 2, 2, 130817], 665765, 793371, 1, 44804, [130817]], [130817, 7, [2, 2, 7, 4663], 26992, 105206, 0, 75747, [4663]], [4663, 7, [2, 2, 2, 599], 4587, 3058, 0, 2288, [599]]

[1048583, 7, [2, 2, 2, 130817], 665765, 793371, 1, 44804, [130817]], [130817, 7, [2, 2, 7, 4663

numlib::checkPrimalityCertificate can be used to check the result:
numlib::checkPrimalityCertificate(%)TRUE

[4663, 7, [2, 2, 2, 599], 4587, 3058, 0, 2288, [599]]

TRUE

Example 3

Use setuserinfo to get more detailed information: setuserinfo(Any,1): numlib::proveprime(1048583)Info: found next candidate: 130817 Info: found next candidate: 4663 Info: s not large enough, 7 <= 85.81325096 Info: found next candidate: 599 [1048583, 7, [2, 2, 2, 130817], 665765, 793371, 1, 44804, [130817]], [130817, 7, [2, 2, 7, 4663], 26992, 105206, 0, 75747, [4663]], [4663, 7, [2, 2, 2, 599], 4587, 3058, 0, 2288, [599]]

[1048583, 7, [2, 2, 2, 130817], 665765, 793371, 1, 44804, [130817]], [130817, 7, [2, 2, 7, 4663], 26

numlib::checkPrimalityCertificate(%)Info: 1048583 is prime if 130817 is prime Info: 130817 is prime if 4663 is prime Info: 4663 is prime if 599 is prime TRUE

[4663, 7, [2, 2, 2, 599], 4587, 3058, 0, 2288, [599]]

TRUE

Parameters

n

Positive integer

Return Values

TRUE, FALSE, FAIL, or a list or sequence of lists.

References

This function implements the algorithm described in “Elliptic curves and primality proving”, by A. O. Atkin and F. Morain, Mathematics of Computation, volume 61, number 203, 1993.

ifactorisprimeithprimenextprimeprevprime

numlib::primedivisors

Purpose

Prime factors of an integer

Syntax

```
numlib::primedivisors(n)
```

Description

`numlib::primedivisors(n)` returns a list containing the different prime divisors of the integer `n`.

If `a` is a non-zero integer then, `numlib::primedivisors(a)` returns the sorted list of the different prime divisors of `a`.

`numlib::primedivisors(0)` returns `[0]`.

`numlib::primedivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::primedivisors` returns an error if the argument evaluates to a number of wrong type.

Examples

Example 1

We compute the list of prime divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):
numlib::primedivisors(6746328388800)[2, 3, 5, 7, 11, 13, 17, 19, 23]

```
[2, 3, 5, 7, 11, 13, 17, 19, 23]
```

Parameters

`n`

An integer

Return Values

`numlib::primedivisors(n)` returns a list of nonnegative integers.

Algorithms

Internally, ifactor is used for factoring `n`.

See Also

ifactorisprimenumlib::divisorsnumlib::numdivisorsnumlib::numprimedivisorsnumlib::prov

numlib::primroot

Purpose

Primitive roots

Syntax

```
numlib::primroot(m)
numlib::primroot(a, m)
```

Description

`numlib::primroot(m)` returns the least positive primitive root modulo `m` if there exist primitive roots modulo `m`.

`numlib::primroot(a, m)` returns the least primitive root modulo `m` not smaller than `a` if there exist primitive roots modulo `m`.

Examples

Example 1

We compute the least positive primitive root modulo the prime number 40487:
numlib::primroot(40487)5

```
5
```

Example 2

We compute the least primitive root modulo $40487^2 = 1639197169$:
numlib::primroot(1639197169)10

```
10
```

Example 3

Now we compute least primitive root modulo 40487 which is >=111111111:
numlib::primroot(111111111,40487)111111116

```
111111116
```

Example 4

There are no primitive roots modulo 324013370:

```
numlib::primroot(324013370)FAIL
```

FAIL

Parameters

a

An integer

m

A natural number

Return Values

`numlib::primroot` returns an integer or FAIL.

Algorithms

`numlib::primroot` uses ifactor.

See Also

numlib::order

numlib::reconstructRational

Purpose

Reconstruct a rational number from its image modulo N

Syntax

```
numlib::reconstructRational(a, n)
```

Description

`numlib::reconstructRational(a, n)` returns two integers `p, q` of absolute value smaller than `sqrt(n/2)` with `p` congruent to `a*q` modulo `n`, or FAIL if such `p, q` do not exist.

`numlib::reconstructRational(a, n)` returns `p, q` solving equivMod(p, a*q,n)$p = a\,q \pmod{n}$. However, `p/q mod n` equals `a` only if `p` and `q` are relatively prime.

The solution `p, q` satisfies the following conditions: `p` is strictly between `-sqrt(n/2)` and `sqrt(n/2)`, `q` is strictly between `0` and `sqrt(n/2)`.

Several pairs `p, q` satisfying these conditions may exist, in which case their ratios `p/q` are all the same; then the smallest of them is returned.

Examples

Example 1

We want to solve equivMod(p, 7*q, 12)$p = 7\,q \pmod{12}$:
numlib::reconstructRational(7, 12)2, 2

```
2, 2
```

Modulo 98, the same congruence has no small solution. The solution `p=7, q=1` is not small enough as `7` is not smaller than `sqrt(98/2)` but just equal.
numlib::reconstructRational(7, 98)FAIL

```
FAIL
```

Example 2

Rational number reconstruction is mostly used as the last step of a modular algorithm. Let us compute the gcd of the following polynomials:

f:= poly(x^5 + 22/35*x^3 + 3/8*x^2 + 3/35*x + 9/56, [x]): g:= poly(x^5 + 2/5*x^4 + 22/35*x^3 + 153/280*x^2 + 3/35*x + 9/56, [x]):

Of course, the function gcd is able to do this. However, suppose we know that for some reason that the gcd has small coefficients with numerator and denominator both smaller than 10. Then we can use a modular algorithm with a smaller modulus than gcd would do: to be able to reconstruct these from their residue class modulo n, it is sufficient that sqrt(n/2) > 10 $\sqrt{\frac{n}{2}} > 10$, e.g., n=211.
gcd(poly(f, IntMod(211)), poly(g, IntMod(211)))poly(x^2 - 90, [x], IntMod(211))

$$\text{poly}\left(x^2 - 90, [x], \text{IntMod}(211)\right)$$

Rational number reconstruction shows that the constant coefficient must be 3/7:
numlib::reconstructRational(-90, 211)3, 7

$$3, 7$$

This is true indeed:
gcd(f,g)poly(x^2 + 3/7, [x])

$$\text{poly}\left(x^2 + \frac{3}{7}, [x]\right)$$

Parameters

a

Integer

n

A positive integer

Return Values

Sequence consisting of an integer and a positive integer; or FAIL

The algorithm may be found in Davenport/Siret/Tournier, Computer algebra, p. 142.

See Also

numlib::lincongruence

numlib::sigma

Purpose

Sum of divisors of an integer

Syntax

```
numlib::sigma(n)
numlib::sigma(n, k)
```

Description

`numlib::sigma(n)` returns the sum of the positive divisors of `n`.

`numlib::sigma(n, k)` returns the sum of the `k`-th powers of the positive divisors of `n`.

`numlib::sigma(0)` returns `0`.

`numlib::sigma` returns the function call with evaluated argument if at least one argument is not a number.

`numlib::sigma` returns an error if one of its arguments evaluates to a number of wrong type.

`numlib::sigma(n,0)` is the same as numlib::numdivisors`(n)` and `numlib::tau(n)`.

`numlib::sigma(n,1)` is the same function as numlib::sumdivisors`(n)` and `numlib::sigma(n)`.

Examples

Example 1

The sum of the positive divisors of 120 is 360:
numlib::sigma(120)360

```
360
```

Example 2

The sum of the fifth powers of the positive divisors of 120 is 25799815800:
numlib::sigma(120,5)25799815800

```
25799815800
```

Parameters

n

An integer

k

A nonnegative integer

Return Values

`numlib::sigma` returns an integer.

Algorithms

Internally, ifactor is used for factoring `n`.

See Also

numlib::divisorsnumlib::numdivisors

numlib::sqrt2cfrac

Purpose

Continued fraction expansion of square roots

Syntax

```
numlib::sqrt2cfrac(a)
```

Description

`numlib::sqrt2cfrac(a)` returns the continued fraction expansion of the square root of `a` as a sequence of two lists: the first one contains the non-periodic (integer) part, the second one contains the periodic part of the expansion.

Examples

Example 1

The square root of 87 can be written as 9 + q, where q is a number satisfying $q=\frac{1}{3+\frac{1}{18+q}}$:

```
numlib::sqrt2cfrac(87)[9], [3, 18]
```

```
[9], [3, 18]
```

Example 2

Since 81 is a perfect square, there is no periodic part in the continued fraction expansion of its square root:

```
numlib::sqrt2cfrac(81)[9]
```

```
[9]
```

Parameters

`a`

A positive integer

Return Values

If `a` is a perfect square, `numlib::sqrt2cfrac` returns a list with one entry; otherwise `numlib::sqrt2cfrac` returns a sequence of two lists, the first consisting of one integer, the second consisting of one or more integers.

See Also numlib::contfrac

numlib::sqrtmodp

Purpose

Square root of a quadratic residue modulo a prime

Syntax

```
numlib::sqrtmodp(a, p)
```

Description

`numlib::sqrtmodp(a, p)` computes a solution x to the congruence equivMod(x^2, a, p)$x^2 = a \pmod{p}$.

`numlib::sqrtmodp(a, p)` computes an integer x that satisfies equivMod(x^2, a, p)$x^2 = a \pmod{p}$.

`a` must be a quadratic residue modulo `p`, and `p` must be a prime. This is not checked! Unless this is known to be the case, numlib::msqrts must be used. On the other hand, `numlib::sqrtmodp` is faster than numlib::msqrts.

Examples

Example 1

One square root of 132132 modulo 3231227 is 3012020: numlib::sqrtmodp(132132,3231227)3012020

```
3012020
```

Parameters

a

An integer

p

A prime unequal to 2

Return Values

`numlib::sqrtmodp` returns an integer.

Algorithms

`numlib::sqrtmodp` uses D. Shanks' algorithm RESSOL.

See Also

numlib::msqrts

numlib::sumdivisors

Purpose

Sum of divisors of an integer

Syntax

```
numlib::sumdivisors(n)
```

Description

`numlib::sumdivisors(n)` returns the sum of the positive divisors of the integer `n`.

`numlib::sumdivisors(0)` returns `0`.

`numlib::sumdivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::sumdivisors` returns an error if the argument evaluates to a number of wrong type.

`numlib::sumdivisors(n)` is the same as numlib::sigma`(n, 1)`.

Examples

Example 1

The sum of the positive divisors of 120 is 360:
numlib::sumdivisors(120)360

```
360
```

Example 2

The sum of the positive divisors of - 63 is 104:
numlib::sumdivisors(-63)104

```
104
```

Parameters

`n`

An integer

Return Values

`numlib::sumdivisors(n)` returns a nonnegative integer.

Algorithms Internally, ifactor is used for factoring n.

See Also numlib::sigmanumlib::divisorsnumlib::numdivisors

numlib::sumOfDigits

Purpose

Sum of digits of an integer

Syntax

```
numlib::sumOfDigits(n, <base>)
```

Description

`numlib::sumOfDigits(n, base)` computes the sum of digits of `n` in the given base `base`); if the base is not given, it defaults to 10.

The sum of digits may be larger than the base. For certain purposes (testing divisibility by b - 1, where b is the base), it may be useful to apply `numlib::sumOfDigits` over and over to the result. This is not done automatically. See “Example 2” on page 20-86.

Examples

Example 1

We compute the decimal and the binary sum of digits of 11: numlib::sumOfDigits(11), numlib::sumOfDigits(11, 2)2, 3

```
2, 3
```

Example 2

We want to test whether 9 divides a given number, using the school method:
n:= 24373463462374324: repeat n:= numlib::sumOfDigits(n); print(n) until n < 10 end: delete n:67

```
67
```

13

```
13
```

4

```
4
```

This only makes sense for demonstration purposes, as the following command achieves the same but much faster:

24373463462374324 mod 94

4

Parameters

n

Non-negative integer

base

Integer greater than one

Return Values

Non-negative integer

See Also

numlib::g_adic

numlib::tau

Purpose

Number of divisors of an integer

Syntax

```
numlib::tau(n)
```

Description

`numlib::tau(n)` returns the number of positive divisors of `n`.

`numlib::tau(0)` returns `0`.

`numlib::tau` returns the function call with evaluated argument if the argument is not a number.

`numlib::tau` returns an error if the argument evaluates to a number of wrong type.

`numlib::tau` is the same function as `numlib::numdivisors`.

Examples

Example 1

We compute the number of positive divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):
numlib::tau(6746328388800)10080

```
10080
```

Parameters

`n`

An integer

Return Values

`numlib::tau` returns a nonnegative integer.

Algorithms

Internally, ifactor is used for factoring `n`.

See Also

numlib::divisorsnumlib::numprimedivisorsnumlib::primedivisors

numlib::toAscii

Purpose

ASCII encoding of a string

Syntax

```
numlib::toAscii(s)
```

Description

`numlib::toAscii(s)` returns the list of ASCII codes of the characters in the string `s`.

`numlib::toAscii` returns an error if its argument is not a string.

Examples

Example 1

The ASCII coding of a well-known name:

```
numlib::toAscii("MuPAD - Multi Processing Algebra Data Tool")
```

```
[77, 117, 80, 65, 68, 32, 45, 32, 77, 117, 108, 116, 105, 32, 80, 114, 111, 99, 101, 115, 115, 105, 110, 103, 32, 65, 108, 103, 101, 98, 114, 97, 32, 68, 97, 116, 97, 32, 84, 111, 111, 108]
```

and the ASCII coding of an empty string:

```
numlib::toAscii("")
```

```
[]
```

Parameters

`s`

A string

Return Values

`numlib::toAscii(s)` returns a list of nonnegative integers.

See Also

numlib::fromAscii

21

ode – Ordinary Differential Equations

==REFNAME==

ode::companionSystem

Purpose

Companion matrix of a linear homogeneous ordinary differential equation

Syntax

```
ode::companionSystem(Ly, y(x), <R>)
```

Description

`ode::companionSystem(Ly, y(x))` returns the companion matrix associated to `Ly`. If the optional argument `R` is given, the elements of the matrix are in `R`.

Examples

Example 1

We compute the companion matrix of the following differential equation:

```
Ly  :=
4*x^2*diff(y(x),x$3)+diff(y(x),x$2)+4*x*diff(y(x),x)-y(x)4*x*diff(y(x), x) -
y(x) + 4*x^2*diff(y(x), x, x, x) + diff(y(x), x, x)
```

$$4\,x\,\frac{\partial}{\partial x}\,y(x) - y(x) + 4\,x^2\,\frac{\partial^3}{\partial x^3}\,y(x) + \frac{\partial^2}{\partial x^2}\,y(x)$$

```
ode::companionSystem(Ly,
y(x))Dom::Matrix(Dom::ExpressionField(normal, iszero@normal))([[0,
1, 0], [0, 0, 1], [1/(4*x^2), -1/x, -1/(4*x^2)]])
```

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{1}{4\,x^2} & -\frac{1}{x} & -\frac{1}{4\,x^2} \end{pmatrix}$$

Parameters

Ly

A linear homogeneous ordinary differential equation.

y(x)

The dependent function of `Ly`.

R

A field of functions or numbers of characteristic zero, default is `Dom::ExpressionField(normal)`.

Return Values

Object of type Dom::Matrix.

ode::cyclicVector

Purpose

Transforms a linear differential system to an equivalent linear differential system with a companion matrix.

Syntax

```
ode::cyclicVector(A, x, <v>)
```

Description

`ode::cyclicVector(A, x, v)` converts a first order homogeneous differential system Y'=AY$Y' = AY$ into a corresponding first order homogeneous differential system Z'=BZ$Z' = BZ$, where `B` is a companion matrix, by substituting $Z = PY$ using the potential cyclic vector `v`. If `v` is not cyclic then an empty list is returned otherwise a list is returned whose first element is a list corresponding to the last row of `B` and second element is the invertible matrix `P`.

When the optional argument `v` is not given then the vector `[1,0,...,0]` is tested. If it is not cyclic then a suitable one is determined randomly by the procedure.

Examples

Example 1

We compute a differential system equivalent to the following differential system:
A := matrix([[x^2-1,1,0], [0,x^2+5*x+1/3,1], [0,0,2]])matrix([[x^2 - 1, 1, 0], [0, x^2 + 5*x + 1/3, 1], [0, 0, 2]])

$$\begin{pmatrix} x^2-1 & 1 & 0 \\ 0 & x^2+5x+\frac{1}{3} & 1 \\ 0 & 0 & 2 \end{pmatrix}$$

ode::cyclicVector(A, x)[[2*x^4 + 6*x^3 - (49*x^2)/3 - (38*x)/3 + 19/3, - x^4 - 5*x^3 - (10*x^2)/3 + x + 20/3, 2*x^2 + 5*x + 4/3], Dom::Matrix(Dom::ExpressionField(normal, iszero@normal))([[1, 0, 0], [x^2 - 1, 1, 0], [2*x - 2*x^2 + x^4 + 1, 5*x + 2*x^2 - 2/3, 1]])]

$$\left[\left[2x^4+6x^3-\frac{49x^2}{3}-\frac{38x}{3}+\frac{19}{3},\ -x^4-5x^3-\frac{10x^2}{3}+x+\frac{20}{3},\ 2x^2+5x+\frac{4}{3}\right],\ \begin{pmatrix}1\\ x^2-1\\ 2x-2x^2+x^4+\end{pmatrix}\right.$$

So `[1,0,0]` is a cyclic vector; `[x,0,0]` is also a cyclic vector:

```
l := ode::cyclicVector(A, x, [x,0,0])[[(6*x^7 + 21*x^6 - 34*x^5 - 28*x^4
+ 28*x^3 + 10*x^2 + 8*x + 18)/(3*x^3), -(3*x^6 + 15*x^5 + 10*x^4 +
9*x^3 + 10*x^2 + 8*x + 18)/(3*x^2), (6*x^3 + 15*x^2 + 4*x + 9)/(3*x)],
Dom::Matrix(Dom::ExpressionField(normal, iszero@normal))([[x, 0, 0],
[- x + x^3 + 1, x, 0], [x + 4*x^2 - 2*x^3 + x^5 - 2, - (2*x)/3 + 5*x^2 +
2*x^3 + 2, x]])]
```

$$\left[\left[\frac{6x^7+21x^6-34x^5-28x^4+28x^3+10x^2+8x+18}{3x^3},\ -\frac{3x^6+15x^5+10x^4+9x^3+10x^2+8x}{3x^2}\right.\right.$$

And we can build easily a linear homogeneous differential equation associated to it (c.f. ode::mkODE):

```
-ode::mkODE(l[1].[-1], y, x)((3*x^6 + 15*x^5 + 10*x^4 + 9*x^3 + 10*x^2
+ 8*x + 18)*diff(y(x), x))/(3*x^2) - ((6*x^3 + 15*x^2 + 4*x + 9)*diff(y(x),
x, x))/(3*x) - (y(x)*(6*x^7 + 21*x^6 - 34*x^5 - 28*x^4 + 28*x^3 + 10*x^2
+ 8*x + 18))/(3*x^3) + diff(y(x), x, x, x)
```

$$\left.\left.\begin{pmatrix}x & 0 & 0\\ x^3-1 & 1 & 0\\ x+4x^2-2x^3+x^5-2 & -\frac{2x}{3}+5x^2+2x^3+2 & x\end{pmatrix}\right]\right.$$

$$\frac{(3x^6+15x^5+10x^4+9x^3+10x^2+8x+18)\,\frac{\partial}{\partial x}y(x)}{3x^2}-\frac{(6x^3+15x^2+4x+9)\,\frac{\partial^2}{\partial x^2}y(x)}{3x}$$

$$-\frac{y(x)\,(6x^7+21x^6-34x^5-28x^4+28x^3+10x^2+8x+18)}{3x^3}+\frac{\partial^3}{\partial x^3}y(x)$$

Parameters

A

A square matrix of type Dom::Matrix.

x

The independent variable.

v

A list of size the dimension of `A`, default is `[1,0,...,0]`.

Return Values

List, possibly empty, of two lists.

See Also

ode::scalarEquation

ode::dAlembert

Purpose

D'Alembert reduction of a linear homogeneous ordinary differential equation

Syntax

```
ode::dAlembert(Ly, y(x), v)
```

Description

`ode::dAlembert(Ly, y(x), v)` returns the reduced differential equation of `Ly` using the method of reduction of d'Alembert and the function `v`. If `v` is a solution of `Ly` and `u` is a solution of the reduced differential equation then $v \ tu$ is another solution of `Ly`.

Examples

Example 1

Consider the following differential equation:
Ly := 2/x^3*y(x)-2/x^2*diff(y(x),x)+1/x*diff(y(x),x$2)+ diff(y(x),x$3)(2*y(x))/x^3 - (2*diff(y(x), x))/x^2 + diff(y(x), x, x)/x + diff(y(x), x, x, x)

$$\frac{2\,y(x)}{x^3} - \frac{2\,\frac{\partial}{\partial x}y(x)}{x^2} + \frac{\frac{\partial^2}{\partial x^2}y(x)}{x} + \frac{\partial^3}{\partial x^3}y(x)$$

We easily check that `x` is a particular solution of `Ly`:
ode::evalOde(Ly, y(x)=x)0

$$0$$

Then we reduce the equation `Ly` using this special solution:
R := ode::dAlembert(Ly, y(x), x)(4*diff(y(x), x))/x + diff(y(x), x, x)

$$\frac{4\,\frac{\partial}{\partial x}y(x)}{x} + \frac{\partial^2}{\partial x^2}y(x)$$

The solutions of the equation `R` are not too hard to find:
ode::evalOde(R, y(x)=1), ode::evalOde(R, y(x)=1/x^3)0, 0

0, 0

So a basis of solutions of `Ly` is therefore {x, x*hold(int)(1,x)=x^2, x*hold(int)(1/x^3,x)=-(1)/(2 * x)}$\left\{x,\ x\ \mathrm{hold}(\mathrm{int})(1,\ x) = x^2,\ x\ \mathrm{hold}(\mathrm{int})\left(\frac{1}{x^3},\ x\right) = -\frac{1}{2\,x}\right\}$ which can be checked directly:

```
ode::solve(Ly, y(x)){C4/x - (x*(C3 + 2*C2*x))/6}
```

$$\left\{\frac{C4}{x} - \frac{x\,(C3 + 2\,C2\,x)}{6}\right\}$$

Parameters

`Ly`

A homogeneous linear differential equation.

`y(x)`

The dependent function of `Ly`.

`v`

An expression.

Return Values

Expression.

ode::evalOde

Purpose

Applies an expression at a linear ordinary differential equation

Syntax

```
ode::evalOde(Ly, y(x))
```

Description

`ode::evalOde(Ly, y(x) = v)` evaluates `Ly` replacing `y(x)` by `v` and simplifying the result. This can be useful to check a solution candidate, for example.

Examples

Example 1

We evaluate the following differential equation for various expressions:
Ly := (x^2+1)*diff(y(x),x$2)+x*diff(y(x),x)-4*y(x)(x^2 + 1)*diff(y(x), x, x) + x*diff(y(x), x) - 4*y(x)

$$(x^2+1)\frac{\partial^2}{\partial x^2}y(x)+x\frac{\partial}{\partial x}y(x)-4\,y(x)$$

ode::evalOde(Ly, y(x) = 2*x^2+1), ode::evalOde(Ly, y(x) = exp(x)), ode::evalOde(Ly, y(x) = RootOf(Z^3+x*Z+1, Z))0, x^2*exp(x) - 3*exp(x) + x*exp(x), - 18*Z^2*x^4 - 54*Z^2*x^2 + 243*Z^2*x - 60*Z*x^6 - 4*Z*x^4 - 756*Z*x^3 + 54*Z*x - 2916*Z - 12*x^5 - 36*x^3 + 162*x^2

$$0,\ x^2 e^x - 3 e^x + x e^x,\ -18 Z^2 x^4 - 54 Z^2 x^2 + 243 Z^2 x - 60 Z x^6 - 4 Z x^4 - 756 Z x^3 + 54 Z x - 2916 Z$$

Parameters

Ly

A linear ordinary differential equation.

y(x)

The dependent function of `Ly`.

v

An expression.

Return Values

Expression.

ode::exponentialSolutions

Purpose

Exponential solutions of a homogeneous linear ordinary differential equation

Syntax

```
ode::exponentialSolutions(Ly, y(x), <Generic>)
```

Description

`ode::exponentialSolutions(Ly, y(x))` returns a fundamental set of the exponential solutions of `Ly`, i.e. solutions `z` such that (z')/(z) is a rational function of `x`. When the option `Generic` is given, a generic form of them is returned.

Note `ode::exponentialSolutions` does not return any eventual solution that is exponential over the algebraic closure of (*x*) but not over (*x*).

Examples

Example 1

We compute the exponential solutions of the following differential equation :

Ly:=diff(y(x),x$4)-2*x*diff(y(x),x$3)+(-x+x^2-5)*diff(y(x),x$2)+(4*x+2*x^2)*diff(y(x),x)+(2+x-x^3)*y(x)diff(y(x), x, x, x, x) - 2*x*diff(y(x), x, x, x) - (- x^2 + x + 5)*diff(y(x), x, x) + (2*x^2 + 4*x)*diff(y(x), x) + y(x)*(- x^3 + x + 2)

$$\frac{\partial^4}{\partial x^4} y(x) - 2\,x\,\frac{\partial^3}{\partial x^3} y(x) - \left(-x^2 + x + 5\right)\frac{\partial^2}{\partial x^2} y(x) + \left(2\,x^2 + 4\,x\right)\frac{\partial}{\partial x} y(x) + y(x)\left(-x^3 + x + 2\right)$$

ode::exponentialSolutions(Ly, y(x)), ode::exponentialSolutions(Ly, y(x), Generic){exp(x^2/2), x*exp(x^2/2)}, C2*exp(x^2/2) + C1*x*exp(x^2/2)

$$\left\{e^{\frac{x^2}{2}},\ x\,e^{\frac{x^2}{2}}\right\},\ C2\,e^{\frac{x^2}{2}} + C1\,x\,e^{\frac{x^2}{2}}$$

Example 2

No exponential solution over the algebraic closure of (*x*) is returned:
ode::exponentialSolutions(diff(y(x),x$2)+y(x), y(x)){}

∅

whereas {e^(ix), e^(-ix)} $\left\{ e^{ix}, \frac{1}{e^{ix}} \right\}$ is a basis of solutions of the above differential equation.

Parameters

Ly

A homogeneous linear ordinary differential equation with coefficients in the field (*x*) of rational functions over the rationals.

y(x)

The dependent function of `Ly`.

Return Values

set, possibly empty, of functions or an expression.

ode::exponents

Purpose

Exponents of a linear ordinary differential equation

Syntax

```
ode::exponents(Ly, y(x), p)
```

Description

`ode::exponents` returns the set of exponents of a homogeneous linear differential equation at a given point.

`ode::exponents(Ly, y(x), p)` returns the set of (local) exponents of `Ly` at the place `p`. If the place is infinity then one uses $1/x$ instead. They are defined as roots (in an algebraic closure of (x)) of the indicial equation (c.f. ode::indicialEquation) of `Ly` so the set of exponents may be empty, see “Example 2” on page 21-14.

Examples

Example 1

We compute the exponents of the following differential equation at the regular point `0` and at the singular points `-1` and *infinity*:

```
Ly := diff(y(x),x$2)+4/(x+1)*diff(y(x),x)+2/(x+1)^2*y(x)(4*diff(y(x), x))/(x
+ 1) + (2*y(x))/(x + 1)^2 + diff(y(x), x, x)
```

$$\frac{4\,\frac{\partial}{\partial x}y(x)}{x+1}+\frac{2\,y(x)}{(x+1)^2}+\frac{\partial^2}{\partial x^2}y(x)$$

```
ode::exponents(Ly, y(x), x){0, 1}
```

$$\{0,\ 1\}$$

```
ode::exponents(Ly, y(x), x+1){-2, -1}
```

$$\{-2,\ -1\}$$

```
ode::exponents(Ly, y(x), 1/x){1, 2}
```

$$\{1,\ 2\}$$

Example 2

It may happen that at a place the set of exponents is empty; this corresponds to an irregular singular point:
Ly := (2*x+4)*diff(y(x),x)/(2*x+x^2-2)-2*y(x)/(2*x+x^2-2)-(4*x+x^2)/(2*x+x^2-2)*diff(y(x),x$2)+diff(y(x),x$3)((2*x + 4)*diff(y(x), x))/(x^2 + 2*x - 2) - ((x^2 + 4*x)*diff(y(x), x, x))/(x^2 + 2*x - 2) - (2*y(x))/(x^2 + 2*x - 2) + diff(y(x), x, x, x)

$$\frac{(2x+4)\,\frac{\partial}{\partial x}y(x)}{x^2+2x-2}-\frac{(x^2+4x)\,\frac{\partial^2}{\partial x^2}y(x)}{x^2+2x-2}-\frac{2\,y(x)}{x^2+2x-2}+\frac{\partial^3}{\partial x^3}y(x)$$

ode::exponents(Ly, y(x), 1/x){}

$$\varnothing$$

ode::exponents(Ly, y(x), x^2+2*x-2){0, 1, 3}

$$\{0, 1, 3\}$$

Parameters

Ly

A homogeneous linear differential equation over (x).

y(x)

The dependent function of `Ly`.

p

An irreducible polynomial in `x` or `1/x`.

Return Values

set, possibly empty.

See Also

ode::indicialEquationode::isFuchsian

ode::getOrder

Purpose

Order of an ordinary differential equation

Syntax

```
ode::getOrder(Ly, y(x))
```

Description

`ode::getOrder(Ly, y(x))` returns the order of `Ly` for the dependent function `y(x)`, i.e. the highest degree of derivative of `Ly`.

Examples

Example 1

We can compute orders for linear and nonlinear ordinary differential equations:
ode::getOrder(diff(y(x),x$2)-x*y(x)-airyAi(x), y(x))2

$$2$$

ode::getOrder(y(x)*diff(y(x),x$3)^2-exp(y(x)), y(x))3

$$3$$

ode::getOrder(y(x)*diff(y(x),x$3)^2-exp(y(x)), z(x))-infinity

$$-\infty$$

Parameters

Ly

An ordinary differential equation.

y(x)

The dependent function of `Ly`.

Return Values

Either `-infinity` or a positive integer.

ode::indicialEquation

Purpose

Indicial equation of a linear ordinary differential equation

Syntax

```
ode::indicialEquation(Ly, y(x), p, u)
```

Description

`ode::indicialEquation(Ly, y(x), p, u)` returns the indicial equation in the variable `u` of `Ly` at the place `p`. If the place is infinity then one uses (1)/(x)$\frac{1}{x}$ instead. The result if `FAIL` if the place corresponds to an irregular singular point of `Ly`.

Examples

Example 1

We compute the indicial equations of the following differential equation at the regular point `1` and at the singular points `0` and *infinity*:

```
Ly := 1/x^3*y(x)*(4*x-10)-1/x^2*(4*x^3-10)*diff(y(x),x)-
9/2/x*diff(y(x),x$2)+diff(y(x),x$3)(y(x)*(4*x - 10))/x^3 - (9*diff(y(x), x,
x))/(2*x) - ((4*x^3 - 10)*diff(y(x), x))/x^2 + diff(y(x), x, x, x)
```

$$\frac{y(x)\,(4\,x-10)}{x^3}-\frac{9\,\frac{\partial^2}{\partial x^2}\,y(x)}{2\,x}-\frac{(4\,x^3-10)\,\frac{\partial}{\partial x}\,y(x)}{x^2}+\frac{\partial^3}{\partial x^3}\,y(x)$$

```
ode::indicialEquation(Ly, y(x), x-1, U)U^3 - 3*U^2 + 2*U
```

$$U^3-3\,U^2+2\,U$$

```
ode::indicialEquation(Ly, y(x), 1/x, U)FAIL
```

```
FAIL
```

```
ode::indicialEquation(Ly, y(x), x, U)2*U^3 - 15*U^2 + 33*U - 20
```

$$2\,U^3-15\,U^2+33\,U-20$$

The roots of the indicial equation correspond to the (local) exponents:

```
solve(%, U), ode::exponents(Ly, y(x), x){1, 5/2, 4}, {1, 5/2, 4}
```

$$\left\{1, \frac{5}{2}, 4\right\}, \left\{1, \frac{5}{2}, 4\right\}$$

Parameters

Ly

A homogeneous linear differential equation over (*x*).

y(x)

The dependent function of `Ly`.

P

An irreducible polynomial in `x` or `1/x`.

u

An element of type DOM_IDENT.

Return Values

`FAIL` or a polynomial expression in `u`.

See Also

ode::indicialEquationode::isFuchsian

ode::isFuchsian

Purpose

Tests if a homogeneous linear ordinary differential equation is of Fuchsian type

Syntax

```
ode::isFuchsian(Ly, y(x), <AllExponents>)
```

Description

`ode::isFuchsian` returns `TRUE` if `Ly` is of Fuchsian type, i.e., all the singular points (including the point at infinity) of `Ly` are regular. It returns `FALSE` if at least one singular point is irregular. When the option `AllExponents` is given, either `FALSE` is returned or a list where each element is a table containing, at each regular singular point of `Ly` the place, the indicial equation and the exponents.

Examples

Example 1

We test if the following differential equation is Fuchsian:
Ly:=x*(1-x)*diff(y(x),x$2)+(1-x)*diff(y(x),x)+10*y(x)- x*(x - 1)*diff(y(x), x, x) - (x - 1)*diff(y(x), x) + 10*y(x)

$$-x\,(x-1)\,\frac{\partial^2}{\partial x^2}\,y(x)-(x-1)\,\frac{\partial}{\partial x}\,y(x)+10\,y(x)$$

ode::isFuchsian(Ly, y(x))TRUE

TRUE

We can have a look of the indicial equations, exponents at each regular singular point of `Ly`:
ode::isFuchsian(Ly, y(x), AllExponents)[table(place = x, indicialEq = X22^2, exponents = {0}), table(place = x - 1, indicialEq = - X22^2 + X22, exponents = {0, 1}), table(place = 1/x, indicialEq = - X22^2 + 10, exponents = {sqrt(10), -sqrt(10)})]

exponents	{0}	exponents	{0, 1}	exponents	$\{\sqrt{10}, -\sqrt{10}\}$
indicialEq	$X22 - X22^{2'}$	indicialEq	$X22 - X22^{2'}$	indicialEq	$-X22^2 + 10$
place	x	place	$x - 1$	place	$\frac{1}{x}$

Example 2

In this example, the Airy equation, the only singular point is at infinity and is irregular:
ode::isFuchsian(diff(y(x),x$2)-x*y(x), y(x))FALSE

FALSE

Parameters

Ly

A homogeneous linear ordinary differential equation with coefficients in the field (x) of rational functions over the rationals.

y(x)

The dependent function of `Ly`.

Options

AllExponents

Return a list of tables of indical equations and exponents for regular singular points.

Return Values

TRUE, FALSE or a list.

ode::isLODE

Purpose

Test for a linear ordinary differential equation

Syntax

```
ode::isLODE(Ly, y(x), <Homogeneous | HlodeOverRF |
Hlode | LodeOverRF | Lode>)
```

Description

`ode::isLODE(Ly, y(x))` returns `TRUE` if `Ly` is a linear ordinary differential equation in `y(x)`, `FALSE` otherwise. If an optional argument is given then the result is discussed as follows:

- `Homogeneous`: returns `TRUE` if `Ly` is homogeneous, `FALSE` otherwise.
- `HlodeOverRF`: returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is homogeneous with rational functions coefficients, `FALSE` otherwise.
- `Hlode`: returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is homogeneous, `FALSE` otherwise.
- `LodeOverRF`: returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` has rational functions coefficients, `FALSE` otherwise.
- `Lode`: returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is a linear ordinary differential equation, `FALSE` otherwise.

Examples

Example 1

We test the following differential equations:
ode::isLODE(y(x)^2+x^2*diff(y(x),x)+x, y(x))FALSE

```
FALSE
```

ode::isLODE(y(x)+x^2*diff(y(x),x)+x, y(x))TRUE

```
TRUE
```

ode::isLODE(y(x)+x^2*diff(y(x),x)+x, y(x), Hlode)FALSE

```
FALSE
```

```
ode::isLODE( y(x)+x^2*diff(y(x),x)+x*diff(y(x),x$2), y(x),
HlodeOverRF)y(x) + x^2*diff(y(x), x) + x*diff(y(x), x, x), y, x, 2
```

```
ode::isLODE( x+x^2*diff(y(x),x)+exp(x)*diff(y(x),x$2), y(x),
LodeOverRF)FALSE
```

FALSE

Parameters

Ly

An expression.

y(x)

The dependent function of `Ly`.

Return Values

Either `TRUE`, `FALSE` or a sequence of type _exprseq.

ode::mkODE

Purpose

Builds a linear homogeneous ordinary differential equation from a list of coefficient functions

Syntax

```
ode::mkODE(l, y, x)
```

Description

`ode::mkODE(l, y, x)` returns a linear homogeneous ordinary differential equation `Ly` in `y(x)` where the coefficients are the entries of the list `l`. The last element of the list `l` corresponds to the leading coefficients of `Ly`.

Examples

Example 1

We generate the linear ODE for `y(x)` with the coefficients `-1`, `4*x` and `4*x^2` of `y(x)`, `y'(x)` and `y''(x)`, respectively:

```
ode::mkODE([-1, 4*x, 4*x^2], y, x)
```

```
4*x^2*diff(y(x), x, x) - y(x) + 4*x*diff(y(x), x)
```

$$4\,x^2\,\frac{\partial^2}{\partial x^2}\,y(x) - y(x) + 4\,x\,\frac{\partial}{\partial x}\,y(x)$$

Parameters

l

A list of coefficient functions.

y

The dependent variable of the resulting differential equation.

x

The independent variable of the resulting differential equation.

Return Values

Expression.

ode::normalize

Purpose

Normalized form of a linear ordinary differential equation

Syntax

```
ode::normalize(Ly, y, x, n)
```

Description

`ode::normalize(Ly, y, x, n)` computes the normalized form of the `n`-th order linear ordinary differential equation `Ly`, i.e. whose leading coefficient (the coefficient of the highest derivative of `y(x)` in `Ly`) is 1.

Examples

Example 1

We normalize the following differential equation:
Ly:=-diff(y(x),x,x)/x+y(x)/4/x^3-diff(y(x),x)/x^2y(x)/(4*x^3) - diff(y(x), x)/x^2 - diff(y(x), x, x)/x

$$\frac{y(x)}{4\,x^3} - \frac{\frac{\partial}{\partial x}\,y(x)}{x^3} - \frac{\frac{\partial^2}{\partial x^2}\,y(x)}{x}$$

ode::normalize(Ly, y, x, 2)diff(y(x), x)/x - y(x)/(4*x^2) + diff(y(x), x, x)

$$\frac{\frac{\partial}{\partial x}\,y(x)}{x} - \frac{y(x)}{4\,x^2} + \frac{\partial^2}{\partial x^2}\,y(x)$$

Parameters

Ly

A homogeneous linear ordinary differential equation.

y

The dependent variable of `Ly`.

x

The independent variable of `Ly`.

n

The order of `Ly`.

Return Values

Expression representing a linear differential equation.

ode::polynomialSolutions

Purpose

Polynomial solutions of a homogeneous linear ordinary differential equation

Syntax

```
ode::polynomialSolutions(Ly, y(x), <Generic>)
```

Description

`ode::polynomialSolutions` computes a fundamental set of polynomial solutions of a homogeneous linear ordinary differential equation.

`ode::polynomialSolutions` returns a fundamental set of the polynomial solutions of `Ly`, i.e., solutions in the ring _outputSequence(Symbol::Qopf,[x])$\mathbb{Q}[x]$. When the option `Generic` is given, a generic form of them is returned.

Examples

Example 1

We compute the polynomial solutions of the following differential equation:
Ly:=3*x*diff(y(x),x,x)-x*diff(y(x),x)+9*y(x)3*x*diff(y(x), x, x) - x*diff(y(x), x) + 9*y(x)

$$3\,x\,\frac{\partial^2}{\partial x^2}\,y(x) - x\,\frac{\partial}{\partial x}\,y(x) + 9\,y(x)$$

ode::polynomialSolutions(Ly, y(x)){x^9 - 216*x^8 + 18144*x^7 - 762048*x^6 + 17146080*x^5 - 205752960*x^4 + 1234517760*x^3 - 3174474240*x^2 + 2380855680*x}

$$\{x^9 - 216\,x^8 + 18144\,x^7 - 762048\,x^6 + 17146080\,x^5 - 205752960\,x^4 + 1234517760\,x^3 - 3174474$$

Parameters

Ly

A homogeneous linear ordinary differential equation with coefficients in the field (x) of rational functions over the rationals.

y(x)

The dependent function of `Ly`.

Return Values

set, possibly empty, of functions or an expression

See Also

ode::rationalSolutions

ode::rationalSolutions

Purpose

Rational solutions of a homogeneous linear ordinary differential equation

Syntax

```
ode::rationalSolutions(Ly, y(x), <Generic>)
```

Description

`ode::rationalSolutions` returns a fundamental set of the rational solutions of `Ly`, i.e., solutions in the field (x). When the option `Generic` is given, a generic form of them is returned.

Examples

Example 1

We compute the rational solutions of the following differential equation:

```
Ly:=(4*x^5+8*x^3+4*x)*diff(y(x),x,x)+
(36*x^4+32*x^2-4)*diff(y(x),x)+48*x^3*y(x)48*x^3*y(x) + (4*x^5 +
8*x^3 + 4*x)*diff(y(x), x, x) + (36*x^4 + 32*x^2 - 4)*diff(y(x), x)
```

$$48 x^3 y(x) + (4 x^5 + 8 x^3 + 4 x) \frac{\partial^2}{\partial x^2} y(x) + (36 x^4 + 32 x^2 - 4) \frac{\partial}{\partial x} y(x)$$

```
ode::rationalSolutions(Ly, y(x)){1/(x^6 + 3*x^4 + 3*x^2 + 1), (x^4 +
2*x^2)/(x^6 + 3*x^4 + 3*x^2 + 1)}
```

$$\left\{ \frac{1}{x^6 + 3 x^4 + 3 x^2 + 1}, \frac{x^4 + 2 x^2}{x^6 + 3 x^4 + 3 x^2 + 1} \right\}$$

```
ode::rationalSolutions(Ly, y(x), Generic)C1/(x^6 + 3*x^4 + 3*x^2 + 1) +
(C2*(x^4 + 2*x^2))/(x^6 + 3*x^4 + 3*x^2 + 1)
```

$$\frac{C1}{x^6 + 3 x^4 + 3 x^2 + 1} + \frac{C2 (x^4 + 2 x^2)}{x^6 + 3 x^4 + 3 x^2 + 1}$$

Parameters

Ly

A homogeneous linear ordinary differential equation with coefficients in the field (x) of rational functions over the rationals.

y(x)

The dependent function of `Ly`.

Return Values set, possibly empty, of functions or an expression

See Also ode::polynomialSolutions

ode::ratSys

Purpose

Rational solutions of a first order homogeneous linear differential system

Syntax

```
ode::ratSys(M, x)
```

Description

`ode::ratSys(M, x)` computes a fundamental set of rational solutions of the first order homogeneous linear differential system `Y'=MY`. This method uses a cyclic vector and therefore is not optimal.

Examples

Example 1

We compute the rational solutions of the following differential system:
A := matrix([[2*(x+x^2-9)/x/(x-2),2*(x^2-6)/x/(x-2)], [-3*(2*x+x^2-12)/x/(x-2),-(2*x+3*x^2-24)/x/(x-2)]])matrix([[(2*x^2 + 2*x - 18)/(x*(x - 2)), (2*x^2 - 12)/(x*(x - 2))], [-(3*x^2 + 6*x - 36)/(x*(x - 2)), -(3*x^2 + 2*x - 24)/(x*(x - 2))]])

$$\begin{pmatrix} \frac{2x^2+2x-18}{x(x-2)} & \frac{2x^2-12}{x(x-2)} \\ -\frac{3x^2+6x-36}{x(x-2)} & -\frac{3x^2+2x-24}{x(x-2)} \end{pmatrix}$$

v := ode::ratSys(A, x){Dom::Matrix(Dom::ExpressionField(normal, iszero@normal))([[(x + 2)/x^3], [-(x + 4)/x^3]])}

$$\left\{ \begin{pmatrix} \frac{x+2}{x^3} \\ -\frac{x+4}{x^3} \end{pmatrix} \right\}$$

And we can check the result:
diff(v[1], x) = normal(A*v[1])Dom::Matrix(Dom::ExpressionField(normal, iszero@normal))([[-(2*(x + 3))/x^4], [(2*(x + 6))/x^4]]) = matrix([[-(2*(x + 3))/x^4], [(2*(x + 6))/x^4]])

Parameters

$$\begin{pmatrix} -\frac{2\,(x+3)}{x^4} \\ \frac{2\,(x+6)}{x^4} \end{pmatrix} = \begin{pmatrix} -\frac{2\,(x+3)}{x^4} \\ \frac{2\,(x+6)}{x^4} \end{pmatrix}$$

M

A square matrix of type Dom::Matrix with coefficients in the field (x) of rational functions over the rationals.

x

The independent function.

Return Values

set, possibly empty, of objects of type Dom::Matrix.

See Also

ode::rationalSolutionsode::cyclicVectorode::scalarEquation

ode::scalarEquation

Purpose

Transforms a linear differential system to an equivalent scalar linear differential equation

Syntax

```
ode::scalarEquation(A, x, y, <Transform>)
```

Description

`ode::scalarEquation` converts a first order homogeneous linear differential system to an equivalent homogeneous scalar linear differential equation using the method of cyclic vector.

`ode::scalarEquation(A, x, y)` returns a scalar homogeneous linear differential equation in `y(x)` equivalent to the first order homogeneous differential system Y'=AY$Y' = AY$ using the method of the cyclic vector. If the option `Transform` is given then a list is returned whose first element is the corresponding differential equation `Ly` and second element is an invertible matrix `P` such that C=P' * invMatrix(P)+P * A * invMatrix(P)$C = P' P^{-1} + PAP^{-1}$ is the companion matrix associated to `Ly`; hence if `Z` is a solution of the differential system Y'=AY$Y' = AY$ then *PZ* is a solution of the system Y'=CY$Y' = CY$.

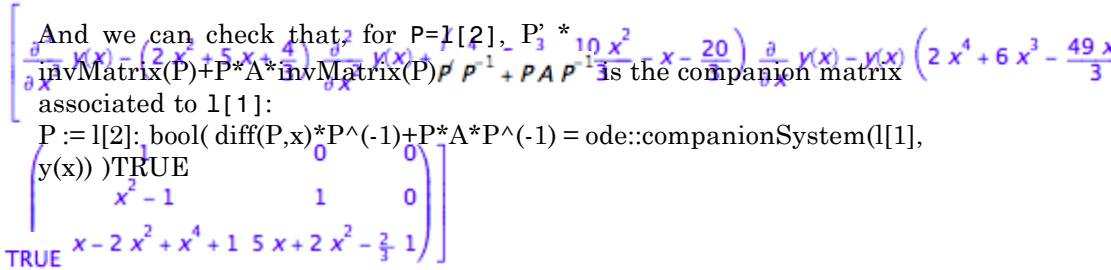
Examples

Example 1

We compute a linear differential equation equivalent to the following differential system:
A := matrix([[x^2-1,1,0], [0,x^2+5*x+1/3,1], [0,0,2]])matrix([[x^2 - 1, 1, 0], [0, x^2 + 5*x + 1/3, 1], [0, 0, 2]])

$$\begin{pmatrix} x^2-1 & 1 & 0 \\ 0 & x^2+5x+\frac{1}{3} & 1 \\ 0 & 0 & 2 \end{pmatrix}$$

l := ode::scalarEquation(A, x, y, Transform)[diff(y(x), x, x, x) - (2*x^2 + 5*x + 473)*diff(y(x), x, x) + (x^4 + 5*x^3 + (10*x^2)/3 - x - 20/3)*diff(y(x), x) - y(x)*(2*x^4 + 6*x^3 - (49*x^2)/3 - (38*x)/3 + 19/3), Dom::Matrix(Dom::ExpressionField(normal, iszero@normal))([[1, 0, 0], [x^2 - 1, 1, 0], [2*x - 2*x^2 + x^4 + 1, 5*x + 2*x^2 - 2/3, 1]])]



And we can check that, for `P=l[2]`, P' * invMatrix(P)+P*A*invMatrix(P)$P' P^{-1} + P A P^{-1}$ is the companion matrix associated to `l[1]`:

```
P := l[2]: bool( diff(P,x)*P^(-1)+P*A*P^(-1) = ode::companionSystem(l[1],
y(x)) )
```

TRUE

Parameters

A

A square matrix of type Dom::Matrix.

x

The independent variable of the resulting scalar differential equation.

y

The dependent variable of the resulting scalar differential equation.

Return Values

Expression or a list.

See Also

ode::cyclicVector

ode::series

Purpose

Series solutions of an ordinary differential equation

Syntax

```
ode::series(Ly, y(x), x | x = x0, <order>)
ode::series({Ly, <inits>}, y(x), x | x = x0, <order>)
```

Description

`ode::series(Ly, y(x), x = x0)` computes the first terms of the series expansions of the solutions of `Ly` with respect to the variable `x` around the point `x0`.

`ode::series` tries to compute either the Taylor series, the Laurent series or the Puiseux series of the solutions of the differential equation `Ly` around the point `x=x0`.

Suppose that `Ly` is a nonlinear differential equation. If `x0` is an ordinary point of `Ly` then a Taylor series is computed otherwise an expression of type `"series"` is returned. If initial conditions are given at the point `x0` then the answer is expressed in terms of the function `y(x)` and its derivatives evaluated at the point `x0`. See “Example 1” on page 21-33.

Suppose that `Ly` is a linear differential equation. If `x0` is an ordinary point of `Ly` then a Taylor series is computed, if `Ly` is furthermore homogeneous and `x0` is a regular point then a Puiseux series is computed (containing possible logarithmic terms), otherwise an expression of type `"series"` is returned. If initial conditions are given at the point `x0` then the answer is either expressed in terms of the function `y(x)` and its derivatives evaluated at the point `x0` or it may be expressed in terms of arbitrary constants.

Examples

Example 1

Consider the following nonlinear differential equation:
Ly := x^2*diff(y(x),x)+y(x)-xy(x) - x + x^2*diff(y(x), x)

We compute the series solutions at the point 0 which is a singular point:

ode::series(Ly, y(x), x=0)series(y(x) - x + x^2*diff(y(x), x), y(x), x = 0)

$$\text{series}\left(y(x) - x + x^2 \frac{\partial}{\partial x} y(x),\ y(x),\ x = 0\right)$$

Then we compute the series solutions at the regular point 1:
ode::series(Ly, y(x), x=1){y(1) - (x - 1)*(y(1) - 1) + ((3*y(1))/2 - 1)*(x - 1)^2 - ((13*y(1))/6 - 4/3)*(x - 1)^3 + ((73*y(1))/24 - 11/6)*(x - 1)^4 - ((167*y(1))/40 - 5/2)*(x - 1)^5 + O((x - 1)^6)}

$$\left\{y(1) - (x-1)\,(y(1)-1) + \left(\frac{3\,y(1)}{2} - 1\right)(x-1)^2 - \left(\frac{13\,y(1)}{6} - \frac{4}{3}\right)(x-1)^3 + \left(\frac{73\,y(1)}{24} - \frac{11}{6}\right)(x-1)^4 - \left(\right.\right.$$

And we can also put some initial conditions at the point 1:
ode::series({y(1)=1, Ly}, y(x), x=1){1 + (x - 1)^2/2 - (5*(x - 1)^3)/6 + (29*(x - 1)^4)/24 - (67*(x - 1)^5)/40 + O((x - 1)^6)}

$$\left\{1 + \frac{(x-1)^2}{2} - \frac{5\,(x-1)^3}{6} + \frac{29\,(x-1)^4}{24} - \frac{67\,(x-1)^5}{40} + O\left((x-1)^6\right)\right\}$$

Example 2

Consider the following linear differential equation:
Ly := (2*x+x^3)*diff(y(x),x$2)-diff(y(x),x)-6*x*y(x)(x^3 + 2*x)*diff(y(x), x, x) - diff(y(x), x) - 6*x*y(x)

$$\left(x^3 + 2\,x\right)\frac{\partial^2}{\partial x^2} y(x) - \frac{\partial}{\partial x} y(x) - 6\,x\,y(x)$$

We compute the series solutions at the regular point 1:
ode::series(Ly, y(x), x=1){y(1) + D(y)(1)*(x - 1) + (x - 1)^2*(D(y)(1)/6 + y(1)) - (y(1)/9 - (7*D(y)(1))/27)*(x - 1)^3 + (y(1)/12 - D(y)(1)/36)*(x - 1)^4 + (y(1)/90 - (2*D(y)(1))/135)*(x - 1)^5 + O((x - 1)^6)}

$$\left\{y(1) + y'(1)\,(x-1) + (x-1)^2\left(\frac{y'(1)}{6} + y(1)\right) - \left(\frac{y(1)}{9} - \frac{7\,y'(1)}{27}\right)(x-1)^3 + \left(\frac{y(1)}{12} - \frac{y'(1)}{36}\right)(x-1)^4 + \left(\frac{y(1)}{90}\right.\right.$$

The series solutions at the regular singular point 0:
ode::series(Ly, y(x), x=0){1 + 3*x^2 + (3*x^4)/5 + O(x^6), x^(3/2) + (3*x^(7/2))/8 - (3*x^(11/2))/128 + O(x^(15/2))}

$$\left\{1 + 3\,x^2 + \frac{3\,x^4}{5} + O(x^6),\ x^{3/2} + \frac{3\,x^{7/2}}{8} - \frac{3\,x^{11/2}}{128} + O\left(x^{15/2}\right)\right\}$$

An also the series solutions at the regular singular point *infinity*:
ode::series(Ly, y(x), x=infinity){1/x^2 - 1/x^4 + 11/(9*x^6) + O(1/x^8), 2880*x^3 + 4320*x - 1080/x + O(1/x^3)}

$$\left\{\frac{1}{x^2} - \frac{1}{x^4} + \frac{11}{9\,x^6} + O\left(\frac{1}{x^8}\right),\ 2880\,x^3 + 4320\,x - \frac{1080}{x} + O\left(\frac{1}{x^3}\right)\right\}$$

Example 3

Consider the following linear differential equation:
Ly := x^2*diff(y(x),x$2)-x*diff(y(x),x)+(1-x)*y(x)x^2*diff(y(x), x, x) - y(x)*(x - 1) - x*diff(y(x), x)

$$x^2\,\frac{\partial^2}{\partial x^2}\,y(x) - y(x)\,(x-1) - x\,\frac{\partial}{\partial x}\,y(x)$$

We compute the series solutions at the regular singular point 0:
ode::series(Ly, y(x), x){x*ln(x) + x^2*(ln(x) - 2) + x^3*(ln(x)/4 - 3/4) + x^4*(ln(x)/36 - 11/108) + x^5*(ln(x)/576 - 25/3456) + x^6*(ln(x)/14400 - 137/432000) + O(x^7), x + x^2 + x^3/4 + x^4/36 + x^5/576 + x^6/14400 + O(x^7)}

$$\left\{x\ln(x) + x^2(\ln(x) - 2) + x^3\left(\frac{\ln(x)}{4} - \frac{3}{4}\right) + x^4\left(\frac{\ln(x)}{36} - \frac{11}{108}\right) + x^5\left(\frac{\ln(x)}{576} - \frac{25}{3456}\right) + x^6\left(\frac{\ln(x)}{14400} - \right.\right.$$

And at the same point we look for solutions satisfying the initial condition $y(0) = 1$ and $y(0) = 0$:

$$\left.\left. x + x^2 + \frac{x^3}{4} + \frac{x^4}{36} + \frac{x^5}{576} + \frac{x^6}{14400} + O(x^7)\right\}\right.$$

ode::series({y(0)=1, Ly}, y(x), x){}

∅

ode::series({y(0)=0, Ly}, y(x), x){C4*x*ln(x) + C4*x^2*(ln(x) - 2) + C4*x^3*(ln(x)/4 - 3/4) + C4*x^4*(ln(x)/36 - 11/108) + C4*x^5*(ln(x)/576 - 25/3456) + C4*x^6*(ln(x)/14400 - 137/432000) + O(x^7), C3*x + C3*x^2 + (C3*x^3)/4 + (C3*x^4)/36 + (C3*x^5)/576 + (C3*x^6)/14400 + O(x^7)}

Parameters

$$\left\{C4\,x\ln(x) + C4\,x^2(\ln(x)-2) + C4\,x^3\left(\frac{\ln(x)}{4}-\frac{3}{4}\right) + C4\,x^4\left(\frac{\ln(x)}{36}-\frac{11}{108}\right) + C4\,x^5\left(\frac{\ln(x)}{576}-\frac{25}{3456}\right) + C\right.$$

$$\left. C3\,x + C3\,x^2 + \frac{C3\,x^3}{4} + \frac{C3\,x^4}{36} + \frac{C3\,x^5}{576} + \frac{C3\,x^6}{14400} + O(x^7)\right\}$$

Ly

An ordinary differential equation.

y(x)

The dependent function of `Ly`.

x

The independent variable of `Ly`.

x0

The expansion point: an arithmetical expression. If not specified, the default expansion point 0 is used .

inits

The initial or boundary conditions: a sequence of equations.

order

The number of terms to be computed: a nonnegative integer. The default order is given by the environment variable ORDER (default value 6).

Return Values

Either a list, maybe empty, of objects of type Series::Puiseux or an expression of type `"series"`.

ode::solve

Purpose

Solving ordinary differential equations

Syntax

```
ode::solve(o, options)
solve(o, options)
```

Description

`ode::solve` computes solutions for ordinary differential equations.

`ode::solve(o)` returns the set of solutions of the ordinary differential equation `o`. You can also call the generic function `solve(o)`.

The solver detects the type of the differential equation and chooses an algorithm according to the detected equation type. If you know the type of the equation, you can use the option `Type = OdeType` to pass the equation type to the solver. Passing the equation type to the solver increases performance.

The solver recognizes the following values of `OdeType`:

- `Abel` - Abel differential equation
- `Bernoulli` - Bernoulli differential equation
- `Chini` - Chini differential equation
- `Clairaut` - Clairaut differential equation
- `ExactFirstOrder` - exact first order ordinary differential equation
- `ExactSecondOrder` - exact second order ordinary differential equation
- `Homogeneous` - homogeneous first order ordinary differential equation
- `Lagrange` - Lagrange differential equation
- `Riccati` - Riccati differential equation

See the Background section for more details on the classes of ordinary differential equations.

If the solver cannot identify the equation with the type you indicated, it issues a warning and returns the special value FAIL.

To solve an ordinary differential equation disregarding possible conditions on the parameters of the equation, use `IgnoreSpecialCases` option. This option eliminates receiving a set of special cases as an answer.

To solve an ordinary differential equation in a simplified manner, use the `IgnoreAnalyticConstraints` option. This option can provide simple solutions for the equations for which the direct use of the solver gives complicated results. If you use the `IgnoreAnalyticConstraints` option, always check the answer. This option can lead to wrong or incomplete results. See "Example 3" on page 21-41.

The solutions of ordinary differential equations can contain arbitrary constants of integration. The solver generates the constants of integration using the format of an uppercase letter `C` followed by an automatically generated number, for example `C13`.

The solver does not always verify the uniqueness and completeness of the returned solution. For example:

- The solver does not validate the Lipschitz-conditions on the ordinary differential equation for the Picard-Lindelöf Theorem.
- For some complex nonlinear systems of differential equations the solver returns constant solutions and does not warn you that other solutions exist.

The solver might ignore assumptions that you set on symbolic parameters and variables or use them only partially. More precisely, `ode::solve` passes assumptions to the functions that it calls internally. While these functions can use the specified assumptions, `ode::solve` itself does not use them in most of its internal algorithms. The same happens if you define an ordinary differential equation using ode and solve it using solve.

Examples

Example 1

To define an ordinary differential equation, use the ode command:
o:= ode(y'(x) = y(x)^2, y(x))ode(D(y)(x) - y(x)^2, y(x))

$$\text{ode}\left(y'(x) - y(x)^2,\ y(x)\right)$$

To solve the equation, enter:
ode::solve(o){0, -1/(C3 + x)}

$$\left\{0,\ -\frac{1}{C3 + x}\right\}$$

or more efficiently:
solve(o){0, -1/(C7 + x)}

$$\left\{0,\ -\frac{1}{C7 + x}\right\}$$

Internally, the function `ode::solve` calls the function solve.
delete o:

Example 2

You can solve an ordinary differential equation with a symbolic parameter and an initial condition:
o:= ode({y'(x) = a*y(x)^2, y(a) = ln(a)}, y(x)): solve(o)piecewise([a = 1, {0}], [a <> 1, {1/(1/ln(a) - a*x + a^2)}])

$$\begin{cases} \{0\} & \text{if } a = 1 \\ \left\{\frac{1}{\frac{1}{\ln(a)} - a\,x + a^2}\right\} & \text{if } a \neq 1 \end{cases}$$

To reduce the number of returned solutions, use the option `IgnoreSpecialCases`. For example, you can drop the solution for the parameter $a = 1$:
solve(o, IgnoreSpecialCases){1/(1/ln(a) - a*x + a^2)}

$$\left\{\frac{1}{\frac{1}{\ln(a)} - a\,x + a^2}\right\}$$

With the `IgnoreSpecialCases` option, a returned set of solutions can be incomplete.
delete o:

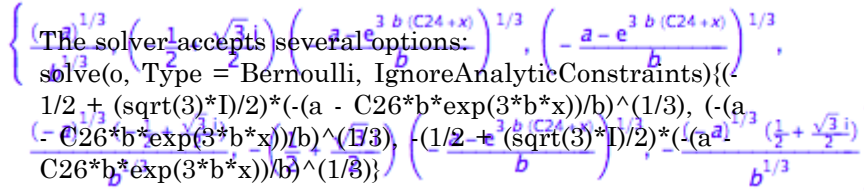
Example 3

The solver can return piecewise solutions:
o:= ode(y'(x) = a/y(x)^2 + b*y(x), y(x)): solve(o)piecewise([a = 0 and b = 0, {C18}], [a <> 0 and b <> 0, {(-a)^(1/3)/b^(1/3), (- 1/2 + (sqrt(3)*I)/2)*(-(a - exp(3*b*(C19 + x)))/b)^(1/3), (-(a - exp(3*b*(C19 + x)))/b)^(1/3), ((-a)^(1/3)*(- 1/2 + (sqrt(3)*I)/2))/b^(1/3), -(1/2 + (sqrt(3)*I)/2)*(-(a - exp(3*b*(C19 + x)))/b)^(1/3), -((-a)^(1/3)*(1/2 + (sqrt(3)*I)/2))/b^(1/3)}], [(a = 0 or b = 0) and (a = 0 or b <> 0) and (a <> 0 or b = 0) and (a <> 0 or b <> 0), {}], [(a = 0 and b <> 0 or a <> 0 and b = 0) and (a = 0 or b = 0) and (a <> 0 or b <> 0), {(- 1/2 + (sqrt(3)*I)/2)*(-(a - exp(3*b*(C19 + x)))/b)^(1/3), (-(a - exp(3*b*(C19 + x)))/b)^(1/3), -(1/2 + (sqrt(3)*I)/2)*(-(a - exp(3*b*(C19 + x)))/b)^(1/3)}])

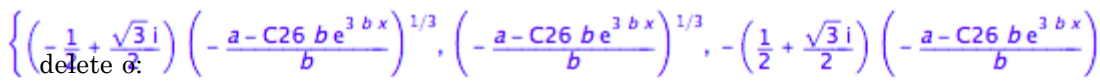
$$\begin{cases} \{C18\} & \text{if } a = 0 \wedge b = 0 \\ \left\{ \frac{(-a)^{1/3}}{b^{1/3}}, \left(-\frac{1}{2}+\frac{\sqrt{3}\,i}{2}\right)\left(-\frac{a-e^{3\,b\,(C19+x)}}{b}\right)^{1/3}, \left(-\frac{a-e^{3\,b\,(C19+x)}}{b}\right)^{1/3}, \right. & \text{if } a \neq 0 \wedge b \neq 0 \\ \left. \left(-\frac{a-e^{3\,b\,(C19+x)}}{b}\right)^{1/3}, -\left(\frac{1}{2}+\frac{\sqrt{3}\,i}{2}\right)\left(-\frac{a-e^{3\,b\,(C19+x)}}{b}\right)^{1/3} \right\} & \\ \{\} & \text{if } (a = 0 \vee b = 0) \wedge (a = 0 \vee b \neq 0) \wedge (a \neq 0 \vee b = 0) \wedge (a \neq 0 \vee b \neq 0) \end{cases}$$

This solution is complete and mathematically correct for all possible values of the parameter *a* and variable *x*. Also you can try the option `IgnoreAnalyticConstraints` to obtain a particular solution that is correct under a set of common assumptions:
solve(o, IgnoreAnalyticConstraints){(-a)^(1/3)/b^(1/3), (- 1/2 + (sqrt(3)*I)/2)*(-(a - exp(3*b*(C24 + x)))/b)^(1/3), (-(a - exp(3*b*(C24

+ x)))/b)^(1/3), ((-a)^(1/3)*(- 1/2 + (sqrt(3)*I)/2))/b^(1/3), -(1/2 + (sqrt(3)*I)/2)*(-(a - exp(3*b*(C24 + x)))/b)^(1/3), -((-a)^(1/3)*(1/2 + (sqrt(3)*I)/2))/b^(1/3)}



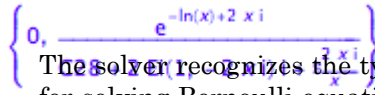
The solver accepts several options:
solve(o, Type = Bernoulli, IgnoreAnalyticConstraints){(-1/2 + (sqrt(3)*I)/2)*(-(a - C26*b*exp(3*b*x))/b)^(1/3), (-(a - C26*b*exp(3*b*x))/b)^(1/3), -(1/2 + (sqrt(3)*I)/2)*(-(a - C26*b*exp(3*b*x))/b)^(1/3)}



delete o:

Example 4

Suppose, you want to solve an ordinary differential equation from the class of Bernoulli equations:
o:= ode(y'(x) = (- 1/x + 2*I)*y(x) + 1/x*y(x)^2, y(x)): solve(o){0, exp(- ln(x) + 2*x*I)/(C28 + 2*Ei(1, -2*x*I)*I + exp(2*x*I)/x)}



The solver recognizes the type of the equation and uses the algorithm for solving Bernoulli equations. To improve performance, you can explicitly pass the type of the equation to the solver:
solve(o, Type = Bernoulli){0, (x*exp(- ln(x) + 2*x*I))/(exp(2*x*I) + C29*x + 2*x*Ei(1, -2*x*I)*I)}

$$\left\{0,\ \frac{x\,e^{-\ln(x)+2\,x\,i}}{e^{2\,x\,i}+C2\,x+C1\,x-2\,x\,i}\right\}$$

To solve the Clairaut equation with the initial conditions, enter:
o:= ode({(x*y'(x)-y(x))^2 - y'(x)^2 - 1 = 0, y(1) = 1}, y(x)): solve(o, Type = Clairaut){1}

$$\{1\}$$

If the solver cannot identify the equation with the type you indicated, it issues a warning and returns the special value FAIL:
o:= ode({(x*y'(x)-y(x))^2 - y'(x)^2 - 1 = 0, y(1) = 1}, y(x)): solve(o, Type = Lagrange) Warning: Cannot detect the Lagrange ODE. [ode::lagrange]
FAIL

FAIL

delete o:

Example 5

Some ordinary differential equations belong to several classes. For example, some Chini equations are also homogeneous and some Lagrange equations are also Clairaut equations. If an equation belongs to several classes simultaneously, the solver can present its solution in different forms. The form of a solution depends on the class with which an equation is identified. For example, suppose you want to solve the Chini differential equation. You can explicitly pass the type of the equation to the solver:
o:= ode(y'(x) = 1/x*y(x)^2 + 1/x*y(x) + x, y(x)): L:= solve(o, Type = Chini){x*tan(C31 + x), -x*I, x*I}

$$\{x\tan(C31+x),\ -x\,i,\ x\,i\}$$

You also can let the solver recognize the type of the equation:
solve(o){-x*I, - x*I + (2*exp(2*x*I)*exp(ln(x) + (-2*x*I)))/(2*C33*exp(2*x*I) - I)}

$$\left\{-x\,i,\ -x\,i+\frac{2\,e^{2\,x\,i}\,e^{\ln(x)-2\,x\,i}}{2\,C33\,e^{2\,x\,i}+1}\right\}$$

The solver does not return the type with which an ordinary differential equation is internally identified. If you want to verify that both solution sets are equivalent, use the rewrite function with target exp on the first set of solutions:
rewrite(L, exp){-x*I, x*I, -(x*(exp(2*C31*I + 2*x*I)*I - I))/(exp(2*C31*I + 2*x*I) + 1)}

$$\left\{-x\,i,\ x\,i,\ -\frac{x\left(e^{2\,C31\,i+2\,x\,i}\,i-i\right)}{e^{2\,C31\,i+2\,x\,i}+1}\right\}$$

delete o, L:

Example 6

MuPAD solves some classes of Riccati ordinary differential equations that involve arbitrary functions. For example, the following equation contains the arbitrary function `f(x)`:
eq := diff(y(x), x) - f(x)*y(x)^2 + a^2*x^(2*n)*f(x) - a*n*x^(n - 1)diff(y(x), x) - f(x)*y(x)^2 + a^2*x^(2*n)*f(x) - a*n*x^(n - 1)

$$\frac{\partial}{\partial x}\,y(x)-f(x)\,y(x)^2+a^2\,x^{2\,n}\,f(x)-a\,n\,x^{n-1}$$

For this equation the solver returns:
solve(ode(eq,y(x))){a*x^n, a*x^n + exp(int(2*a*x^n*f(x), x))/(C35 - int(exp(int(2*a*x^n*f(x), x))*f(x), x))}

$$\left\{a\,x^n,\ a\,x^n+\frac{e^{\int 2\,a\,x^n\,f(x)\,dx}}{C35-\int e^{\int 2\,a\,x^n\,f(x)\,dx}\,f(x)\,dx}\right\}$$

You also can solve an equation with more than one arbitrary function. For example, the following equations contain `f(x)` and `g(x)`:

eq:= diff(y(x), x) - g(x)*f(x)*y(x) - g(x) - diff(f(x), x)*y(x)^2- y(x)^2*diff(f(x), x) + diff(y(x), x) - f(x)*g(x)*y(x) - g(x)

$$-y(x)^2 \frac{\partial}{\partial x} f(x) + \frac{\partial}{\partial x} y(x) - f(x)\, g(x)\, y(x) - g(x)$$

The returned solution is:
solve(ode(eq,y(x)))\{exp(int(f(x)*g(x), x) - 2*ln(f(x)))/(C37 - int(exp(int(f(x)*g(x), x) - 2*ln(f(x)))*diff(f(x), x), x)) - 1/f(x), -1/f(x)\}

$$\left\{ \frac{e^{\int f(x)\, g(x) dx - 2 \ln(f(x))}}{C37 - \int e^{\int f(x)\, g(x) dx - 2 \ln(f(x))} \frac{\partial}{\partial x} f(x)\, dx} - \frac{1}{f(x)}, -\frac{1}{f(x)} \right\}$$

Example 7

Suppose, you want to solve the following second-order ordinary differential equation:
eq:=
x^2*(x^2+1)*diff(y(x),x,x)+x*(2*x^2+1)*diff(y(x),x)-(nu*(nu+1)*x^2+n^2)*y(x)x*(2*
+ 1)*diff(y(x), x) - y(x)*(n^2 + nu*(nu + 1)*x^2) + x^2*(x^2
+ 1)*diff(y(x), x, x)

$$x\left(2x^2+1\right)\frac{\partial}{\partial x} y(x) - y(x)\left(n^2 + \mathrm{nu}\,(\mathrm{nu}+1)\,x^2\right) + x^2\left(x^2+1\right)\frac{\partial^2}{\partial x^2} y(x)$$

The solver returns the result in terms of the hypergeometric function ${}_1F_2$ (see hypergeom):
solve(ode(eq,y(x)))\{(C39*hypergeom([nu/2 - n/2 + 1/2, n/2 + nu/2 + 1/2], [nu + 3/2], -1/x^2))/x^(nu + 1) + C40*x^nu*hypergeom([- n/2 - nu/2, n/2 - nu/2], [1/2 - nu], -1/x^2)\}

$$\left\{ \frac{C39\ {}_2F_1\left(\frac{\mathrm{nu}}{2} - \frac{n}{2} + \frac{1}{2}, \frac{n}{2} + \frac{\mathrm{nu}}{2} + \frac{1}{2}; \mathrm{nu} + \frac{3}{2}; -\frac{1}{x^2}\right)}{x^{\mathrm{nu}+1}} + C40\ x^{\mathrm{nu}}\ {}_2F_1\left(-\frac{n}{2} - \frac{\mathrm{nu}}{2}, \frac{n}{2} - \frac{\mathrm{nu}}{2}; \frac{1}{2} - \mathrm{nu}; -\frac{1}{x^2}\right) \right\}$$

Example 8

The solver can handle some third- and higher-order ordinary differential equations. For example, solve the following third-order linear differential equations:

```
eq := ode(sin(x)*y'''(x) + cos(x)*y(x), y(x)): solve(eq){C42*sin(x)}
```

$$\{C42\ \sin(x)\}$$

```
eq := ode(6*y(x) + x^3*y'''(x), y(x)): solve(eq){C47*x^(2 + sqrt(2)*I)
- (x^(2 + sqrt(2)*I)*(C46/22 + (3*sqrt(2)*C46*I)/44))/x^(3 +
sqrt(2)*I) + (sqrt(2)*C48*(1/x^(2*sqrt(2)*I))*x^(2 + sqrt(2)*I)*I)/4
+ (sqrt(2)*(1/x^(2*sqrt(2)*I))*x^(2 + sqrt(2)*I)*((3*C46)/11 +
(sqrt(2)*C46*I)/11)*I)/(4*x^(3 - sqrt(2)*I))}
```

$$\left\{C47\ x^{2+\sqrt{2}\,i} - \frac{x^{2+\sqrt{2}\,i}\left(\frac{C46}{22} + \frac{3\sqrt{2}\,C46\,i}{44}\right)}{x^{3+\sqrt{2}\,i}} + \frac{\sqrt{2}\,C48\,\frac{1}{x^{2\sqrt{2}\,i}}\,x^{2+\sqrt{2}\,i}\,i}{4} + \frac{\sqrt{2}\,\frac{1}{x^{2\sqrt{2}\,i}}\,x^{2+\sqrt{2}\,i}\left(\frac{3\,C46}{11} + \frac{\sqrt{2}\,C46\,i}{11}\right)i}{4\,x^{3-\sqrt{2}\,i}}\right\}$$

Example 9

The solver also can handle some nonlinear first-order ordinary differential equations. For example, solve the following first-order linear differential equations:

```
eq := ode(y(x)*diff(y(x), x) - y(x) - x^3 - 4*x^4 - 4*x^7, y(x)): solve(eq){x^4
+ x + 1/4}
```

$$\left\{x^4 + x + \frac{1}{4}\right\}$$

```
eq := ode(exp(x/2)/4 - 2*exp(x) - y(x) + x*exp(x/2) + y(x)*y'(x), y(x)):
solve(eq){x - 2*exp(x/2) + 1/4}
```

$$\left\{x - 2\,e^{\frac{x}{2}} + \frac{1}{4}\right\}$$

Parameters

o

An ordinary differential equation, an object of the type ode.

Options

Type

Option, specified as `Type = OdeType`

Indicates the type of the ordinary differential equation and accepts the following arguments: `Abel`, `Bernoulli`, `Chini`, `Clairaut`, `ExactFirstOrder`, `ExactSecondOrder`, `Homogeneous`, `Lagrange`, `Riccati`.

MaxDegree

Option, specified as `MaxDegree = n`

Pass the option to the generic solver, which is called internally for all intermediate equations. See the list of options for the solve function for further information.

IgnoreSpecialCases

Pass the option to the generic solver, which is called internally for all intermediate equations, and to the integrator int, which is called for computing all intermediate integrals. See the list of options for the solve function for further information.

IgnoreAnalyticConstraints

Pass the option to the generic solver, which is called internally for all intermediate equations, and to the integrator int, which is called for computing all intermediate integrals. See the list of options for the solve function for further information.

Return Values

Set of solutions of the ordinary differential equation or the special value FAIL. For additional information on the return values, see the solve help page.

ode::symmetricPower

Purpose

Symmetric power of a homogeneous linear ordinary differential equation

Syntax

```
ode::symmetricPower(Ly, y(x), m)
```

Description

`ode::symmetricPower(Ly, y(x), m)` computes the *m*-th symmetric power of `Ly`. This is the lowest order linear ordinary differential equation whose solution space consists exactly of all possible *m*-th powerproducts of solutions of `Ly`.

Examples

Example 1

We compute the second symmetric power of the following differential equation:
Ly:=x^2*diff(y(x),x$2)-(36*x^6*exp(4*x^3)+9*x^6+2)*y(x)x^2*diff(y(x), x, x) - y(x)*(36*x^6*exp(4*x^3) + 9*x^6 + 2)

$$x^2 \frac{\partial^2}{\partial x^2} y(x) - y(x) \left(36 x^6 e^{4 x^3} + 9 x^6 + 2\right)$$

ode::symmetricPower(Ly, y(x), 2)diff(y(x), x, x, x) - (144*x^4*exp(4*x^3) + 8/x^2 + 36*x^4)*diff(y(x), x) - y(x)*(288*x^3*exp(4*x^3) + 864*x^6*exp(4*x^3) - 8/x^3 + 72*x^3)

$$\frac{\partial^3}{\partial x^3} y(x) - \left(144 x^4 e^{4 x^3} + \frac{8}{x^2} + 36 x^4\right) \frac{\partial}{\partial x} y(x) - y(x) \left(288 x^3 e^{4 x^3} + 864 x^6 e^{4 x^3} - \frac{8}{x^3} + 72 x^3\right)$$

Parameters

Ly

A homogeneous linear ordinary differential equation.

y(x)

The dependent function of `Ly`.

m

A positive integer.

Return Values

Linear differential equation

ode::unimodular

Purpose

Unimodular transformation of a linear ordinary differential equation

Syntax

```
ode::unimodular(Ly, y(x), <Transform>)
```

Description

`ode::unimodular(Ly, y(x))` tests if the linear homogeneous differential equation `Ly` has a unimodular Galois group (i.e. the wronskian lies in the base field (*x*)), if not transforms `Ly` into a unimodular one (by changing the second highest coefficient to zero) and returns a table with index `equation` and `factorOfTransformation` containing respectively the transformed differential equation and the factor of transformation `Wn` such that a solution of the transformed equation multiplied by `Wn` is a solution of `Ly`.

If the option `Transform` is given then `Ly` is transformed unconditionally even if `Ly` has yet a unimodular Galois group.

Examples

Example 1

We test if the following differential equation has a unimodular Galois group:

```
Ly := y(x)*6+x*diff(y(x),x)*(-2)+diff(y(x),x$2)*(-x^2+1)- (x^2 -
1)*diff(y(x), x, x) - 2*x*diff(y(x), x) + 6*y(x)
```

$$-\left(x^2-1\right)\frac{\partial^2}{\partial x^2}y(x)-2x\frac{\partial}{\partial x}y(x)+6y(x)$$

```
ode::unimodular(Ly, y(x))table(factorOfTransformation = 1, equation = -
(x^2 - 1)*diff(y(x), x, x) - 2*x*diff(y(x), x) + 6*y(x))
```

equation	$6y(x)-2x\frac{\partial}{\partial x}y(x)-\left(x^2-1\right)\frac{\partial^2}{\partial x^2}y(x)$
factorOfTransformation	1

It is unimodular since the factor of transformation is `1`. We can also check this by computing the wronskian of `Ly` which is a rational function:

ode::wronskian(Ly,y(x))1/(x^2 - 1)

$$\frac{1}{x^2-1}$$

Now we transform Ly into a differential equation whose wronskian is 1:
ode::unimodular(Ly, y(x), Transform)table(factorOfTransformation = sqrt(1/(x^2 - 1)), equation = diff(y(x), x, x) - (y(x)*(6*x^2 - 7))/(x^4 - 2*x^2 + 1))

ode::wronskian(%[equation], y(x))1

factorOfTransformation	$\sqrt{\frac{1}{x^2-1}}$
1	

Parameters

Ly

A homogeneous linear differential equation over (*x*).

y(x)

The dependent function of Ly.

Return Values

table.

See Also

ode::wronskian

ode::vectorize

Purpose

Coefficients of a homogeneous linear ODE

Syntax

```
ode::vectorize(Ly, y, x, n)
```

Description

`ode::vectorize(Ly, y, x, n)` returns the list of coefficients of the `n`-th order homogeneous linear ordinary differential equation `Ly`.

Examples

Example 1

We compute the list of coefficients of the following differential equation:
Ly := 4*x^2*diff(y(x), x$3)+exp(x^2)*diff(y(x),x$2)+
4*x*diff(y(x),x)-y(x)4*x*diff(y(x), x) - y(x) + exp(x^2)*diff(y(x),
x, x) + 4*x^2*diff(y(x), x, x, x)

$$4\,x\,\frac{\partial}{\partial x}\,y(x)-y(x)+e^{x^2}\,\frac{\partial^2}{\partial x^2}\,y(x)+4\,x^2\,\frac{\partial^3}{\partial x^3}\,y(x)$$

ode::vectorize(Ly, y, x, 3)[-1, 4*x, exp(x^2), 4*x^2]

$$\left[-1,\,4\,x,\,e^{x^2},\,4\,x^2\right]$$

Parameters

Ly

A homogeneous linear ordinary differential equation.

y

The dependent variable of `Ly`.

x

The independent variable of `Ly`.

n

The order of `Ly`, a positive integer.

Return Values list

ode::wronskian

Purpose

Wronskian of functions or of a linear homogeneous ordinary differential equation

Syntax

```
ode::wronskian(l, x, <R>)
ode::wronskian(Ly, y(x), <R>)
```

Description

`ode::wronskian` computes the wronskian (determinant) of functions or of a linear homogeneous ordinary differential equation.

`ode::wronskian(l, x)` returns the wronskian, i.e. the determinant of the wronskian matrix, of the elements of `l` with respect to `x`.

`ode::wronskian(Ly, y(x))` returns the wronskian of `Ly` defined as the element `w` such that w'=-a[(n-1)] * w$w' = -a_{n-1}\,w$, where a_{n-1} is the coefficient of `Ly` of degree n - 1 and n the order of `Ly`.

If the optional argument `R` is given, then the specified differential ring will be chosen for representing the entries of the wronskian matrix.

Examples

Example 1

We compute the wronskian of `[2*x^2+1, x*sqrt(1+x^2), y(x)]` which is a linear differential equation in `y(x)`:

```
Ly:=ode::wronskian([2*x^2+1, x*sqrt(1+x^2), y(x)], x)4*x*sqrt(x^2 +
1)*diff(y(x), x) - 4*x^2*sqrt(x^2 + 1)*diff(y(x), x, x) - 4*y(x)*(sqrt(x^2
+ 1) + x^2/sqrt(x^2 + 1)) - (2*x^2 + 1)*((3*x)/sqrt(x^2 + 1) - x^3/(x^2
+ 1)^(3/2))*diff(y(x), x) + 4*x*y(x)*((3*x)/sqrt(x^2 + 1) - x^3/(x^2 +
1)^(3/2)) + (2*x^2 + 1)*(sqrt(x^2 + 1) + x^2/sqrt(x^2 + 1))*diff(y(x), x, x)
```

```
Ly := numer( normal(Ly) )x^2*diff(y(x), x, x) - 4*y(x) + x*diff(y(x), x)
+ diff(y(x), x, x)
```

$$4\,x\sqrt{x^2+1}\,\frac{\partial}{\partial x}y(x) - 4\,x^2\sqrt{x^2+1}\,\frac{\partial^2}{\partial x^2}y(x) - 4\,y(x)\left(\sqrt{x^2+1}+\frac{x^2}{\sqrt{x^2+1}}\right) - (2\,x^2+1)\left(\frac{3\,x}{\sqrt{x^2+1}}\right.$$

$$+\,4\,x\,y(x)\left(\frac{3\,x}{\sqrt{x^2+1}} - \frac{x^3}{(x^2+1)^{3/2}}\right) + (2\,x^2+1)\left(\sqrt{x^2+1}+\frac{x^2}{\sqrt{x^2+1}}\right)\frac{\partial^2}{\partial x^2}y(x)$$

$$x^2 \frac{\partial^2}{\partial x^2} y(x) - 4\, y(x) + x \frac{\partial}{\partial x} y(x) + \frac{\partial^2}{\partial x^2} y(x)$$

And we can check that a basis of solutions of `Ly` is as expected:
ode::solve(Ly, y(x)){C2*(x + sqrt(x^2 + 1))^2 + C3/(x + sqrt(x^2 + 1))^2}

$$\left\{ C2 \left(x + \sqrt{x^2+1}\right)^2 + \frac{C3}{\left(x + \sqrt{x^2+1}\right)^2} \right\}$$

We can also compute the wronskian of `Ly`, which is, up to a constant, the wronskian of `x^2+1` and `x*sqrt(x^2+1)`:
ode::wronskian(Ly, y(x)),
simplify(ode::wronskian([x^2+1/2,x*sqrt(1+x^2)], x))1/sqrt(x^2 + 1), 1/(2*sqrt(x^2 + 1))

$$\frac{1}{\sqrt{x^2+1}}, \frac{1}{2\sqrt{x^2+1}}$$

Parameters

I

A list of functions of the variable `x`.

Ly

A homogeneous linear ordinary differential equation.

y(x)

The dependent function of `Ly`.

R

A differential ring, default is `Dom::ExpressionField(id, iszero@normal)`.

Return Values

Expression in `x`.

orthpoly – Orthogonal Polynomials

==REFNAME==

orthpoly::chebyshev1

Purpose

The Chebyshev polynomials of the first kind

Syntax

```
orthpoly::chebyshev1(n, x)
```

Description

`orthpoly::chebyshev1(n,x)` computes the value of the n-th degree Chebyshev polynomial of the first kind at the point x.

These polynomials have integer coefficients.

Evaluation is fast and numerically stable for real floating point values x from the interval [- 1.0, 1.0]. Cf. “Example 2” on page 22-3.

orthpoly::chebyshev2 implements the Chebyshev polynomials of the second kind.

Examples

Example 1

Polynomials of domain type DOM_POLY are returned, if identifiers or indexed identifiers are specified:
orthpoly::chebyshev1(2, x)poly(2*x^2 - 1, [x])

$$\mathrm{poly}(2\,x^2 - 1, [x])$$

orthpoly::chebyshev1(3, x[1])poly(4*x[1]^3 - 3*x[1], [x[1]])

$$\mathrm{poly}(4\,x_1^3 - 3\,x_1, [x_1])$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:
orthpoly::chebyshev1(2, 6*x)72*x^2 - 1

$$72\,x^2 - 1$$

orthpoly::chebyshev1(3, x[1] + 2)4*x[1]^3 + 24*x[1]^2 + 45*x[1] + 26

$$4\,x_1^3 + 24\,x_1^2 + 45\,x_1 + 26$$

"Arithmetical expressions" include numbers:
orthpoly::chebyshev1(2, sqrt(2)), orthpoly::chebyshev1(3, 8 + I), orthpoly::chebyshev1(1000, 0.3)3, 1928 + 761*I, -0.9991251116

$$3,\ 1928 + 761\,i,\ -0.9991251116$$

If no integer degree is specified, `orthpoly::chebyshev1` returns itself symbolically:
orthpoly::chebyshev1(n, x), orthpoly::chebyshev1(1/2, x)orthpoly::chebyshev1(n, x), orthpoly::chebyshev1(1/2, x)

$$\text{orthpoly::chebyshev1}(n, x),\ \text{orthpoly::chebyshev1}\left(\frac{1}{2}, x\right)$$

Example 2

If a floating-point value is desired, then a direct call such as
orthpoly::chebyshev1(200, 0.3)-0.3169632681

$$-0.3169632681$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:
T200 := orthpoly::chebyshev1(200, x):DIGITS := 10: evalp(T200, x = 0.3)-3912167.235

$$-3912167.235$$

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:
DIGITS := 20: evalp(T200, x = 0.3)-0.31710101442512309682

$$-0.31710101442512309682$$

delete DIGITS, T200:

Parameters

n

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If `x` is an arithmetical expression, then the value of the Chebyshev polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::chebyshev1` returns itself symbolically.

Algorithms

The Chebyshev polynomials are given by $T(n, x) = cos(n acos(x))$ for real $x \in [-1, 1]$. This representation is used by `orthpoly::chebyshev1` for floating-point values in this range.

These polynomials satisfy the recursion formula

T(n, x)=2*x*T(n-1, x)-T(n-2, x)

$$T(n, x) = 2\,x\,T(n-1, x) - T(n-2, x)$$

with $T(0, x) = 1$ and $T(1, x) = x$.

They are orthogonal on the interval [- 1, 1] with respect to the weight function w(x)=fenced(1-x^2)^(-1/2) $w(x) = \frac{1}{\sqrt{(1-x^2)}}$.

$T(n, x)$ is a special Jacobi polynomial:

T(n,x) = 2^(2*n) * (n!)^2 / (2*n)! * P(n,-1/2,-1/2,x)

$$T(n, x) = \frac{2^{2n}\, n!^2}{(2n)!}\, P\left(n, -\frac{1}{2}, -\frac{1}{2}, x\right)$$

See Also orthpoly::chebyshev2orthpoly::jacobi

orthpoly::chebyshev2

Purpose

The Chebyshev polynomials of the second kind

Syntax

```
orthpoly::chebyshev2(n, x)
```

Description

`orthpoly::chebyshev2(n,x)` computes the value of the n-th degree Chebyshev polynomial of the second kind at the point x.

These polynomials have integer coefficients.

Evaluation is fast and numerically stable for real floating point values x from the interval [- 1.0, 1.0]. Cf. “Example 2” on page 22-7.

orthpoly::chebyshev1 implements the Chebyshev polynomials of the first kind.

Examples

Example 1

Polynomials of domain type DOM_POLY are returned, if identifiers or indexed identifiers are specified:
orthpoly::chebyshev2(2, x)poly(4*x^2 - 1, [x])

$$\mathrm{poly}\left(4\,x^2-1,\,[x]\right)$$

orthpoly::chebyshev2(3, x[1])poly(8*x[1]^3 - 4*x[1], [x[1]])

$$\mathrm{poly}\left(8\,x_1^3-4\,x_1,\,[x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:
orthpoly::chebyshev2(2, 6*x)144*x^2 - 1

$$144\,x^2-1$$

orthpoly::chebyshev2(3, x[1] + 2)8*x[1]^3 + 48*x[1]^2 + 92*x[1] + 56

$$8\,x_1^3+48\,x_1^2+92\,x_1+56$$

"Arithmetical expressions" include numbers:
orthpoly::chebyshev2(2, sqrt(2)), orthpoly::chebyshev2(3, 8 + I), orthpoly::chebyshev2(1000, 0.3)7, 3872 + 1524*I, -1.012277265

$$7,\ 3872 + 1524\,i,\ -1.012277265$$

If no integer degree is specified, then `orthpoly::chebyshev2` returns itself symbolically:
orthpoly::chebyshev2(n, x), orthpoly::chebyshev2(1/2, x)orthpoly::chebyshev2(n, x), orthpoly::chebyshev2(1/2, x)

$$\text{orthpoly::chebyshev2}(n, x),\ \text{orthpoly::chebyshev2}\left(\frac{1}{2}, x\right)$$

Example 2

If a floating-point value is desired, then a direct call such as orthpoly::chebyshev2(200, 0.3)-0.01869337443

$$-0.01869337443$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:
U200 := orthpoly::chebyshev2(200, x):DIGITS := 10: evalp(U200, x = 0.3)-3872355.739

$$-3872355.739$$

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:
DIGITS := 20: evalp(U200, x = 0.3)-0.018233184138451814741

$$-0.018233184138451814741$$

delete DIGITS, U200:

Parameters

n

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If `x` is an arithmetical expression, then the value of the Chebyshev polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::chebyshev2` returns itself symbolically.

Algorithms

The Chebyshev polynomials of the second kind are given by

U(n, x)=(sin(fenced(n+1)*acos(x)))/(sin(acos(x)))

$$U(n, x) = \frac{\sin((n+1)\,\mathrm{acos}(x))}{\sin(\mathrm{acos}(x))}$$

for real x [- 1, 1]. This representation is used by `orthpoly::chebyshev2` for floating-point values in this range.

These polynomials satisfy the recursion formula

U(n, x)=2*x*U(n-1, x)-U(n-2, x)

$$U(n, x) = 2\,x\,U(n-1, x) - U(n-2, x)$$

with $U(0, x) = 1$ and $U(1, x) = 2x$.

They are orthogonal on the interval [- 1, 1] with respect to the weight function w(x)=sqrt(1-x^2)$w(x) = \sqrt{1-x^2}$.

$U(n, x)$ coincides with the Gegenbauer polynomial$G(n, 1, x)$.

$U(n, x)$ is a special Jacobi polynomial:

U(n,x) = 2^(2*n) * n! * (n+1)! / (2*n+1)! * P(n,1/2,1/2,x)

$$U(n, x) = \frac{2^{2n}\, n!\, (n+1)!}{(2n+1)!}\, P\left(n, \frac{1}{2}, \frac{1}{2}, x\right)$$

See Also orthpoly::chebyshev1orthpoly::gegenbauerorthpoly::jacobi

orthpoly::curtz

Purpose

The Curtz polynomials

Syntax

```
orthpoly::curtz(n, x)
```

Description

`orthpoly::curtz(n,x)` computes the value of the n-th degree Curtz polynomial at the point x.

These polynomials have rational coefficients.

Evaluation for real floating-point values x is numerically stable. Cf. “Example 2” on page 22-11.

Examples

Example 1

Polynomials of domain type DOM_POLY are returned, if identifiers or indexed identifiers are specified:
orthpoly::curtz(2, x)poly(x^2 - x + 1/3, [x])

$$\mathrm{poly}\left(x^2 - x + \frac{1}{3}, [x]\right)$$

orthpoly::curtz(3, x[1])poly(x[1]^3 - (3*x[1]^2)/2 + (11*x[1])/12 - 1/4, [x[1]])

$$\mathrm{poly}\left(x_1^3 - \frac{3\,x_1^2}{2} + \frac{11\,x_1}{12} - \frac{1}{4}, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:
orthpoly::curtz(2, 6*x)36*x^2 - 6*x + 1/3

$$36\,x^2 - 6\,x + \frac{1}{3}$$

orthpoly::curtz(3, x[1] + 2)x[1]^3 + (9*x[1]^2)/2 + (83*x[1])/12 + 43/12

$$x_1^3 + \frac{9\,x_1^2}{2} + \frac{83\,x_1}{12} + \frac{43}{12}$$

"Arithmetical expressions" include numbers:
orthpoly::curtz(2, sqrt(2)), orthpoly::curtz(3, 8 + I), orthpoly::curtz(100, 0.3)7/3 - sqrt(2), 4807/12 + (2015/12)*I, 0.001395122936

$$\frac{7}{3} - \sqrt{2},\ \frac{4807}{12} + \frac{2015\,i}{12},\ 0.001395122936$$

If no integer degree is specified, then `orthpoly::curtz` returns itself symbolically:
orthpoly::curtz(n, x), orthpoly::curtz(1/2, x)orthpoly::curtz(n, x), orthpoly::curtz(1/2, x)

$$\text{orthpoly::curtz}(n, x),\ \text{orthpoly::curtz}\left(\frac{1}{2}, x\right)$$

Example 2

If a floating-point value is desired, then a direct call such as orthpoly::curtz(50, 1.2)0.0003843630923

$$0.0003843630923$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:
orthpoly::curtz(50, x): evalp(%, x = 1.2)0.0003849036173

$$0.0003849036173$$

Note that only 3 digits are correct due to numerical round-off.

Parameters

n

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If `x` is an arithmetical expression, then the value of the Curtz polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::curtz` returns itself symbolically.

Algorithms

The Curtz polynomials are given by the recursion formula

C(n,x) = x^n + x*sum((-1)^i/(i+1) * C(n-i-1,x), i = 1..n-1) + (-1)^n/(n+1)

$$C(n, x) = x^n + x\left(\sum_{i=1}^{n-1} \frac{(-1)^i}{i+1} C(n-i-1, x)\right) + \frac{(-1)^n}{n+1}$$

with $C(0, x) = 1$.

orthpoly::gegenbauer

Purpose

The Gegenbauer (ultraspherical) polynomials

Syntax

```
orthpoly::gegenbauer(n, a, x)
```

Description

`orthpoly::gegenbauer(n,a,x)` computes the value of the n-th degree Gegenbauer polynomial with parameter a at the point x.

Evaluation for real floating-point values x from the interval [- 1.0, 1.0] is numerically stable. See "Example 2" on page 22-14.

Examples

Example 1

Polynomials of domain type DOM_POLY are returned, if identifiers or indexed identifiers are specified:
orthpoly::gegenbauer(2, a, x)poly((2*a + 2*a^2)*x^2 - a, [x])

$$\mathrm{poly}\left(\left(2\,a+2\,a^2\right)\,x^2-a,\,[x]\right)$$

orthpoly::gegenbauer(3, 2, x[1])poly(32*x[1]^3 - 12*x[1], [x[1]])

$$\mathrm{poly}\left(32\,x_1^3-12\,x_1,\,[x_1]\right)$$

However, using arithmetical expressions as input the "values" of these polynomials are returned:
orthpoly::gegenbauer(2, a, 6*x)72*a^2*x^2 + 72*a*x^2 - a

$$72\,a^2\,x^2+72\,a\,x^2-a$$

orthpoly::gegenbauer(3, 2, x[1] + 2)32*x[1]^3 + 192*x[1]^2 + 372*x[1] + 232

$$32\,x_1^3+192\,x_1^2+372\,x_1+232$$

"Arithmetical expressions" include numbers:

orthpoly::gegenbauer(2, a, sqrt(2)), orthpoly::gegenbauer(3, 0.4, 8 + I), orthpoly::gegenbauer(1000, -1/3, 0.3)4*a^2 + 3*a, 865.536 + 341.152*I, 0.00006046127974

$$4\,a^2 + 3\,a,\ 865.536 + 341.152\,i,\ 0.00006046127974$$

If no integer degree is specified, then `orthpoly::gegenbauer` returns itself symbolically:
orthpoly::gegenbauer(n, a, x), orthpoly::gegenbauer(1/2, 2, x)orthpoly::gegenbauer(n, a, x), orthpoly::gegenbauer(1/2, 2, x)

$$\text{orthpoly::gegenbauer}(n,\ a,\ x),\ \text{orthpoly::gegenbauer}\left(\frac{1}{2},\ 2,\ x\right)$$

Example 2

If a floating-point value is desired, then a direct call such as orthpoly::gegenbauer(200, 4, 0.3)165549.7263

$$165549.7263$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:
G200 := orthpoly::gegenbauer(200, 4, x):DIGITS := 10: evalp(G200, x = 0.3)-6.270612376e11

$$-6.270612376\ 10^{11}$$

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:
DIGITS := 20: evalp(G200, x = 0.3)165454.59819021060509

$$165454.59819021060509$$

delete DIGITS, G200:

Parameters

n

A nonnegative integer: the degree of the polynomial.

a

An arithmetical expression.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type "_index").

Return Values

If x is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If x is an arithmetical expression, then the value of the Gegenbauer polynomial at this point is returned as an arithmetical expression. If n is not a nonnegative integer, then orthpoly::gegenbauer returns itself symbolically.

Algorithms

The Gegenbauer polynomials are given by the recursion formula

G(n, a, x)=(2*fenced(n-1+a))/(n)*x*G(n-1, a, x)+(n-2+2*a)/(n)*G(n-2, a, x)

$$G(n, a, x) = \frac{2\,(n-1+a)}{n}\,x\,G(n-1, a, x) + \frac{n-2+2\,a}{n}\,G(n-2, a, x)$$

with $G(0, a, x) = 1$, $G(1, a, x) = 2ax$.

For fixed real a>-1/2 $a > -\frac{1}{2}$ these polynomials are orthogonal on the interval [- 1, 1] with respect to the weight function

w(x)=fenced(1-x^2)^(a-1/2) $w(x) = \left(1-x^2\right)^{a-\frac{1}{2}}$.

G(n, 1/2, x) $G(n, \frac{1}{2}, x)$ coincides with the Legendre polynomial $P(n, x)$.

$G(n, 1, x)$ coincides with the Chebyshev polynomial $U(n, x)$ of the second kind.

The polynomials $G(n, 0, x)$ are trivial.

See Also orthpoly::chebyshev2orthpoly::legendre

orthpoly::hermite

Purpose

The Hermite polynomials

Syntax

```
orthpoly::hermite(n, x)
```

Description

`orthpoly::hermite(n,x)` computes the value of the n-th degree Hermite polynomial at the point x.

These polynomials have integer coefficients.

Examples

Example 1

Polynomials of domain type DOM_POLY are returned, if identifiers or indexed identifiers are specified:
orthpoly::hermite(2, x)poly(4*x^2 - 2, [x])

$$\mathrm{poly}(4\,x^2 - 2, [x])$$

orthpoly::hermite(3, x[1])poly(8*x[1]^3 - 12*x[1], [x[1]])

$$\mathrm{poly}(8\,x_1^3 - 12\,x_1, [x_1])$$

However, using arithmetical expressions as input the "values" of these polynomials are returned:
orthpoly::hermite(2, 6*x)144*x^2 - 2

$$144\,x^2 - 2$$

orthpoly::hermite(3, x[1] + 2)8*x[1]^3 + 48*x[1]^2 + 84*x[1] + 40

$$8\,x_1^3 + 48\,x_1^2 + 84\,x_1 + 40$$

"Arithmetical expressions" include numbers:
orthpoly::hermite(2, sqrt(2)), orthpoly::hermite(3, 8 + I), orthpoly::hermite(1000, 0.3);6, 3808 + 1516*I, 2.26821486e1433

$6,\ 3808 + 1516\ i,\ 2.26821486\ 10^{1433}$

If no integer degree is specified, then `orthpoly::hermite` returns itself symbolically:
orthpoly::hermite(n, x), orthpoly::hermite(1/2, x)orthpoly::hermite(n, x), orthpoly::hermite(1/2, x)

$\text{orthpoly::hermite}(n, x),\ \text{orthpoly::hermite}\left(\frac{1}{2}, x\right)$

Parameters

n

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If `x` is an arithmetical expression, then the value of the Hermite polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::hermite` returns itself symbolically.

Algorithms

The Hermite polynomials are given by the recursion formula

H(n, x)=2*x*H(n-1, x)-2*fenced(n-1)*H(n-2, x)

$H(n, x) = 2\ x\ H(n-1, x) - 2\ (n-1)\ H(n-2, x)$

with $H(0, x) = 1$ and $H(1, x) = 2x$.

These polynomials are orthogonal on the real line with respect to the weight function w(x)=e^(-x^2)$w(x) = \frac{1}{e^{x^2}}$.

orthpoly::jacobi

Purpose

The Jacobi polynomials

Syntax

```
orthpoly::jacobi(n, a, b, x)
```

Description

`orthpoly::jacobi(n,a,b,x)` computes the value of the n-th degree Jacobi polynomial with parameters a and b at the point x.

Evaluation for real floating-point values x from the interval [- 1.0, 1.0] is numerically stable. Cf. “Example 2” on page 22-20.

Examples

Example 1

Polynomials of domain type DOM_POLY are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::jacobi(2, a, b, x)poly(((7*a)/8 + (7*b)/8 + (a*b)/4 + a^2/8 + b^2/8
+ 3/2)*x^2 + ((3*a)/4 - (3*b)/4 + a^2/4 - b^2/4)*x - a/8 - b/8 - (a*b)/4
+ a^2/8 + b^2/8 - 1/2, [x])
```

$$\mathrm{poly}\left(\left(\frac{7\,a}{8}+\frac{7\,b}{8}+\frac{a\,b}{4}+\frac{a^2}{8}+\frac{b^2}{8}+\frac{3}{2}\right)x^2+\left(\frac{3\,a}{4}-\frac{3\,b}{4}+\frac{a^2}{4}-\frac{b^2}{4}\right)x-\frac{a}{8}-\frac{b}{8}-\frac{a\,b}{4}+\frac{a^2}{8}+\frac{b^2}{8}-\frac{1}{2},\,[x]\right)$$

```
orthpoly::jacobi(3, 4, 5, x[1])poly((455*x[1]^3)/8 - (91*x[1]^2)/8 -
(91*x[1])/8 + 7/8, [x[1]])
```

$$\mathrm{poly}\left(\frac{455\,x_1^3}{8}-\frac{91\,x_1^2}{8}-\frac{91\,x_1}{8}+\frac{7}{8},\,[x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::jacobi(2, 4, b, 6*x)(9*b^2*x^2)/2 - (3*b^2*x)/2 + b^2/8 +
(135*b*x^2)/2 - (9*b*x)/2 - (9*b)/8 + 252*x^2 + 42*x + 1
```

$$\frac{9\,b^2\,x^2}{2}-\frac{3\,b^2\,x}{2}+\frac{b^2}{8}+\frac{135\,b\,x^2}{2}-\frac{9\,b\,x}{2}-\frac{9\,b}{8}+252\,x^2+42\,x+1$$

```
orthpoly::jacobi(2, 0, I, x[1] + 2)x[1]^2*(11/8 + (7/8)*I) + x[1]*(23/4 +
(11/4)*I) + 43/8 + (15/8)*I
```

$$x_1^2\left(\frac{11}{8}+\frac{7\,i}{8}\right)+x_1\left(\frac{23}{4}+\frac{11\,i}{4}\right)+\frac{43}{8}+\frac{15\,i}{8}$$

"Arithmetical expressions" include numbers:
orthpoly::jacobi(2, 1/2, -1/2, sqrt(2)), orthpoly::jacobi(3, 2, 5, 8 + I), orthpoly::jacobi(1000, 1, 2, 0.3);(3*sqrt(2))/4 + 21/8, 31733/2 + (12859/2)*I, -0.06546648097

$$\frac{3\sqrt{2}}{4}+\frac{21}{8},\ \frac{31733}{2}+\frac{12859\,i}{2},\ -0.06546648097$$

If no integer degree is specified, then `orthpoly::jacobi` returns itself symbolically:
orthpoly::jacobi(n, a, b, x), orthpoly::jacobi(1/2, 0, 1, 1)orthpoly::jacobi(n, a, b, x), orthpoly::jacobi(1/2, 0, 1, 1)

$$\text{orthpoly::jacobi}(n,\,a,\,b,\,x),\ \text{orthpoly::jacobi}\left(\frac{1}{2},\,0,\,1,\,1\right)$$

Example 2

If a floating-point value is desired, then a direct call such as orthpoly::jacobi(100, 1/2, 3/2, 0.9)0.2560339406

$$0.2560339406$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:
P100 := orthpoly::jacobi(100, 1/2, 3/2, x):evalp(P100, x = 0.9)-8.6781052e15

$$-8.6781052\,10^{15}$$

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:
DIGITS := 30: evalp(P100, x = 0.9)0.256030968488207303016930946513

0.25603096848820730301693094651 3
delete P100, DIGITS:

Parameters

n

A nonnegative integer: the degree of the polynomial.

a

b

Arithmetical expressions.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If `x` is an arithmetical expression, then the value of the Jacobi polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::jacobi` returns itself symbolically.

Algorithms

The Jacobi polynomials are given by the recursion formula

2*n*c[n]*c[2*n-2]*P(n,a,b,x) =
c[2*n-1]*(c[2*n-2]*c[2*n]*x+a^2-b^2)*P(n-1,a,b,x)
-2*(n-1+a)*(n-1+b)*c[2*n]*P(n-2,a,b,x)

$$2\,n\,c_n\,c_{2\,n-2}\,P(n,a,b,x) = c_{2\,n-1}\left(c_{2\,n-2}\,c_{2\,n}\,x + a^2 - b^2\right) P(n-1,a,b,x) - 2\,(n-1+a)\,(n-1+b)\,c_2$$

with $c_i = i + a + b$ and

P(0, a, b, x)=1, P(1,a,b,x) =(a-b)/2 + (1+(a+b)/2)*x

$$P(0, a, b, x) = 1,\ P(1, a, b, x) = \frac{a-b}{2} + \left(1 + \frac{a+b}{2}\right) x$$

For fixed real $a > -1$, $b > -1$ the Jacobi polynomials are orthogonal on the interval [- 1, 1] with respect to the weight function $w(x) = (1 - x)^a(1 + x)^b$.

For special values of the parameters a, b the Jacobi polynomials are related to the Legendre polynomials

P(n, x)=P(n, 0, 0, x)

$$P(n, x) = P(n, 0, 0, x)$$

to the Chebyshev polynomials of the first kind

T(n,x) = 2^(2*n) * (n!)^2 / (2*n)! * P(n,-1/2,-1/2,x)

$$T(n, x) = \frac{2^{2n} n!^2}{(2n)!} P\left(n, -\frac{1}{2}, -\frac{1}{2}, x\right)$$

to the Chebyshev polynomials of the second kind

U(n,x) = 2^(2*n) * n! * (n+1)! / (2*n+1)! * P(n,1/2,1/2,x)

$$U(n, x) = \frac{2^{2n} n! (n+1)!}{(2n+1)!} P\left(n, \frac{1}{2}, \frac{1}{2}, x\right)$$

and to the Gegenbauer polynomials, respectively:

G(n,a,x) = Symbol::Gamma(a+1/2) * Symbol::Gamma(n+2*a) / (Symbol::Gamma(2*a) * Symbol::Gamma(n+a+1/2)) * P(n,a-1/2,a-1/2,x)

$$G(n, a, x) = \frac{\Gamma\left(a + \frac{1}{2}\right) \Gamma(n + 2a)}{\Gamma(2a) \Gamma\left(n + a + \frac{1}{2}\right)} P\left(n, a - \frac{1}{2}, a - \frac{1}{2}, x\right)$$

orthpoly::chebyshev1orthpoly::chebyshev2orthpoly::gegenbauerorthpoly::legendre

orthpoly::laguerre

Purpose

The (generalized) Laguerre polynomials

Syntax

```
orthpoly::laguerre(n, a, x)
```

Description

`orthpoly::laguerre(n,a,x)` computes the value of the generalized n-th degree Laguerre polynomial with parameter a at the point x.

The standard Laguerre polynomials correspond to $a = 0$. They have rational coefficients.

Examples

Example 1

Polynomials of domain type DOM_POLY are returned, if identifiers or indexed identifiers are specified:
orthpoly::laguerre(2, a, x)poly(x^2/2 + (- a - 2)*x + (3*a)/2 + a^2/2 + 1, [x])

$$\mathrm{poly}\left(\frac{x^2}{2} + (-a-2)\,x + \frac{3\,a}{2} + \frac{a^2}{2} + 1, [x]\right)$$

orthpoly::laguerre(3, a, x[1])poly(- x[1]^3/6 + (a/2 + 3/2)*x[1]^2 + (- (5*a)/2 - a^2/2 - 3)*x[1] + (11*a)/6 + a^2 + a^3/6 + 1, [x[1]])

$$\mathrm{poly}\left(-\frac{x_1^3}{6} + \left(\frac{a}{2} + \frac{3}{2}\right) x_1^2 + \left(-\frac{5\,a}{2} - \frac{a^2}{2} - 3\right) x_1 + \frac{11\,a}{6} + a^2 + \frac{a^3}{6} + 1, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:
orthpoly::laguerre(2, 4, 6*x)18*x^2 - 36*x + 15

$$18\,x^2 - 36\,x + 15$$

orthpoly::laguerre(2, 2/3*I, x[1] + 2)x[1]^2/2 - (2*x[1]*I)/3 - 11/9 - (1/3)*I

$$\frac{x_1^2}{2} - \frac{2\,x_1\,i}{3} - \frac{11}{9} - \frac{i}{3}$$

“Arithmetical expressions” include numbers:

orthpoly::laguerre(2, a, sqrt(2)), orthpoly::laguerre(3, 0.4, 8 + I), orthpoly::laguerre(1000, 3, 0.3);(3*a)/2 - sqrt(2)*a - 2*sqrt(2) + a^2/2 + 2, - 4.969333333 + (- 8.713333333*I), -15691.69498

$$\frac{3\,a}{2} - \sqrt{2}\,a - 2\,\sqrt{2} + \frac{a^2}{2} + 2,\ -4.969333333 - 8.713333333\,i,\ -15691.69498$$

If no integer degree is specified, then `orthpoly::laguerre` returns itself symbolically:
orthpoly::laguerre(n, a, x), orthpoly::laguerre(1/2, a, x)orthpoly::laguerre(n, a, x), orthpoly::laguerre(1/2, a, x)

$$\text{orthpoly::laguerre}(n,\ a,\ x),\ \text{orthpoly::laguerre}\left(\frac{1}{2},\ a,\ x\right)$$

Parameters

n

A nonnegative integer: the degree of the polynomial.

a

An arithmetical expression.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If `x` is an arithmetical expression, then the value of the Laguerre polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::laguerre` returns itself symbolically.

Algorithms

The Laguerre polynomials are given by the recursion formula

L(n, a, x)=(2*n+a-1-x)/(n)*L(n-1, a, x)-(n+a-1)/(n)*L(n-2, a, x)

$$L(n, a, x) = \frac{2n + a - 1 - x}{n} L(n - 1, a, x) - \frac{n + a - 1}{n} L(n - 2, a, x)$$

with $L(0, a, x) = 1$ and $L(1, a, x) = 1 + a - x$.

For fixed real $a > -1$ these polynomials are orthogonal on the interval Interval([0],infinity)$[0, \infty)$ with respect to the weight function w(x)=x^ae^(-x) $w(x) = \frac{1}{(x^{ae})^x}$.

orthpoly::legendre

Purpose

The Legendre polynomials

Syntax

```
orthpoly::legendre(n, x)
```

Description

`orthpoly::legendre(n,x)` computes the value of the n-th degree Legendre polynomial at the point x.

These polynomials have rational coefficients.

Evaluation for real floating-point values x from the interval [- 1.0, 1.0] is numerically stable. Cf. “Example 2” on page 22-27.

Use numeric::gldata to compute the roots of the Legendre polynomials. Cf. “Example 3” on page 22-28.

Examples

Example 1

Polynomials of domain type DOM_POLY are returned, if identifiers or indexed identifiers are specified:
orthpoly::legendre(2, x)poly((3*x^2)/2 - 1/2, [x])

$$\mathrm{poly}\left(\frac{3\,x^2}{2} - \frac{1}{2}, [x]\right)$$

orthpoly::legendre(3, x[1])poly((5*x[1]^3)/2 - (3*x[1])/2, [x[1]])

$$\mathrm{poly}\left(\frac{5\,x_1^3}{2} - \frac{3\,x_1}{2}, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:
orthpoly::legendre(2, 6*x)54*x^2 - 1/2

$$54\,x^2 - \frac{1}{2}$$

orthpoly::legendre(3, x[1] + 2)(5*x[1]^3)/2 + 15*x[1]^2 + (57*x[1])/2 + 17

$$\frac{5\,x_1^3}{2} + 15\,x_1^2 + \frac{57\,x_1}{2} + 17$$

"Arithmetical expressions" include numbers:
orthpoly::legendre(2, sqrt(2)), orthpoly::legendre(3, 8 + I),
orthpoly::legendre(1000, 0.3)5/2, 1208 + 476*I, -0.02566916751

$$\frac{5}{2},\ 1208 + 476\,i,\ -0.02566916751$$

If no integer degree is specified, then `orthpoly::legendre` returns itself symbolically:
orthpoly::legendre(n, x), orthpoly::legendre(1/2, x)orthpoly::legendre(n, x), orthpoly::legendre(1/2, x)

$$\text{orthpoly::legendre}(n,\ x),\ \text{orthpoly::legendre}\left(\frac{1}{2},\ x\right)$$

Example 2

If a floating-point value is desired, then a direct call such as
orthpoly::legendre(100, 0.9)0.1022658206

$$0.1022658206$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:
P100 := orthpoly::legendre(100, x):evalp(P100, x = 0.9)8.284745953e14

$$8.284745953\ 10^{14}$$

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:
DIGITS := 30: evalp(P100, x = 0.9)0.10227630391054687554826696711 2

$$0.10227630391054687554826696711 2$$

delete P100, DIGITS:

Example 3

We recommend to use numeric::gldata for computing roots of the Legendre polynomial $P(n, x)$. This routine provides all roots of the function $Q(n, y) = P(n, 2y - 1)$:

```
QRoots := numeric::gldata(5, DIGITS)[2][0.04691007703, 0.2307653449,
1/2, 0.7692346551, 0.953089923]
```

$$\left[0.04691007703,\ 0.2307653449,\ \frac{1}{2},\ 0.7692346551,\ 0.953089923\right]$$

These values are easily transformed to roots of $P(n, x)$:

```
PRoots := map(QRoots, y -> 2*y - 1)[-0.9061798459, -0.5384693101,
0, 0.5384693101, 0.9061798459]
```

$$\left[-0.9061798459,\ -0.5384693101,\ 0,\ 0.5384693101,\ 0.9061798459\right]$$

```
orthpoly::legendre(5, r) $ r in PRoots-1.080385781e-14,
-1.387778781e-18, 0, 1.387778781e-18, 1.081218448e-14
```

$$-1.080385781\ 10^{-14},\ -1.387778781\ 10^{-18},\ 0,\ 1.387778781\ 10^{-18},\ 1.081218448\ 10^{-14}$$

delete QRoots, PRoots:

Parameters

n

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If `x` is an arithmetical expression, then the value of the Legendre polynomial at this point is returned as an arithmetical

expression. If `n` is not a nonnegative integer, then `orthpoly::legendre` returns itself symbolically.

Algorithms

The Legendre polynomials are given by P(n,x) = 1/(2^n*n!) * _outputSequence(d^n/dx^n, (x^2 - 1)^n) $P(n, x) = \frac{1}{2^n n!} \frac{d^n}{dx^n}\left(x^2 - 1\right)^n$.

They satisfy the recursion formula

P(n,x) = (2*n-1)/n * x * P(n-1,x) - (n-1)/n * P(n-2,x)

$$P(n, x) = \frac{2n-1}{n} x P(n-1, x) - \frac{n-1}{n} P(n-2, x)$$

with $P(0, x) = 1$ and $P(1, x) = x$.

They are orthogonal on the interval [- 1, 1] with respect to the weight function $w(x) = 1$.

$P(n, x)$ coincides with the Gegenbauer polynomial G(n, 1/2, x) $G(n, \frac{1}{2}, x)$.

$P(n, x)$ coincides with the Jacobi polynomial $P(n, 0, 0, x)$.

output – Formatted Output

==REFNAME==

output::asciiAbbreviate

Purpose

Generates a procedure for creating an ASCII formatted output

Syntax

```
output::asciiAbbreviate(<varname>)
```

Description

`output::asciiAbbreviate` generates a procedure for creating ASCII formatted outputs of expressions

By default, MuPAD generates ASCII abbreviations using the # symbol followed by numbers. Using the argument `varname` you can customize the names of abbreviated subexpressions. See “Example 2” on page 23-2.

If you want to use abbreviations in all ASCII PrettyPrint output expressions, pass the procedure generated by `output::asciiAbbreviate` to Pref::output. See “Example 3” on page 23-2.

Examples

Example 1

The generated procedure `ascii` produces ASCII code for MuPAD expressions:

```
ascii:=output::asciiAbbreviate(): y := solve(x^3 + x + 1 = 0, x, MaxDegree
= 3): ascii(y) { 1/2 / 1 \ 1/2 / 1 \ } { 3 | ---- + #1 | I 3 | ---- + #1 | I } { 1
1 #1 \ 3 #1 / 1 #1 \ 3 #1 / } { #1 - ----, ---- - -- - ----------------------, ---- - -- +
---------- } { 3 #1 6 #1 2 2 6 #1 2 2 } where / 1/2 1/2 \1/3 | 31 108 1
| #1 = | ------------ - - | \ 108 2 /
```

Example 2

You can customize the names of abbreviated subexpressions:

```
ascii:=output::asciiAbbreviate(t): y := solve(x^3 + x + 1 = 0, x,
MaxDegree = 3): ascii(y) { 1/2 / 1 \ 1/2 / 1 \ } { 3 | ---- + t1 | I 3 | ---- + t1
| I } { 1 1 t1 \ 3 t1 / 1 t1 \ 3 t1 / } { t1 - ----, ---- - -- - ----------------------, ---- - --
+ ---------- } { 3 t1 6 t1 2 2 6 t1 2 2 } where / 1/2 1/2 \1/3 | 31 108
1 | t1 = | ------------ - - | \ 108 2 /
```

Example 3

The generated procedure can serve as an input for Pref::output:

```
Pref::output(output::asciiAbbreviate(u)): y := solve(x^3 + x + 1 = 0, x,
MaxDegree = 3) { 1/2 / 1 \ 1/2 / 1 \ } { 3 | ---- + u1 | I 3 | ---- + u1 | I } { 1
1 u1 \ 3 u1 / 1 u1 \ 3 u1 / } { u1 - ----, ---- - -- + ----------, ---- - -- -
---------- } { 3 u1 6 u1 2 2 6 u1 2 2 } where / 1/2 1/2 \1/3 | 31 108 1
| u1 = | ------------ - - | \ 108 2 /
```

Parameters

varname

A base name for the abbreviation variables

Return Values

Procedure for creating an ASCII formatted output

See Also

output::subexprPref::abbreviateOutputPref::output

output::fence

Purpose

Put delimiters around multi-line strings

Syntax

```
output::fence(left, right, string, <width, <base>>)
```

Description

`output::fence(l, r, str)` encloses the multi-line string in the delimiters indicated by `l` and `r`

`output::fence`, in combination with strprint, can be used for overloading print (and thereby, standard screen output) for "pretty-printing". (Note: This will not affect "Typesetting" output.)

Examples

Example 1

For all examples on this page we assume the TEXTWIDTH 75:
TEXTWIDTH := 75:

Since useful examples are more complicated, we present the effect of `output::fence` with some more-or-less random garbage. First, we define a domain that uses `output::fence` for output:
domain Fence print := x -> output::fence("(", ")", extop(x, 1)); new := x -> new(dom, x); end_domain:

`Fence` expects a string in its constructor and we defined the output to use `output::fence` to put parentheses around the input:
print(Plain, Fence("abc")) (abc)

Strings of height two are only partly placed inside parentheses, for consistency with the pretty-printer:
print(Plain, Fence("abc\ndef"), sin(x^2)) abc 2 (def), sin(x)

Strings of height more than two are fully bracketed:
print(Plain, Fence("abc\ndef\nghi")) / abc \ | def | \ ghi /

Example 2

The next step in using `output::fence` is to enclose expressions in parentheses. For this, the information from strprint is useful:
domain FenceExpr print := proc(x) local str, h1, w1, h, w, b; begin [str, h1, w1, h, w, b] := strprint(All, extop(x)); output::fence("{", "]", str,

w, b); end_proc; new := x -> new(dom, x); end_domain:print(Plain, FenceExpr(x), FenceExpr(x^2), FenceExpr(x^2/2*y)) { 2 -- 2 { x y | {x], {x], { ---- | { 2 --

As you can see, the sixth operand of the return value of `strprint(All, )` should be given to `output::fence` to get nicely aligned baselines.

Example 3

The non-typeset screen output of abs is as follows:
print(Plain, abs(x), abs(x^y), abs((x/y)^z)) | y| |/ x \z| |x|, |x |, || - | | |\ y / |

The code responsible for this output is the second operand of the `abs`function environment:
expose(op(abs, 2)) proc(ex) local str; begin if PRETTYPRINT then str := strprint(All, op(ex)); if str[1] <> "" and str[2] = str[4] then if str[1][1] = "\n" then str[1] := str[1][2..-1]; str[6] := str[6] - 1 else if str[1][1..2] = "\r\n" then str[1] := str[1][3..-1]; str[6] := str[6] - 1 end_if end_if; output::fence("|", "|", str[1], str[3], str[6]) else FAIL end_if else FAIL end_if end_proc

There are two differences to what we have done in the example above: First, the code reacts to PRETTYPRINT. This is because with `PRETTYPRINT = FALSE`, the `abs` function shall be printed in functional notation:
PRETTYPRINT := FALSE: print(Plain, abs(x)); delete PRETTYPRINT: abs(x)

The second difference is more subtle: strprint reacts to TEXTWIDTH and may return a string consisting or more than one logical line. In this case, fencing the returned string leads to strange results:
print(Plain, FenceExpr(_plus(x.i $ i = 0..30))) { x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9 + x10 + x11 + x12 + x13 \ + -- { \ | { x14 + x15 + x16 + x17 + x18 + x19 + x20 + x21 + x22 + x23 + x24 + x25\ + | { \ | { x26 + x27 + x28 + x29 + x30 \ --

Apart from the fact that the string with added delimiter symbols is too wide for TEXTWIDTH, drawing large delimiters to the left and the right of the long string is hardly the right thing to do. `output::fence`

does not offer a way to handle line breaks gracefully (which should not be done on formatted strings in any case and is outside the regime of `output::fence`), and for abs it would be a highly questionable thing to do. Therefore, abs will print in functional notation for long arguments: print(Plain, abs(_plus(x.i $ i = 0..30))) abs(x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9 + x10 + x11 + x12 + x13 + x14 + x15 + x16 + x17 + x18 + x19 + x20 + x21 + x22 + x23 + x24 + x25 + x26 + x27 + x28 + x29 + x30)

Parameters

left

right

Strings indicating the type of delimiter: `"("`, `")"`, `"["`, `"]"`, `"[+"`, `"+]"`, `"{"`, `"}"`, `"|"`, `"| "`, or `" |"`.

string

The string to enclose

width

The width of the string to enclose. Defaults to the width of the widest line in `string`.

base

The baseline of the string, counted from the first line. Defaults to the bottom line of the string. If set to `-1`, the baseline is vertically centered.

Return Values

String

See Also

strprint

output::mathText

Purpose

Pretty output of text combined with formulas

Syntax

`output::mathText(str1, expr1, <str2, <expr2>, >)`

Description

`output::mathText( str1, expr1, str2, )` creates an object of combined strings and expressions. This object prints itself nicely in various output formats.

Examples

Example 1

`output::mathText` creates an object representing combined text and formulas:

```
messageWithMath := output::mathText("The integral ",
hold(int(sin(x)*cos(x), x)), " is equal to ", int(sin(x)*cos(x),
x))output::mathText("The integral ", int(sin(x)*cos(x), x), " is equal to ",
sin(x)^2/2)
```

$$\text{The integral } \int \cos(x)\sin(x)\,dx \text{ is equal to } \frac{\sin(x)^2}{2}$$

They can be printed with the ASCII pretty-printer as well:

```
print(Plain, messageWithMath)
                                  / 2
                                  | sin(x)
The integral | sin(x) cos(x) dx is equal to -------
                                  / 2
```

Same for the ASCII lineprint output:

```
PRETTYPRINT := FALSE: print(Plain, messageWithMath): delete
PRETTYPRINT:
The integral int(sin(x)*cos(x), x) is equal to (1/2)*sin(x)^2
```

Parameters

str1

str2

Strings

expr1

expr2

Expressions

Return Values Object of type `output::mathText`

See Also strprint

output::ordinal

Purpose

Ordinal numbers

Syntax

```
output::ordinal(i)
```

Description

`output::ordinal` converts an integer to the corresponding english ordinal number. The return value is a string and can be used in messages.

Examples

Example 1

Convert some numbers to the corresponding english ordinal string: map([0, 1, 2, 3, 4, 22, 134, 2001], output::ordinal)["0th", "1st", "2nd", "3rd", "4th", "22nd", "134th", "2001st"]

```
["0th", "1st", "2nd", "3rd", "4th", "22nd", "134th", "2001st"]
```

Parameters

i

An integer number

Return Values

String with the english ordinal number

See Also

infouserinfoprint

output::roman

Purpose

Roman numerals

Syntax

```
output::roman(n)
```

Description

`output::roman` converts an integer to the corresponding roman numeral. The return value is a string and can be used in messages.

Examples

Example 1

Convert some numbers to the corresponding roman numerals:
map([1, 2, 3, 4, 22, 134, 2001], output::roman)["I", "II", "III", "IV", "XXII", "CXXXIV", "MMI"]

```
["I", "II", "III", "IV", "XXII", "CXXXIV", "MMI"]
```

Now, thanks to alias backsubstitution, we can trick MuPAD into computing with roman numerals:
alias(‘I‘=1): // I is a reserved word in MuPAD,
so we use ‘I‘ instead for i from 2 to 1000 do
eval(text2expr("alias(".output::roman(i)."=".expr2text(i).");")); end_for:
II+II; XIII*XXIVIV

```
IV
```

CCCXII

```
CCCXII
```

unalias(‘I‘): for i from 2 to 1000 do
eval(text2expr("unalias(".output::roman(i).");")); end_for:

Parameters

n

Positive integer

Return Values String containing the roman numeral

See Also infouserinfoprint

output::subexpr

Purpose

Abbreviates a expression

Syntax

```
output::subexpr(e, <varname>)
```

Description

`output::subexpr` rewrites symbolic expression in terms of common subexpressions.

If an expression `e` contains common subexpressions, `output::subexpr(e)` returns a list that contains the abbreviated expression and the abbreviations in a form of equations. With `output::subexpr` you get the same abbreviations as you see in the outputs. See “Example 1” on page 23-12.

An output of this command does not depend on the current setting of Pref::abbreviateOutput.

By default, MuPAD generates abbreviations using the # symbol followed by numbers. Using the argument `varname`, you can customize the names of abbreviated subexpressions. See “Example 2” on page 23-12.

Examples

Example 1

You can abbreviate an expression:

```
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3): output::subexpr(y)[{#[1] - 1/(3*#[1]), 1/(6*#[1]) - #[1]/2 + (sqrt(3)*(1/(3*#[1]) + #[1])*I)/2, 1/(6*#[1]) - #[1]/2 - (sqrt(3)*(1/(3*#[1]) + #[1])*I)/2}, #[1] = ((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)]
```

$$\left[\left\{\#_1 - \frac{1}{3\,\#_1},\ \frac{1}{6\,\#_1} - \frac{\#_1}{2} + \frac{\sqrt{3}\left(\frac{1}{3\,\#_1} + \#_1\right)\mathrm{i}}{2},\ \frac{1}{6\,\#_1} - \frac{\#_1}{2} - \frac{\sqrt{3}\left(\frac{1}{3\,\#_1} + \#_1\right)\mathrm{i}}{2}\right\},\ \#_1 = \left(\frac{\sqrt{31}\,\sqrt{108}}{108} - \frac{1}{2}\right)^{1/3}\right]$$

Example 2

You can customize the names of abbreviated subexpressions:

```
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3): output::subexpr(y, t)[{t1 - 1/(3*t1), 1/(6*t1) - t1/2 - (sqrt(3)*(1/(3*t1) + t1)*I)/2, 1/(6*t1) - t1/2 + (sqrt(3)*(1/(3*t1) + t1)*I)/2}, t1 = ((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)]
```

$$\left[\left\{t1 - \frac{1}{3\,t1},\ \frac{1}{6\,t1} - \frac{t1}{2} - \frac{\sqrt{3}\left(\frac{1}{3\,t1} + t1\right)i}{2},\ \frac{1}{6\,t1} - \frac{t1}{2} + \frac{\sqrt{3}\left(\frac{1}{3\,t1} + t1\right)i}{2}\right\},\ t1 = \left(\frac{\sqrt{31}\,\sqrt{108}}{108} - \frac{1}{2}\right)^{1/}\right.$$

Parameters

e

A MuPAD expression

varname

A base name for the abbreviation variables

Return Values

List that contains the abbreviated expression and the abbreviations as equations

See Also

Pref::abbreviateOutputoutput::asciiAbbreviate

output::tableForm

Purpose

Printing objects in table form

Syntax

```
output::tableForm(obj, <separator>, options)
```

Description

`output::tableForm(obj)` prints the elements of the given object `obj` in table form.

The width of the table and the number of columns depends on the size of TEXTWIDTH (see options `Width` and `Columns`). The width of a column depends on the widest entry in this column.

`output::tableForm` determines the number of columns, that the total width of the table fits into TEXTWIDTH.

The columns are separated by one space by default.

If `separator` is given, then it is printed between each column (instead of one space). Appending spaces to the separator results additionally space between columns. By default the separator is one space.

If the first argument `obj` is a table or a domain, `output::tableForm` uses the option `Columns = 2` (two columns) and the separator `"= "` as default.

Without the option `Sort` the objects are converted to strings and then sorted alphabetically. To avoid any sorting the option `Sort = FALSE` must be given.

Examples

Example 1

For all examples on this page we assume the TEXTWIDTH 75:
TEXTWIDTH := 75:

Print some random numbers in table form:
SEED := -1: output::tableForm([random(100000)() $ k = 1..30])11647 12826 26280 26292 28315 30908 36523 42073 4682 47334 52640 564265829 615 62580 65904 66223 6719 69451 69903 77904 78221 80528 8101386068 89016 90516 91008 92791 9532

Some random strings are created. The columns should have all the same width (`Unique`) and be printed centered. The strings should not be sorted:

```
output::tableForm([_concat("*" $ random(10)()) $ k = 1..20], Unique,
Center, Sort = FALSE) "*********" "*******" "**********" "*********" "*"
"******""**********" "******" "*****" "*********" "*****" "******""**********"
"********" "********" "*******" "***" "*****"
```

The option `Unquoted` prevents printing of quotes (see fprint):

```
output::tableForm([_concat("*" $ random(10)()) $ k = 1..20], Unique,
Center, Sort = FALSE, Unquoted)******** * ****** ****** **** ******
** ** ***** * **** **** ** ******** ******* ** * *******
```

Example 2

The next object is a MuPAD table and should be printed as a table with two columns. The table contains some random numbers and their sum of the digits:

```
SEED := -1: T := table(op(map([random(100000000)() $ k = 1..10], proc(X)
local Xs, k; begin Xs := expr2text(X); X = _plus(text2expr(substring(Xs,
k)) $ k = 1..length(Xs)) end_proc))): output::tableForm(T)19962580 =
4025878221 = 3537777904 = 4441281013 = 2043856426 = 3846169451 =
3666926292 = 4280330908 = 3189306719 = 4394386068 = 44
```

Domains are also printed in this form by default:

```
output::tableForm(newDomain("Test", table("type" = "Test", "info" =
"only a testdomain")))"info" = "only a testdomain""key" = "Test""type"
= "Test"
```

Example 3

The next table should consist of four columns:

```
SEED := -1: output::tableForm([random(100000)() $ k = 1..30], Columns
= 4)11647 12826 26280 2629228315 30908 36523 420734682 47334
52640 564265829 615 62580 6590466223 6719 69451 6990377904 78221
80528 8101386068 89016 90516 9100892791 9532
```

The next table should have a maximal width of `50` characters:

```
SEED := -1: output::tableForm([random(100000)() $ k = 1..30], Width
= 50)11647 12826 26280 26292 28315 30908 36523 420734682 47334
```

52640 56426 5829 615 62580 6590466223 6719 69451 69903 77904
78221 80528 8101386068 89016 90516 91008 92791 9532 delete T:

Example 4

The next examples show different usage of separators. First one single separator:

```
SEED := -1: output::tableForm([random(100000)() $ k = 1..30],
"|")11647|12826|26280|26292|28315|30908|36523|42073|4682
|47334|52640|564265829|615  |62580|65904|66223|6719
|69451|69903|77904|78221|80528|8101386068|89016|90516|91008|92791|9532
```

Now a list with a separator character between each column. If the list is too short, the characters are used from beginning of the list again etc.:

```
SEED := -1: output::tableForm([random(100000)() $ k = 1..30], ["|",
" ", " "])11647|12826 26280 26292|28315 30908 36523|42073 4682
47334|52640 564265829|615 62580 65904|66223 6719 69451|69903
77904 78221|80528 8101386068|89016 90516 91008|92791 9532
```

Only the first both colunms should be separated by a vertical line:

```
SEED := -1: output::tableForm([random(100000)() $ k = 1..30], ["|", " " $
10])11647|12826 26280 26292 28315 30908 36523 42073 4682 47334
52640 564265829|615 62580 65904 66223 6719 69451 69903 77904
78221 80528 8101386068|89016 90516 91008 92791 9532
```

Additionally a character can be appended to each entry:

```
SEED := -1: output::tableForm([random(100000)() $ k = 1..30], ["|", " "
$ 10], Append = ",")11647,|12826, 26280, 26292, 28315, 30908, 36523,
42073, 4682, 47334, 52640,56426,|5829, 615, 62580, 65904, 66223,
6719, 69451, 69903, 77904, 78221,80528,|81013, 86068, 89016, 90516,
91008, 92791, 9532,
```

Example 5

The next examples show different usage of sorting. Without the option `Sort` the numbers are sorted as strings in lexicographical order:

```
SEED := -1: output::tableForm([random(100000)() $ k = 1..30])11647
12826 26280 26292 28315 30908 36523 42073 4682 47334 52640
564265829 615 62580 65904 66223 6719 69451 69903 77904 78221
80528 8101386068 89016 90516 91008 92791 9532
```

`Sort = FALSE` avoids any sorting:
SEED := -1: output::tableForm([random(100000)() $ k = 1..30], Sort = FALSE)30908 6719 26292 56426 81013 69451 77904 78221 86068 62580 47334 128269532 5829 28315 65904 42073 80528 4682 52640 69903 92791 36523 2628089016 91008 615 66223 90516 11647

Any sorting can be done with a special defined procedure, e.g., sort the numbers in reverse order:
SEED := -1: output::tableForm([random(100000)() $ k = 1..30], Sort = ((X,Y) -> Y < X))92791 91008 90516 89016 86068 81013 80528 78221 77904 69903 69451 6622365904 62580 56426 52640 47334 42073 36523 30908 28315 26292 26280 1282611647 9532 6719 5829 4682 615

At last a user defined procedure is given that sorts the numbers by the sum of their digits ascending:
SEED := -1: output::tableForm([random(100000)() $ k = 1..30], Sort = proc(X,Y) local crossfoot; begin crossfoot := proc(X) local Xs, k; begin Xs := expr2text(X); _plus(text2expr(substring(Xs, k)) $ k = 1..length(Xs)) end_proc; crossfoot(X) < crossfoot(Y) end_proc)615 81013 42073 52640 91008 26280 36523 11647 12826 66223 9532 2831530908 4682 78221 26292 90516 47334 62580 56426 80528 6719 5829 6590489016 69451 77904 69903 92791 86068

Parameters

obj

A list, set or table of any MuPAD objects or a domain

separator

A string between columns

Options

Unquoted

Strings are printed without quotes

The output function fprint is called with the option `Unquoted`.

Unique

All columns are of the same width

All columns are printed with the same width, the widest column determines the width of each column.

Width

Option, specified as `Width = w`

The maximal width of the table is set to `w` (instead of TEXTWIDTH). `w` must be a positive integer.

Columns

Option, specified as `Columns = c`

The number of columns is set to `c`. The width of the table depends on the width of any column.

Note `output::tableForm` called with this option takes not care about the value of TEXTWIDTH.

`c` must be a positive integer.

Center

Left

Right

The entries of each column are aligned left-justified, centered or justified.

Sort

Option, specified as `Sort = procedure`

The entries are sorted with the given procedure. Entries can be printed unsorted, when `procedure` is the object FALSE.

Output

Option, specified as `Output = file`

Output into a file. If `file` is a string, a file named `file` is opened and overwritten and closed after writing. If `file` is a file descriptor (the return value of fopen), the table is appended to `file` without closing `file`.

String

Return as a string that can be printed

The string contains line breaks, and can be printed with print or fprint and option `Unquoted`.

Append

Option, specified as `Append = string`

Character string is appended to each entry of the list

Return Values

Void object `null()`

See Also

output::treeprintfopenfprintfclosesort

output::tree

Purpose

Display of trees

Syntax

```
output::tree(Tree, <indentdepth, <charlist>, <Small>>)
```

Description

`output::tree` displays trees given as specially MuPAD lists.

The first object of the list is the root of the tree. All further objects are nodes or subtrees of the tree. A subtree is again a special list (as described), and any other MuPAD object will be interpreted as node of the tree.

The elements of the tree will be printed by MuPAD, when the tree will be displayed, so it's recommended to use strings as objects or objects with a well defined display.

The return value is a string that contains all chars to display the tree. With functions print and fprint*and* the option `Unquoted` the tree can be displayed.

The parameter `charlist` is a list with five characters. The default value is `["|", "+", "-",  ", " "]`. The characters have the following meaning (described in the order of the list).

The vertical lines of the tree, the connection between vertical and horizontal line (i.e., an arm, but not the last arm), an arm (vertical line), the last connection to an arm in a subtree, a char between an arm and the description of the arm.

Examples

Example 1

`output::tree` displayes special nested lists as trees:
TREE := ["a1", "a2", ["b1", "b2", ["c1", "c2"], "b3"], ["d1", "d2", "d3"]]:
print(Unquoted, output::tree(TREE)) a1 | +-- a2 | +-- b1 | | | +-- b2 | | | +-- c1 | | | | | `-- c2 | | | `-- b3 | `-- d1 | +-- d2 | `-- d3
print(Unquoted, output::tree(TREE, 3, Small)): a1 +- a2 +- b1 | +- b2 | +- c1 | | `- c2 | `- b3 `- d1 +- d2 `- d3

The chars can be defined by the user:

```
print(Unquoted, output::tree(TREE, 6, ["|", "|", ".", "\\", " "])): a1 | |....
a2 | |.... b1 | | | |.... b2 | | | |.... c1 | | | | | \.... c2 | | | \....
b3 | \.... d1 | |.... d2 | \.... d3
```

Parameters

Tree

The tree, given as a special list

indentdepth

Indent depth for each subtree

charlist

The chars that illustrate the tree structure

Options

Small

Suppresses the display of a space line between every tree entry to reduce the height of the tree

Return Values

String object to display

Graphics and Animations

RGB::ColorNames

Purpose

Find predefined colors by name

Syntax

```
RGB::ColorNames()
RGB::ColorNames(subname)
```

Description

`RGB::ColorNames(str)` returns a list of names of colors in the `RGB` name space whose names contain `str`.

`RGB::ColorNames` goes through the list of predefined color names and returns those whose names contain the string or identifier given as input, if any.

Environment Interactions

`RGB::plotColorPalette` plots a list of color samples with names.

Examples

Example 1

The following call returns all predefined color names containing "`Olive`": RGB::ColorNames("Olive")[Olive, OliveDrab, OliveGreen, OliveGreenDark]

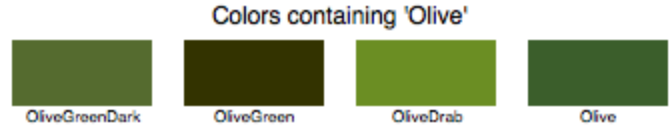
[Olive, OliveDrab, OliveGreen, OliveGreenDark]

The RGB values of these colors are: RGB::Olive, RGB::OliveDrab, RGB::OliveGreen, RGB::OliveGreenDark[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0], [0.333293, 0.419599, 0.184301]

[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0], [0.333293, 0.4195

Example 2

The following call plots all predefined colors containing "`Olive`": RGB::plotColorPalette("Olive")



When the list of colors found gets larger, they are distributed over more lines:
RGB::plotColorPalette("Blue")

Colors containing 'Blue'
AliceBlue

Parameters

subname

A part of a color name: a string or an identifier

Return Values

`RGB::ColorNames` returns a list of predefined color names.
`RGB::plotColorPalette` returns the empty object, `null()`.

See Also

RGB::plotColorPalette

RGB::plotColorPalette

Purpose

Display predefined colors

Syntax

```
RGB::plotColorPalette(subname)
```

Description

`RGB::plotColorPalette(str)` displays the colors in the `RGB` name space whose names contain `str`.

`RGB::plotColorPalette` uses RGB::ColorNames and plots samples of the colors found by this routine, in tabular fashion.

Environment Interactions

`RGB::plotColorPalette` plots a list of color samples with names.

Examples

Example 1

The following call returns all predefined color names containing "`Olive`": RGB::ColorNames("Olive")[Olive, OliveDrab, OliveGreen, OliveGreenDark]

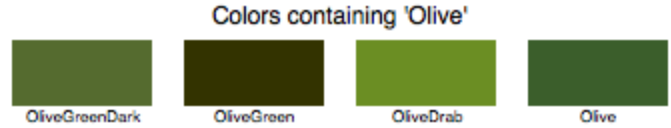
[Olive, OliveDrab, OliveGreen, OliveGreenDark]

The RGB values of these colors are: RGB::Olive, RGB::OliveDrab, RGB::OliveGreen, RGB::OliveGreenDark[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0], [0.333293, 0.419599, 0.184301]

[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0], [0.333293, 0.4195

Example 2

The following call plots all predefined colors containing "`Olive`": RGB::plotColorPalette("Olive")



When the list of colors found gets larger, they are distributed over more lines:
RGB::plotColorPalette("Blue")

Colors containing 'Blue'

Parameters

subname

A part of a color name: a string or an identifier

Return Values

`RGB::ColorNames` returns a list of predefined color names.
`RGB::plotColorPalette` returns the empty object, `null()`.

See Also

RGB::ColorNames

RGB::colorName

Purpose

Find names of predefined colors

Syntax

```
RGB::colorName(rgb, <Exact>)
```

Description

`RGB::colorName([r, g, b])` looks for the predefined color with values closest to `[r, g, b]` and returns its name.

`RGB::colorName([r, g, b], Exact)` looks for a predefined color with values exactly `[r, g, b]` and returns its name.

The `RGB` namespace contains predefined color names, accessible as `RGB::Blue` etc. `RGB::colorName` performs a reverse lookup, finding the name of a color given as RGB values.

Since rather often, colors will stem from calculations with floating-point numbers, no exact matches can be expected in this reverse lookup. Therefore, by default, `RGB::colorName` will perform a "fuzzy" search, returning the predefined color which is closest (in Euclidean distance in RGB space) to the input. Cf. "Example 2" on page 24-10.

Examples

Example 1

`RGB::colorName` returns the symbolic name of predefined colors:
RGB::colorName([0, 1, 0])RGB::Green

RGB::Green
RGB::colorName([0, 1, 0, 0.5])RGB::Green.[0.5]

RGB::Green.[0.5]

Example 2

When performing calculations on color values, the results will rarely be exact, even if the unavoidable round-off errors are too small to be displayed on the screen:

a := RGB::Olive; b := RGB::fromHSV(RGB::toHSV(RGB::Olive))[0.230003, 0.370006, 0.170003]

[0.230003, 0.370006, 0.170003]
[0.230003, 0.370006, 0.170003]

[0.230003, 0.370006, 0.170003]
bool(a = b)FALSE

FALSE

Therefore, `RGB::colorName` by default searches in a "fuzzy" fashion:
RGB::colorName(a); RGB::colorName(b)RGB::Olive

RGB::Olive
RGB::Olive

RGB::Olive

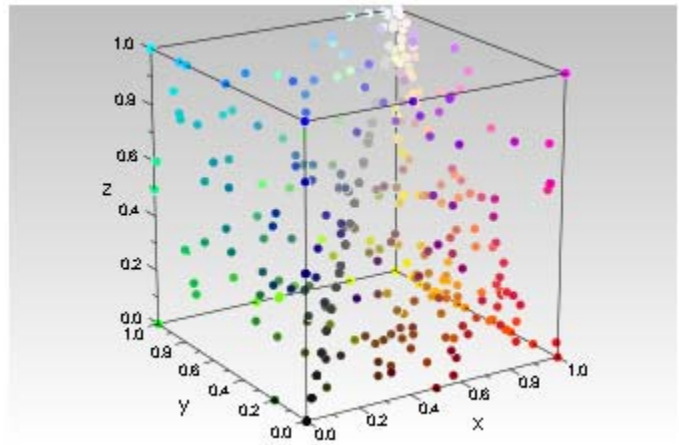
In cases where this is undesirable, the option `Exact` can be used to switch to exact searching:
RGB::colorName(a, Exact); RGB::colorName(b, Exact)RGB::Olive

RGB::Olive
FAIL

FAIL

The predefined color names do not fill RGB space uniformly, therefore, the color found by `RGB::colorName` may be quite different from the one entered. The following plot shows the predefined colors in RGB space:

```
plot(plot::Scene3d( plot::PointList3d([c.[c] $ c in RGB::ColorList]),
ZXRatio = 1, BackgroundStyle = TopBottom, BackgroundColor =
RGB::Grey, BackgroundColor2 = RGB::White, Margin=0))
```



Parameters

rgb

An RGB or RGBa color specification: A list of three or four real numbers in the interval Interval([0],[1])`[0, 1]`.

Options

Exact

Only return an exact match, FAIL if none exists.

Return Values

If a color was found, `RGB::colorName` returns an expression of the form `RGB::Name` or `RGB::Name.[a]`. If given `Exact` and no match was found, FAIL is returned. If given symbolic input parameters, an unevaluated call is returned.

See Also

RGB

RGB::fromWaveLength

Purpose

Get the RGB color of monochromatic light

Syntax

```
RGB::fromWaveLength(º, <ª>)
```

Description

`RGB::fromWaveLength( º )` returns an approximative RGB specification for light of wavelength λnm.

Light consists of photons, each of which has a distinct wavelength. These different wavelengths cause color perception. `RGB::fromWaveLength` calculates an RGB triple corresponding to a given wave length.

Different displays show the same RGB color in slightly different ways. For this reason, the so-called “gamma correction” has been invented. `RGB::fromWaveLength` accepts a second argument, for fine-tuning the assumed gamma correction that enters the calculation.

Color perception depends on a number of factors, including individual differences. Therefore, such a calculation can only return an approximation. `RGB::fromWaveLength` uses the model published by Dan Bruton for the conversion.

For wavelengths outside the visible spectrum (which ranges from $380nm$ to $780nm$), `RGB::fromWaveLength` returns black.

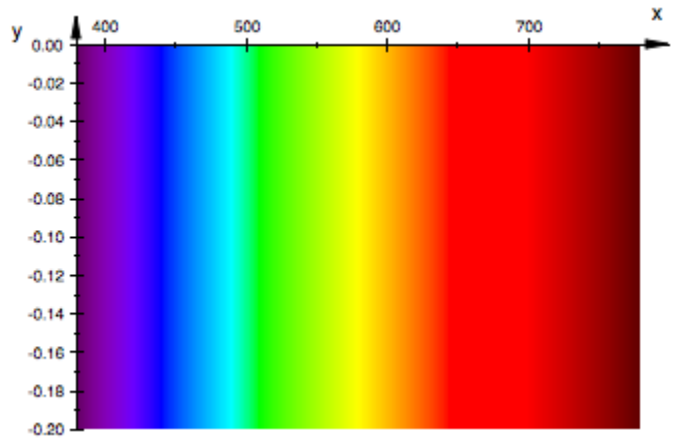
Examples

Example 1

White light, when sent through a prism, is split into the commonly known spectrum, because the prism refracts different wavelengths differently. This spectrum can easily be reproduced by `RGB::fromWaveLength`:
plot(plot::Raster([[RGB::fromWaveLength(i) $ i=380..780]]), Scaling = Unconstrained, Height = 20)

Example 2

Bruton's conversion model looks like this:
plotfunc2d(plot::Raster([[RGB::fromWaveLength(i) $ i = 380..780]], x = 380..780, y = -0.2..0), (x -> RGB::fromWaveLength(x)[i]) $ i = 1..3, x = 380..780, Colors = [RGB::Red, RGB::Green, RGB::Blue], LegendVisible = FALSE, XTicksNumber = Low, Scaling = Unconstrained, Axes = Automatic)



Parameters

The wavelength: a real-valued constant (interpreted as nanometers) or a length expression

The "gamma correcture" for the display, defaults to 0.8

Return Values

RGB color: a list of three floating-point values

See Also

RGBRGB::fromHSV

RGB::random

Purpose

Pick a color uniformly at random in RGB color space

Syntax

```
RGB::random()
```

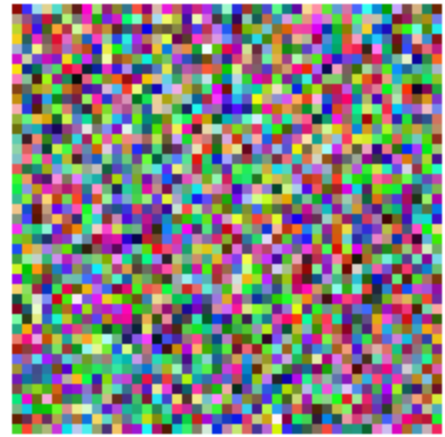
Description

`RGB::random()` returns a random color. The colors returned are distributed independently and uniformly in the RGB color space.

Examples

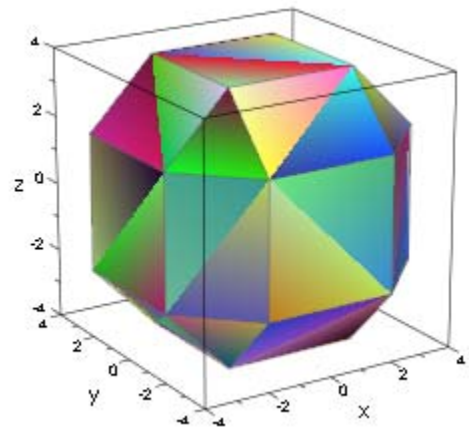
Example 1

`RGB::random` can be used to produce high-frequency noise:
plot(plot::Raster([[RGB::random() $ x = 0..42] $ y = 0..42]))



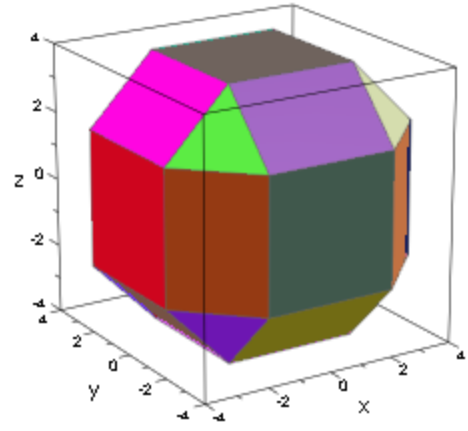
Example 2

It is possible to use `RGB::random` directly as a color function, but the result may be unexpected:
plot(plot::Waterman(5, FillColorFunction = RGB::random))



The reason is that the color function will be called repeatedly if the same point is met again. It is a better idea to create a bunch of random colors and then use the parameters passed into the color functions to get some consistency into the choice of colors:

```
colors := [RGB::random() $ i = 1..42]:  plot(plot::Waterman(5,
FillColorFunction=((x,y,z,i) -> colors[i])))
```



Return Values RGB color: A list of three floating-point values.

See Also RGBfrandom

RGB::toHSV

Purpose

Convert RGB colors to HSV

Syntax

```
RGB::toHSV([r, g, b, <a>])
```

Description

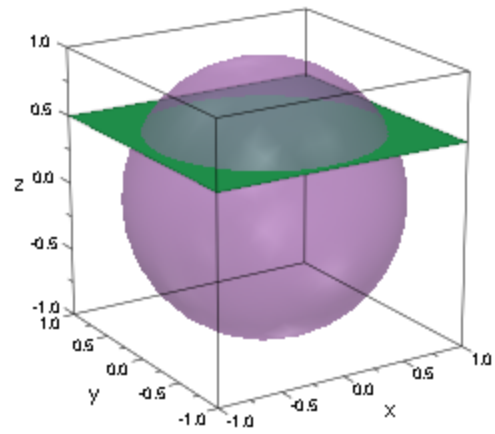
`RGB::toHSV(RGBcolor)` returns `RGBcolor` expressed in HSV values, with hue in the range 0..360`0..360` (i.e., in degrees) and saturation and value in the range 0..1`0..1`.

Examples

Example 1

With the `RGB::fromHSV` utility, all colors in a MuPAD graphics can be specified easily as HSV colors. For example, the color “violet” is given by the HSV values `[290, 0.4, 0.6]`, whereas “dark green” is given by the HSV specification `[120, 1, 0.4]`. Hence, a semi-transparent violet sphere intersected by an opaque dark green plain may be specified as follows:

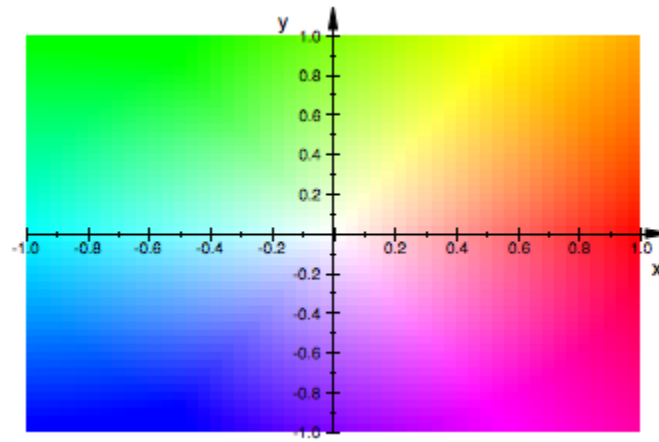
```
plot(plot::Sphere(1, [0, 0, 0], Color = RGB::fromHSV([290, 0.4,
0.6]).[0.5]), plot::Surface([x, y, 0.5], x = -1 .. 1, y = -1 .. 1, Mesh = [2, 2],
Color = RGB::fromHSV([120, 1, 0.4])) ):
```



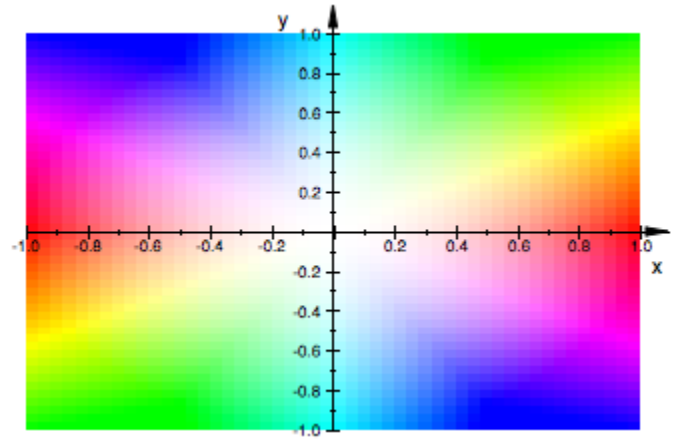
Example 2

There are numerous ways of displaying complex-valued functions of a complex argument, see for example plot::Conformal. One of these is to use a color scheme that interprets the complex plane as a section through HSV color space at a fixed value, say, 1. To plot this scheme in MuPAD, we use plot::Density, providing the following color function:
f_color := (x, y, fz, a) -> RGB::fromHSV([180/float(PI)*arg(fz), abs(fz), 1]):

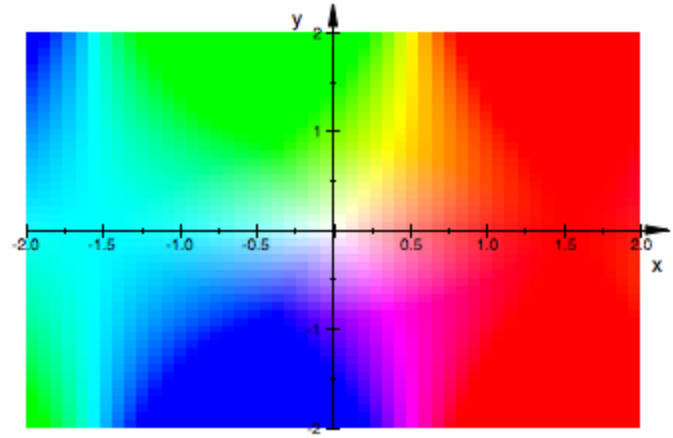
The identity function is thus shown as follows:
plot(plot::Density((x, y) -> x + I*y, x = -1..1, y = -1..1, XMesh = 50, YMesh = 50, FillColorFunction = f_color))



(z) -> z^2$z \to z^2$ doubles the argument of a complex function, resulting in the following picture:
plot(plot::Density((x, y) -> (x + I*y)^2, x = -1..1, y = -1..1, XMesh = 50, YMesh = 50, FillColorFunction = f_color))

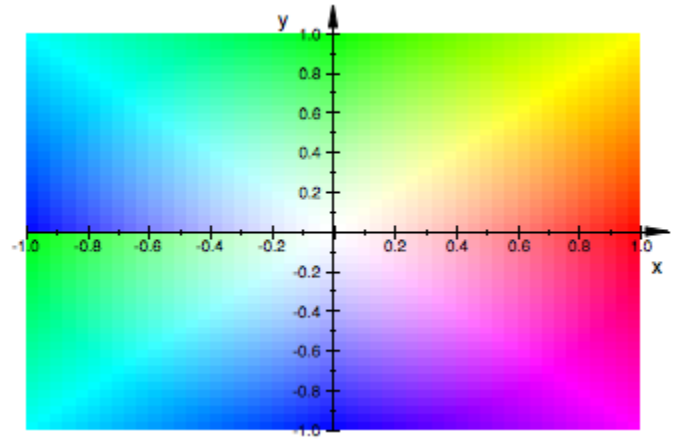


To plot the complex sine function, we choose a larger rectangle, since the sine is too similar to the identity in small neighborhoods of th origin to be of interest:
plot(plot::Density((x, y) -> sin(x + I*y), x = -2..2, y = -2..2, XMesh = 50, YMesh = 50, FillColorFunction = f_color))



(z) -> z^(4/3)$z \to z^{4/3}$ is clearly discontinuous along the negative real axis:

plot(plot::Density((x, y) -> (x + I*y)^(4/3), x = -1..1, y = -1..1, XMesh = 50, YMesh = 50, FillColorFunction = f_color))



Parameters

r

g

b

The red, green, and blue contributions of an RGB color: numerical values between 0 and 1.

a

The translucency (alpha) value: a numerical value between 0 and 1.

Return Values

a list with three or four floating-point values, depending on whether `a` was given in the input.

See Also

RGB::fromHSV

RGB::fromHSV

Purpose

Convert HSV colors to RGB

Syntax

```
RGB::fromHSV([h, s, v, <a>])
```

Description

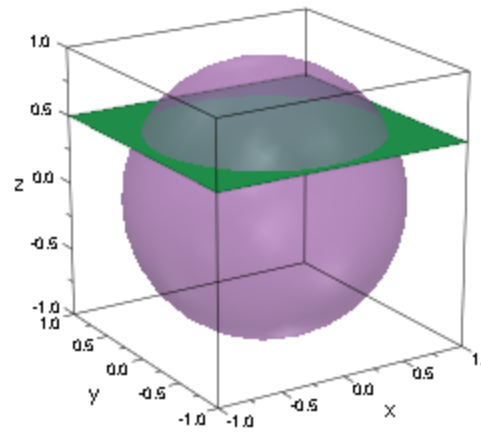
`RGB::fromHSV(HSVcolor)` is the inverse of `RGB::toHSV`: Given color coordinates in HSV, this function returns the corresponding RGB color. Cf. “Example 2” on page 24-23.

Examples

Example 1

With the `RGB::fromHSV` utility, all colors in a MuPAD graphics can be specified easily as HSV colors. For example, the color “violet” is given by the HSV values `[290, 0.4, 0.6]`, whereas “dark green” is given by the HSV specification `[120, 1, 0.4]`. Hence, a semi-transparent violet sphere intersected by an opaque dark green plain may be specified as follows:

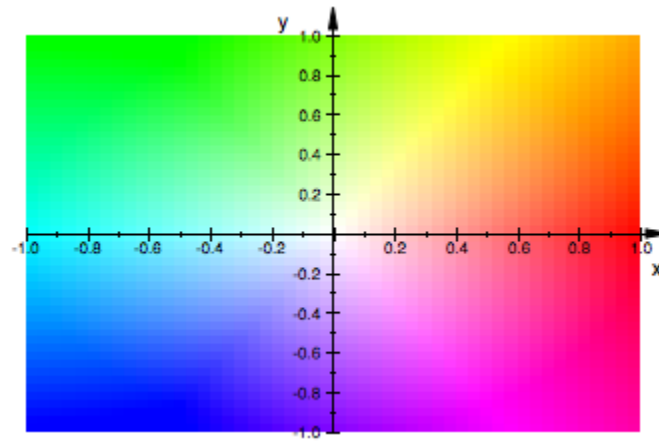
```
plot(plot::Sphere(1, [0, 0, 0], Color = RGB::fromHSV([290, 0.4,
0.6]).[0.5]), plot::Surface([x, y, 0.5], x = -1 .. 1, y = -1 .. 1, Mesh = [2, 2],
Color = RGB::fromHSV([120, 1, 0.4])) ):
```



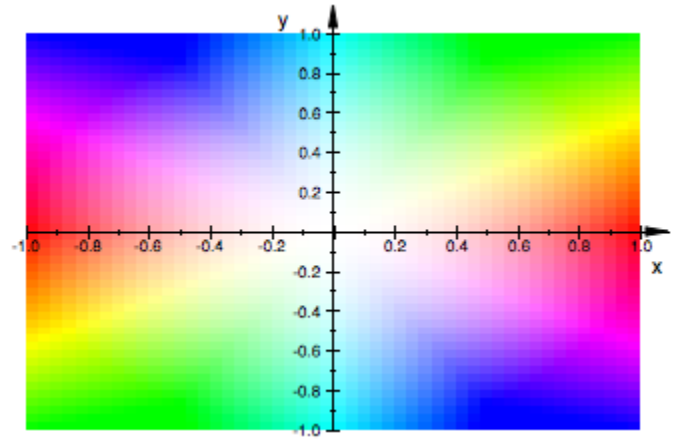
Example 2

There are numerous ways of displaying complex-valued functions of a complex argument, see for example plot::Conformal. One of these is to use a color scheme that interprets the complex plane as a section through HSV color space at a fixed value, say, 1. To plot this scheme in MuPAD, we use plot::Density, providing the following color function:
f_color := (x, y, fz, a) -> RGB::fromHSV([180/float(PI)*arg(fz), abs(fz), 1]):

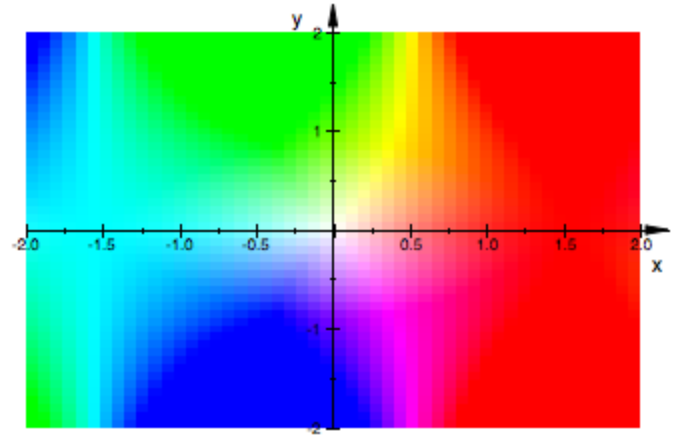
The identity function is thus shown as follows:
plot(plot::Density((x, y) -> x + I*y, x = -1..1, y = -1..1, XMesh = 50, YMesh = 50, FillColorFunction = f_color))



(z) -> z^2$z \to z^2$ doubles the argument of a complex function, resulting in the following picture:
plot(plot::Density((x, y) -> (x + I*y)^2, x = -1..1, y = -1..1, XMesh = 50, YMesh = 50, FillColorFunction = f_color))

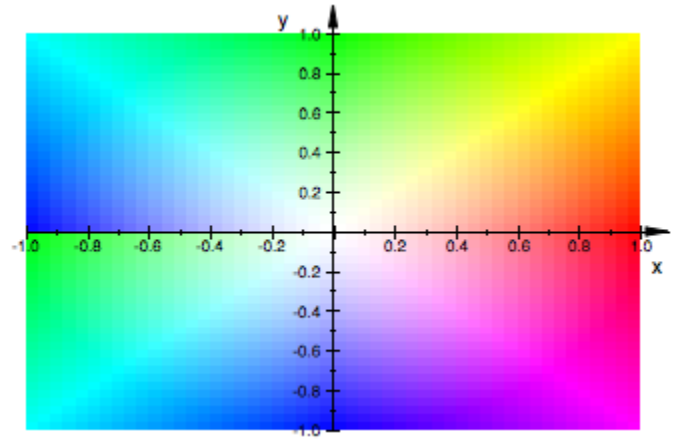


To plot the complex sine function, we choose a larger rectangle, since the sine is too similar to the identity in small neighborhoods of th origin to be of interest:
plot(plot::Density((x, y) -> sin(x + I*y), x = -2..2, y = -2..2, XMesh = 50, YMesh = 50, FillColorFunction = f_color))



(z) -> z^(4/3)$z \to z^{4/3}$ is clearly discontinuous along the negative real axis:

plot(plot::Density((x, y) -> (x + I*y)^(4/3), x = -1..1, y = -1..1, XMesh = 50, YMesh = 50, FillColorFunction = f_color))



Parameters

a

The translucency (alpha) value: a numerical value between 0 and 1.

h

The “hue” in an HSV specification: a numerical value between 0 and 360

s

The “saturation” in an HSV specification: a numerical value between 0 and 1

v

The “value” in an HSV specification: a numerical value between 0 and 1

Return Values a list with three or four floating-point values, depending on whether `a` was given in the input.

See Also RGB::toHSV

plot::easy

Purpose

Easy plotting

Syntax

```
plot::easy(<arg,  >, options)
```

Description

`plot::easy( arg , <options>,  )` transforms data and expressions into graphical objects.

`plot::easy` accepts graphical objects and graphical attributes as input and returns them unchanged.

`plot::easy` supports the options listed above. Additionally, it accepts arbitrary data and expressions and tries to transform them into valid graphical objects.

`plot::easy` supports the option `Colors=`$[c_1,...c_2]$ for automatically coloring newly generated graphical objects. The given list is used instead of the internally defined default color list.

`plot::easy` accepts the options `Mesh` and `Submesh` and uses them for each newly generated graphical object.

The function plot calls `plot::easy` for preprocessing its input before plotting.

`plot::easy` tries to handle standard situations intuitively in order to make plotting as easy as possible. However, it supports only a small subset of the graphical objects, attributes and expressions available in MuPAD and thus does not claim to be complete.

Users that want to plot other objects or control specific details of their graphics explicitly, still have to create their graphical objects manually, e.g. using plot::Function2d and plot::Point2d, and to use graphical attributes like `LineStyle =Dashed` directly.

`plot::easy` sets a new color for each object that it creates, if no color is predefined in the given context.

`plot::easy` accepts sets {...} as group definition and transforms them into graphical objects of type `plot::Group2d(...)` or `plot::Group3d(...)`, respectively. All elements of a group share the

same color, if colors were not specified explicitly for single objects.Note that, regular graphical objects usually have a predefined color.

`plot::easy` accepts a nested set {{...}} as scene definition and transforms it into the graphical object `plot::Scene2d(...)` or `plot::Scene3d(...)`, respectively.

Creating a graphical object may require the specification of value ranges for variables. If they are not specified explicitly then `plot::easy` tries use ranges specified for other variables and/or uses the default value range `-5..5`.

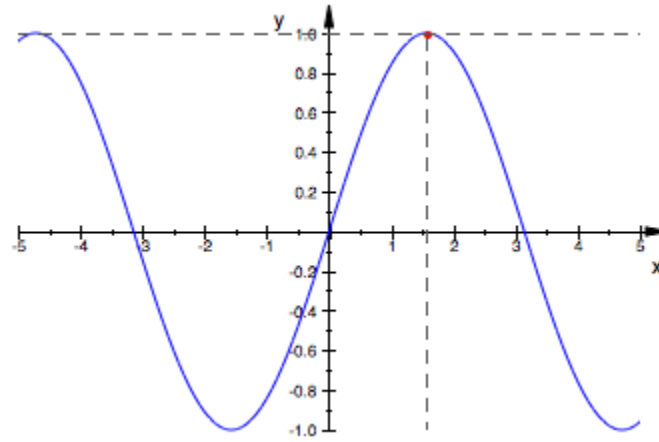
Examples

Example 1

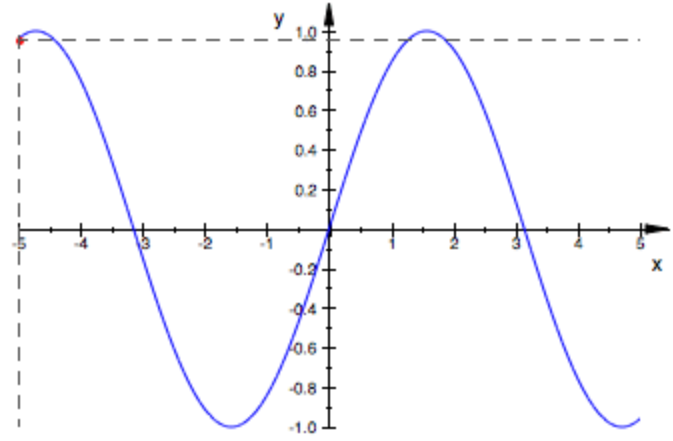
`plot::easy` tries to transform all given data and expressions into valid graphical objects and attributes:
plot::easy(sin(x), [PI/2,1])plot::Function2d(sin(x), x = -5..5), plot::Point2d(PI/2, 1, PointColor = RGB::Red, LegendText = "[PI/2, 1]")

Since the function plot calls the function `plot::easy` for preprocessing its input data, scenes like above can directly be plotted using plot:
plot(sin(x), [PI/2,1], #x=PI/2, #y=1)

plot::Function2d(sin(x), x = -5..5), plot::Point2d($\frac{\pi}{2}$, 1, PointColor = RGB::Red, LegendText = "[PI/2, 1]")



Now, it is only a small step to animate this scene:
plot(sin(x), {[x,sin(x)], #Points}, #x=x, #y=sin(x))



Note: Graphical objects and attributes, as well as data that `plot::easy` cannot transform, are returned unchanged:

plot::easy(x, plot::Point2d(1,1), LineStyle=Dashed, "UnknownObject")plot::Function2d(x, x = -5..5), plot::Point2d(1, 1), LineStyle = Dashed, "UnknownObject"

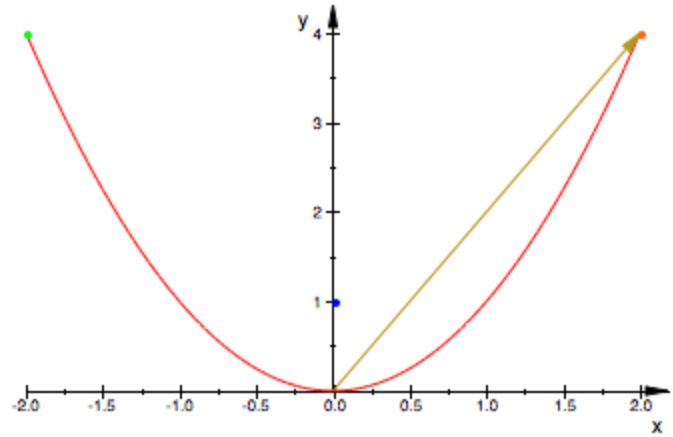
plot::Function2d(*x*, *x* = −5..5), plot::Point2d(1, 1), LineStyle = Dashed, "UnknownObject"

This is why plot returns the following error message when it is executed with the above arguments:
plot(x, plot::Point2d(1,1), LineStyle=Dashed, "UnknownObject"); Error: The arguments 'UnknownObject' are unexpected. [plot::Canvas::new]

Example 2

Points can be entered as lists with two or three values. Alternatively, a corresponding column vector in combination with the option `#Points` (alias `#P`, see "Example 18" on page 24-51) can be used.

Note that for plotting animated points the option `#Points` is required. Otherwise a curve (when entered a list) or an arrow (when entered a vector) is plotted:
plot([0,1], [s,s^2], {[s,s^2], #Points}, s=-2.. 2, matrix([t,t^2]), {matrix([t,t^2]), #Points}, t= 2..-2)

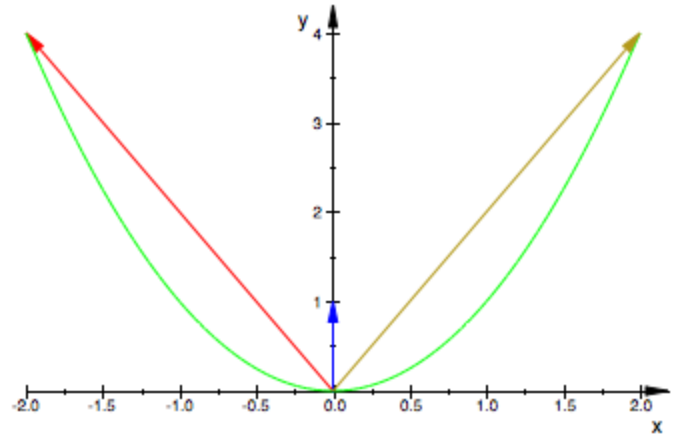


See also: plot::Point2d, plot::Point3d.

Example 3

Arrows can be specified as column vectors with two or three elements. Alternatively, a list in combination with the option `#Arrows` (alias `#A`, see “Example 13” on page 24-47) can be used:

```
plot(matrix([0,1]), matrix([s,s^2]), s=2..-2, [t,t^2], {[t,t^2], #Arrows},
t=-2..2 )
```

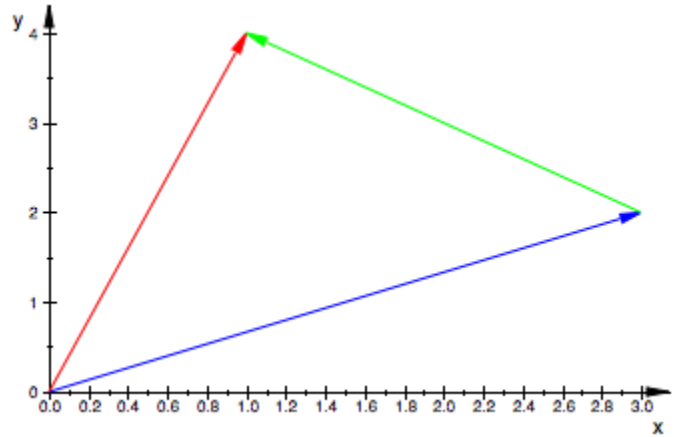


If an arrow should start at coordinates other than (0,0) or (0,0,0), respectively, then a list of two column vectors or a corresponding list of lists in combination with the option `#Arrows` (alias `#A`, see “Example 13” on page 24-47) can be used:

```
u:= matrix([3,2]): v:= matrix([1,4]): w:= (1-a)*u + a*v: u, v, w;matrix([[3],
[2]]), matrix([[1], [4]]), matrix([[3 - 2*a], [2*a + 2]])
```

$$\begin{pmatrix} 3 \\ 2 \end{pmatrix}, \begin{pmatrix} 1 \\ 4 \end{pmatrix}, \begin{pmatrix} 3-2a \\ 2a+2 \end{pmatrix}$$

```
plot(u, v, [u,w], a=0.1..1, #Arrows)
```

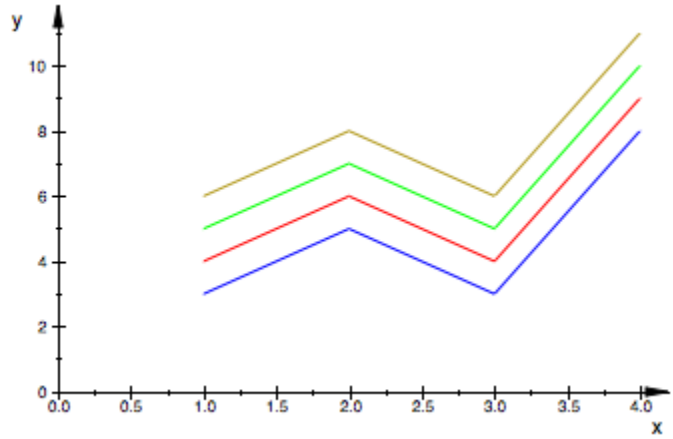


delete u, v, w:

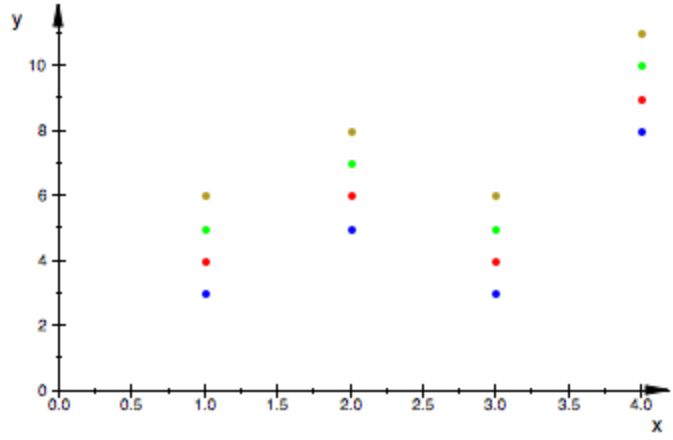
See also: plot::Arrow2d, plot::Arrow3d.

Example 4

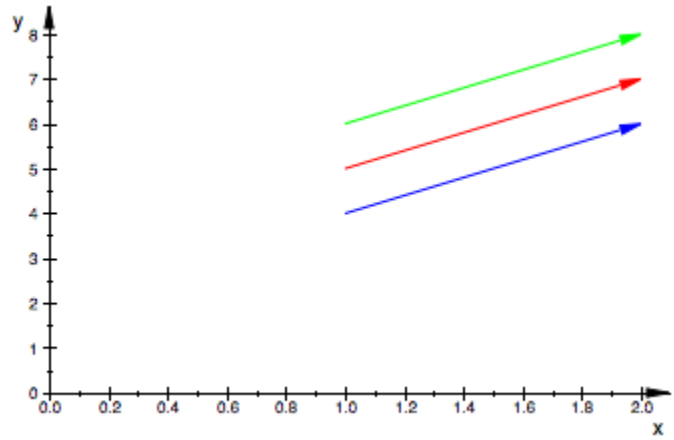
Polygons can be specified as lists, tables or matrices. In the following example, polygons are plotted using different input styles. The option `#Origin` (alias `#O`, see "Example 17" on page 24-50) ensures that the origin of the coordinate system is visible in the scene as well:
plot([[1,3],[2,5],[3,3],[4,8]], table(1=4,2=6,3=4,4=9),
[matrix([1,5]),matrix([2,7]),matrix([3,5]),matrix([4,10])],
matrix([[1,6],[2,8],[3,6],[4,11]]), #Origin)



Note that polygons are displayed as points when option `#Points` (alias `#P`, see “Example 18” on page 24-51) is used:
plot([[1,3],[2,5],[3,3],[4,8]], table(1=4,2=6,3=4,4=9),
[matrix([1,5]),matrix([2,7]),matrix([3,5]),matrix([4,10])],
matrix([[1,6],[2,8],[3,6],[4,11]]), #Points, #Origin)



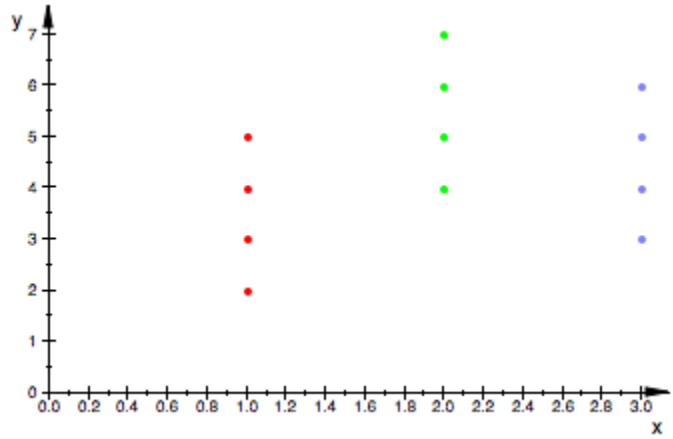
Note that the following polygons with two elements are displayed as arrows when option `#Arrows` (alias `#A`, see “Example 13” on page 24-47) is used:
plot([[1,4],[2,6]], [matrix([1,5]),matrix([2,7])], matrix([[1,6],[2,8]]), #Arrows, #Origin)



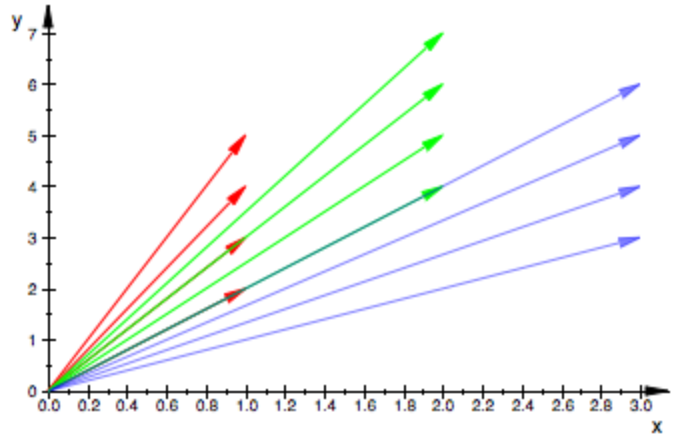
See also: plot::Polygon2d, plot::Polygon3d.

Example 5

Point lists can be specified as lists, tables or matrices. For each point an RGBa color has to be specified. In the following example, point lists are plotted using different input styles. The option `#Origin` (alias `#O`, see “Example 17” on page 24-50) ensures that the origin of the coordinate system is visible in the scene as well:
plot([[1,2,RGB::Red], [2,4,[0,1,0]], [3,3,[0,0,1,0.5]]], [matrix([1,3,RGB::Red]),matrix([2,5,[0,1,0]]),matrix([3,4,[0,0,1,0.5]])], matrix([[1,4,RGB::Red], [2,6,[0,1,0]], [3,5,[0,0,1,0.5]]]), table(1=[5,RGB::Red], 2=[7,[0,1,0]], 3=[6,[0,0,1,0.5]]), #Origin)



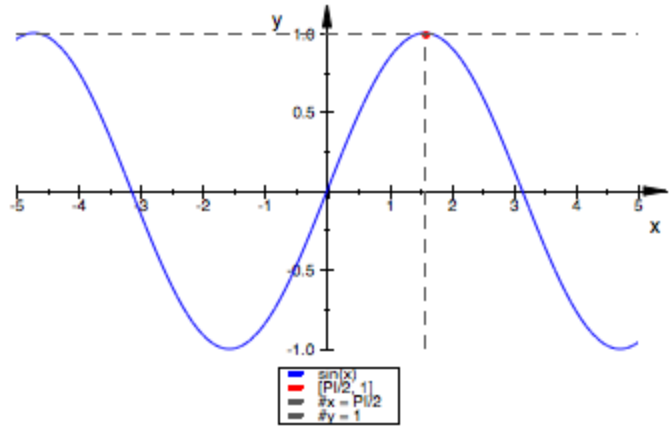
Note that the following point lists are displayed as arrows when option `#Arrows` (alias `#A`, see “Example 13” on page 24-47) is used:
plot([[1,2,RGB::Red], [2,4,[0,1,0]] ,[3,3,[0,0,1,0.5]]],
[matrix([1,3,RGB::Red]),matrix([2,5,[0,1,0]]),matrix([3,4,[0,0,1,0.5]])],
matrix([[1,4,RGB::Red], [2,6,[0,1,0]], [3,5,[0,0,1,0.5]]]),
table(1=[5,RGB::Red], 2=[7,[0,1,0]] ,3=[6,[0,0,1,0.5]]), #Arrows, #Origin)



See also: plot::PointList2d, plot::PointList2d.

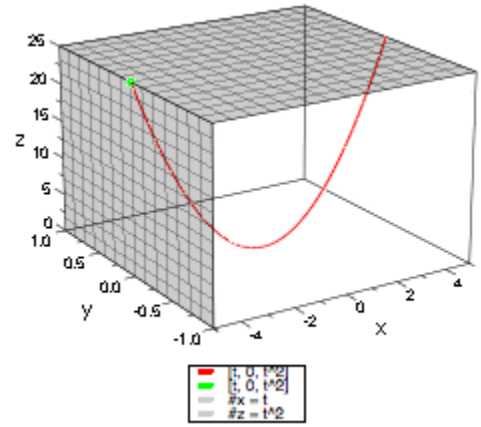
Example 6

For drawing horizontal and vertical infinite lines, the short syntax `#x = e` and `#y = e` with `e` is a real expression,can be used:
plot(sin(x), [PI/2,1], #x=PI/2, #y=1, #Legend)



For drawing horizontal and vertical infinite planes, the short syntax`#x = e`, `#y = e` and `#z = e`, with `e` is a real expression, can be used.

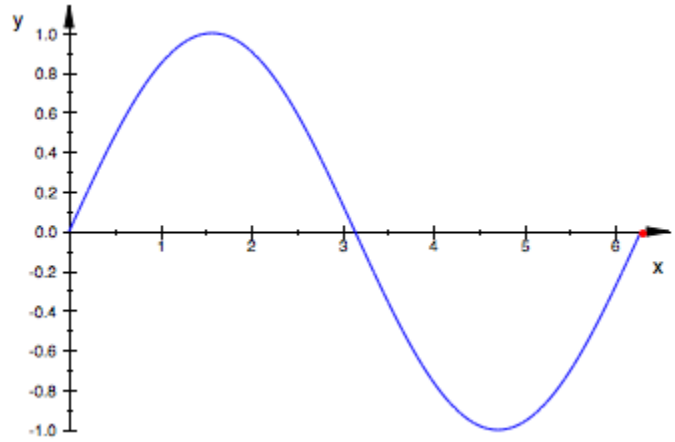
Both, lines and planes can also be animated:
plot([t,0,t^2], {[t,0,t^2], #Points}, #x=t, #z=t^2, #Legend)



See also: plot::Line2d, plot::Plane.

Example 7

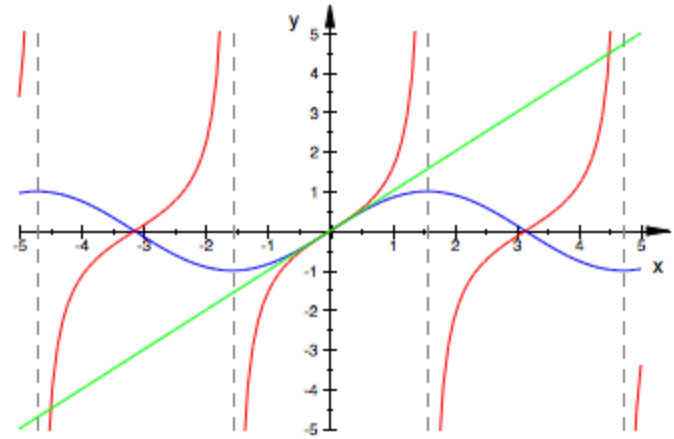
A curve can be specified as list with two or three elements, where at least one element depends on a free variable. If option `#Points` (alias `#P`, see “Example 18” on page 24-51) is set, then instead of a curve, an animated point is plotted that moves along the curve.
plot([t,sin(t)], {[t,sin(t)], #Points}, t=0..2*PI)



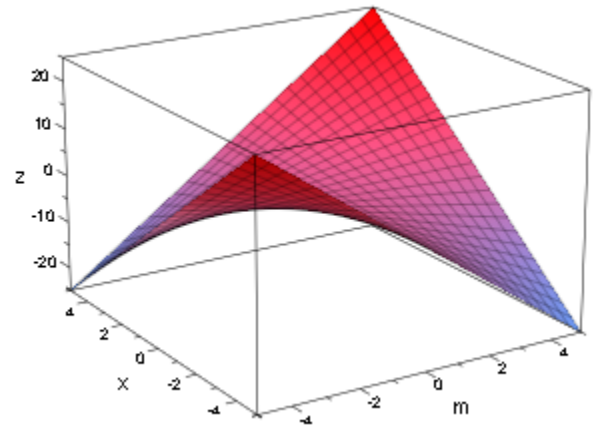
See also: plot::Curve2d, plot::Curve3d.

Example 8

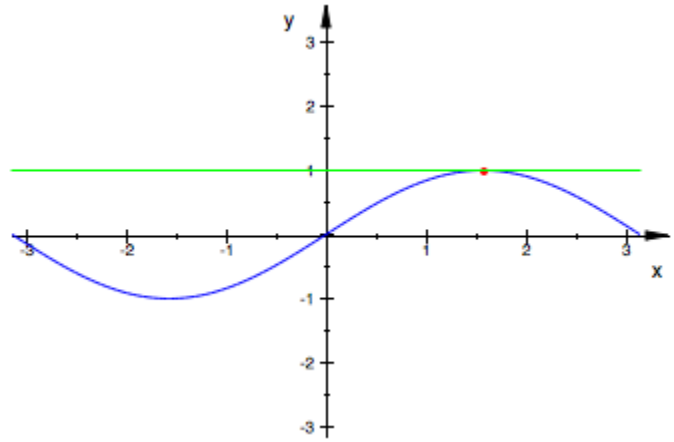
`plot::easy` tries to transform expressions that are no lists, sets, matrices, equations or inequalities into graphs of 2D or 3D functions. We plot some graphs of 2D functions:
plot(sin(x), tan(x), x)



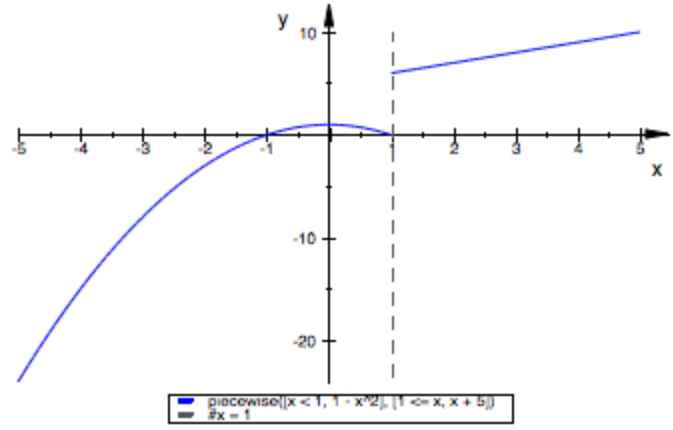
We plot a simple 3D function. Note that the option `#3D` (alias `#3`, see "Example 12" on page 24-45) is required in the following example for plotting a 3D function. Otherwise, an animated 2D function is created.
plot(m*x, #3D)



We plot a simple 2D animation: a point and the corresponding tangent of the sine function move along the sine function graph:
f:= x -> sin(x): plot(f(x), x = -PI..PI, {[a, f(a)], #Points}, f'(a)*(x-a) + f(a), a = -PI/2..PI/2)

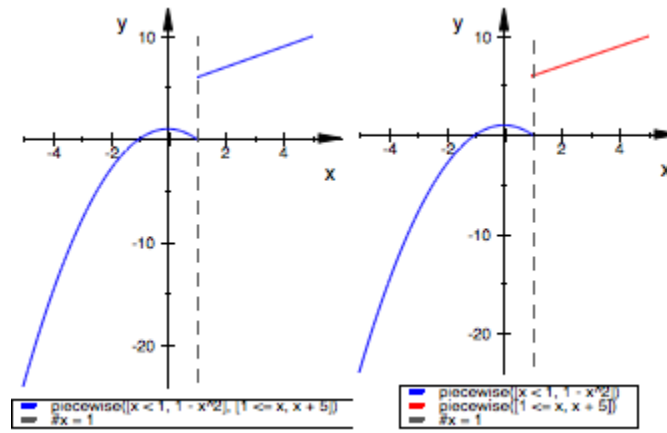


We plot a piecewise defined function:
plot(piecewise([x < 1, -x^2 + 1], [x >= 1, x + 5]), #x=1, #Legend)



The same piecewise defined function is now written in a shorter syntax. Note the difference between defining one function with two branches (left) and defining two functions (right):

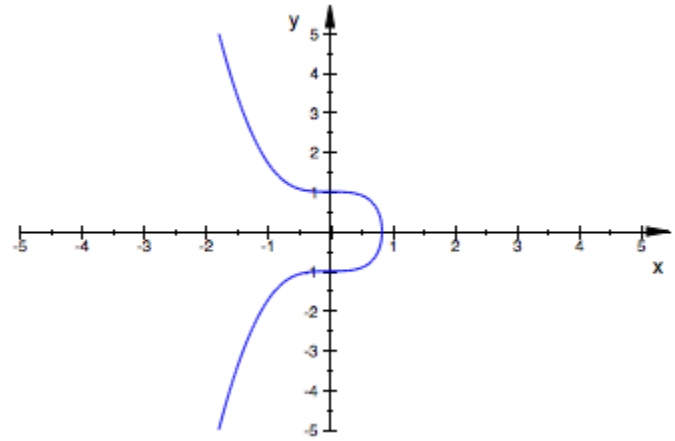
plot({{[[x < 1, -x^2 + 1], [x >= 1, x + 5]], #x=1}}, {{ [x < 1, -x^2 + 1], [x >= 1, x + 5] , #x=1}}, #Legend)



See also: plot::Function2d, plot::Function3d.

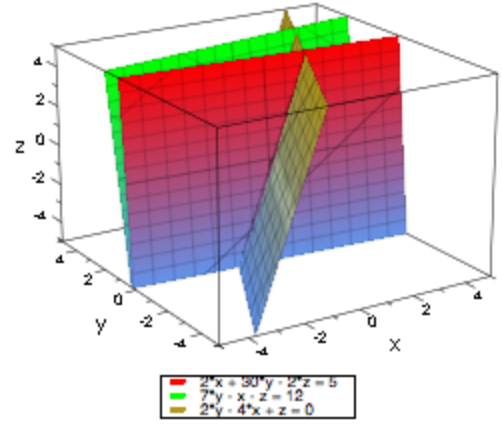
Example 9

An implicit function can be specified as an equation:
plot(u^5 + x^2 = 1 - u^3)



Note that the option #3D (alias #3, see “Example 12” on page 24-45) may be required to plot planes given as cartesian equations. Otherwise, an animated 2D graph might be created. This depends on the number of variable of the equation.

```
E1:= 2*x + 30*y - 2*z = 5: E2:= -x + 7*y - z = 12: E3:= -4*x + 2*y + z = 0: plot(E1, E2, E3, #3D, #Legend)
```

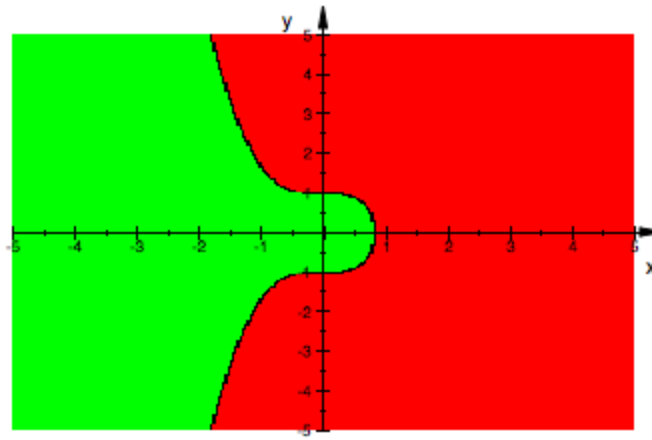


delete E1, E2, E3:

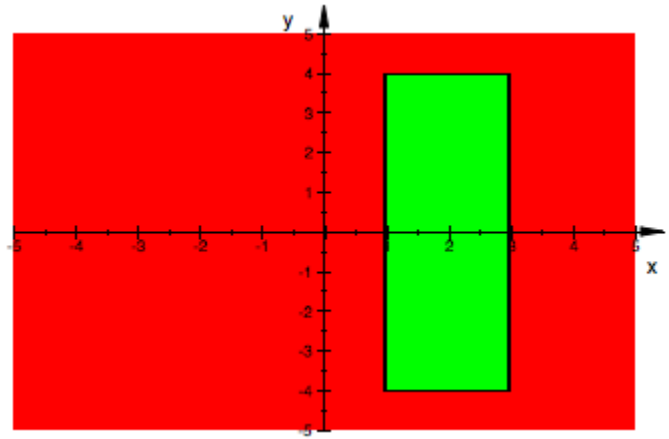
See also: plot::Implicit2d, plot::Implicit3d.

Example 10

An inequality can be displayed directly:
plot(u^5+x^2 < 1-u^3)



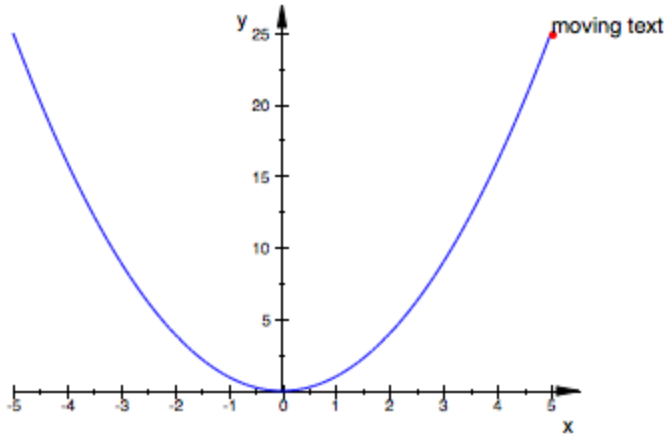
The same is true for a list of inequalities and equations:
plot([x < 3, x > 1, y < 4, y > -4])



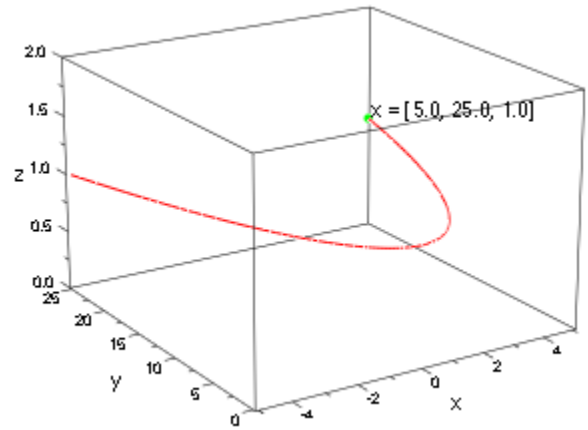
See also: plot::Inequality.

Example 11

To display a 2D text at a certain position, an equation of a coordinate tuple and a character string or a procedure can be entered:
plot([t, t^2], {[t, t^2], #Points}, [t, t^2] = "moving text")



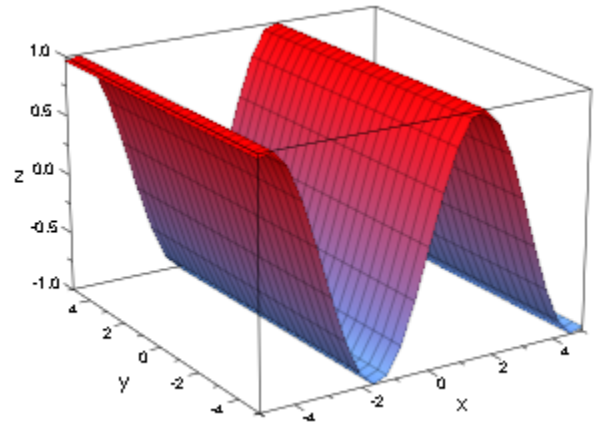
We display a 3D text. As in any other context of `plot::easy`, we can use regular graphical attributes like `TextFont =Center` as well:
DIGITS := 2: plot([t, t^2, 1], {[t, t^2, 1], #Points}, [t, t^2, 1] = (t->" x = ".[t, t^2, 1.0]), TextFont=[Bold]): delete DIGITS:



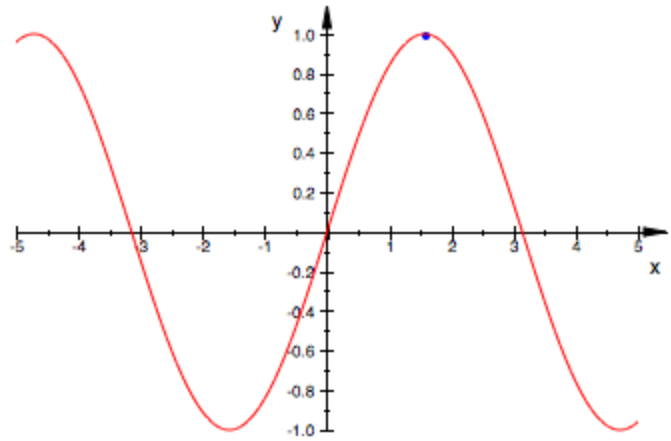
See also: plot::Text2d, plot::Text3d.

Example 12

Usually `plot::easy` creates a 2D scene, unless one of the arguments is a 3D object or can only be transformed to a 3D object or the option `#3D` is used.
plot(sin(x), #3)

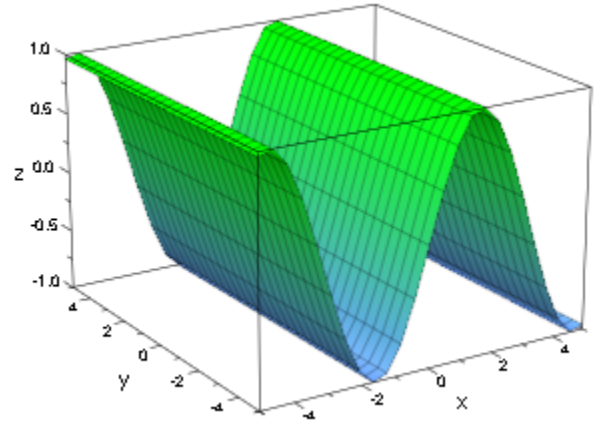


However, the option `#3D` is only a hint. It is ignored if the current scene can only be a 2D scene. In the following example, the 2D point determines the dimension of the scene:
plot([PI/2,1], sin(x), #3)



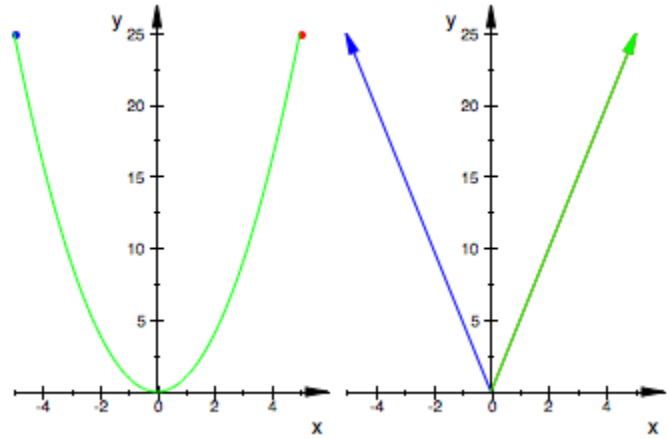
In the following example, the 3D point determines the dimension of the scene. There is no need to use option `#3D` in order to create a 3d scene:

plot([PI/2,1,0], sin(x))



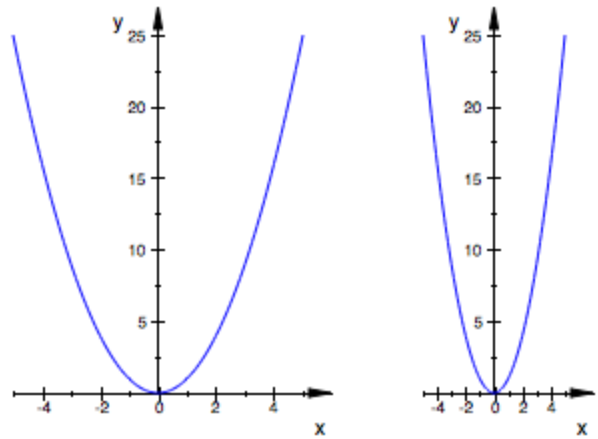
Example 13

With option `#Arrows`, arrows instead of points or curves are created. When used within a {...}-group, it affects the elements of this group or scene only.
plot({{ [-5,25], [5,25], [x,x^2] }}, {{ [-5,25], [5,25], [x,x^2], #A }})



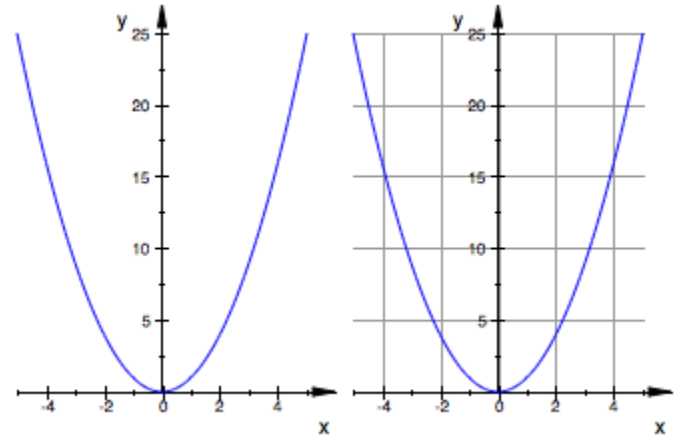
Example 14

Option `#Constrained` creates a coordinate system with constrained scaled axes. This is a shortcut for `Scaling = Constrained`.
plot({{ x^2 }}, {{ x^2, #C }})



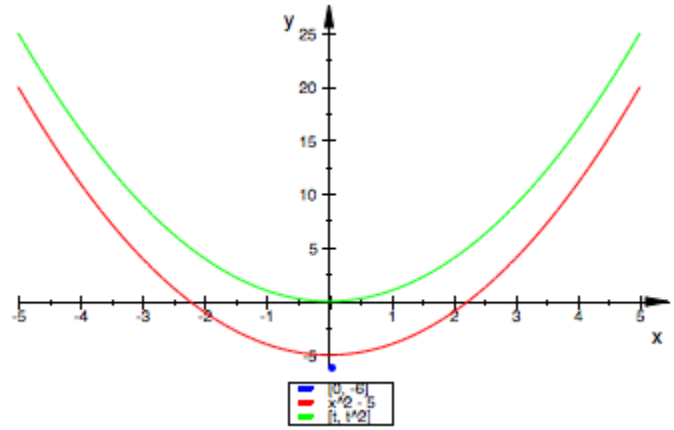
Example 15

Option `#Grid` creates a coordinate system with grid lines. This is a shortcut for `GridVisible = TRUE`.
plot({{ x^2 }}, {{ x^2, #G }})



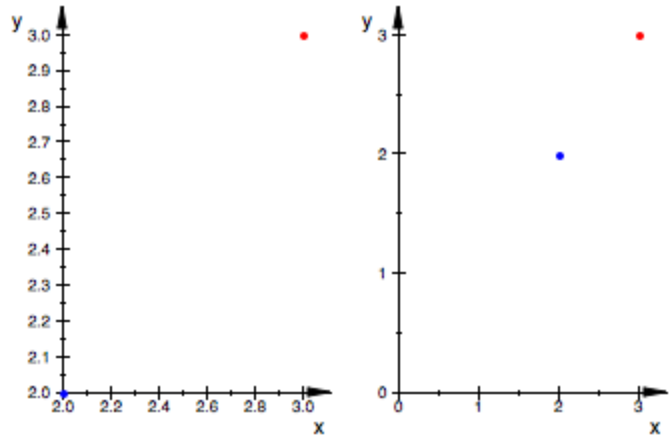
Example 16

Option `#Legend` creates a legend. This is a shortcut for `LegendVisible = TRUE` in combination with `LegendEntry = TRUE`. Note that `plot::easy` explicitly sets a legend text for each graphical object it creates.
plot([0,-6], x^2-5, [t,t^2], #L)



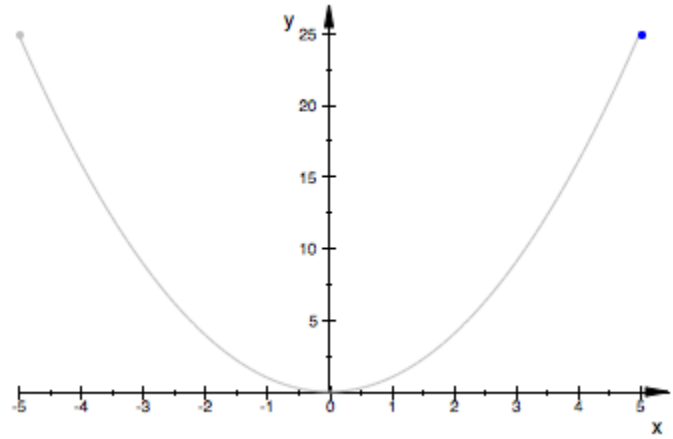
Example 17

Option `#Origin` includes the coordinates (0,0) or (0,0,0), respectively, into the viewing box of the current scene.
plot({{[2,2], [3,3]}}, {{[2,2], [3,3], #O}})



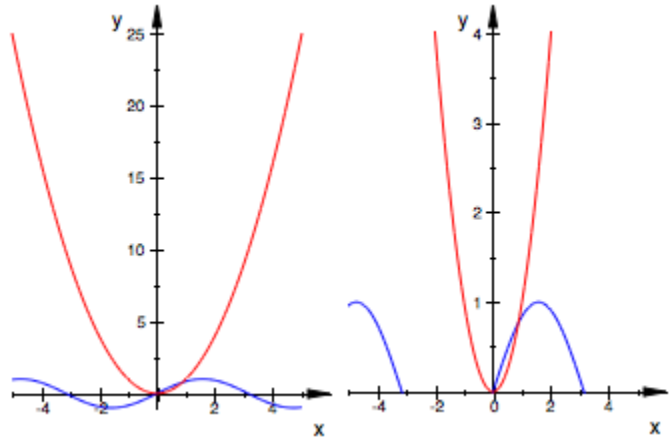
Example 18

Using option `#Points`, points instead of arrows or curves are created. Furthermore, this option sets the attributes `PointsVisible =TRUE` and `LinesVisible =FALSE`. When used within a {...}-group, it affects the elements of this group or scene only.
plot({[-5,25], [x,x^2], #Gray}, {matrix([5,25]), [x,x^2], #P})

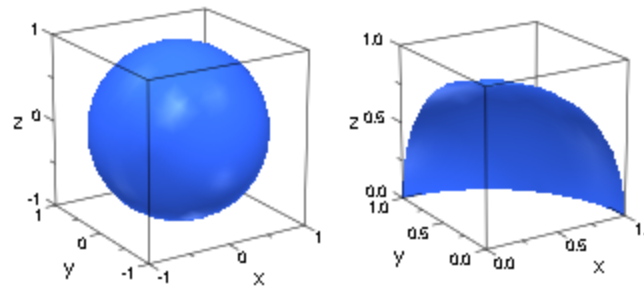


Example 19

`#X / #Y / #Z = a..b` sets the x- / y- / z-range of the viewing box of the scene to `a..b`. This is a shortcut for ViewingBoxXRange / ViewingBoxYRange / `ViewingBoxZRange = a..b`.
plot({{x^2, sin(x)}}, {{x^2, sin(x), #Y=0..4}})



We draw a 3D scene with a restricted viewing box. Therefore, only a quater of the shere is visible:
plot({{plot::Sphere(1)}}, {{plot::Sphere(1), #X=0..1, #Y=0..1, #Z=0..1}})



Parameters

arg

Any object

Options

#3D

Alias #3. Creates a 3D instead of a 2D scene, if possible. Usually, a 2D scene is created unless one of the arguments is a 3D object or can only be transformed into one.

#Arrows

Alias #A. Creates arrows instead of points. When used within a {...}-group, it affects the elements of this group or scene only.

#Constrained

Alias #C. Creates a coordinate system with axes having the same scaling. This is a shortcut for `Scaling =Constrained`.

#Grid

Alias #G. Creates a coordinate system with grid lines. This is a shortcut for `GridVisible =TRUE`.

#Legend

Alias #L. Creates a legend. This is a shortcut for `LegendEntry =TRUE` and `LegendVisible =TRUE`. When used within a {...}-group, it affects the elements of this group or scene only. Note that `plot::easy` explicitly sets a legend text for each graphical object it creates.

#Origin

Alias #O. Includes the coordinates (0,0) or (0,0,0), respectively, into the viewing box of the current scene.

#Points

Alias #P. Creates points instead arrows or curves. Furthermore, it sets the attributes `PointsVisible =TRUE` and `LinesVisible =FALSE`. When used within a {...}-group, it affects the elements of this group or scene only.

#XRange

Option, specified as `#XRange = a .. b`

Alias `#X = a .. b`. Sets the x-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxXRange =a..b`.

#YRange

Option, specified as `#YRange = a .. b`

Alias `#Y = a .. b`. Sets the y-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxYRange =a..b`.

#ZRange

Option, specified as `#ZRange = a .. b`

Alias `#Z = a .. b`. Sets the z-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxZRange =a..b`.

#<Colorname>

If `RGB ::<Colorname>` is a valid color name in MuPAD, `#<Colorname>` is transformed to: `Color = RGB ::<Colorname>`, `LineColorType =Flat` and for 3D objects additionally `FillColorType =Flat`. Transparent RGB colors can be specified as `#<Colorname>.[t]`, with t is in 0..1. If `#<Colorname>` is a valid color following the html conventions then instead of `RGB ::<Colorname>`, the corresponding RGB or RGBa color value is inserted. When used within a {...}-group, it affects the elements of this group or scene only.

#<Colorname1> .. #<Colorname2>

If `RGB ::<Colorname1>` and `RGB ::<Colorname2>` are valid color names in MuPAD, this option is transformed to:

`Color = RGB ::<Colorname1>`, `LineColorType =Dichromatic`, `LineColor2 = RGB ::<Colorname2>` in 2D scenes and to:

`Color = RGB ::<Colorname1>`, `FillColorType =Dichromatic`, `FillColor2 = RGB ::<Colorname2>` in 3D scenes.

Transparent RGB colors can be specified as `#<Colorname>.[t]`, with t is in 0..1. If `#<Colorname1>` and/or `#<Colorname2>` are valid colors following the html conventions then instead of `RGB`

`::<Colorname1>` and/or, `RGB ::<Colorname2>` the corresponding RGB or RGBa color values are inserted. When used within a {...}-group, it affects the elements of this group or scene only.

Return Values

A sequence of graphical objects and graphical attributes as well as objects that could not be transformed by `plot::easy`.

Overloaded By

`arg`

Algorithms

Let c_i be real constants and `f` and f_i be real functions. `plot::easy` automatically carries out the following transformations:

Graphical object	Data or mathematical expression
plot::Point2d:	$[c_1, c_2]$, {$[f_1(x), f_2(x)]$, #Points}, {matrix($[f_1(x), f_2(x)]$), #Points}.
plot::Point3d:	$[c_1, c_2, c_3]$, {$[f_1(x), f_2(x), f_3(x)]$, #Points}, {matrix($[f_1(x), f_2(x), f_3(x)]$), #Points}.
plot::Arrow2d:	matrix($[c_1, c_2]$), {$[c_1, c_2]$, #Arrows}, {[matrix($[f_1(x), f_2(x)]$), matrix($[f_3(x), f_4(x)]$)], #Arrows}, {matrix($[[f_1(x), f_2(x)], [f_3(x), f_4(x)]]$), #Arrows}, {$[[f_1(x), f_2(x)], [f_3(x), f_4(x)]]$, #Arrows}.

Graphical object	Data or mathematical expression
plot::Arrow3d:	matrix([c_1, c_2, c_3]), {[c_1, c_2, c_3], #Arrows}, {[matrix([$f_1(x)$, $f_2(x)$, $f_3(x)$]), matrix([$f_4(x)$, $f_5(x)$, $f_6(x)$])], #Arrows}, {matrix([[$f_1(x)$, $f_2(x)$, $f_3(x)$], [$f_4(x)$, $f_5(x)$, $f_6(x)$]]), #Arrows}, {[[$f_1(x)$, $f_2(x)$, $f_3(x)$], [$f_4(x)$, $f_5(x)$, $f_6(x)$]], #Arrows}.
plot::Polygon2d:	[[$f_1(x)$, $f_2(x)$],...], [matrix([$f_1(x)$, $f_2(x)$]),...], matrix([[$f_1(x)$, $f_2(x)$],...]), table($f_1(x)$=$f_2(x)$,...).
plot::Polygon3d:	[[$f_1(x)$, $f_2(x)$, $f_3(x)$],...], [matrix([$f_1(x)$, $f_2(x)$, $f_3(x)$]),...], matrix([[$f_1(x)$, $f_2(x)$, $f_3(x)$],...]). table($f_1(x)$=[$f_2(x)$, $f_3(x)$],...).
plot::PointList2d:	[[$f_1(x)$, $f_2(x)$, RGBa],...], [matrix([$f_1(x)$, $f_2(x)$, RGBa]),...], matrix([[$f_1(x)$, $f_2(x)$, RGBa],...]), table($f_1(x)$=[$f_2(x)$, RGBa],...).
plot::PointList3d:	[[$f_1(x)$, $f_2(x)$, $f_3(x)$, RGBa],...], [matrix([$f_1(x)$, $f_2(x)$, $f_3(x)$, RGBa]),...], matrix([[$f_1(x)$, $f_2(x)$, $f_3(x)$, RGBa],...]). table($f_1(x)$=[$f_2(x)$, $f_3(x)$, RGBa],...).
plot::Line2d:	#x= $f(x)$, #y= $f(x)$.
plot::Plane:	#z= $f(x)$, {#x= $f(x)$, #3D}, {#y= $f(x)$, #3D}, {#z= $f(x)$, #3D}.
plot::Curve2d:	[$f_1(x)$, $f_2(x)$].

Graphical object	Data or mathematical expression
plot::Curve3d:	[f1(x), f2(x), f3(x)].
plot::Function2d:	f(x), f(x, a), [cond1, f(x)], [[cond1, f(x)],...].
plot::Function3d:	f(x, y, a), [cond1, f(x, y, a)], [[cond1, f(x, y, a)],...], {f(x), #3D}, {f(x, a), #3D}.
plot::Implicit2d:	f1(x, y, a)=f2(x, y, a).
plot::Implicit3d:	f1(x, y, z, a)=f2(x, y, z, a), {f1(x, y, a)=f2(x, y, a), #3D}.
plot::Inequality:	f1(x, a) < f2(x, a), f1(x, a) <= f2(x, a), f1(x, a) > f2(x, a), f1(x, a) >= f2(x, a), [f1(x, a)<f2(x, a), f3(x, a)>f4(x, a), f5(x, a)=f6(x, a),...].
plot::Text2d:	[f1(x), f2(x)]=text, matrix([f1(x), f2(x)])=text, [f1(x), f2(x)]=procedure, matrix([f1(x), f2(x)])=procedure.
plot::Text3d:	[f1(x), f2(x), f3(x)]=text, matrix([f1(x), f2(x), f3(x)])=text, [f1(x), f2(x), f3(x)]=procedure, matrix([f1(x), f2(x), f3(x)])=procedure.

See Also plot

plot::getDefault

Purpose

Get current default setting of attributes

Syntax

```
plot::getDefault(type::attr)
```

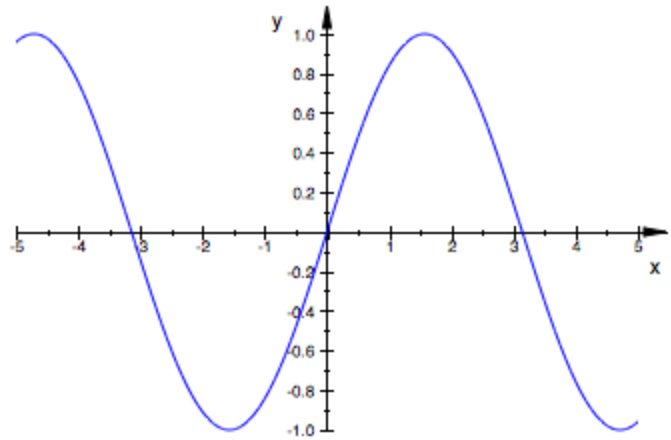
Description

`plot::getDefault(plot::Object::Attribute)` enquires the current default.

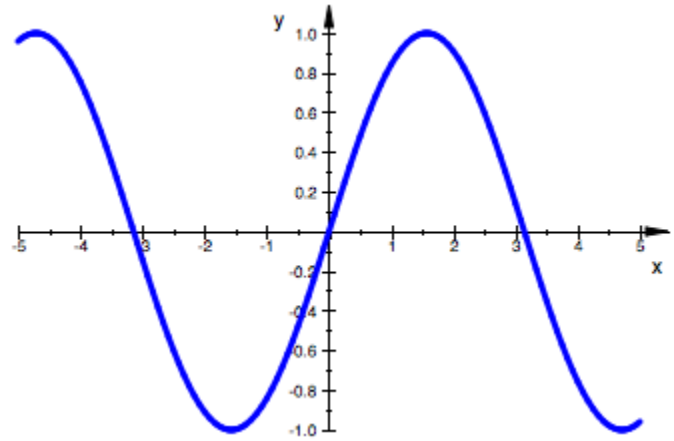
Examples

Example 1

By default, function plots use relatively thin lines:
plotfunc2d(sin(x))

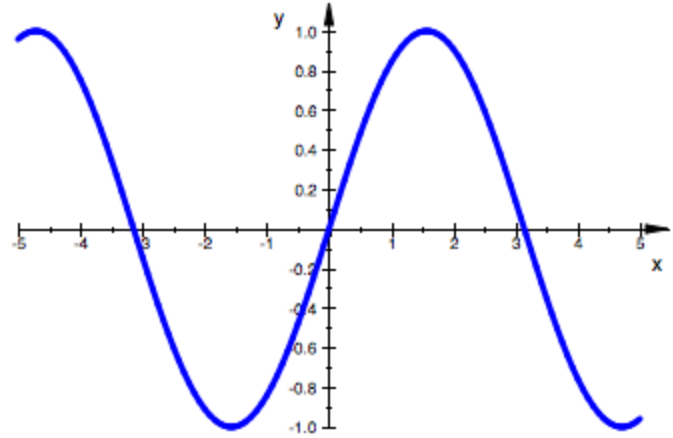


For some applications, this is undesirable, for example when projecting graphics for a larger audience. It is always possible to set thicker lines in the call:
plotfunc2d(sin(x), LineWidth = 1*unit::mm)



However, this is distracting and cumbersome. Using `plot::setDefault`, we change the default setting once and for the whole session:

```
plot::setDefault(plot::Function2d::LineWidth = 1*unit::mm):
plotfunc2d(sin(x))
```



One thing you should know in this context: plotfunc2d and plotfunc3d use plot::Function2d and plot::Function3d for the actual plotting.

Changing color and legend settings of the latter two does not influence the former, however, since plotfunc2d and plotfunc3d set color and legend settings explicitly.

Parameters

type

A domain of the plot library, i.e., an object type such as plot::Function2d

attr

Attributes admissible for the object type `type`

Return Values

`plot::setDefault` returns the previous default value(s).
`plot::getDefault` returns the current default value.

Algorithms

"Admissible attributes" includes all the attributes the object itself reacts to. Hints cannot be set or changed with `plot::setDefault`.

For attributes marked as "mandatory," default values are read and used the moment an object is created. Default values of attributes marked as "optional" or "inherited" are read when the object is plotted and can therefore be changed after creating an object.

See Also

plot::setDefault

plot::setDefault

Purpose

Set default setting of attributes

Syntax

```
plot::setDefault(type::attr = value,  )
```

Description

`plot::setDefault(plot::Object::Attribute = Value)` sets the default of the attribute `Attribute` for objects of type `plot::Object` to `Value`.

While not all attributes have defaults, it is in general possible to set defaults for them, although some examples like setting a default function to plot for plot::Function2d are probably more exotic than others, to say the least.

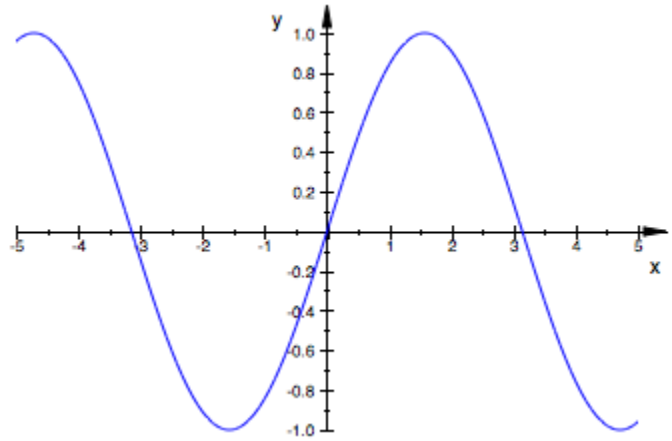
Defaults are set and retrieved per object; with the exception of OutputFile and OutputOptions, the attribute must be prefixed with the name of the object type the setting shall be valid for. There is, e.g., no function to turn of all lines on all 3D objects. OutputFile and OutputOptions are not associated with an object and must be set directly.

To delete a default (which is not recommended for attributes having a default in the standard installation), set `value` to `FAIL`.

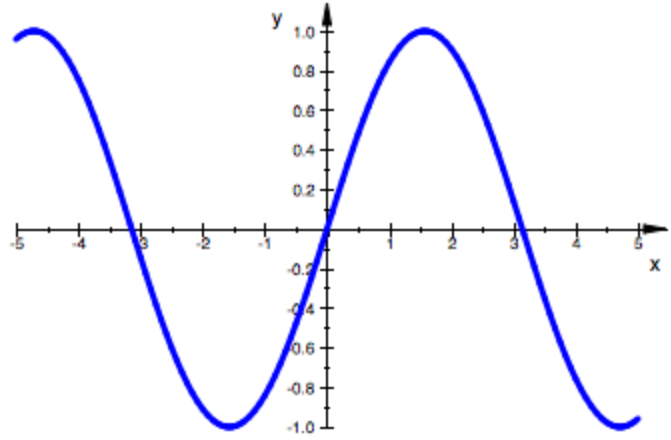
Examples

Example 1

By default, function plots use relatively thin lines:
plotfunc2d(sin(x))

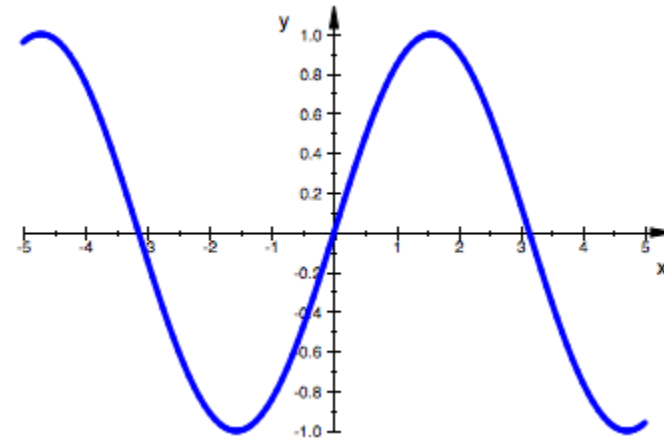


For some applications, this is undesirable, for example when projecting graphics for a larger audience. It is always possible to set thicker lines in the call:
plotfunc2d(sin(x), LineWidth = 1*unit::mm)



However, this is distracting and cumbersome. Using `plot::setDefault`, we change the default setting once and for the whole session:

```
plot::setDefault(plot::Function2d::LineWidth = 1*unit::mm):
plotfunc2d(sin(x))
```



One thing you should know in this context: plotfunc2d and plotfunc3d use plot::Function2d and plot::Function3d for the actual plotting. Changing color and legend settings of the latter two does not influence the former, however, since plotfunc2d and plotfunc3d set color and legend settings explicitly.

Parameters

type

A domain of the plot library, i.e., an object type such as plot::Function2d

attr

Attributes admissible for the object type `type`

value

The new default value: a value admissible for `attr` in objects of type `type`

Return Values

`plot::setDefault` returns the previous default value(s).
`plot::getDefault` returns the current default value.

Algorithms

"Admissible attributes" includes all the attributes the object itself reacts to. Hints cannot be set or changed with `plot::setDefault`.

For attributes marked as "mandatory," default values are read and used the moment an object is created. Default values of attributes marked as "optional" or "inherited" are read when the object is plotted and can therefore be changed after creating an object.

See Also plot::getDefault

plot::copy

Purpose

Make a physical copy of a plot object

Syntax

```
plot::copy(obj)
```

Description

Plot objects usually have a reference effect. `plot::copy` creates copies which are independent of the original.

Objects created from inside the `plot` library have a *reference effect:* If you make another reference to some object, say by calling `o2 := o1;` and then change an attribute of `o2`, e.g., setting `o2::Visible := FALSE`, this change will also effect the object referred to by `o1`, since they actually refer to the same object. To create an actual copy of an object instead, use `o2 := plot::copy(o1);`.

The function `plot::modify` is a variant of `plot::copy`. It allows setting new values of attributes in the same call, as in `o2 := plot::modify(o1, Visible = FALSE);`.

Examples

Example 1

The following call does *not* create two points, but rather one which we can access by two names:
A := plot::Point2d(0, 0): B := A:

This surfaces as soon as we try to modify 'one of the points':
B::Position := [1, 1]: Aplot::Point2d(1, 1)

plot::Point2d(1, 1)

Instead, we can use `plot::modify` to achieve the desired effect:
B := plot::modify(A, Position = [2, 2]): A, Bplot::Point2d(1, 1), plot::Point2d(2, 2)

plot::Point2d(1, 1), plot::Point2d(2, 2)

Note Note that `plot::modify` does not modify its argument, but returns a modified copy instead, whatever the name may suggest.

Parameters

obj

Plot objects

Return Values

Object of the same type as `obj`

See Also

plot::modify

plot::modify

Purpose

Make a physical copy of a plot object setting new values of attributes in the same call

Syntax

```
plot::modify(obj, <attr,  >)
```

Description

Plot objects usually have a reference effect. `plot::modify` creates copies which are independent of the original.

Objects created from inside the `plot` library have a *reference effect:* If you make another reference to some object, say by calling `o2 := o1;` and then change an attribute of `o2`, e.g., setting `o2::Visible := FALSE`, this change will also effect the object referred to by `o1`, since they actually refer to the same object. To create an actual copy of an object instead, use `o2 := plot::copy(o1);`.

The function `plot::modify` is a variant of `plot::copy`. It allows setting new values of attributes in the same call, as in `o2 := plot::modify(o1, Visible = FALSE);`.

Examples

Example 1

The following call does *not* create two points, but rather one which we can access by two names:
A := plot::Point2d(0, 0): B := A:

This surfaces as soon as we try to modify 'one of the points':
B::Position := [1, 1]: Aplot::Point2d(1, 1)

```
plot::Point2d(1, 1)
```

Instead, we can use `plot::modify` to achieve the desired effect:
B := plot::modify(A, Position = [2, 2]): A, Bplot::Point2d(1, 1), plot::Point2d(2, 2)

```
plot::Point2d(1, 1), plot::Point2d(2, 2)
```

Note Note that `plot::modify` does not modify its argument, but returns a modified copy instead, whatever the name may suggest.

Parameters

obj

Plot objects

attr

Attributes admissible for the object `obj`, in the form `Attribute = Value`

Return Values

Object of the same type as `obj`

See Also

plot::copy

plot::delaunay

Purpose

Compute the Delaunay triangulation of a set of points

Syntax

```
plot::delaunay(L)
```

Description

`plot::delaunay` computes the Delaunay triangulation of a list of points in arbitrary dimension.

The Delaunay triangulation of a list of points is a triangulation of their convex hull such that for each edge of the triangulation, there is a circle containing the two endpoints of this edge but no other point of the list.

Environment Interactions

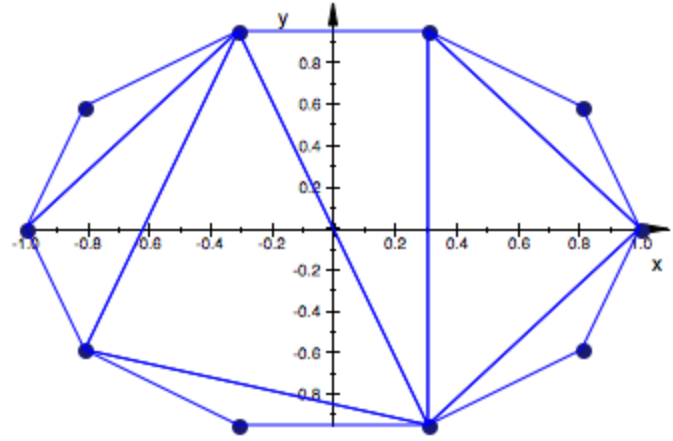
Although `plot::delaunay` accepts and returns floating-point values, the actual computations take place in hardware floating-points and are therefore *not* affected by the value of DIGITS.

Examples

Example 1

Delaunay triangulation does not introduce new points:

```
n0 := 10: l := [[Re, Im](exp(float(2*I*PI*n)/n0)) $ n = 1..  n0]:
d := plot::delaunay(l):  plot(plot::PointList2d(l, PointSize=3),
plot::Polygon2d(t, Closed) $ t in d)
```



Parameters

L

A list of points, which are given as lists of real values

Return Values

List of simplices in the dimension of the points in L, given as lists of lists of floating-point values.

Algorithms

`plot::delaunay` uses qhull from the Geometry Center of the University of Minnesota, see www.qhull.org.

plot::hull

Purpose

Compute the convex hull of a set of points

Syntax

```
plot::hull(L)
```

Description

`plot::hull` computes the convex hull of a list of points in any dimension, i.e., the smallest convex region containing all the points. Such a region is bounded by simplices (straight lines in the plane, triangles in 3D) and it is these simplices which `plot::hull` returns.

Environment Interactions

Although `plot::hull` accepts and returns floating point values, the actual computations take place in hardware floating points and are therefore *not* affected by the value of DIGITS.

Examples

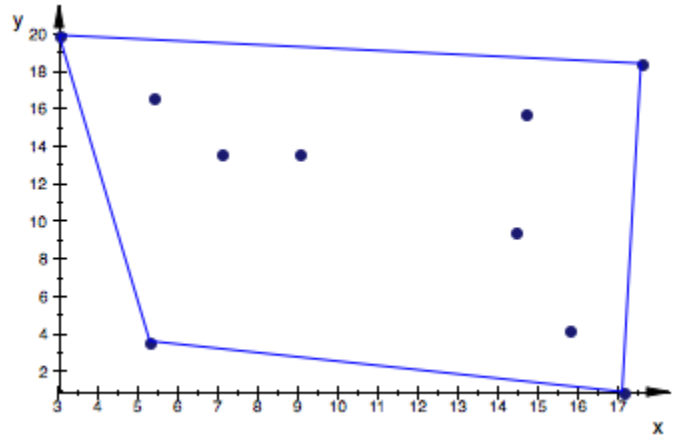
Example 1

We generate a list of random points and compute their convex hull:
X := stats::uniformRandom(0, 20): l := [[X(), X()] $ i = 1..10]: h := plot::hull(l):

The convex hull is returned as lists of lists, as accepted by plot::Polygon2d:
h[1][[17.58320254, 18.38769696], [3.063130321, 19.89625562]]

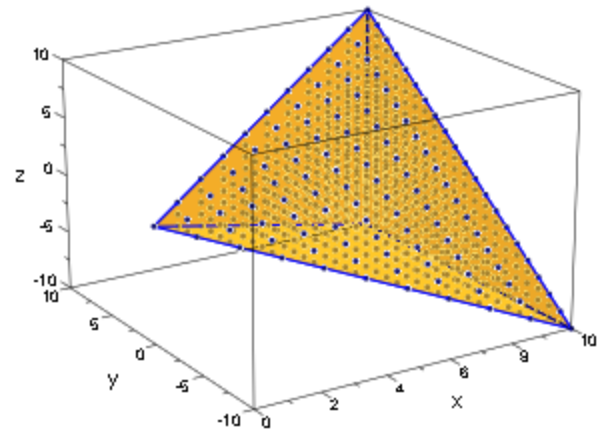
[[17.58320254, 18.38769696], [3.063130321, 19.89625562]]

plot(plot::PointList2d(l), plot::Polygon2d(t) $ t in h, Closed, PointSize=2)



Example 2

The convex hull of a list of points in 3D is also easy to visualize:
l := [[x, y, z] $ y = z..x $ z = -x..x $ x = 0..10]: h := plot::hull(l):
plot(plot::PointList3d(l, PointSize=1), plot::Polygon3d(t) $ t in h, Closed, Filled, FillColor=RGB::LightOrange.[0.6])



Parameters

`L`

A list of points, which are given as lists of real values

Return Values

List of simplices of dimension one less than that of the points in `L`, given as lists of lists of floating-point values.

Algorithms

`plot::hull` uses qhull from the Geometry Center of the University of Minnesota, see www.qhull.org.

plot::Arc2d

Purpose

Circular and elliptical arcs in 2D

Syntax

```
plot::Arc2d(r, <[c_x, c_y]>, <Æ ..  >, <a =
a_min .. a_max>, options)
plot::Arc2d([r_1, r_2], <[c_x, c_y]>, <Æ ..  >, <a =
a_min .. a_max>, options)
```

Description

`plot::Arc2d(r, [x, y], Æ ..  )` creates a circular arc with radius r and center (x, y) with a polar angle between α and β.

`plot::Arc2d([ r_1, r_2], [x, y], Æ ..  )` creates a corresponding elliptical arc with semi-axes r_1, r_2.

The angle of a point on the arc is the usual polar angle to the positive x-axis known from polar coordinates. It is measured in radians.

If no range for the polar angle is specified, a full circle/ellipse is created.

If no center point is specified, an arc with center [0, 0] is created.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Angle	rotation angle	`0`
AngleEnd	end of angle range	`PI/2`
AngleBegin	begin of angle range	`0`
AngleRange	angle range	`0 .. PI/2`
AntiAliased	antialiased lines and points?	`TRUE`
Center	center of objects, rotation center	`[0, 0]`

Attribute	Purpose	Default Value
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
Closed	open or closed polygons	FALSE
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	

Attribute	Purpose	Default Value
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
SemiAxes	semi axes of ellipses and ellipsods	[1, 1]
SemiAxisX	first semi axis of ellipses and ellipsods	1
SemiAxisY	second semi axis of ellipses and ellipsods	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center

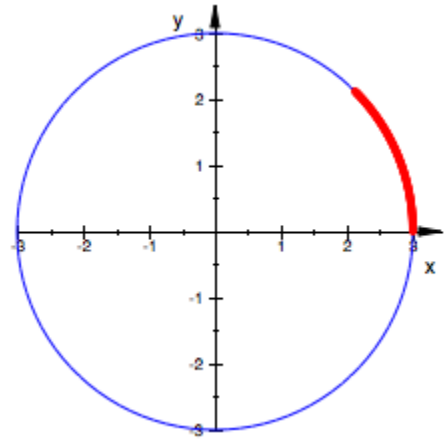
Attribute	Purpose	Default Value
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

An arc is a segment of a circle:

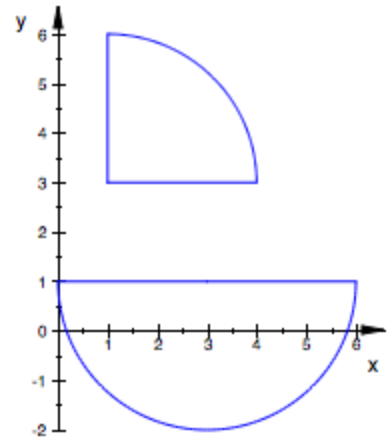
```
circle := plot::Circle2d(3, [0, 0]): arc := plot::Arc2d(3, [0, 0], 0 .. PI/4,
LineColor = RGB::Red, LineWidth = 1.5*unit::mm): plot(circle, arc)
```



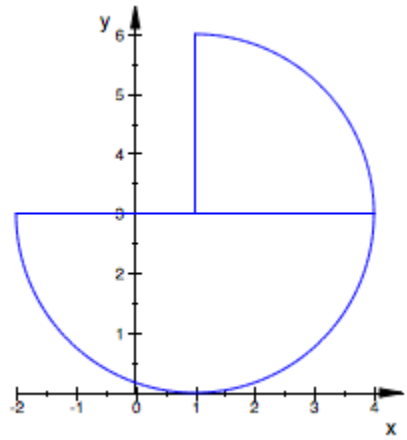
delete circle, arc:

Example 2

The center of an arc may be given as the second argument to `plot::Arc2d`:
arc1 := plot::Arc2d(3, [1, 3], 0..PI/2, Closed = TRUE): arc2 := plot::Arc2d(3, [3, 1], -PI ..0, Closed = TRUE): plot(arc1, arc2)



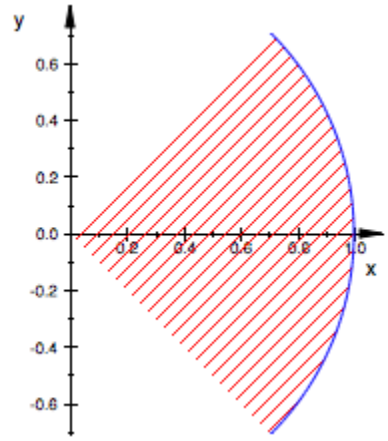
The center is accessible as the attribute `Center` of the arc object. We change the center of the second arc:
arc2::Center := [1, 3]: plot(arc1, arc2)



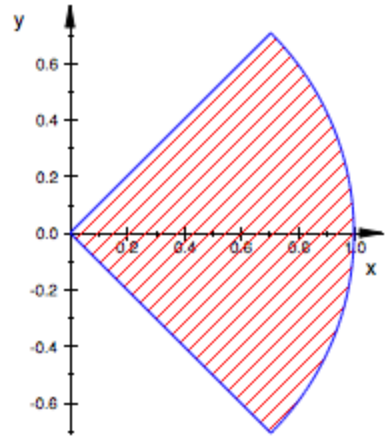
delete arc1, arc2:

Example 3

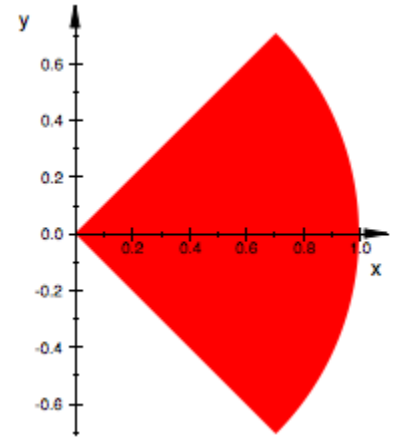
A filled arc is a segment of a circle, like a piece of pie:
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE))



plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE, Closed = TRUE))

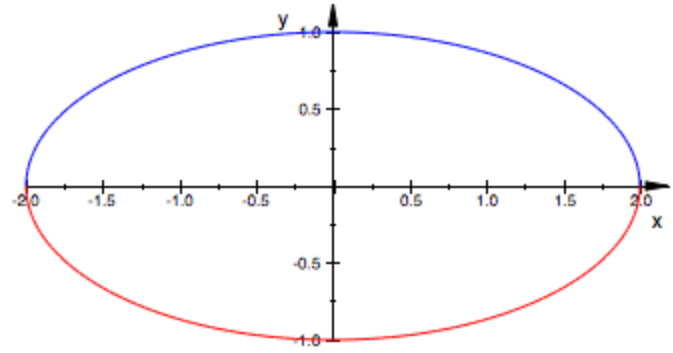


plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE, FillPattern = Solid, LinesVisible = FALSE), AxesInFront = TRUE)



Example 4

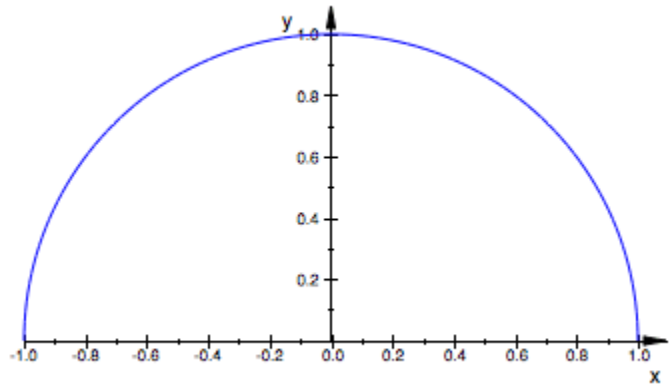
When giving a list of two radii, `plot::Arc2d` draws a segment of anellipse with the corresponding semi-axes:
arc1 := plot::Arc2d([2, 1], 0 .. PI, Color = RGB::Blue): arc2 := plot::Arc2d([2, 1], -PI .. 0, Color = RGB::Red): plot(arc1, arc2)



delete arc1, arc2:

Example 5

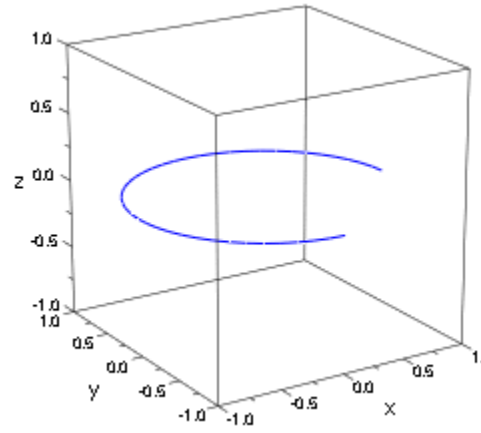
To plot or animate segments of a tilted ellipse, use the attribute Angle:
arc:= [1, 1], [0, 0], PI/4..PI/2, Filled, Closed, FillPattern=Solid:
plot(plot::Arc2d(arc, Angle=a+0, a=0..2*PI, FillColor=RGB::Red),
plot::Arc2d(arc, Angle=a+1/2*PI, a=0..2*PI, FillColor=RGB::Green),
plot::Arc2d(arc, Angle=a+PI, a=0..2*PI, FillColor=RGB::Yellow),
plot::Arc2d(arc, Angle=a+3/2*PI, a=0..2*PI, FillColor=RGB::Blue))



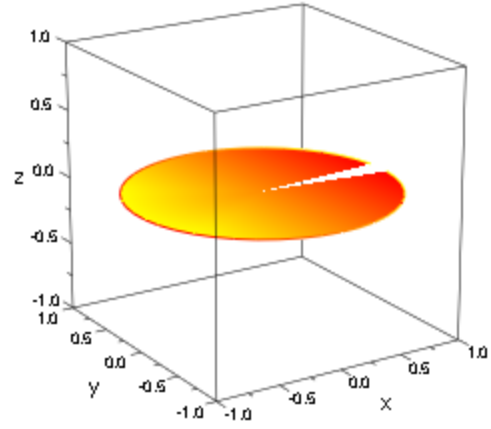
delete arc:

Example 6

Further examples of animated 2D arcs:
plot(plot::Arc2d(1, a .. PI, a = 0..PI))

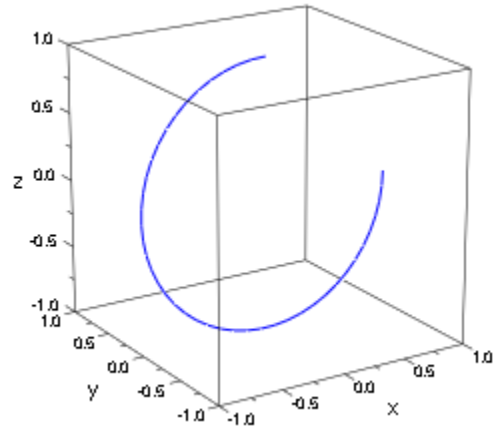


plot(plot::Arc2d([1 + a^2/2, 1 + a], -PI/2 .. PI/2, a = 0..4))



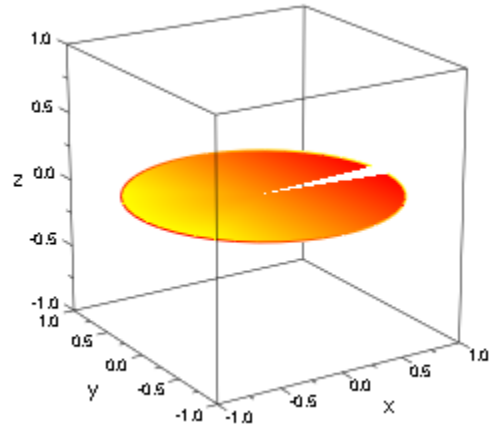
Example 7

We plot an animated 3D arc:
plot(plot::Arc3d(1, [0,0,0], [0,a,1-a], 0..3/2*PI, a = 0..1))



Example 8

We plot a colored 3D arcs:
plot(plot::Arc3d(1, [0,0,0], 0.1..2*PI-0.1, Filled, LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType = Dichromatic, LineColorDirection=[+1,0,0], FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType = Dichromatic, FillColorDirection=[-1,0,0]))



Parameters

r

The radius of the circle. This must be a real numerical value or an arithmetical expression of the animation parameter a.

r is equivalent to the attributes SemiAxisX, SemiAxisY.

r_1

r_2

The semi-axes of an elliptical arc. They must be real numerical values or arithmetical expressions of the animation parameter a.

r_1, r_2 are equivalent to the attributes SemiAxisX, SemiAxisY.

c_x

c_y

The center point. The coordinates c_x, c_y must be real numerical values or arithmetical expressions of the animation parameter a. If no center is specified, an arc centered at the origin is created.

c_x, c_y are equivalent to the attribute Center.

..

The angle range in radians: Æ and must be real numerical values or arithmetical expressions of the animation parameter a. The default range is 0 .. 2*PI.

Æ .. is equivalent to the attribute AngleRange.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Arc3dplot::Circle2dplot::Ellipse2dplot::Ellipse3d

plot::Arc3d

Purpose

Circular and elliptical arcs in 3D

Syntax

```
plot::Arc3d(r, <[c_x, c_y, c_z], <[n_x, n_y, n_z]>>, <Æ ..
 >, <a = a_min .. a_max>, options)
plot::Arc3d([r_1, r_2], <[c_x, c_y, c_z], <[n_x, n_y, n_z]>>,
<Æ ..  >, <a = a_min .. a_max>, options)
```

Description

`plot::Arc3d(r, [x, y, z], [nx, ny, nz], Æ ..  )` creates a circular arc with radius *r* and center (*x*, *y*, *z*) with a polar angle between α and β in the plane with the normal vector (*nx*, *ny*, *nz*).

`plot::Arc3d([ r_1, r_2], [x, y, z], [nx, ny, nz], Æ ..  )` creates a corresponding elliptical arc with semi-axes r_1, r_2.

The angle of a point on the arc is the usual polar angle to the positive *x*-axis known from polar coordinates. It is measured in radians.

If no range for the polar angle is specified, a full circle/ellipse is created.

If no center point is specified, an arc with center [0, 0, 0], is created.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Angle	rotation angle	`0`
AngleEnd	end of angle range	`PI/2`
AngleBegin	begin of angle range	`0`
AngleRange	angle range	`0 .. PI/2`
Center	center of objects, rotation center	`[0, 0, 0]`

Attribute	Purpose	Default Value
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
CenterZ	center of objects, rotation center, z-component	0
Closed	open or closed polygons	FALSE
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::LightBlue
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Flat
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0

Attribute	Purpose	Default Value
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0

Attribute	Purpose	Default Value
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
Normal	normal vector of circles and discs, etc. in 3D	[0, 0, 1]
NormalX	normal vector of circles and discs, etc. in 3D, x-component	0
NormalY	normal vector of circles and discs, etc. in 3D, y-component	0
NormalZ	normal vector of circles and discs, etc. in 3D, z-component	1
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
SemiAxes	semi axes of ellipses and ellipsods	
SemiAxisX	first semi axis of ellipses and ellipsods	1

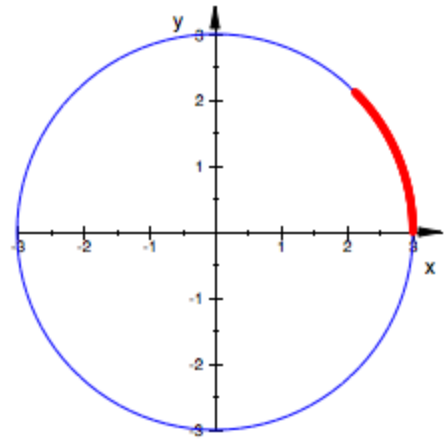
Attribute	Purpose	Default Value
SemiAxisY	second semi axis of ellipses and ellipsods	`1`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

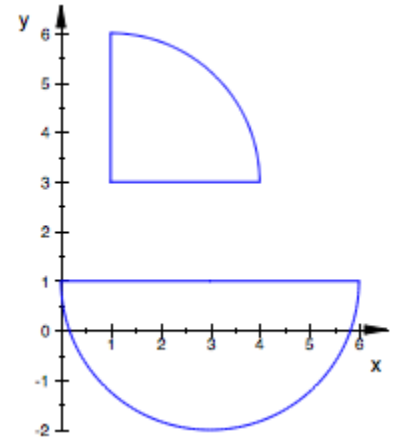
An arc is a segment of a circle:
circle := plot::Circle2d(3, [0, 0]): arc := plot::Arc2d(3, [0, 0], 0 .. PI/4, LineColor = RGB::Red, LineWidth = 1.5*unit::mm): plot(circle, arc)



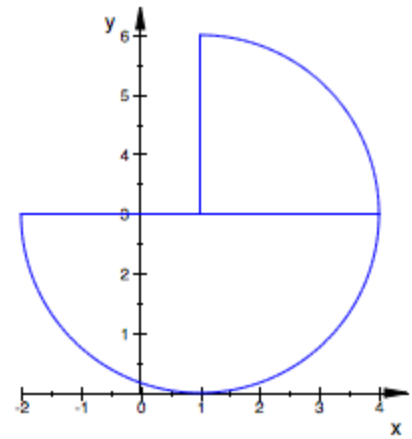
delete circle, arc:

Example 2

The center of an arc may be given as the second argument to plot::Arc2d:
arc1 := plot::Arc2d(3, [1, 3], 0..PI/2, Closed = TRUE): arc2 := plot::Arc2d(3, [3, 1], -PI ..0, Closed = TRUE): plot(arc1, arc2)



The center is accessible as the attribute `Center` of the arc object. We change the center of the second arc:
arc2::Center := [1, 3]: plot(arc1, arc2)

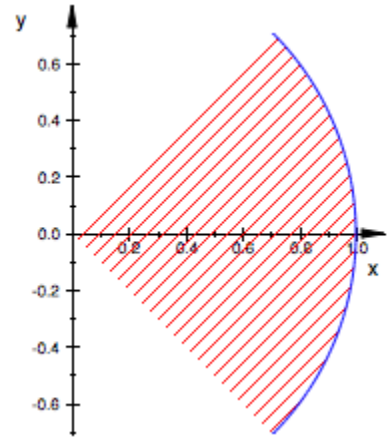


delete arc1, arc2:

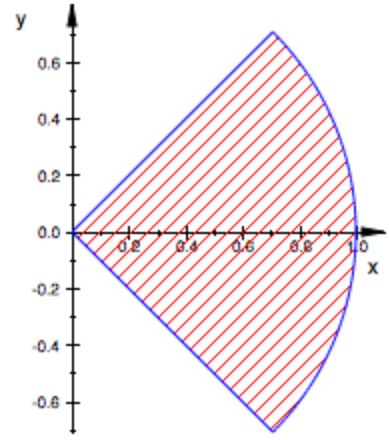
Example 3

A filled arc is a segment of a circle, like a piece of pie:

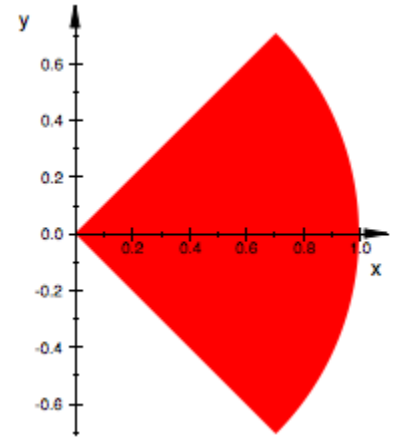
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE))



plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE, Closed = TRUE))

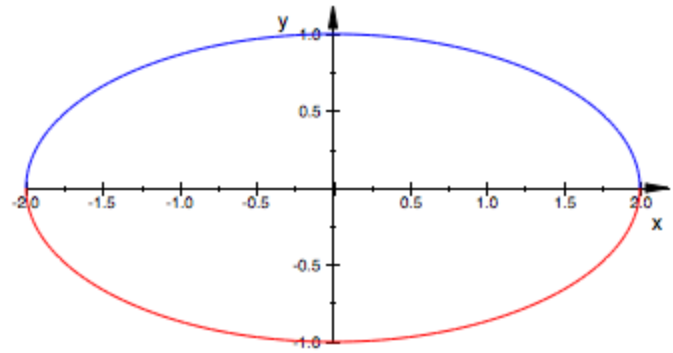


plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE, FillPattern = Solid, LinesVisible = FALSE), AxesInFront = TRUE)



Example 4

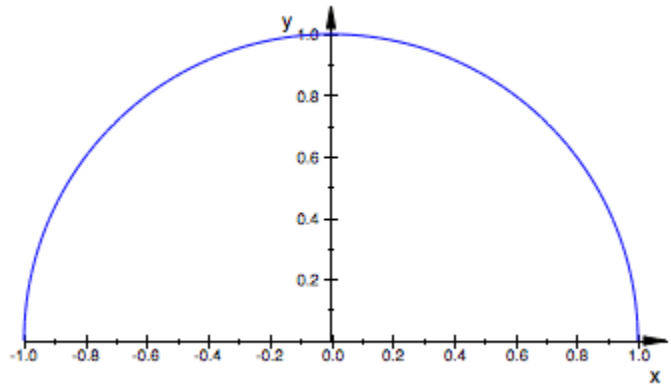
When giving a list of two radii, plot::Arc2d draws a segment of anellipse with the corresponding semi-axes:
arc1 := plot::Arc2d([2, 1], 0 .. PI, Color = RGB::Blue): arc2 := plot::Arc2d([2, 1], -PI .. 0, Color = RGB::Red): plot(arc1, arc2)



delete arc1, arc2:

Example 5

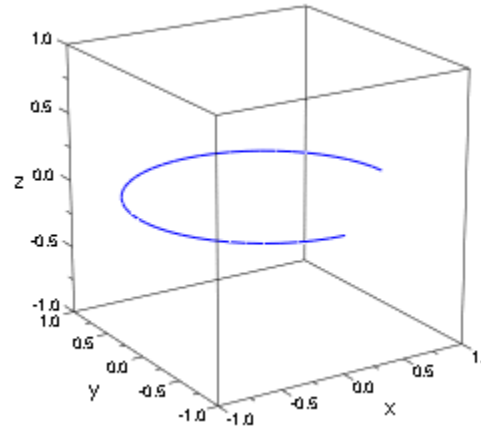
To plot or animate segments of a tilted ellipse, use the attribute Angle:
arc:= [1, 1], [0, 0], PI/4..PI/2, Filled, Closed, FillPattern=Solid:
plot(plot::Arc2d(arc, Angle=a+0, a=0..2*PI, FillColor=RGB::Red),
plot::Arc2d(arc, Angle=a+1/2*PI, a=0..2*PI, FillColor=RGB::Green),
plot::Arc2d(arc, Angle=a+PI, a=0..2*PI, FillColor=RGB::Yellow),
plot::Arc2d(arc, Angle=a+3/2*PI, a=0..2*PI, FillColor=RGB::Blue))



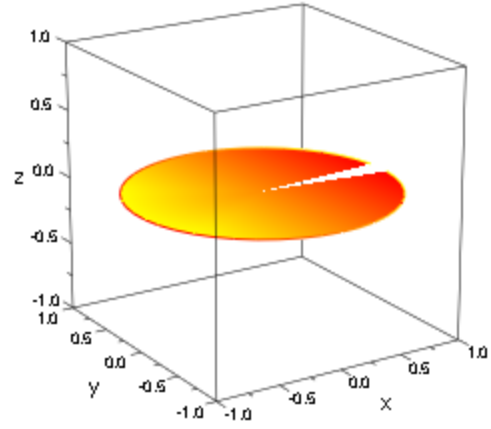
delete arc:

Example 6

Further examples of animated 2D arcs:
plot(plot::Arc2d(1, a .. PI, a = 0..PI))

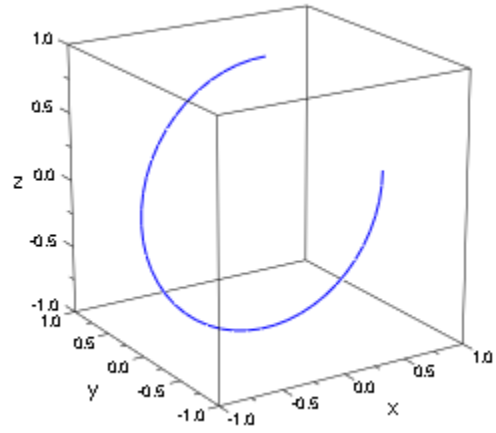


plot(plot::Arc2d([1 + a^2/2, 1 + a], -PI/2 .. PI/2, a = 0..4))



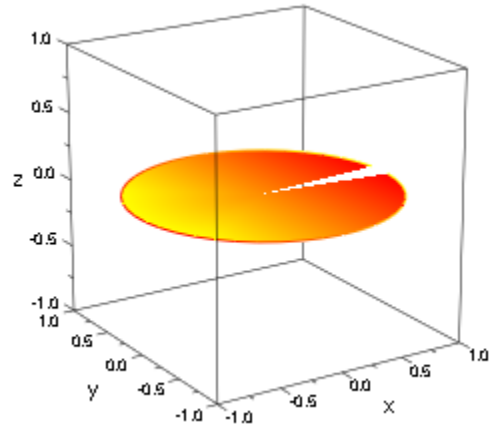
Example 7

We plot an animated 3D arc:
plot(plot::Arc3d(1, [0,0,0], [0,a,1-a], 0..3/2*PI, a = 0..1))



Example 8

We plot a colored 3D arcs:
plot(plot::Arc3d(1, [0,0,0], 0.1..2*PI-0.1, Filled, LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType = Dichromatic, LineColorDirection=[+1,0,0], FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType = Dichromatic, FillColorDirection=[-1,0,0]))



Parameters

r

The radius of the circle. This must be a real numerical value or an arithmetical expression of the animation parameter a.

r is equivalent to the attributes SemiAxisX, SemiAxisY.

r_1

r_2

The semi-axes of an elliptical arc. They must be real numerical values or arithmetical expressions of the animation parameter a.

r_1, r_2 are equivalent to the attributes SemiAxisX, SemiAxisY.

c_x

c_y

c_z

The center point. The coordinates c_x, c_y, c_z must be real numerical values or arithmetical expressions of the animation parameter a. If no center is specified, an arc centered at the origin is created.

c_x, c_y, c_z are equivalent to the attribute Center.

n_x

n_y

n_z

The normal vector. The coordinates n_x, n_y, n_z must be real numerical values or arithmetical expressions of the animation parameter a. If no normal vector is specified, the arc is created in the xy-plane.

n_x, n_y, n_z are equivalent to the attribute Normal.

..

The angle range in radians: Æ and must be real numerical values or arithmetical expressions of the animation parameter a. The default range is `0 .. 2*PI`.

Æ .. is equivalent to the attribute AngleRange.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Arc2dplot::Circle2dplot::Ellipse2dplot::Ellipse3d

plot::Arrow2d

Purpose

2D arrows

Syntax

```
plot::Arrow2d(<[x1, y1]>, [x2, y2], <a = amin .. amax>, options)
```

Description

`plot::Arrow2d([ x1, y1], [ x2, y2])` creates a 2D arrow from the point (x_1, y_1) to the point (x_2, y_2).

`plot::Arrow2d([ x2, y2])` creates a 2D arrow from the point (0, 0) to the point (x_2, y_2).

The points defining an arrow can also be passed as vectors.

The appearance of arrows can be controlled by various attributes:

- Color sets the color.
- LineWidth and LineStyle set the width and the style (solid, dashed, dotted).
- TipLength, TipAngle, and TipStyle control the arrow tip.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Color	the main color	RGB::Blue
Frames	the number of frames in an animation	`50`
From	starting point of arrows and lines	`[0, 0]`

Attribute	Purpose	Default Value
FromX	starting point of arrows and lines, x-coordinate	0
FromY	starting point of arrows and lines, y-coordinate	0
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

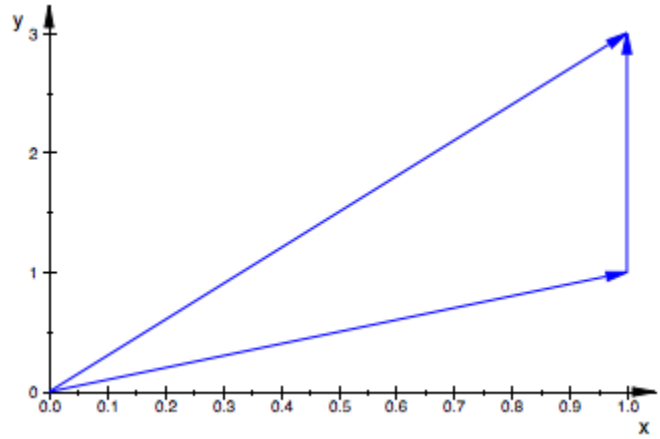
Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
TipAngle	opening angle of arrow heads	`(2*PI)/15`
TipStyle	presentation style of arrow heads	`Filled`
TipLength	length of arrow heads	`4`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	

Attribute	Purpose	Default Value
To	end point of arrows and lines	[1, 0]
ToX	end point of arrows and lines, x-coordinate	1
ToY	end point of arrows and lines, y-coordinate	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

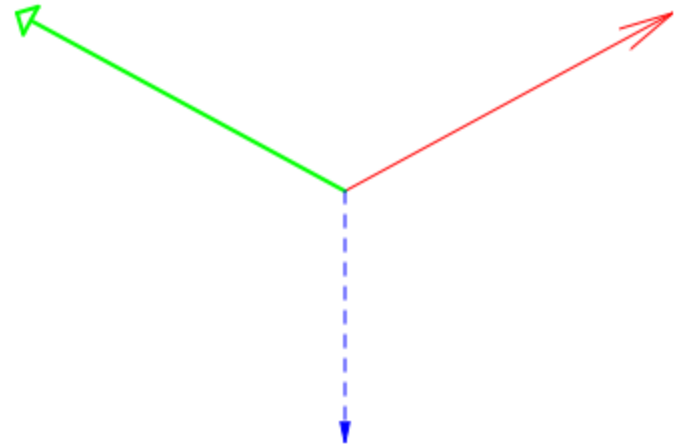
Example 1

We create and plot some arrows:
plot(plot::Arrow2d([1, 1]), plot::Arrow2d([1, 3]), plot::Arrow2d([1, 1], [1, 3]))

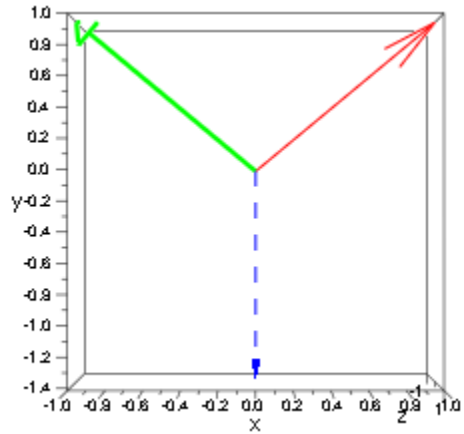


Various attributes are available to control the presentation style of an arrow:

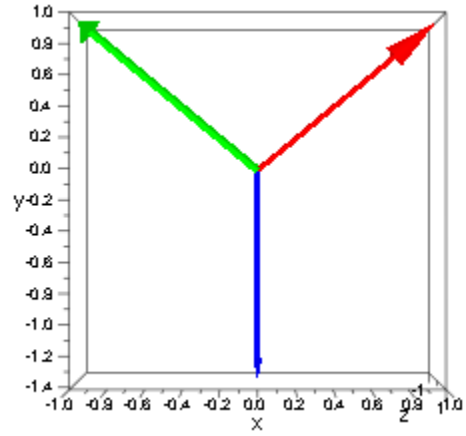
```
plot(plot::Arrow2d([1, 1], Color = RGB::Red, TipStyle = Open, TipLength
= 10*unit::mm), plot::Arrow2d([-1, 1], Color = RGB::Green, LineWidth
= 0.8*unit::mm, TipStyle = Closed, TipAngle = PI/2), plot::Arrow2d([0,
-sqrt(2)], Color = RGB::Blue, LineStyle = Dashed), Axes = None)
```



Here are corresponding arrows in 3D:
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red, TipStyle = Open, TipLength = 10*unit::mm), plot::Arrow3d([-1, 1, 0], Color = RGB::Green, LineWidth = 0.8*unit::mm, TipStyle = Closed, TipAngle = PI/2), plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue, LineStyle = Dashed), CameraDirection = [0, -1, 1000])

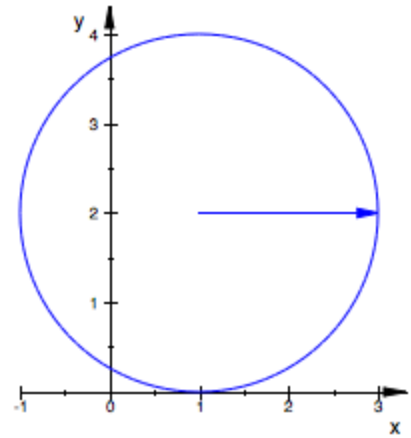


We use Tubular = TRUE:
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red, TipLength = 10*unit::mm), plot::Arrow3d([-1, 1, 0], Color = RGB::Green, TubeDiameter = 1.5*unit::mm, TipAngle = PI/2), plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue), Tubular = TRUE, CameraDirection = [0, -1, 1000])



Example 2

We plot an arrow with fixed starting point and animated end point:
plot(plot::Circle2d(2, [1, 2]), plot::Arrow2d([1, 2], [1 + 2*cos(a), 2 + 2*sin(a)], a = 0..2*PI))



Parameters

x_1

y_1

The coordinates of the starting point: real numerical values or arithmetical expressions of the animation parameter `a`. If no starting point is specified, an arrow starting at the origin is created.

x_1, y_1 are equivalent to the attributes FromX, FromY.

x_2

y_2

The coordinates of the end point: real numerical values or arithmetical expressions of the animation parameter `a`.

x_2, y_2 are equivalent to the attributes ToX, ToY.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Arrow3dplot::Line2dplot::Line3dplot::VectorField2d

plot::Arrow3d

Purpose

3D arrwos

Syntax

```
plot::Arrow3d(<[x1, y1, z1]>, [x2, y2, z2], <a =
amin .. amax>, options)
```

Description

`plot::Arrow3d([ x1, y1, z1], [ x2, y2, z2])` creates a 3D arrow from the point (x_1, y_1, z_1) to the point (x_2, y_2, z_2).

`plot::Arrow3d([ x2, y2, z2])` creates a 3D arrow from the point (0, 0, 0) to the point (x_2, y_2, z_2).

The points defining an arrow can also be passed as vectors.

The appearance of arrows can be controlled by various attributes:

- Color sets the color.
- LineWidth and LineStyle set the width and the style (solid, dashed, dotted).
- TipLength, TipAngle, and TipStyle control the arrow tip.
- With Tubular = `TRUE`, 3D arrows are rendered as 3D tubes with a diameter set by TubeDiameter. The arrow head is rendered as a cone.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::Blue
Frames	the number of frames in an animation	`50`
From	starting point of arrows and lines	[0, 0, 0]

Attribute	Purpose	Default Value
FromX	starting point of arrows and lines, x-coordinate	0
FromY	starting point of arrows and lines, y-coordinate	0
FromZ	starting point of arrows and lines, z-coordinate	0
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
Name	the name of a plot object (for browser and legend)	

Attribute	Purpose	Default Value
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
TipAngle	opening angle of arrow heads	`(2*PI)/15`
TipStyle	presentation style of arrow heads	`Filled`
TipLength	length of arrow heads	`4`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	

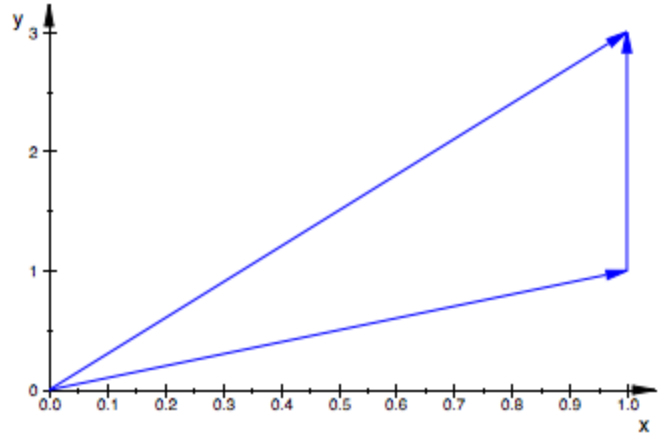
Attribute	Purpose	Default Value
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
To	end point of arrows and lines	[1, 0, 0]
ToX	end point of arrows and lines, x-coordinate	1
ToY	end point of arrows and lines, y-coordinate	0
ToZ	end point of arrows and lines, z-coordinate	0
Tubular	display 3D arrows and lines as tubes?	FALSE
TubeDiameter	diameter of tubular arrows and lines.	1.0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

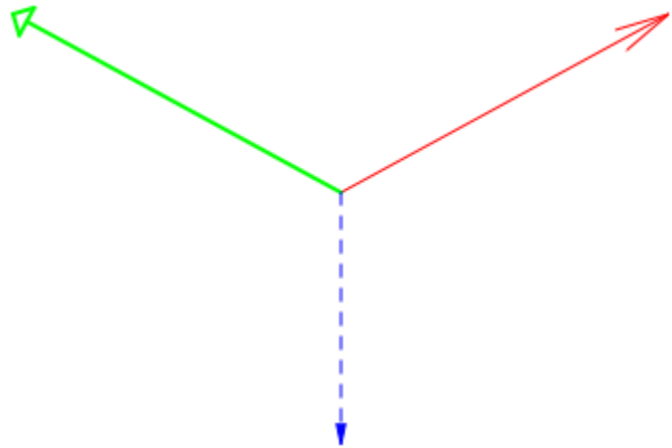
Examples

Example 1

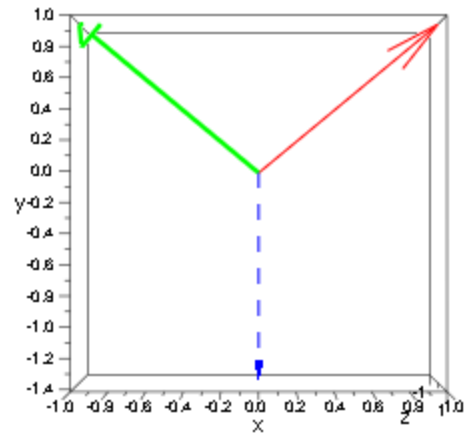
We create and plot some arrows:
plot(plot::Arrow2d([1, 1]), plot::Arrow2d([1, 3]), plot::Arrow2d([1, 1], [1, 3]))



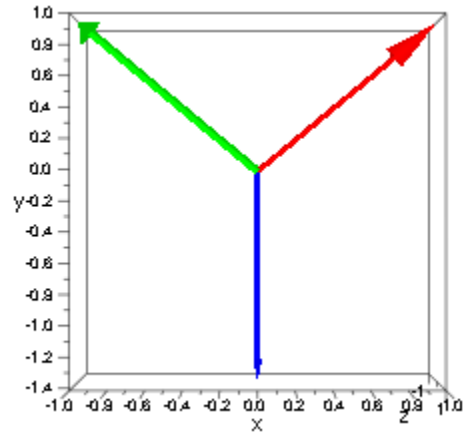
Various attributes are available to control the presentation style of an arrow:
plot(plot::Arrow2d([1, 1], Color = RGB::Red, TipStyle = Open, TipLength = 10*unit::mm), plot::Arrow2d([-1, 1], Color = RGB::Green, LineWidth = 0.8*unit::mm, TipStyle = Closed, TipAngle = PI/2), plot::Arrow2d([0, -sqrt(2)], Color = RGB::Blue, LineStyle = Dashed), Axes = None)



Here are corresponding arrows in 3D:
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red, TipStyle = Open, TipLength = 10*unit::mm), plot::Arrow3d([-1, 1, 0], Color = RGB::Green, LineWidth = 0.8*unit::mm, TipStyle = Closed, TipAngle = PI/2), plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue, LineStyle = Dashed), CameraDirection = [0, -1, 1000])

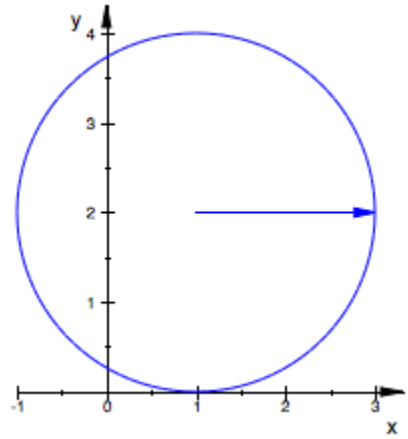


We use Tubular = TRUE:
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red, TipLength = 10*unit::mm), plot::Arrow3d([-1, 1, 0], Color = RGB::Green, TubeDiameter = 1.5*unit::mm, TipAngle = PI/2), plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue), Tubular = TRUE, CameraDirection = [0, -1, 1000])



Example 2

We plot an arrow with fixed starting point and animated end point:
plot(plot::Circle2d(2, [1, 2]), plot::Arrow2d([1, 2], [1 + 2*cos(a), 2 + 2*sin(a)], a = 0..2*PI))



Parameters

x_1

y_1

z_1

The coordinates of the starting point: real numerical values or arithmetical expressions of the animation parameter `a`. If no starting point is specified, an arrow starting at the origin is created.

x_1, y_1, z_1 are equivalent to the attributes FromX, FromY, FromZ.

x_2

y_2

z_2

The coordinates of the end point: real numerical values or arithmetical expressions of the animation parameter `a`.

x_2, y_2, z_2 are equivalent to the attributes ToX, ToY, ToZ.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Arrow2dplot::Line2dplot::Line3dplot::VectorField2d

plot::Bars2d

Purpose

2D bar chart

Syntax

```
plot::Bars2d([[a1, a2,  ], [b1, b2,  ],  ], <a =
amin .. amax>, options)
plot::Bars2d([a1, a2,  ], <a = amin .. amax>, options)
```

Description

`plot::Bars2d([[ a1, a2, ...], [ b1, b2, ...], ...])` generates a bar chart with bar heights a_1, b_1, ..., a_2, b_2, ...

`plot::Bars2d([ a1, a2, ...])` creates a bar chart with bars of height a_1, a_2, ...

With `plot::Bars2d([[ a1, a2,...], [ b1, b2,...], ...])`, bars are plotted in the order a_1, b_1, ..., a gap, a_2, b_2, ... Cf. "Example 2" on page 24-122.

The horizontal positions and the widths of the bars may be controlled by the attributes BarCenters and BarWidths, respectively.

The attribute GroupStyle provides grouping options.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`FALSE`
BarStyle	display style of bar plots	`Boxes`
BarWidths	widths of bars	[[1.0]]
BarCenters	position of bars	
Color	the main color	

Attribute	Purpose	Default Value
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson, RGB::Aqua, RGB::Lavender, RGB::SeaGreen, RGB::AureolineYellow, RGB::Banana, RGB::Beige, RGB::YellowGreen, RGB::Wheat, RGB::IndianRed, RGB::Black]
Data	the (statistical) data to plot	
DrawMode	orientation of boxes and bars	`Vertical`
Filled	filled or transparent areas and surfaces	`TRUE`
FillPatterns	list of area fill types	[`Solid`]
Frames	the number of frames in an animation	`50`
GroupStyle	grouping options in 2D bar plots	`MultipleBars`
Legend	makes a legend entry	

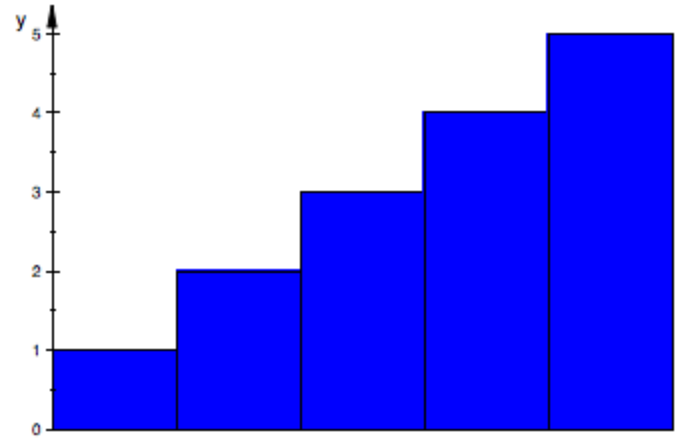
Attribute	Purpose	Default Value
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Black
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
Shadows	display “shadows” for bar plots?	`FALSE`
TimeEnd	end time of the animation	`10.0`

Attribute	Purpose	Default Value
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

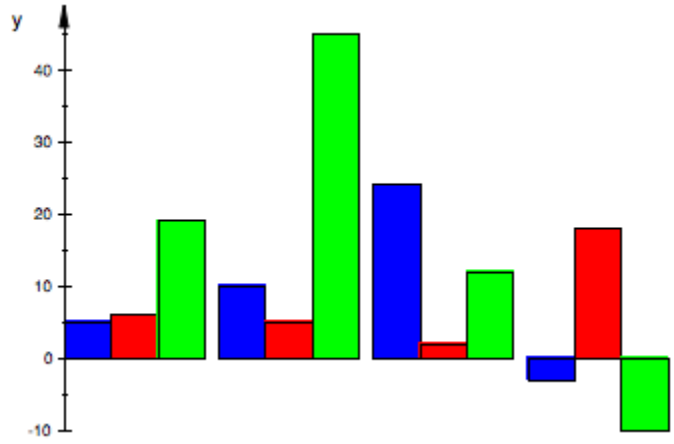
Example 1

Given a single list of values, `plot::Bars2d` plots bars of the corresponding height, filled solidly in one color:
plot(plot::Bars2d([1, 2, 3, 4, 5]))



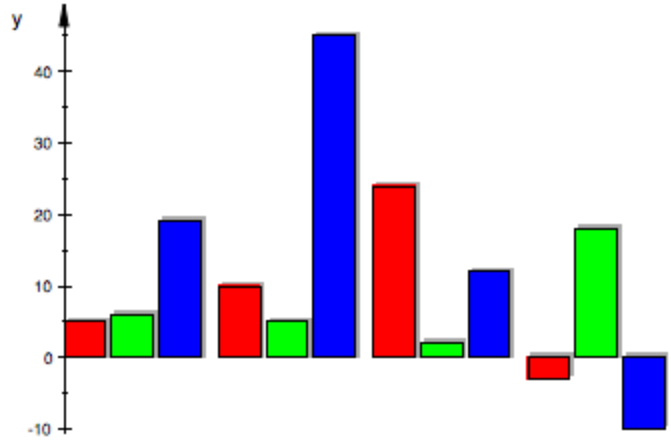
Example 2

When asked to plot a list of lists of values, `plot::Bars2d` will group the first entries of all lists, the second entries and so on, with a small gap between the groups:
plot(plot::Bars2d([[5, 10, 24, -3], [6, 5, 2, 18], [19, 45, 12,-10]]))

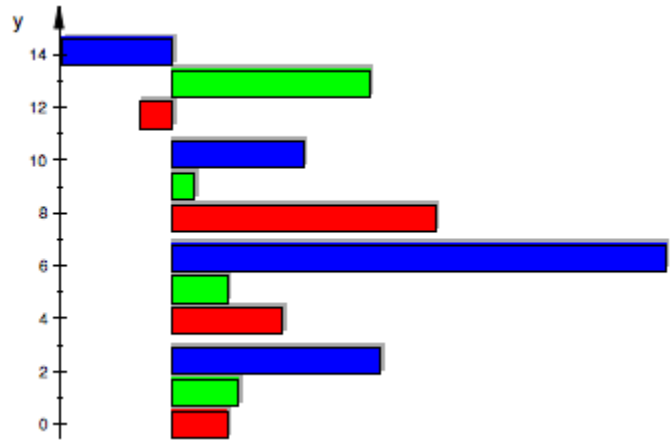


Example 3

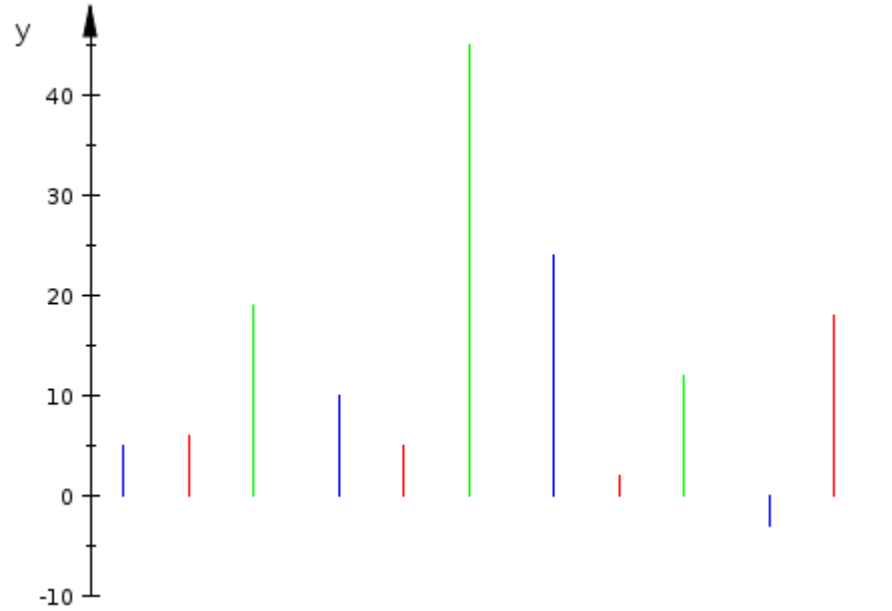
The appearance of the plots can be controlled with a number of attributes. For example, Colors accepts a list of colors for the bars and Shadows switches on “shadows,” giving a slight impression of depth: plot(plot::Bars2d([[5, 10, 24, -3], [6, 5, 2, 18], [19, 45, 12, -10]], Colors = [RGB::Red, RGB::Green, RGB::Blue], Shadows = TRUE))



Using DrawMode, `plot::Bars2d` can be made to draw horizontal bars instead of vertical ones:
plot(plot::Bars2d([[.5, 1.0, 2.4, -.3], [.6, .5, .2, 1.8], [1.9, 4.5, 1.2, -1.0]], Colors = [RGB::Red,RGB::Green,RGB::Blue], Shadows = TRUE, DrawMode = Horizontal))

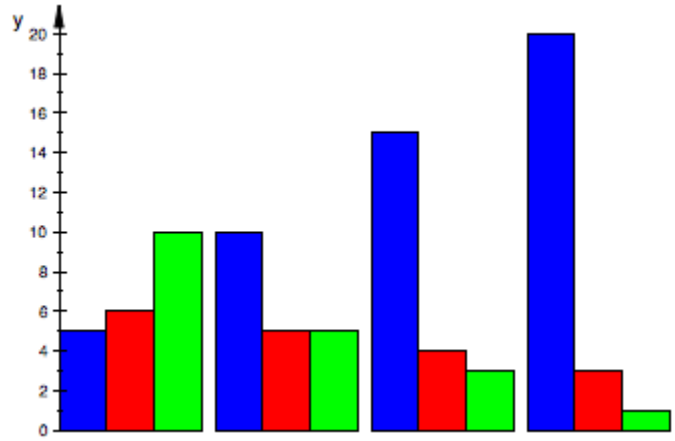


BarStyle is used to plot points or lines instead of rectangles:
plot(plot::Bars2d([[5, 10, 24, -3], [6, 5, 2, 18], [19, 45, 12, -10]], BarStyle = Lines))

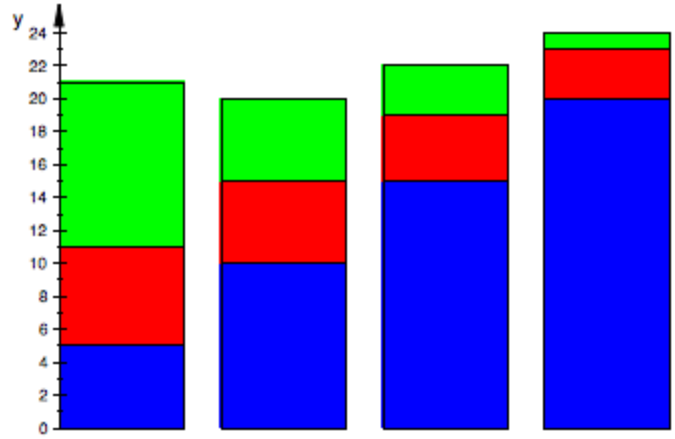


Example 4

We demonstrate alternative grouping styles:
plot(plot::Bars2d([[5, 10, 15, 20], [6, 5, 4, 3], [10, 5, 3, 1]], GroupStyle = MultipleBars))



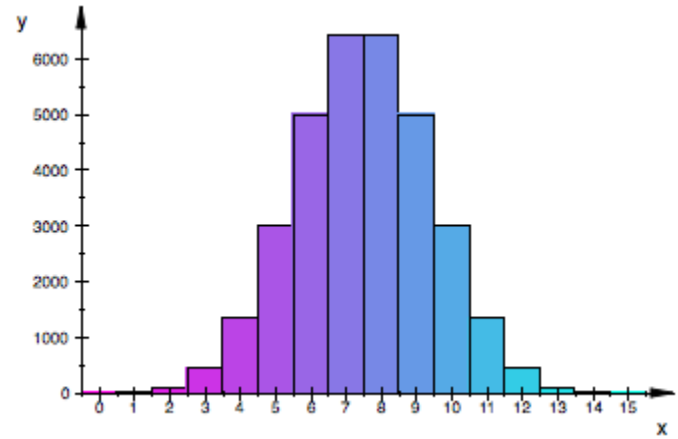
plot(plot::Bars2d([[5, 10, 15, 20], [6, 5, 4, 3], [10, 5, 3, 1]], GroupStyle = SingleBars))



Example 5

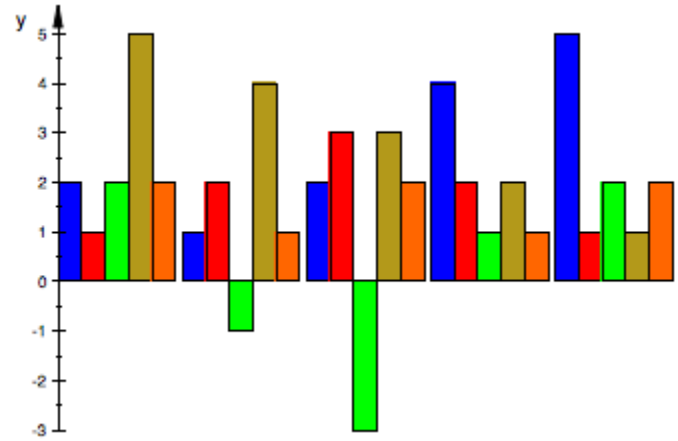
To plot a single group of data with different colors, they must be placed in individual lists:

plot(plot::Bars2d([[binomial(15,i)] $ i = 0..15], Colors = [[1-j/15, j/15, 0.9] $ j = 0..15]), XAxisVisible)

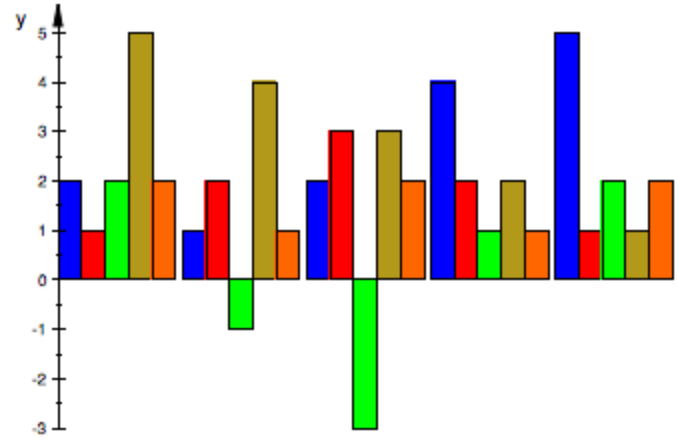


Example 6

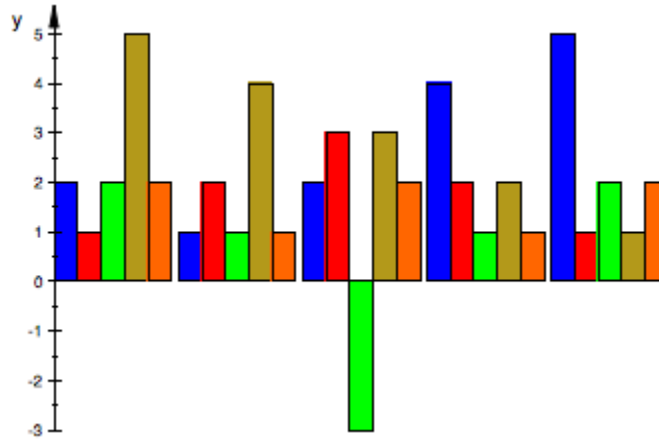
`plot::Bars2d` accepts input in form of lists (as above), as a matrix, or as a one- or two-dimensional array:
L := [[2, 1, 2, 4, 5], [1, 2, 3, 2, 1], [2, -1, -3, 1, 2], [5, 4, 3, 2, 1], [2, 1, 2, 1, 2]]: M := matrix(L): A :=array(1..5, 1..5, (1,1) = 2, (1,2) = 1, (1,3) = 2, (1,4) = 4, (1,5) = 5, (2,1) = 1, (2,2) = 2, (2,3) = 3, (2,4) = 2, (2,5) = 1, (3,1) = 2, (3,2) = 1, (3,3) = -3, (3,4) = 1, (3,5) = 2, (4,1) = 5, (4,2) = 4, (4,3) = 3, (4,4) = 2, (4,5) = 1, (5,1) = 2, (5,2) = 1, (5,3) = 2, (5,4) = 1, (5,5) = 2):
plot(plot::Bars2d(L))



plot(plot::Bars2d(M))



plot(plot::Bars2d(A))



Example 7

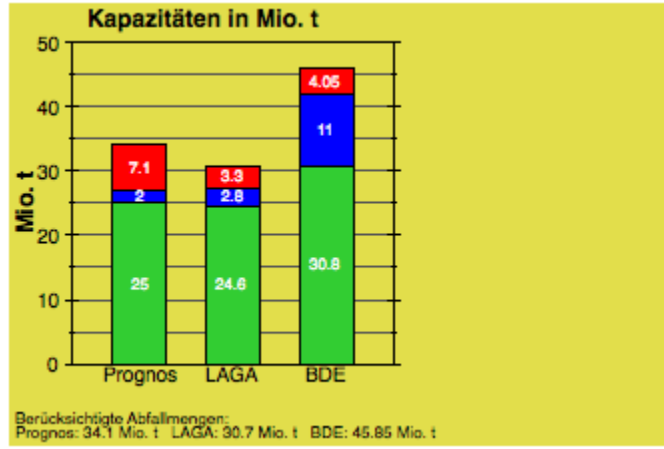
Here is a real life example of a bar plot taken from a German magazine. It visualizes data related to waste management. We reproduce the plot via MuPAD. The main ingredient is a bar plot generated via `plot::Bars2d` with the option GroupStyle = `SingleBars`. Generating the annotations is somewhat tricky:

```
data := [[25 , 24.6, 30.8 ], [ 2 , 2.8, 11 ], [ 7.1, 3.3, 4.05]]: sw := 1.5: bw := 2.0: n := nops(data): w := sw + bw: myticks := [(i-1)* w + sw + bw/2 $ i = 1..n]: m := nops(data[1]): datalabels := ["Prognos", "LAGA", "BDE"]: // cumulative data for the groups datasums := _concat(datalabels[i].": ". expr2text(_plus(data[j][i]$j=1..m)). " Mio. t " $i=1..n): // generate a list of text objects containing the data values // and place them in the centers of the bars: datatext := []: for i from 1 to n do h := 0; for j from 1 to m do d := data[j][i]; datatext := datatext, plot::Text2d(expr2text(d), [myticks[i], h + d/2], TextFont = [8, RGB::White], VerticalAlignment = Center, HorizontalAlignment = Center); h := h + d end end:
```

Here is the bar plot with the annotations. Many scene options are used to fine tune the graphics:

```
S1:=plot::Scene2d( plot::Bars2d(data, Colors=[RGB::LimeGreen, RGB::Blue, RGB::Red], GroupStyle = SingleBars, BarCenters = [myticks[i] $ i=1..n], BarWidths = [[bw]], DrawMode = Vertical), //
```

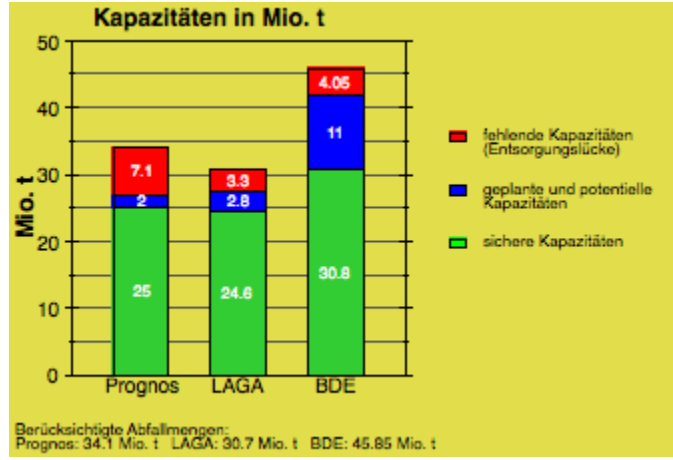
scene options: ViewingBox = [0 .. w*n + sw, 0 .. 50], // options for the grid XGridVisible = FALSE, YGridVisible = TRUE, XSubgridVisible = FALSE, YSubgridVisible = TRUE, GridLineColor = RGB::DarkGrey, SubgridLineColor = RGB::DarkGrey, // options for the axes Axes = Boxed, AxesTips = FALSE, AxesInFront = TRUE, AxesTitleFont = ["Arial", 12, Bold], XAxisVisible = TRUE, YAxisTitleOrientation = Vertical, YAxisTitleAlignment = Center, YAxisTitle = "Mio. t", XAxisTitle = "", // options for the ticks along the axes TicksLabelFont = ["Arial", 10], XTicksVisible = FALSE, XTicksNumber = None, XTicksAt = [myticks[i] = datalabels[i] $ i=1..n], // layout RightMargin = 50, // annotation datatext, // header and footer Header = "Kapazitäten in Mio. t", HeaderFont = ["Arial", 12, Bold], Footer = "\n\nBerücksichtigte Abfallmengen:\n".datasums, FooterFont = ["Arial", 8], FooterAlignment = Left, // use a yellowish background BackgroundColor = [0.886275, 0.870588, 0.294118]): plot(S1)



Next, we build a legend made of colored rectangles and text objects: S2 := plot::Scene2d(ViewingBox = [0..20, 0..50], Axes = None, plot::Rectangle(13..13.5, 35..36, Filled = TRUE, FillPattern = Solid, FillColor = RGB::Red, LineColor = RGB::Black), plot::Text2d("fehlende Kapazitäten\n(Entsorgungslücke)", [14, 35], HorizontalAlignment = Left, TextFont = ["Arial", 8]), plot::Rectangle(13..13.5, 29..30, Filled

= TRUE, FillPattern = Solid, FillColor = RGB::Blue, LineColor = RGB::Black), plot::Text2d("geplante und potentielle\nKapazitäten", [14, 29], HorizontalAlignment = Left, TextFont = ["Arial", 8]), plot::Rectangle(13..13.5, 23..24, Filled = TRUE, FillPattern = Solid, FillColor = RGB::Green, LineColor = RGB::Black), plot::Text2d("sichere Kapazitäten", [14, 23], HorizontalAlignment = Left, TextFont = ["Arial", 8])): plot(S2, BorderWidth = 0.2)

The final picture consists of the bar plot `S1` and the legend `S2`. We just put `S2` on top of `S1`, making the background of `S2` transparent: S1::Width := 1: S1::Height := 1: S2::Width := 1: S2::Height := 1: S1::Bottom := 0: S1::Left := 0: S2::Bottom := 0: S2::Left := 0: S1::BackgroundTransparent := FALSE: S2::BackgroundTransparent := TRUE: plot(S1, S2, Layout = Relative)



delete data, datalabels, datasums, datatext, myticks, sw, bw, n, m, w, i, h, j, d, S1, S2:

Parameters

a_1, a_2, ..., b_1, b_2, ..., ...

Real-valued expressions, possibly in the animation parameter.

a_1, a_2, ..., b_1, b_2, ..., ... is equivalent to the attribute Data.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Bars3dplot::Histogram2dplot::Scatterplot

plot::Bars3d

Purpose

3D bar chart of matrix data

Syntax

```
plot::Bars3d(A, <x = x_min .. x_max, y = y_min .. y_max>,
<a = a_min .. a_max>, options)
plot::Bars3d(L, <x = x_min .. x_max, y = y_min .. y_max>,
<a = a_min .. a_max>, options)
```

Description

`plot::Bars3d(A)` generates a 3D bar chart with bar heights given by the entries of the matrix `A`.

The rows of the matrix are plotted along the *x* coordinate, the columns along the *y* coordinate.

Different rows may be regarded as different classes of data. Each row has a different color determined by the the attribute Colors = `[ c1, c2, ...]` with RGB or RGBa colors c_1, c_2 etc.

The simplest way to obtain a uniform coloring of all rows with the color `c` is to specify the attribute `Color = c`.

Arrays/matrices do not need to be indexed from 1. E.g.,

```
A = array( `i_{min}` ..  `i_{max}` , `j_{min}` ..
`j_{max}` , [..data..])
```

yields a bar chart with $i_{max} - i_{min} + 1$ rows and $j_{max} - j_{min} + 1$ columns, stretching from x_{min} to x_{max} in *x* direction and from y_{min} to y_{max} in *y* direction.

If no plot range `` `x_{min}` .. `x_{max}` ``, `` `y_{min}` .. `y_{max}` `` is specified, $x_{min} = j_{min} - 1$, $x_{max} = j_{max}$, $y_{min} = i_{min} - 1$, $y_{max} = i_{max}$ is used.

When the values are specified by a list of lists *L* and no plot range `` `x_{min}` .. `x_{max}` ``, `` `y_{min}` .. `y_{max}` `` is specified, $x_{min} = 0$, $x_{max} = m$, $y_{min} = 0$, $y_{max} = n$ is used, where *n* is the length of *L* and *m* is the (common) length of the sublists in *L*. All sublists ("rows") must have the same length.

The attribute BarStyle allows to switch the style of the bars between `Boxes` (bars), `Lines` (vertical lines), `LinesPoints` (vertical lines and points), and `Points`(points only). See “Example 1” on page 24-138.

The attribute Gap = `[`g_x`, `g_y`]` or, equivalently, XGap = g_x, YGap = g_y allows to introduce gaps between adjacent bars. The values g_x, g_y may be real numerical values between 0 and 1 or expressions of the animation parameter `a`. These values set the fraction of the space reserved for a bar that is not filled by the bar.

With g_x `= 0`, g_y `= 0`, there are no gaps. With g_x `= 0.5`, g_y `= 0.5`, the gaps between adjacent bars are of the same size as the bars. With g_x `= 1`, g_y `= 1`, there bars become lines.

Values of g_x, g_y larger than 1 are treated like 1, negative values like 0.

The Gap attribute has an effect only for BarStyle = `Boxes`.

The attribute Ground = z_0 determines the *z* value of the lower or upper face of the bars. Matrix values `m >` z_0 are displayed as bars stretching in *z* direction from the lower face z_0 to the upper face `m`. Matrix values `m <` z_0 are displayed as bars stretching in *z* direction from the upper face z_0 down to the lower face `m`.

The parameter z_0 has to be a numerical real value or an expression of the animation parameter `a`.

If the attribute Ground = z_0 is not specified, the default value z_0 `= 0` is used.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
BarStyle	display style of bar plots	`Boxes`
Color	the main color	

Attribute	Purpose	Default Value
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson, RGB::Aqua, RGB::Lavender, RGB::SeaGreen, RGB::AureolineYellow, RGB::Banana, RGB::Beige, RGB::YellowGreen, RGB::Wheat, RGB::IndianRed, RGB::Black]
Data	the (statistical) data to plot	
Filled	filled or transparent areas and surfaces	`TRUE`
Frames	the number of frames in an animation	`50`
Gap	gaps between the bars of a bar chart	`[0, 0]`
Ground	base value	`0`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	

Attribute	Purpose	Default Value
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	`RGB::Black.[0.25]`
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	

Attribute	Purpose	Default Value
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`
XGap	gaps in x direction between the bars of a bar chart	`0`

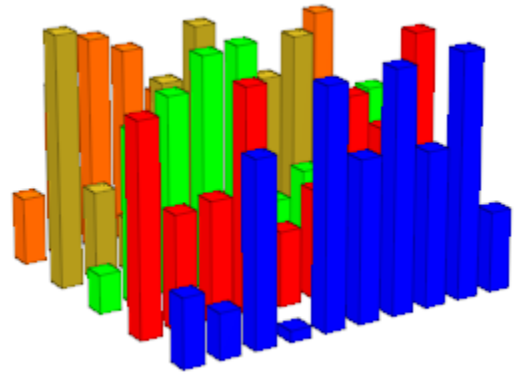
Attribute	Purpose	Default Value
XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YGap	gaps in y direction between the bars of a bar chart	0
YMax	final value of parameter “y”	
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

Examples

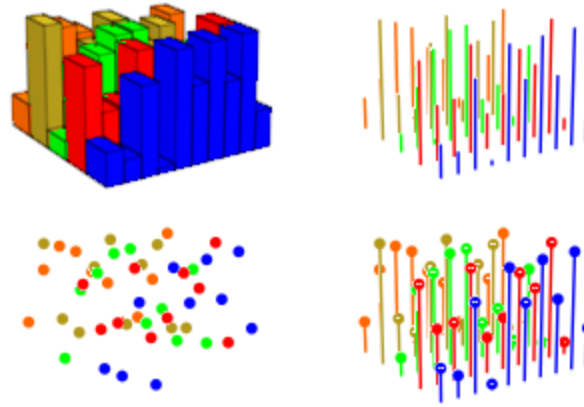
Example 1

We create some random matrix data and plot them as a bar chart:

```
A := matrix::random(5, 10, frandom) : plot(plot::Bars3d(A, Gap = [0.4, 0.7]))
```



We create bar charts of the data with different BarStyle options:
plot(plot::Scene3d(plot::Bars3d(A, BarStyle = Boxes)),
plot::Scene3d(plot::Bars3d(A, BarStyle = Lines)),
plot::Scene3d(plot::Bars3d(A, BarStyle = Points)),
plot::Scene3d(plot::Bars3d(A, BarStyle = LinesPoints)), PointSize = 2.0*unit::mm, LineWidth = 0.5*unit::mm):

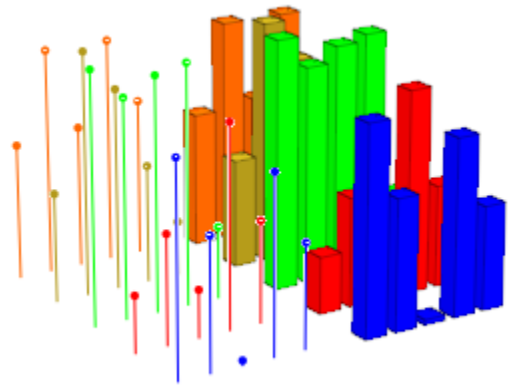


delete A:

Example 2

We demonstrate the positioning of bar charts by specifying ranges for the *x* and the *y* coordinate. The following two bar charts are plotted in one scene. They are placed side by side via suitable *x* ranges:

```
A := matrix::random(5, 5, frandom): plot(plot::Bars3d(A, x = 0 .. 0.9, y = 0 .. 1, BarStyle = LinesPoints), plot::Bars3d(A, x = 1.1 .. 2, y = 0 .. 1, Gap = [0.3, 0.7])):
```

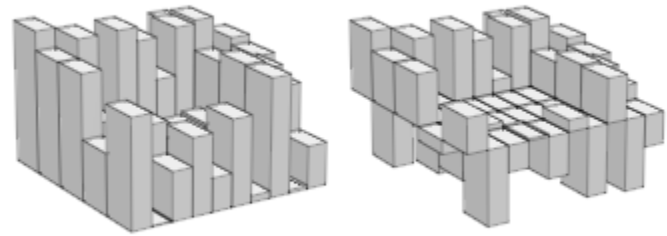


delete A:

Example 3

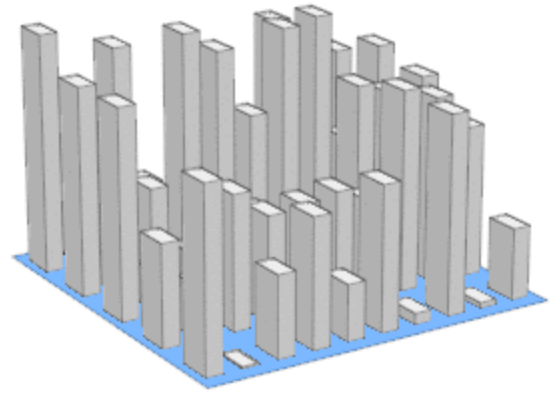
We demonstrate the attributes Ground and Color:

```
A := matrix::random(5, 10, frandom): plot(plot::Scene3d(plot::Bars3d(A, Ground = 0, Color = RGB::Grey)), plot::Scene3d(plot::Bars3d(A, Ground = 0.5, Color = RGB::Grey)), Layout = Horizontal):
```



In the next call, the ground level is animated. Note that in animations one must specify ranges for the *x* and *y* coordinates.We include a transparent plane visualizing the ground level:

```
plot(plot::Bars3d(A, x = 0 .. 1, y = 0 .. 1, a = 0 .. PI, Color = RGB::Grey,
Gap = [0.5, 0.5], Ground = sin(a)), plot::Surface([x, y, sin(a) + 0.001], x =
0 .. 1, y = 0 .. 1, a = 0 .. PI, Mesh = [2, 2], Color = RGB::Blue.[0.5])):
```



delete A:

Parameters

A

An array of domain type DOM_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) containing real numerical values or expressions of the animation parameter *a*. Rows/columns of the array, respectively matrix, correspond to rows/columns of the bar chart.

A is equivalent to the attribute Data.

L

A list of lists of real numerical values or expressions of the animation parameter *a*. Each sublist of *L* represents a row of the bar chart.

L is equivalent to the attribute Data.

x

Name of the horizontal variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in *x* direction.

x is equivalent to the attribute XName.

x_{min} .. x_{max}

The range of the horizontal variable: x_{min}, x_{max} must be numerical real value or expressions of the animation parameter *a*.

x_{min} .. x_{max} is equivalent to the attribute XRange.

y

Name of the vertical variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in *y* direction.

y is equivalent to the attribute YName.

y_{min} .. y_{max}

The range of the vertical variable: y_{min}, y_{max} must be numerical real value or expressions of the animation parameter *a*.

y_{min} .. y_{max} is equivalent to the attribute YRange.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Bars2dplot::Histogram2dplot::Matrixplot

plot::Box

Purpose

Boxes in 3D

Syntax

```
plot::Box(x_min .. x_max, y_min .. y_max, z_min .. z_max, <a
= a_min .. a_max>, options)
plot::Box([x_min, y_min, z_min], [x_max, y_max, z_max], <a =
a_min .. a_max>, options)
```

Description

`plot::Box(`x_{min}`..`x_{max}`, `y_{min}`..`y_{max}`, `z_{min}`..`z_{max}`)` creates the 3D box

ImageSet(matrix([[x, y, z]]), x_min <= x <= x_max, y_min <= y <= y_max, z_min <= z <= z_max)

$$\{(x\ y\ z) \mid x_{min} \le x \le x_{max}, y_{min} \le y \le y_{max}, z_{min} \le z \le z_{max}\}$$

`plot::Box([x_min, y_min, z_min], [x_max, y_max, z_max])` produces the same box.

`plot::Box` creates 3D boxes with edges parallel to the coordinate axes. Using plot::Rotate3d or plot::Transform3d one can create boxes and parallelepipeds with arbitrary orientation. Cf. examples “Example 3” on page 24-149 and “Example 4” on page 24-151.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::LightBlue
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::LightBlue

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	

Attribute	Purpose	Default Value
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

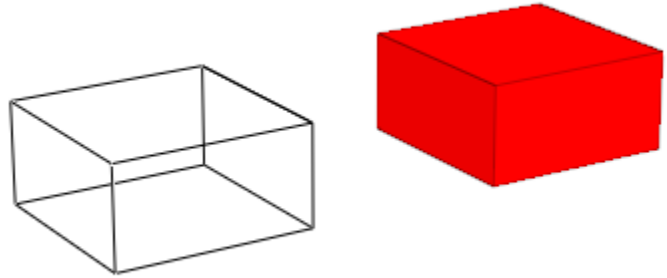
Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter “x”	1
XMin	initial value of parameter “x”	-1
XRange	range of parameter “x”	-1 .. 1
YMax	final value of parameter “y”	1
YMin	initial value of parameter “y”	-1
YRange	range of parameter “y”	-1 .. 1
ZMax	final value of parameter “z”	1
ZMin	initial value of parameter “z”	-1
ZRange	range of parameter “z”	-1 .. 1

Examples

Example 1

We draw a box consisting of its edges and a filled box:

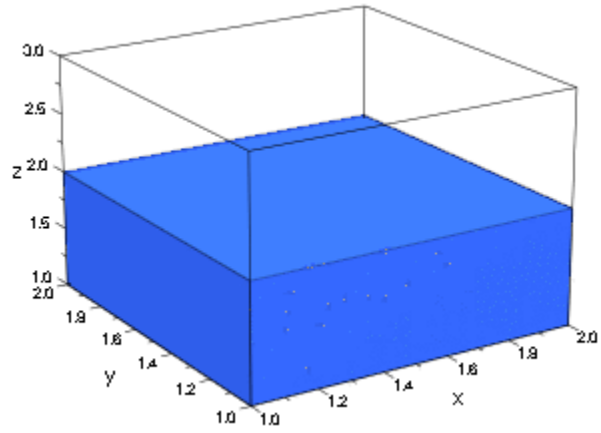
```
plot(plot::Box(-3..-1, 0..2, 0..1, Filled = FALSE, LineColor = RGB::Black),
plot::Box(1..3, 0..2, 0..1, Filled = TRUE, FillColor = RGB::Red), Axes
= None, Scaling = Constrained)
```



Example 2

The borders of a box can be animated:

```
plot(plot::Box([1, 1, 1], [2, 2, 2 + sin(r)], r = 0..2*PI)):
```

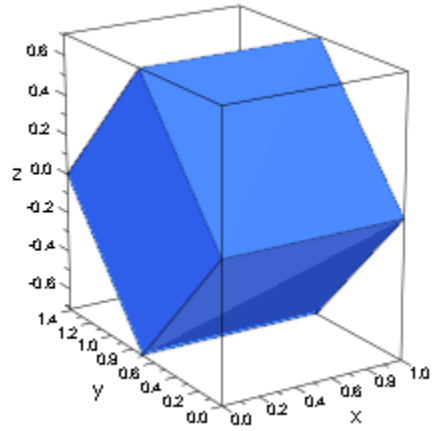


Example 3

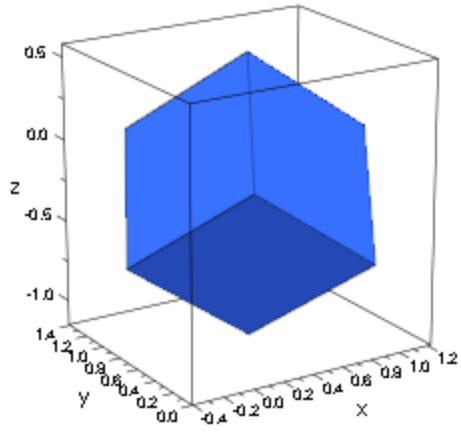
We want to display a cube "standing" on one of its corners. First, we define the cube:
b0 := plot::Box(0..1, 0..1, 0..1)plot::Box(0..1, 0..1, 0..1)

plot::Box(0..1, 0..1, 0..1)

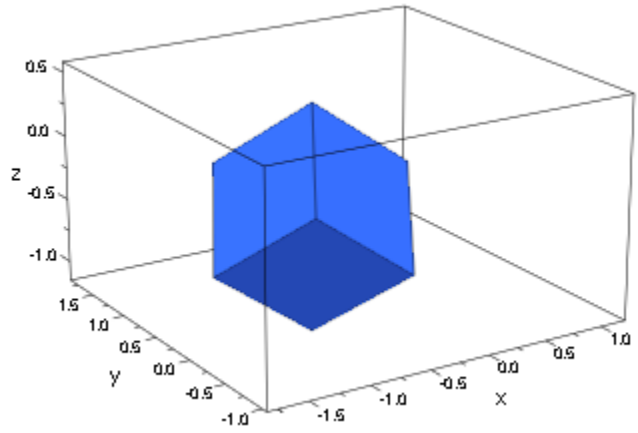
Now, rotating the cube to stand on a corner is equivalent to first rotating around the *x*-axis by 45 degrees, then rotating around the *y*-axis:
b1 := plot::Rotate3d(b0, Axis = [1, 0, 0], Angle = -PI/4): plot(b1, Scaling = Constrained)



b2 := plot::Rotate3d(b1, Axis = [0, 1, 0], Angle = 7*PI/36): plot(b2, Scaling = Constrained)



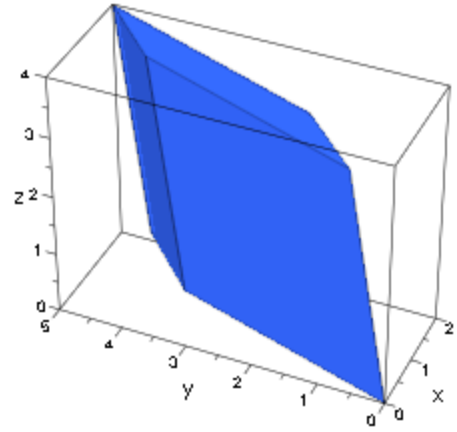
Finally, we let it rotate around the *z*-axis:
plot(plot::Rotate3d(b2, Axis = [0, 0, 1], Angle = a, a = 0..2*PI/3), Scaling = Constrained)



delete b0, b1, b2:

Example 4

A parallelepiped can be obtained from a `plot::Box` by a linear transformation:
plot(plot::Transform3d([0, 0, 0], [1, 1, 0, 1, 1, 3, 0, 3, 1], plot::Box(0..1, 0..1, 0..1)), Scaling = Constrained, CameraDirection = [-27, -12, 22])



Parameters

x_{min}

y_{min}

z_{min}

The lower borders: numerical real values or arithmetical expressions of the animation parameter `a`.

x_{min}, y_{min}, z_{min} are equivalent to the attributes XMin, YMin, ZMin.

x_{max}

y_{max}

z_{max}

The upper borders: numerical real values or arithmetical expressions of the animation parameter `a`.

x_{max}, y_{max}, z_{max} are equivalent to the attributes XMax, YMax, ZMax.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Boxplot

Purpose

Statistical box plots

Syntax

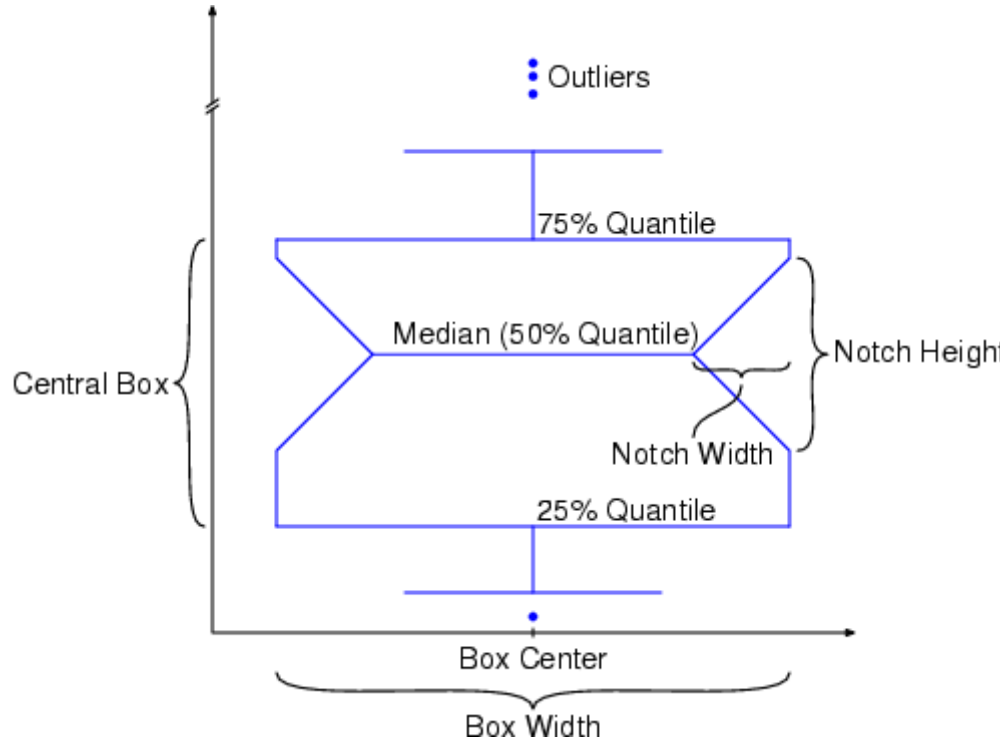
```
plot::Boxplot(L1,  , <a = amin .. amax>, options)
plot::Boxplot([L1,  ], <a = amin .. amax>, options)
plot::Boxplot(A, <a = amin .. amax>, options)
plot::Boxplot(s, <c1,  >, <a = amin .. amax>, options)
plot::Boxplot(s, <[c1,  ]>, <a = amin .. amax>, options)
```

Description

`plot::Boxplot(data)` creates a box plot of the given data.

`plot::Boxplot` creates a box plot of discrete data samples. Box plots reduce data samples to a number of descriptive parameters and are a useful means of comparing statistical data.

In particular, each data sample is represented as one box. A typical box consists of the following subparts:



- A “central box” representing the central 50% of the data. Its lower and upper boundary lines are at the 25%/75% quantile of the data. A central line indicates the median of the data.
- Two vertical lines extending from the central box indicating the remaining data outside the central box that are not regarded as outliers. These lines extend maximally to 3/2 times the height of the central box but not past the range of the data.
- Outliers: these are points indicating the remaining data.

With the special attribute Notched = `TRUE`, the sides of the boxes can be notched, thus providing additional information on the data sample. The horizontal width of the notches may be set by the attribute NotchWidth.

The special attributes BoxCenters and BoxWidths allow to center the boxes at arbitrary positions along the horizontal axis and to set the horizontal width of the boxes, respectively.

The special attribute Averaged determines whether the quantile values are computed with or without the option `Averaged` (cf. stats::empiricalQuantile).

Specifying DrawMode = `Horizontal`, the boxes are rotated by 90 degrees.

The attribute Colors allows to specify the color of each box in a box plot. A common color for all boxes may be specified via Color.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`FALSE`
Averaged	mode for computing quantile lines in box plots	`TRUE`
BoxWidths	widths of boxes in a box plot	[`0.8`]
BoxCenters	position of boxes in a box plot	[1]
Color	the main color	

Attribute	Purpose	Default Value
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson]
Data	the (statistical) data to plot	
DrawMode	orientation of boxes and bars	`Vertical`
Filled	filled or transparent areas and surfaces	`TRUE`
FillPattern	type of area filling	`DiagonalLines`
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`

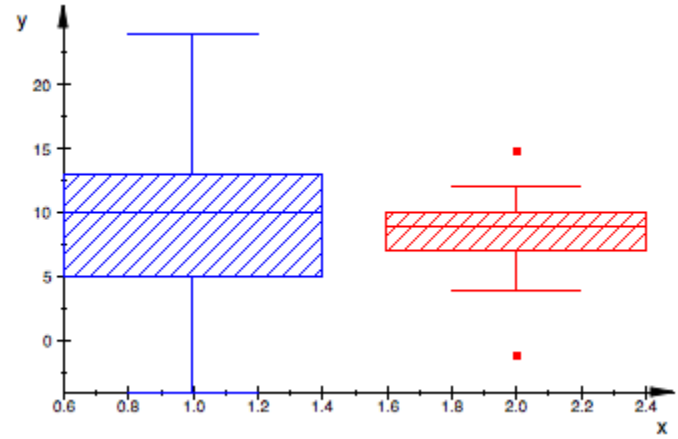
Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
Notched	notched boxes in box plots	FALSE
NotchWidth	width of notches in box plots	0.2
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center

Attribute	Purpose	Default Value
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

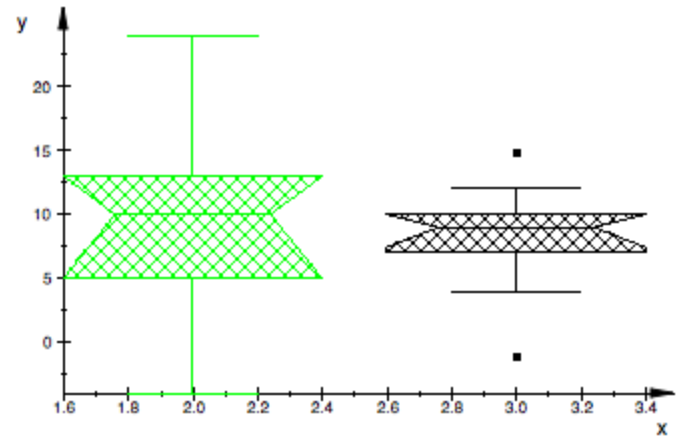
Examples

Example 1

Just to show basic usage of `plot::Boxplot`, we plot some data samples chosen arbitrarily:
data1 := [5, 10, 24, -4, 13]: data2 := [7, 9, -1, 4, 10, 8, 12, 10, 15]: b := plot::Boxplot(data1, data2): plot(b)



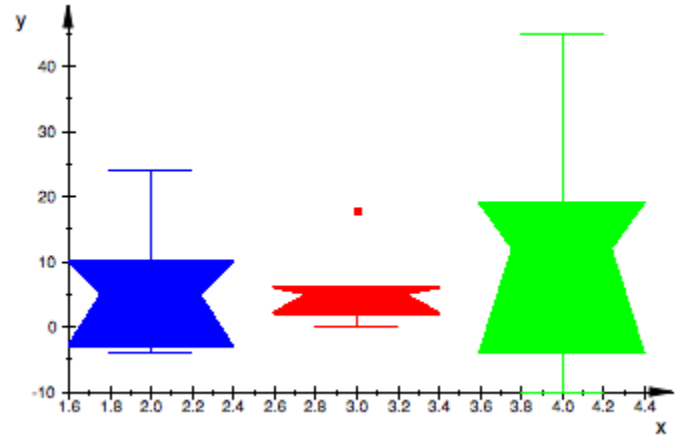
We can modify the appearance of the box plot in various ways: b::Notched := TRUE: b::Colors := [RGB::Green, RGB::Black]: b::BoxCenters := [2, 3]: b::FillPattern := XCrossedLines:plot(b)



delete b:

Example 2

It is possible to shift the whole plot in x-direction by providing a center for the first box via BoxCenters:
A := matrix([[5, 6, 19], [10, 5, 45], [24, 2, 12], [-3, 18, -10], [-4, 0, -4]]):plot(plot::Boxplot(A, BoxCenters = [2], Notched = TRUE, FillPattern = Solid))

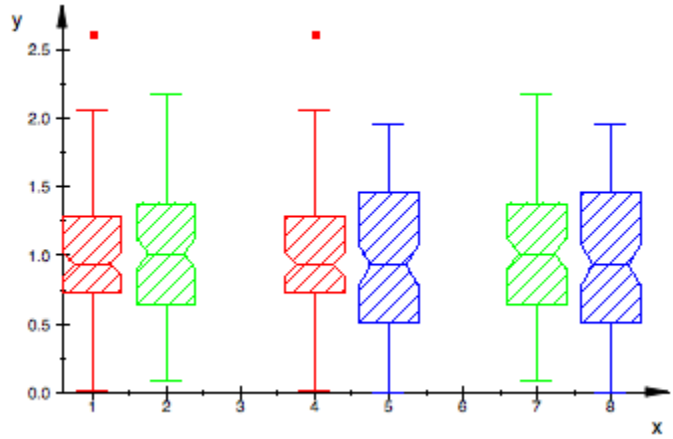


delete A:

Example 3

The primary use of `plot::Boxplot` is comparing data sets. We shall do this for data produced by the following random number generators:
f := stats::normalRandom(1, 0.2): g := stats::uniformRandom(0, 2):

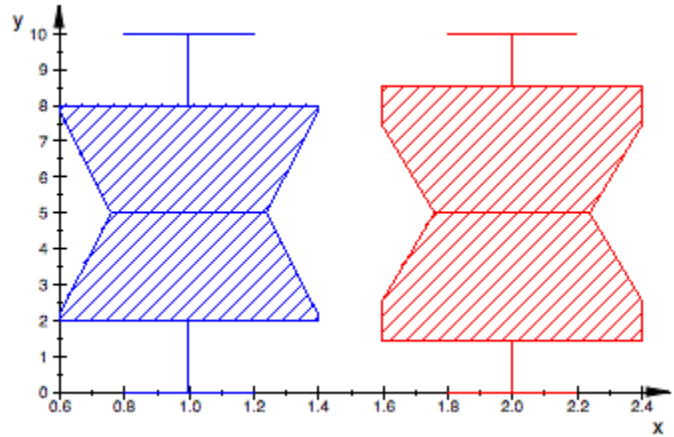
Now, we create small samples and compare their boxes:
data1 := [f() $ k = 1..100]: // Red data2 := [f() $ k = 1..100]: // Green data3 := [g() $ k = 1..100]: // Blue plot(plot::Boxplot(data1, data2, data1, data3, data2, data3, Colors = [RGB::Red, RGB::Green, RGB::Red, RGB::Blue, RGB::Green, RGB::Blue], BoxCenters = [1, 2, 4, 5, 7, 8], Notched = TRUE))



Comparing the central boxes, the blue data differ significantly from the red and the green data. The red and green boxes, however, are quite similar – as they should, given that the red and green data were produced by the same random generator `f`.
delete f, g, data1, data2, data3:

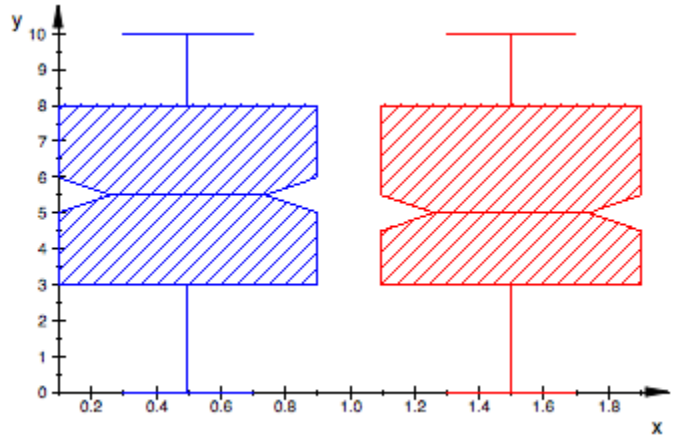
Example 4

For symmetric input data, the images generated by `plot::Boxplot` are symmetric, too:
plot(plot::Boxplot([$0..10], [5+5*sin(PI*n/20) $ n=-10..10], Notched))



Example 5

By default, the quantile lines of the boxes are computed with the option `Averaged` (see stats::empiricalQuantile for details). When using `Averaged` = `FALSE`, the quantiles are computed without this option:
r := random(0..10): SEED := 123: data := [r() $ k = 1..250]:
plot(plot::Boxplot(data, Averaged = TRUE, BoxCenters = 0.5, Color = RGB::Blue, Notched), plot::Boxplot(data, Averaged = FALSE, BoxCenters = 1.5, Color = RGB::Red, Notched)):



delete r, SEED, data:

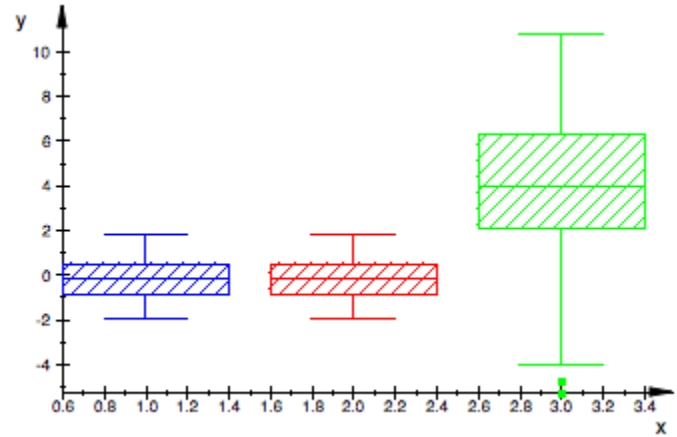
Example 6

Box plots can be animated. We create two data samples and fuse them to a symbolic superposition:

```
f1 := stats::normalRandom(0, 1): f2 := stats::normalRandom(4, 8): data0 := sort([f1() $ k = 1..100]): data1 := sort([f2() $ k = 1..100]): data01 := [(1 - a)*data0[i] + a*data1[i] $ i = 1..100]:
```

The box associated with the data sample `data01` changes from the box associated with `data0` to the box associated with `data1` as the animation parameter increases from $a = 0$ to $a = 1$:

```
plot(plot::Boxplot(data0, data01, data1, a = 0..1))
```



delete f1, f2, data0, data1, data01:

Parameters

L_1, ...

Data samples: lists of numerical real values or arithmetical expressions of the animation parameter `a`.

L_1, ... is equivalent to the attribute Data.

A

An array of domain type DOM_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) providing numerical real values or arithmetical expressions of the animation parameter `a`. The columns are regarded as separate data samples. Also a 1-dimensional array, regarded as a single data sample, is accepted.

`A` is equivalent to the attribute Data.

s

A data collection of domain type stats::sample. The columns in `s` are regarded as separate data samples.

`s` is equivalent to the attribute Data.

c_1, ...

Column indices into `s`: positive integers. These indices, if given, indicate that only the specified columns in `s` should be used as data samples. If no column indices are specified, *all* columns in `s` are used as data samples.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Bars2dplot::Bars3dplot::Histogram2dplot::Scatterplot

plot::Circle2d

Purpose

2D circles

Syntax

`plot::Circle2d(r, <[x, y]>, <a = a_min .. a_max>, options)`

Description

`plot::Circle2d(r, [x, y])` creates a 2D circle with radius *r* and center (*x*, *y*).

Per default circles are drawn as lines both in 2D and 3D. The attribute LineColor or, equivalently, Color serves for setting the line color.

Use the attribute Filled = `TRUE` to create filled circles in 2D.

In 2D, one can choose between hatched and solidly filled circles via the attribute FillPattern. The fill color is determined by FillColor. The circumferential line can be "switched off" via `LinesVisible = FALSE`.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Center	center of objects, rotation center	`[0, 0]`
CenterX	center of objects, rotation center, x-component	`0`
CenterY	center of objects, rotation center, y-component	`0`
Color	the main color	RGB::Blue

Attribute	Purpose	Default Value
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	

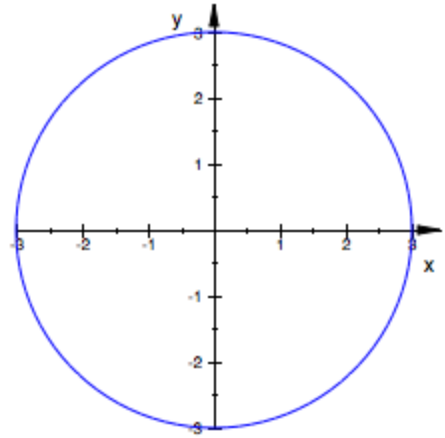
Attribute	Purpose	Default Value
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Radius	radius of circles, spheres etc.	`1`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`

Attribute	Purpose	Default Value
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

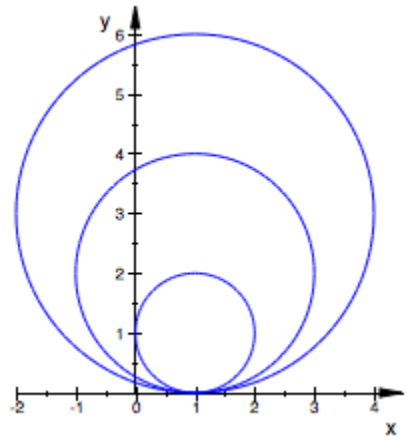
Examples

Example 1

Circles centered at the origin are created if only a radius is specified: plot(plot::Circle2d(3)):

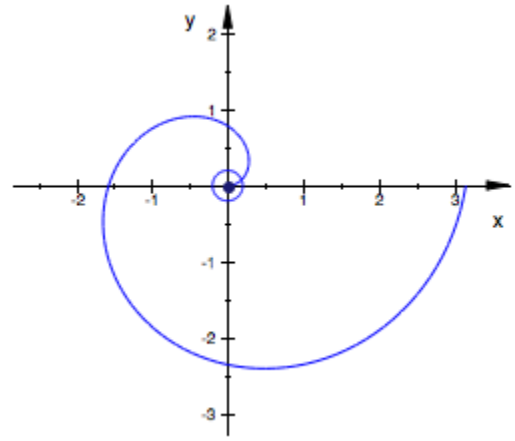


A center may be given as a list of coordinates:
plot(plot::Circle2d(1, [1, 1]), plot::Circle2d(2, [1, 2]), plot::Circle2d(3, [1, 3])):



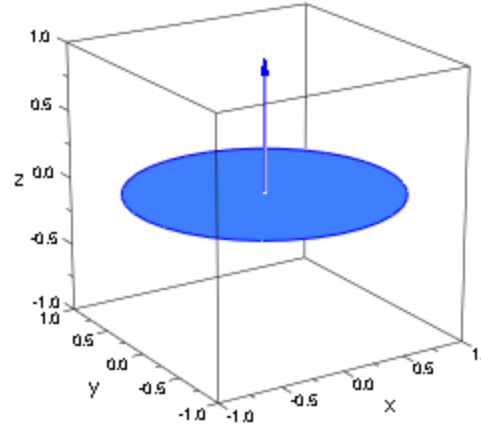
Example 2

Radius and center of a circle can be animated. We plot an animated circle with a changing radius and a center moving on a spiral:
plot(plot::Curve2d([a*cos(2*a), a*sin(2*a)], a = 0..PI), plot::Point2d([a*cos(2*a), a*sin(2*a)], a = 0..PI, PointSize = 2*unit::mm), plot::Circle2d(0.2 + sin(a), [a*cos(2*a), a*sin(2*a)], a = 0..PI))



Example 3

In three dimensions, a circle requires a normal vector. We animate this vector:
normal_ := plot::Arrow3d([0, 0, 0], [sin(2*a), sin(a)*cos(2*a), cos(a)*cos(2*a)], a = 0..2*PI): circle := plot::Circle3d(1, [0, 0, 0], normal_::To, a = 0..2*PI, Filled): plot(normal_, circle)



Parameters

r

The radius: a real numerical value or an arithmetical expression in the animation parameter `a`.

`r` is equivalent to the attribute Radius.

x

y

The center. The coordinates `x`, `y` must be real numerical values or arithmetical expressions in the animation parameter `a`. If no center is specified, a circle centered at the origin is created.

`x`, `y` are equivalent to the attributes CenterX, CenterY.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Circle3dplot::Coneplot::Sphere

plot::Circle3d

Purpose

3D circles

Syntax

```
plot::Circle3d(r, <[x, y, z]>, <a = a_min .. a_max>, options)
plot::Circle3d(r, [x, y, z], [n_x, n_y, n_z], <a =
a_min .. a_max>, options)
```

Description

`plot::Circle3d(r, [x, y, z], [ n_x, n_y, n_z])` creates a 3D circle with radius r, center (x, y, z), and normal vector (n_x, n_y, n_z).

Per default circles are drawn as lines both in 2D and 3D. The attribute LineColor or, equivalently, Color serves for setting the line color.

Use the attribute Filled = `TRUE` to create circular discs in 3D.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Center	center of objects, rotation center	`[0, 0, 0]`
CenterX	center of objects, rotation center, x-component	`0`
CenterY	center of objects, rotation center, y-component	`0`
CenterZ	center of objects, rotation center, z-component	`0`
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	`FALSE`

Attribute	Purpose	Default Value
FillColor	color of areas and surfaces	RGB::LightBlue

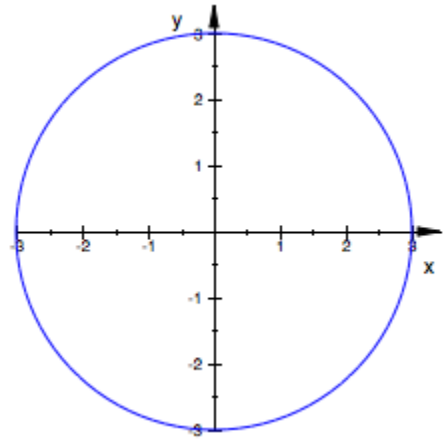
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

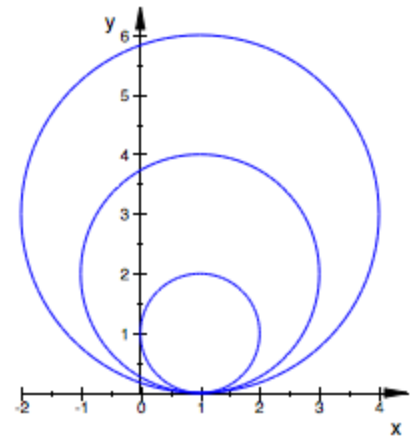
Examples

Example 1

Circles centered at the origin are created if only a radius is specified:
plot(plot::Circle2d(3)):



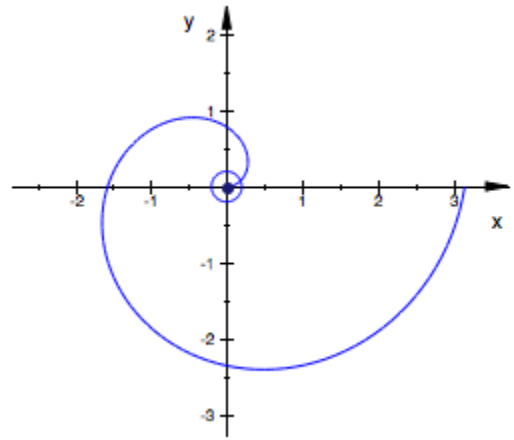
A center may be given as a list of coordinates:
plot(plot::Circle2d(1, [1, 1]), plot::Circle2d(2, [1, 2]), plot::Circle2d(3, [1, 3])):



Example 2

Radius and center of a circle can be animated. We plot an animated circle with a changing radius and a center moving on a spiral:

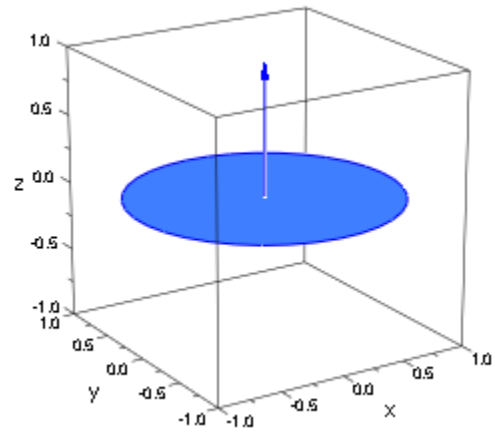
```
plot(plot::Curve2d([a*cos(2*a), a*sin(2*a)], a = 0..PI),
plot::Point2d([a*cos(2*a), a*sin(2*a)], a = 0..PI, PointSize = 2*unit::mm),
plot::Circle2d(0.2 + sin(a), [a*cos(2*a), a*sin(2*a)], a = 0..PI))
```



Example 3

In three dimensions, a circle requires a normal vector. We animate this vector:

```
normal_ := plot::Arrow3d( [0, 0, 0], [sin(2*a), sin(a)*cos(2*a),
cos(a)*cos(2*a)], a = 0..2*PI): circle := plot::Circle3d(1, [0, 0, 0],
normal_::To, a = 0..2*PI, Filled): plot(normal_, circle)
```



Parameters

r

The radius: a real numerical value or an arithmetical expression in the animation parameter a.

r is equivalent to the attribute Radius.

x

y

z

The center. The coordinates x, y, z must be real numerical values or arithmetical expressions in the animation parameter a. If no center is specified, a circle centered at the origin is created.

x, y, z are equivalent to the attributes CenterX, CenterY, CenterZ.

n_x

n_y

n_z

The normal vector. The components n_x, n_y, n_z must be real numerical values or arithmetical expressions in the animation parameter a. If no normal is specified, the normal (0, 0, 1) is used.

n_x, n_y, n_z are equivalent to the attributes NormalX, NormalY, NormalZ.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Circle2dplot::Coneplot::Sphere

plot::Cone

Purpose

Cones and frustums

Syntax

```
plot::Cone(br, [b_x, b_y, b_z], <tr>, [t_x, t_y, t_z], <a
= a_min .. a_max>, options)
```

Description

`plot::Cone(br, [ b_x, b_y, b_z], [ t_x, t_y, t_z])` creates a cone stretching from the base with radius `br` and center `[b_x, b_y, b_z]` to the top `[t_x, t_y, t_z]`.

`plot::Cone(br, [ b_x, b_y, b_z], tr, [ t_x, t_y, t_z])` creates a conical frustum from the base center `[b_x, b_y, b_z]` to the top center `[t_x, t_y, t_z]`. The base radius is `br`, the top radius is `tr`.

The lower center and upper center of the cone can also be passed as vectors.

The optional "top radius" `tr` for creating a frustum may also be specified as the attribute `TopRadius = tr`.

The upper and lower faces of a cone/frustum are not filled. They can be added as filled plot::Circle3ds.

Note that only circular cones can be created with `plot::Cone`. For elliptical bases, use a plot::Surface primitive or apply a plot::Scale3d transformation.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Base	base center of cones, cylinders, pyramids and prisms	`[0, 0, 0]`

Attribute	Purpose	Default Value
BaseX	x-coordinate of top center of cones, cylinders, pyramids and prisms	0
BaseY	y-coordinate of top center of cones, cylinders, pyramids and prisms	0
BaseZ	z-coordinate of top center of cones, cylinders, pyramids and prisms	0
BaseRadius	base radius of cones/conical frustums and pyramids/frustums of pyramids	1
Color	the main color	RGB::LightBlue
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]

Attribute	Purpose	Default Value
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
LineColorDirection	the direction of color transitions on lines	`[0, 0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`0`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Shading	smooth color blend of surfaces	`Smooth`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`

Attribute	Purpose	Default Value
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Top	top center of cones, cylinders, pyramids and prisms	`[0, 0, 1]`
TopX	base and top center of cones, cylinders, pyramids and prisms	`0`
TopY	base and top center of cones, cylinders, pyramids and prisms	`0`
TopZ	base and top center of cones, cylinders, pyramids and prisms	`1`

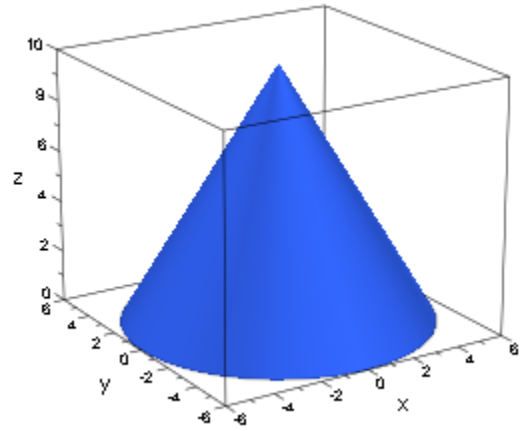
Attribute	Purpose	Default Value
TopRadius	top radius of cones/conical frustums and pyramids/frustums of pyramids	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

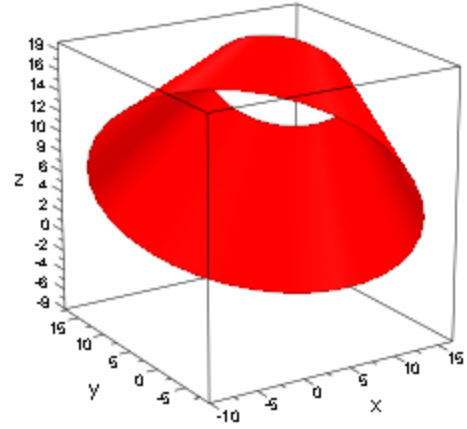
We draw a cone with base radius 6:

```
plot(plot::Cone(6, [0, 0, 0], [0, 0, 10])):
```

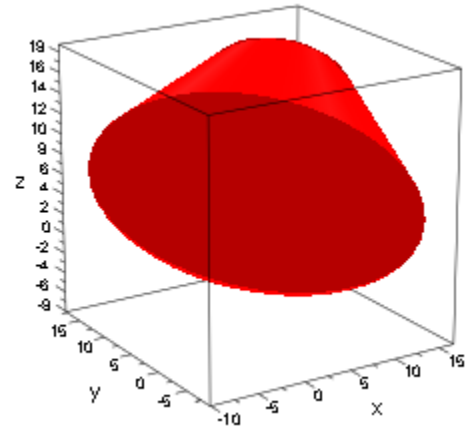


Example 2

We create a conical frustum by specifying a non-zero top radius. Note that no discs are attached to the base and the top. You can look through the frustum:
br := 16: base := [3, 4, 5]: tr:= 7: top := [11, 12, 13]: plot(plot::Cone(br, base, tr, top, FillColor = RGB::Red)):



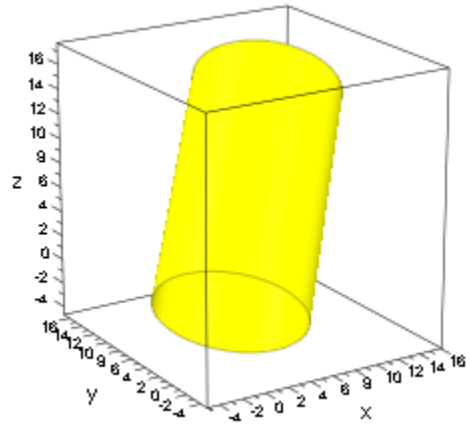
We add the discs at the base and the top. Their normals n are given as the vector from the base to the top:
n := zip(top, base, _subtract): plot(plot::Circle3d(br, base, n, Filled = TRUE), plot::Circle3d(tr, top, n, Filled = TRUE), plot::Cone(br, base, tr, top), LinesVisible = FALSE, FillColor = RGB::Red):



delete br, base, tr, top, n:

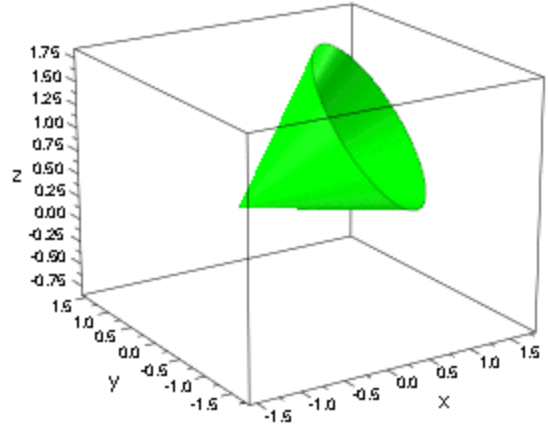
Example 3

A tube or cylinder (in the mathematical sense, i.e., the lateral sides of a physical cylinder) is a special case of a conical frustum with the same top and bottom radius:
plot(plot::Cone(6, [0, 0, 0], 6, [11, 12, 13], FillColor = RGB::Yellow, LinesVisible = TRUE)):



Example 4

Bottom and top radii and centers can be animated:
plot(plot::Cone(sin(a)^2, [sin(2*a), cos(2*a), 0], cos(a)^2, [cos(2*a), sin(2*a), 1], a = 0..PI, FillColor = RGB::Green)):



Parameters

br

The base radius of the cone. This must be a real numerical value or an arithmetical expression of the animation parameter `a`.

`br` is equivalent to the attribute BaseRadius.

b_x

b_y

b_z

The lower center point. The coordinates b_x, b_y, b_z must be real numerical values or arithmetical expressions of the animation parameter `a`.

b_x, b_y, b_z are equivalent to the attributes BaseX, BaseY, BaseZ.

tr

The top radius of the cone/conical frustum. This must be a real numerical value or an arithmetical expression of the animation parameter `a`. If no top radius is specified, a cone with top radius *tr* = 0 is created.

`tr` is equivalent to the attribute TopRadius.

t_x

t_y

t_z

The upper center point. The coordinates t_x, t_y, t_z must be real numerical values orarithmetical expressions of the animation parameter `a`.

t_x, t_y, t_z are equivalent to the attributes TopX, TopY, TopZ.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also plotplot::copyplot::Cylinderplot::Pyramidplot::Prism

plot::Conformal

Purpose

(complex-valued) conformal function plot

Syntax

`plot::Conformal(f, z = z1 .. z2, <a = amin .. amax>, options)`

Description

`plot::Conformal(f(z), z = z_1..z_2 )` is a plot of the conformal function *f* over the complex interval `z_1..z_2`.

`plot::Conformal` creates plots of (conformal) complex-valued functions of one complex variable. They are displayed by showing the image of a rectangular grid over an interval.

By default, the attribute `LineColorType = Flat` is set. All curves are displayed with the color given by the attribute LineColor (or Color for short).

When specifying the attribute `LineColorType = Dichromatic`, a color blend from LineColor to LineColor2 is used ("height coloring").

When specifying the attribute `LineColorType = Functional` without specifying a LineColorFunction, all curves parametrized by the real part of the pre-image points are displayed with the flat color LineColor, whereas all curves parametrized by the imaginary part of the pre-image points are displayed with the flat color LineColor2.

A user defined LineColorFunction is a procedure `(z, x, y, flag) -> RGB-color` that will be called with complex floating-point arguments `z` from the range of pre-images of the conformal function `f`, the real floating point values `x = Re(f(z))`, `y = Im(f(z))`, and the integer value `flag` which has the values 1 or 2. The flag value 1 determines the color of the curves parametrized by the real part of `z`, the flag value 2 determines the color of the curves parametrized by the imaginary part of `z`. The color function must return an RGB color, i.e., a list of 3 real floating point values between 0.0 and 1.0. For example,

```
LineColorFunction = proc(z, x, y, flag) begin if flag = 1 then return(
```

displays all curves parametrized by `Re(z)` in blue, while the orthogonal curves, parametrized by `Im(z)`, are displayed in red.

See the examples in the documentation of RGB for another way of displaying complex functions.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	`0`
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Color	the main color	RGB::Blue
Frames	the number of frames in an animation	`50`
Function	function expression or procedure	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`TRUE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`

Attribute	Purpose	Default Value
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`1`
Mesh	number of sample points	`[11, 11]`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointsVisible	visibility of mesh points	`FALSE`

Attribute	Purpose	Default Value
Submesh	density of submesh (additional sample points)	[0, 0]
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

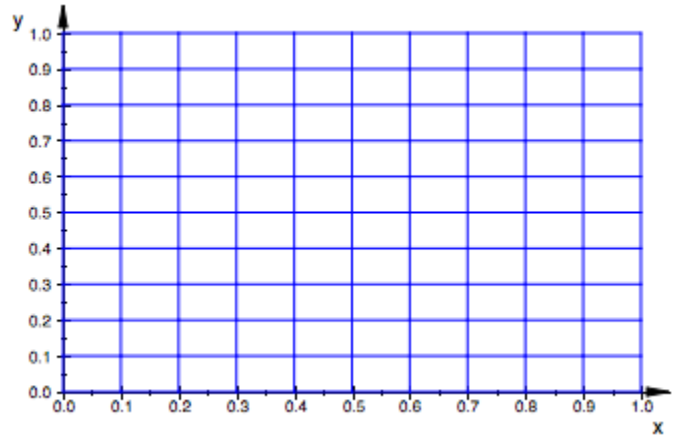
Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMesh	number of sample points for parameter “x”	11
XSubmesh	density of additional sample points for parameter “x”	0
YMesh	number of sample points for parameter “y”	11
YSubmesh	density of additional sample points for parameter “y”	0
ZMax	final value of parameter “z”	
ZMin	initial value of parameter “z”	
ZName	name of parameter “z”	
ZRange	range of parameter “z”	

Examples

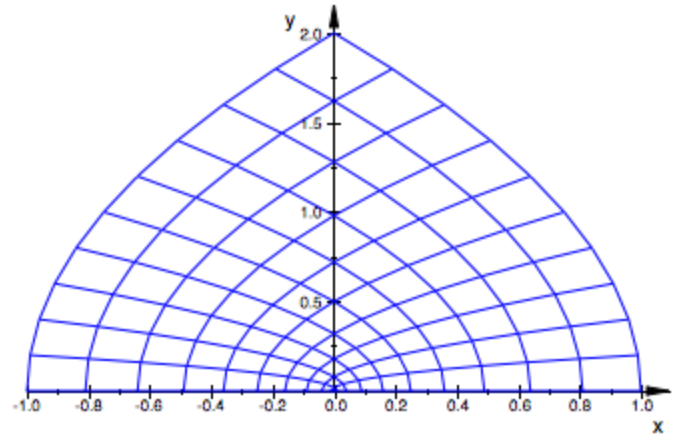
Example 1

By plotting the identity function, we are presented the pre-image used by `plot::Conformal`:

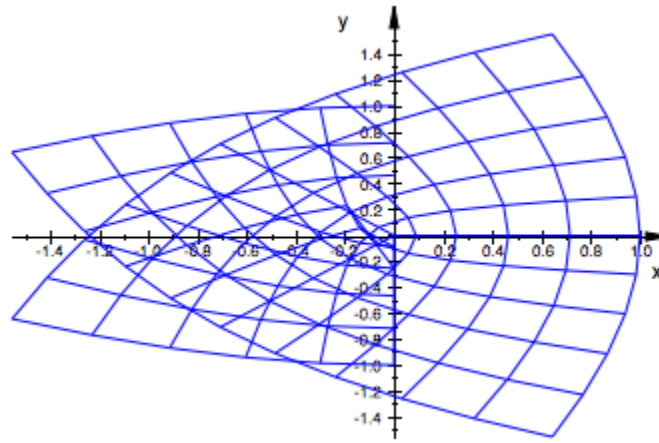
plot(plot::Conformal(z, z = 0..1+I))



The important property of conformal functions, as far as plots are concerned, is that orthogonal lines are mapped onto curves meeting orthogonally:
plot(plot::Conformal(z^2, z = 0..1+I))

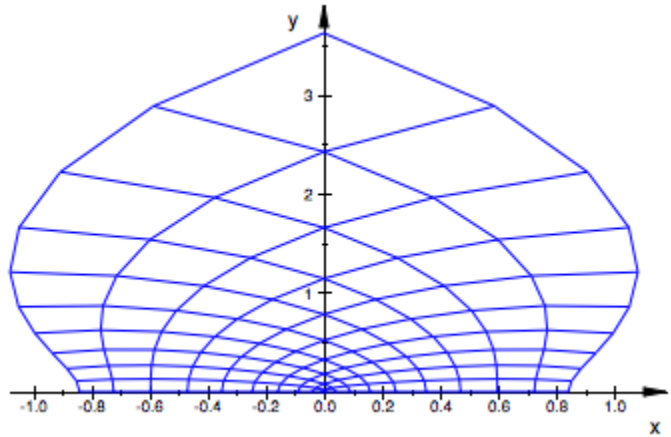


This property allows to visually detect overlapping regions (in some cases); in the following example this is the case in the left semi-plane:
plot(plot::Conformal(z^(3/2), z = -1-I..1+I))

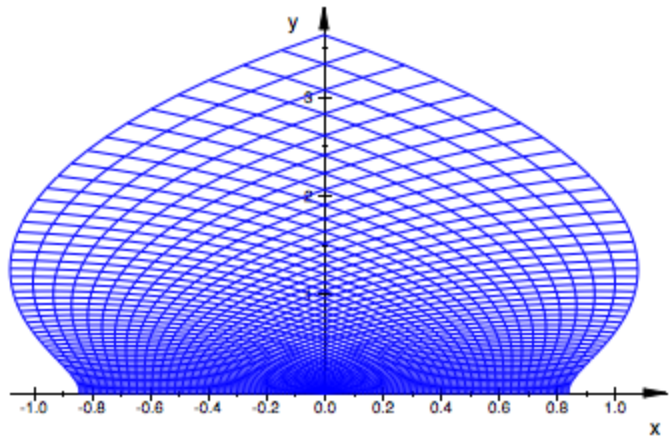


Example 2

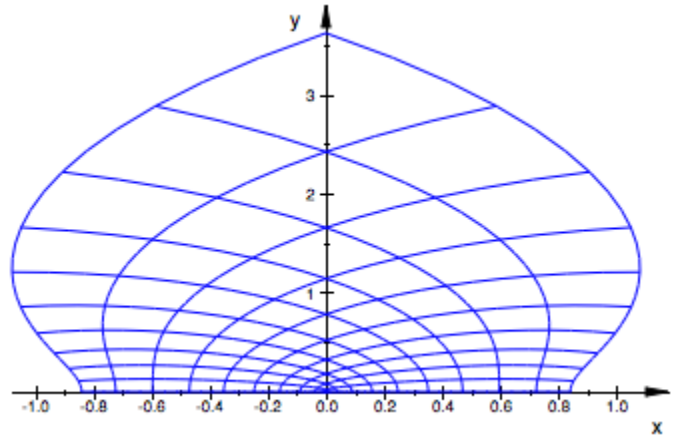
The default mesh may in some cases be too coarse:
plot(plot::Conformal(sin(z^2), z = 0..1+I))



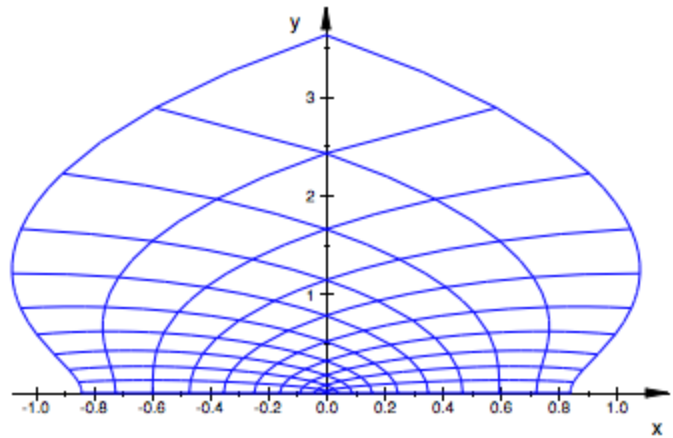
There are at least three ways of improving this plot. Firstly, we can set Mesh to a higher value:
plot(plot::Conformal(sin(z^2), z = 0..1+I, Mesh = [50, 50]))



Another option would be to increase Submesh to get smoother, not more, lines:
plot(plot::Conformal(sin(z^2), z = 0..1+I, Submesh = [2, 2]))



Finally, we can also ask for an adaptive refinement of the submesh by setting AdaptiveMesh to some positive value:
plot(plot::Conformal(sin(z^2), z = 0..1+I, AdaptiveMesh = 2))



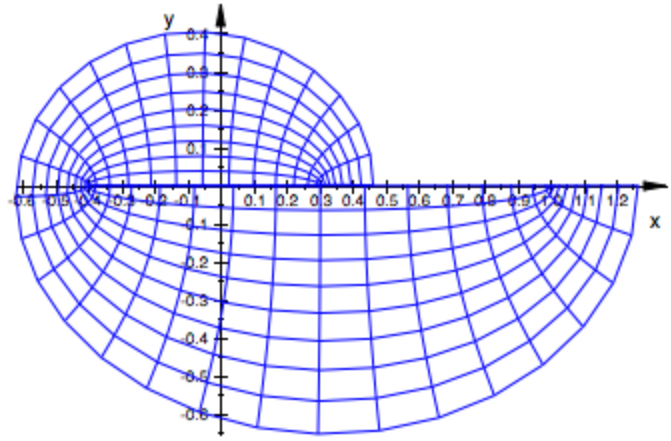
Example 3

Here is the image of the complex rectangle $0 \le Re(z) \le x$, $0 \le \Im(z) \le 1$ under the map `z→besselJ(0, z)`. We choose x as the second positive root of `Im(besselJ(0, x + I))`:

```
numeric::solve(Im(besselJ(0, x + I)), x = i .. i+1) $ i = 0..7
```

{0.0}, ∅, ∅, {3.791394324}, ∅, ∅, {6.993364687}, ∅

```
plot(plot::Conformal(besselJ(0, z), z = 0 .. 6.9934 + I, Mesh = [31, 10]))
```



Parameters

f

An expression in `z` and the animation parameter, if present. Expected to be conformal in `z`.

`f` is equivalent to the attribute Function.

z

The independent variable: An identifier or indexed identifier.

`z` is equivalent to the attribute ZName.

z_1 .. z_2

The (complex) range over which `f` should be plotted: z_1 and z_2 should be complex-valued expressions, possibly in the animation parameter.

z_1 .. z_2 is equivalent to the attribute ZRange.

a

Animation parameter, specified as `a = `a_{min}`..`a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Curve2dplot::Function2d

plot::Curve2d

Purpose

Parameterized 2D curves

Syntax

```
plot::Curve2d([x, y], t = t_min .. t_max, <a =
a_min .. a_max>, options)
plot::Curve2d(A_2d, t = t_min .. t_max, <a = a_min ..
a_max>, options)
plot::Curve2d(piecewiseF(t), t = t_min .. t_max, <a
= a_min .. a_max>, options)
```

Description

`plot::Curve2d([x(t), y(t)], t = t_min.. t_max)` creates the planar curve

ImageSet(fenced(x(t), y(t)), 't_{min}' <= t <= 't_{max}')

$\{(x(t), y(t)) \mid t_{min} \le t \le t_{max}\}$

`plot::Curve2d` and `plot::Curve3d` construct curves in one parameter (see "Example 1" on page 24-206), possibly animated (see "Example 2" on page 24-207). The curves may contain poles, in which case automatic clipping is used by default (see "Example 4" on page 24-210).

By default, curves are sampled at equidistant values of the parameter `t`. The attribute AdaptiveMesh can be used to change this behavior, such that a denser sampling rate is used in areas of higher curvature. Cf. "Example 5" on page 24-211.

Curves are graphical objects that can be manipulated, see the examples and the documentation of the parameters listed below for details.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	0
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`

Attribute	Purpose	Default Value
AntiAliased	antialiased lines and points?	TRUE
Color	the main color	RGB::Blue
DiscontinuitySearch	semi-symbolic search for discontinuities	TRUE
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE

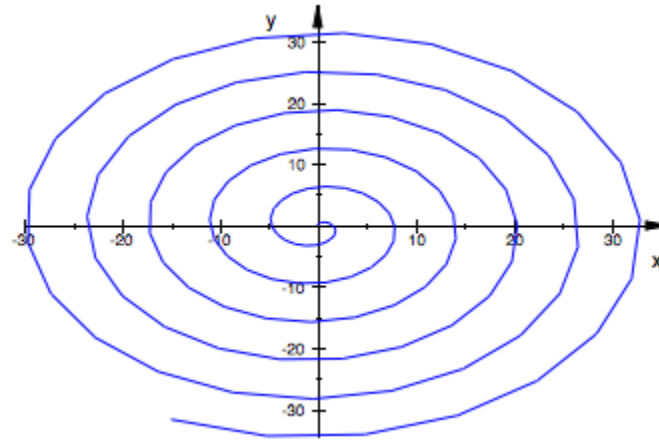
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
YFunction	function for y values	

Examples

Example 1

Archimedes' Spiral is defined by $f(r) = (r\sin(r), r\cos(r))$. The corresponding call to `plot::Curve2d` reads:
curve := plot::Curve2d([r*sin(r), r*cos(r)], r = 0..35)plot::Curve2d([r*sin(r), r*cos(r)], r = 0..35)

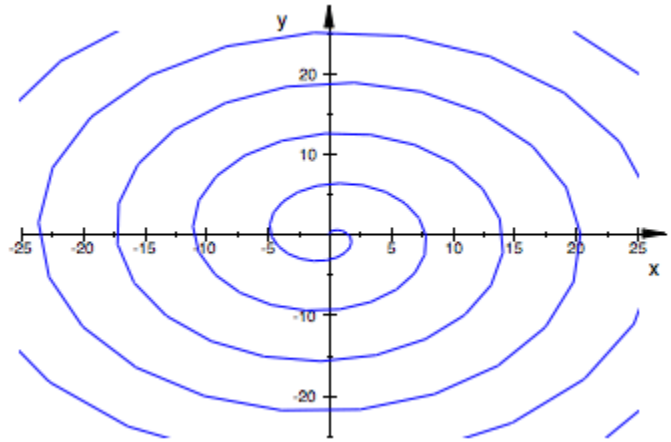
```
plot::Curve2d([r sin(r), r cos(r)], r = 0..35)
plot(curve)
```



Note that this particular example is even more straightforward to plot using plot::Polar.

Example 2

Continuing the example from above, we define an easy animation by making the angular part time-dependent:
curve := plot::Curve2d([r*sin(r-t), r*cos(r-t)], r = 0..35, t = 0..2*PI, TimeEnd = 5, ViewingBox = [-25..25, -25..25]): plot(curve)

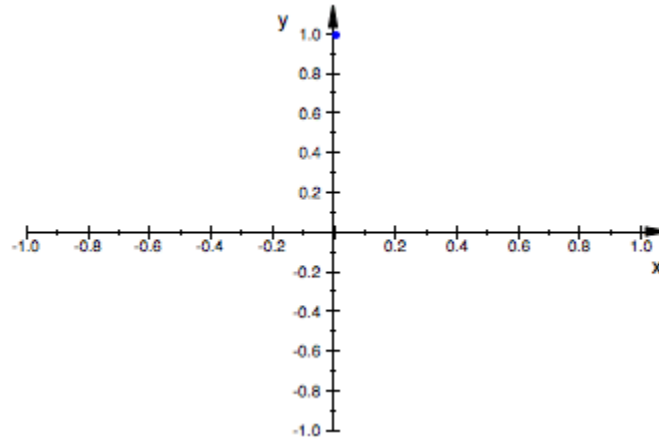


Note that to start the animation, you have to double-click the image in the notebook and choose “Start” from the “Animation” menu.

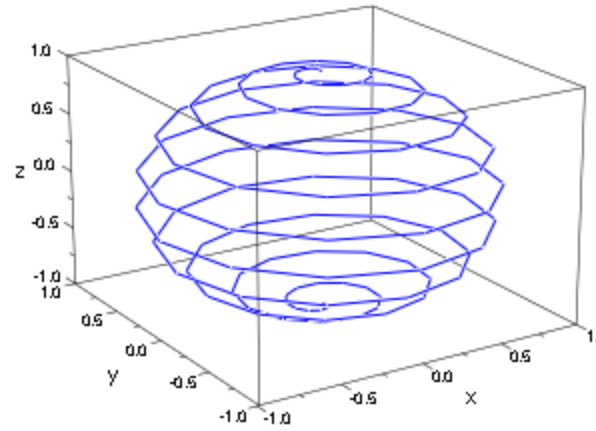
Example 3

Another useful and easy type of animation is achieved by animating the parameter range. This creates the illusion of the curve being drawn in real time:

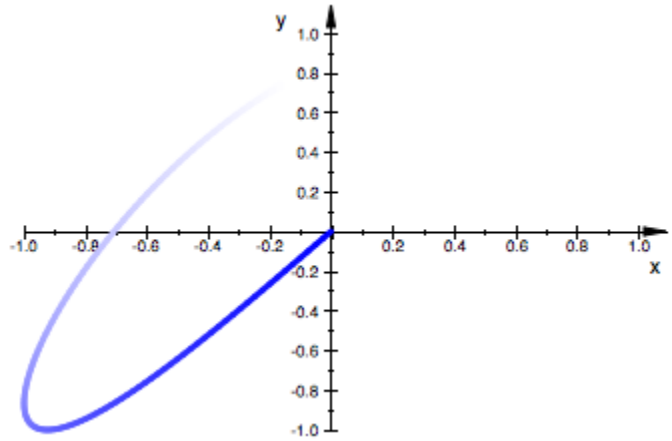
```
curve := plot::Curve2d([sin(thet), cos(thet)], thet = 0..a, a = 0..2*PI):
plot(curve)
```



curve := plot::Curve3d([sin(thet)*cos(20*thet), sin(thet)*sin(20*thet), cos(thet)], thet = 0..a, a = 0..PI): plot(curve)

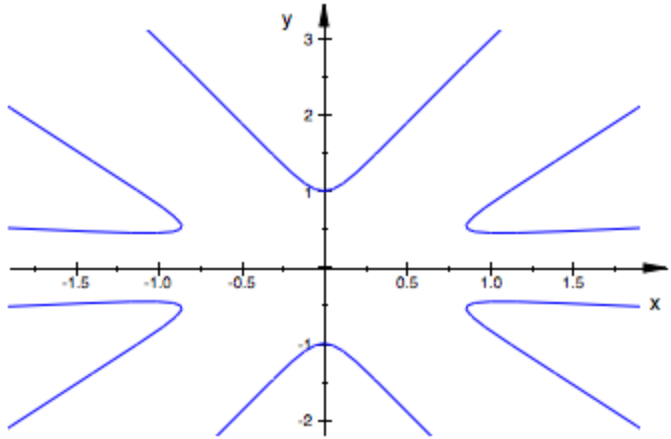


Combining this with an animated LineColorFunction, you can even simulate motion:
colorfunc := (thet, x, y, a) -> [a-thet, a-thet, 1.0]: curve := plot::Curve2d([sin(3*thet), sin(4*thet)], thet = a-1..a, LineColorFunction = colorfunc, LineWidth = 1, a = 0..2*PI): plot(curve)



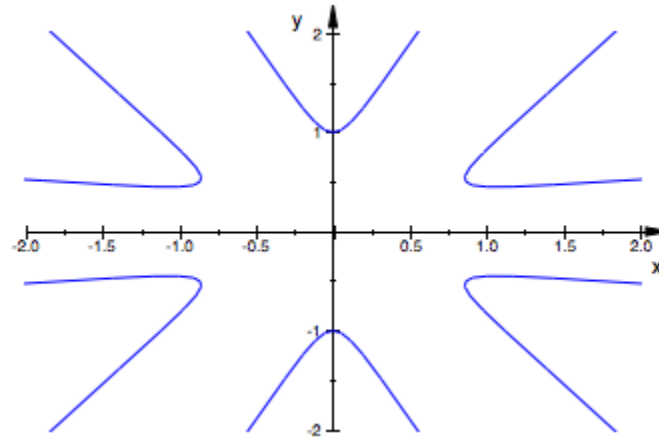
Example 4

Curves with poles are automatically clipped:
curve := plot::Curve2d([(1+tan(3*t)^2)*sin(t), (1+tan(3*t)^2)*cos(t)], t = 0..2*PI): plot(curve);



If the automatically chosen viewing box is not to your liking, you can explicitly set other values:

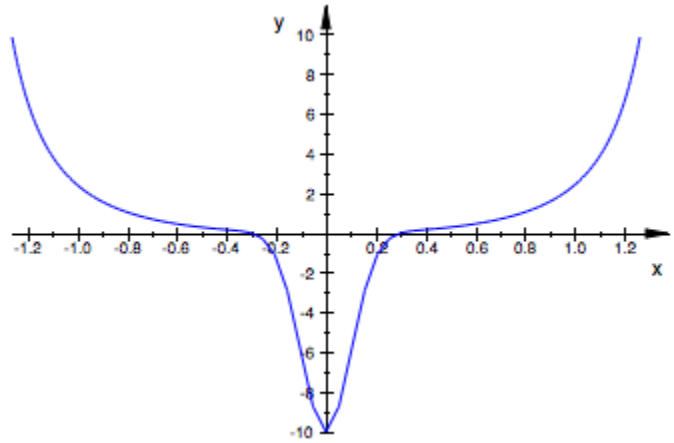
```
curve::ViewingBox := [-2..2, -2..2]: plot(curve)
```



Example 5

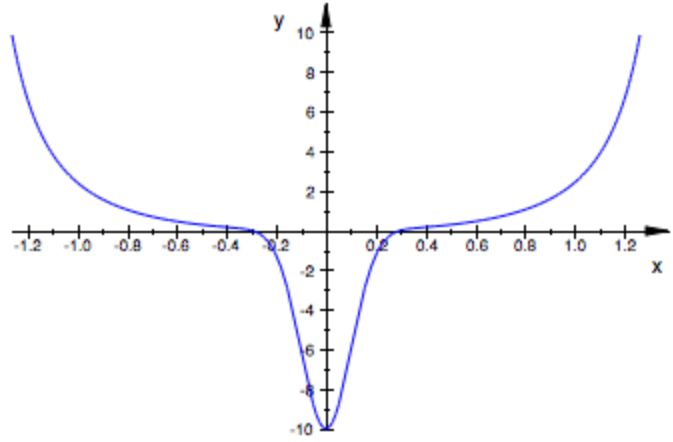
By default, curves are drawn by evaluating at equidistant values of the curve parameter. For curves that have few regions of high curvature, this may be inappropriate:

```
plot(plot::Curve2d([arctan(t), t^2-10*exp(-50*t^2)], t = -PI..PI))
```



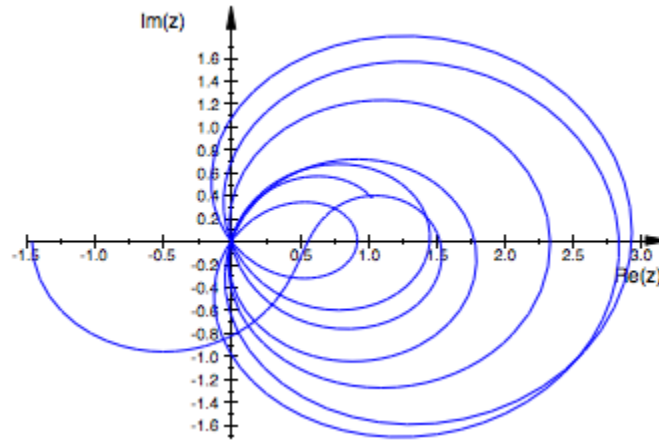
Note the hard “kink” at the bottom of the picture. On the other hand, the remainder of the curve is sufficiently smooth, so globally increasing the number of evaluation points is not desirable. AdaptiveMesh makes `plot::Curve2d` look for these kinks and adaptively increase the mesh density in problematic areas:

```
plot(plot::Curve2d([arctan(t), t^2-10*exp(-50*t^2)], t = -PI..PI,
AdaptiveMesh = 2))
```



Example 6

To display a curve in the complex plane, map the list-valued function `[Re, Im]` to the curve:
plot(plot::Curve2d([Re, Im](zeta(I*y+1/2)), y=0..42, AdaptiveMesh=3), XAxisTitle = "Re(z)", YAxisTitle = "Im(z)")

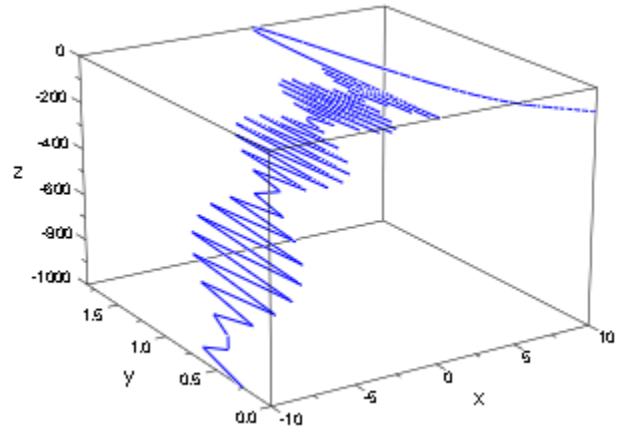


Example 7

Create the following piecewise function:
f := piecewise([t < 0, [t, sin(10*t)^2, t^3]], [t >= 0, [t, 5*t/exp(t), -t^2]])piecewise([t < 0, [t, sin(10*t)^2, t^3]], [0 <= t, [t, 5*t*exp(-t), -t^2]])

$$\begin{cases} [t, \sin(10\,t)^2, t^3] & \text{if } t < 0 \\ [t, 5\,t\,e^{-t}, -t^2] & \text{if } 0 \le t \end{cases}$$

Now, plot this function:
plot(plot::Curve3d(f, t = -10..10))



Parameters

x

y

Real-valued expressions in `t` (and possibly the animation parameter)

A_{2d}

A matrix of category Cat::Matrix with two entries that provide the parametrization `x`, `y` of a 2D curve

piecewiseF(t)

A piecewise object

t

An identifier or an indexed identifier

t_{min}

t_{max}

Real-valued expressions (possibly in the animation parameter)

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Curve3dplot::Function2dplot::Function3dplot::Polygon2dplot::Pol

plot::Curve3d

Purpose

Parameterized 3D curves

Syntax

```
plot::Curve3d([x, y, z], t = t_min .. t_max, <a = a_min .. a_max>, options)
plot::Curve3d(A_3d, t = t_min .. t_max, <a = a_min .. a_max>, options)
plot::Curve3d(piecewiseF(t), t = t_min .. t_max, <a = a_min .. a_max>, options)
```

Description

`plot::Curve3d([x(t), y(t), z(t)], t = t_min.. t_max)` creates the space curve

ImageSet(fenced(x(t), y(t), z(t)), 't_{min}' <= t <= 't_{max}')

$$\{(x(t), y(t), z(t)) \mid t_{min} \le t \le t_{max}\}$$

`plot::Curve2d` and `plot::Curve3d` construct curves in one parameter (see "Example 1" on page 24-220), possibly animated (see "Example 2" on page 24-221). The curves may contain poles, in which case automatic clipping is used by default (see "Example 4" on page 24-224).

By default, curves are sampled at equidistant values of the parameter `t`. The attribute AdaptiveMesh can be used to change this behavior, such that a denser sampling rate is used in areas of higher curvature. Cf. "Example 5" on page 24-225.

Curves are graphical objects that can be manipulated, see the examples and the documentation of the parameters listed below for details.

Attributes

Attribute	Purpose	Default Value

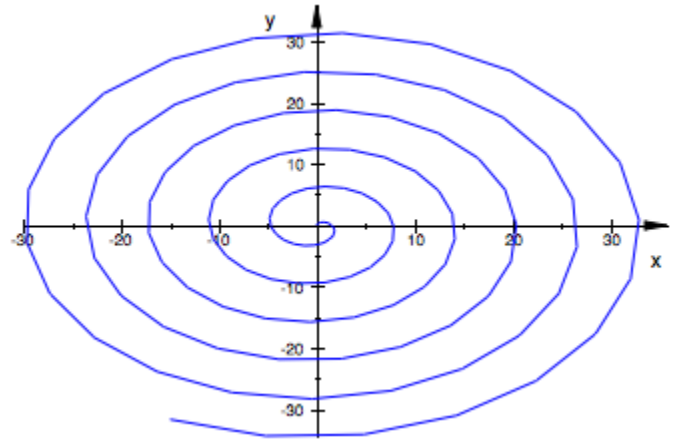
Examples

Example 1

Archimedes' Spiral is defined by $f(r) = (r\sin(r), r\cos(r))$. The corresponding call to `plot::Curve2d` reads:
curve := plot::Curve2d([r*sin(r), r*cos(r)], r = 0..35)plot::Curve2d([r*sin(r), r*cos(r)], r = 0..35)

```
plot::Curve2d([r sin(r), r cos(r)], r = 0..35)
plot(curve)
```

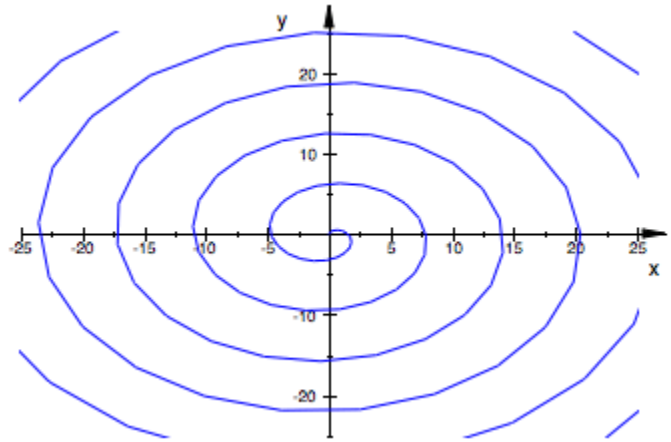


Note that this particular example is even more straightforward to plot using plot::Polar.

Example 2

Continuing the example from above, we define an easy animation by making the angular part time-dependent:

```
curve := plot::Curve2d([r*sin(r-t), r*cos(r-t)], r = 0..35, t = 0..2*PI,
TimeEnd = 5, ViewingBox = [-25..25, -25..25]): plot(curve)
```

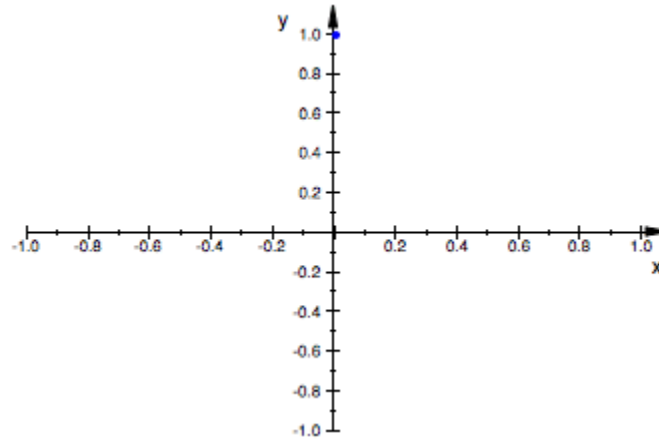


Note that to start the animation, you have to double-click the image in the notebook and choose “Start” from the “Animation” menu.

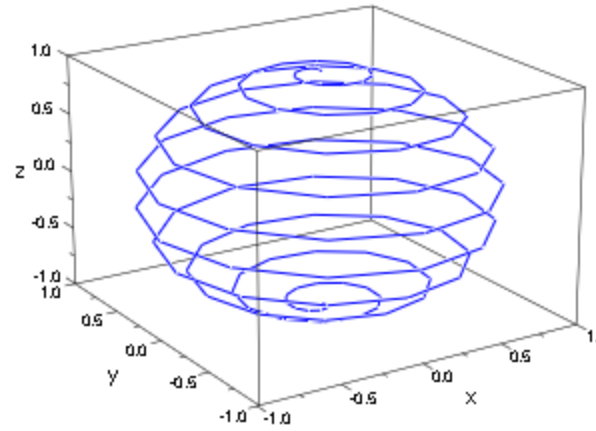
Example 3

Another useful and easy type of animation is achieved by animating the parameter range. This creates the illusion of the curve being drawn in real time:

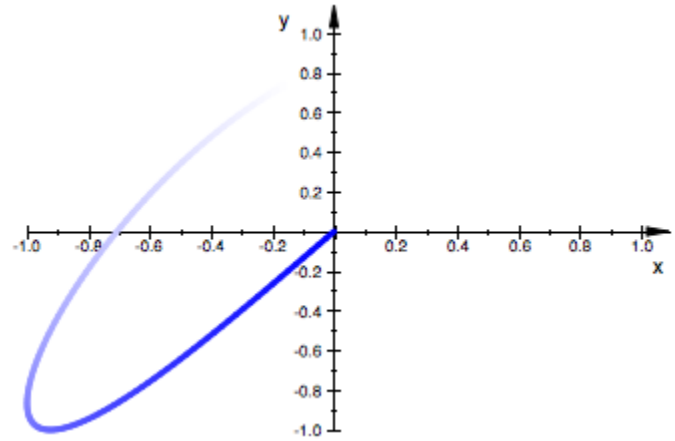
```
curve := plot::Curve2d([sin(thet), cos(thet)], thet = 0..a, a = 0..2*PI):
plot(curve)
```



curve := plot::Curve3d([sin(thet)*cos(20*thet), sin(thet)*sin(20*thet), cos(thet)], thet = 0..a, a = 0..PI): plot(curve)

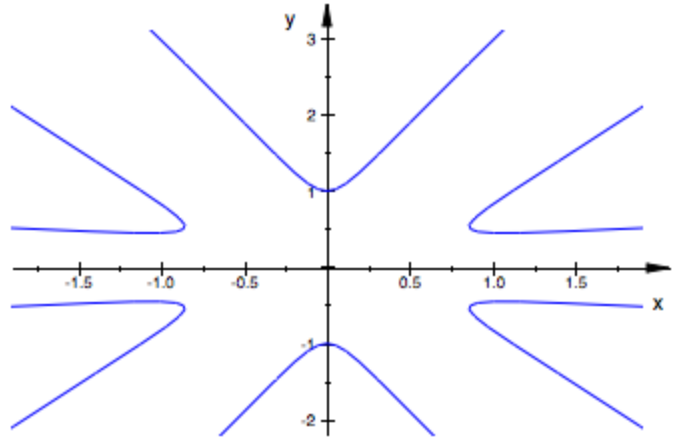


Combining this with an animated LineColorFunction, you can even simulate motion:
colorfunc := (thet, x, y, a) -> [a-thet, a-thet, 1.0]: curve := plot::Curve2d([sin(3*thet), sin(4*thet)], thet = a-1..a, LineColorFunction = colorfunc, LineWidth = 1, a = 0..2*PI): plot(curve)



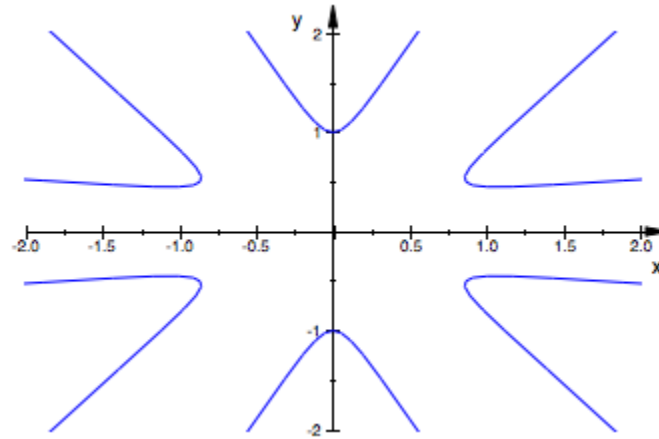
Example 4

Curves with poles are automatically clipped:
curve := plot::Curve2d([(1+tan(3*t)^2)*sin(t), (1+tan(3*t)^2)*cos(t)], t = 0..2*PI): plot(curve);



If the automatically chosen viewing box is not to your liking, you can explicitly set other values:

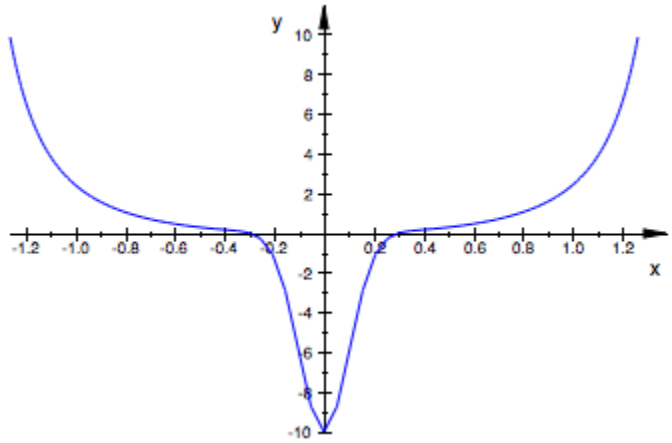
```
curve::ViewingBox := [-2..2, -2..2]: plot(curve)
```



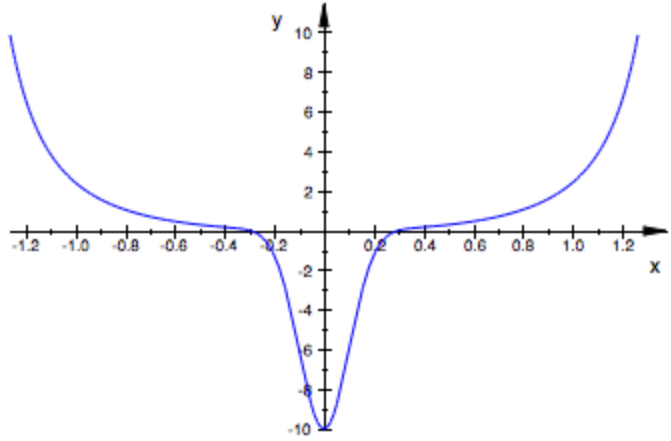
Example 5

By default, curves are drawn by evaluating at equidistant values of the curve parameter. For curves that have few regions of high curvature, this may be inappropriate:

```
plot(plot::Curve2d([arctan(t), t^2-10*exp(-50*t^2)], t = -PI..PI))
```

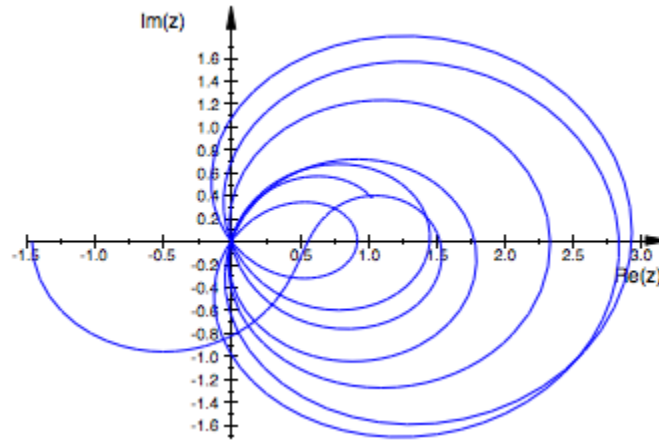


Note the hard “kink” at the bottom of the picture. On the other hand, the remainder of the curve is sufficiently smooth, so globally increasing the number of evaluation points is not desirable. AdaptiveMesh makes `plot::Curve2d` look for these kinks and adaptively increase the mesh density in problematic areas:
plot(plot::Curve2d([arctan(t), t^2-10*exp(-50*t^2)], t = -PI..PI, AdaptiveMesh = 2))



Example 6

To display a curve in the complex plane, map the list-valued function `[Re, Im]` to the curve:
plot(plot::Curve2d([Re, Im](zeta(I*y+1/2)), y=0..42, AdaptiveMesh=3), XAxisTitle = "Re(z)", YAxisTitle = "Im(z)")

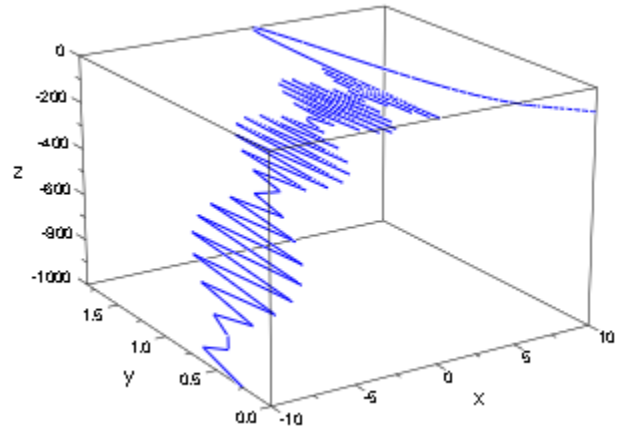


Example 7

Create the following piecewise function:
f := piecewise([t < 0, [t, sin(10*t)^2, t^3]], [t >= 0, [t, 5*t/exp(t), -t^2]])piecewise([t < 0, [t, sin(10*t)^2, t^3]], [0 <= t, [t, 5*t*exp(-t), -t^2]])

$$\begin{cases} [t, \sin(10\,t)^2, t^3] & \text{if } t < 0 \\ [t, 5\,t\,e^{-t}, -t^2] & \text{if } 0 \le t \end{cases}$$

Now, plot this function:
plot(plot::Curve3d(f, t = -10..10))



Parameters

x

y

z

Real-valued expressions in `t` (and possibly the animation parameter)

A_{3d}

A matrix of category Cat::Matrix with three entries that provide the parametrization `x`, `y`, `z` of a 3D curve

piecewiseF(t)

A piecewise object

t

An identifier or an indexed identifier

t_{min}

t_{max}

Real-valued expressions (possibly in the animation parameter)

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Cylinder

Purpose

Cylinders

Syntax

```
plot::Cylinder(r, [x1, y1, z1], [x2, y2, z2], <a = amin .. amax>, options)
```

Description

`plot::Cylinder(r, [x1, y1, z1] , [x2, y2, z2] )` creates a cylinder of radius *r* with an axis from the point `[x1, y1, z1]` to the point `[x2, y2, z2]`.

The base center and top center of the cylinder can also be passed as vectors.

A cylinder created by `plot::Cylinder` consists of the lateral surface and the "lids" (discs with centers `[x1, y1, z1]` and `[x2, y2, z2]`, respectively.)

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Base	base center of cones, cylinders, pyramids and prisms	`[0, 0, 0]`
BaseX	x-coordinate of top center of cones, cylinders, pyramids and prisms	`0`
BaseY	y-coordinate of top center of cones, cylinders, pyramids and prisms	`0`

Attribute	Purpose	Default Value
BaseZ	z-coordinate of top center of cones, cylinders, pyramids and prisms	0
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	

Attribute	Purpose	Default Value
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Radius	radius of circles, spheres etc.	`1`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Top	top center of cones, cylinders, pyramids and prisms	`[0, 0, 1]`

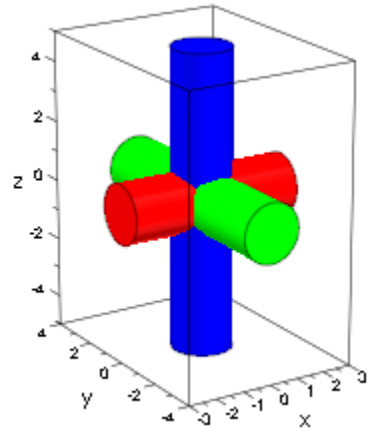
Attribute	Purpose	Default Value
TopX	base and top center of cones, cylinders, pyramids and prisms	0
TopY	base and top center of cones, cylinders, pyramids and prisms	0
TopZ	base and top center of cones, cylinders, pyramids and prisms	1
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

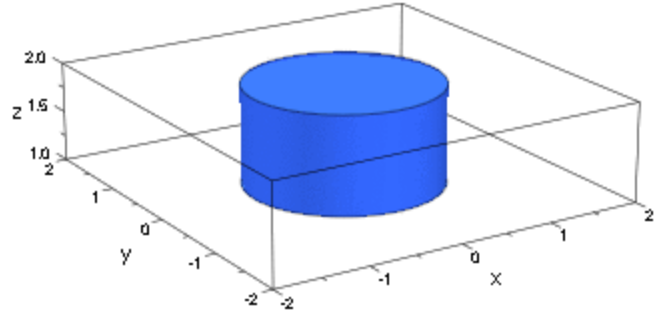
We plot three cylinders with symmetry axes given by the coordinate axes:

```
plot(plot::Cylinder(1, [-3, 0, 0], [3, 0, 0], Color = RGB::Red),
plot::Cylinder(1, [0, -4, 0], [0, 4, 0], Color = RGB::Green),
plot::Cylinder(1, [0, 0, -5], [0, 0, 5], Color = RGB::Blue)):
```



Example 2

All parameters of a cylinder can be animated:
plot(plot::Cylinder(a, [0, 0, a], [0, 0, 3 - a], a = 1 .. 2))



Parameters

r

The radius of the cylinder: a real numerical value or an arithmetical expression of the animation parameter a.

r is equivalent to the attribute Radius.

x_1

y_1

z_1

Components of the base center: real numerical values or expressions of the animation parameter a.

x_1, y_1, z_1 are equivalent to the attributes BaseX, BaseY, BaseZ.

x_2

y_2

z_2

Components of the top center: real numerical values or expressions of the animation parameter a.

x_2, y_2, z_2 are equivalent to the attributes TopX, TopY, TopZ.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Cylindrical

Purpose

Surfaces in 3D parameterized in cylindrical coordinates

Syntax

`plot::Cylindrical([r, , z], u = u_min .. u_max, v = v_min .. v_max, <a = a_min .. a_max>, options)`

Description

`plot::Cylindrical` creates surfaces parametrized in cylindrical coordinates.

The surface given by a mapping (“parametrization”) (u, v) -> fenced(r(u, v), Symbol::phi(u, v), z(u, v))$(u, v) \to (r(u, v), \phi(u, v), z(u, v))$ is the set of all image points

ImageSet(matrix([r(u,v), Symbol::phi(u,v), z(u,v)]), u in [‘u_{min}‘, ‘u_{max}‘], v in [‘v_{min}‘, ‘v_{max}‘])

$$\left\{ \begin{pmatrix} r(u, v) \\ \phi(u, v) \\ z(u, v) \end{pmatrix} \;\middle|\; u \in [u_{min}, u_{max}],\ v \in [v_{min}, v_{max}] \right\}$$

in cylindrical coordinates, which translate to the usual “Cartesian” coordinates as

eqsys(x = r * cos(Symbol::phi), y = r * sin(Symbol::phi), z = z)

$$x = r \cos(\phi)$$

$$y = r \sin(\phi)$$

$$z = z$$

r is referred to as “radius,” φ as “polar angle,” and z as the “height” of a point.

The functions r, φ, z are evaluated on a regular equidistant mesh of sample points in the u-v plane. This mesh is determined by the attributes UMesh, VMesh. By default, the attribute `AdaptiveMesh = 0` is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of UMesh, VMesh or USubmesh, VSubmesh,or set `AdaptiveMesh = n` with some (small) positive integer `n`. If necessary, up to 2^n - 1 additional points are placed in each direction of the *u*-*v* plane between adjacent points of the initial equidistant mesh. Cf. "Example 2" on page 24-245.

"Coordinate lines" ("parameter lines") are curves on the surface.

The phrase "`ULines`" refers to the curves $(r(u, v_0), \varphi(u, v_0), z(u, v_0))$ with the parameter u running from u_{min} to u_{max}, while v_0 is some fixed value from the interval $[v_{min}, v_{max}]$.

The phrase "`VLines`" refers to the curves $(r(u_0, v), \varphi(u_0, v), z(u_0, v))$ with the parameter v running from v_{min} to v_{max}, while u_0 is some fixed value from the interval $[u_{min}, u_{max}]$.

By default, the parameter curves are visible. They may be switched off by specifying `ULinesVisible = FALSE` and `VLinesVisible = FALSE`, respectively.

The coordinate lines controlled by `ULinesVisible = TRUE/FALSE` and `VLinesVisible = TRUE/FALSE` indicate the equidistant mesh in the *u*-*v* plane set via the UMesh, VMesh attributes. If the mesh is refined by the USubmesh, VSubmesh attributes, or by the adaptive mechanism controlled by `AdaptiveMesh = n`, no additional parameter lines are drawn.

As far as the numerical approximation of the surface is concerned, the settings

$\texttt{UMesh} = n_u, \texttt{VMesh} = n_v, \texttt{USubmesh} = m_u, \texttt{VSubmesh} = m_v$

and

$\texttt{UMesh} = (n_u - 1)\ (m_u + 1) + 1, \texttt{VMesh} = (n_v - 1)\ (m_v + 1) + 1,$

$\texttt{USubmesh} = 0, \texttt{VSubmesh} = 0$

are equivalent. However, in the first setting, n_u parameter lines are visible in the *u* direction, while in the latter setting $(n_u - 1)\ (m_u + 1) + 1$ parameter lines are visible. Cf. "Example 2" on page 24-245.

Use Filled = FALSE to obtain a wireframe representation of the surface.

If the expressions/functions *r* and/or *z* contain singularities, it is recommended (but not strictly necessary) to use the attribute ViewingBox to set a suitable viewing box. No such precautions are necessary for φ, although singularities in this function may result in poorly rendered surfaces – in many cases setting the attributes Mesh and/or AdaptiveMesh to higher values will help. Cf. "Example 3" on page 24-248.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	0
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]

Attribute	Purpose	Default Value
FillColorDirectionX	x-component of the direction of color transitions on surfaces	`0`
FillColorDirectionY	y-component of the direction of color transitions on surfaces	`0`
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	`1`
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`TRUE`
LineColor	color of lines	`RGB::Black.[0.25]`
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]

Attribute	Purpose	Default Value
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	[25, 25]
MeshVisible	visibility of irregular mesh lines in 3D	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE

Attribute	Purpose	Default Value
Submesh	density of submesh (additional sample points)	[0, 0]
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

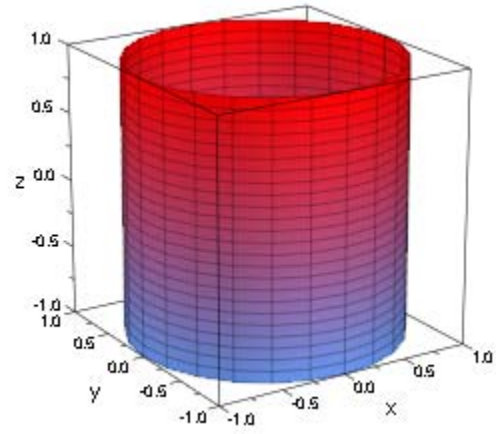
YFunction	function for y values	
ZContours	contour lines at constant z values	[]
ZFunction	function for z values	

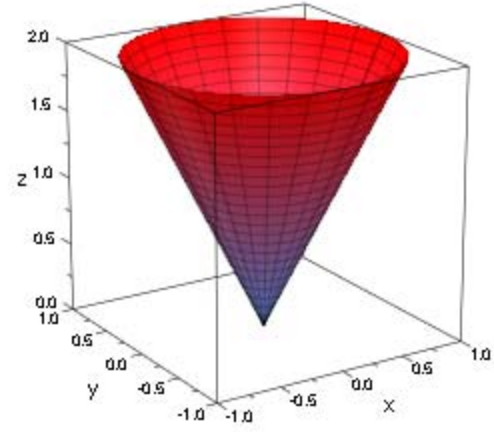
Examples

Example 1

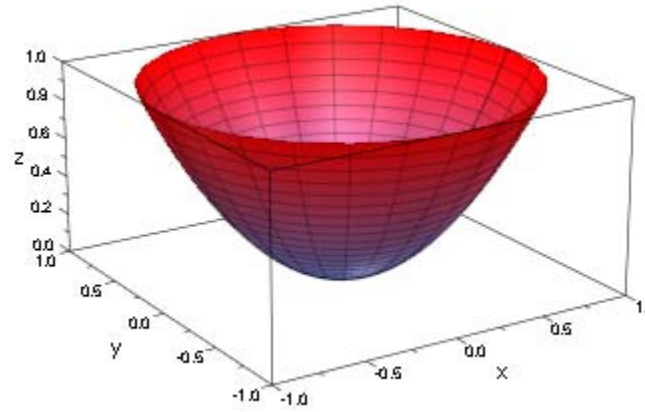
Using a constant radius for `plot::Cylindrical`, with the other two functions straight from the surface parameters, results in a right cylinder. This explains the name “cylindrical coordinates”:
plot(plot::Cylindrical([1, phi, z], phi = 0..2*PI, z = -1..1))



Other straightforward examples include cones and paraboloids of revolution:
plot(plot::Cylindrical([r, phi, 2*r], r = 0..1, phi = 0..2*PI))

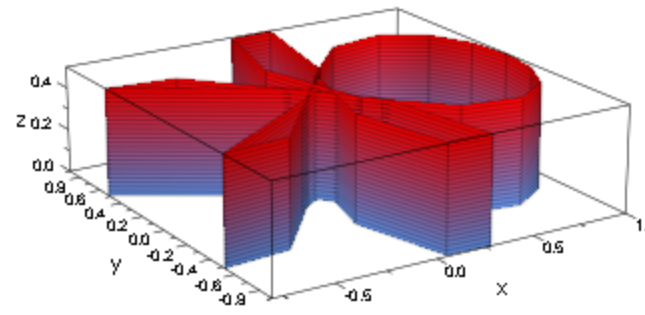


plot(plot::Cylindrical([r, phi, r^2], r = 0..1, phi = 0..2*PI))

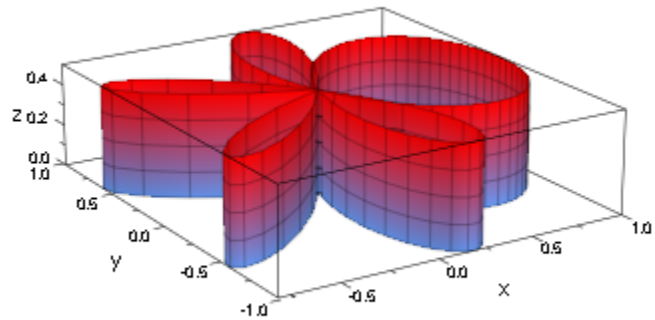


Example 2

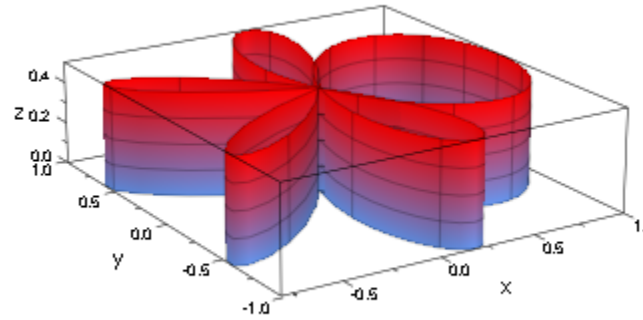
Cylindrical surfaces are drawn from evaluations on an equidistant mesh of points. In some cases, the default mesh density is insufficient or otherwise inappropriate:
plot(plot::Cylindrical([cos(phi^2), phi, z], phi=-2.8..2.8, z=0..1/2))



One possible change to this plot command is to explicitly set the mesh with the attribute Mesh. Note that this setting influences the density of parameter lines:
plot(plot::Cylindrical([cos(phi^2), phi, z], phi=-2.8..2.8, z=0..1/2, Mesh = [100, 5]))

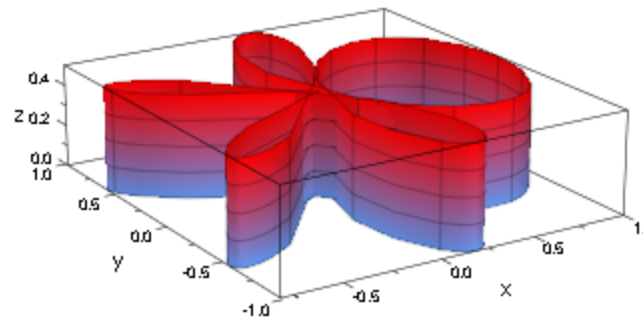


To increase the mesh density without introducing additional parameter lines, you can use submesh settings:
plot(plot::Cylindrical([cos(phi^2), phi, z], phi=-2.8..2.8, z=0..1/2, VMesh = 5, USubmesh = 3))



Finally, we can also ask `plot::Cylindrical` to refine the mesh only in areas of higher curvature. In the following example, we allow for $2^3 = 8$ additional points between each two neighboring points of the initial mesh:

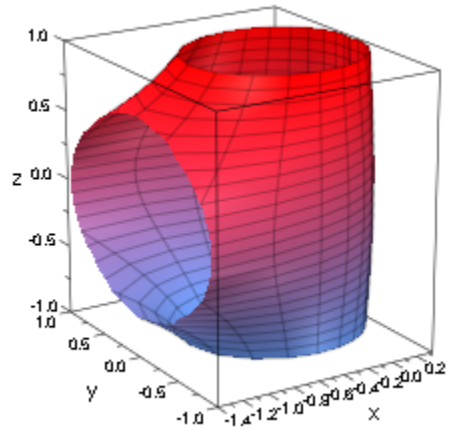
```
plot(plot::Cylindrical([cos(phi^2), phi, z], phi=-2.8..2.8, z=0..1/2, VMesh = 5, AdaptiveMesh = 3))
```



Example 3

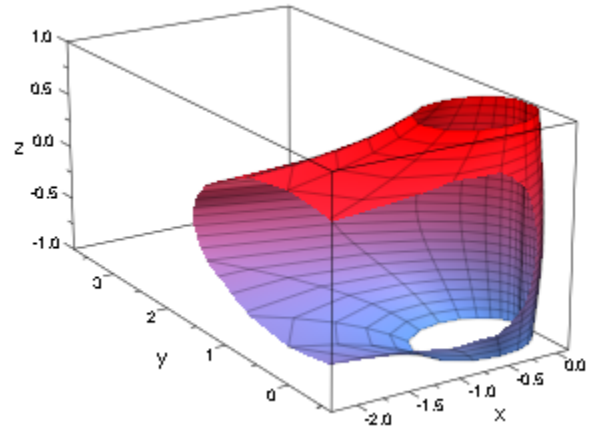
If the radius- or the *z*-function/expression contains singularities, `plot::Cylindrical` employs heuristic clipping to select a range to display:

```
plot(plot::Cylindrical([1/sqrt((phi - PI)^2 + z^2), phi, z], phi = 0..2*PI, z = -1..1))
```

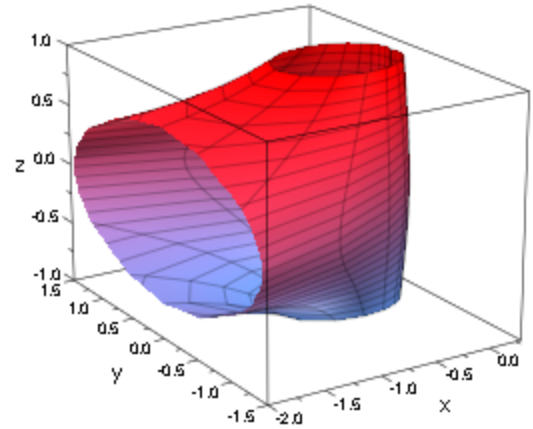


While these heuristics work well in many cases, there are also examples where they do not select a useful box:

```
plot(plot::Cylindrical([1/((phi - PI)^2 + z^2), phi, z], phi = 0.. 2*PI, z = -1..1))
```



In these cases, the user should set the range to display explicitly: plot(plot::Cylindrical([1/((phi - PI)^2+z^2), phi, z], phi = 0..2*PI, z = -1..1), ViewingBox = [-2..0.3, -1.5..1.5, -1..1])



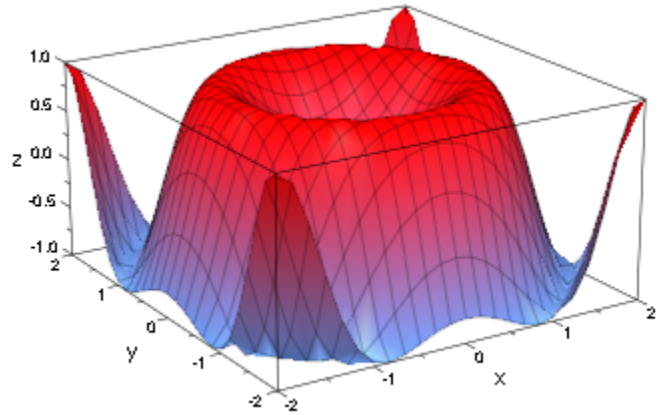
Example 4

Since the transformation from cylindrical to orthogonal coordinates is reversible (up to reducing the angle to the range [0, 2π], it is possible to

plot any surface with `plot::Cylindrical` (although this is probably more a curiosity than really useful):
trans := linalg::ogCoordTab[Cylindrical, InverseTransformation]: cyl := trans(x, y, sin(x^2+y^2))[sqrt(x^2 + y^2), arccos(x/sqrt(x^2 + y^2)) + sign(y)*(sign(y) - 1)*(PI - arccos(x/sqrt(x^2 + y^2))), sin(x^2 + y^2)]

plot(plot::Cylindrical(cyl, x = -2..2, y = -2..2))

$$\left[\sqrt{x^2+y^2},\ \arccos\left(\frac{x}{\sqrt{x^2+y^2}}\right)+\operatorname{sign}(y)\,(\operatorname{sign}(y)-1)\left(\pi-\arccos\left(\frac{x}{\sqrt{x^2+y^2}}\right)\right),\ \sin(x^2+y^2)\right]$$



Parameters

r

•

z

The coordinate functions: arithmetical expressions or piecewise objects depending on the surface parameters *u*, *v* and the animation parameter *a*. Alternatively, procedures that accept 2 input parameters *u*, *v* or 3 input parameters *u*, *v*, *a* and return a real numerical value when the input parameters are numerical.

`r, , z` are equivalent to the attributes XFunction, YFunction, ZFunction.

`u`

The first surface parameter: an identifier or an indexed identifier.

`u` is equivalent to the attributes UName, UMin, UMax.

u_{min} .. u_{max}

The plot range for the parameter *u*: u_{min}, u_{max} must be numerical real values or expressions of the animation parameter *a*.

u_{min} .. u_{max} is equivalent to the attributes URange, UMin, UMax.

`v`

The second surface parameter: an identifier or an indexed identifier.

`v` is equivalent to the attribute VName.

v_{min} .. v_{max}

The plot range for the parameter *v*: v_{min}, v_{max} must be numerical real values or expressions of the animation parameter *a*.

v_{min} .. v_{max} is equivalent to the attributes VRange, VMin, VMax.

`a`

Animation parameter, specified as `a = `a_{min}`..`a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

linalg::ogCoordTabplotplot::copyplot::Polarplot::Sphericalplot::Tube

plot::Density

Purpose

Density plot

Syntax

```
plot::Density(f, x = x_min .. x_max, y = y_min .. y_max,
<a = a_min .. a_max>, options)
plot::Density(A, <x = x_min .. x_max, y = y_min .. y_max>,
<a = a_min .. a_max>, options)
plot::Density(L, <x = x_min .. x_max, y = y_min .. y_max>,
<a = a_min .. a_max>, options)
```

Description

`plot::Density(f(x, y), x = `x_{min}`..`x_{max}` , y = `y_{min}`..`y_{max}` )` generates a regular 2D mesh of rectangles extending from the lower left corner (x_{min}, y_{min}) to the upper right corner (x_{max}, y_{max}). The rectangle with midpoint (x, y) is colored according to a color scheme based on the "density" value $f(x, y)$.

`plot::Density` serves for the visualization of 3D data (x, y, $f(x, y)$) by a 2D plot. Roughly speaking, it corresponds to a colored 3D function graph of the density function $f(x, y)$ viewed from above. However, in contrast to the 3D function graph, `plot::Density` does not use smooth interpolation ("shading") of the color between adjacent rectangles.

If the density data are provided by an array or matrix `A` or by a list `L`, the number of rectangles in the density plot is given automatically by the format of `A` or `L`, respectively.

If the density data are given by an expression or function `f`, the attribute Mesh = `[m, n]` serves for advising `plot::Density` to create a grid of m n rectangles. Alternatively, one may set XMesh = `m`, YMesh = `n`.

With the default FillColorType = `Dichromatic`, the rectangle with density value $f(x, y)$ at the midpoint (x, y) is colored with the color

(f(x, y)-f[(min)])/(f[(max)]-f[(min)]) times (fillcolor)+(f[(max)]-f(x, y))/(f[(max)]-f[(min)]) times (fillcolor2)

$$\frac{f(x, y) - f_{min}}{f_{max} - f_{min}} \times \text{fillcolor} + \frac{f_{max} - f(x, y)}{f_{max} - f_{min}} \times \text{fillcolor2}$$

where f[(min)]/f[(max)] f_{min} are the minimal/maximal density values in the graphics and `fillcolor`, `fillcolor2` are the RGB values of the attributes FillColor and FillColor2, respectively. Thus, `fillcolor` indicates high density values whereas `fillcolor2` indicates low density values.

If $f_{min} = f_{max}$, a flat coloring with `fillcolor` is used.

With FillColorType = `Monochrome`, the rectangle with density value $f(x, y)$ at the midpoint (x, y) is colored with the color

(f(x, y)-f[(min)])/(f[(max)]-f[(min)]) times (fillcolor)

$\frac{f(x,y) - f_{min}}{f_{max} - f_{min}} \times \text{fillcolor}$

The user may specify a fill color function via `FillColorFunction = mycolorfunction` to override the density coloring described above. The procedure `mycolorfunction` will be called with the arguments

```
mycolorfunction(x, y, f(x, y, a ) a ),
```

where (x, y) are the midpoints of the rectangles and a is the animation parameter. The color function must return an RGB or RGBa color value.

When density values are specified by an array or a matrix A, the low indices correspond to the lower left corner of the graphics. The high indices correspond to the upper right corner.

Arrays/matrices do not need to be indexed from 1. E.g.,

```
A = array( `i_{min}` ..  `i_{max}` , `j_{min}` ..
`j_{max}` , [..density values..])
```

yields a graphical array with

`XMesh` = j_{max} - j_{min} + 1, `YMesh` = i_{max} - i_{min} + 1.

If no plot range `` `x_{min}` .. `x_{max}` ``, `` `y_{min}` .. `y_{max}` `` is specified,

$x_{min} = j_{min} - 1$, $x_{max} = j_{max}$, $y_{min} = i_{min} - 1$, $y_{max} = i_{max}$

is used.

When density values are specified by a list of lists L, the first entries in the list correspond to the lower left corner of the graphics. The last entries correspond to the upper right corner.

If no plot range `` `x_{min}` .. `x_{max}` ``, `` `y_{min}` .. `y_{max}` `` is specified,

$x_{min} = 0$, $x_{max} = m$, $y_{min} = 0$, $y_{max} = n$

is used, where n is the length of L and m is the (common) length of the sublists in L. All sublists ("rows") must have the same length.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter `a` that is different from the variables `x`, `y`. Thus, in animations, both the ranges `x = `x_{min}` .. `x_{max}``, `y = `y_{min}` .. `y_{max}`` as well as the animation range `a = `a_{min}` .. `a_{max}`` must be specified.

The related plot routine plot::Raster provides a similar functionality. However, plot::Raster does not use an automatic color scheme based on density values. The user must provide RGB or RGBa values instead.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`FALSE`
Color	the main color	RGB::Red
DensityData	density values for a density plot	
DensityFunction	density function for a density plot	

Attribute	Purpose	Default Value
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`
FillColorFunction	functional area/surface coloring	
Frames	the number of frames in an animation	`50`

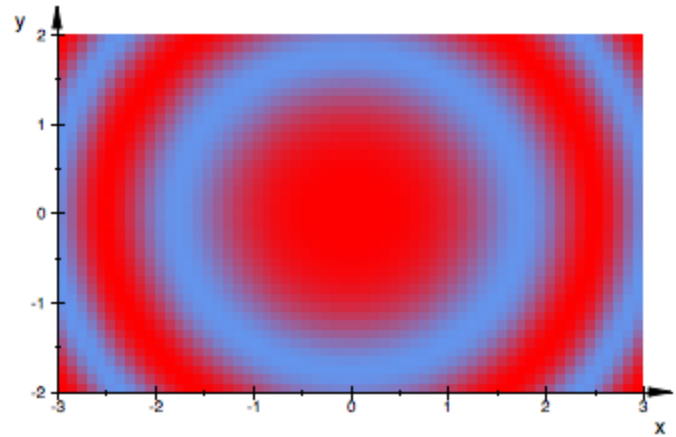
YMax	final value of parameter “y”	
YMesh	number of sample points for parameter “y”	25
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

Examples

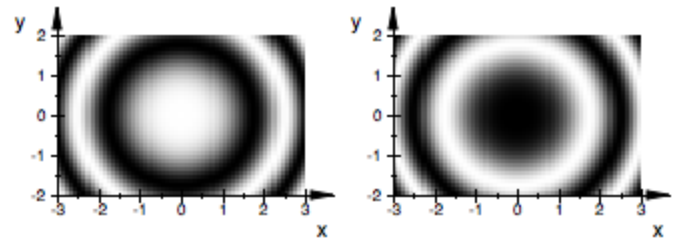
Example 1

We generate a density plot:
p := plot::Density(cos(x^2 + y^2), x = -3..3, y = -2..2, Mesh = [60, 40]):

The plot object is rendered:
plot(p, Axes = Frame):



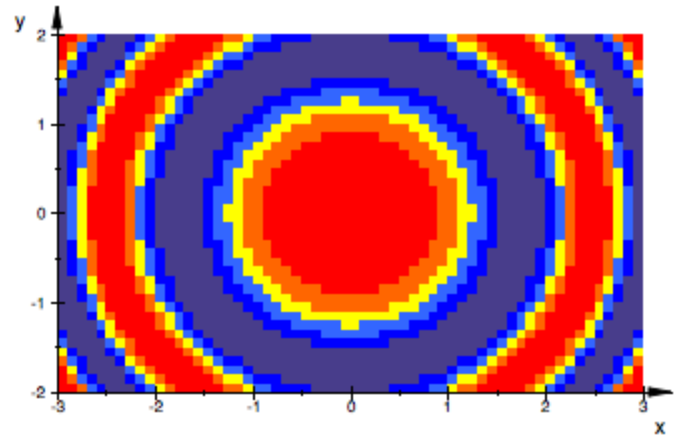
This turns into a black and white graphics when suitable colors are specified:
plot(plot::Scene2d(p, FillColor = RGB::White, FillColor2 = RGB::Black), plot::Scene2d(p, FillColor = RGB::Black, FillColor2 = RGB::White), Width = 120*unit::mm, Height = 45*unit::mm, Layout = Horizontal, Axes = Frame):



delete p:

Example 2

We demonstrate the use of a user-defined color function:
mycolor := proc(x, y, f) begin if f >= 2/3 then RGB::Red elif f >= 1/3 then RGB::Orange; elif f >= 0 then RGB::Yellow; elif f >= -1/3 then RGB::BlueLight; elif f >= -2/3 then RGB::Blue; else RGB::SlateBlueDark; end_if; end_proc: plot(plot::Density(cos(x^2 + y^2), x = -3..3, y = -2..2, Mesh = [60, 40], FillColorFunction = mycolor), Axes = Frame):



delete mycolor:

Example 3

In this example, we demonstrate how `plot::Density` can be used to plot gray data from an external source. Assume, there is an external PortableGrayMap text file `Norton.pgm` containing data such as

```
P2
240 180
255
249 237 228 231 245 218 229 195 ...
```

The first line contains the “magic value” `P2` indicating that this is a PGM text file. The second line contains the pixel width and pixel height of the picture. The number `255` in the third line is the scale of the following gray values.

The remaining data consist of integers between 0 (black) and 255 (white), each representing the gray value of a pixel (row by row).

We import the text data via import::readdata:
READPATH := READPATH, "DATA":graydata := import::readdata("Norton.pgm", NonNested):

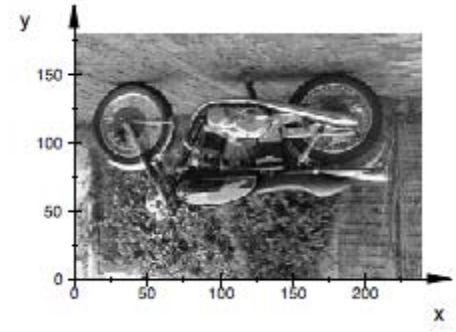
This is a long list of all data items in the file. We extract the 4 items in the first three lines:
[magicvalue, xmesh, ymesh, maxgray] := graydata[1..4][P2, 240, 180, 255]

```
[P2, 240, 180, 255]
```

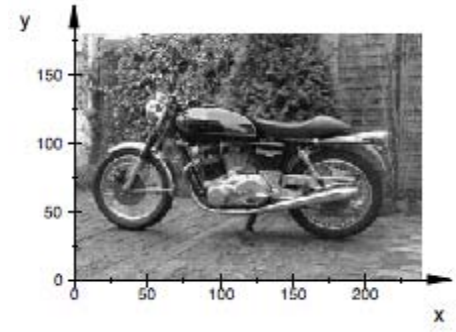
We delete the header from the pixel data. (If there are comments in the PGM file, they must be deleted, too).
for i from 1 to 4 do delete graydata[1]; end_for:

We transform the plain data list to a nested list containing the gray data of the rows as sublists. (The call to level is not really necessary, but it speeds up the conversion considerably on the interactive level.)
L := level([graydata[(i - 1)*xmesh + 1 .. i*xmesh] $ i=1..ymesh], 1):

This list can be passed to `plot::Density`:
plot(plot::Density(L, FillColor = RGB::White, FillColor2 = RGB::Black), Width = 80*unit::mm, Height = 60*unit::mm):



The image is upside down, because the PGM files stores the pixel data row by row in the usual reading order starting with the upper left corner of the image. The MuPAD routine `plot::Density`, however, follows the mathematical orientation of the coordinate axes, i.e., the first pixel value is interpreted as the lower left corner of the image. We have to re-order the rows in the `graydata` list via revert:
plot(plot::Density(revert(L), FillColor = RGB::White, FillColor2= RGB::Black), Width = 80*unit::mm, Height = 60*unit::mm):



The routines import::readbitmap and plot::Raster provide an alternative way to import and display the bitmap image. See the help page of plot::Raster for examples. This, however, takes more memory, because the bitmap data are imported as RGB color values, whereas only density values (gray data) are needed for `plot::Density`.

delete graydata, magicvalue, xmesh, ymesh, maxgray, i, L:

Example 4

The Mandelbrot set is one of the best-known fractals. It arises when considering the iteration $z_{n+1} = z_n^2 + c$, $z_0 = 0$ in the complex plane. For sufficiently large values $|c|$ of the complex parameter c, the sequence z_n diverges to infinity; it converges for sufficiently small values of $|c|$. The boundary of the region of those c values that lead to divergence of z_n is of particular interest: this border is highly complicated and of a fractal nature.

In particular, it is known that the series z_n diverges to infinity, whenever one of the iterates satisfies $|z_n| > 2$. This fact is used by the following procedure `f` as stopping criterion. The return value provides information, how many iterates $z_0, \ldots, z_n$ it takes to escape from the region $|z| \le 2$ of (potential) convergence. These data are to be used to color the complex c plane (i.e., the (x,y) plane) by a density plot:

```
f := proc(x, y) local c, z, n; begin c := x + I*y: z := 0.0: for n from 0 to 100
do z := z^2 + c: if abs(z) > 2 then break; end_if; end_for: if n < 70 then n
mod 5; else n - 70; end_if; end_proc:
```

Depending on your computer, the following computations may take some time. On a very fast machine, you can increase the following values of `xmesh`, `ymesh`. This will use up more computing time but will lead to better graphical results:

```
xmesh := 100: ymesh := 100:
```

The following region in the x-y plane is to be considered:

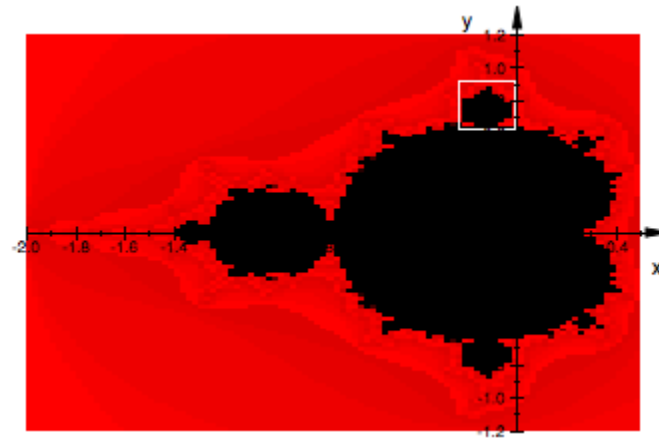
```
xmin[1] := -2.0: xmax[1] := 0.5: ymin[1] := -1.2: ymax[1] := 1.2:
```

The region $xmin_1 \le x \le xmax_1$, $ymin_1 \le y \le ymax_1$ is divided into *xmesh* *ymesh* rectangles. Each rectangle is colored by a density plot according to the "escape times" computed by the procedure `f`. This procedure can be passed directly to `plot::Density`:

```
p1 := plot::Density(f, x = xmin[1].. xmax[1], y = ymin[1] .. ymax[1], Mesh
= [xmesh, ymesh], FillColor = RGB::Black, FillColor2 = RGB::Red):
```

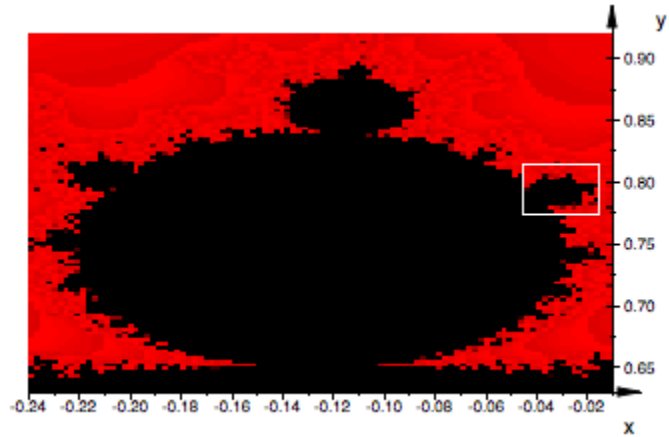
In addition, a rectangle is produced that indicates a region that is to be magnified in the following:

xmin[2] := -0.24: xmax[2] := -0.01: ymin[2] := 0.63: ymax[2] := 0.92: r1 := plot::Rectangle(xmin[2] .. xmax[2], ymin[2] .. ymax[2], LineColor = RGB::White):plot(p1, r1):



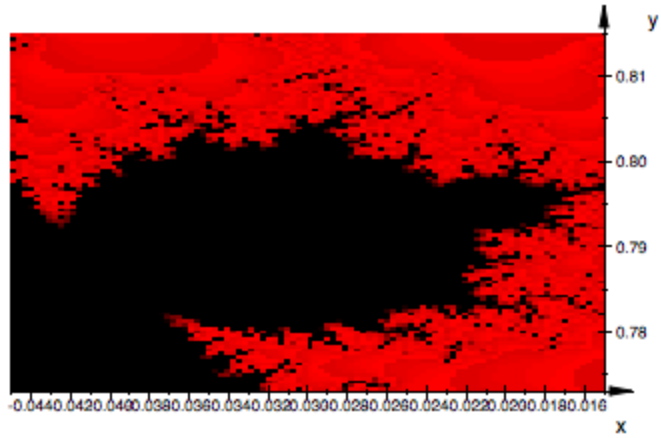
The density values of the blow-up are not computed directly by `plot::Density`. They are computed separately and stored in an array *A*:
dx := (xmax[2] - xmin[2])/xmesh: dy := (ymax[2] - ymin[2])/ymesh: A := array(1..ymesh, 1..xmesh, [[f(xmin[2]+ (j - 1/2)*dx, ymin[2] + (i - 1/2)*dy) $ j = 1..xmesh] $ i = 1..ymesh]): p2 := plot::Density(A, x = xmin[2] .. xmax[2], y = ymin[2] .. ymax[2], FillColor = RGB::Black, FillColor2 = RGB::Red):

In addition, a further rectangle is produced to indicate a region of interest to be blown up lateron:
xmin[3] := -0.045: xmax[3] := -0.015: ymin[3] := 0.773: ymax[3] := 0.815: r2 := plot::Rectangle(xmin[3] .. xmax[3], ymin[3] .. ymax[3], LineColor = RGB::White):plot(p2, r2):



The density values of the next blow-up are again computed separately and stored in a nested list *L*:

```
dx := (xmax[3] - xmin[3])/xmesh: dy := (ymax[3] - ymin[3])/ymesh: L
:= [[f(xmin[3] + (j - 1/2)*dx, ymin[3] + (i - 1/2)*dy) $ j= 1..xmesh] $ i =
1..ymesh]: p3 := plot::Density(L, x = xmin[3] .. xmax[3], y = ymin[3] ..
ymax[3], FillColor = RGB::Black, FillColor2 = RGB::Red):plot(p3):
```

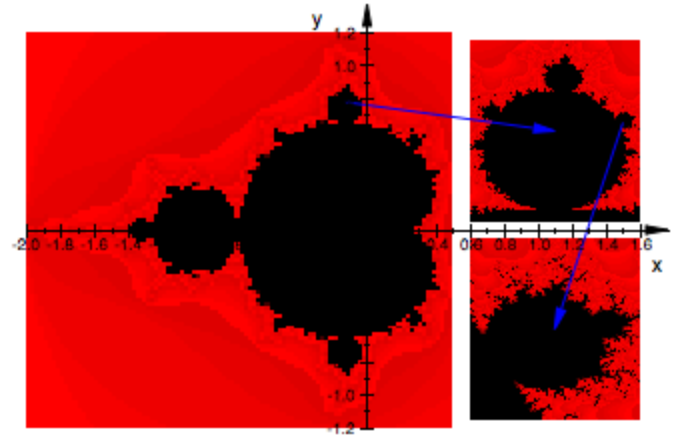


The density objects are to be placed in a single graphics. It consists of the Mandelbrot set `p1` as computed above and of modifications of the density plots `p2` and `p3`. Redefining the attributes `XRange`, `YRange`, we move `p2`, `p3` to places in the *x*-*y* plane where they are not overlapped by `p1`. Note that this does not change the graphical content of `p2`, `p3`, because it is given by the data *A* and *L*, respectively, which remain unchanged. (If the ranges were changed in `p1`, another plot call of `p1` would call the procedure `f` at different points of the plane resulting in a different graphics.)

```
p2::XRange := 0.60 .. 1.60: p2::YRange := 0.05 .. 1.15: p3::XRange :=
0.60 .. 1.60: p3::YRange := -1.15 .. -0.05:
```

The Mandelbrot set and the two blow-ups are placed in one scene. In addition, some arrows are added to indicate the origin of the blow-ups. Note that it is quite important here that the arrows are passed to the plot command after the density plots. Otherwise, they would be hidden by the density plots: graphical objects are painted in the ordering in which they are passed to plot:

```
plot(p1, p2, p3, plot::Arrow2d([(xmin[2] + xmax[2])/2, (ymin[2] +
ymax[2])/2], [(p2::XMin + p2::XMax)/2, (p2::YMin + p2::YMax)/2],
LineColor = RGB::Blue), plot::Arrow2d([1.50, 0.65], [(p3::XMin +
p3::XMax)/2, (p3::YMin + p3::YMax)/2], LineColor = RGB::Blue) ):
```



delete f, xmesh, ymesh, xmin, xmax, ymin, ymax, dx, dy, p1, p2, p3, r1, r2, A, L:

Parameters

f

The density values: an arithmetical expression in 2 variables *x*, *y* and the animation parameter *a*. Alternatively, a procedure that accepts 2 input parameters *x*, *y* or 3 input parameters *x*, *y*, *a* and returns a real density value.

`f` is equivalent to the attribute DensityFunction.

x

Name of the horizontal variable: an identifier or an indexed identifier.

`x` is equivalent to the attribute XName.

x_{min} .. x_{max}

The range of the horizontal variable: x_{min}, x_{max} must be numerical real value or expressions of the animation parameter *a*.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

y

Name of the vertical variable: an identifier or an indexed identifier.

`y` is equivalent to the attribute YName.

y_{min} .. y_{max}

The range of the vertical variable: y_{min}, y_{max} must be numerical real value or expressions of the animation parameter *a*.

y_{min} .. y_{max} is equivalent to the attributes YRange, YMin, YMax.

A

An array of domain type DOM_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) providing numerical density values or expressions of the animation

parameter *a*. Rows/columns of the array, respectively matrix, correspond to rows/columns of the graphical array.

A is equivalent to the attribute DensityData.

L

A list of lists of numerical density values or expressions of the animation parameter *a*. Each sublist of *L* represents a row of the graphical array. The number of sublists in *L* yields the value of the attribute XMesh. The (common) length of the sublists yields the value of the attribute YMesh.

L is equivalent to the attribute DensityData.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Ellipse2d

Purpose

Ellipses in 2D

Syntax

```
plot::Ellipse2d(r1, r2, <[cx, cy]>, <a = amin .. amax>, options)
```

Description

`plot::Ellipse2d( r1, r2, [cx, cy] )` creates a 2D ellipse with center point `[cx, cy]` and semi-axes of lengths `r1` and `r2` for the horizontal and the vertical axis, respectively.

The symmetry axes of the ellipse are parallel to the coordinate axes. Use plot::Rotate2d to create ellipses of different orientation.

If no center point is specified, an ellipse with center [0, 0] is created.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Center	center of objects, rotation center	`[0, 0]`
CenterX	center of objects, rotation center, x-component	`0`
CenterY	center of objects, rotation center, y-component	`0`
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	`FALSE`

Attribute	Purpose	Default Value
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	`DiagonalLines`
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`

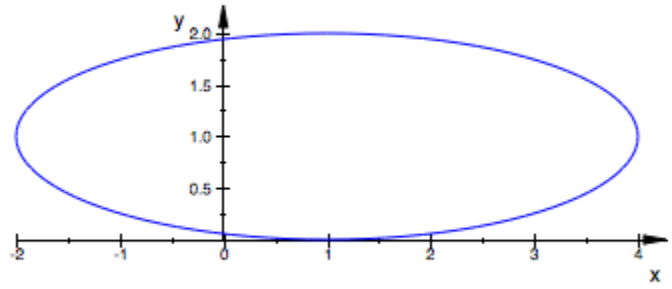
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

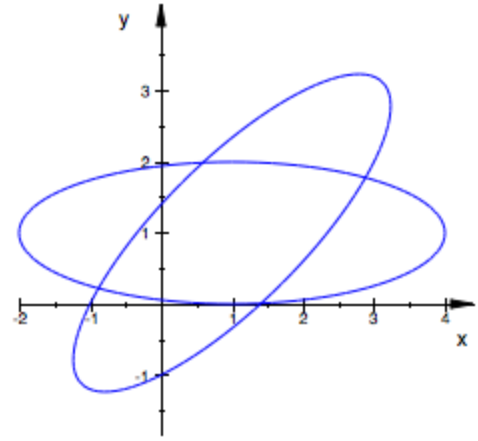
Example 1

We create a plot of an ellipse with center point (1, 1) and semi-axes of lengths 3 and 1:

```
ellipse := plot::Ellipse2d(3, 1, [1, 1]): plot(ellipse)
```



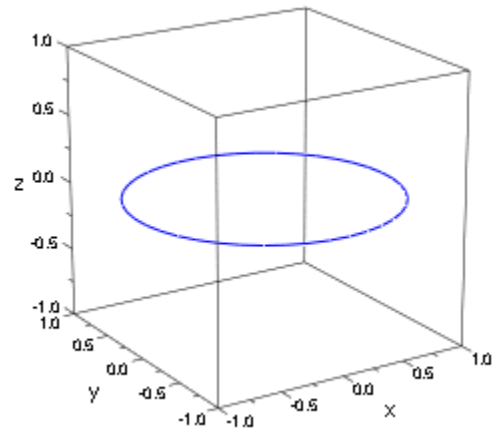
We apply a rotation:
plot(ellipse, plot::Rotate2d(PI/4, [1, 1], ellipse))



delete ellipse:

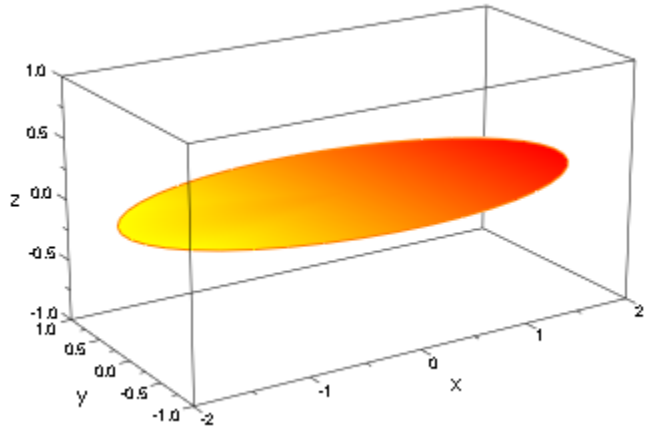
Example 2

We plot an animated 3D ellipse:
plot(plot::Ellipse3d(1, 1, [0,0,0], [0,a,1-a], a = 0..1))



Example 3

We plot a colored 3D ellipse:
plot(plot::Ellipse3d(2, 1, [0,0,0], Filled, LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType = Dichromatic, FillColorDirection=[+1,0,0], FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType = Dichromatic, FillColorDirection=[-1,0,0]))



Parameters

r_1

r_2

The semi-axes of an ellipse. They must be real numerical values or arithmetical expressions of the animation parameter `a`.

r_1, r_2 are equivalent to the attributes SemiAxisX, SemiAxisY.

c_x

c_y

The center. The coordinates c_x, c_y must be real numerical values or arithmetical expressions of the animation parameter `a`. If no center is specified, the ellipse is centered at the origin.

c_x, c_y are equivalent to the attribute Center.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

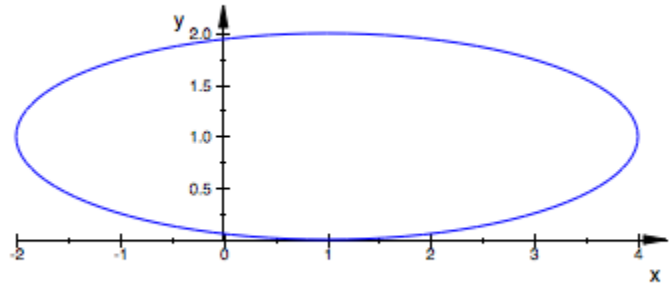
Examples

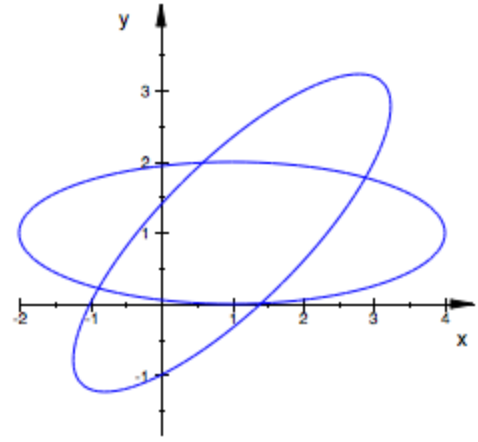
Example 1

We create a plot of an ellipse with center point (1, 1) and semi-axes of lengths 3 and 1:

```
ellipse := plot::Ellipse2d(3, 1, [1, 1]): plot(ellipse)
```



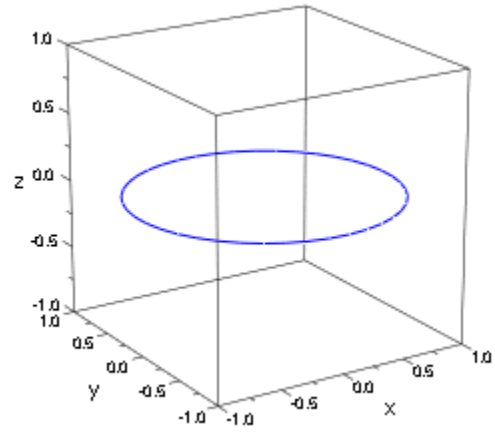
We apply a rotation:
plot(ellipse, plot::Rotate2d(PI/4, [1, 1], ellipse))



delete ellipse:

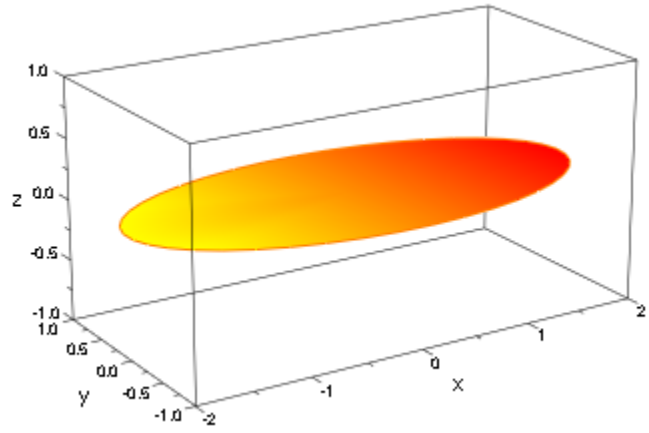
Example 2

We plot an animated 3D ellipse:
plot(plot::Ellipse3d(1, 1, [0,0,0], [0,a,1-a], a = 0..1))



Example 3

We plot a colored 3D ellipse:
plot(plot::Ellipse3d(2, 1, [0,0,0], Filled, LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType = Dichromatic, FillColorDirection=[+1,0,0], FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType = Dichromatic, FillColorDirection=[-1,0,0]))



Parameters

r_1

r_2

The semi-axes of an ellipse. They must be real numerical values or arithmetical expressions of the animation parameter `a`.

r_1, r_2 are equivalent to the attributes SemiAxisX, SemiAxisY.

c_x

c_y

c_z

The center. The coordinates c_x, c_y, c_z must be real numerical values or arithmetical expressions of the animation parameter `a`. If no center is specified, the ellipse is centered at the origin.

c_x, c_y, c_z are equivalent to the attribute Center.

n_x

n_y

n_z

The normal vector. The coordinates n_x, n_y, n_z must be real numerical values or arithmetical expressions of the animation parameter a. If no normal vector is specified, the ellipse is created in the xy-plane.

n_x, n_y, n_z are equivalent to the attribute Normal.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Ellipse2dplot::Arc2dplot::Arc3dplot::Circle2d

plot::Function2d

Purpose

2D function graphs

Syntax

```
plot::Function2d(f, options)
plot::Function2d(f, x = x_min .. x_max, <a =
a_min .. a_max>, options)
```

Description

`plot::Function2d` creates the 2D graph of a univariate function.

The graphics ignores all points, where the expression/function `f` does not produce a numerical real value. See "Example 2" on page 24-291.

The expression/function `f` may have singularities in the plot range. Although a heuristics is used to find a reasonable *y* range when singularities are present, it is highly recommended to specify a *y* range via ViewingBoxYRange = `` `y_{min}` .. `y_{max}` `` with suitable numerical real values y_{min}, y_{max}. See "Example 3" on page 24-292.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter `a` that is different from the independent variable `x`. Thus, in animations, both the *x*-range `x = `x_{min}` .. `x_{max}`` as well as the animation range `a = `a_{min}` .. `a_{max}`` must be specified. See "Example 4" on page 24-293.

The function `f` is evaluated on an equidistant mesh of sample points determined by the attribute XMesh (or the shorthand notation Mesh). By default, the attribute `AdaptiveMesh = 0` is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of XMesh or set `AdaptiveMesh = n` with some (small) positive integer `n`. If necessary, up to 2^n additional points are placed between adjacent points of the initial equidistant mesh. See "Example 5" on page 24-293.

By default, the attribute `DiscontinuitySearch = TRUE` is set. This triggers a semi-symbolic preprocessing of the expression `f` to search for discontinuities and singularities. At each singular point, the function graph is split into disjoint branches to the left and to the right of the

singularity. This avoids graphical artifacts such as lines connecting points to the left and to the right of a singularity.

If the function is known to be regular in the plot range, the semi-symbolic search may be disabled by specifying `DiscontinuitySearch = FALSE`. This will improve the efficiency of the plot commands.

Singular points are highlighted by a vertical line unless `VerticalAsymptotesVisible = FALSE` is specified. Its style may be set by the attributes VerticalAsymptotesStyle, VerticalAsymptotesWidth, and VerticalAsymptotesColor.

Note This functionality is only available if the function is specified by a an arithmetical expression or a procedure that accepts symbolic arguments. It is not available if the function is specified by a piecewise object or by a procedure that accepts only numerical arguments.

See “Example 6” on page 24-296.

plot::Hatch allows to hatch areas between function graphs. See “Example 7” on page 24-297.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	2
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Color	the main color	RGB::Blue
DiscontinuitySearch	semi-symbolic search for discontinuities	`TRUE`

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
Function	function expression or procedure	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Mesh	number of sample points	121

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`FALSE`
Submesh	density of submesh (additional sample points)	`0`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`

Attribute	Purpose	Default Value
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
VerticalAsymptotesColor	color of vertical asymptotes indicating poles	RGB::Grey50
VerticalAsymptotesWidth	line width of vertical asymptotes indicating poles	`0.2`
VerticalAsymptotesStyle	line style of vertical asymptotes indicating poles	`Dashed`
VerticalAsymptotesVisible	vertical asymptotes indicating poles	`TRUE`
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter “x”	5
XMesh	number of sample points for parameter “x”	121
XMin	initial value of parameter “x”	-5
XName	name of parameter “x”	
XRange	range of parameter “x”	-5 .. 5
XSubmesh	density of additional sample points for parameter “x”	0

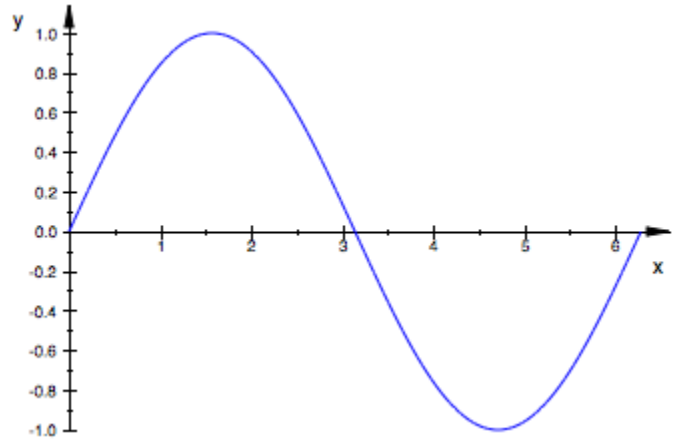
Examples

Example 1

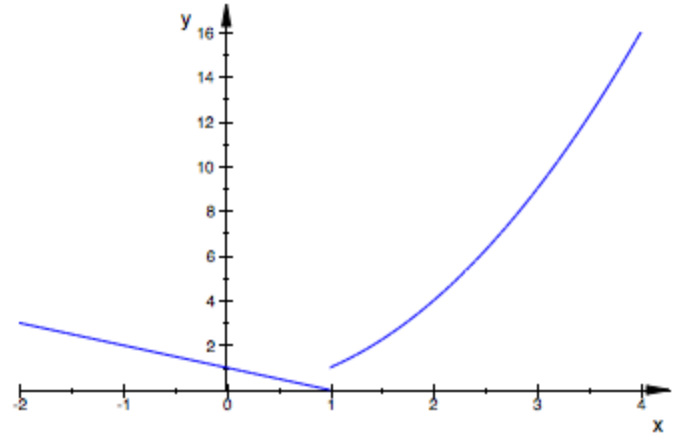
The following call returns an object representing the graph of the sine function over the interval [0, 2π]:
f := plot::Function2d(sin(x), x = 0 .. 2*PI)plot::Function2d(sin(x), x = 0..2*PI)

plot::Function2d(sin(x), x = 0..2 π)

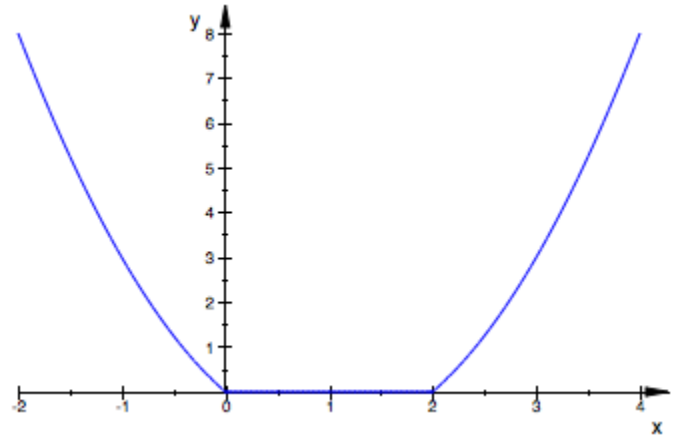
Call plot to plot the graph:
plot(f):



Functions can also be specified by piecewise objects or procedures:
f := piecewise([x < 1, 1 - x], [x >= 1, x^2]): plot(plot::Function2d(f, x = -2 .. 4)):



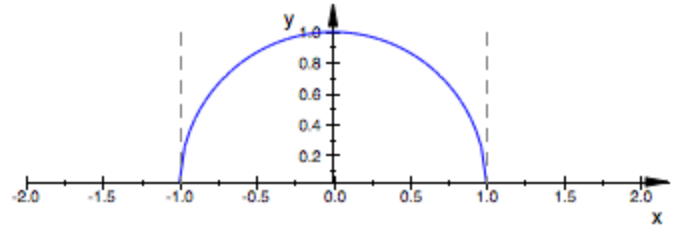
f := proc(x) begin if x^2 - 2*x < 0 then 0 else x^2 - 2*x end_if: end_proc:
plot(plot::Function2d(f, x = -2 .. 4)):



delete f:

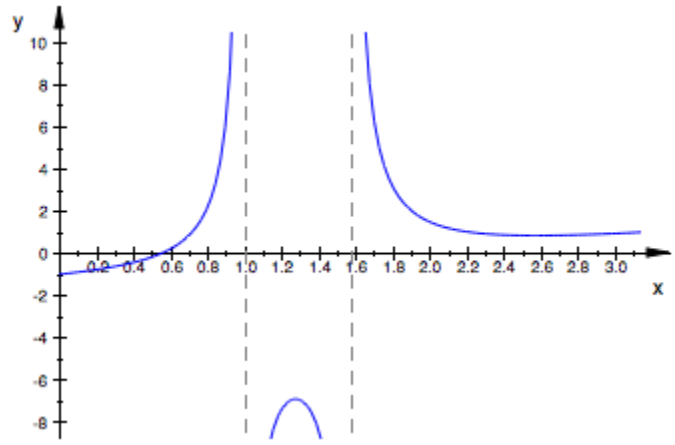
Example 2

Non-real values are ignored in a plot:
plot(plot::Function2d(sqrt(1 - x^2), x = -2 .. 2), Scaling = Constrained):

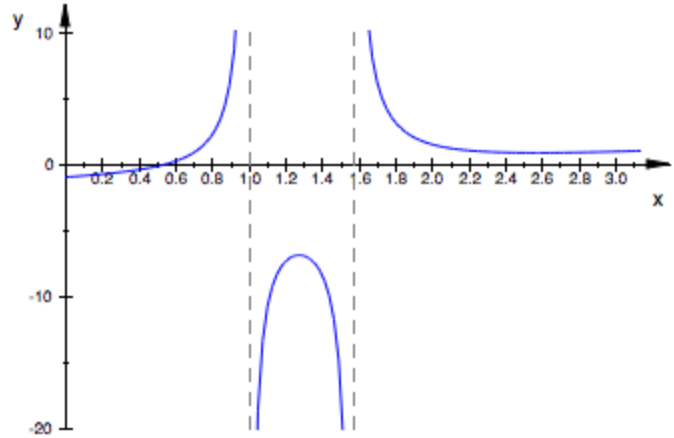


Example 3

We plot a function with singularities:
f := plot::Function2d(sin(x)/(1 - x) - 1/cos(x), x = 0 .. PI): plot(f):



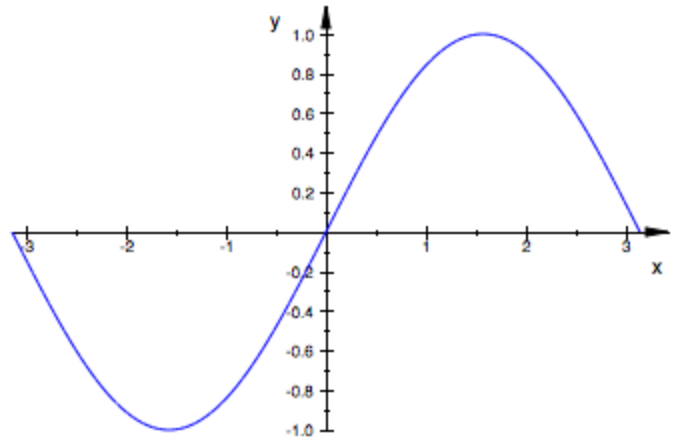
We specify an explicit viewing range for the *y* direction:
plot(f, ViewingBoxYRange = -20 .. 10):



delete f:

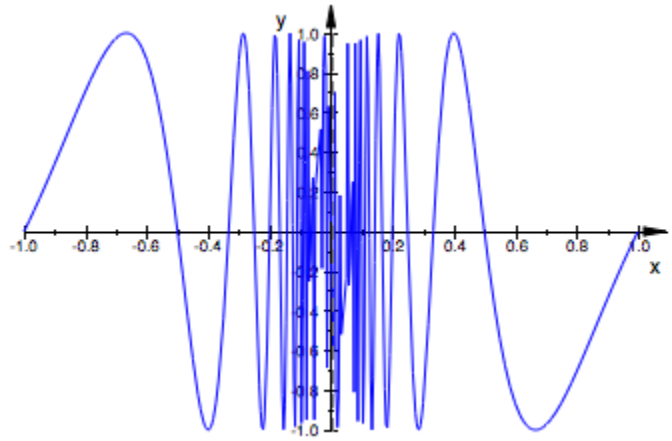
Example 4

We generate an animation of a parametrized function:
plot(plot::Function2d(a*sin(x) + (1 - a)*cos(x), x = -PI .. PI, a = 0 .. 1)):

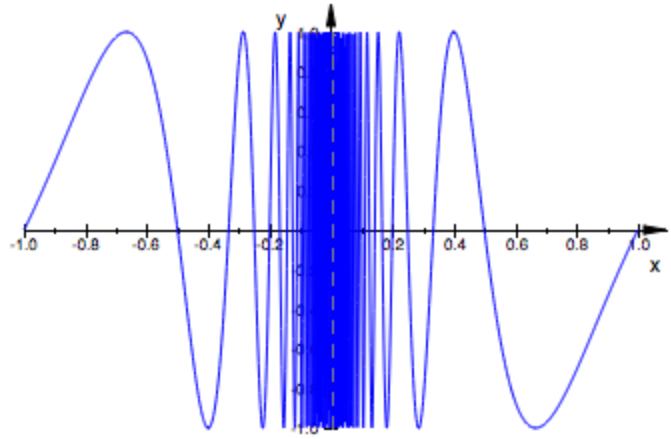


Example 5

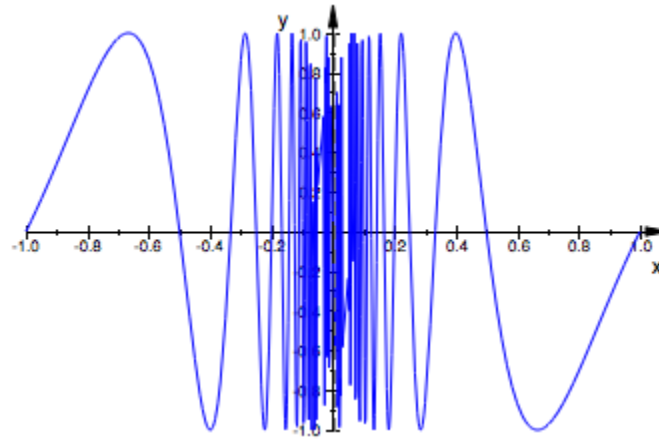
The standard mesh for the numerical evaluation of a function graph does not suffice to generate a satisfying graphics in the following case:
plot(plot::Function2d(sin(PI/x), x = -1 .. 1)):



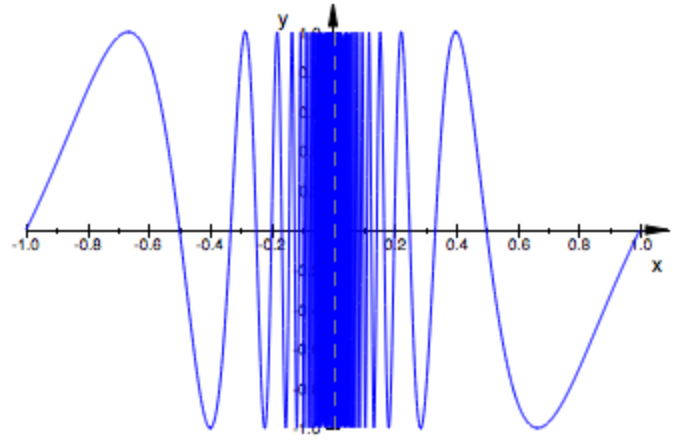
We increase the number of mesh points:
plot(plot::Function2d(sin(PI/x), x = -1 .. 1, XMesh = 1000)):



Alternatively, we enable adaptive sampling by setting AdaptiveMesh to some positive value:
plot(plot::Function2d(sin(PI/x), x = -1 .. 1, AdaptiveMesh = 3)):



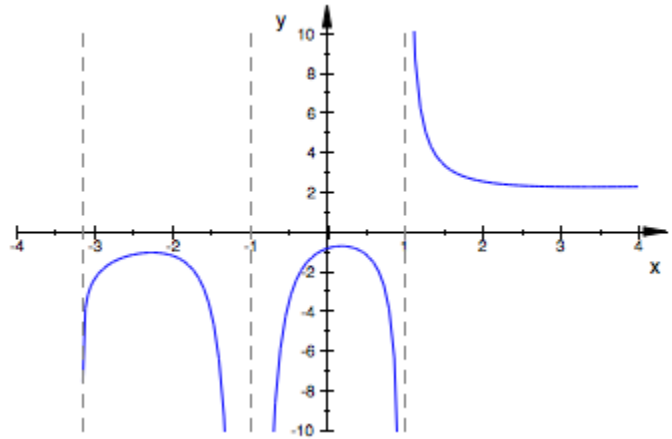
Finally, we increase the XMesh value and use adaptive sampling:
plot(plot::Function2d(sin(PI/x), x = -1 .. 1, XMesh = 1000, AdaptiveMesh = 3)):



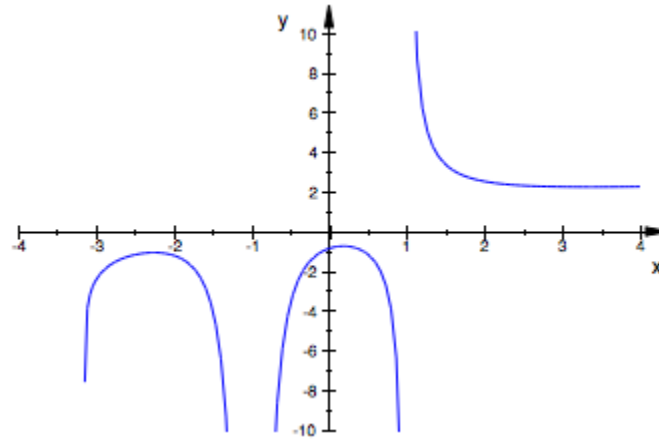
Example 6

With `VerticalAsymptotesVisible = TRUE/FALSE`, singular points are highlighted by a vertical asymptote, or this highlighting is switched off, respectively:

```
plot(plot::Function2d(ln(x + PI) + 1/(x - 1) - 1/(x + 1)^2, x = -4 .. 4,
VerticalAsymptotesVisible = TRUE, ViewingBoxYRange = -10 .. 10)):
```

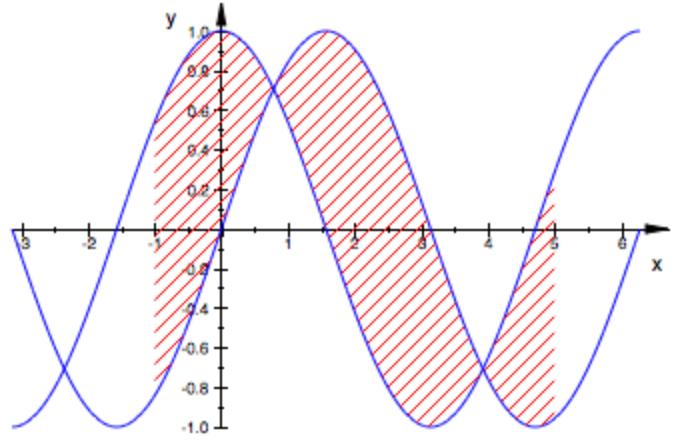


```
plot(plot::Function2d(ln(x + PI) + 1/(x - 1) - 1/(x + 1)^2, x = -4 .. 4,
VerticalAsymptotesVisible = FALSE, ViewingBoxYRange = -10 .. 10)):
```



Example 7

The plot::Hatch object allows to hatch regions between functions. It expects graphical objects of type `plot::Function2d` or plot::Curve2d as boundaries:
f1:= plot::Function2d(sin(x), x = -PI .. 2*PI): f2:= plot::Function2d(cos(x), x = -PI .. 2*PI): plot(f1, f2, plot::Hatch(f1, f2, -1 .. 5)):



delete f1, f2:

Parameters

f

The function: an arithmetical expression or a piecewise object in the independent variable *x* and the animation parameter *a*. Alternatively, a procedure that accepts 1 input parameter *x* or 2 input parameters *x*, *a* and returns a real numerical value when the input parameters are numerical.

`f` is equivalent to the attribute Function.

x

The independent variable: an identifier or an indexed identifier.

`x` is equivalent to the attribute XName.

x_{min} .. x_{max}

The plot range: x_{min}, x_{max} must be numerical real values or expressions of the animation parameter *a*. If not specified, the default range `x = -5 .. 5` is used.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotfunc2dplotfunc3dplotplot::copyplot::Function3d

plot::Function3d

Purpose

3D function graphs

Syntax

```
plot::Function3d(f, options)
plot::Function3d(f, x = x_min .. x_max, y = y_min .. y_max,
<a = a_min .. a_max>, options)
```

Description

`plot::Function3d` creates the 3D graph of a function in 2 variables.

The expression `f(x, y)` is evaluated at finitely many points x, y in the plot range. There may be singularities. Although a heuristics is used to find a reasonable z range when singularities are present, it is highly recommended to specify a z range via `ViewingBoxZRange = `z_{min}` .. `z_{max}`` with suitable numerical real values z_{min}, z_{max}. See "Example 2" on page 24-308.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter `a` that is different from the indedependent variables `x`, `y`. Thus, in animations, the $x$-range `x = `x_{min}` .. `x_{max}``, the y-range `y = `y_{min}` .. `y_{max}`` as well as the animation range `a = `a_{min}` .. `a_{max}`` must be specified. See "Example 3" on page 24-309.

The function `f` is evaluated on a regular equidistant mesh of sample points determined by the attributes XMesh and YMesh (or the shorthand-notation for both, Mesh). By default, the attribute `AdaptiveMesh = 0` is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of XMesh and YMesh or set `AdaptiveMesh = n` with some (small) positive integer `n`. This may result in up to 4^n times as many triangles as used with `AdaptiveMesh = 0`, potentially more when `f` has non-isolated singularities. See "Example 4" on page 24-309.

The "coordinate lines" ("parameter lines") are curves on the function graph.

The phrase "XLines" refers to the curves $(x, y_0, f(x, y_0))$ with the parameter x running from x_{min} to x_{max}, while y_0 is some fixed value from the interval $[y_{min}, y_{max}]$.

The phrase "YLines" refers to the curves $(x_0, y, f(x_0, y))$ with the parameter y running from ymin to ymax, while x_0 is some fixed value from the interval $[x_{min}, x_{max}]$.

By default, the parameter lines are visible. They may be "switched off" by specifying XLinesVisible = FALSE and YLinesVisible = FALSE, respectively.

The coordinate lines controlled by XLinesVisible = TRUE/FALSE and YLinesVisible = TRUE/FALSE indicate the equidistant regular mesh set via the Mesh attributes. If the mesh is refined by the Submesh attributes or by the adaptive mechanism controlled by AdaptiveMesh = n, no additional parameter lines are drawn.

As far as the numerical approximation of the function graph is concerned, the settings

Mesh = $[n_x, n_y]$, Submesh = $[m_x, m_y]$

and

Mesh = $[(n_x - 1)\ (m_x + 1) + 1, (n_y - 1)\ (m_y + 1) + 1]$, Submesh = [0, 0]

are equivalent. However, in the first setting, nx parameter lines are visible in the x direction, while in the latter setting $(n_x - 1)\ (m_x + 1) + 1$ parameter lines are visible. See "Example 5" on page 24-311.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	0
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Color	the main color	RGB::Red

Attribute	Purpose	Default Value
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Function	function expression or procedure	
Legend	makes a legend entry	

Attribute	Purpose	Default Value
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`TRUE`
LineColor	color of lines	`RGB::Black.[0.25]`
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`0`
LineColorDirectionZ	z-component of the direction of color transitions on lines	`1`
Mesh	number of sample points	`[25, 25]`
MeshVisible	visibility of irregular mesh lines in 3D	`FALSE`

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`FALSE`
Shading	smooth color blend of surfaces	`Smooth`
Submesh	density of submesh (additional sample points)	`[0, 0]`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	

Attribute	Purpose	Default Value
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XLinesVisible	visibility of parameter lines (x lines)	TRUE

Attribute	Purpose	Default Value
XMax	final value of parameter “x”	5
XMesh	number of sample points for parameter “x”	25
XMin	initial value of parameter “x”	-5
XName	name of parameter “x”	
XRange	range of parameter “x”	-5 .. 5
XSubmesh	density of additional sample points for parameter “x”	0
YLinesVisible	visibility of parameter lines (y lines)	TRUE
YMax	final value of parameter “y”	5
YMesh	number of sample points for parameter “y”	25
YMin	initial value of parameter “y”	-5
YName	name of parameter “y”	
YRange	range of parameter “y”	-5 .. 5

Attribute	Purpose	Default Value
YSubmesh	density of additional sample points for parameter “y”	0
ZContours	contour lines at constant z values	[]

Examples

Example 1

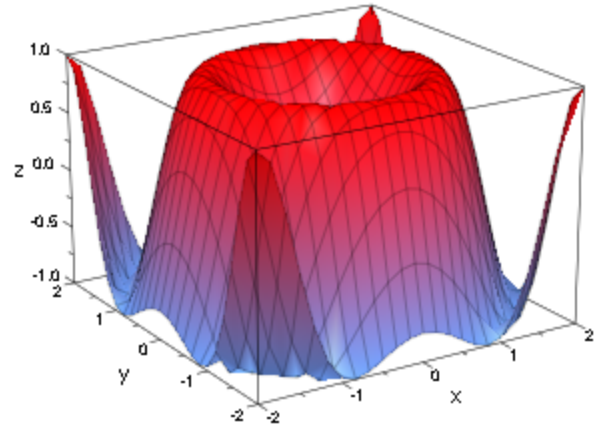
The following call returns an object representing the graph of the function $sin(x^2 + y^2)$ over the region $-2 \le x \le 2$, $-2 \le y \le 2$:

```
g := plot::Function3d(sin(x^2 + y^2), x = -2..2, y =
-2..2)plot::Function3d(sin(x^2 + y^2), x = -2..2, y = -2..2)
```

$$\text{plot::Function3d}\left(\sin\left(x^2+y^2\right),\ x=-2..2,\ y=-2..2\right)$$

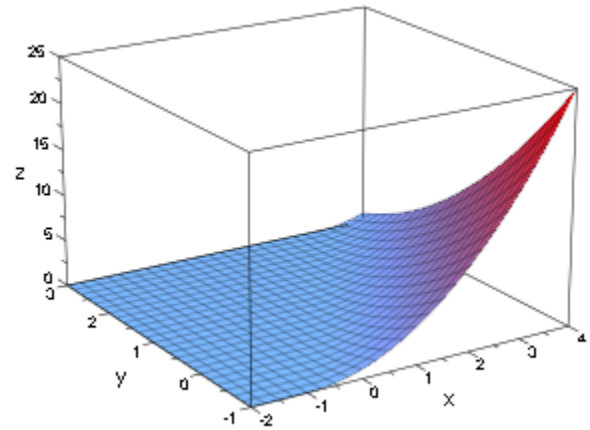
Call plot to plot the graph:

```
plot(g)
```

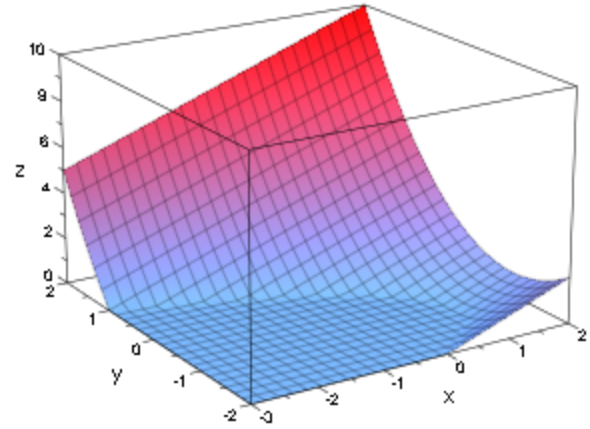


Functions can also be specified by piecewise objects or procedures:

f := piecewise([x < y, 0], [x >= y, (x - y)^2]): plot(plot::Function3d(f, x = -2 .. 4, y = -1 .. 3))



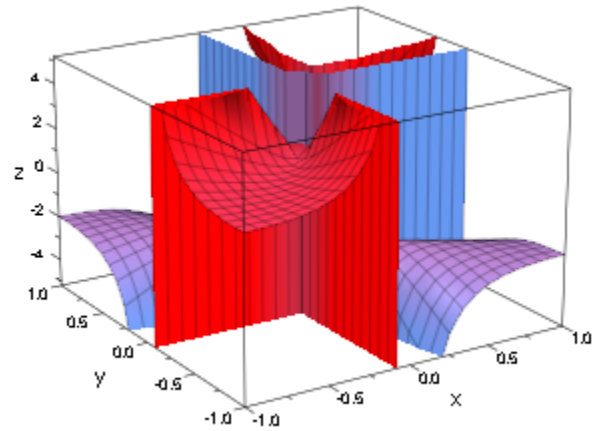
f := proc(x, y) begin if x + y^2 + 2*y < 0 then 0 else x + y^2 + 2*y end_if: end_proc: plot(plot::Function3d(f, x = -3 .. 2, y = -2 .. 2))



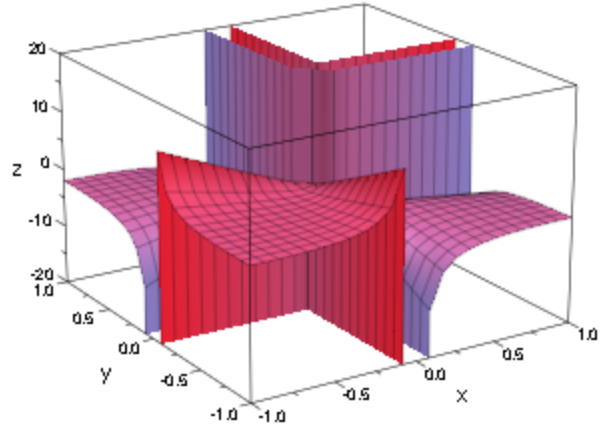
delete g, f

Example 2

We plot a function with singularities:
f := plot::Function3d(x/y + y/x, x = -1 .. 1, y = - 1 .. 1): plot(f)



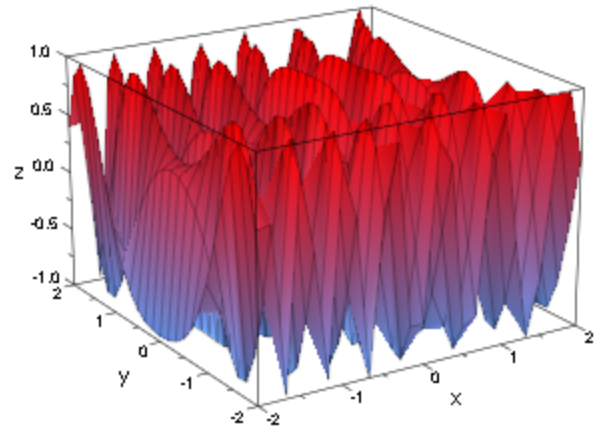
We specify an explicit viewing range for the *z* direction:
plot(f, ViewingBoxZRange = -20 .. 20)



delete f

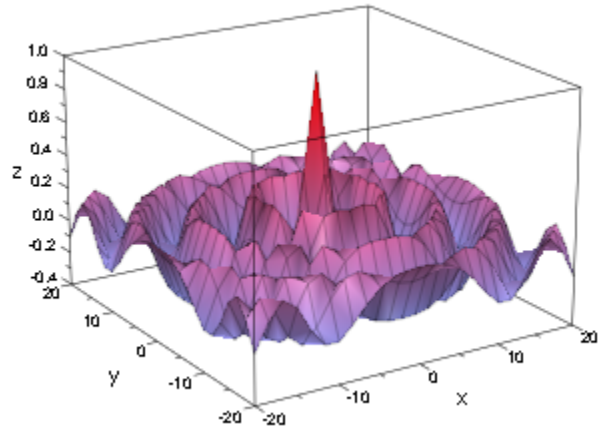
Example 3

We generate an animation of a parametrized function:
plot(plot::Function3d(sin((x - a)^2 + y^2), x = -2 .. 2, y = -2 .. 2, a = 0 .. 5))

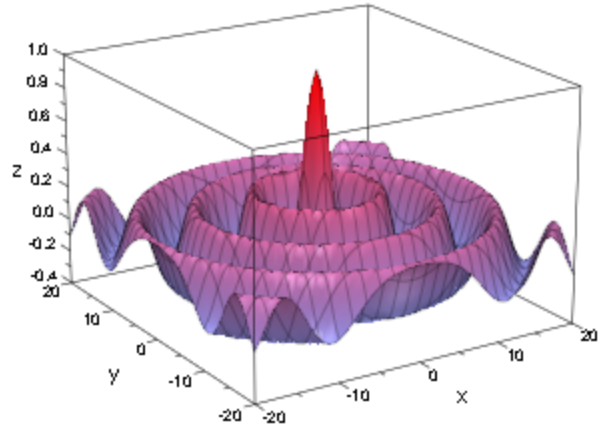


Example 4

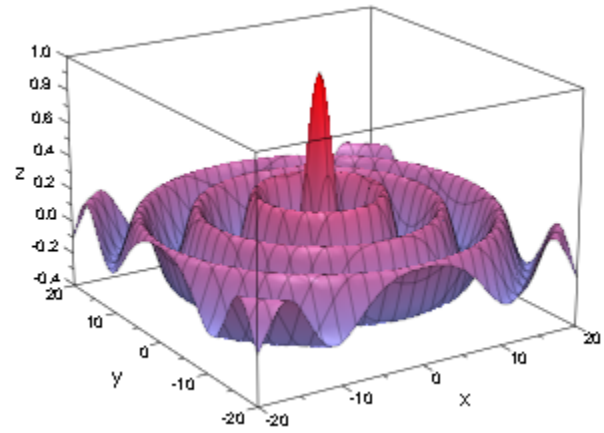
The standard mesh for the numerical evaluation of a function graph does not suffice to generate a satisfying graphics in the following case:
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)), x = -20 .. 20, y = -20 .. 20))



We increase the number of mesh points. Here, we use XSubmesh and YSubmesh to place 2 additional points in each direction between each pair of neighboring points of the default mesh. This increases the runtime by a factor of 9:
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)), x = -20 .. 20, y = -20 .. 20, Submesh = [2, 2]))

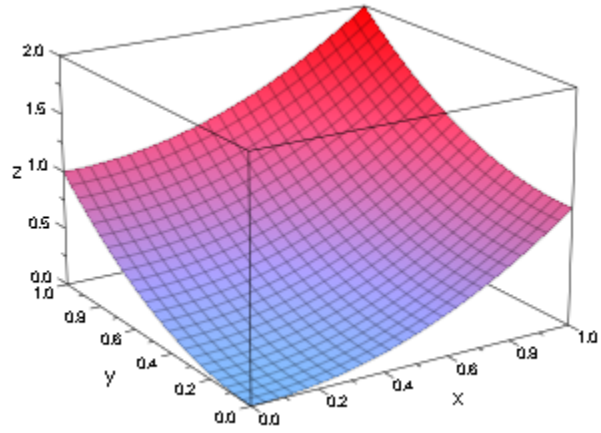


Alternatively, we enable adaptive sampling by setting the value of AdaptiveMesh to some positive value:
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)), x = -20 .. 20, y = -20 .. 20, AdaptiveMesh = 2))

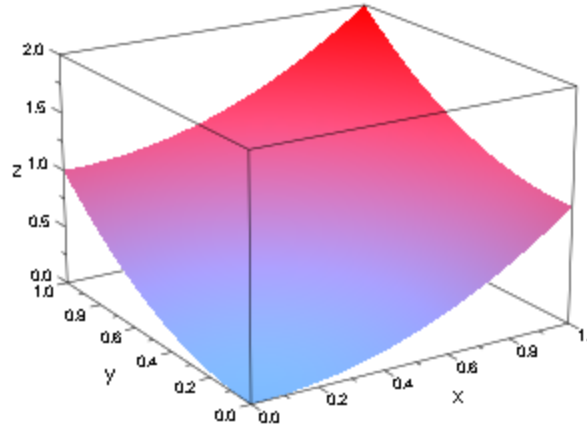


Example 5

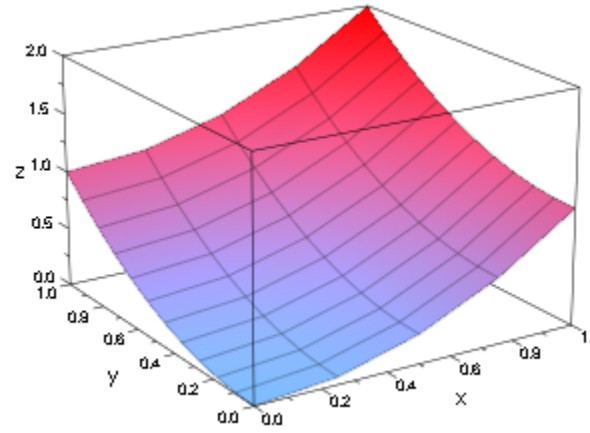
By default, the parameter lines of a function graph are “switched on”:
plot(plot::Function3d(x^2 + y^2, x = 0 .. 1, y = 0 .. 1))



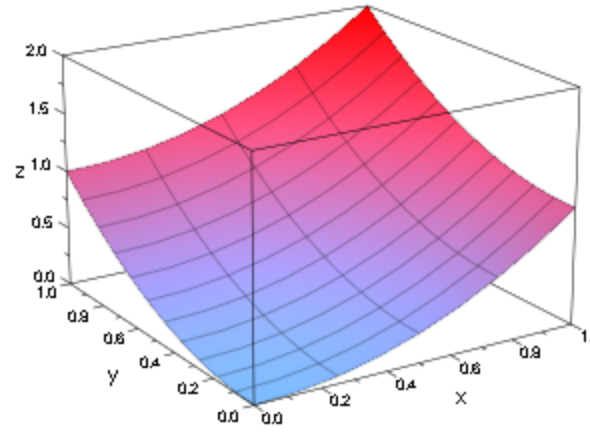
The parameter lines are “switched off” by setting XLinesVisible, YLinesVisible:
plot(plot::Function3d(x^2 + y^2, x = 0 .. 1, y = 0 .. 1, XLinesVisible = FALSE, YLinesVisible = FALSE))



The number of parameter lines are determined by the `Mesh` attributes:
plot(plot::Function3d(x^2 + y^2, x = 0 .. 1, y = 0 .. 1, Mesh = [5, 12]))

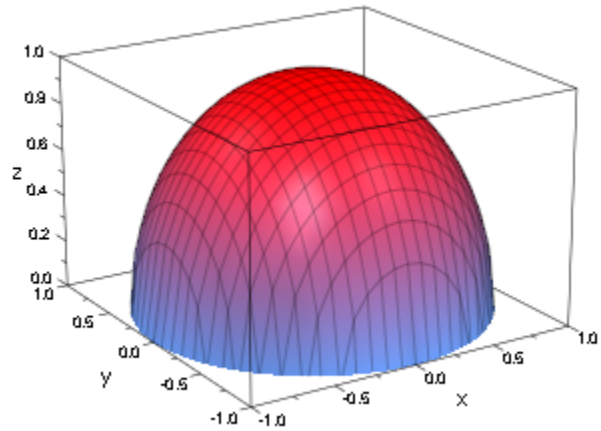


When the mesh is refined via the Submesh attributes, the numerical approximation of the surface becomes smoother. However, the number of parameter lines is not increased:
plot(plot::Function3d(x^2 + y^2, x = 0 .. 1, y = 0 .. 1, Mesh = [5, 12], XSubmesh = 1, YSubmesh = 2))

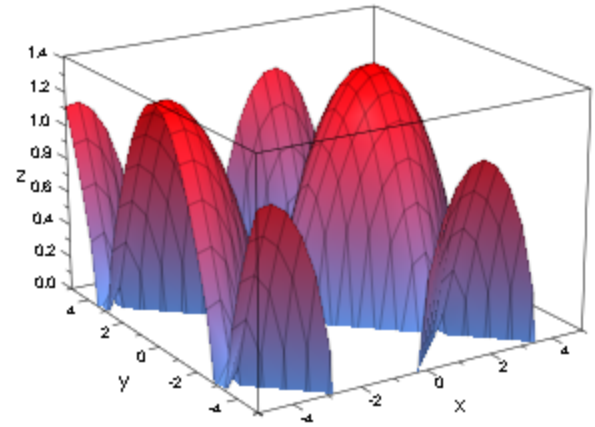


Example 6

Functions need not be defined over the whole parameter range:
plot(plot::Function3d(sqrt(1-x^2-y^2), x=-1..1, y=-1..1))



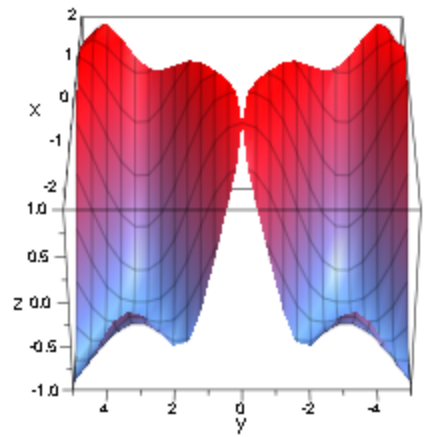
plot(plot::Function3d(sqrt(sin(x)+cos(y))))



This makes for an easy way of plotting a function over a non-rectangular area:
chi := piecewise([x^2 < abs(y), 1])piecewise([x^2 < abs(y), 1])

$$\begin{cases} 1 & \text{if } x^2 < |y| \end{cases}$$

plot(plot::Function3d(chi*sin(x+cos(y))), CameraDirection=[-1,0,0.5])



Parameters

f

The function: an arithmetical expression or a piecewise object in the independent variables *x*, *y* and the animation parameter `a`. Alternatively, a procedure that accepts 2 input parameter *x*, *y* or 3 input parameters *x*, *y*, *a* and returns a numerical value when the input parameters are numerical.

`f` is equivalent to the attribute Function.

x

The first independent variable: an identifier or an indexed identifier.

`x` is equivalent to the attribute XName.

x_{min} .. x_{max}

The plot range in *x* direction: x_{min}, x_{max} must be numerical real values or expressions of the animation parameter *a*. If not specified, the default range `x = -5 .. 5` is used.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

y

The second independent variable: an identifier or an indexed identifier.

`y` is equivalent to the attribute YName.

y_{min} .. y_{max}

The plot range in *y* direction: y_{min}, y_{max} must be numerical real values or expressions of the animation parameter *a*. If not specified, the default range `y = -5 .. 5` is used.

y_{min} .. y_{max} is equivalent to the attributes YRange, YMin, YMax.

a

Animation parameter, specified as `a =` a_{min}`..`a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplotfunc2dplotfunc3dplot::Function2dplot::Surface

plot::Hatch

Purpose

Hatched area

Syntax

```
plot::Hatch(f1, f2, <x1 .. x2>, <a = amin .. amax>, options)
plot::Hatch(f1, <base>, <x1 .. x2>, <a = amin ..
amax>, options)
plot::Hatch(c, <a = amin .. amax>, options)
```

Description

`plot::Hatch(f)` hatches the area between the function `f` and the x-axis.

`plot::Hatch(f, base)` hatches the area between the function `f` and the horizontal line $y = base$.

`plot::Hatch(f, g)` hatches the area between the two functions `f` and `g`.

`plot::Hatch(c)` hatches the area enclosed by the curve `c`.

`plot::Hatch(f, base)` is the hatched area between a function `f` of type plot::Function2d and a line parallel to the x-axis with $y = base$. If `base` is omitted, the area between the function and the x-axis will be hatched (the baseline is assumed to be the x-axis). See "Example 1" on page 24-320.

`plot::Hatch( f1, f2)` is the hatched area between two functions f_1 and f_2. See "Example 2" on page 24-323.

`plot::Hatch(c)` is the hatched area enclosed by a plot::Curve2d. A curve is closed automatically by connecting the starting point and the end point. See "Example 3" on page 24-323.

The hatch may be restricted to the left and to the right by a range `x_..x_`. See "Example 4" on page 24-325.

The attributes FillColor and FillPattern can be used to change the color and pattern of the hatched area. See "Example 5" on page 24-328.

Note A `plot::Hatch` is only the hatched area *without* outlining functions or curves! To see the border lines, you need to plot them separately as demonstrated in the examples.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Baseline	constant second function delimiting hatch	
Color	the main color	RGB::Red
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	`DiagonalLines`
Frames	the number of frames in an animation	`50`
Function1	first function/curve delimiting hatch	
Function2	second function delimiting hatch	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	

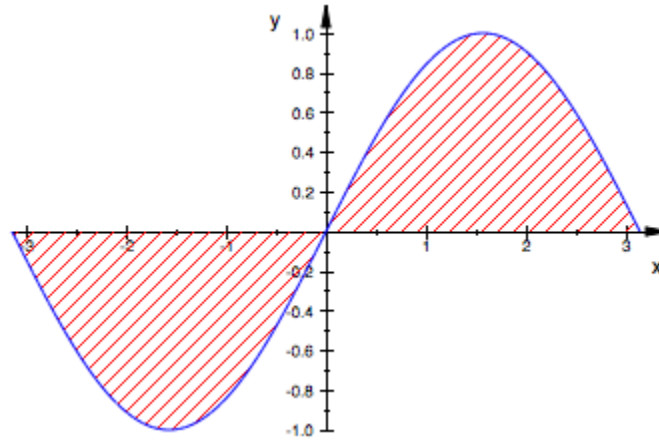
Attribute	Purpose	Default Value
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`
XMax	final value of parameter “x”	`infinity`
XMin	initial value of parameter “x”	`-infinity`
XRange	range of parameter “x”	`-infinity .. infinity`

Examples

Example 1

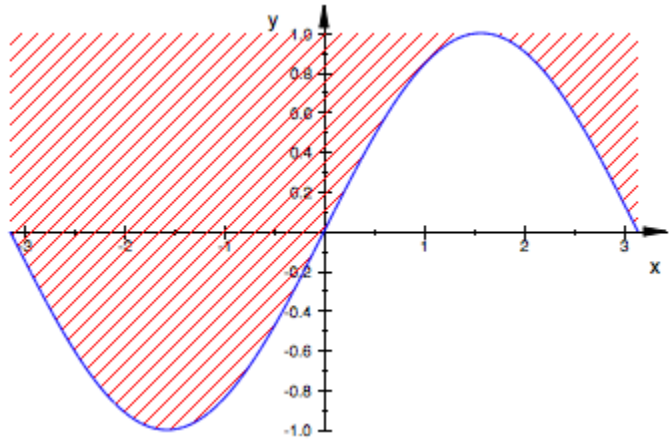
If given a single `plot::Function2d` object, `plot::Hatch` hatches the area between the curve and the x-axis:

```
f := plot::Function2d(sin(x), x = -PI..PI): plot(plot::Hatch(f), f)
```



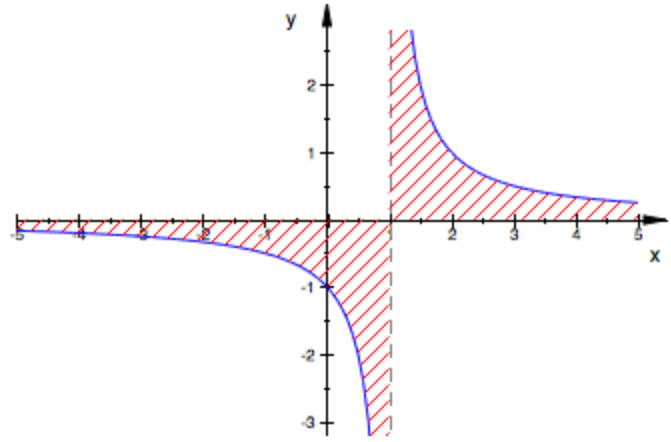
Note that `plot::Hatch` requires an *object* of type plot::Function2d, not just a function expression:
plot::Hatch(sin(x)) Error: No 'plot::Function2d' or 'plot::Curve2d' is given. [plot::Hatch::new]

`plot::Hatch` can be asked to hatch the area between a function graph and some constant value (i.e., some line parallel to the x-axis):
plot(plot::Hatch(f, 1), f)



For functions with poles, keeping VerticalAsymptotesVisible set to `TRUE` is highly recommended:

```
f := plot::Function2d(1/(x - 1)): h := plot::Hatch(f): plot(f, h)
```

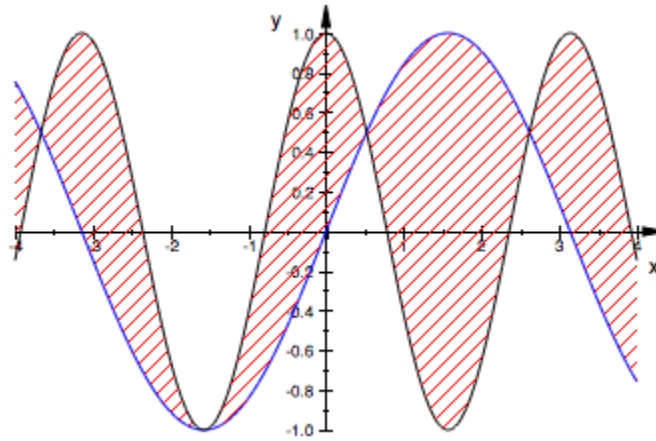


```
delete f, h:
```

Example 2

By passing two functions to `plot::Hatch`, we ask for a hatch of the area between the two:

```
f := plot::Function2d(sin(x), x = -4 .. 4, Color = RGB::Blue): g := plot::Function2d(cos(2*x), x = -4 .. 4, Color=RGB::Black): h := plot::Hatch(f, g): plot(f, g, h)
```

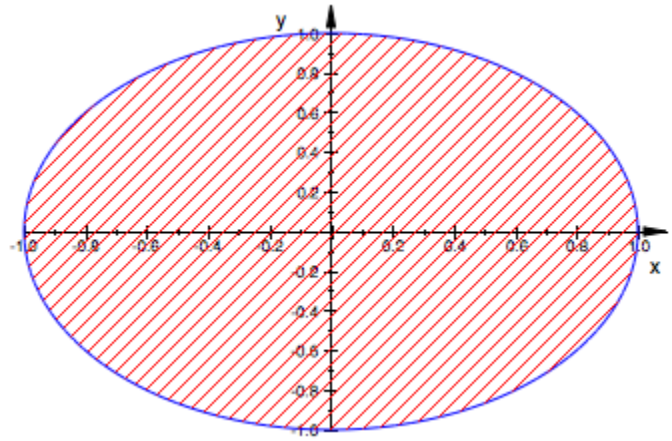


delete f, g, h:

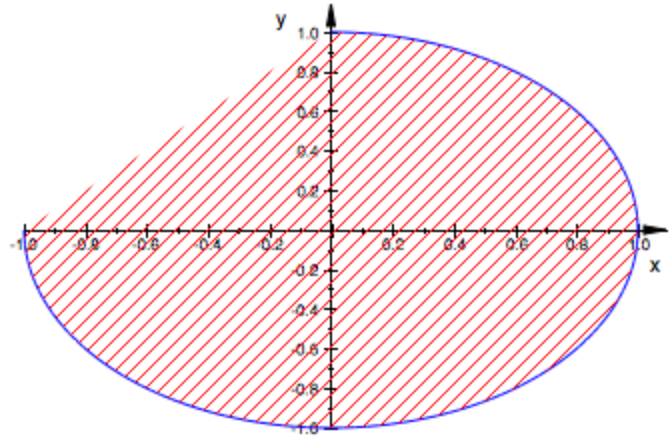
Example 3

`plot::Hatch` can also hatch the inner part of a plot::Curve2d object:

```
circle := plot::Curve2d([sin(t), cos(t)], t=0..2*PI): plot(circle, plot::Hatch(circle))
```



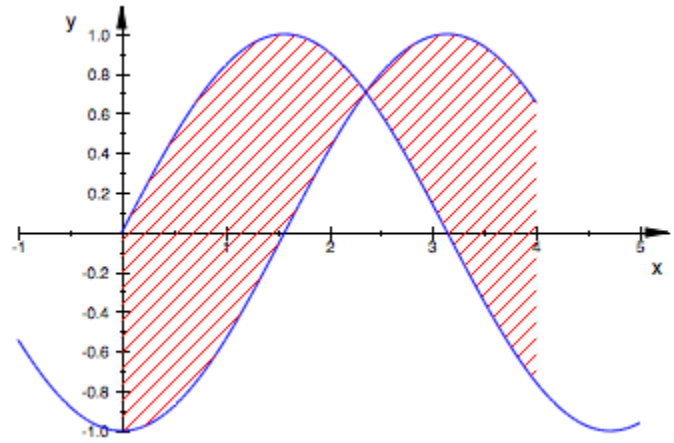
If the curve is not closed, `plot::Hatch` regards the first and last point to be connected:
circle::UMax := 3*PI/2: plot(circle, plot::Hatch(circle))



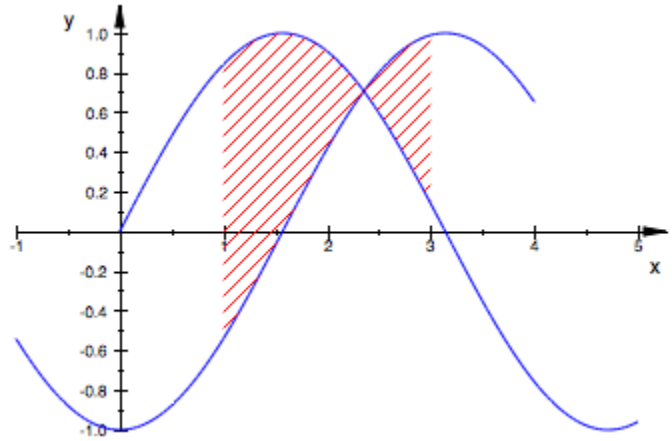
delete circle:

Example 4

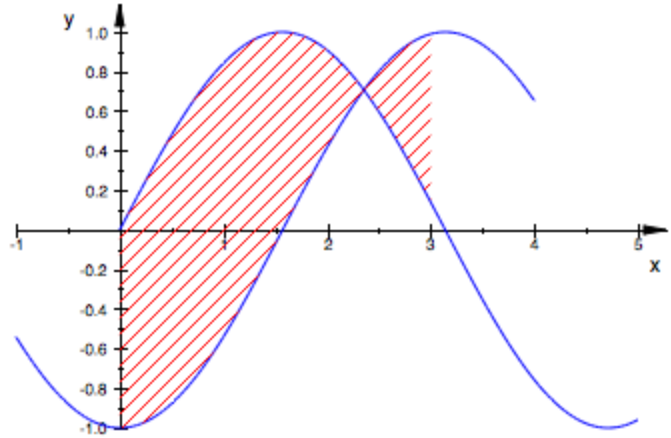
By default, `plot::Hatch` extends as far to the left and right as possible without leaving the common definition area of all given functions:
f := plot::Function2d(sin(x), x = 0 .. 5): g := plot::Function2d(-cos(x), x = -1 .. 4): h := plot::Hatch(f, g): plot(f, g, h)



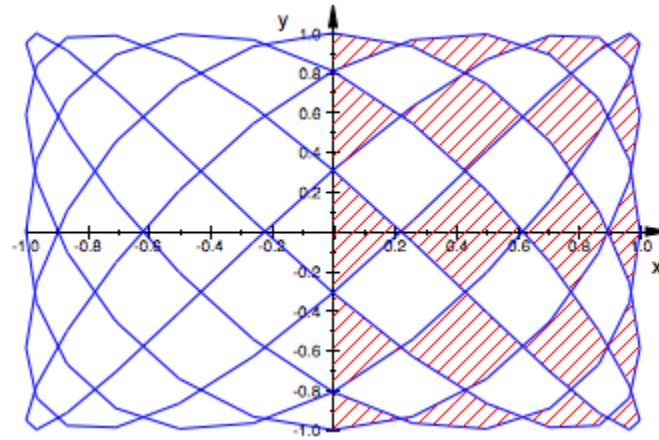
You can restrict this range by giving an explicit range of x values:
h := plot::Hatch(f, g, 1 .. 3): plot(f, g, h)



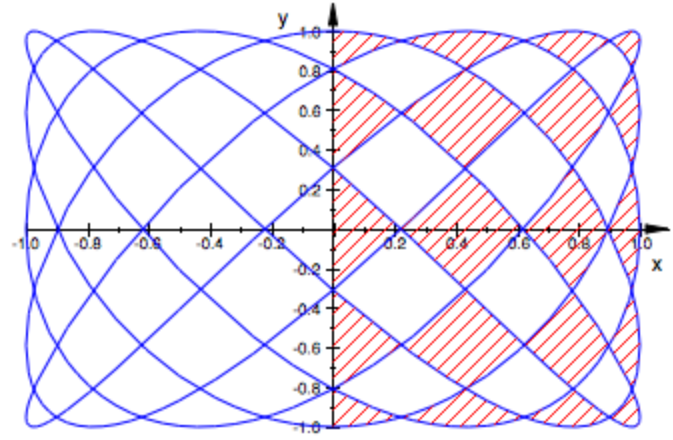
However, it is *not* possible to extend the range beyond the common definition range of both functions:
h := plot::Hatch(f, g, -1 .. 3): plot(f, g, h)



The restriction of the *x* range also works for hatching curve objects:
c := plot::Curve2d([sin(5*x), cos(7*x)], x = 0 .. 2*PI): h := plot::Hatch(c, 0 .. 1): plot(c, h)



Note that `plot::Hatch` reacts to the smoothness of the curve. This is one of the reasons why you have to provide a *objects* instead of expressions for the functions or curves:
c::AdaptiveMesh := 2: plot(c, h)

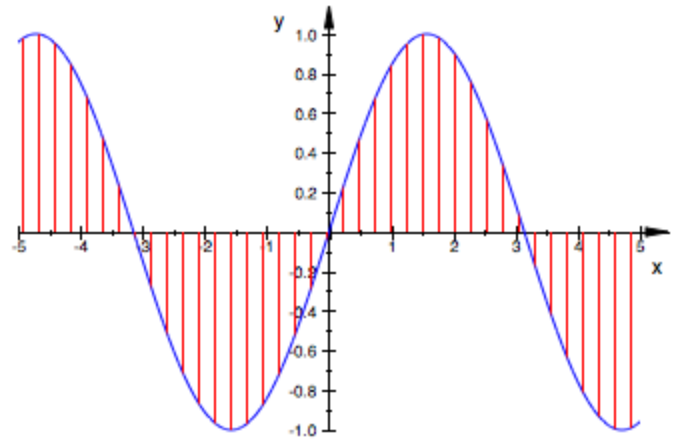


delete f, g, h, c:

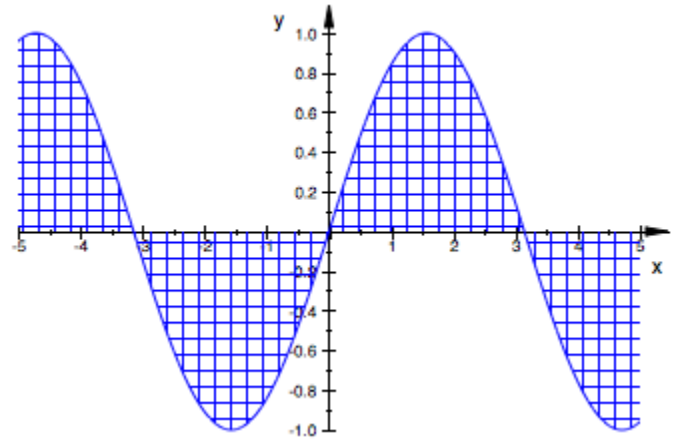
Example 5

One of the most useful attributes of `plot::Hatch` is FillPattern, which can take one of the values `DiagonalLines` (the default), `FDiagonalLines`, `HorizontalLines`, `VerticalLines`, `CrossedLines`, `XCrossedLines`, or `Solid`:
plot::attributes[FillPattern][3]{CrossedLines, DiagonalLines, FDiagonalLines, HorizontalLines, Solid, VerticalLines, XCrossedLines}

```
f := plot::Function2d(sin(x)): h := plot::Hatch(f, FillPattern =
{CrossedLines, DiagonalLines, FDiagonalLines, HorizontalLines, Solid, VerticalLines, XCrossedLines}
  VerticalLines): plot(f, h)
```



Another attribute that will often be useful is FillColor, to change the color of the hatch. We set the value right in our existing hatch object:
h::FillPattern := CrossedLines: h::FillColor := RGB::Blue: plot(f, h)

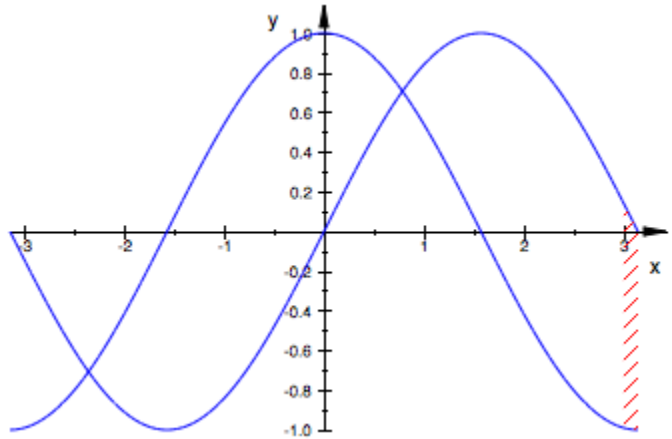


delete f, h:

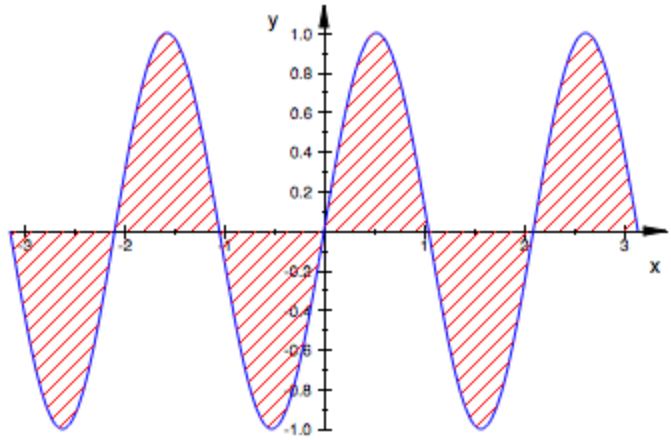
Example 6

The function(s) or curve, the baseline, and the restriction of the *x* range can be animated:

```
f := plot::Function2d(sin(x + a), x = -PI..PI, a = 0..2*PI): g :=
plot::Function2d(cos(x - a), x = -PI..PI, a = 0..4*PI): plot(f, g,
plot::Hatch(f, g, x0 .. x0+1, x0 = -PI..3))
```



f := plot::Function2d(sin(a*x), x=-PI..PI, a=0.2..3): plot(f, plot::Hatch(f))



delete f, g:

Example 7

A “hatch” may also be a solid area fill:
plot(plot::Hatch(plot::Curve2d([abs(r)*sin(r), abs(r)*cos(r)], r = -PI..PI), FillPattern = Solid, FillColor = RGB::Red, Axes = None))

Parameters

f_1

f_2

The outlining function(s) of the hatch: objects of type plot::Function2d.

f_1, f_2 are equivalent to the attributes Function1, Function2.

c

The outlining curve of the hatch: a parametrized curve of type plot::Curve2d.

c is equivalent to the attribute Function1.

base

The base line of the hatch: a numerical real value or an arithmetical expression of the animation parameter a.

base is equivalent to the attribute Baseline.

x_1 .. x_2

A range on the x-axis limiting the hatch to the left and the right hand side:numerical real values or arithmetical expressions of the animation paramater a.

x_1 .. x_2 is equivalent to the attributes XMin, XMax, XRange.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Curve2dplot::Function2dplot::Sweep

plot::Histogram2d

Purpose

Histogram plots of data

Syntax

```
plot::Histogram2d(data, <a = a_min .. a_max>, options)
```

Description

`plot::Histogram2d` creates a histogram plot of the given data, showing the frequency distribution in a user-definable cell array.
plot::getDefault(plot::Histogram2d::Cells)[7]

[7]

By default, data is grouped into 7 classes of equal width. To increase the number of cells, but still have them be of equal width, set `Cells = [n]`, as in “Example 1” on page 24-337. For full control over the classes, set `Cells` to a list specifying the cells, as in “Example 2” on page 24-339.

As long as the attribute Area is not changed from its default value of 0, `plot::Histogram2d` displays the absolute number of data in a class as the height of the corresponding bar. With `Area = a`, `a > 0`, the whole plot will take area `a`, with each rectangle area proportional to the number of data points in its cell. “Example 3” on page 24-340 shows the difference in detail.

By default, cells (“classes”) given by the attribute Cells = `[a_1 .. b_1, a_2 .. b_2, dots]` are interpreted as a collection of semi-open intervals Interval(a[i], [b[i]])$(a_i, b_i]$ that are closed at the right boundary. A data item `x` is tallied into the i-th cell if it satisfies $a_i < x \quad b_i$. Use the option CellsClosed = `Left` or the equivalent ClassesClosed = `Left` to interpret the classes as the semi-open intervals Interval([a[i]], b[i])$[a_i, b_i)$ that are closed at the left boundary.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Area	the area of a histogram plot	`0`
Cells	classes of histogram plots	[7]
CellsClosed	interpretation of the classes in histogram plots	`Right`
ClassesClosed	interpretation of the classes in histogram plots	[`Right`]
Color	the main color	RGB::GeraniumLake
Data	the (statistical) data to plot	
DrawMode	orientation of boxes and bars	`Vertical`
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::GeraniumLake
FillPattern	type of area filling	`Solid`
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	

Attribute	Purpose	Default Value
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Black
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`

Attribute	Purpose	Default Value
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

Example 1

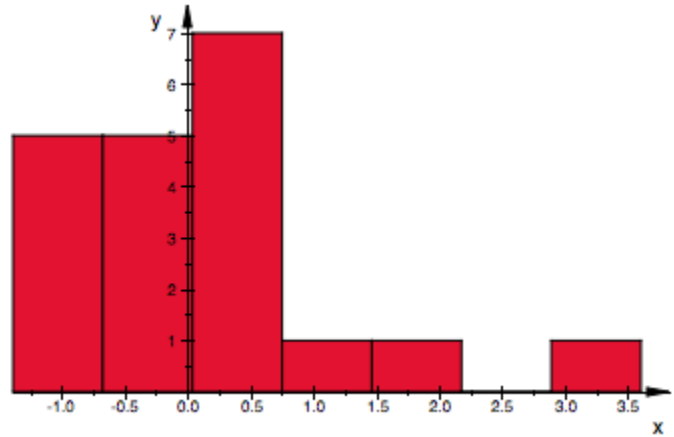
To plot a histogram of a normally distributed process, we first create a generator of random numbers with this distribution:
X := stats::normalRandom(0, 1)‘proc X() ... end‘

```
proc X() ... end
```

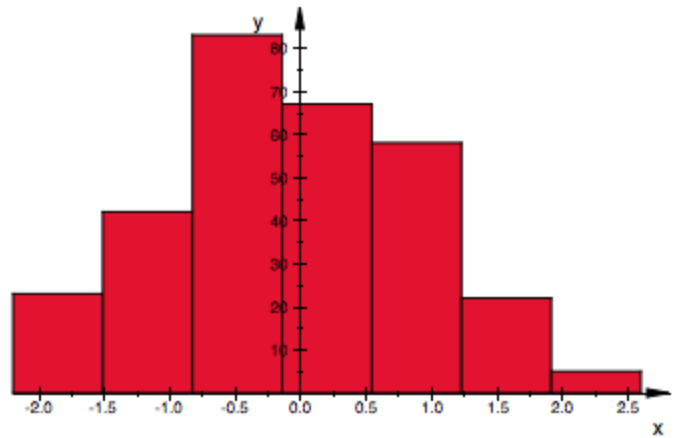
Next, we create a small number of “measurements”:
data := [X() $ i = 1..20][-0.5297400457, -0.5694234147, -0.5161446272, -1.090814471, 1.782520584, 0.6370330472, 0.6902341601, 0.3399758858, 1.177699186, -0.5970692982, -1.386247581, -0.9783222199, -0.7891413081, 0.2090732178, 0.2186783746, -0.7392138209, 0.6496128588, 0.6258699055, 3.606896706, -0.3319378999]

This data is ready to be put into `plot::Histogram2d`:
plot(plot::Histogram2d(data))

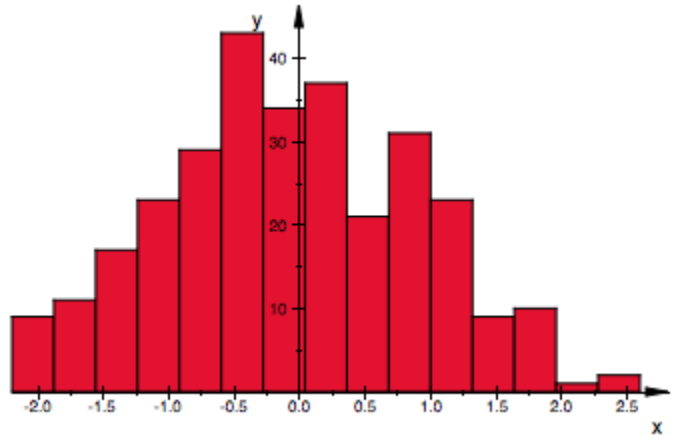
```
[-0.5297400457, -0.5694234147, -0.5161446272, -1.090814471, 1.782520584, 0.6370330
  1.177699186, -0.5970692982, -1.386247581, -0.9783222199, -0.7891413081, 0.2090732
  0.6496128588, 0.6258699055, 3.606896706, -0.3319378999]
```



This plot, if nothing else, shows that 20 samples are very few. Let us repeat the process with more data:
data := [X() $ i = 1..300]: plot(plot::Histogram2d(data))



On the other hand, this amount of data certainly justifies a finer classification:
plot(plot::Histogram2d(data, Cells = [15]))



Example 2

It is also possible to give the cells (classes) directly. To do so, you should give them as ranges or lists with two elements, as in the following example:

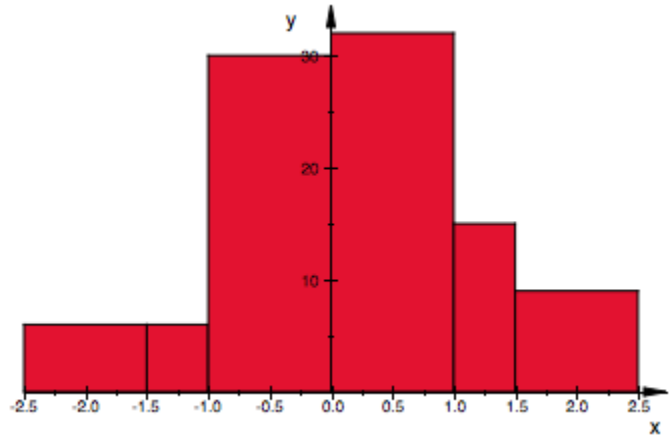
```
X := stats::normalRandom(0, 1): data := [X() $ i = 1 .. 100]: min(data), max(data)-3.266420216, 2.409775834
```

```
-3.266420216, 2.409775834
```

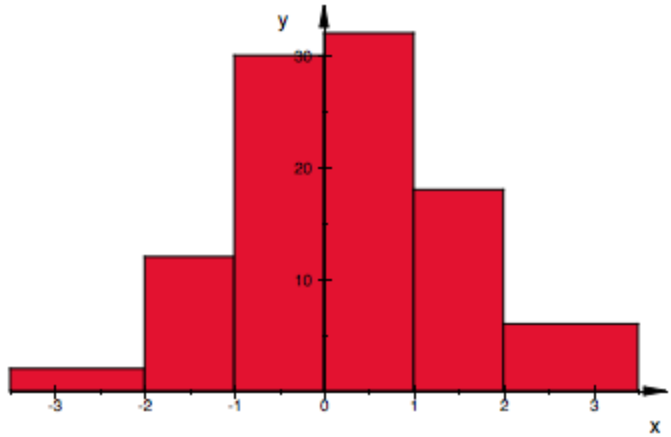
```
h := plot::Histogram2d(data, Cells = [-2.5..-1.5, -1.5..-1, -1..0, 0..1, 1..1.5, 1.5..2.5])‘plot::Histogram2d(...)‘
```

```
plot::Histogram2d(...)
```

```
plot(h)
```



It is even possible to use - `infinity` and `infinity` as border values in the cells:
h::Cells := [-infinity..-2, -2..-1, -1..0, 0..1, 1..2, 2..infinity]: plot(h)

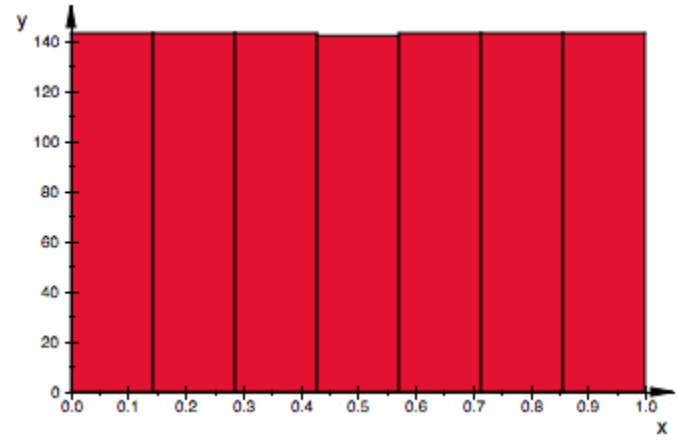


Example 3

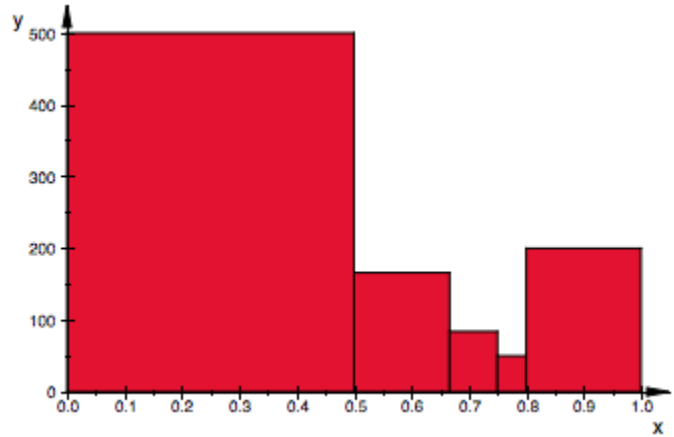
One potential problem with classes of non-equal width is that still the *height* of the bars corresponds to the *number* of data points in a class.

To see why this may be a problem, consider data perfectly uniformly distributed:
data := [i/1000 $ i = 1..1000]:

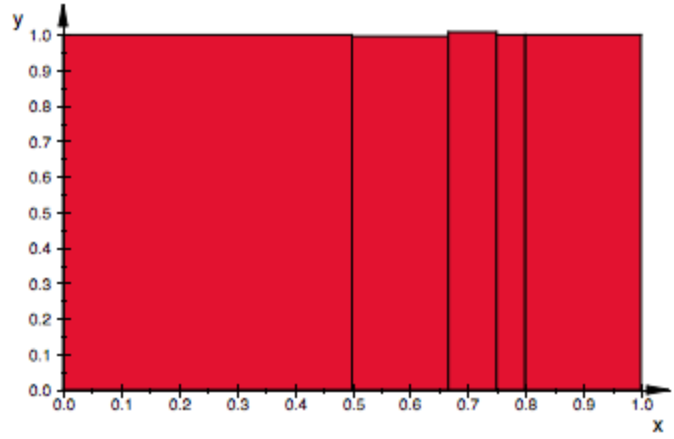
Plotting a histogram of this data, we see only very small deviations from a rectangle, caused by the fact that 1000 and 7 are coprime:
plot(plot::Histogram2d(data))



However, plotting a histogram with uneven classes, the image looks very much different:
plot(plot::Histogram2d(data, Cells = [0..1/2, 1/2..2/3, 2/3..3/4, 3/4..4/5, 4/5..1]))

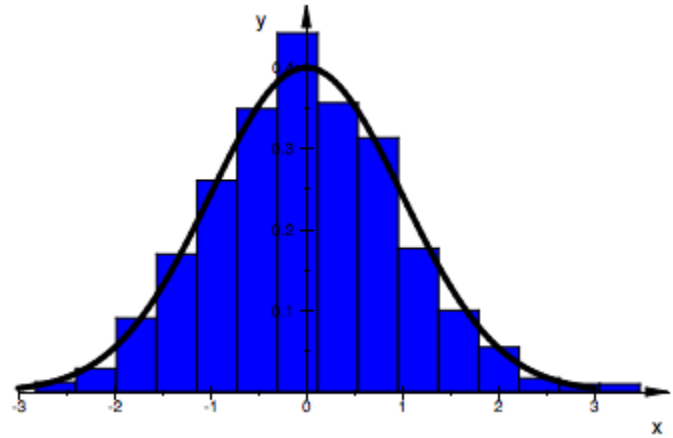


To make not the *height*, but rather the *area* of a bar depend on the number of samples in a class, set Area to a positive value:
plot(plot::Histogram2d(data, Cells = [0..1/2, 1/2..2/3, 2/3..3/4, 3/4..4/5, 4/5..1], Area = 1))



Note that with `Area = 1`, a histogram plot is scaled accordingly to the probability density function of the variable displayed:

```
X := stats::normalRandom(0, 1): data := [X() $ i = 1..1000]: h :=
plot::Histogram2d(data, Cells = [15], Area = 1, Color = RGB::Blue):
f := plot::Function2d(stats::normalPDF(0, 1), x = -3..3, LineWidth =
1*unit::mm, Color = RGB::Black): plot(h, f)
```



delete X, data, h, f:

Parameters

data

The data to plot: A list of real values or expressions in the animation parameter `a`.

`data` is equivalent to the attribute Data.

a

Animation parameter, specified as `a = a`$_{min}$`..a`$_{max}$, where `a`$_{min}$ is the initial parameter value, and `a`$_{max}$ is the final parameter value.

See Also

plotplot::copystats::frequencyplot::Bars2dplot::Boxplotplot::Scatterplot

plot::Implicit2d

Purpose

Contour lines of a function from R^2 to R

Syntax

```
plot::Implicit2d(f, x = x_min .. x_max, y = y_min .. y_max,
<a = a_min .. a_max>, options)
```

Description

`plot::Implicit2d(f(x, y), x = `x_{min}`..`x_{max}` , y = `y_{min}`..`y_{max}` )` plots the curves where the smooth function `f` is zero.

`plot::Implicit2d(f, x = `x_{min}`..`x_{max}` , y = `y_{min}`..`y_{max}` )` plots the zeroes of *f* in the given range, i.e., the set ImageSet(fenced(x,y), x_min <= x <= x_max, y_min <= y <= y_max, f(x, y) = 0) $\{(x, y) \mid x_min \le x \le x_max,\ y_min \le y \le y_max,\ f(x, y) = 0\}$.

`plot::Implicit2d` assumes that *f* is *regular almost everywhere* on this curve, which means that *f* must be differentiable and at least one of its partial derivatives must be nonzero.

To plot other contours than zeroes, use the option Contours.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Color	the main color	RGB::Blue
Contours	the contours of an implicit function	[0]
Frames	the number of frames in an animation	`50`

Attribute	Purpose	Default Value
Function	function expression or procedure	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`TRUE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`1`
Mesh	number of sample points	`[11, 11]`

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	

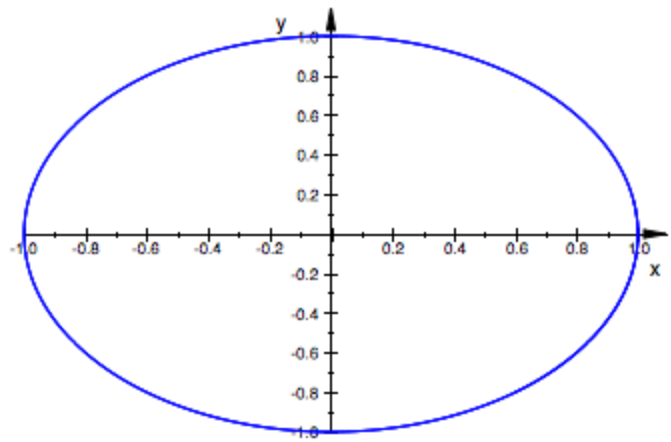
Attribute	Purpose	Default Value
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter “x”	
XMesh	number of sample points for parameter “x”	11
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YMax	final value of parameter “y”	
YMesh	number of sample points for parameter “y”	11

Attribute	Purpose	Default Value
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

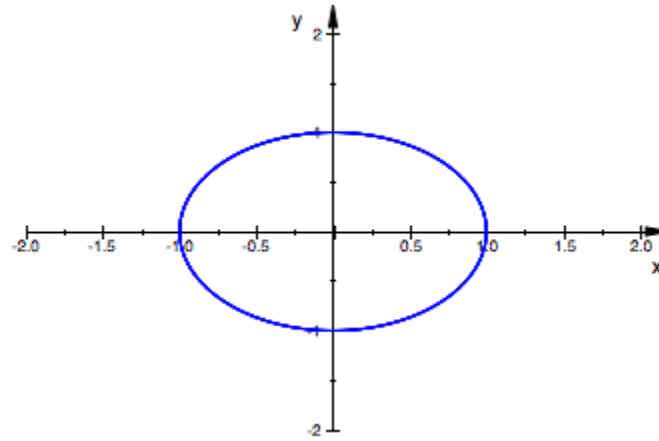
Examples

Example 1

It is well-known that a circle can be described as ImageSet(fenced(x,y), x^2+y^2 = r^2)$\{(x, y) \mid x^2 + y^2 = r^2\}$:
plot(plot::Implicit2d(x^2+y^2-1, x = -1..1, y = -1..1))

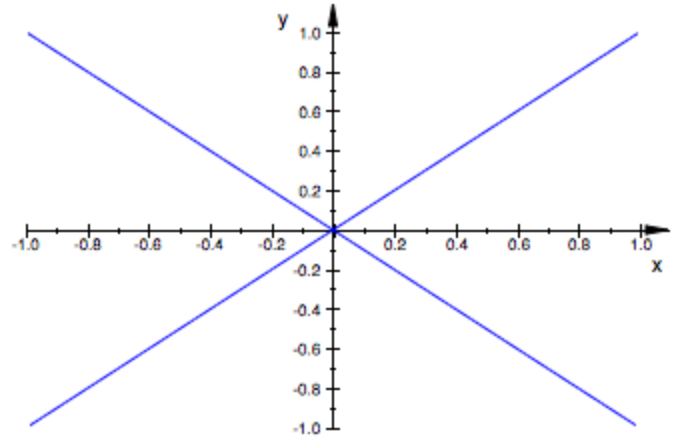


Note that `plot::Implicit2d` uses the given range completely, even if there is nothing to plot at a border:
plot(plot::Implicit2d(x^2+y^2-1, x = -2..2, y = -2..2))

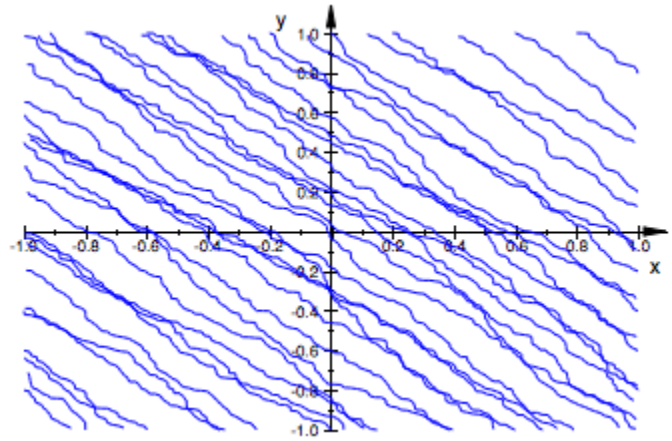


Example 2

`plot::Implicit2d` handles functions which are not regular at isolated points on the contours:
plot(plot::Implicit2d((x-y)*(x+y), x = -1..1, y = -1..1))

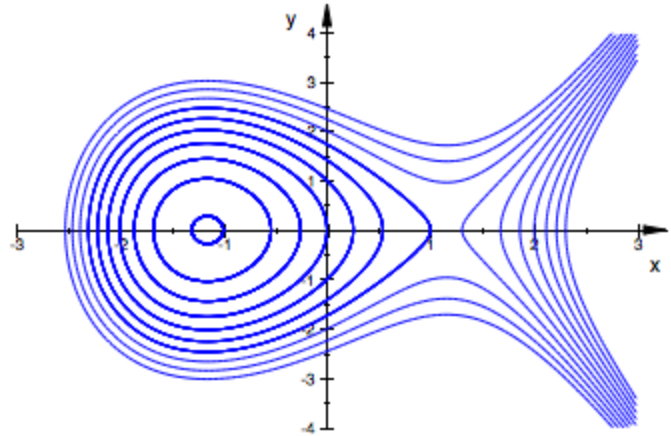


However, it fails if the function is singular on more than isolated points:
plot(plot::Implicit2d(0, x = -1..1, y = -1..1))



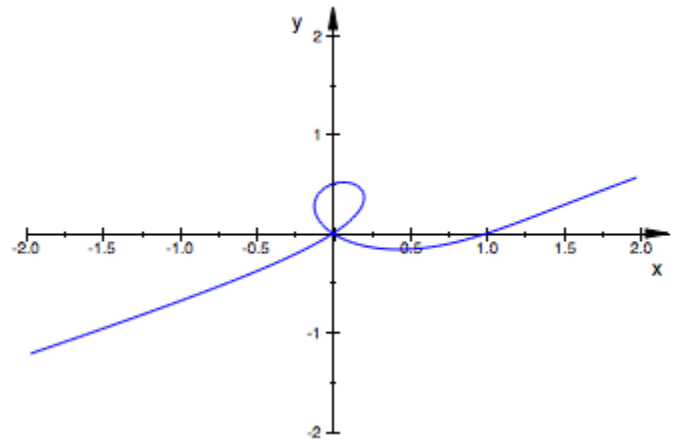
Example 3

We plot some of the elliptic curves $y^2 = x^3 + 4x + c$:
plot(plot::Implicit2d(y^2 - x^3 + 4*x, x = -3..3, y = -4..4, Contours = [c $ c = -3..6]))



Example 4

Like most graphical objects, `plot::Implicit2d` can be animated easily:
plot(plot::Implicit2d(x^2 - y^2 = (x - a*y)*(x^2 + y^2), x = -2..2, y = -2..2, a = -2..2))



Parameters

f

A real-valued expression or an equation in `x`, `y`, and possibly the animation parameter.

`f` is equivalent to the attribute Function.

x

y

identifiers.

`x`, `y` are equivalent to the attributes XName, YName.

$x_{min} .. x_{max}$

$y_{min} .. y_{max}$

Real-valued expressions, possibly in the animation parameter. The image is plotted with x in the range $x_min \le x \le x_max$ and $y_min \le y \le y_max$.

x_{min} .. x_{max}, y_{min} .. y_{max} are equivalent to the attributes XRange, XMin, XMax, YRange, YMin, YMax.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

Algorithms

plot::Implicit2d uses a curve tracking method: It first generates starting points on the curve and then uses a predictor-corrector method to follow the curve thus found in both directions, using the implicit function theorem.

See Also

plotplot::copyplot::Curve2dplot::Implicit3d

plot::Implicit3d

Purpose

Contour surfaces of a function from R^3 to R

Syntax

```
plot::Implicit3d(f, x = x_min .. x_max, y = y_min .. y_max, z
= z_min .. z_max, <a = a_min .. a_max>, options)
```

Description

`plot::Implicit3d(f(x, y, z), x = `x_{min}`..`x_{max}` , y = `y_{min}`..`y_{max}` , z = `z_{min}`..`z_{max}` )` plots the surfaces where the smooth function `f` is zero.

`plot::Implicit3d(f, x = `x_{min}`..`x_{max}` , y = `y_{min}`..`y_{max}` , z = `z_{min}`..`z_{max}` )` plots the (two-dimensional part of the) zeroes of *f* in the given range, i.e., the set ImageSet(fenced(x,y,z), x_min <= x <= x_max, y_min<= y <= y_max, z_min<= z <= z_max, f(x, y, z)=0) $\{(x, y, z) \mid x_{min} \le x \le x_{max}, y_{min} \le y \le y_{max}, z_{min} \le z \le z_{max}, f(x, y, z) = 0\}$.

`plot::Implicit3d` assumes that *f* is *regular almost everywhere* on this surface, which means that *f* must be differentiable and at least two of its partial derivatives must be nonzero.

`plot::Implicit3d` evaluates the given function on an equidistant, three-dimensional mesh, the coarsity of which can be set with the attributes XMesh, YMesh, and ZMesh for each of the three directions, or with the combining attribute Mesh that sets all three of these simultaneously.

After finding an initial triangulation of the surface from the numerical data on the initial grid, `plot::Implicit3d` optionally performs adaptive subdivision of the triangles. To make a long story short: If the initial calculation misses details altogether, adaptive refinement will not find them either. On the other hand, if the initial calculation shows spurious spikes, adaptive refinement will result in a much more realistic image, at the expense of time; the higher the value of AdaptiveMesh, the more. Increasing `AdaptiveMesh` by one may in extreme cases increase calculation time by a factor of eight or more!

The details of the algorithm are as follows: On top level, the “effective adaptive level” is set to the value of the attribute `AdaptiveMesh`. If, for

a given edge, the effective adaptive level is positive and the edge is not very short already, compared with the size of the complete image, and inserting a new point on the implicit surface near the middle of this edge would cause the two new edges to have an angle of less than 170 degrees, then the edge is split, the adjoining triangles are split accordingly (taking into account all their edges) and all the new edges caused by this operation are examined with an effective adaptive level reduced by one.

To plot other contours than zeroes, use the option Contours.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	`0`
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::Red
Contours	the contours of an implicit function	`[0]`
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`
FillColorFunction	functional area/surface coloring	

Attribute	Purpose	Default Value
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Function	function expression or procedure	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Black.[0.15]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid

Attribute	Purpose	Default Value
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`0`
LineColorDirectionZ	z-component of the direction of color transitions on lines	`1`
Mesh	number of sample points	`[11, 11, 11]`
MeshVisible	visibility of irregular mesh lines in 3D	`FALSE`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	

Attribute	Purpose	Default Value
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`FALSE`
Shading	smooth color blend of surfaces	`Smooth`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	

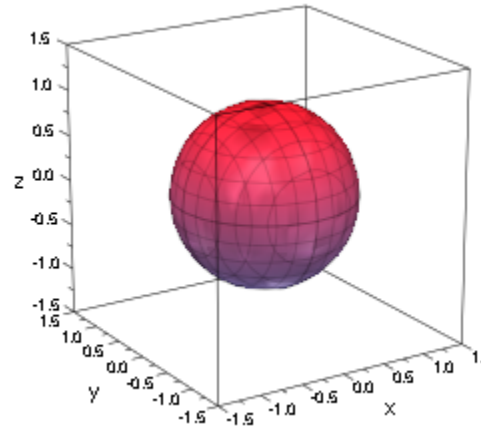
Attribute	Purpose	Default Value
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XContours	contour lines at constant x values	[Automatic, 15]
XMax	final value of parameter “x”	
XMesh	number of sample points for parameter “x”	11
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YContours	contour lines at constant y values	[Automatic, 15]
YMax	final value of parameter “y”	

Attribute	Purpose	Default Value
YMesh	number of sample points for parameter “y”	11
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	
ZContours	contour lines at constant z values	[Automatic, 15]
ZMax	final value of parameter “z”	
ZMesh	number of sample points for parameter “z”	11
ZMin	initial value of parameter “z”	
ZName	name of parameter “z”	
ZRange	range of parameter “z”	

Examples

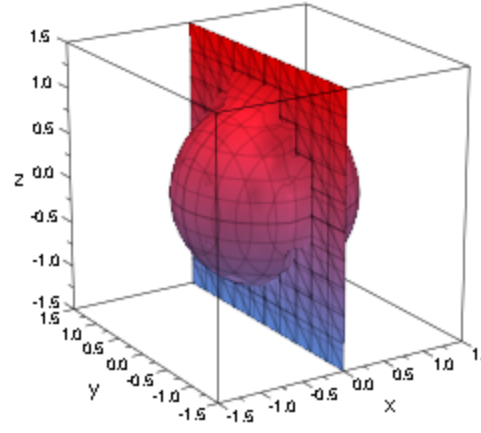
Example 1

The set of x, y, z where $x^2 + y^2 + z^2 = 1$ form a sphere:
plot(plot::Implicit3d(x^2 + y^2 + z^2 - 1, x = -1.5..1.5, y = -1.5..1.5, z = -1.5..1.5), Scaling = Constrained)

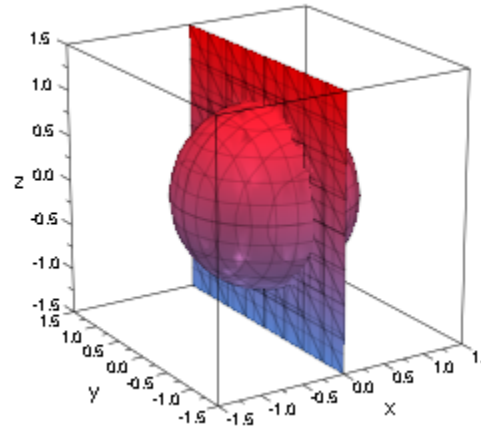


Example 2

The set of zeroes of a product is the union of the zeroes of the individual functions:
plot(plot::Implicit3d((x^2 + y^2 + z^2 - 1) * x, x = -1.5..1.5, y = -1.5..1.5, z = -1.5..1.5), Scaling = Constrained)

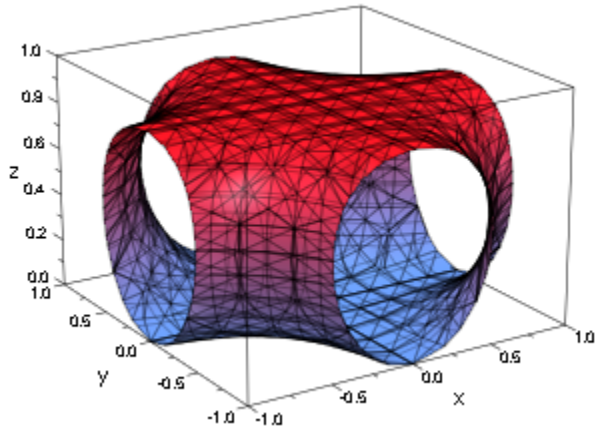


Note that this image is largely dominated by artifacts caused by the coarse evaluation mesh. Increasing this mesh improves the graphics, but increases computation time:
plot(plot::Implicit3d((x^2 + y^2 + z^2 - 1) * x, x = -1.5..1.5, y = -1.5..1.5, z = -1.5..1.5, Mesh = [21, 9, 9], AdaptiveMesh = 2), Scaling = Constrained)



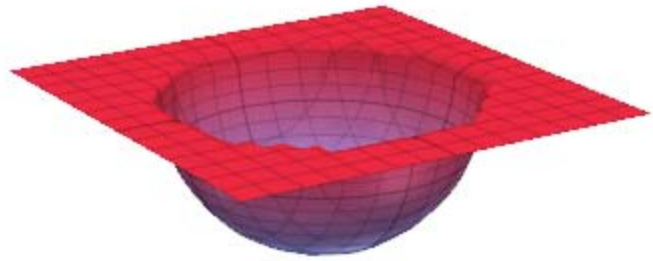
Example 3

With `MeshVisible = TRUE`, the internal triangulation becomes visible:
plot(plot::Implicit3d(z^2 - sin(z - x^2*y^2) = 0, x = -1 .. 1, y = -1 .. 1, z = 0 .. 1, AdaptiveMesh = 2, MeshVisible = TRUE, LineColor = RGB::Black.[0.25])):



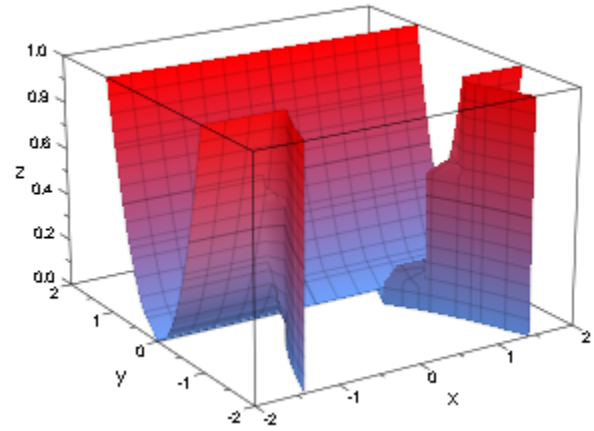
Example 4

Using functions that are not continuously differentiable, it is possible to generate sharp edges in the images:
plot(plot::Implicit3d(min(x^2 + y^2 + z^2 - 2, -z), x = -2..2, y = -2..2, z = -1.5..0.5), Axes = None, Scaling = Constrained)

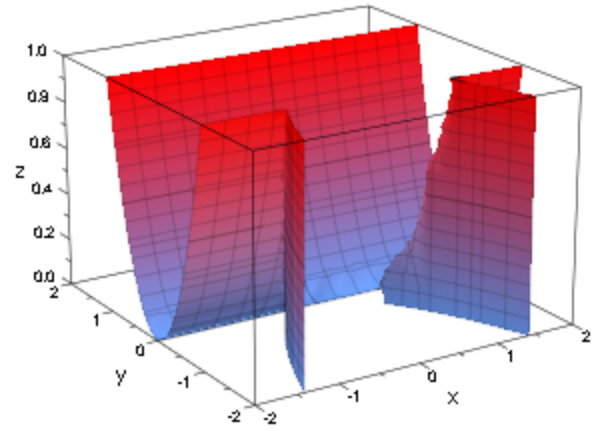


Just like in the preceding example, these sharp corners are prime sources of artifacts, which may require a finer initial mesh and/or adaptive mesh refinement:

```
im := plot::Implicit3d(min(x^2 + y, y^2 - z), x = -2..2, y = -2..2, z = 0..1):
plot(im)
```

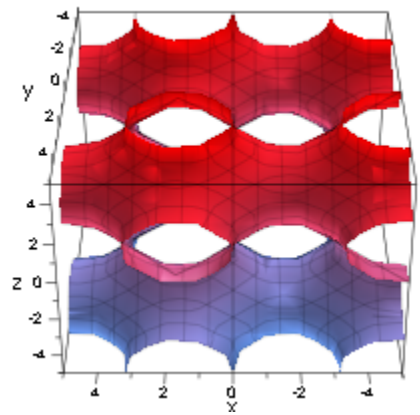


```
plot(im, AdaptiveMesh = 3)
```



Example 5

Animating `plot::Implicit3d` objects takes a lot of time. It is easy and fast, though, to add an animated camera object:
plot(plot::Implicit3d(sin(x)+sin(y)+sin(z), x=-5..5, y=-5..5, z=-5..5), plot::Camera([42*sin(t),42*cos(t),42*cos(t-sin(t))], [0,0,0], PI/12, t=0..2*PI), AnimationStyle=Loop)



Parameters

f

A real-valued expression or an equation in `x`, `y`, `z`, and possibly the animation parameter.

`f` is equivalent to the attribute Function.

x

y

z

identifiers.

`x`, `y`, `z` are equivalent to the attributes XName, YName, ZName.

$x_{min} .. x_{max}$

y_{min} .. y_{max}

z_{min} .. z_{max}

Real-valued expressions, possibly in the animation parameter. The image is plotted with x in the range x_{min} x x_{max}, y_{min} y y_{max} and z_{min} z z_{max}.

x_{min} .. x_{max}, y_{min} .. y_{max}, z_{min} .. z_{max} are equivalent to the attributes XRange, XMin, XMax, YRange, YMin, YMax, ZRange, ZMin, ZMax.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Implicit2dplot::Surface

plot::Inequality

Purpose

Display areas where inequalities are fulfilled

Syntax

```
plot::Inequality(ineq, x = x_min .. x_max, y = y_min ..
y_max, <a = a_min .. a_max>, options)
plot::Inequality([ineq_1,  ], x = x_min .. x_max, y = y_min ..
y_max, <a = a_min .. a_max>, options)
```

Description

`plot::Inequality(f(x, y) < g(x, y), x = `x_{min}`..`x_{max}` , y = `y_{min}`..`y_{max}` )` fills the rectangle x_{min} x x_{max}, y_{min} y y_{max} with several colors, indicating which points satisfy the inequality.

`plot::Inequality` computes a (more or less coarse) rasterization of the area specified by `` `x_{min}`..`x_{max}` `` and `` `y_{min}`..`y_{max}` `` and colors subareas according to whether all of the given inequalities are fulfilled (these are colored in FillColorTrue), at least one inequality is nowhere fulfilled in the subarea (FillColorFalse) or the granularity is insufficient to decide for either of these cases (FillColorUnknown).

You can control the density of the rasterization with the attribute Mesh. Cf. “Example 2” on page 24-371.

`plot::Inequality` uses interval numerics for evaluation, so the results are reliable, but certain special functions (such as hypergeom) cannot be used because they are not supported for intervals.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`FALSE`
FillPattern	type of area filling	`Solid`

Attribute	Purpose	Default Value
FillColorTrue	the color for “true” areas (inequality plot)	RGB::Green
FillColorFalse	the color for “false” areas (inequality plot)	RGB::Red
FillColorUnknown	the color for “unknown” areas (inequality plot)	RGB::Black
Frames	the number of frames in an animation	`50`
Inequalities	inequalities displayed in inequality plots	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`FALSE`
Mesh	number of sample points	[256, 256]
Name	the name of a plot object (for browser and legend)	

Attribute	Purpose	Default Value
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	

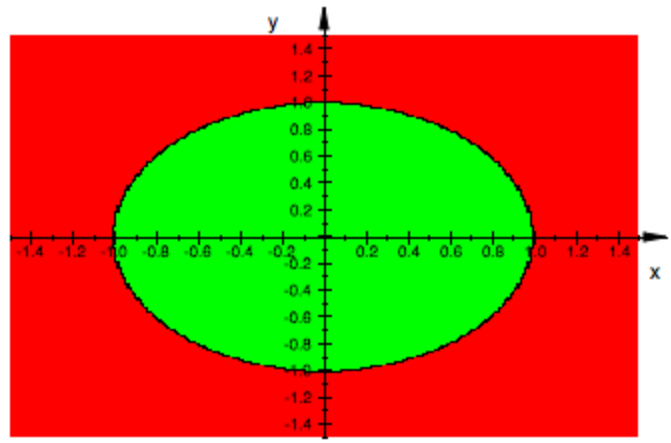
Attribute	Purpose	Default Value
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter “x”	
XMesh	number of sample points for parameter “x”	256
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YMax	final value of parameter “y”	
YMesh	number of sample points for parameter “y”	256
YMin	initial value of parameter “y”	

Attribute	Purpose	Default Value
YName	name of parameter “y”	
YRange	range of parameter “y”	

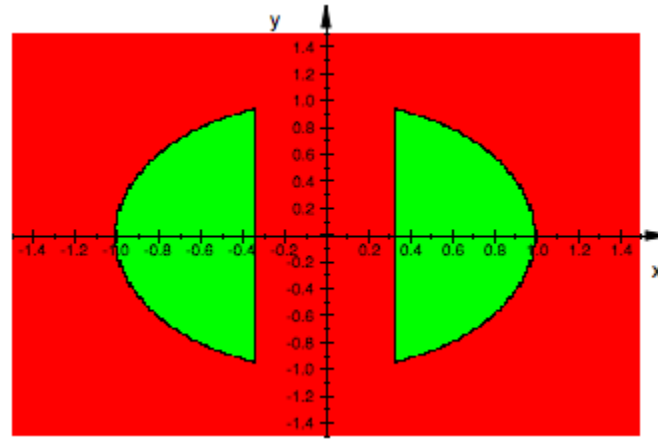
Examples

Example 1

With a single inequality, `plot::Inequality` colors the area where it is fulfilled or violated, with areas at the border line, where the inequality is fulfilled in some parts of the rectangle and violated in other parts:
plot(plot::Inequality(x^2 + y^2 < 1, x = -1.5..1.5, y = -1.5..1.5))

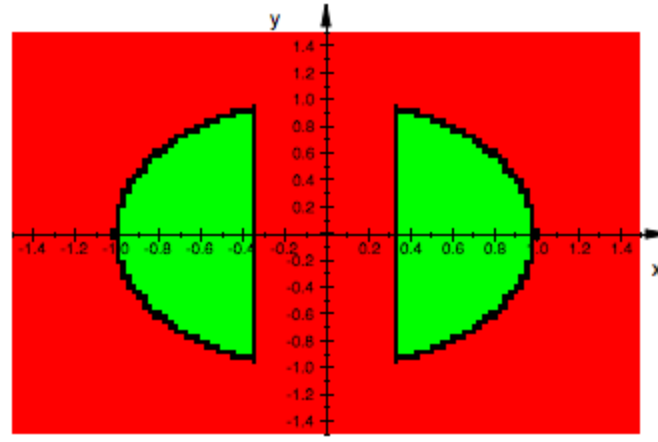


When giving more than one inequality, only those areas where *all* inequalities are fulfilled are painted in blue (or whatever you set `FillColorTrue` to), while all rectangles where *any* inequality is violated (over the whole rectangle) are colored red:
plot(plot::Inequality([x^2 + y^2 < 1, abs(x) > 1/3], x = -1.5..1.5, y = -1.5..1.5))



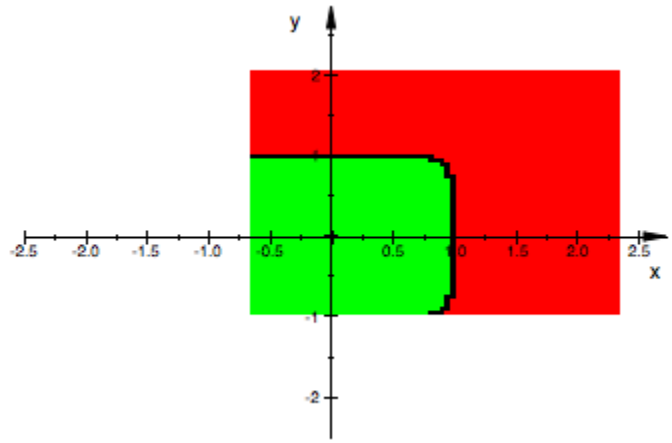
Example 2

To get a more detailed image from `plot::Inequality`, increase the mesh density:
plot(plot::Inequality([x^2 + y^2 < 1, abs(x) > 1/3], x = -1.5..1.5, y = -1.5..1.5, Mesh = [120, 80]))



Example 3

Almost all parameters of `plot::Inequality` can be animated (the mesh is one exception though):
plot(plot::Inequality([abs(x)^a + abs(y)^a < 1], x = -1.5+sin(a)..1.5+sin(a), y = -1.5+cos(a)..1.5+cos(a), Mesh = [64, 64], a = 1..2*PI+1))



Parameters

ineq, ineq$_1$, ...

Inequalities to plot: Expressions of the form `f(x, y) < g(x, y)`, `f(x, y) <= g(x, y)`, `f(x, y) = g(x, y)`, `f(x, y) >= g(x, y)`, or `f(x, y) > g(x, y)`.

`ineq`, `ineq`$_1$, ... is equivalent to the attribute Inequalities.

x

y

Identifiers or indexed identifiers. These denote the free variables spanning the plane.

`x`, `y` are equivalent to the attributes XName, YName.

x$_{min}$ .. x$_{max}$

y_{min} .. y_{max}

The ranges for x and y. x_{min}, x_{max}, y_{min}, and y_{max} must be real numerical values, or expressions of the animation parameter a.

x_{min} .. x_{max}, y_{min} .. y_{max} are equivalent to the attributes XRange, YRange.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Densityplot::Implicit2dplot::Raster

plot::Integral

Purpose

Numerical approximation of an integral

Syntax

```
plot::Integral(f, <n>, <IntMethod = m>, <a =
a_min .. a_max>, options)
```

Description

`plot::Integral(f, IntMethod = m)` visualizes the approximation of the integral of the function `f` using the numerical quadrature method `m`. Riemann sums, the trapezoidal rule, and the Simpson rule are available.

`plot::Integral(f, n, IntMethod = m)` uses `n` subintervals to approximate the integral.

The attribute IntMethod determines the numerical method. Riemann sums, the trapezoidal rule, or the Simpson rule are available. See the help page of IntMethod for further details. Cf. “Example 1” on page 24-378.

`plot::Integral` does not plot the function graph of the integrand. If the integrand is to be plotted, too, `f` has to be passed to the plot command together with the approximation object of type `plot::Integral`.

If no quadrature method is specified by IntMethod = m, `plot::Integral` just hatches the area between the function `f` and the x-axis.

Several `plot::Integral` objects can be plotted together to illustrate the difference between various quadrature methods. The order of the objects in the plot command determines the object in front.

The plot contains a text object providing information about the quadrature method, the value of the approximation, the exact value of the integral, the quadrature error, and the number of nodes. See the help page of the attribute ShowInfo for further details.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Color	the main color	RGB::PaleBlue
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::PaleBlue
FillPattern	type of area filling	`Solid`
Frames	the number of frames in an animation	`50`
Function1	first function/curve delimiting hatch	
HorizontalAlignment	horizontal alignment of text objects w.r.t. their coordinates	`Left`
IntMethod	method for integral approximation	`Exact`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Black
LineWidth	width of lines	`0.35`

Attribute	Purpose	Default Value
LineColor2	color of lines	RGB::Grey
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
Name	the name of a plot object (for browser and legend)	
Nodes	number of subintervals or list of x-values for subintervals	`[10]`
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`FALSE`

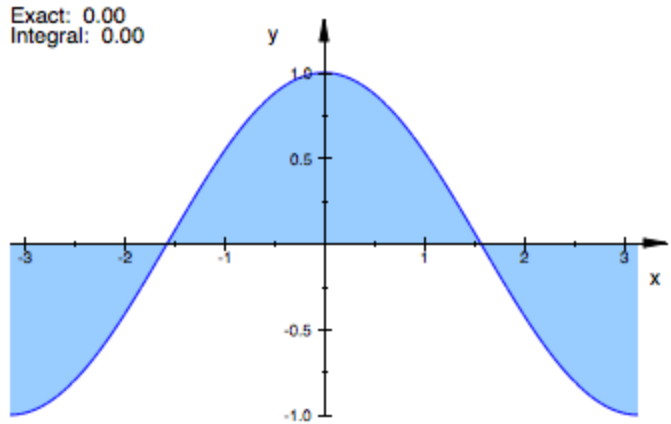
Attribute	Purpose	Default Value
ShowInfo	Information about integral approximation	[2, IntMethod, Integral]
TextFont	font of text objects	[" sans-serif ", 11]
TextRotation	rotation of a 2D text	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
VerticalAlignment	vertical alignment of text objects w.r.t. their coordinates	Bottom
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	

Attribute	Purpose	Default Value
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

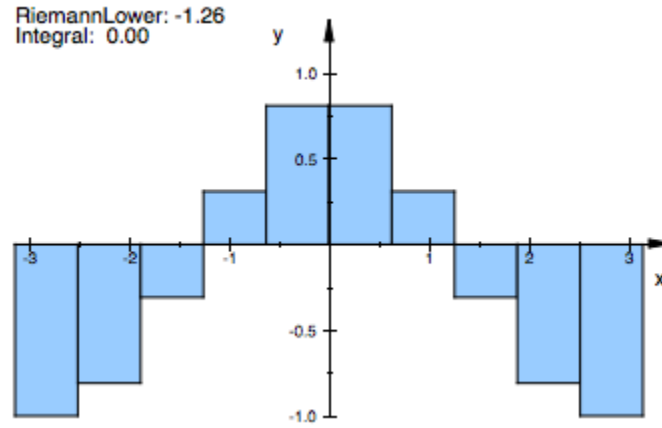
Example 1

If a single plot::Function2d object is given without specifying an approximation method, `plot::Integral` just hatches the area between the function graph and the x-axis:
f := plot::Function2d(cos(x), x = -PI..PI): plot(plot::Integral(f), f)

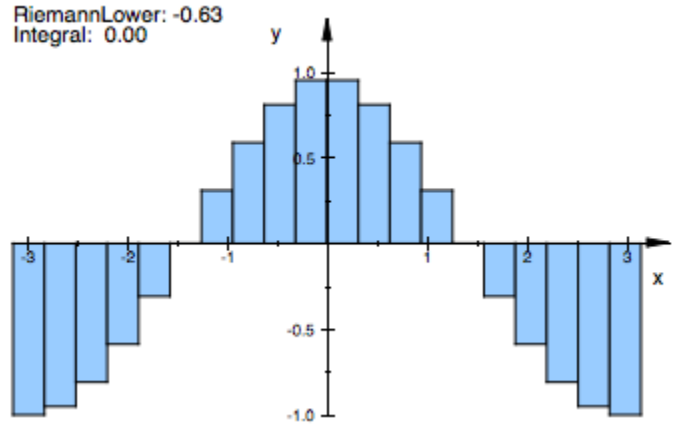


Note that `plot::Integral` requires an *object* of type plot::Function2d, not just a function expression:
plot::Integral(sin(x)) Error: The first argument must be a 'plot::Function2d' object. [plot::Integral::new]

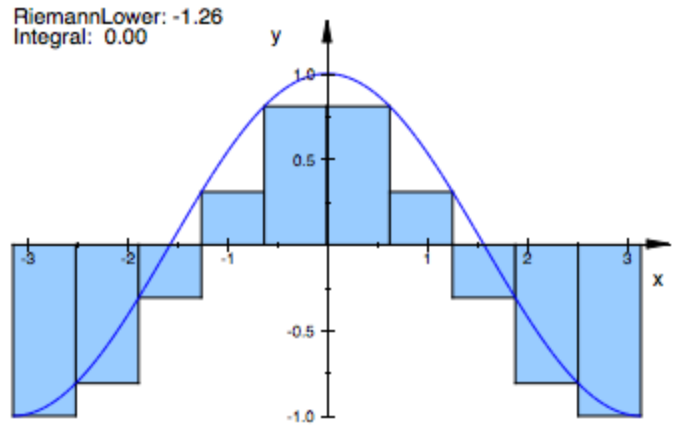
If an approximation method is specified, the numerical quadrature value computed by this method is displayed:
plot(plot::Integral(f, IntMethod = RiemannLower))



The number of quadrature intervals can be set by passing a second argument `n` or by specifying `Nodes = n`:
plot(plot::Integral(f, 20, IntMethod = RiemannLower))



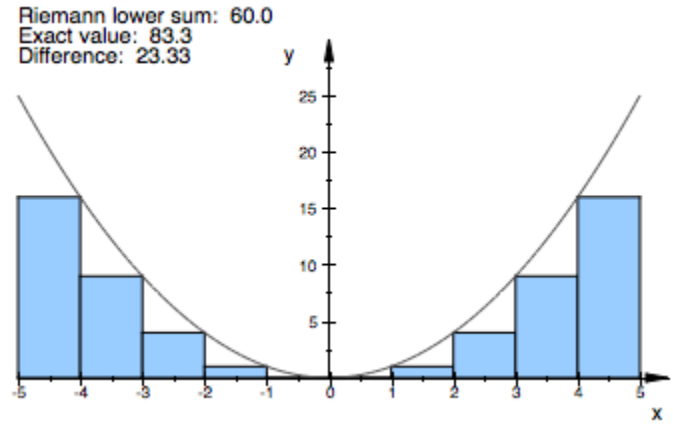
To see the integrand in the plot, the function object must be passed together with the approximation object. The order determines which object is in front:
plot(plot::Integral(f, IntMethod = RiemannLower), f)



delete f:

Example 2

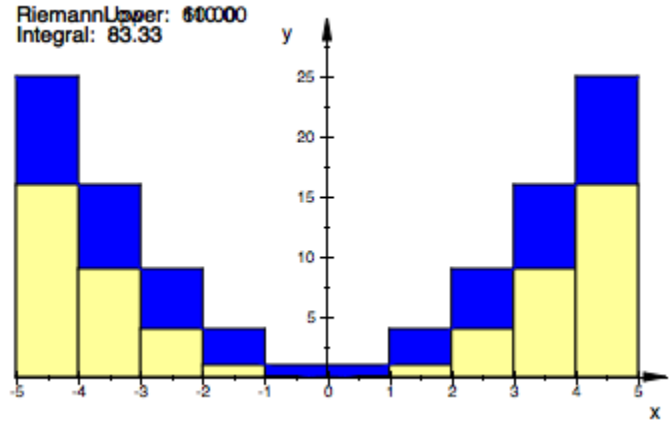
The displayed information can be configured by the user:
f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannLower, ShowInfo = [1, IntMethod = "Riemann lower sum", Integral = "Exact value", 2, Error = "Difference"]), f)



delete f:

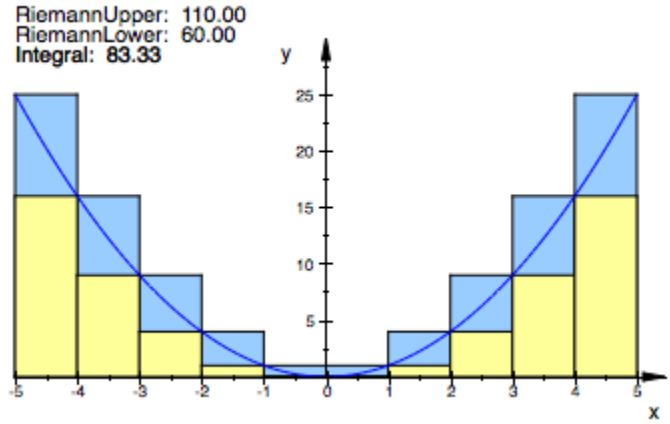
Example 3

One may combine several approximation objects, e.g., lower and upper sum:
f := plot::Function2d(x^2, x = -5..5): plot(plot::Integral(f, IntMethod = RiemannUpper, Color = RGB::Blue), plot::Integral(f, IntMethod = RiemannLower, Color = RGB::LightYellow), f)

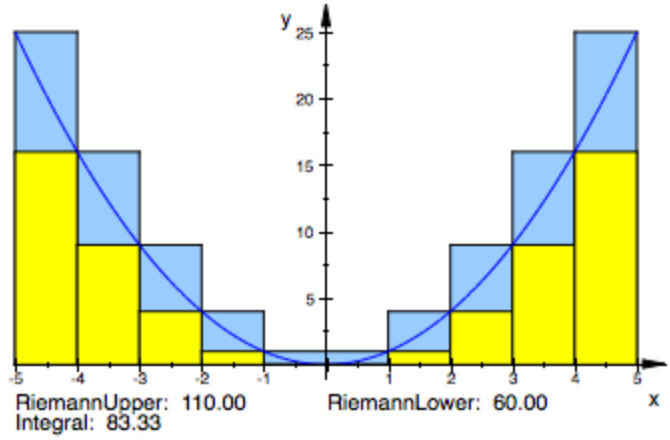


The automatically placed information texts overlap. To correct this, the option ShowInfo must be used. In the text of the upper sum, one additional empty line is inserted. Apart from this, both objects use the default value, therefore there is not need to specify `ShowInfo` in the second object:

```
plot(plot::Integral(f, IntMethod = RiemannUpper, ShowInfo =
[IntMethod, "", Integral]), plot::Integral(f, IntMethod = RiemannLower,
Color = RGB::LightYellow), f)
```



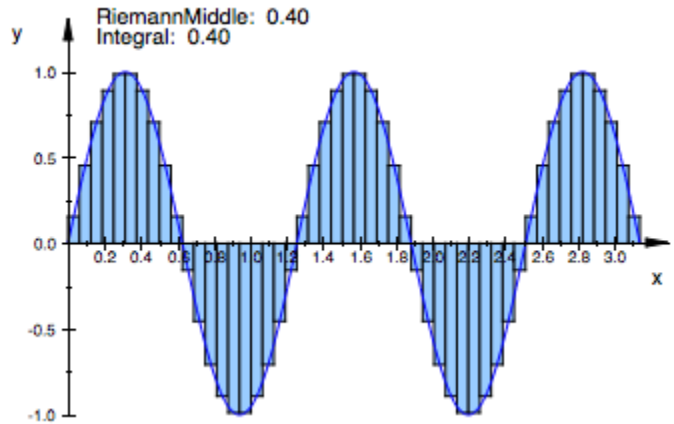
The info text can be positioned explicitly:
plot(plot::Integral(f, IntMethod = RiemannUpper, ShowInfo = [IntMethod, Integral, Position = [-5, -1]], VerticalAlignment = Top), plot::Integral(f, IntMethod = RiemannLower, Color = RGB::Yellow, ShowInfo = [IntMethod, Position = [0, -1]], VerticalAlignment = Top), f)



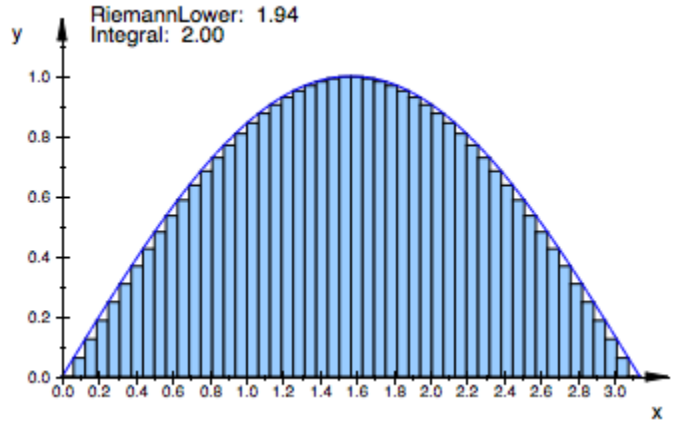
delete f:

Example 4

`plot::Integral` can be animated:
f := plot::Function2d(sin(a*x), x = 0..PI, a = 1..5): plot(plot::Integral(f, 50, IntMethod = RiemannMiddle), f)

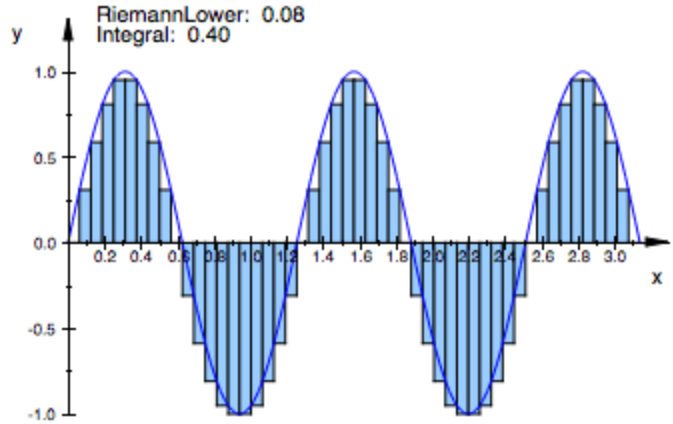


Increasing the number of nodes decreases the quadrature error:
f := plot::Function2d(sin(x), x = 0..PI): plot(plot::Integral(f, N, N = 10..50, IntMethod = RiemannLower), f)



The function and the number of nodes can be animated simultaneously:

```
f := plot::Function2d(sin(a*x), x = 0..PI, a = 1..5):
plot(plot::Integral(f, N, N = 10..50, IntMethod = RiemannLower), f)
```



delete f:

Parameters

f

The integrand: an object of type plot::Function2d.

`f` is equivalent to the attribute Function1.

n

The number of subintervals (a positive integer) or a list of real numbers representing nodes of the integration variable.

`n` is equivalent to the attribute Nodes.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

Options

IntMethod

Option, specified as `IntMethod = m`

The quadrature method; see IntMethod

See Also

plotplot::copyplot::Function2dplot::Hatchplot::Text2d

plot::Iteration

Purpose

Plotting iterated functions

Syntax

```
plot::Iteration(f, x_0, <n>, x = x_min .. x_max, <a =
a_min .. a_max>, options)
```

Description

`plot::Iteration`(f, x_0, n, x = `` `x_{min}` .. `x_{max}` ``) is a graphical object visualizing the iteration $x_i = f(x_{i-1})$ ($i = 1, \ldots, n$) of the given starting point x_0.

The iteration is visualized by connecting the points $(x_0, 0)$ and (x_0, x_1) by a vertical line. For any step of the iteration, a horizontal line is drawn from the point (x_{i-1}, x_i) (on the graph of f) to the point (x_i, x_i) on the main diagonal. From there, a vertical line is drawn to the next pair (x_i, x_{i+1}) of the iteration.

The iteration object neither includes the graph of the function $y = f(x)$ nor the main diagonal $y = x$. You need to plot them separately if you wish the function and/or the diagonal to be in your picture! See the examples.

The iteration is stopped prematurely when the iterated point leaves the plot range `` `x_{min}`..`x_{max}` ``. Cf. “Example 3” on page 24-394.

Despite the fact that the number of iterations `n` represents an integer, it can be animated! Cf. “Example 4” on page 24-395

The default color used for the iteration plot is `RGB::Grey50`. It can be modified by setting the attribute Color or LineColor. Cf. “Example 1” on page 24-390.

The default line style is solid. It can be modified by setting the attribute LineStyle.
plot::getDefault(plot::Iteration::Color),
plot::getDefault(plot::Iteration::LineColor),
plot::getDefault(plot::Iteration::LineStyle)[0.5, 0.5, 0.5], [0.5, 0.5, 0.5], Solid

[0.5, 0.5, 0.5], [0.5, 0.5, 0.5], Solid

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`FALSE`
Color	the main color	RGB::Grey50
Frames	the number of frames in an animation	`50`
Function	function expression or procedure	
Iterations	number of iterations in plot::Iteration	`10`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Grey50
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	

Attribute	Purpose	Default Value
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
StartingPoint	starting point of the iteration	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles

TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	

Examples

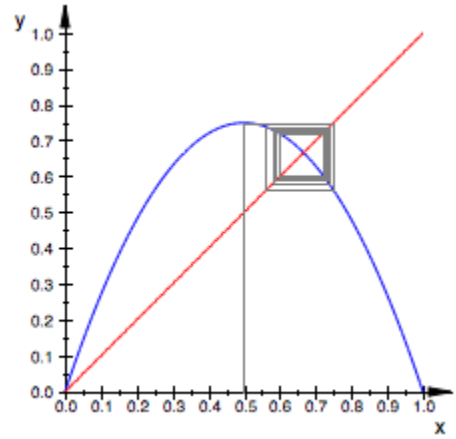
Example 1

We consider the logistic map for the parameter value 3, i.e., the parabola $f(x) = 3x(1 - x)$ for $x \in [0, 1]$. We iterate the starting point $x_0 = 0.5$:

```
f := plot::Function2d(3*x*(1 - x), x = 0..1, Color = RGB::Blue): x0 := 0.5:
```

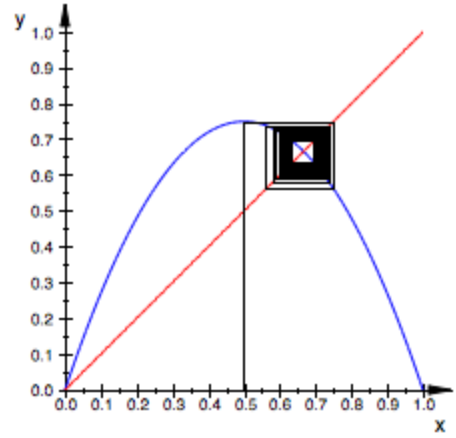
We plot the iteration (without specifying the number of iterations), the parabola f and the diagonal line $g(x) = x$:

```
g := plot::Function2d(x, x = 0..1, Color = RGB::Red): it :=
plot::Iteration(3*x*(1 - x), x0, x = 0..1): plot(f, g, it)
```



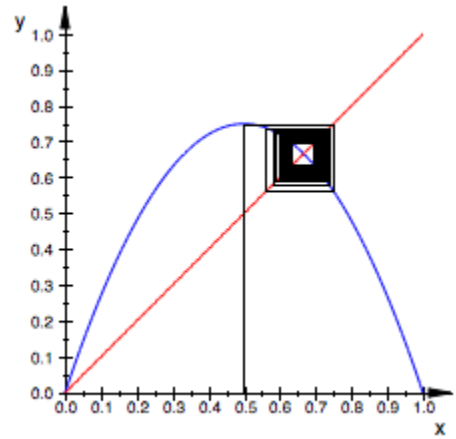
We increase the number of iterations to 50 and change the color of the lines to `RGB::Black`:

```
it::Iterations := 50: it::Color := RGB::Black: plot(f, g, it)
```



Finally, we animate the number of steps, allowing to follow the course of the iteration:

```
it := plot::Iteration(3*x*(1 - x), x0, n, x = 0..1, n = 1..50, Color =
RGB::Black): plot(f, g, it)
```



delete f, g, it:

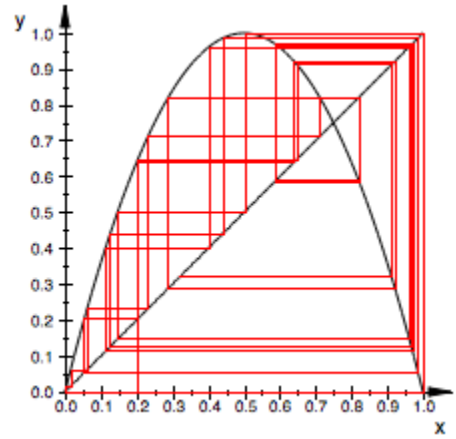
Example 2

We consider the logistic map $f(x) = ax(1 - x)$ for $x \in [0, 1]$ and the animation parameter a running from $a = 2$ to $a = 4$:

```
f := plot::Function2d(a*x*(1 - x), x = 0..1, a = 2..4, Color = RGB::Black):
```

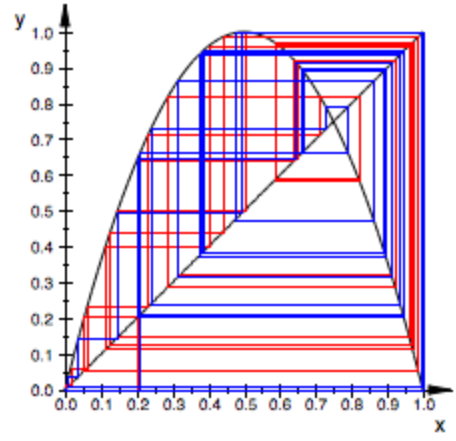
We define the iteration of the starting point $x_0 = 0.2$ by f and plot it together with the function graph of $f(x)$ and the diagonal line $g(x) = x$:

```
g := plot::Function2d(x, x = 0..1, Color = RGB::Black): it1 :=
plot::Iteration(a*x*(1 - x), 0.2, 30, x = 0..1, a = 2..4, Color = RGB::Red):
plot(f, g, it1)
```



We define an additional iteration starting at $x_0 = 0.21$ and add it to the plot:

```
it2 := plot::Iteration(a*x*(1 - x), 0.21, 30, x = 0..1, a = 2..4, Color =
RGB::Blue): plot(f, g, it1, it2)
```

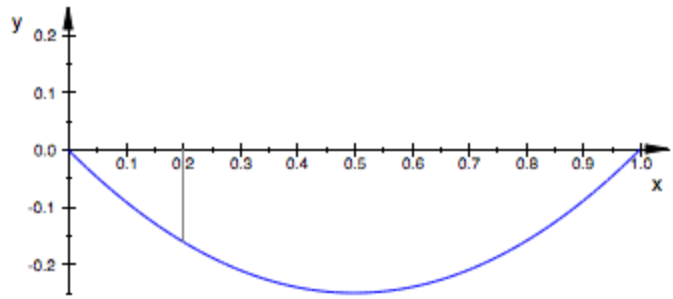


For small values of a, the two iterations converge to the same fixed point. When a approaches the value 4, the iterations drift into chaos.

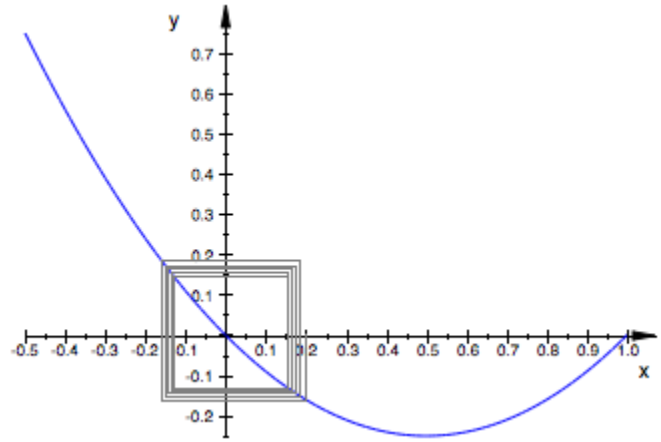
delete f, g, it1, it2:

Example 3

Consider the iteration of the starting point $x_0 = 0.2$ by the logistic map $f(x) = x(x - 1)$ with the plot range $x \in [0, 1]$:
f := plot::Function2d(x*(x - 1), x = 0..1): it := plot::Iteration(x*(x - 1), 0.2, x = 0..1): plot(f, it)



We see that only one step of the iteration is plotted. The reason is that the point $x_1 = f(x_0)$ is negative and, hence, not contained in the requested plot range `x = 0..1`. We modifiy the plot range:
f::XRange:= -0.5..1: it::XRange:= -0.5..1: plot(f, it)

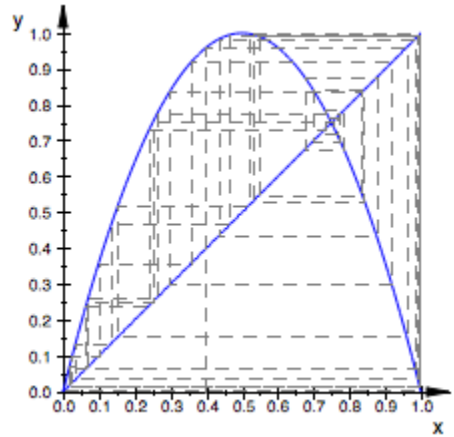


delete f, it:

Example 4

We animate the parameter n that sets the number of iterations. We set the time range for the animation to 40 (seconds). Using Frames, the total number of frames is chosen such that approximately 10 frames are used to visualize the step from n to $n + 1$:

```
f := plot::Function2d(4*x*(1 - x), x = 0..1): g := plot::Function2d(x, x =
0..1): it := plot::Iteration(4*x*(1 - x), 0.4, n, x = 0..1, LineStyle = Dashed,
n = 0..40, Frames = 411, TimeRange = 0..40): plot(f, g, it)
```



delete f, g, it:

Parameters

f

The iteration function: an arithmetical expression in the independent variable `x` and the animation parameter `a`. Alternatively, a procedure that accepts 1 input parameter `x` or 2 input parameters `x`, `a` and returns a real numerical value when the input parameters are numerical.

`f` is equivalent to the attribute Function.

x_0

The starting point for the iteration: x_0 must be a numerical real value or an expression in the animation parameter `a`.

x_0 is equivalent to the attribute StartingPoint.

n

The number of iterations: `n` must be a positive integer or an expression in the animation parameter `a`.

`n` is equivalent to the attribute Iterations.

x

The independent variable: an identifier or an indexed identifier.

`x` is equivalent to the attribute XName.

x_{min} .. x_{max}

The plot range: x_{min}, x_{max} must be numerical real values or expressions in the animation parameter *a*.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Lsys

plot::Line2d

Purpose

2D line segments

Syntax

```
plot::Line2d([x1, y1], [x2, y2], <a = amin .. amax>, options)
```

Description

`plot::Line2d([x1, y1], [x2, y2])` creates a 2D line segment between the points (x_1, y_1) and (x_2, y_2).

The end points may be passed as lists or vectors.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`

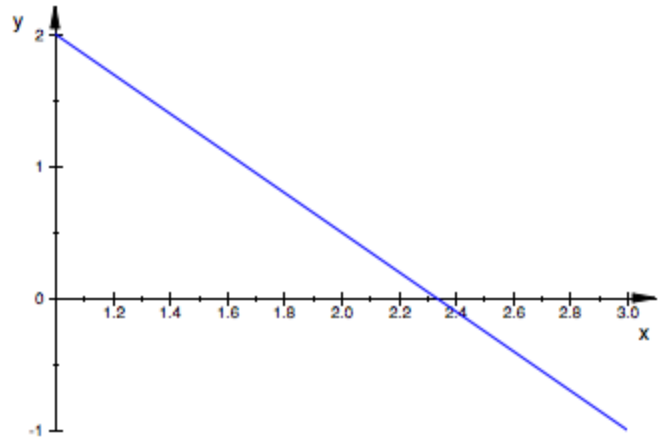
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

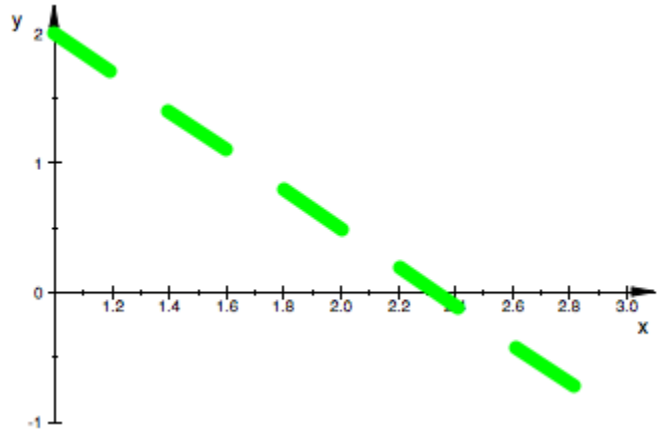
Examples

Example 1

We create a 2D line segement:
plot(plot::Line2d([1, 2], [3,-1]))

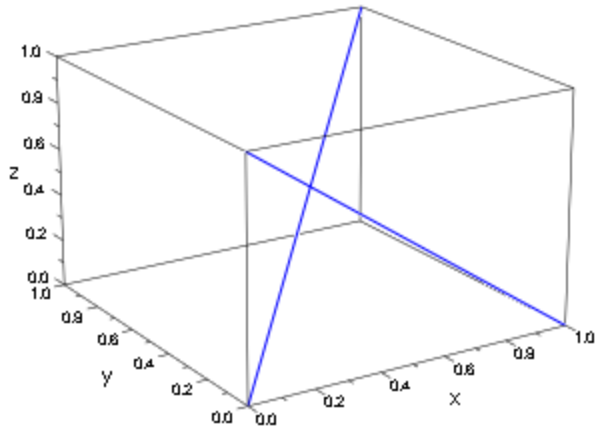


The LineStyle can be changed from `Solid`, as is the default, to `Dashed` or `Dotted`. Likewise LineColor and LineWidth can be set explicitly:
plot(plot::Line2d([1, 2], [3, -1], LineStyle = Dashed, LineWidth = 2.5*unit::mm, LineColor = RGB::Green))

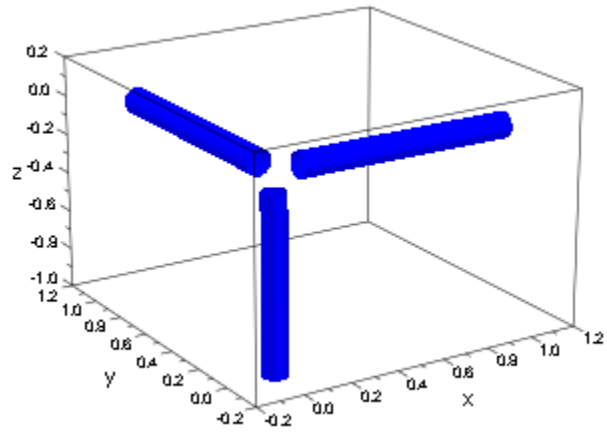


Example 2

We plot two animated 3D line segements starting off parallel, ending up skew:
plot(plot::Line3d([0, 0, 0], [a, a, 1], a = 0..1), plot::Line3d([1, 0, 0], [a, 0, 1], a = 1..0))



In addition to LineStyle, LineColor and LineWidth, 3D line segments support the style option Tubular. If this is set to TRUE, the TubeDiameter can be set explicitly:
plot(plot::Line3d([0.1, 0, 0], [1, 0, 0]), plot::Line3d([0, 0.1, 0], [0, 1, 0]), plot::Line3d([0, 0, -0.1], [0, 0,-1]), ViewingBox = [-0.2..1.2, -0.2..1.2, -1..0.2], Tubular = TRUE, TubeDiameter = 5.0*unit::mm)



Parameters

x_1

y_1

The coordinates of one end point: real numerical values or arithmetical expressions of the animation parameter a.

x_1, y_1 are equivalent to the attributes FromX, FromY.

x_2

y_2

The coordinates of the other end point: real numerical values or arithmetical expressions of the animation parameter a.

x_2, y_2, z_2 are equivalent to the attributes ToX, ToY, ToZ.

a

Animation parameter, specified as `a = a_min..a_max`, where `a_min` is the initial parameter value, and `a_max` is the final parameter value.

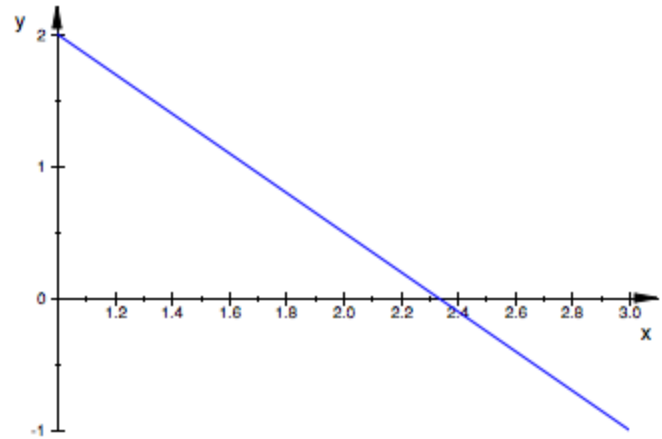
Examples

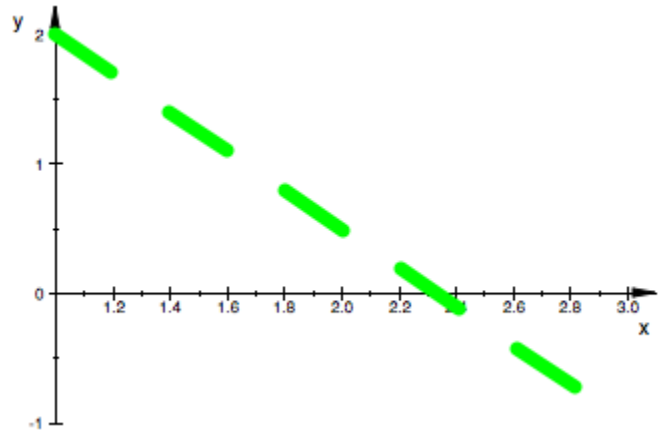
Example 1

We create a 2D line segement:
plot(plot::Line2d([1, 2], [3,-1]))



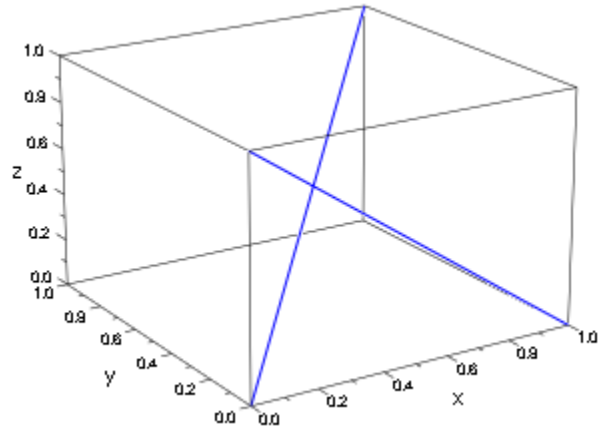
The LineStyle can be changed from `Solid`, as is the default, to `Dashed` or `Dotted`. Likewise LineColor and LineWidth can be set explicitly:

plot(plot::Line2d([1, 2], [3, -1], LineStyle = Dashed, LineWidth = 2.5*unit::mm, LineColor = RGB::Green))

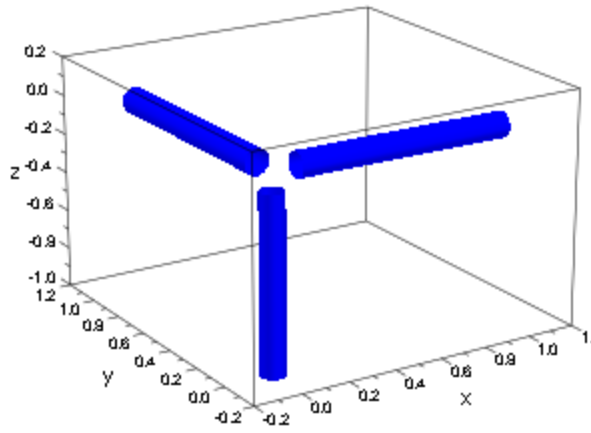


Example 2

We plot two animated 3D line segements starting off parallel, ending up skew:
plot(plot::Line3d([0, 0, 0], [a, a, 1], a = 0..1), plot::Line3d([1, 0, 0], [a, 0, 1], a = 1..0))



In addition to LineStyle, LineColor and LineWidth, 3D line segments support the style option Tubular. If this is set to TRUE, the TubeDiameter can be set explicitly:
plot(plot::Line3d([0.1, 0, 0], [1, 0, 0]), plot::Line3d([0, 0.1, 0], [0, 1, 0]), plot::Line3d([0, 0, -0.1], [0, 0,-1]), ViewingBox = [-0.2..1.2, -0.2..1.2, -1..0.2], Tubular = TRUE, TubeDiameter = 5.0*unit::mm)



Parameters

x_1

y_1

z_1

The coordinates of one end point: real numerical values or arithmetical expressions of the animation parameter `a`.

x_1, y_1, z_1 are equivalent to the attributes FromX, FromY, FromZ.

x_2

y_2

z_2

The coordinates of the other end point: real numerical values or arithmetical expressions of the animation parameter `a`.

x_2, y_2, z_2 are equivalent to the attributes ToX, ToY, ToZ.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Line2dplot::Polygon2dplot::Polygon3dplot::Rectangle

plot::Listplot

Purpose

Finite lists of 2D points

Syntax

```
plot::Listplot([y1, y2,  ], <x = xmin .. xmax>, <a
= amin .. amax>, options)
plot::Listplot(A1, <x = xmin .. xmax>, <a =
amin .. amax>, options)
plot::Listplot([[x1, y1], [x2, y2],  ], <a =
amin .. amax>, options)
plot::Listplot(A2, <a = amin .. amax>, options)
```

Description

`plot::Listplot` serves for visualizing discrete data values `[y1, y2, ]`. If no range `x = `x_{min}` .. `x_{max}`` is specified, the data are plotted as the points `[x1, y1]`, `[x2, y2]` etc. with equidistant *x*-values `x1 = 1`, `x2 = 2` etc. If a range `x = `x_{min}` .. `x_{max}`` is specified, equidistant *x*-values between x_{min} and x_{max} are used.

If the data are specified as a list of coordinate pairs `[[x1, y1], [x2, y2], ]`, `plot::Listplot` generates plot points with these coordinates.

With the attribute LinesVisible = `TRUE`, each pair of consecutive data points is connected by a curve.

With InterpolationStyle = `Linear` (default), the points are connected by straight line segments.

With InterpolationStyle = `Cubic`, a cubic spline curve is used to connect the points. The spline curve between two data points is rendered as a collection of $m + 1$ straight line segments, where m is specified by the attribute Submesh = `m`.

Use LinesVisible = `FALSE`, if only the data points without connecting lines are to be rendered.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Data	the (statistical) data to plot	
FillColorDirection	the direction of color transitions on surfaces	`[0, 0]`
Frames	the number of frames in an animation	`50`
InterpolationStyle	interpolation via linear or cubic splines	`Linear`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
LineColorType	line coloring types	`Flat`

Attribute	Purpose	Default Value
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointColor	the color of points	RGB::Black
PointStyle	the presentation style of points	FilledCircles

Attribute	Purpose	Default Value
PointsVisible	visibility of mesh points	`TRUE`
Submesh	density of submesh (additional sample points)	`6`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

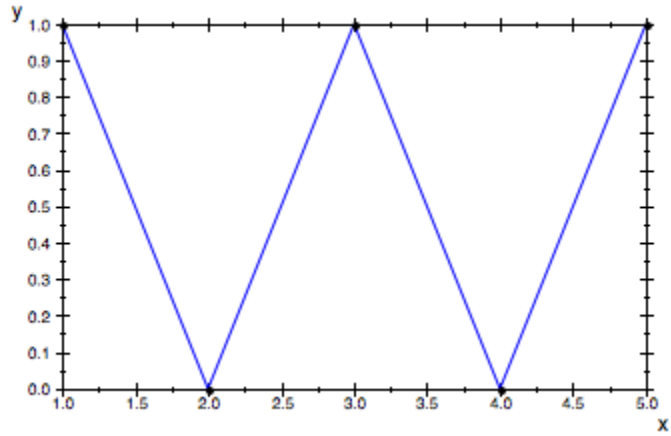
Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
XSubmesh	density of additional sample points for parameter “x”	6

Examples

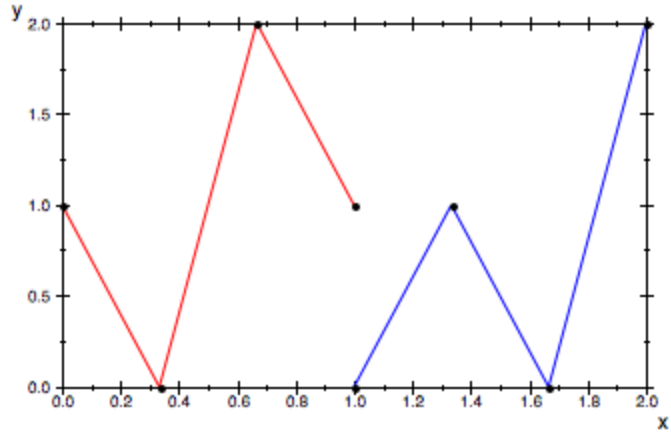
Example 1

We plot 5 discrete data values as points with equidistant *x*-values 1, 2, 3, 4, 5:

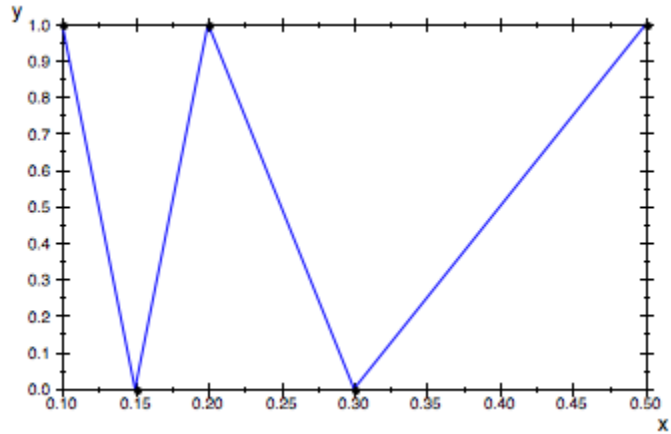
```
plot(plot::Listplot([1, 0, 1, 0, 1]))
```



We plot two data samples and place them side by side by specifing suitable ranges for the horizontal variable:
plot(plot::Listplot([1, 0, 2, 1], x = 0..1, Color = RGB::Red),
plot::Listplot([0, 1, 0, 2], x = 1..2, Color = RGB::Blue))

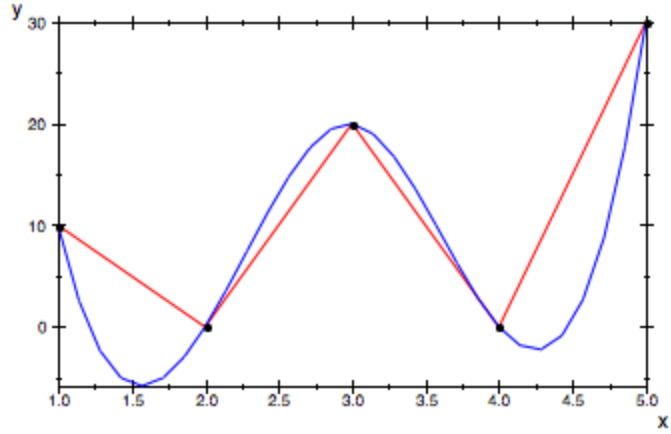


We specify *x*-coordinates for the data points:
plot(plot::Listplot([[0.1, 1], [0.15, 0], [0.2, 1], [0.3, 0], [0.5, 1]]))

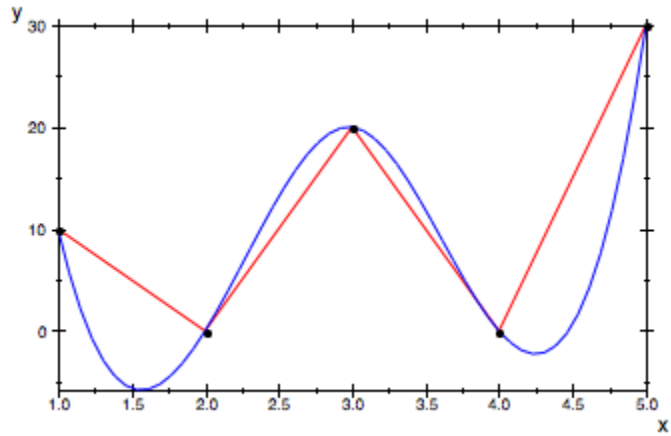


Example 2

We demonstrate the difference between linear and cubic spline interpolation:
plot(plot::Listplot([10, 0, 20, 0, 30], Color = RGB::Red, InterpolationStyle = Linear), plot::Listplot([10, 0, 20, 0, 30], Color = RGB::Blue, InterpolationStyle = Cubic))



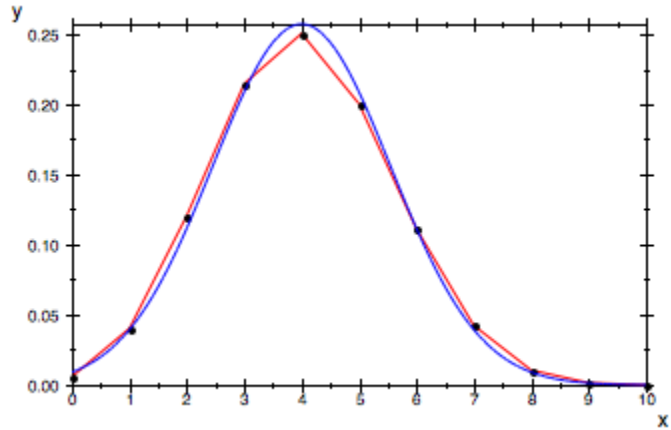
We smoothen the cubic spline curve by increasing the Submesh value:
plot(plot::Listplot([10, 0, 20, 0, 30], Color = RGB::Red, InterpolationStyle = Linear), plot::Listplot([10, 0, 20, 0, 30], Color = RGB::Blue, InterpolationStyle = Cubic, Submesh = 12))



Example 3

A random variable describing the number of successes in n Bernoulli trials with success probability p is binomially distributed with expectation value np and variance $np(1 - p)$. For large values of n, the binomial distribution is approximated by a corresponding normal distribution.

We use `plot::Listplot` to visualize the discrete probability values of the binomial distribution. The normal distribution is visualized via plot::Function2d:
n := 10: p:= 0.4: plot(plot::Listplot([stats::binomialPF(n, p)(i) $ i = 0..n], x = 0..n, Color = RGB::Red), plot::Function2d(stats::normalPDF(n*p, n*p*(1 - p))(x), x = 0..n, Color = RGB::Blue)):



delete n, p:

Parameters

y_1, y_2, ...

Vertical coordinates: numerical values or expressions of the animation parameter `a`.

y_1, y_2, ... is equivalent to the attribute Data.

x

Name of the horizontal coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in *x* direction.

`x` is equivalent to the attribute XName.

x_{min} .. x_{max}

The range of the horizontal coordinate: `xmin`, `xmax` must be numerical real value or expressions of the animation parameter `a`.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

A_1

A 1-dimensional array of domain type DOM_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) with 1 row or 1 column. The entries must be numerical real values or arithmetical expressions of the animation parameter `a`. The entries in A_1 are regarded as data values $[y_1, y_2]$ etc..

A_1 is equivalent to the attribute Data.

x_1, x_2, ...

Horizontal coordinates: numerical values or expressions of the animation parameter `a`.

A_2

A 2-dimensional array of domain type DOM_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) with at least two rows and two columns. The entries must be numerical real values or arithmetical expressions of the animation parameter `a`. The i-th row is regarded as the data point (x_i, y_i). If more than 2 columns are provided, only the data in the first two columns are considered; all additional columns are ignored.

A_2 is equivalent to the attribute Data.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Lsys

Purpose

Lindenmayer systems

Syntax

```
plot::Lsys(alpha, start, trans,  , <a = a_min ..
a_max>, options)
```

Description

`plot::Lsys` creates Lindenmayer systems, i.e., string rewriting systems controlling turtle graphics.

Lindenmayer systems, or L-systems for short, are based on the concept of iteratively transforming a string of symbols into another string. After a finite number of iterations, the resulting string is translated into a sequence of movement commands to a "turtle" (see plot::Turtle), which can be drawn on the screen.

In `plot::Lsys`, the string of symbols is represented by a string of characters, i.e., a DOM_STRING. *Transformation rules* are given as equations mapping strings of length 1 to strings of arbitrary length. *Turtle rules* are given as equations mapping strings of length 1 to simple movement commands: `Line`, `Move`, `Left`, `Right`, `Push`, `Pop`, `Noop`, or a color specification.

The commands are mostly self-explanatory. `Left` and `Right` turn by the amount set in the slot `"RotationAngle"`; the initial direction is "up". `Line` and `Move` move by the amount set in `"StepLength"`, where `Move` does not draw a line. `Push` stores the current state (position, direction, color) on a stack from where it can later be reactivated using `Pop`. `Noop` means "ignore this, no operation". A color specification changes the line color.

The following turtle rules are used by default (but can be disabled by giving other rules for the left-hand sides):

`"F" = Line`, `"f" = Move`, `"[" = Push`, `"]" = Pop`, `"+" = Left`, `"-" = Right`.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`FALSE`
Color	the main color	RGB::Blue
Frames	the number of frames in an animation	`50`
Generations	number of iterations of L-system rules	`5`
IterationRules	iteration rules of an L-system	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
RotationAngle	angle of rotation commands in L-systems	
StartRule	start rule of an L-system	
StepLength	length of movement commands in L-systems	`1.0`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	

Attribute	Purpose	Default Value
TitlePositionY	position of object titles, y component	
TurtleRules	rules translating L-system symbols to turtle movements	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

As a very simple system, we consider the following iteration rule: “replace each line forward by the sequence “line forward, move forward without painting, line forward.””:
l := plot::Lsys(0, "F", "F" = "FfF"):

Note that we do not provide an iteration rule for `"f"`. This means “leave `f` alone, do not change it.”

The start state is displayed by plotting the system after zero generations:
l::Generations := 0: plot(l)

Increasing the number of generations, we see the effect of our transformation rule:
l::Generations := 1: plot(l)

l::Generations := 2: plot(l)

```
l::Generations := 3: plot(l)
```

The following variant of this simple example produces approximations to the Cantor set:

```
l := plot::Lsys(0, "F", "F" = "FfF", "f" = "fff"): plot(l)
```

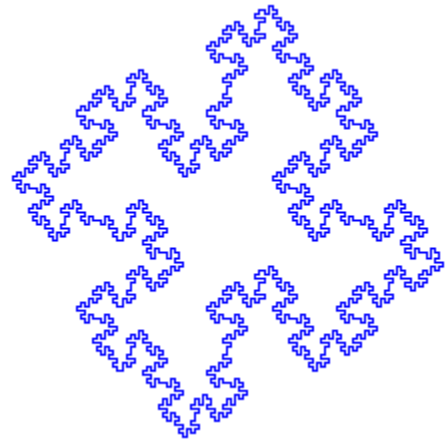
Example 2

To get more interesting examples, we include rotations into our rules:
l := plot::Lsys(PI/2, "F-F-F-F", "F" = "F-F+F+FF-F-F+F", Generations = 3)plot::Lsys(PI/2, "F-F-F-F", IterationRules = ["F" = "F-F+F+FF-F-F+F"], TurtleRules = [], Generations = 3)

As you can see, `plot::Lsys` has detected that our rule is an iteration rule. We could have used this syntax directly when creating the object. We have not given turtle rules, so the defaults are used:

```
plot(l)
```

plot(Lsys(π/2, "F-F-F-F", IterationRules = ["F" = "F-F+F+FF-F-F+F"], TurtleRules = [], Generations = 3))



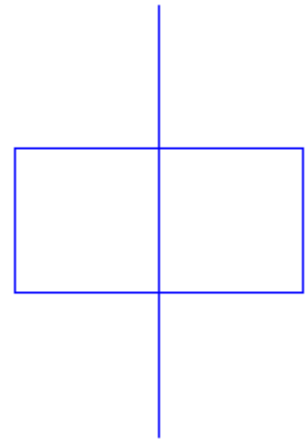
Example 3

The Peano curve is a famous example of a space filling curve. In the limit process, increasing the number of iterations while decreasing the length of the forward steps, it actually fills the plane. There are different constructions known, the one shown here fills a square tilted by _outputSequence(45, Symbol::deg)$_{45^\circ}$:

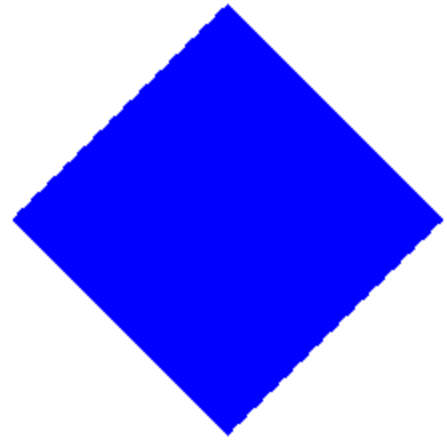
```
peano := plot::Lsys(PI/2, "F", "F" = "F+F-F-F-F+F+F+F-F"):
```

The transformation rule says to replace each straight line with the following construction:

```
peano::Generations := 1: plot(peano)
```



After a few iterations, the lines already get very close to one another:
peano::Generations := 5: plot(peano)

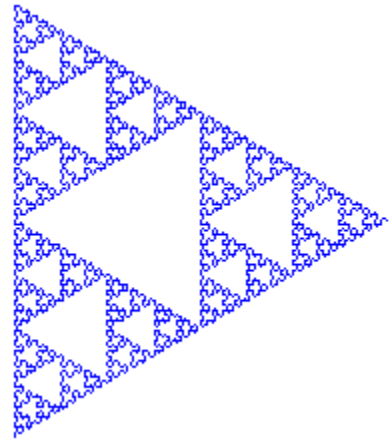


Example 4

Many L-systems contain different types of lines: While they are drawn exactly the same, their transformation rules are different from

one another. The following example shows an image similar to the Sierpinski triangle:

```
l := plot::Lsys(PI/3, "R", "L" = "R+L+R", "R" = "L-R-L", "L" = Line, "R"
= Line, Generations = 7): plot(l)
```



Example 5

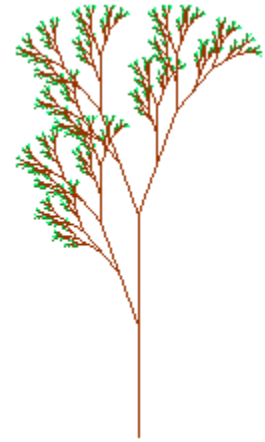
The `Push` and `Pop` operations can be used to draw “arms” in an L-system:

```
plot(plot::Lsys(23*PI/180, "F", "F" = "FF-[-F+F+F]+[+F-F-F]",
Generations = 4))
```

Example 6

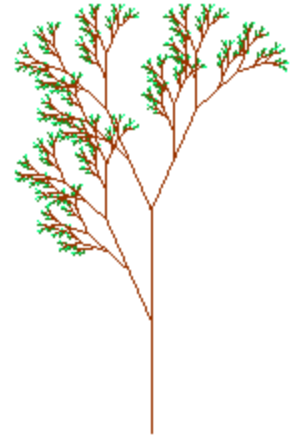
L-systems have been used to simulate plant growth. We show an example here that uses the symbols `B`, `H`, and `G` to change the color of lines:

```
l := plot::Lsys(PI/9, "BL", "L" = "BR[+HL]BR[-GL]+HL", "R" = "RR", "L" = Line, "R" = Line, "B" = RGB::Brown, "H" = RGB::ForestGreen, "G" = RGB::SpringGreen, Generations = 6): plot(l)
```



The attribute `Generations` can be animated. This way, we can actually make the “plant” “grow:”

```
plot(plot::Lsys(a*PI/45, "BL", "L" = "BR[+HL]BR[-GL]+HL", "R" = "RR",
"L" = Line, "R" = Line, "B" = RGB::Brown, "H" = RGB::ForestGreen, "G"
= RGB::SpringGreen, Generations = a, a = 1 .. 6)):
```



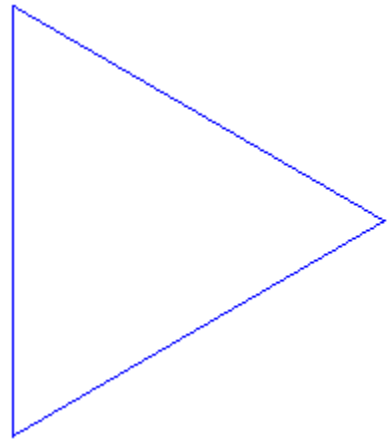
Example 7

L-systems can display a couple of popular fractals. One example is the Koch snowflake, generated by replacing each straight line with a straight line, followed by a left turn of _outputSequence(60, Symbol::deg)$60°$, another straight line, a right turn of _outputSequence(120, Symbol::deg)$120°$, another straight line, another left turn of _outputSequence(60, Symbol::deg)$60°$ and a final straight line:

```
koch := plot::Lsys(PI/3, "F--F--F", "F" = "F+F--F+F"):
```

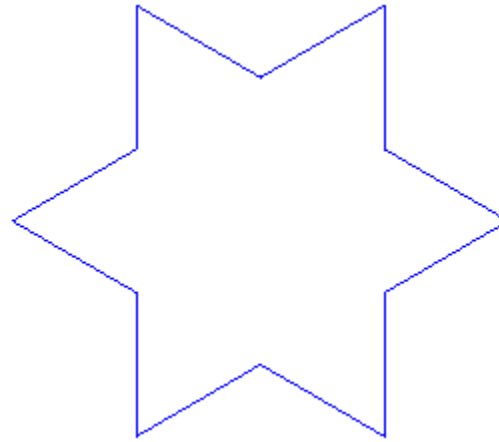
The starting rule has been chosen to be an equilateral triangle:

```
koch::Generations := 0: plot(koch)
```

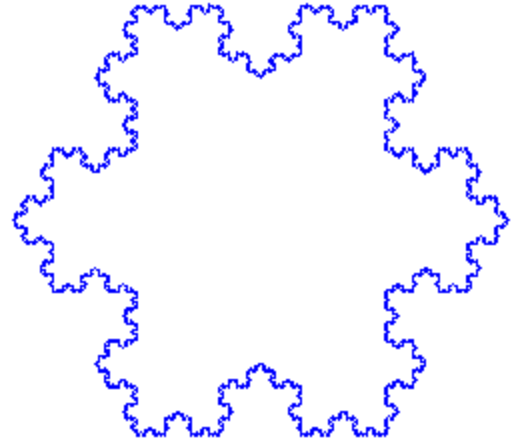


The first generation looks like this:

```
koch::Generations := 1: plot(koch)
```

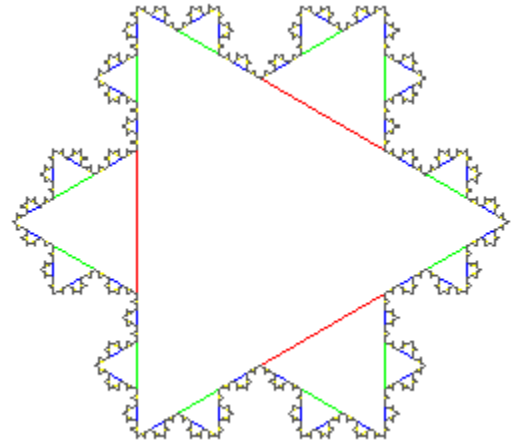


The limit is pretty well approximated after five generations:
koch::Generations := 5: plot(koch)



Finally, we use plot::modify and the `"StepLength"` slot to show the first couple of iterations superimposed on one another:

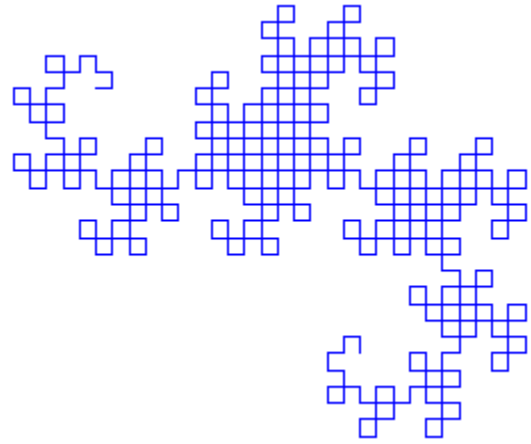
```
colors := [RGB::Red, RGB::Green, RGB::Blue, RGB::Yellow,
RGB::DimGrey]: plot(plot::modify(koch, Generations = i, StepLength =
3^(-i), LineColor = colors[i+1]) $ i = 0..4)
```



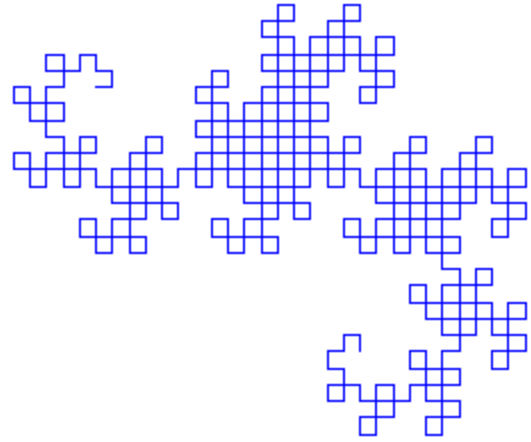
Example 8

Another well-known example of a fractal generated by an L-system is Heighway's Dragon curve. Informally, it is generated by "drawing a right angle and then replacing each right angle by a smaller right angle" (Gardner). It has been used in the book "Jurassic Park" by Michael Crichton and thereby got another nickname, the "Jurassic Park fractal:"

```
plot(plot::Lsys(PI/2, "L", "L" = "L+R+", "R" = "-L-R", "L" = Line, "R"
= Line, Generations = 9))
```

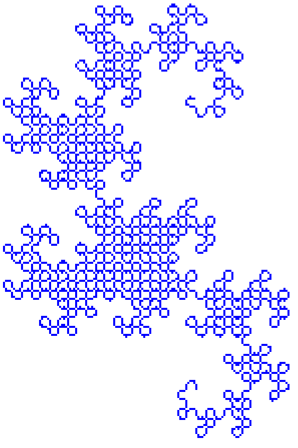


It is interesting to note that the iteration rules of this curve are equivalent to appending a mirrored copy of the curve to its end:
plot(plot::Lsys(PI/2, "L", "L" = "L+R+", "R" = "-L-R", "L" = Line, "R" = Line, Generations = a, a = 1..9))



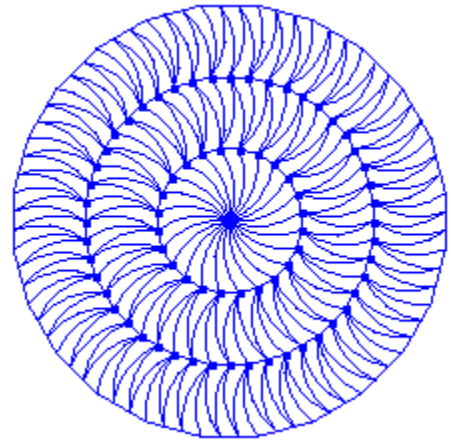
Example 9

While the L-system of the previous example corresponds to the definition found in the literature, the images in at least one popular source show another system (while the definition given is the one from above), namely:
plot(plot::Lsys(PI/4, "X-F-Y", "X" = "X+F+Y", "Y" = "X-F-Y", "X" = Line, "Y" = Line, Generations = 9)):

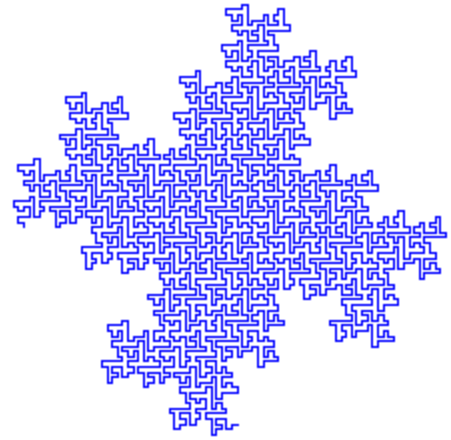


Example 10

An L-system may contain letters that are not meant to show in the final graphic, so they form some sort of “markers” for subsequent iteations. For this purpose, you may use the turtle rule `Noop`:
plot(plot::Lsys(PI/12,
"X+X+X+X+X+X+X+X+X+X+X+X+X+X+X+X+X+X+X+X+X+X+X+X",
"X" = "[F+F+F+F[---X-Y]+++++F+++++++++F-F-F-F]", "Y" =
"[F+F+F+F[---Y]+++++F+++++++++F-F-F-F]", "X" = Noop, "Y" = Noop,
Generations = 3))



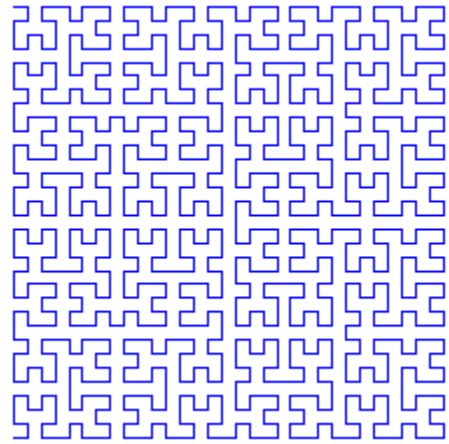
plot(plot::Lsys(PI/2, "FB", "A" = "FBFA+HFA+FB-FA", "B" = "FB+FA-FB-JFBFA", "F" = "", "H" = "-", "J" = "+", "A" = Noop, "B" = Noop, "H" = Noop, "J" = Noop))



Example 11

Using this rule, we can use the following formulation of the popular Hilbert curve due to Ken Philip:

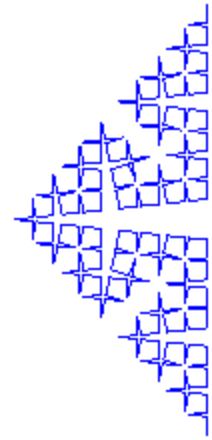
plot(plot::Lsys(PI/2, "x", "x" = "-yF+xFx+Fy-", "y" = "+xF-yFy-Fx+", "x" = Noop, "y" = Noop))



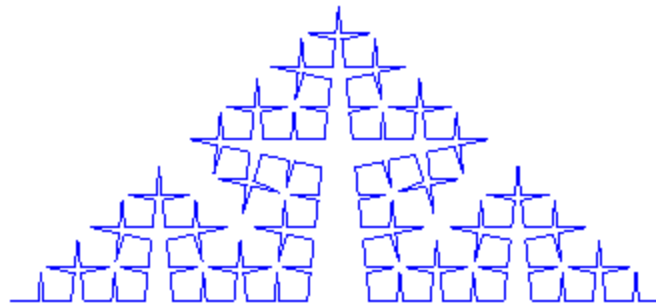
To animate the creation process of the Hilbert curve, we adjust the length of the lines to the current number of iteration steps:
plot(plot::Lsys(PI/2, "x", "x" = "-yF+xFx+Fy-", "y" = "+xF-yFy-Fx+", "x" = Noop, "y" = Noop, Generations = i, StepLength = 1/(2^i-1), i = 1..6, Frames = 6))

Example 12

In some cases, systems will need small angles and long strings in order to specify the desired directions. Take for example the following system:
plot(plot::Lsys(7*PI/15, "F", "F"="F+F--F+F", Generations=4))



The rotations to the right use an angle of 7 * PI/15 $\frac{7\,\pi}{15}$, while that to the left (the sharp spike) is a turn of 14 * PI/15 $\frac{14\,\pi}{15}$. It would look more natural, however, to have the turtle start to the right, i.e., at an angle of -PI/2 $-\frac{\pi}{2}$. Since no multiple of 7 * PI/15 $\frac{7\,\pi}{15}$ is equal to PI/2 $\frac{\pi}{2}$ modulo 2π, this requires that we use a smaller angle, adjusting our iteration rule:
plot(plot::Lsys(7*PI/30,"++++++++++++++++F", "F"="F++F----F++F", Generations=4))



Parameters

alpha

Angle (in radians) for turning commands. Animatable.

`alpha` is equivalent to the attribute RotationAngle.

start

String used as the starting rule.

`start` is equivalent to the attribute StartRule.

trans, ...

Iteration and Turtle command rules (see below).

`trans`, ... is equivalent to the attributes IterationRules, TurtleRules.

a

Animation parameter, specified as `a = a_min..a_max`, where `a_min` is the initial parameter value, and `a_max` is the final parameter value.

Algorithms

Lindenmayer systems are “string rewriting systems.” MuPAD implements only context-free L-systems, which are analyzed in a similar context as context-free grammars.

Many examples of L-systems can be found, among other places, in “The Fractal Geometry of Nature” by Benoît Mandelbrot.

plotplot::copyplot::Turtle

plot::Matrixplot

Purpose

Surface plot of matrix data

Syntax

```
plot::Matrixplot(A, options)
plot::Matrixplot(A, x = x_min .. x_max, y = y_min .. y_max,
<a = a_min .. a_max>, options)
plot::Matrixplot(row_1, row_2,  , options)
plot::Matrixplot(row_1, row_2,  , x = x_min .. x_max, y =
y_min .. y_max, <a = a_min .. a_max>, options)
plot::Matrixplot([row_1, row_2,  ], options)
plot::Matrixplot([row_1, row_2,  ], x = x_min .. x_max, y =
y_min .. y_max, <a = a_min .. a_max>, options)
plot::Matrixplot(s, <c_1, c_2,  >, options)
plot::Matrixplot(s, <c_1, c_2,  >, x = x_min .. x_max, y =
y_min .. y_max, <a = a_min .. a_max>, options)
plot::Matrixplot(s, <[c_1, c_2,  ]>, options)
plot::Matrixplot(s, <[c_1, c_2,  ]>, x = x_min .. x_max, y =
y_min .. y_max, <a = a_min .. a_max>, options)
```

Description

`plot::Matrixplot(A)` visualizes the matrix *A* as a 3D function graph by interpolating the matrix values as a function of the matrix indices.

`Matrixplot` interprets the indices of a matrix as *x* and *y* coordinates and the corresponding matrix entry as the corresponding *z* coordinate. Thus, the matrix is regarded as a discretized function in 2 variables. The function graph is displayed as a 3D surface using interpolation between the data points.

If no ranges `x = `x_{min}` .. `x_{max}`, y = `y_{min}` .. `y_{max}`` are specified, the matrix entry `A[i, j]` is diplayed as the 3D point $x = j$, $y = i$, $z =$ `A[i, j]` with integer positions *i*, *j*. If plot ranges are specified, the matrix indices *i*, *j* are used to define an equidistant mesh in the plot range.

The attribute InterpolationStyle allows to define the surface via linear or cubic spline interpolation of the data points: Choose between `InterpolationStyle` = `Linear` or `InterpolationStyle` = `Cubic`. The default is linear interpolation. With cubic interpolation, the data

surface may be smoothened by setting the numbers m_x, m_y of plot points between the data points via the attribute Submesh = [m_x, m_y]. The numbers m_x, m_y must be (small) non-negative integers.

With InterpolationStyle = `Linear`, symbolic values and complex numbers are accepted and ignored, leading to gaps in the surface. With InterpolationStyle = `Cubic`, symbolic values or complex numbers lead to an error. Cf. “Example 4” on page 24-454.

Per default, the data points are rendered on the surface. Use PointsVisible = `FALSE` to make them disappear.

Animations are triggered by specifying a range `a = ``a_{min}`` .. ``a_{max}``` for a parameter `a` that is different from the variables `x`, `y`. Thus, in animations, both the ranges `x = ``x_{min}`` .. ``x_{max}``, `y = ``y_{min}`` .. ``y_{max}`` as well as the animation range `a = ``a_{min}`` .. ``a_{max}`` must be specified.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::Red
Data	the (statistical) data to plot	
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`

Attribute	Purpose	Default Value
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
InterpolationStyle	interpolation via linear or cubic splines	Linear
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink

Attribute	Purpose	Default Value
LineStyle	solid, dashed or dotted lines?	`Solid`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`0`
LineColorDirectionZ	z-component of the direction of color transitions on lines	`1`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointColor	the color of points	RGB::MidnightBlue

Attribute	Purpose	Default Value
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`TRUE`
Shading	smooth color blend of surfaces	`Smooth`
Submesh	density of submesh (additional sample points)	`[2, 2]`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	

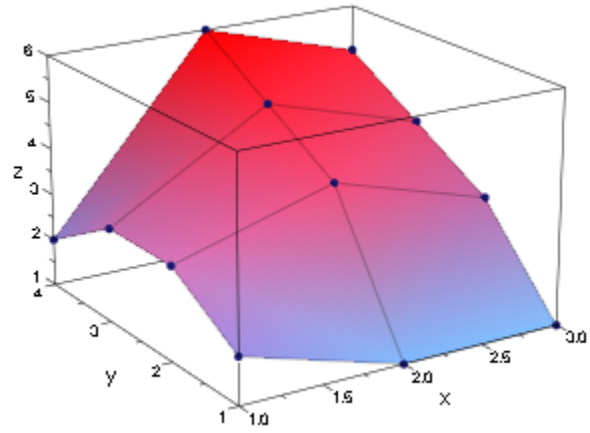
Attribute	Purpose	Default Value
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XLinesVisible	visibility of parameter lines (x lines)	TRUE
XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
XSubmesh	density of additional sample points for parameter “x”	2

Attribute	Purpose	Default Value
YLinesVisible	visibility of parameter lines (y lines)	TRUE
YMax	final value of parameter “y”	
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	
YSubmesh	density of additional sample points for parameter “y”	2

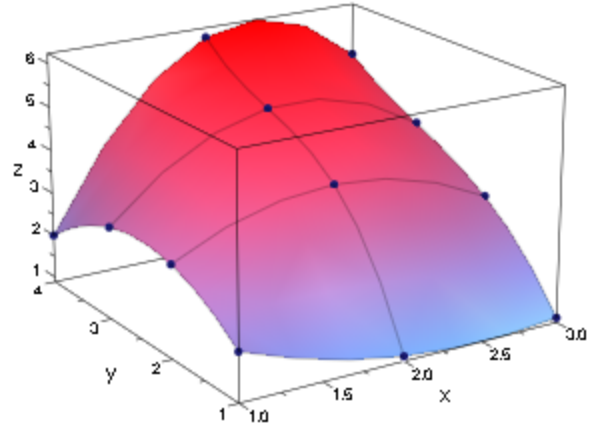
Examples

Example 1

This example demonstrates the general calling syntax. The data are passed in different ways using a list of rows, an array, and a matrix, respectively:
A := [[2, 1, 1], [3, 4, 3], [3, 5, 4], [2, 6, 5]]: plot(plot::Matrixplot(A))

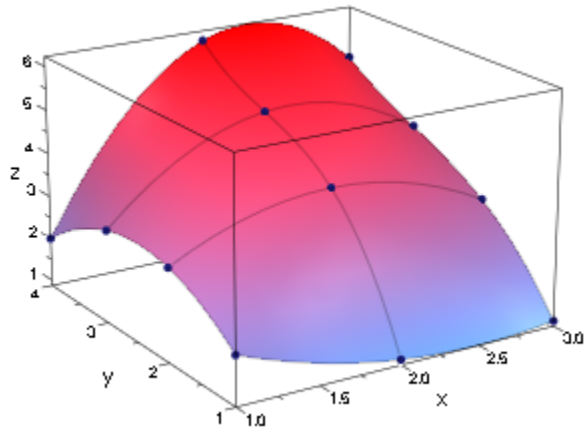


With InterpolationStyle = `Cubic`, the matrix data are plotted as a cubic spline surface:
A := array(1..4, 1..3, A): plot(plot::Matrixplot(A, InterpolationStyle = Cubic)):



The spline surface can be smoothened by using the Submesh attribute to add further evaluation points:

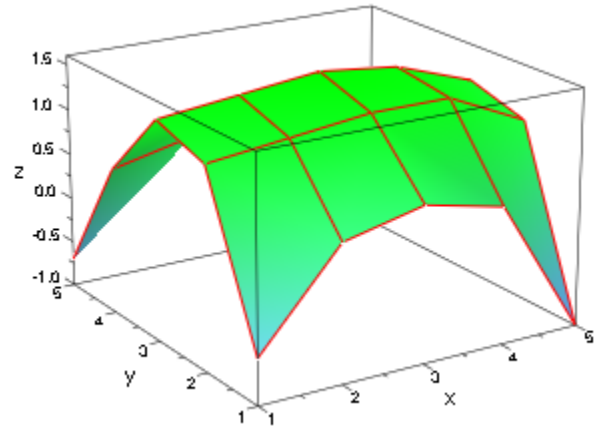
A := matrix(A): plot(plot::Matrixplot(A, Submesh = [6, 6], InterpolationStyle = Cubic)):



delete A:

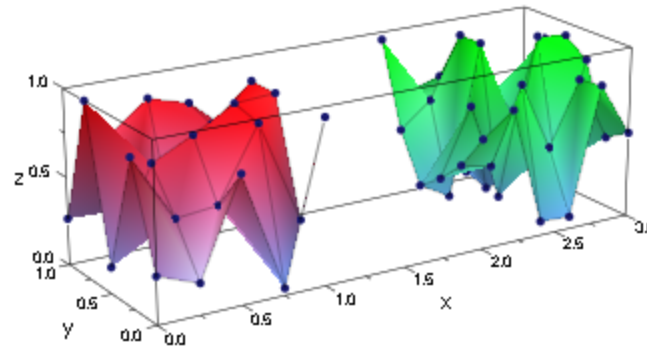
Example 2

Various plot attributes can be specified:
plot(plot::Matrixplot([[-0.5, 0.5, 0.7, 0.5, -1], [1.2, 1.3, 1.4, 1.4, 1], [1.4, 1.5, 1.6, 1.5, 1.2], [0.6, 0.8, 1, 1, 1], [-0.7, 0.5, 0.5, 0, -1]], PointsVisible = FALSE, FillColor = RGB::Green, LineColor = RGB::Red))



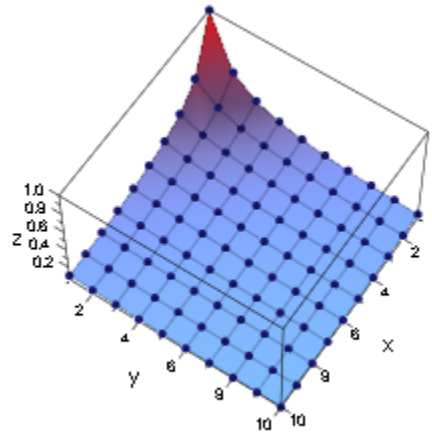
Example 3

Choosing appropriate coordinate ranges, we place two matrix plots side by side:
plot(plot::Matrixplot(matrix::random(5, 5, frandom), x = 0..1, y = 0..1, Color = RGB::Red), plot::Matrixplot(matrix::random(6, 6, frandom), x = 2..3, y = 0..1, Color = RGB::Green), Scaling = Constrained)

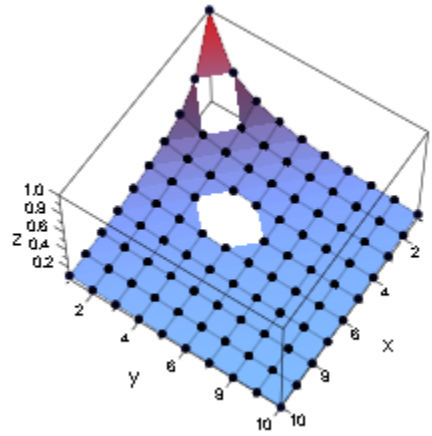


Example 4

We plot a Hilbert matrix:
A := linalg::hilbert(10): plot(plot::Matrixplot(A), CameraDirection = [3, 2, 1])



Some of the entries are replaced by values that cannot be plotted. Consequently, the plot contains holes:
A[2, 2] := NIL: A[4, 5] := infinity: A[5, 5] := x: plot(plot::Matrixplot(A), CameraDirection = [3, 2, 1])



With InterpolationStyle = `Cubic`, an error is raised: plot(plot::Matrixplot(A, InterpolationStyle = Cubic)) Error: Data contains nonreal numeric values. Use 'Style = Linear' to plot matrices containing such data. [plot::Matrixplot::doPlotStatic] delete A:

Parameters

A

A matrix of category Cat::Matrix or an array containing real numerical values or expressions of the animation parameter `a`.

`A` is equivalent to the attribute Data.

row_1, row_2, ...

The matrix rows: each row must be a list of real numerical values or expressions of the animation parameter `a`. All rows must have the same length.

row_1, row_2, ... is equivalent to the attribute Data.

s

A data sample of domain type stats::sample.

`s` is equivalent to the attribute Data.

c_1, c_2, ...

Column indices of s: positive integers. These indices, if given, indicate that only the specified columns should be used. The indexed columns must contain real numerical values or expressions of the animation parameter a, If no columns are specified, all columns of s are used.

x

Name of the first coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in *x* direction.

x is equivalent to the attribute XName.

x_{min} .. x_{max}

The range of the first coordinate: x_{min}, x_{max} must be numerical real value or expressions of the animation parameter *a*.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

y

Name of the second coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in *y* direction.

y is equivalent to the attribute YName.

y_{min} .. y_{max}

The range of the second coordinate: y_{min}, y_{max} must be numerical real value or expressions of the animation parameter *a*.

y_{min} .. y_{max} is equivalent to the attributes YRange, YMin, YMax.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Function3dplot::Surface

plot::MuPADCube

Purpose

"the cube" (the logo)

Syntax

```
plot::MuPADCube(<r>, <[c_x, c_y, c_z]>, <a = a_min .. a_max>, options)
```

Description

`plot::MuPADCube()` creates the "MuPAD cube" as a graphical 3D primitive.

This object only exists for demonstration purposes.

`plot::MuPADCube` accepts the attribute `Colors` which defines the colors of the spheres and the cylinders between the spheres. Its value is a list of RGB or RGBa colors:

- The color list may contain one to four values determining the colors of the spheres.
- If a 5th color is given, it determines the color of the cylinders.
- If the list contains nine colors (not less), the first and last four determine the colors of the 8 spheres. The fifth color determines the color of the cylinders.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Center	center of objects, rotation center	`[0, 0, 0]`
CenterX	center of objects, rotation center, x-component	`0`

Attribute	Purpose	Default Value
CenterY	center of objects, rotation center, y-component	0
CenterZ	center of objects, rotation center, z-component	0
Colors	list of colors to use	[RGB::Green, RGB::Blue, RGB::Red, RGB::Yellow, RGB::Antique]
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	

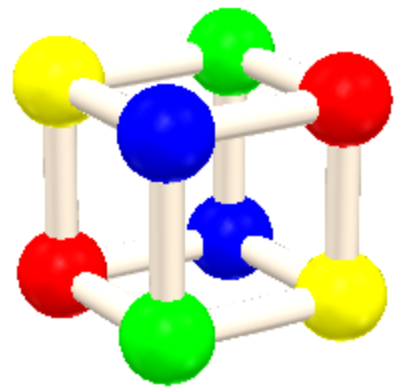
Attribute	Purpose	Default Value
Radius	radius of circles, spheres etc.	`1`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

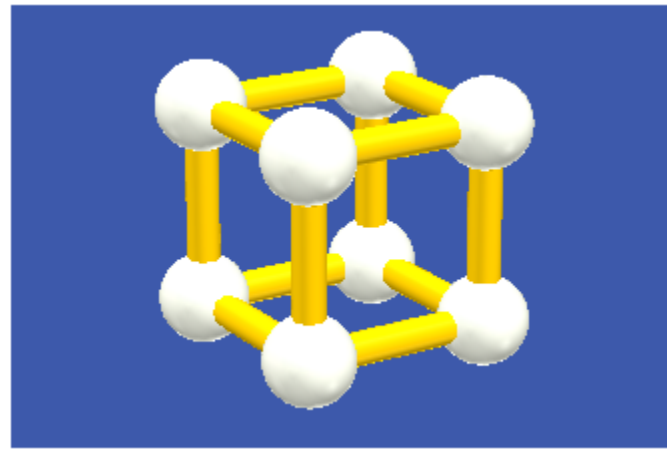
Examples

Example 1

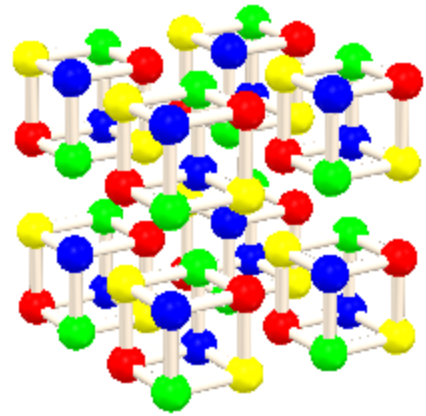
The MuPAD logo:
plot(plot::MuPADCube())



The MuPAD logo with strange colors:
plot(plot::MuPADCube(Colors = [RGB::Titanium $ 4, RGB::Gold],
BackgroundColor = RGB::Cobalt))



A collection of “MuPAD cubes”:
plot(plot::MuPADCube(Center = [2*k, 2*l, 2*m]) $ k = 0..1 $ l = 0..1 $ m = 0..1)



The MuPAD logo with animated size:
plot(plot::MuPADCube(1 - abs(a), [0, 0, 0], a = -1..1))

Parameters

r

The size of the object (the radius of the surrounding sphere): a real numerical value or an arithmetical expression of the animation parameter `a`. The default value of the radius is `1`.

`r` is equivalent to the attribute Radius.

c_x

c_y

c_z

The coordinates of the center: real numerical values or arithmetical expressions of the animation parameter `a`. By default, a cube centered at the origin is created.

c_x, c_y, c_z are equivalent to the attributes CenterX, CenterY, CenterZ.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also plotplot::copyplot::Coneplot::Cylinderplot::Sphere

plot::Ode2d

Purpose

2D plots of ODE solutions

Syntax

```
plot::Ode2d(f, [t0, t1,  ], Y0, <[G1, <Style = style1>,
<Color = c1>], [G2, <Style = style2>, <Color = c2>],  >,
<method>, <RelativeError = rtol>, <AbsoluteError = atol>,
<Stepsize = h>, <a = amin .. amax>, options)

style2>, <Color = c2>],  >, <method>, <RelativeError
= rtol>, <AbsoluteError = atol>, <Stepsize = h>,
<a = amin .. amax>, options)
plot::Ode2d([t0, t1,  ], f, Y0, <[G1, <Style = style1>,
<Color = c1>], [G2, <Style = style2>, <Color = c2>],  >,
<method>, <RelativeError = rtol>, <AbsoluteError = atol>,
<Stepsize = h>, <a = amin .. amax>, options)
plot::Ode2d([Automatic, tstart, tend, tstep], f, Y0,
<[G1, <Style = style1>, <Color = c1>], [G2, <Style =
style2>, <Color = c2>],  >, <method>, <RelativeError
= rtol>, <AbsoluteError = atol>, <Stepsize = h>,
<a = amin .. amax>, options)
```

Description

`plot::Ode2d(f, [t0, t1,  ], Y0)` renders two-dimensional projections of the solutions of the initial value problem given by `f`, t_0 and Y_0.

`plot::Ode2d(f, [t0, t1,  ], Y0, [G])` computes a mesh of numerical sample points $Y(t_0)$, $Y(t_1)$, … representing the solution $Y(t)$ of the first order differential equation (dynamical system)

diff(Y, t)=f(t, Y), Y(t_0)=Y_0, t_0, t in Symbol::Ropf , Y_0, Y(t) in Symbol::Copf ^n

$$\frac{\partial}{\partial t} Y = f(t, Y),\ Y(t_0) = Y_0,\ t_0,\ t \in \mathbb{R},\ Y_0,\ Y(t) \in \mathbb{C}^n$$

The procedure

_outputSequence(funcDecl(G, fenced(t, Y), [x(t, Y), y(t, Y)]), Symbol::Tab, 'or', Symbol::Tab, funcDecl(G, fenced(t, Y), [x(t, Y), y(t, Y), z(t, Y)]))

$G: (t, Y) \to [x(t, Y), y(t, Y)]$ or $G: (t, Y) \to [x(t, Y), y(t, Y), z(t, Y)]$ maps these solution points $(t_i, Y(t_i))$ in ^{n} to a mesh of 2D plot points $[x_i, y_i]$. These points can be connected by straight lines or interpolating splines.

The calling syntax of `plot::Ode2d` and `plot::Ode3d` as well as the functionality of these two procedures is identical. The only difference is that `plot::Ode2d` expects graphical generators G_1, G_2 etc. that produce graphical 2D points, whereas `plot::Ode3d` expects graphical generators producing 3D points.

Internally, a sequence of numerical sample points

`Y_1 := numeric::odesolve(f, t_0..t_1, Y_0, Options)`,

`Y_2 := numeric::odesolve(f, t_1..t_2, Y_1, Options)` etc.

is computed, where `Options` is some combination of `method`, `RelativeError = rtol`, `AbsoluteError = atol`, and `Stepsize = h`. See numeric::odesolve for details on the vector field procedure `f`, the initial condition Y_0, and the options.

The utility function numeric::ode2vectorfield may be used to produce the input parameters `f`, t_0, Y_0 from a set of differential expressions representing the ODE. Cf. "Example 1" on page 24-471.

Each of the "generators of plot data" G_1, G_2 etc. creates a graphical solution curve from the numerical sample points Y_0, Y_1 etc. Each generator `G`, say, is internally called in the form `G(`t_0`, `Y_0`)`, `G(`t_1`, `Y_1`)`, to produce a sequence of plot points in 2D.

The solver numeric::odesolve returns the solution points Y_0, Y_1 etc. as lists or 1-dimensional arrays (the actual type is determined by the initial value Y_0). Consequently, each generator `G` must accept two arguments `(t, Y)`: `t` is a real parameter, `Y` is a "vector" (either a list or a 1-dimensional array).

Each generator must return a list with 2 elements representing the (*x*, *y*) coordinates of the graphical point associated with a solution point `(t, Y)` of the ODE.

All generators must produce graphical data of the same dimension, i.e., 2D data as lists with 2 elements for `plot::Ode2d`.

Some examples:

`G := (t, Y) -> [t, Y_1]` creates a 2D plot of the first component of the solution vector along the *y*-axis, plotted against the time variable `t` along the *x*-axis

`G := (t, Y) -> [Y_1, Y_2]` creates a 2D phase plot, plotting the first component of the solution along the *x*-axis and the second component along the *y*-axis. The result is a solution curve in phase space (parametrized by the time `t`).

If no generators are given, `plot::Ode2d` by default plots all components of the solution as functions of time, using `[Splines, Points]` as the style.

Note that arbitrary values associated with the solution curve may be displayed graphically by an appropriate generator `G`. See “Example 2” on page 24-472 and “Example 5” on page 24-476.

Several generators G_1, G_2 etc. can be specified to generate several curves associated with the same numerical mesh Y_0, Y_1, . See “Example 1” on page 24-471, “Example 2” on page 24-472, and “Example 3” on page 24-474.

The graphical data produced by each of the generators G_1, G_2 etc. consists of a sequence of mesh points in 2D or 3D, respectively.

With `Style = Points`, the graphical data are displayed as a discrete set of points.

With `Style = Lines`, the graphical data points are displayed as a curve consisting of straight line segments between the sample points. The points themselves are not displayed.

With `Style = Splines`, the graphical data points are displayed as a smooth spline curve connecting the sample points. The points themselves are not displayed.

With `Style = [Splines, Points]` and `Style = [Lines, Points]`, the effects of the styles used are combined, i.e., both the evaluation points and the straight lines or splines, respectively, are displayed.

The plot attributes accepted by `plot::Ode2d,Ode3d` include `Submesh = n`, where *n* is some positive integer. This attribute only has an effect on the curves which are returned for the graphical generators with `Style = Splines` and `Style = [Splines, Points]`, respectively. It serves for smoothening the graphical spline curve using a sufficiently high number of plot points.

n is the number of plot points between two consecutive numerical points corresponding to the time mesh. The default value is $n = 4$, i.e., the splines are plotted as 5 straight line segments connecting the numerical sample points.

Attributes

Attribute	Purpose	Default Value
AbsoluteError	maximal absolute discretization error	
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`

Attribute	Purpose	Default Value
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson, RGB::Aqua, RGB::Lavender, RGB::SeaGreen, RGB::AureolineYellow, RGB::Banana, RGB::Beige, RGB::YellowGreen, RGB::Wheat, RGB::IndianRed, RGB::Black]
Frames	the number of frames in an animation	`50`
Function	function expression or procedure	
InitialConditions	initial conditions of the ODE	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineWidth	width of lines	`0.35`

Attribute	Purpose	Default Value
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
Name	the name of a plot object (for browser and legend)	
ODEMethod	the numerical scheme used for solving the ODE	`DOPRI78`
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`TRUE`
Projectors	project an ODE solution to graphical points	
RelativeError	maximal relative discretization error	
Stepsize	set a constant step size	

Attribute	Purpose	Default Value
Submesh	density of submesh (additional sample points)	`4`
TimeEnd	end time of the animation	`10.0`
TimeMesh	the numerical time mesh	
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
USubmesh	density of additional sample points for parameter “u”	`4`
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	

Attribute	Purpose	Default Value
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

The following procedure `f` together with the initial value `Y0` represent the initial value problem diff(Y, t)=f(t, Y)=t*Y-Y^2 $\dot{Y} = f(t, Y) = tY - Y^2$, $Y(0) = 2$. In MuPAD, the 1-dimensional vector Y is represented by a list with one element. The body of the function `f` below addresses the first (and only) entry of this list as Y_1 and returns the 1-dimensional vector $tY - Y^2$ as a list with one element. Also the initial condition Y_0 is a 1-dimensional vector represented by a list:

```
f := (t, Y) -> [t*Y[1] - Y[1]^2]: Y0 := [2]:
```

Alternatively, the utility function numeric::ode2vectorfield can be used to generate the input parameters in a more intuitive way:

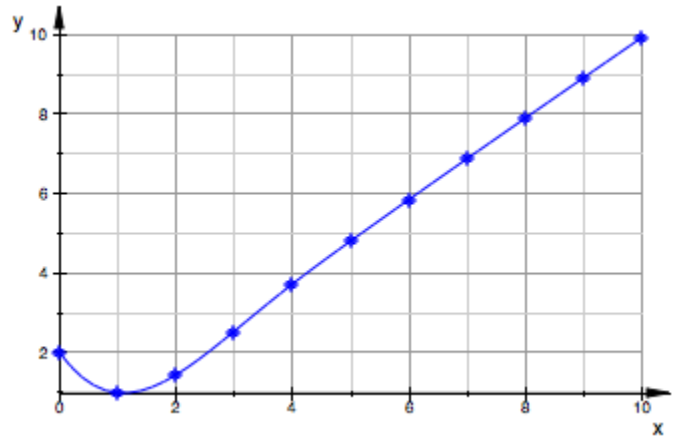
```
[f, t0, Y0] := [numeric::ode2vectorfield( {y'(t) = t*y(t) - y(t)^2, y(0) = 2},
[y(t)])]['proc f(t, Y) ... end', 0, [2]]
```

```
[proc f(t, Y) ... end, 0, [2]]
```

The numerical solution is to consist of sample points over the time mesh $t_i = i$, $i = 0, 1, \ldots, 10$. We use the default generator of `plot::Ode2d`. This generates the sample points together with a smooth spline curve connecting these points:

p := plot::Ode2d(f, [$ 0..10], Y0, PointSize = 2*unit::mm, PointStyle = Stars):

Finally, the ode solution is rendered by a call to plot:
plot(p, TicksDistance = 2.0, GridVisible = TRUE, SubgridVisible = TRUE):



Example 2

We consider the nonlinear oscillator y"+y^7=0$y'' + y^7 = 0$, y(0)=1, y'(0)=0$y(0) = 1,\ y'(0) = 0$. As a dynamical system for Y=[y, y']$Y = [y,\ y']$, we have to solve the following initial value problem diff(Y, t)=f(t, Y) $\frac{\partial}{\partial t} Y = f(t, Y)$, $Y(0) = Y_0$:
f := (t, Y) -> [Y[2], - Y[1]^7]: Y0 := [1, 0]:

The following generator produces a plot of the solution $Y(t)$ against the time parameter t:
G1 := (t, Y) -> [t, Y[1]]:

Further, we are interested in the values of the function

F=y^2/2+(y')^2/2$F = \frac{y^2}{2} + \frac{y'^2}{2}$. The generator `G2` produces the values F(y(t), y'(t))$F(y(t),\ y'(t))$ along the solution and plots these values against t:
G2 := (t, Y) -> [t, Y[1]^2/2 + Y[2]^2/2]:

The energy function (the "Hamiltonian") H=(y')^2/2+y^8/8$H = \frac{y'^2}{2} + \frac{y^8}{8}$ should be conserved along the solution curve. We define a corresponding generator `G3` to plot H(y(t), y'(t))$H(y(t), y'(t))$ as a function of *t*:

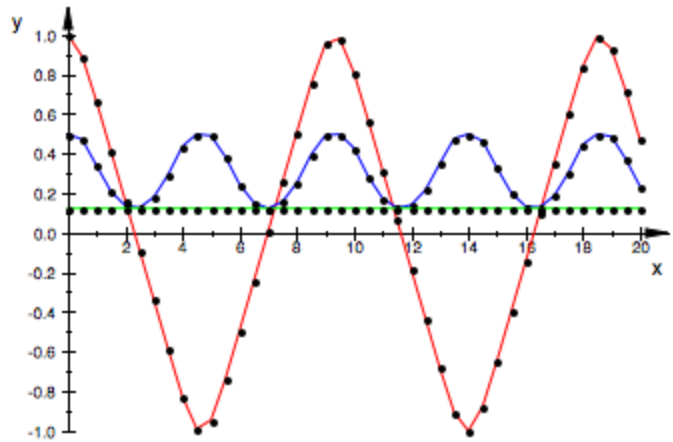
```
G3 := (t, Y) -> [t, Y[1]^8/8 + Y[2]^2/2]:
```

The solution curve is combined with the graph of the function F(t)=F(y(t), y'(t))$F(t) = F(y(t), y'(t))$ and the conserved energy H(t)=H(y(t), y'(t))$H(t) = H(y(t), y'(t))$:

```
p := plot::Ode2d(f, [i/2 $ i = 0..40], Y0, [G1, Style = Lines, Color =
RGB::Red], [G1, Style = Points, Color = RGB::Black], [G2, Style = Lines,
Color = RGB::Blue], [G2, Style = Points, Color = RGB::Black], [G3, Style
= Lines, Color = RGB::Green], [G3, Style = Points, Color = RGB::Black],
PointSize = 1.5*unit::mm, LineWidth = 0.2*unit::mm ):
```

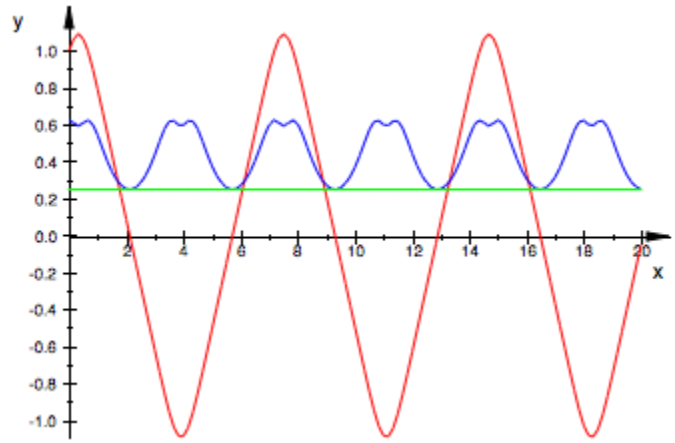
Note that by using each generator twice, we are able to set different colors for the lines and points. The renderer is called:

```
plot(p):
```



To visualize the dependency of the trajectory on the initial conditions, we animate `plot::Ode2d` over different values of y'(0)$y'(0)$:

plot(plot::Ode2d(f, [i/6 $ i = 0..120], [1, a], a = -1/2..1/2, [G1, Style = Lines, Color = RGB::Red], [G2, Style = Lines, Color = RGB::Blue], [G3, Style = Lines, Color = RGB::Green], LineWidth = 0.2*unit::mm, Frames=25))



Example 3

We consider the initial value problem y'=f(t, y)=t*sin(t+y^2)$y' = f(t, y) = t\sin(t + y^2)$, $y(0) = 0$:
f := (t, y) -> t*sin(t + y^2): Y0:= [0]:

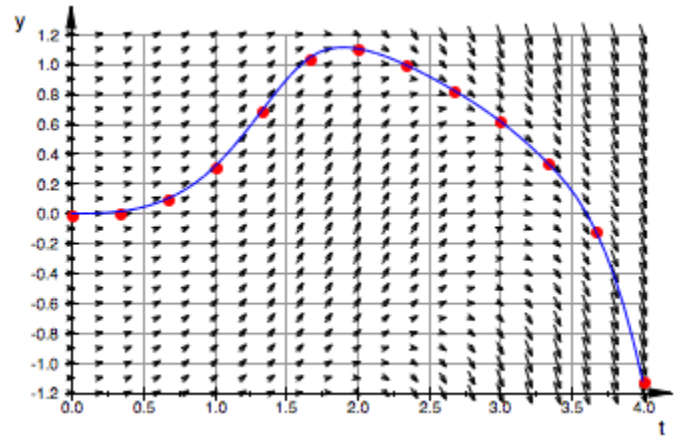
The following vector field is tangent to the solution curves:
p1 := plot::VectorField2d([1, f(t, y)], t = 0..4, y = -1.2..1.2, Mesh = [21, 25], Color = RGB::Black):

The following object represents the plot of the solution as a function of `t`:
p2 := plot::Ode2d((t,Y) -> [f(t, Y[1])], [i/3 $ i=0..12], Y0, [(t, Y) -> [t, Y[1]], Style = Points, Color = RGB::Red], [(t, Y) -> [t, Y[1]], Style = Splines, Color = RGB::Blue]):

We define the point size explicitly:
p2::PointSize := 2*unit::mm:

Finally, we combine the vector field and the ODE plot to a scene and call the renderer:

plot(p1, p2, XTicksDistance = 0.5, YTicksDistance = 0.2, Axes = Frame, AxesTitles = ["t", "y"], GridVisible = TRUE):

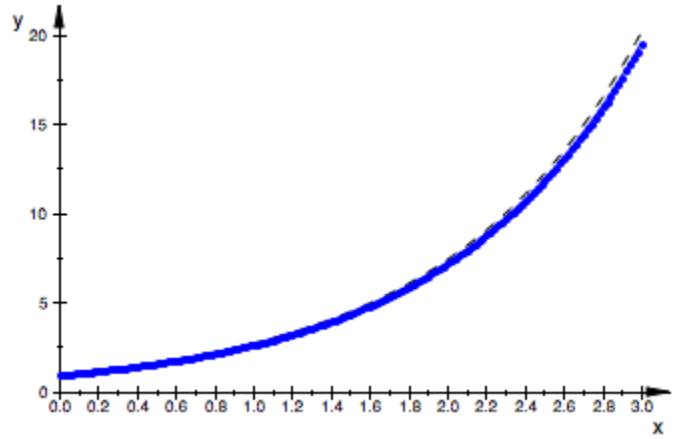


Example 4

By default, numeric::odesolve (which is used by `plot::Ode2d` and `plot::Ode3d` internally) uses adaptive step sizes and a method of order 8. Usually, there is no reason to change these settings, except for demonstrative purposes. In the following animation, we use a straightforward explicit Euler method (of first order) and show how decreasing the step size improves the quality of the calculated solution.

Our differential equation is y'=y$y' = y$, obviously fulfilled by the exponential function:
[f, t0, Y0] := [numeric::ode2vectorfield({y'(t)=y(t), y(0)=1}, [y(t)])]:

To judge the quality of the numerical solution, we plot the symbolic solution alongside the approximation:
plot(plot::Function2d(exp(x), x=0..3, Color = RGB::Black, LineStyle = Dashed), plot::Ode2d(f, [Automatic, 0, 3, 1/n], Y0, n = 1..50, EULER1, Stepsize = 1/n, [(t, Y) -> [t, Y[1]], Style=[Lines, Points]]))



Example 5

We consider the nonlinear oscillator y"+y^3=sin(t) $y'' + y^3 = \sin(t)$, y(0)=0, y'(0)=0.5 $y(0) = 0,\ y'(0) = 0.5$. As a dynamical system for Y=[y, y'] $Y = [y, y']$, we have to solve the following initial value problem diff(Y, t)=f(t, Y) $\frac{\partial}{\partial t} Y = f(t, Y)$, $Y(0) = Y_0$:

```
f := (t, Y) -> [Y[2], sin(t) - Y[1]^3]: Y0 := [0, 0.5]:
```

The following generator produces a phase plot in the (*x*, *y*) plane, embedded in a 3D plot:

```
G1 := (t, Y) -> [Y[1], Y[2], 0]:
```

Further, we use the *z* coordinate of the 3D plot to display the value of the "energy" function E=y^2/2+(y')^2/2 $E = \frac{y^2}{2} + \frac{y'^2}{2}$ over the phase curve:

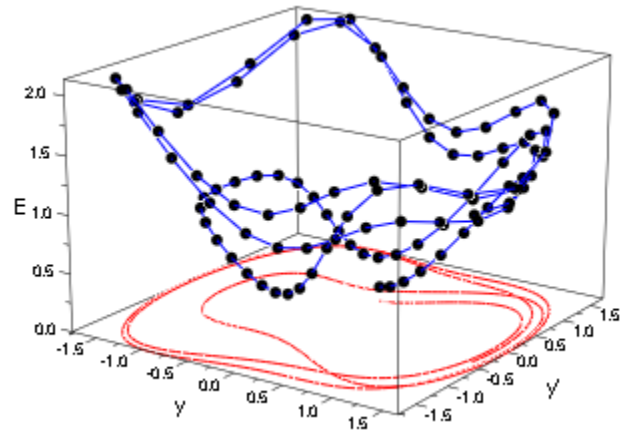
```
G2 := (t, Y) -> [Y[1], Y[2], (Y[1]^2 + Y[2]^2)/2]:
```

The phase curve in the (*x*, *y*) plane is combined with the graph of the energy function:

```
p := plot::Ode3d(f, [i/5 $ i = 0..100], Y0, [G1, Style = Splines, Color =
RGB::Red], [G2, Style = Points, Color = RGB::Black], [G2, Style = Lines,
Color = RGB::Blue]):
```

We set an explicit size of the points used in the representation of the energy:
p::PointSize := 2*unit::mm:

The renderer is called:
plot(p, AxesTitles = ["y", "y'", "E"], CameraDirection = [10, -15, 5]):



Example 6

The Lorenz ODE is the system

diff(matrix([[x], [y], [z]]), t)=matrix([[p*fenced(y-x)], [-x*z+r*x-y], [x*y-b*z]])

$$\frac{\partial}{\partial t}\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} p\,(y-x) \\ -x\,z+r\,x-y \\ x\,y-b\,z \end{pmatrix}$$

with fixed parameters p, r, b. As a dynamical system for $Y = [x, y, z]$, we have to solve the ODE diff(Y, t)=f(t, Y) $\frac{\partial}{\partial t} Y = f(t, Y)$ with the following vector field:

```
f := proc(t, Y) local x, y, z; begin [x, y, z] := Y: [p*(y - x), -x*z + r*x - y,
x*y - b*z] end_proc:
```

We consider the following parameters and the following initial condition `Y0`:

```
p := 10: r := 28: b := 1: Y0 := [1, 1, 1]:
```

The following generator `Gxyz` produces a 3D phase plot of the solution. The generator `Gyz` projects the solution curve to the (*y*, *z*) plane with *x* = 20; the generator `Gxz` projects the solution curve to the (*x*, *z*) plane with *y* = - 15; the generator `Gxy` projects the solution curve to the (*x*, *y*) plane with *z* = 0:

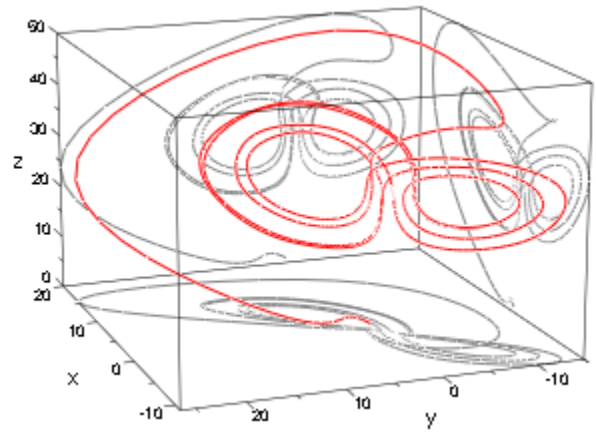
```
Gxyz := (t, Y) -> Y: Gyz := (t, Y) -> [ 20, Y[2], Y[3]]: Gxz := (t, Y) -> [Y[1],
-15, Y[3]]: Gxy := (t, Y) -> [Y[1], Y[2], 0 ]:
```

With these generators, we create a 3D plot object consisting of the phase curve and its projections.

```
object := plot::Ode3d(f, [i/10 $ i=1..100], Y0, [Gxyz, Style = Splines,
Color = RGB::Red], [Gyz, Style = Splines, Color = RGB::Grey50], [Gxz,
Style = Splines, Color = RGB::Grey50], [Gxy, Style = Splines, Color
= RGB::Grey50], Submesh = 7):
```

Finally, the plot is rendered. This call is somewhat time consuming because it calls the numerical solver numeric::odesolve to produce the graphical data:

```
plot(object, CameraDirection = [-220, 110, 150])
```



Parameters

f

The vector field of the ODE: a procedure. See numeric::odesolve for details.

`f` is equivalent to the attribute Function.

t_0, t_1, ...

The time mesh: real numerical values. If data are displayed with `Style = Splines`, these values must be in ascending order.

t_0, t_1, ... is equivalent to the attribute TimeMesh.

t_{start}

t_{end}

t_{step}

The time mesh: real numerical values. t_{end} must be larger than t_{start} and t_{step} must be positive and should be smaller than t_end - t_start.

t_{start}, t_{end}, t_{step} are equivalent to the attribute TimeMesh.

Y_0

The initial condition of the ODE: a list or a 1-dimensional array. See numeric::odesolve.

Y_0 is equivalent to the attribute InitialConditions.

G_1, G_2, ...

"generators of plot data": procedures mapping a solution point `(t, Y(t))` to a list `[x, y]` or `[x, y, z]` representing a plot point in 2D or 3D, respectively.

G_1, G_2, ... is equivalent to the attribute Projectors.

method

Use a specific numerical scheme (see numeric::odesolve)

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

Options

Style

Option, specified as `Style = style`

Sets the style in which the plot data are displayed. The following styles are available: `Points`, `Lines`, `Splines`, `[Lines, Points]`, and `[Splines, Points]`. The default style is `[Splines, Points]`.

Color

Option, specified as `Color = c`

Sets the RGB color `c` in which the plot data are displayed. The default color of the *i*th generator is the *i*th entry of the attribute Colors.

RelErr

Option, specified as `RelErr = rtol`

Sets a numerical discretization tolerance (see numeric::odesolve)

AbsErr

Option, specified as `AbsErr = atol`

Sets a numerical discretization tolerance (see numeric::odesolve)

Stepsize

Option, specified as `Stepsize = h`

Sets a constant stepsize (see numeric::odesolve)

```

Description

`plot::Ode3d(f, [t0, t1,  ], Y0)` renders three-dimensional projections of the solutions of the initial value problem given by `f`, t_0 and Y_0.

`plot::Ode3d(f, [t0, t1,  ], Y0, [G])` computes a mesh of numerical sample points $Y(t_0)$, $Y(t_1)$, … representing the solution $Y(t)$ of the first order differential equation (dynamical system)

diff(Y, t)=f(t, Y), Y(t_0)=Y_0, t_0, t in Symbol::Ropf , Y_0, Y(t) in Symbol::Copf ^n

$$\frac{\partial}{\partial t} Y = f(t, Y),\ Y(t_0) = Y_0,\ t_0,\ t \in \mathbb{R},\ Y_0,\ Y(t) \in \mathbb{C}^n$$

The procedure

_outputSequence(funcDecl(G, fenced(t, Y), [x(t, Y), y(t, Y)]), Symbol::Tab, 'or', Symbol::Tab, funcDecl(G, fenced(t, Y), [x(t, Y), y(t, Y), z(t, Y)]))

$G: (t, Y) \to [x(t, Y), y(t, Y)]$ or $G: (t, Y) \to [x(t, Y), y(t, Y), z(t, Y)]$ maps these solution points $(t_i, Y(t_i))$ in ^{n} to a mesh of 3D plot points $[x_i, y_i, z_i]$. These points can be connected by straight lines or interpolating splines.

The calling syntax of `plot::Ode2d` and `plot::Ode3d` as well as the functionality of these two procedures is identical. The only difference is that `plot::Ode2d` expects graphical generators G_1, G_2 etc. that produce graphical 2D points, whereas `plot::Ode3d` expects graphical generators producing 3D points.

Internally, a sequence of numerical sample points

`Y_1 := numeric::odesolve(f, t_0..t_1, Y_0, Options)`,

`Y_2 := numeric::odesolve(f, t_1..t_2, Y_1, Options)` etc.

is computed, where `Options` is some combination of `method`, `RelativeError = rtol`, `AbsoluteError = atol`, and `Stepsize = h`. See numeric::odesolve for details on the vector field procedure `f`, the initial condition Y_0, and the options.

The utility function numeric::ode2vectorfield may be used to produce the input parameters `f, t_0, Y_0` from a set of differential expressions representing the ODE. Cf. "Example 1" on page 24-489.

Each of the "generators of plot data" G_1, G_2 etc. creates a graphical solution curve from the numerical sample points Y_0, Y_1 etc. Each generator `G`, say, is internally called in the form `G(t_0, Y_0), G(t_1, Y_1),` to produce a sequence of plot points in 3D.

The solver numeric::odesolve returns the solution points Y_0, Y_1 etc. as lists or 1-dimensional arrays (the actual type is determined by the initial value Y_0). Consequently, each generator `G` must accept two arguments `(t, Y)`: `t` is a real parameter, `Y` is a "vector" (either a list or a 1-dimensional array).

Each generator must return a list with 3 elements representing the (*x*, *y*, *z*) coordinates of the graphical point associated with a solution point `(t, Y)` of the ODE.

All generators must produce graphical data of the same dimension, i.e., for `plot::Ode3d`, 3D data as lists with 3 elements.

Some examples:

`G := (t, Y) -> [Y_1, Y_2, Y_3]` creates a 3D phase plot of the first three components of the solution curve.

If no generators are given, `plot::Ode3d` by default plots each group of two components as functions of time with the same style.

Note that arbitrary values associated with the solution curve may be displayed graphically by an appropriate generator `G`. See "Example 2" on page 24-490 and "Example 5" on page 24-494.

Several generators G_1, G_2 etc. can be specified to generate several curves associated with the same numerical mesh Y_0, Y_1, . See "Example 1" on page 24-489, "Example 2" on page 24-490, and "Example 3" on page 24-492.

The graphical data produced by each of the generators G_1, G_2 etc. consists of a sequence of mesh points in 2D or 3D, respectively.

With `Style = Points`, the graphical data are displayed as a discrete set of points.

With `Style = Lines`, the graphical data points are displayed as a curve consisting of straight line segments between the sample points. The points themselves are not displayed.

With `Style = Splines`, the graphical data points are displayed as a smooth spline curve connecting the sample points. The points themselves are not displayed.

With `Style = [Splines, Points]` and `Style = [Lines, Points]`, the effects of the styles used are combined, i.e., both the evaluation points and the straight lines or splines, respectively, are displayed.

The plot attributes accepted by `plot::Ode2d,Ode3d` include `Submesh = n`, where *n* is some positive integer. This attribute only has an effect on the curves which are returned for the graphical generators with `Style = Splines` and `Style = [Splines, Points]`, respectively. It serves for smoothening the graphical spline curve using a sufficiently high number of plot points.

n is the number of plot points between two consecutive numerical points corresponding to the time mesh. The default value is $n = 4$, i.e., the splines are plotted as 5 straight line segments connecting the numerical sample points.

Attributes

Attribute	Purpose	Default Value
AbsoluteError	maximal absolute discretization error	
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson, RGB::Aqua, RGB::Lavender, RGB::SeaGreen, RGB::AureolineYellow, RGB::Banana, RGB::Beige, RGB::YellowGreen,

Attribute	Purpose	Default Value
		RGB::Wheat, RGB::IndianRed, RGB::Black]
Frames	the number of frames in an animation	50
Function	function expression or procedure	
InitialConditions	initial conditions of the ODE	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ODEMethod	the numerical scheme used for solving the ODE	DOPRI78
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	

Attribute	Purpose	Default Value
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`TRUE`
Projectors	project an ODE solution to graphical points	
RelativeError	maximal relative discretization error	
Stepsize	set a constant step size	
Submesh	density of submesh (additional sample points)	`4`
TimeEnd	end time of the animation	`10.0`
TimeMesh	the numerical time mesh	
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`

Attribute	Purpose	Default Value
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
USubmesh	density of additional sample points for parameter “u”	`4`
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

Example 1

The following procedure `f` together with the initial value `Y0` represent the initial value problem diff(Y, t)=f(t, Y)=t*Y-Y^2, $Y(0) = 2$. In MuPAD, the 1-dimensional vector Y is represented by a list with one element. The body of the function `f` below addresses the first (and only) entry of this list as Y_1 and returns the 1-dimensional vector $tY - Y^2$ as a list with one element. Also the initial condition Y_0 is a 1-dimensional vector represented by a list:

```
f := (t, Y) -> [t*Y[1] - Y[1]^2]: Y0 := [2]:
```

Alternatively, the utility function numeric::ode2vectorfield can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] := [numeric::ode2vectorfield( {y'(t) = t*y(t) - y(t)^2, y(0) = 2},
[y(t)])]['proc f(t, Y) ... end', 0, [2]]
```

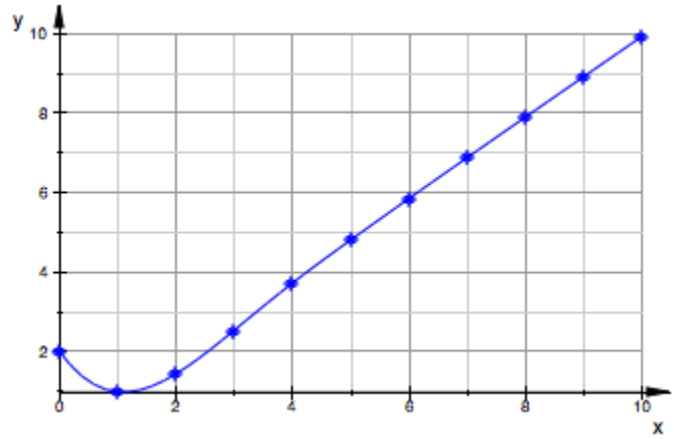
```
[proc f(t, Y) ... end, 0, [2]]
```

The numerical solution is to consist of sample points over the time mesh $t_i = i$, $i = 0, 1, \ldots, 10$. We use the default generator of `plot::Ode2d`. This generates the sample points together with a smooth spline curve connecting these points:

```
p := plot::Ode2d(f, [$ 0..10], Y0, PointSize = 2*unit::mm, PointStyle =
Stars):
```

Finally, the ode solution is rendered by a call to plot:

```
plot(p, TicksDistance = 2.0, GridVisible = TRUE, SubgridVisible =
TRUE):
```



Example 2

We consider the nonlinear oscillator y"+y^7=0 $y'' + y^7 = 0$, y(0)=1, y'(0)=0 $y(0) = 1,\ y'(0) = 0$. As a dynamical system for Y=[y, y'] $Y = [y, y']$, we have to solve the following initial value problem diff(Y, t)=f(t, Y) $\frac{\partial}{\partial t} Y = f(t, Y)$, $Y(0) = Y_0$:

```
f := (t, Y) -> [Y[2], - Y[1]^7]: Y0 := [1, 0]:
```

The following generator produces a plot of the solution $Y(t)$ against the time parameter t:

```
G1 := (t, Y) -> [t, Y[1]]:
```

Further, we are interested in the values of the function F=y^2/2+(y')^2/2 $F = \frac{y^2}{2} + \frac{y'^2}{2}$. The generator `G2` produces the values F(y(t), y'(t)) $F(y(t), y'(t))$ along the solution and plots these values against t:

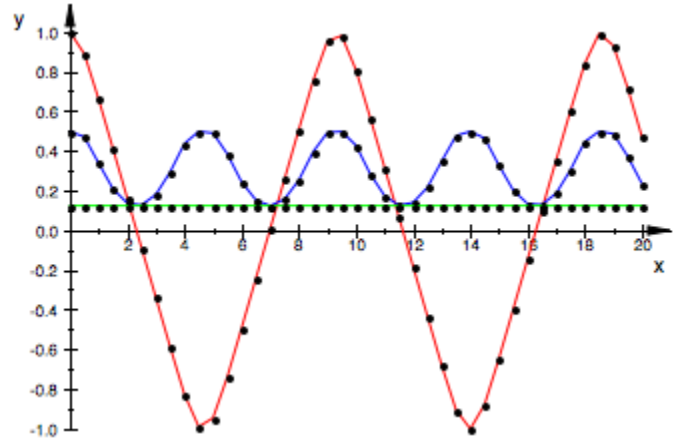
```
G2 := (t, Y) -> [t, Y[1]^2/2 + Y[2]^2/2]:
```

The energy function (the "Hamiltonian") H=(y')^2/2+y^8/8 $H = \frac{y'^2}{2} + \frac{y^8}{8}$ should be conserved along the solution curve. We define a corresponding generator `G3` to plot H(y(t), y'(t)) $H(y(t), y'(t))$ as a function of t:

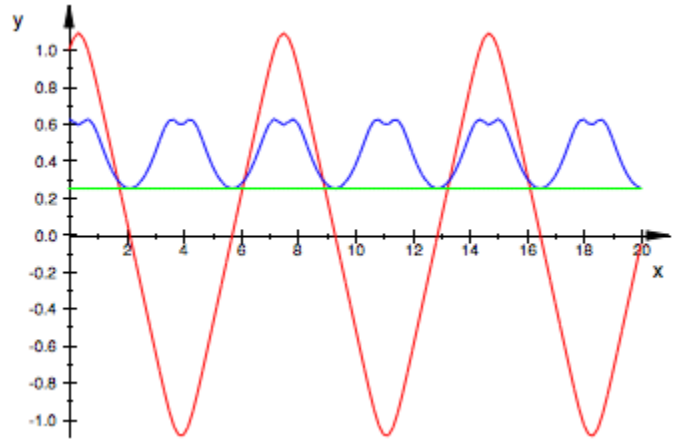
```
G3 := (t, Y) -> [t, Y[1]^8/8 + Y[2]^2/2]:
```

The solution curve is combined with the graph of the function F(t)=F(y(t), y'(t))$F(t) = F(y(t), y'(t))$ and the conserved energy H(t)=H(y(t), y'(t))$H(t) = H(y(t), y'(t))$:
p := plot::Ode2d(f, [i/2 $ i = 0..40], Y0, [G1, Style = Lines, Color = RGB::Red], [G1, Style = Points, Color = RGB::Black], [G2, Style = Lines, Color = RGB::Blue], [G2, Style = Points, Color = RGB::Black], [G3, Style = Lines, Color = RGB::Green], [G3, Style = Points, Color = RGB::Black], PointSize = 1.5*unit::mm, LineWidth = 0.2*unit::mm):

Note that by using each generator twice, we are able to set different colors for the lines and points. The renderer is called:
plot(p):



To visualize the dependency of the trajectory on the initial conditions, we animate `plot::Ode2d` over different values of y'(0)$y'(0)$:
plot(plot::Ode2d(f, [i/6 $ i = 0..120], [1, a], a = -1/2..1/2, [G1, Style = Lines, Color = RGB::Red], [G2, Style = Lines, Color = RGB::Blue], [G3, Style = Lines, Color = RGB::Green], LineWidth = 0.2*unit::mm, Frames=25))



Example 3

We consider the initial value problem y'=f(t, y)=t*sin(t+y^2)$y' = f(t, y) = t\sin(t + y^2)$, $y(0) = 0$:

```
f := (t, y) -> t*sin(t + y^2): Y0:= [0]:
```

The following vector field is tangent to the solution curves:

```
p1 := plot::VectorField2d([1, f(t, y)], t = 0..4, y = -1.2..1.2, Mesh = [21,
25], Color = RGB::Black):
```

The following object represents the plot of the solution as a function of `t`:

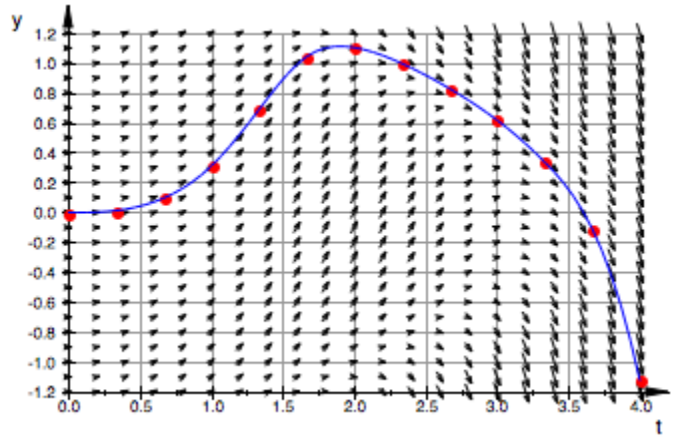
```
p2 := plot::Ode2d( (t,Y) -> [f(t, Y[1])], [i/3 $ i=0..12], Y0, [(t, Y) -> [t,
Y[1]], Style = Points, Color = RGB::Red], [(t, Y) -> [t, Y[1]], Style =
Splines, Color = RGB::Blue]):
```

We define the point size explicitly:

```
p2::PointSize := 2*unit::mm:
```

Finally, we combine the vector field and the ODE plot to a scene and call the renderer:

```
plot(p1, p2, XTicksDistance = 0.5, YTicksDistance = 0.2, Axes = Frame,
AxesTitles = ["t", "y"], GridVisible = TRUE):
```

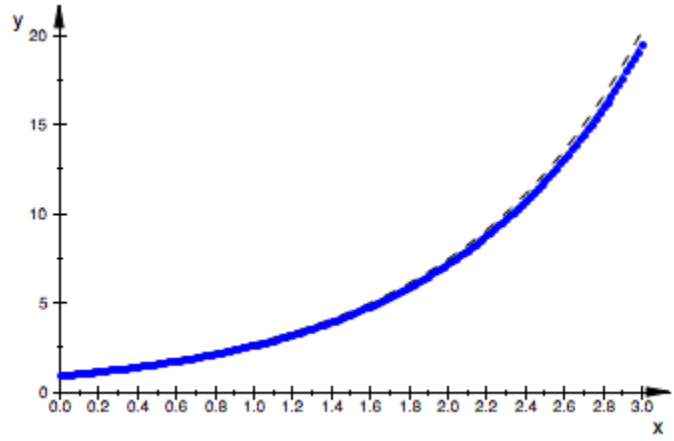


Example 4

By default, numeric::odesolve (which is used by `plot::Ode2d` and `plot::Ode3d` internally) uses adaptive step sizes and a method of order 8. Usually, there is no reason to change these settings, except for demonstrative purposes. In the following animation, we use a straightforward explicit Euler method (of first order) and show how decreasing the step size improves the quality of the calculated solution.

Our differential equation is y'=y$y' = y$, obviously fulfilled by the exponential function:
[f, t0, Y0] := [numeric::ode2vectorfield({y'(t)=y(t), y(0)=1}, [y(t)])]:

To judge the quality of the numerical solution, we plot the symbolic solution alongside the approximation:
plot(plot::Function2d(exp(x), x=0..3, Color = RGB::Black, LineStyle = Dashed), plot::Ode2d(f, [Automatic, 0, 3, 1/n], Y0, n = 1..50, EULER1, Stepsize = 1/n, [(t, Y) -> [t, Y[1]], Style=[Lines, Points]]))



Example 5

We consider the nonlinear oscillator y"+y^3=sin(t) $y'' + y^3 = \sin(t)$, y(0)=0, y'(0)=0.5 $y(0) = 0,\ y'(0) = 0.5$. As a dynamical system for Y=[y, y'] $Y = [y, y']$, we have to solve the following initial value problem diff(Y, t)=f(t, Y) $\frac{\partial}{\partial t} Y = f(t, Y)$, $Y(0) = Y_0$:

```
f := (t, Y) -> [Y[2], sin(t) - Y[1]^3]: Y0 := [0, 0.5]:
```

The following generator produces a phase plot in the (*x*, *y*) plane, embedded in a 3D plot:

```
G1 := (t, Y) -> [Y[1], Y[2], 0]:
```

Further, we use the *z* coordinate of the 3D plot to display the value of the "energy" function E=y^2/2+(y')^2/2 $E = \frac{y^2}{2} + \frac{y'^2}{2}$ over the phase curve:

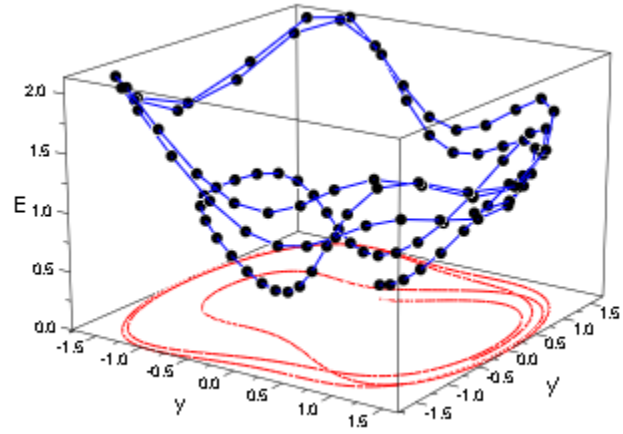
```
G2 := (t, Y) -> [Y[1], Y[2], (Y[1]^2 + Y[2]^2)/2]:
```

The phase curve in the (*x*, *y*) plane is combined with the graph of the energy function:

```
p := plot::Ode3d(f, [i/5 $ i = 0..100], Y0, [G1, Style = Splines, Color =
RGB::Red], [G2, Style = Points, Color = RGB::Black], [G2, Style = Lines,
Color = RGB::Blue]):
```

We set an explicit size of the points used in the representation of the energy:
p::PointSize := 2*unit::mm:

The renderer is called:
plot(p, AxesTitles = ["y", "y'", "E"], CameraDirection = [10, -15, 5]):



Example 6

The Lorenz ODE is the system

diff(matrix([[x], [y], [z]]), t)=matrix([[p*fenced(y-x)], [-x*z+r*x-y], [x*y-b*z]])

$$\frac{\partial}{\partial t}\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} p\,(y-x) \\ -x\,z+r\,x-y \\ x\,y-b\,z \end{pmatrix}$$

with fixed parameters p, r, b. As a dynamical system for $Y = [x, y, z]$, we have to solve the ODE diff(Y, t)=f(t, Y) $\frac{\partial}{\partial t} Y = f(t, Y)$ with the following vector field:

```
f := proc(t, Y) local x, y, z; begin [x, y, z] := Y: [p*(y - x), -x*z + r*x - y,
x*y - b*z] end_proc:
```

We consider the following parameters and the following initial condition `Y0`:

```
p := 10: r := 28: b := 1: Y0 := [1, 1, 1]:
```

The following generator `Gxyz` produces a 3D phase plot of the solution. The generator `Gyz` projects the solution curve to the (*y*, *z*) plane with *x* = 20; the generator `Gxz` projects the solution curve to the (*x*, *z*) plane with *y* = - 15; the generator `Gxy` projects the solution curve to the (*x*, *y*) plane with *z* = 0:

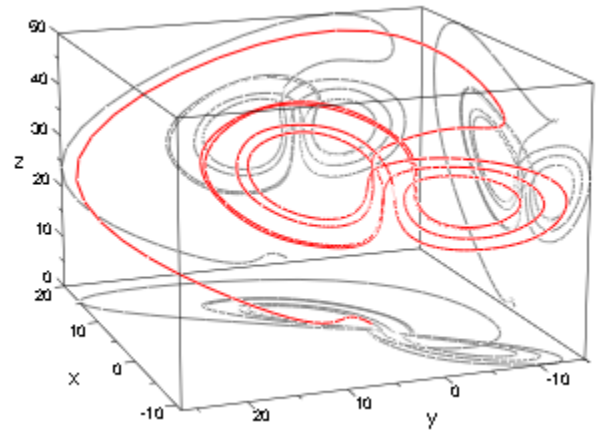
```
Gxyz := (t, Y) -> Y: Gyz := (t, Y) -> [ 20, Y[2], Y[3]]: Gxz := (t, Y) -> [Y[1],
-15, Y[3]]: Gxy := (t, Y) -> [Y[1], Y[2], 0 ]:
```

With these generators, we create a 3D plot object consisting of the phase curve and its projections.

```
object := plot::Ode3d(f, [i/10 $ i=1..100], Y0, [Gxyz, Style = Splines,
Color = RGB::Red], [Gyz, Style = Splines, Color = RGB::Grey50], [Gxz,
Style = Splines, Color = RGB::Grey50], [Gxy, Style = Splines, Color
= RGB::Grey50], Submesh = 7):
```

Finally, the plot is rendered. This call is somewhat time consuming because it calls the numerical solver numeric::odesolve to produce the graphical data:

```
plot(object, CameraDirection = [-220, 110, 150])
```



Parameters

f

The vector field of the ODE: a procedure. See numeric::odesolve for details.

`f` is equivalent to the attribute Function.

t_0, t_1, ...

The time mesh: real numerical values. If data are displayed with `Style = Splines`, these values must be in ascending order.

t_0, t_1, ... is equivalent to the attribute TimeMesh.

t_{start}

t_{end}

t_{step}

The time mesh: real numerical values. t_{end} must be larger than t_{start} and t_{step} must be positive and should be smaller than t_end - t_start.

t_{start}, t_{end}, t_{step} are equivalent to the attribute TimeMesh.

Y_0

The initial condition of the ODE: a list or a 1-dimensional array. See numeric::odesolve.

Y_0 is equivalent to the attribute InitialConditions.

G_1, G_2, ...

"generators of plot data": procedures mapping a solution point `(t, Y(t))` to a list `[x, y]` or `[x, y, z]` representing a plot point in 2D or 3D, respectively.

G_1, G_2, ... is equivalent to the attribute Projectors.

method

Use a specific numerical scheme (see numeric::odesolve)

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

Options

Style

Option, specified as `Style = style`

Sets the style in which the plot data are displayed. The following styles are available: `Points`, `Lines`, `Splines`, `[Lines, Points]`, and `[Splines, Points]`. The default style is `[Splines, Points]`.

Color

Option, specified as `Color = c`

Sets the RGB color `c` in which the plot data are displayed. The default color of the *i*th generator is the *i*th entry of the attribute Colors.

RelErr

Option, specified as `RelErr = rtol`

Sets a numerical discretization tolerance (see numeric::odesolve)

AbsErr

Option, specified as `AbsErr = atol`

Sets a numerical discretization tolerance (see numeric::odesolve)

Stepsize

Option, specified as `Stepsize = h`

Sets a constant stepsize (see numeric::odesolve)

See Also

numeric::odesolvenumeric::odesolve2numeric::ode2vectorfieldplot::Ode2dplot::Curv

plot::Parallelogram2d

Purpose

2D parallelograms

Syntax

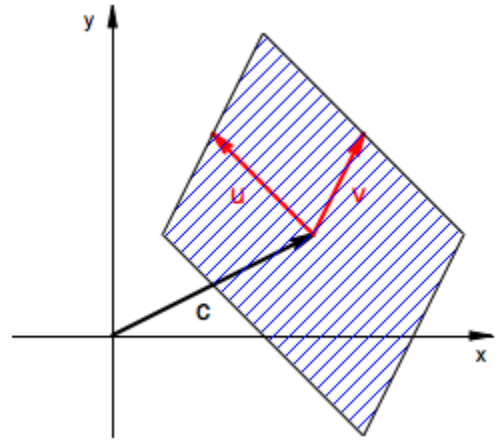
```
plot::Parallelogram2d([c_x, c_y], [u_x, u_y], [v_x, v_y],
<a = a_min .. a_max>, options)
```

Description

`plot::Parallelogram2d(c, u, v)` defines a 2D parallelogram ImageSet(‘c→‘ + Symbol::lambda* ‘u→‘ + Symbol::mu * ‘v→‘, Symbol::lambda in [-1, 1], Symbol::mu in [-1, 1])$\{\vec{c} + \lambda\,\vec{u} + \mu\,\vec{v} \mid \lambda \in [-1, 1], \mu \in [-1, 1]\}$ with center ‘c→‘$\vec{c}$ and vectors ‘u→‘$\vec{u}$, ‘v→‘$\vec{v}$ spanning the plane of the parallelogram. This is a rectangle with sides of length 2*abs(‘u→‘)$2\,|\vec{u}|$, 2*abs(‘v→‘)$2\,|\vec{v}|$ if the vectors ‘u→‘$\vec{u}$ and ‘v→‘$\vec{v}$ are orthogonal.

`plot::Parallelogram2d` creates a 2D parallelogram with center ‘c→‘$\vec{c}$ = `[c_x, c_y]` and sides given by the vectors 2*‘u→‘$2\,\vec{u}$ = `[2 u_x, 2 u_y]` and 2*‘v→‘$2\,\vec{v}$ = `[2 v_x, 2 v_y]`. The corners of the parallelogram are given by ‘c→‘-‘u→‘-‘v→‘$\vec{c} - \vec{u} - \vec{v}$, ‘c→‘-‘u→‘+‘v→‘$\vec{c} - \vec{u} + \vec{v}$, ‘c→‘+‘u→‘-‘v→‘$\vec{c} + \vec{u} - \vec{v}$, and ‘c→‘+‘u→‘+‘v→‘$\vec{c} + \vec{u} + \vec{v}$:

```
plot(plot::Arrow2d([0, 0], [4, 2], Color = RGB::Black, LineWidth
= 0.8*unit::mm, Title = "c", TitlePosition = [1.8, 0.3], TitleFont =
[14]), plot::Arrow2d([4, 2], [2, 4], Color = RGB::Red, LineWidth =
0.8*unit::mm, Title = "u", TitlePosition = [2.5, 2.6], TitleFont = [14,
RGB::Red]), plot::Arrow2d([4, 2], [5, 4],Color = RGB::Red, LineWidth
= 0.8*unit::mm, Title = "v", TitlePosition = [4.9, 2.6], TitleFont = [14,
RGB::Red]), plot::Parallelogram2d([4, 2],[-2, 2], [1, 2], LineColor =
RGB::Black, Filled = TRUE, FillColor = RGB::Blue), Axes = Origin,
ViewingBox = [-2 .. Automatic, Automatic], TicksNumber = None,
Scaling = Constrained):
```



By default, the area of the parallelogram is filled with the color specified by the attribute Color or, equivalently, FillColor. With Filled = `False`, only the border lines of the parallelogram are visible. Their color is set by the attribute LineColor.

Alternatively, the center and the spanning vectors can be given as vectors.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Center	center of objects, rotation center	`[0, 0]`
CenterX	center of objects, rotation center, x-component	`0`

Attribute	Purpose	Default Value
CenterY	center of objects, rotation center, y-component	0
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	

Attribute	Purpose	Default Value
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Tangent1	first vector spanning parallelograms	[0, 1]
Tangent2	second vector spanning parallelograms	[1, 0]
Tangent1X	first vector spanning parallelograms, x component	0
Tangent1Y	first vector spanning parallelograms, y component	1
Tangent2X	second vector spanning parallelograms, x component	1
Tangent2Y	second vector spanning parallelograms, y component	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	

Attribute	Purpose	Default Value
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

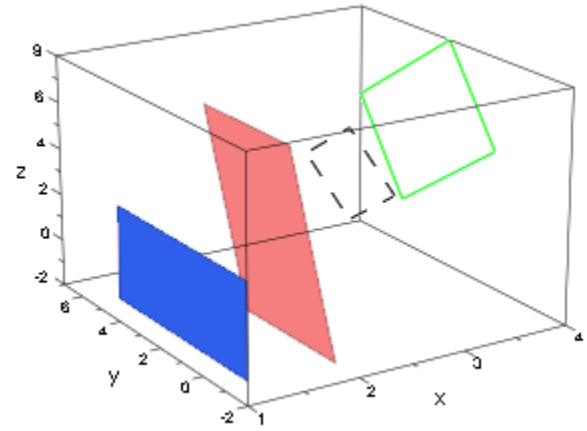
Examples

Example 1

We plot several rectangles and parallelograms using different presentation styles:

```
plot(plot::Parallelogram3d([1, 1, 1], [0, 0, 2], [0, 3, 0]),
plot::Parallelogram3d([2, 2, 2], [0, 1, 4], [0, 2, 0], FillColor =
RGB::Red.[0.5]), plot::Parallelogram3d([3, 3, 3], [0, 1, 1], [0, 1, -1],
```

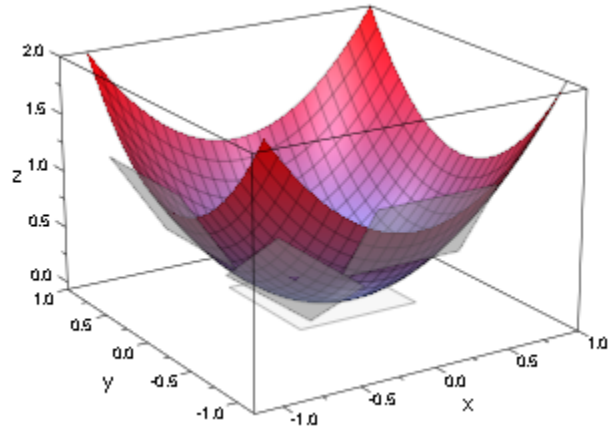
Filled = FALSE, LineStyle = Dashed, LineColor = RGB::Black), plot::Parallelogram3d([4, 4, 4], [0, 1, 2], [0, 2, -2], Filled = FALSE, LineColor = RGB::Green)):



Example 2

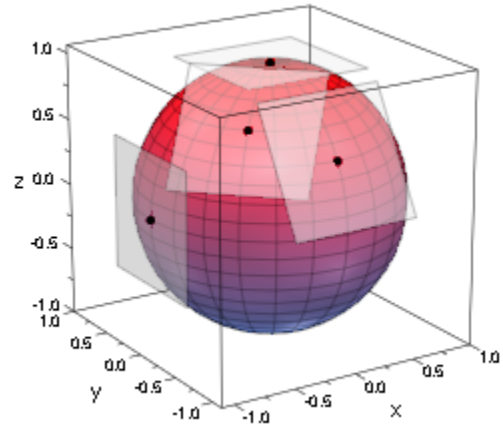
We use `plot::Parallelogram3d` to visualize tangent planes of a surface. The first surface is the graph of the function $f(x, y) = x^2 + y^2$. At a point $(x, y, f(x, y))$ on the graph, the tangent vectors in the x and y direction are given by $(1, 0, 2x)$ and $(0, 1, 2y)$, respectively. After normalization to the length 0.4, they yield the tangent vectors u, v used in the construction of the tangent planes:

```
f := (x, y) -> x^2 + y^2: c:= (x, y) -> [x, y, f(x, y)]: u := (x, y)
-> [0.4/sqrt(1+4*x^2), 0, 0.8*x/sqrt(1+4*x^2)]: v := (x, y) -> [0,
0.4/sqrt(1+4*y^2), 0.8*y/sqrt(1+4*y^2)]: plot(plot::Function3d(f(x, y), x
= -1..1, y = -1..1), plot::Parallelogram3d(c(0, 0), u(0, 0), v(0, 0), Color =
RGB::Grey.[0.5]), plot::Parallelogram3d(c(0, -1), u(0, -1), v(0, -1), Color =
RGB::Grey.[0.5]), plot::Parallelogram3d(c(-1, 0), u(-1, 0), v(-1, 0), Color =
RGB::Grey.[0.5]), plot::Parallelogram3d(c(-1/2, -1/2), u(-1/2, -1/2), v(-1/2,
-1/2), Color = RGB::Grey.[0.5])):
```



The second surface is a sphere, parametrized by spherical coordinates p and t (polar and azimuth angle). At a point ($x(p, t)$, $y(p, t)$, $z(p, t)$) on the sphere, the tangent vectors in the p and t direction are given by differention of x, y, z w.r.t. p and t, respectively. After normalization to the length 0.5, they yield the tangent vectors u, v used in the construction of the tangent planes:

```
x := (p, t) -> cos(p)*sin(t): y := (p, t) -> sin(p)*sin(t): z := (p, t) -> cos(t): c
:= (p, t) -> [x(p, t), y(p, t), z(p, t)]: u := (p, t) -> [-0.5*sin(p), 0.5*cos(p),
0]: v := (p, t) -> [0.5*cos(p)*cos(t), 0.5*sin(p)*cos(t), -0.5*sin(t)]:
plot(plot::Surface(c(p, t), p = 0..2*PI, t = 0..PI), plot::Point3d(c(0,
0), Color = RGB::Black), plot::Parallelogram3d(c(0, 0), u(0, 0), v(0,
0), Color = RGB::Grey.[0.5]), plot::Point3d(c(-3*PI/4, PI/4), Color =
RGB::Black), plot::Parallelogram3d(c(-3*PI/4, PI/4), u(-3*PI/4, PI/4),
v(-3*PI/4, PI/4), Color = RGB::Grey.[0.5]), plot::Point3d(c(-PI/2, PI/3),
Color = RGB::Black), plot::Parallelogram3d(c(-PI/2, PI/3), u(-PI/2, PI/3),
v(-PI/2, PI/3), Color = RGB::Grey.[0.5]), plot::Point3d(c(PI, PI/2), Color =
RGB::Black), plot::Parallelogram3d(c(PI, PI/2), u(PI, PI/2), v(PI, PI/2),
Color = RGB::Grey.[0.5]), Scaling = Constrained):
```



delete f, c, u, v, x, y, z:

Parameters

c_x

c_y

Coordinates of the center: real numerical values or expressions of the animation parameter a.

c_x, c_y are equivalent to the attributes CenterX, CenterY.

u_x

u_y

Components of the first vector spanning the parallelogram: real numerical values or expressions of the animation parameter a.

u_x, u_y are equivalent to the attributes Tangent1X, Tangent1Y.

v_x

v_y

Components of the second vector spanning the parallelogram: real numerical values or expressions of the animation parameter a.

v_x, v_y are equivalent to the attributes Tangent2X, Tangent2Y.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Parallelogram3d

Purpose

3D parallelograms

Syntax

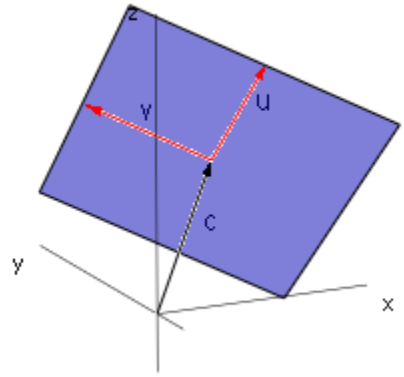
```
plot::Parallelogram3d([c_x, c_y, c_z], [u_x, u_y, u_z], [v_x,
v_y, v_z], <a = a_min .. a_max>, options)
```

Description

`plot::Parallelogram3d(c, u, v)` defines a 3D parallelogram ImageSet(‘c→‘ + Symbol::lambda* ‘u→‘ + Symbol::mu * ‘v→‘, Symbol::lambda in [-1, 1], Symbol::mu in [-1, 1])$\{\vec{c} + \lambda\,\vec{u} + \mu\,\vec{v} \mid \lambda \in [-1, 1], \mu \in [-1, 1]\}$ with center ‘c→‘$\vec{c}$ and vectors ‘u→‘$\vec{u}$, ‘v→‘$\vec{v}$ spanning the plane of the parallelogram. This is a rectangle with sides of length 2*abs(‘u→‘)$2\,|\vec{u}|$, 2*abs(‘v→‘)$2\,|\vec{v}|$ if the vectors ‘u→‘$\vec{u}$ and ‘v→‘$\vec{v}$ are orthogonal.

`plot::Parallelogram3d` creates a 3D parallelogram with center ‘c→‘$\vec{c}$ = `[c_x, c_y, c_z]` and sides given by the vectors 2*‘u→‘$2\,\vec{u}$ = `[2 u_x, 2 u_y, 2 u_z]` and 2*‘v→‘$2\,\vec{v}$ = `[2 v_x, 2 v_y, 2 v_z]`. The corners of the parallelogram are given by ‘c→‘-‘u→‘-‘v→‘$\vec{c} - \vec{u} - \vec{v}$, ‘c→‘-‘u→‘+‘v→‘$\vec{c} - \vec{u} + \vec{v}$, ‘c→‘+‘u→‘-‘v→‘$\vec{c} + \vec{u} - \vec{v}$, and ‘c→‘+‘u→‘+‘v→‘$\vec{c} + \vec{u} + \vec{v}$:

```
plot(plot::Arrow3d([0, 0, 0], [2, 2, 2], Color = RGB::Black, Title = "c",
TitlePosition = [1.5, 1, 1], TitleFont = [14]), plot::Arrow3d([2, 2, 2], [2, 0,
4], Color = RGB::Red, Title = "u", TitlePosition = [2.5, 1, 3], TitleFont
= [14]), plot::Arrow3d([2, 2, 2], [0, 3, 3],Color = RGB::Red, Title = "v",
TitlePosition = [1, 2.5, 2.7], TitleFont = [14]), plot::Parallelogram3d([2,
2, 2],[0,-2, 2], [-2, 1, 1], LineColor = RGB::Black, Filled = TRUE,
FillColor = RGB::Blue.[0.5]), CameraDirection = [-10, -20, 5], Axes
= Origin, TicksNumber = None, AxesTitleAlignment = End, Scaling
= Constrained):
```



By default, the area of the parallelogram is filled with the color specified by the attribute Color or, equivalently, FillColor. With Filled = `False`, only the border lines of the parallelogram are visible. Their color is set by the attribute LineColor.

Alternatively, the center and the spanning vectors can be given as vectors.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Center	center of objects, rotation center	`[0, 0, 0]`
CenterX	center of objects, rotation center, x-component	`0`

Attribute	Purpose	Default Value
CenterY	center of objects, rotation center, y-component	`0`
CenterZ	center of objects, rotation center, z-component	`0`
Color	the main color	RGB::LightBlue
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::LightBlue
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Flat`
FillColorDirection	the direction of color transitions on surfaces	`[0, 0, 1]`
FillColorDirectionX	x-component of the direction of color transitions on surfaces	`0`
FillColorDirectionY	y-component of the direction of color transitions on surfaces	`0`
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	`1`

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Tangent1	first vector spanning parallelograms	[0, 1, 0]
Tangent2	second vector spanning parallelograms	[1, 0, 0]

Attribute	Purpose	Default Value
Tangent1X	first vector spanning parallelograms, x component	0
Tangent1Y	first vector spanning parallelograms, y component	1
Tangent2X	second vector spanning parallelograms, x component	1
Tangent1Z	first vector spanning parallelograms, z component	0
Tangent2Y	second vector spanning parallelograms, y component	0
Tangent2Z	second vector spanning parallelograms, z component	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]

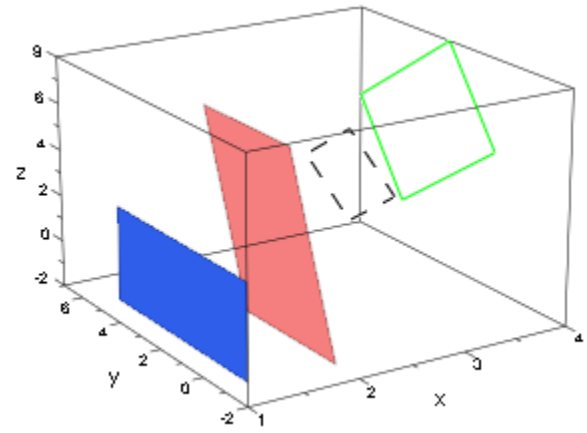
Attribute	Purpose	Default Value
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

Example 1

We plot several rectangles and parallelograms using different presentation styles:
plot(plot::Parallelogram3d([1, 1, 1], [0, 0, 2], [0, 3, 0]),
plot::Parallelogram3d([2, 2, 2], [0, 1, 4], [0, 2, 0], FillColor =

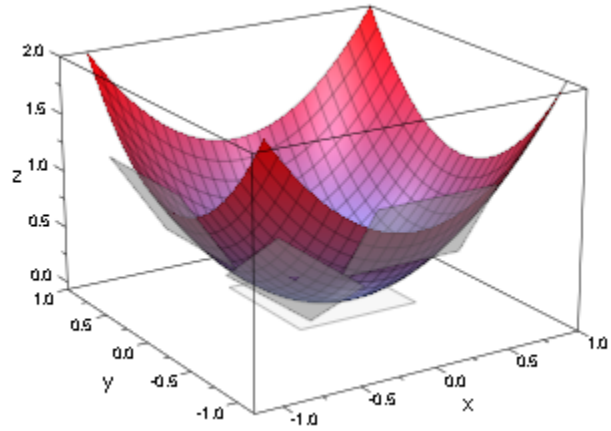
RGB::Red.[0.5]), plot::Parallelogram3d([3, 3, 3], [0, 1, 1], [0, 1, -1], Filled = FALSE, LineStyle = Dashed, LineColor = RGB::Black), plot::Parallelogram3d([4, 4, 4], [0, 1, 2], [0, 2, -2], Filled = FALSE, LineColor = RGB::Green)):



Example 2

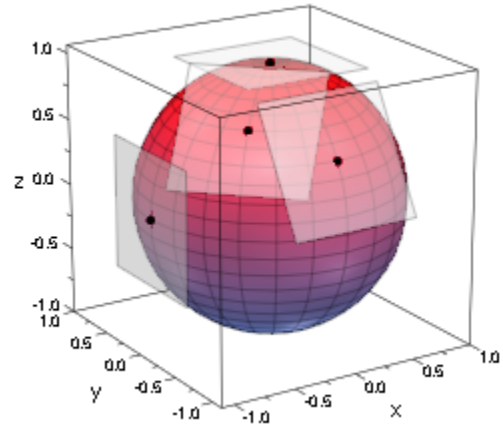
We use `plot::Parallelogram3d` to visualize tangent planes of a surface. The first surface is the graph of the function $f(x, y) = x^2 + y^2$. At a point $(x, y, f(x, y))$ on the graph, the tangent vectors in the x and y direction are given by $(1, 0, 2x)$ and $(0, 1, 2y)$, respectively. After normalization to the length 0.4, they yield the tangent vectors u, v used in the construction of the tangent planes:

```
f := (x, y) -> x^2 + y^2: c:= (x, y) -> [x, y, f(x, y)]: u := (x, y) -> [0.4/sqrt(1+4*x^2), 0, 0.8*x/sqrt(1+4*x^2)]: v := (x, y) -> [0, 0.4/sqrt(1+4*y^2), 0.8*y/sqrt(1+4*y^2)]: plot(plot::Function3d(f(x, y), x = -1..1, y = -1..1), plot::Parallelogram3d(c(0, 0), u(0, 0), v(0, 0), Color = RGB::Grey.[0.5]), plot::Parallelogram3d(c(0, -1), u(0, -1), v(0, -1), Color = RGB::Grey.[0.5]), plot::Parallelogram3d(c(-1, 0), u(-1, 0), v(-1, 0), Color = RGB::Grey.[0.5]), plot::Parallelogram3d(c(-1/2, -1/2), u(-1/2, -1/2), v(-1/2, -1/2), Color = RGB::Grey.[0.5])):
```



The second surface is a sphere, parametrized by spherical coordinates p and t (polar and azimuth angle). At a point ($x(p, t)$, $y(p, t)$, $z(p, t)$) on the sphere, the tangent vectors in the p and t direction are given by differention of x, y, z w.r.t. p and t, respectively. After normalization to the length 0.5, they yield the tangent vectors u, v used in the construction of the tangent planes:

```
x := (p, t) -> cos(p)*sin(t): y := (p, t) -> sin(p)*sin(t): z := (p, t) -> cos(t): c
:= (p, t) -> [x(p, t), y(p, t), z(p, t)]: u := (p, t) -> [-0.5*sin(p), 0.5*cos(p),
0]: v := (p, t) -> [0.5*cos(p)*cos(t), 0.5*sin(p)*cos(t), -0.5*sin(t)]:
plot(plot::Surface(c(p, t), p = 0..2*PI, t = 0..PI), plot::Point3d(c(0,
0), Color = RGB::Black), plot::Parallelogram3d(c(0, 0), u(0, 0), v(0,
0), Color = RGB::Grey.[0.5]), plot::Point3d(c(-3*PI/4, PI/4), Color =
RGB::Black), plot::Parallelogram3d(c(-3*PI/4, PI/4), u(-3*PI/4, PI/4),
v(-3*PI/4, PI/4), Color = RGB::Grey.[0.5]), plot::Point3d(c(-PI/2, PI/3),
Color = RGB::Black), plot::Parallelogram3d(c(-PI/2, PI/3), u(-PI/2, PI/3),
v(-PI/2, PI/3), Color = RGB::Grey.[0.5]), plot::Point3d(c(PI, PI/2), Color =
RGB::Black), plot::Parallelogram3d(c(PI, PI/2), u(PI, PI/2), v(PI, PI/2),
Color = RGB::Grey.[0.5]), Scaling = Constrained):
```



delete f, c, u, v, x, y, z:

Parameters

c_x

c_y

c_z

Coordinates of the center: real numerical values or expressions of the animation parameter a.

c_x, c_y, c_z are equivalent to the attributes CenterX, CenterY, CenterZ.

u_x

u_y

u_z

Components of the first vector spanning the parallelogram: real numerical values or expressions of the animation parameter a.

u_x, u_y, u_z are equivalent to the attributes Tangent1X, Tangent1Y, Tangent1Z.

v_x

v_y

v_z

Components of the second vector spanning the parallelogram: real numerical values or expressions of the animation parameter `a`.

v_x, v_y, v_z are equivalent to the attributes Tangent2X, Tangent2Y, Tangent2Z.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Piechart2d

Purpose

2D pie charts

Syntax

```
plot::Piechart2d([d_1, d_2,  ], <a = a_min .. a_max>, options)
plot::Piechart2d(A, <a = a_min .. a_max>, options)
```

Description

`plot::Piechart2d([d_1, d_2, d_3,  ])` creates a 2D pie chart with pieces of size ratios _outputSequence(d_1, Symbol::blank, ':', Symbol::blank, d_2, Symbol::blank, ':', Symbol::blank, d_3, Symbol::blank, ':', Symbol::blank, Symbol::dots)$d_1 : d_2 : d_3 : \ldots$.

With the input data d_1, d_2 etc., the i-th piece of the pie has the opening angle `2*PI*d_i/(d_1 + d_2 + Symbol::dots)`.

The attribute Titles allows to attach titles to the pieces of the pie. In contrast to the overall title of the pie chart (Title, TitleFont), the titles of the pieces react to TextFont.

The attribute Moves allows to move the pieces away from the pie center for highlighting.

The attributes Center and Radius allow to position and scale a pie chart relative to other graphical objects in the same scene.

Attributes

Attribute	Purpose	Default Value

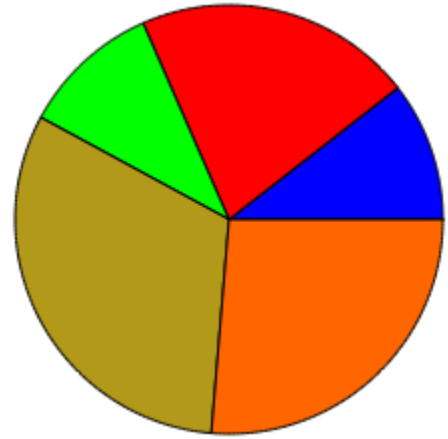
Examples

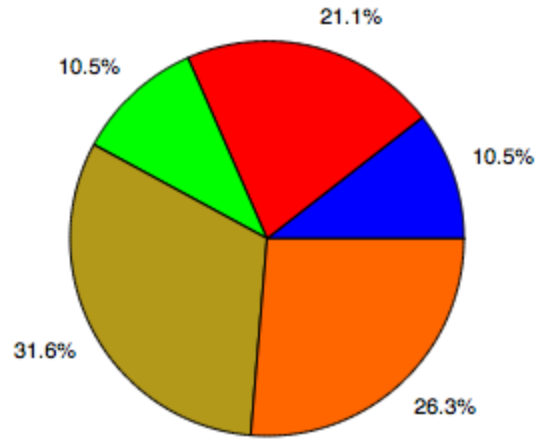
Example 1

We create a 2D pie chart with pieces of the size ratios _outputSequence(1, Symbol::blank, ':', Symbol::blank, 2, Symbol::blank, ':', Symbol::blank, 1, Symbol::blank, ':', Symbol::blank, 3, Symbol::blank, ':', Symbol::blank, 2.5)$_{1\,:\,2\,:\,1\,:\,3\,:\,2.5}$.

```
p := plot::Piechart2d([1, 2, 1, 3, 2.5]): plot(p)
```

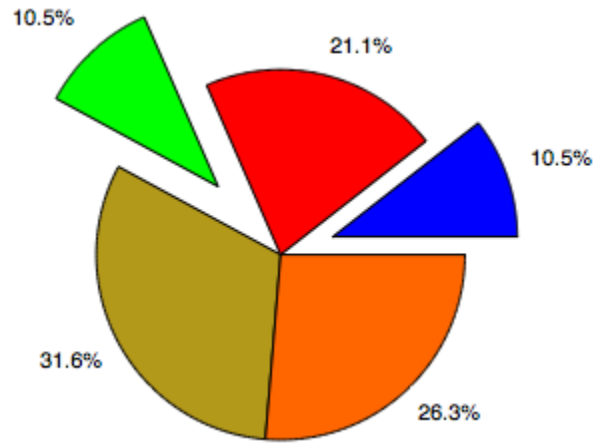


We set titles for the pieces:
p::Titles := ["10.5%", "21.1%", "10.5%", "31.6%", "26.3%"]: plot(p)



Pieces can be moved away from the pie center with the attribute Moves. One or more moves can be given as a list of values `[f1, f2, ]`. The "move factors" f_1, f_2 etc. are positive real values that represent fractions of the pie radius. The *i*-th piece is moved away from the center by f_i. If

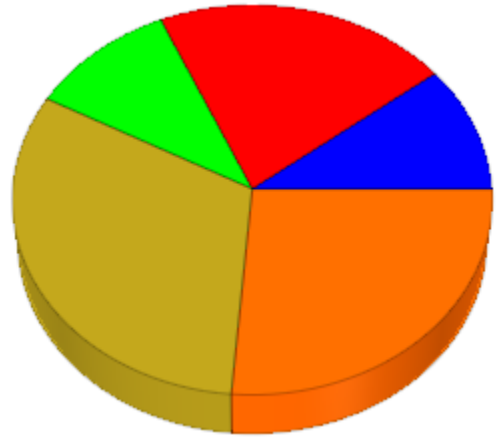
not all pieces are to be, one may specify Moves = [n_1 = f_1, n_2 = f_2,], such that only the pieces with indices n_1, n_2 etc. are moved:
p::Moves := [1 = 0.3, 3 = 0.5]: plot(p)



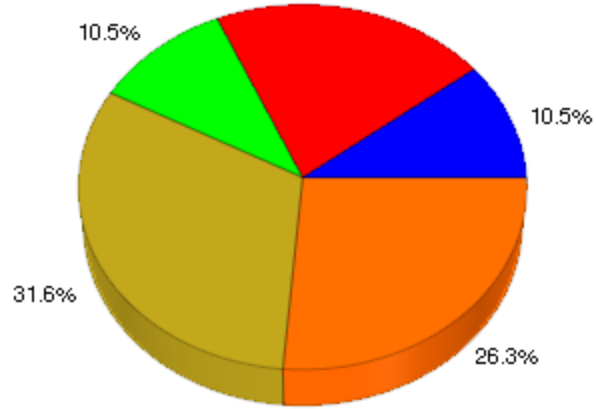
delete p:

Example 2

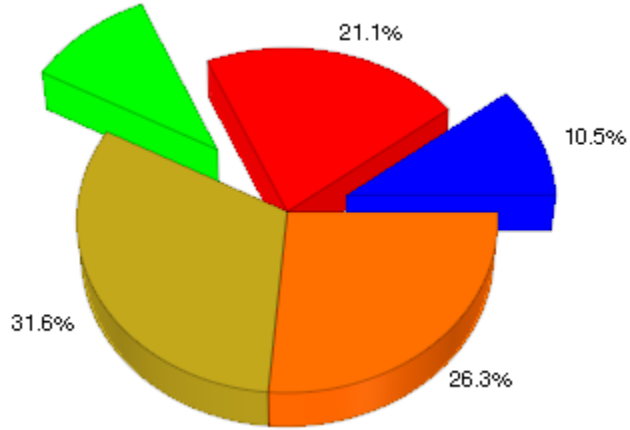
We create a 3D pie chart with pieces of the size ratios _outputSequence(1, Symbol::blank, ':', Symbol::blank, 2, Symbol::blank, ':', Symbol::blank, 1, Symbol::blank, ':', Symbol::blank, 3, Symbol::blank, ':', Symbol::blank, 2.5)$_{1 : 2 : 1 : 3 : 2.5}$.
p := plot::Piechart3d([1, 2, 1, 3, 2.5]): plot(p)



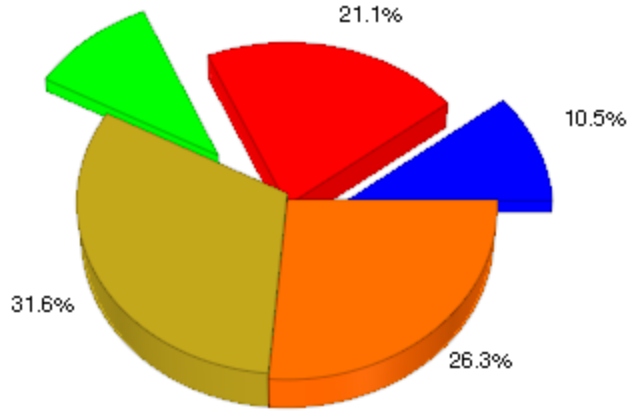
We set titles for the pieces:
p::Titles := ["10.5%", "21.1%", "10.5%", "31.6%", "26.3%"]: plot(p)



Some pieces are moved away from the center:
p::Moves := [1 = 0.3, 3 = 0.5]: plot(p)



The heights of the pieces in a 3D pie chart can vary:
p::Heights := [0.1, 0.2, 0.1, 0.3, 0.25]: plot(p)



delete p:

Example 3

A pie chart can be animated. We plot a pie chart with an animated radius. The pieces move in and out, changing their size:

```
m1 := piecewise([abs(a - PI/4) <= PI/4, sin(2*a)^2/3], [abs(a - PI/4)
> PI/4, 0]): m2 := piecewise([abs(a - 3*PI/4) <= PI/4, sin(2*a)^2/3],
[abs(a - 3*PI/4) > PI/4, 0]): m3 := piecewise([abs(a - 5*PI/4) <= PI/4,
sin(2*a)^2/3], [abs(a - 5*PI/4) > PI/4, 0]): m4 := piecewise([abs(a
- 7*PI/4) <= PI/4, sin(2*a)^2/3], [abs(a - 7*PI/4) > PI/4, 0]): p :=
plot::Piechart3d([5 + sin(a)/4, 2, 1 + sin(a)/2, 4], Title = "crazy pie chart",
TitlePosition = [0, 15, 5], TitleFont = [Italic, 18], Center = [0, 0, 0],
Radius = 10 + sin(2*a), Heights = [1.5 + sin(a), 1.5 + cos(2*a), 1.5 +
sin(a), 1.5 + cos(4*a)], Titles = [1 = "piece 1", 2 = "piece 2", 3 = "piece 3",
4 = "piece 4"], Moves = [m1, m2, m3, m4], a = 0..2*PI): plot(p):
```

```
delete m1, m2, m3, m4, p:
```

Parameters

d_1, d_2, ...

The sizes of the pieces: non-negative real values or arithmetical expressions of the animation parameter `a`.

d_1, d_2, ... is equivalent to the attribute Data.

A

A matrix or array containing the data d_1, d_2 etc.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

Concepts

- "Create Bar Charts, Histograms, and Pie Charts"

plot::Piechart3d

Purpose

3D pie charts

Syntax

```
plot::Piechart3d([d_1, d_2,  ], <a = a_min .. a_max>, options)
plot::Piechart3d(A, <a = a_min .. a_max>, options)
```

Description

`plot::Piechart3d([d_1, d_2, d_3,  ])` creates a corresponding 3D pie chart.

With the input data d_1, d_2 etc., the i-th piece of the pie has the opening angle `2*PI*d_i/(d_1 + d_2 + Symbol::dots)`.

The attribute Titles allows to attach titles to the pieces of the pie. In contrast to the overall title of the pie chart (Title, TitleFont), the titles of the pieces react to TextFont.

The attribute Moves allows to move the pieces away from the pie center for highlighting.

In 3D, the attribute Heights allows to vary the heights of the pieces.

The attributes Center and Radius allow to position and scale a pie chart relative to other graphical objects in the same scene.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Billboarding	text orientation in space or towards observer	`TRUE`
Center	center of objects, rotation center	`[0, 0, 0]`

Attribute	Purpose	Default Value
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
CenterZ	center of objects, rotation center, z-component	0
Color	the main color	
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson]
Data	the (statistical) data to plot	[1]
Filled	filled or transparent areas and surfaces	TRUE
Frames	the number of frames in an animation	50
Heights	heights of pieces in pie charts	[0.3]
Legend	makes a legend entry	

Attribute	Purpose	Default Value
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	`RGB::Black.[0.25]`
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
Moves	displacements of pieces in pie charts	`[0]`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Radius	radius of circles, spheres etc.	`1`
TextFont	font of text objects	`[" sans-serif ", 11]`
TimeEnd	end time of the animation	`10.0`

Attribute	Purpose	Default Value
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
Titles	list of titles for object parts	`[" "]`
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

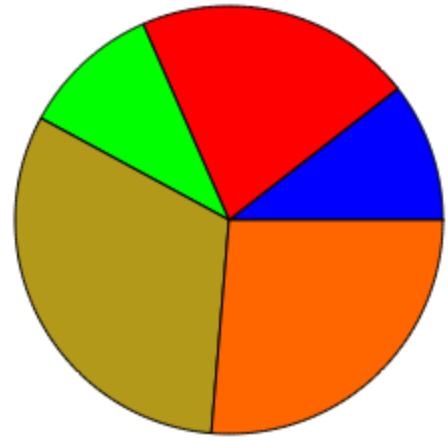
Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

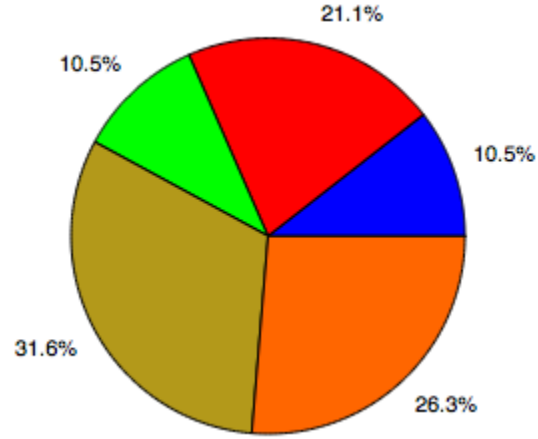
We create a 2D pie chart with pieces of the size ratios _outputSequence(1, Symbol::blank, ':', Symbol::blank, 2, Symbol::blank, ':', Symbol::blank, 1, Symbol::blank, ':', Symbol::blank, 3, Symbol::blank, ':', Symbol::blank, 2.5)1 : 2 : 1 : 3 : 2.5.

```
p := plot::Piechart2d([1, 2, 1, 3, 2.5]): plot(p)
```

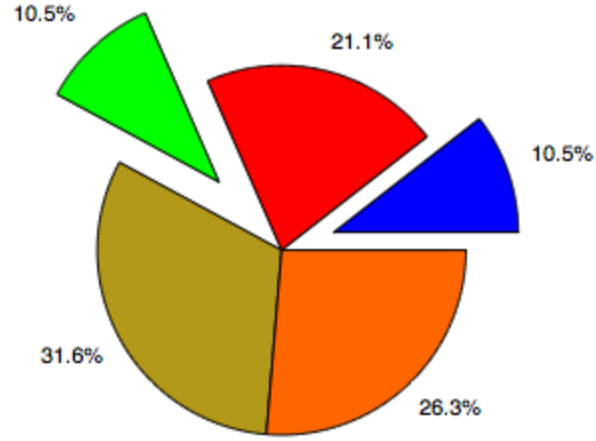


We set titles for the pieces:

```
p::Titles := ["10.5%", "21.1%", "10.5%", "31.6%", "26.3%"]: plot(p)
```



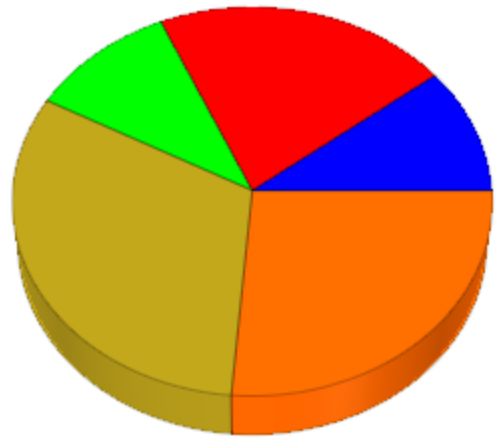
Pieces can be moved away from the pie center with the attribute Moves. One or more moves can be given as a list of values `[`f_1`, `f_2`, ]`. The "move factors" f_1, f_2 etc. are positive real values that represent fractions of the pie radius. The *i*-th piece is moved away from the center by f_i. If not all pieces are to be, one may specify Moves = `[`n_1 `=` f_1`, `n_2 `=` f_2`, ]`, such that only the pieces with indices n_1, n_2 etc. are moved:
p::Moves := [1 = 0.3, 3 = 0.5]: plot(p)



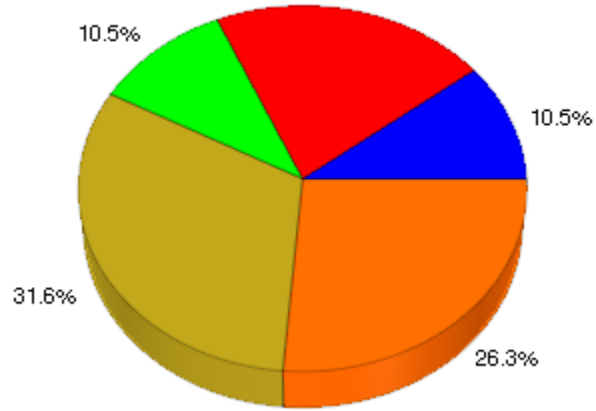
delete p:

Example 2

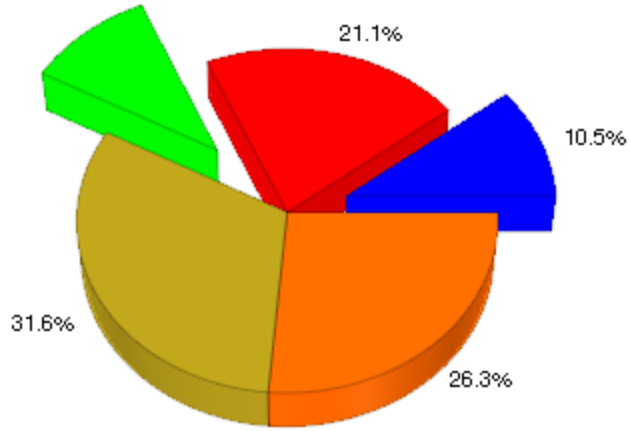
We create a 3D pie chart with pieces of the size ratios _outputSequence(1, Symbol::blank, ':', Symbol::blank, 2, Symbol::blank, ':', Symbol::blank, 1, Symbol::blank, ':', Symbol::blank, 3, Symbol::blank, ':', Symbol::blank, 2.5)$1:2:1:3:2.5$.
p := plot::Piechart3d([1, 2, 1, 3, 2.5]): plot(p)



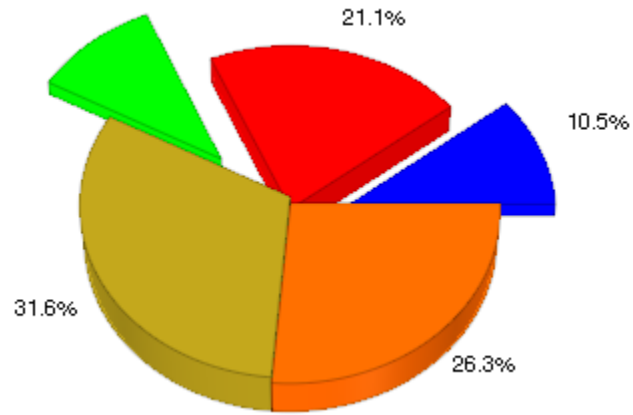
We set titles for the pieces:
p::Titles := ["10.5%", "21.1%", "10.5%", "31.6%", "26.3%"]: plot(p)



Some pieces are moved away from the center:
p::Moves := [1 = 0.3, 3 = 0.5]: plot(p)



The heights of the pieces in a 3D pie chart can vary:
p::Heights := [0.1, 0.2, 0.1, 0.3, 0.25]: plot(p)



delete p:

Example 3

A pie chart can be animated. We plot a pie chart with an animated radius. The pieces move in and out, changing their size:
m1 := piecewise([abs(a - PI/4) <= PI/4, sin(2*a)^2/3], [abs(a - PI/4) > PI/4, 0]): m2 := piecewise([abs(a - 3*PI/4) <= PI/4, sin(2*a)^2/3], [abs(a - 3*PI/4) > PI/4, 0]): m3 := piecewise([abs(a - 5*PI/4) <= PI/4, sin(2*a)^2/3], [abs(a - 5*PI/4) > PI/4, 0]): m4 := piecewise([abs(a - 7*PI/4) <= PI/4, sin(2*a)^2/3], [abs(a - 7*PI/4) > PI/4, 0]): p := plot::Piechart3d([5 + sin(a)/4, 2, 1 + sin(a)/2, 4], Title = "crazy pie chart", TitlePosition = [0, 15, 5], TitleFont = [Italic, 18], Center = [0, 0, 0], Radius = 10 + sin(2*a), Heights = [1.5 + sin(a), 1.5 + cos(2*a), 1.5 + sin(a), 1.5 + cos(4*a)], Titles = [1 = "piece 1", 2 = "piece 2", 3 = "piece 3", 4 = "piece 4"], Moves = [m1, m2, m3, m4], a = 0..2*PI): plot(p):

delete m1, m2, m3, m4, p:

Parameters

d_1, d_2, ...

The sizes of the pieces: non-negative real values or arithmetical expressions of the animation parameter `a`.

d_1, d_2, ... is equivalent to the attribute Data.

A

A matrix or array containing the data d_1, d_2 etc.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Plane

Purpose

Infinite plane in 3D

Syntax

```
plot::Plane([x, y, z], <[n_x, n_y, n_z]>, <a =
a_min .. a_max>, options)
plot::Plane(X, <N>, <a = a_min .. a_max>, options)
plot::Plane(XN, <a = a_min .. a_max>, options)
plot::Plane(p_1, p_2, p_3, <a = a_min .. a_max>, options)
plot::Plane(p_123, <a = a_min .. a_max>, options)
```

Description

`plot::Plane(x, n)` creates the (infinite) plane with normal vector n passing through the point x.

`plot::Plane` provides a graphical plane in 3D that does not require a specification, which part of the plane is to be seen in the picture. The visible part of the plane is determined automatically by the ViewingBox of the entire 3D scene.

The contribution of a plane of type `plot::Plane` to the ViewingBox of a 3D scene consists only of the single point `[x, y, z]` (this is p_1, if the plane is specified by three points p_1, p_2, p_3 on the plane).

Thus, two planes with the same normal but different points may be mathematically equivalent, but may produce different pictures due to different viewing boxes. Cf. “Example 3” on page 24-546.

By default, a mesh of lines is displayed on the plane. Use the attribute Mesh = $[n_1, n_2]$ with positive integer values n_1, n_2 to control the number of mesh lines.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::LightBlue

Attribute	Purpose	Default Value
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	`RGB::Black.[0.25]`
LinesVisible	visibility of lines	`TRUE`
Mesh	number of sample points	`[15, 15]`
Name	the name of a plot object (for browser and legend)	
Normal	normal vector of circles and discs, etc. in 3D	`[0, 0, 1]`
NormalX	normal vector of circles and discs, etc. in 3D, x-component	`0`
NormalY	normal vector of circles and discs, etc. in 3D, y-component	`0`

Attribute	Purpose	Default Value
NormalZ	normal vector of circles and discs, etc. in 3D, z-component	1
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Position	positions of cameras, lights, and text objects	[0, 0, 0]
PositionX	x-positions of cameras, lights, and text objects	0
PositionY	y-positions of cameras, lights, and text objects	0
PositionZ	z-positions of cameras, lights, and text objects	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

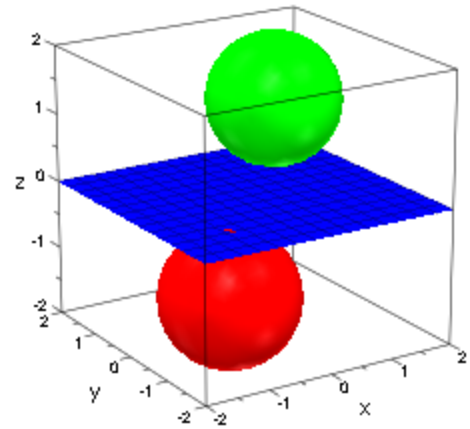
Attribute	Purpose	Default Value
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
UMesh	number of sample points for parameter “u”	15
VMesh	number of sample points for parameter “v”	15
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

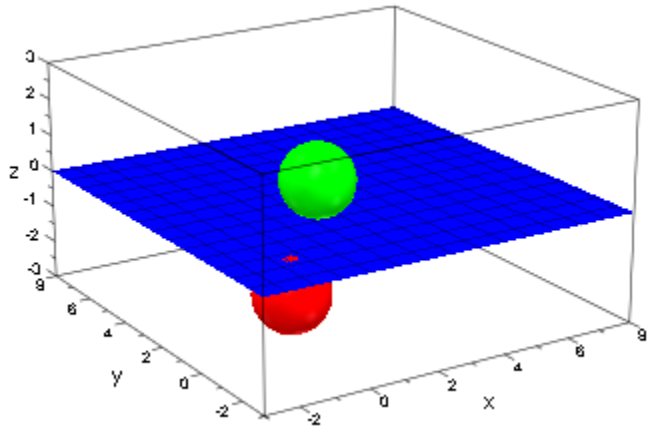
Examples

Example 1

We generate two spheres and a plane:
plot(plot::Sphere(1, [-1, -1, -1], Color = RGB::Red), plot::Sphere(1, [1, 1, 1], Color = RGB::Green), plot::Plane([0, 0, 0], [0, 0, 1], Color = RGB::Blue)):



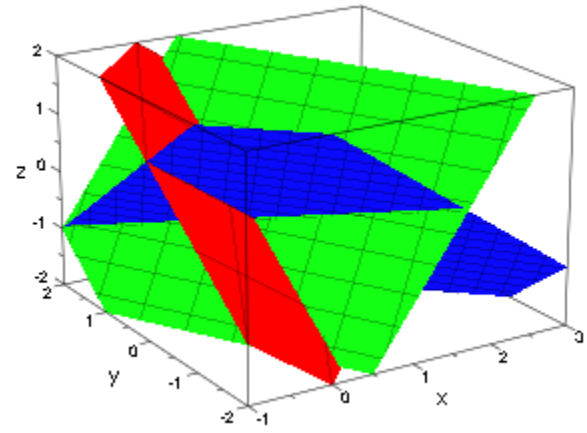
We specify an explicit ViewingBox for the scene:
plot(plot::Sphere(1, [-1, -1, -1], Color = RGB::Red), plot::Sphere(1, [1, 1, 1], Color = RGB::Green), plot::Plane([0, 0, 0], [0, 0, 1], Color = RGB::Blue), ViewingBox = [-3..8, -3..8, -3..3]):



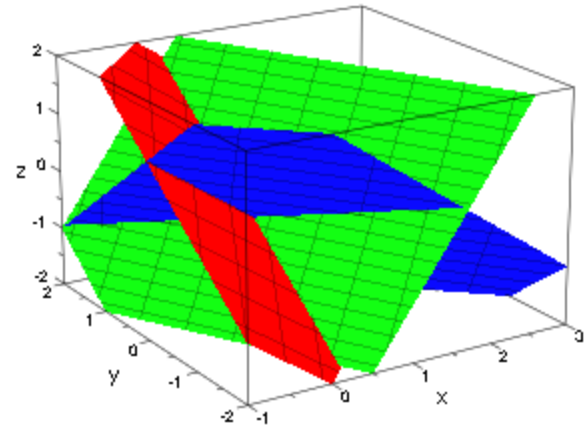
Example 2

We demonstrate the effect of the attribute Mesh that controls the number of mesh lines displayed on planes:

```
plot(plot::Plane([0, 0, 0], [1, -1, 1], Color = RGB::Red, Mesh = [5, 5]),
plot::Plane([0, 1, 0], [2, 1, -1], Color = RGB::Green, Mesh = [10, 10]),
plot::Plane([1, -1, 0], [1, 1, 1], Color = RGB::Blue, Mesh = [20, 20]),
ViewingBox = [-1..3, -2..2, -2..2])
```

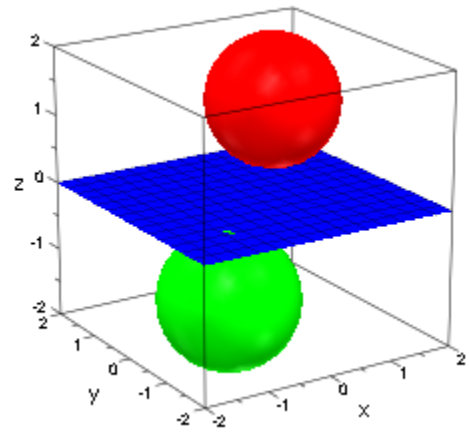


We change the number of mesh lines:
plot(plot::Plane([0, 0, 0], [1, -1, 1], Color = RGB::Red, Mesh = [10, 10]),
plot::Plane([0, 1, 0], [2, 1, -1], Color = RGB::Green, Mesh = [20, 10]),
plot::Plane([1, -1, 0], [1, 1, 1], Color = RGB::Blue, Mesh = [15, 5]),
ViewingBox = [-1..3, -2..2, -2..2])

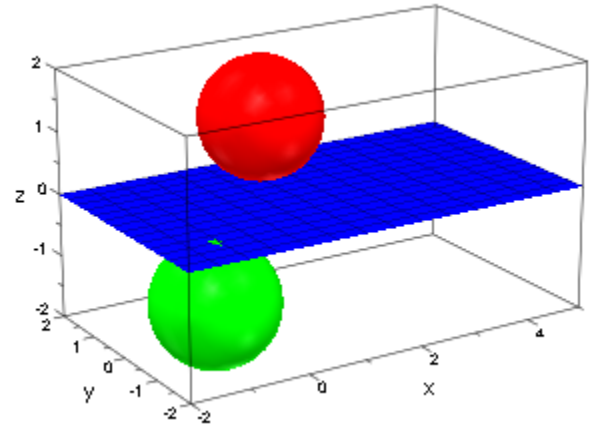


Example 3

The contribution of a plane to the automatic ViewingBox of the whole scene consists only of the point used to specify the plane. In the following scene, this point is the origin. It lies inside the ViewingBox generated by the two spheres. Thus, the ViewingBox of the scene is determined by the two spheres only:
plot(plot::Sphere(1, [1, 1, 1], Color = RGB::Red), plot::Sphere(1, [-1, -1, -1], Color = RGB::Green), plot::Plane([0, 0, 0], [0, 0, 1], Color = RGB::Blue)):

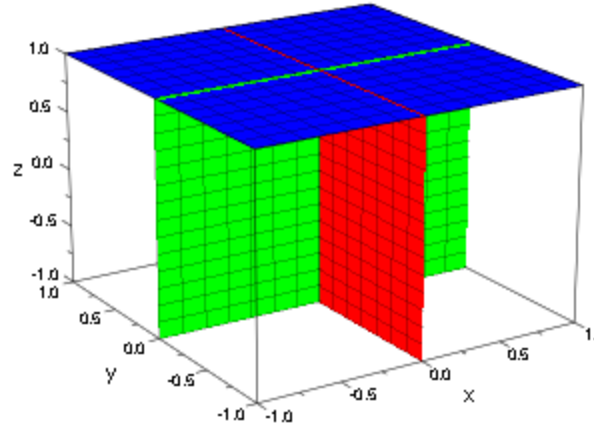


Now, a different point `[5, 0, 0]` is used to specify the same plane. It does not lie inside the ViewingBox generated by the two spheres and thus enlarges the ViewingBox of the scene:
plot(plot::Sphere(1, [1, 1, 1], Color = RGB::Red), plot::Sphere(1, [-1, -1, -1], Color = RGB::Green), plot::Plane([5, 0, 0], [0, 0, 1], Color = RGB::Blue)):



Example 4

We create animated planes:
plot(plot::Plane([0, 0, 0], [cos(a), sin(a), 0], a = 0..PI, Color = RGB::Red), plot::Plane([0, 0, 0], [0, cos(a), sin(a)], a = 0..PI, Color = RGB::Green), plot::Plane([0, 0, a], [0, 0, 1], a = 0..1, Color = RGB::Blue), ViewingBox = [-1..1, -1..1, -1..1])



Parameters

x

y

z

The coordinates of a point on the plane: numerical real values or arithmetical expressions in the animation parameter a.

x, y, z are equivalent to the attributes PositionX, PositionY, PositionZ.

n_x

n_y

n_z

The components of the normal vector; n_x, n_y, n_z must be numerical real values or arithmetical expressions in the animation parameter a. If no normal is specified, the normal (0, 0, 1) is used.

n_x, n_y, n_z are equivalent to the attributes NormalX, NormalY, NormalZ.

X

A matrix of category Cat::Matrix with three entries that provide the coordinates x, y, z of a point on the plane.

X is equivalent to the attribute Position.

N

A matrix of category Cat::Matrix with three entries that provide the components n_x, n_y, n_z of the normal.

N is equivalent to the attribute Normal.

XN

A matrix of category Cat::Matrix with 3 rows and 2 columns. The first column provides the coordinates x, y, z of a point on the plane, the second column provides the components n_x, n_y, n_z of the normal.

XN is equivalent to the attributes Position, Normal.

p_1

p_2

p_3

Three points on the plane: either lists with 3 entries each or matrices of category Cat::Matrix with 3 entries each. The point p_1 correponds to the attribute Position, the normal of the plane (the attribute Normal) is computed as the cross product $(p_2 - p_1)$ $(p_3 - p_1)$.

p_{123}

A matrix of category Cat::Matrix with 3 rows and 3 columns. Each column corresponds to a point on the plane.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Parallelogram3dplot::Surface

plot::Point2d

Purpose

2D points

Syntax

```
plot::Point2d(x, y, <a = a_min .. a_max>, options)
plot::Point2d([x, y], <a = a_min .. a_max>, options)
plot::Point2d(matrix([x, y]), <a = a_min .. a_max>, options)
```

Description

`plot::Point2d(x, y)` creates a two-dimensional point with the coordinates (*x*, *y*).

`plot::Point2d` creates graphical points in two dimensions.

Starting with MuPAD 3.0 software, each type of graphical elements has a fixed dimension. Therefore, `plot::Point2d` and `plot::Point3d` are distinct, but very similar, types.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Color	the main color	RGB::MidnightBlue
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointColor	the color of points	RGB::MidnightBlue
PointStyle	the presentation style of points	`FilledCircles`
Position	positions of cameras, lights, and text objects	`[0, 0]`
PositionX	x-positions of cameras, lights, and text objects	`0`
PositionY	y-positions of cameras, lights, and text objects	`0`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`

Attribute	Purpose	Default Value
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

Example 1

We create three points:

```
p1 := plot::Point2d(1, 3, PointSize = 4*unit::mm); p2 := plot::Point2d(2,
2, PointSize = 5*unit::mm); p3 := plot::Point2d(3, 1, Color = RGB::Green,
PointSize = 6*unit::mm);plot::Point2d(1, 3, PointSize = 4)
```

```
plot::Point2d(1, 3, PointSize = 4)
```

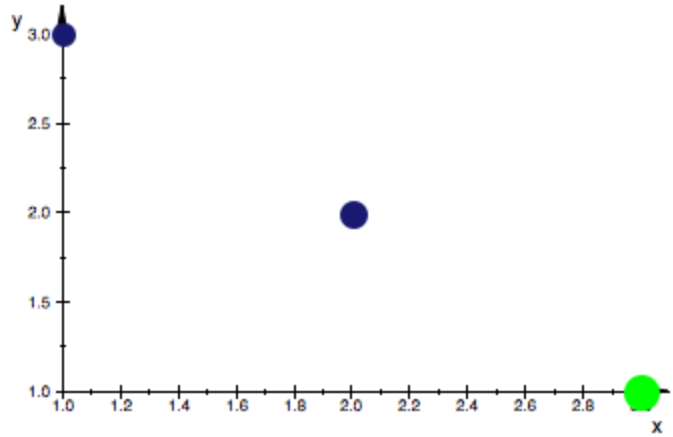
```
plot::Point2d(2, 2, PointSize = 5)
```

```
plot::Point2d(3, 1, PointColor = RGB::Green, PointSize = 6)
```

```
plot::Point2d(3, 1, PointColor = RGB::Green, PointSize = 6)
```

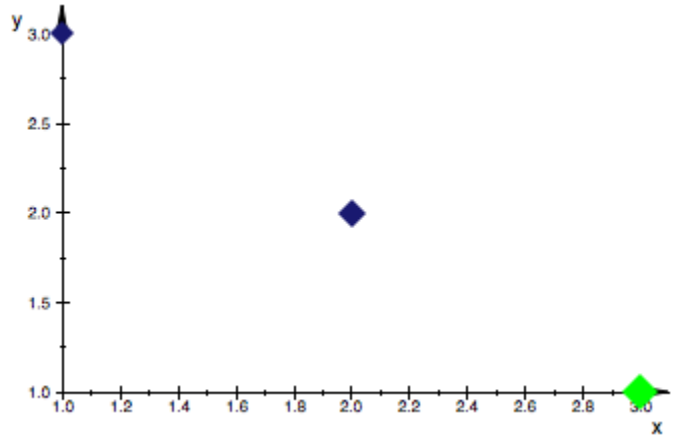
To have these points displayed, we use plot:

```
plot(p1, p2, p3)
```

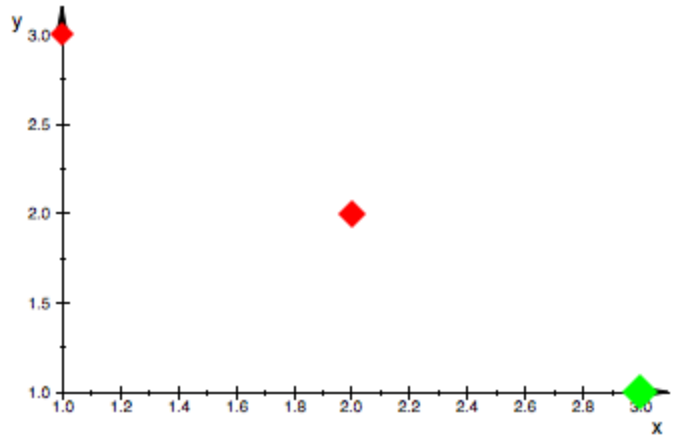


It is possible to set global options directly in the call to plot:

```
plot(p1, p2, p3, PointStyle = FilledDiamonds)
```



These options are regarded as the new *defaults*. This implies that objects having an option set explicitly will silently ignore these options. The green point stays green:
plot(p1, p2, p3, PointStyle = FilledDiamonds, PointColor = RGB::Red)



Example 2

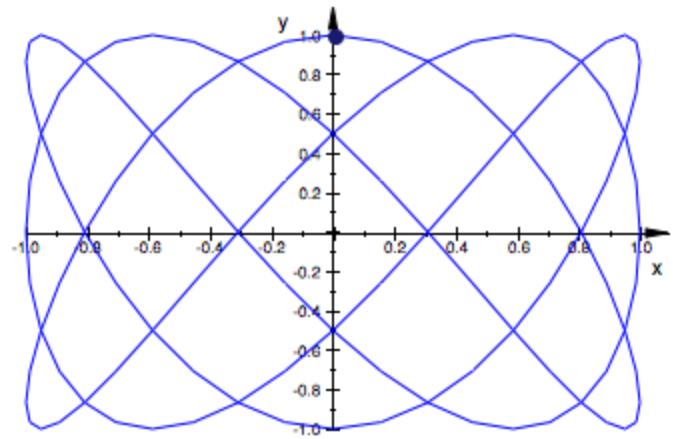
The point position can be animated. As an example, we combine a point with a curve that traces the path of the point:
x := t -> sin(3*t); y := t -> cos(5*t); p := plot::Point2d([x(t), y(t)], t = 0..2*PI); c := plot::Curve2d([x(t), y(t)], t = 0..tmax, tmax = 0..2*PI)t -> sin(3*t)

$t \to \sin(3\,t)$
t -> cos(5*t)

$t \to \cos(5\,t)$
plot::Point2d(sin(3*t), cos(5*t), t = 0..2*PI)

$\mathrm{plot::Point2d}(\sin(3\,t), \cos(5\,t), t = 0..2\,\pi)$
plot::Curve2d([sin(3*t), cos(5*t)], t = 0..tmax)

$\mathrm{plot::Curve2d}([\sin(3\,t), \cos(5\,t)], t = 0..\mathrm{tmax})$
plot(c, p, PointSize = 3*unit::mm, LineWidth = 0.5*unit::mm)



Parameters

x

y

Arithmetical expressions

`x`, `y` are equivalent to the attributes Position, PositionX, PositionY.

a

Animation parameter, specified as `a = a`$_{min}$`..a`$_{max}$, where `a`$_{min}$ is the initial parameter value, and `a`$_{max}$ is the final parameter value.

Algorithms

For reasons of efficiency and clarity in the object browser, you should avoid generating large numbers of `plot::Point2d` and `plot::Point3d` objects. None of the domains in the plot package do. For alternatives, consider plot::PointList2d and plot::PointList3d.

See Also

plotplot::copyplot::Point3dplot::Polygon2dplot::Polygon3d

plot::Point3d

Purpose

3D points

Syntax

```
plot::Point3d(x, y, z, <a = a_min .. a_max>, options)
plot::Point3d([x, y, z], <a = a_min .. a_max>, options)
plot::Point3d(matrix([x, y, z]), <a = a_min .. a_max>, options)
```

Description

`plot::Point3d(x, y, z)` creates a three-dimensional point with the coordinates (*x*, *y*, *z*).

`plot::Point3d` creates graphical points in three dimensions.

Starting with MuPAD 3.0 software, each type of graphical elements has a fixed dimension. Therefore, `plot::Point2d` and `plot::Point3d` are distinct, but very similar, types.

Examples

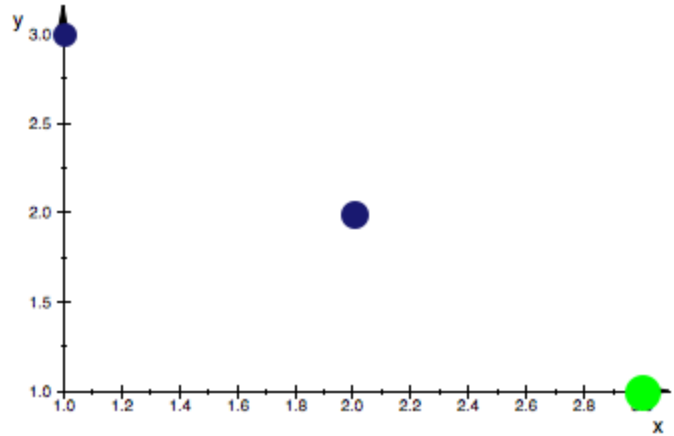
Example 1

We create three points:
p1 := plot::Point2d(1, 3, PointSize = 4*unit::mm); p2 := plot::Point2d(2, 2, PointSize = 5*unit::mm); p3 := plot::Point2d(3, 1, Color = RGB::Green, PointSize = 6*unit::mm);plot::Point2d(1, 3, PointSize = 4)

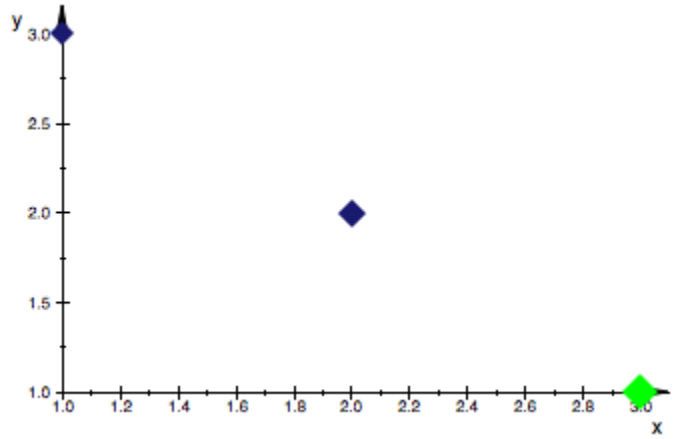
plot::Point2d(1, 3, PointSize = 4)
plot::Point2d(2, 2, PointSize = 5)

plot::Point2d(2, 2, PointSize = 5)
plot::Point2d(3, 1, PointColor = RGB::Green, PointSize = 6)

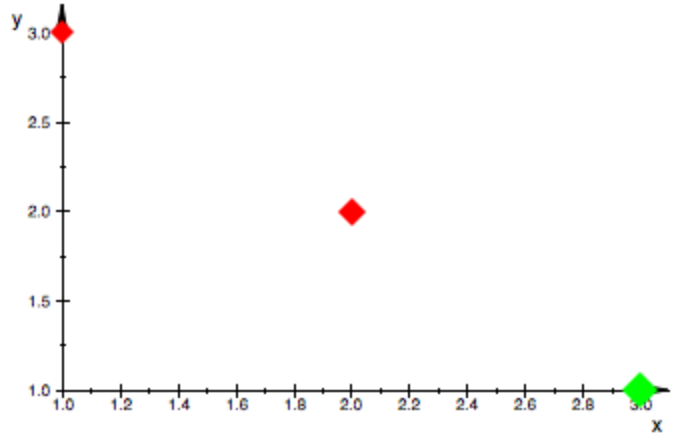
plot::Point2d(3, 1, PointColor = RGB::Green, PointSize = 6)
To have these points displayed, we use plot:
plot(p1, p2, p3)



It is possible to set global options directly in the call to plot:
plot(p1, p2, p3, PointStyle = FilledDiamonds)



These options are regarded as the new *defaults*. This implies that objects having an option set explicitly will silently ignore these options. The green point stays green:
plot(p1, p2, p3, PointStyle = FilledDiamonds, PointColor = RGB::Red)



Example 2

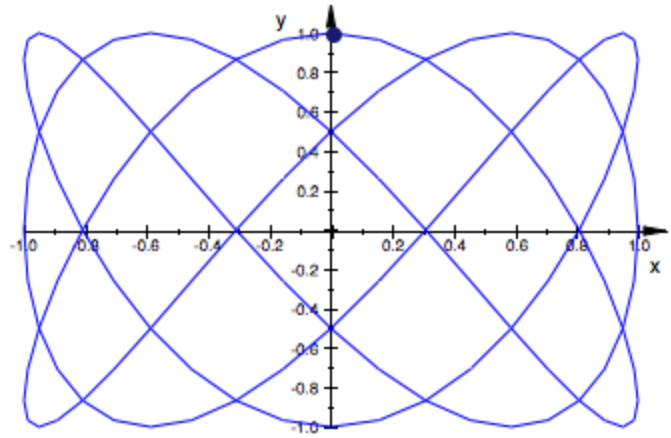
The point position can be animated. As an example, we combine a point with a curve that traces the path of the point:
x := t -> sin(3*t); y := t -> cos(5*t); p := plot::Point2d([x(t), y(t)], t = 0..2*PI); c := plot::Curve2d([x(t), y(t)], t = 0..tmax, tmax = 0..2*PI)t -> sin(3*t)

$t \to \sin(3\,t)$
t -> cos(5*t)

$t \to \cos(5\,t)$
plot::Point2d(sin(3*t), cos(5*t), t = 0..2*PI)

$\mathrm{plot::Point2d}(\sin(3\,t), \cos(5\,t), t = 0..2\,\pi)$
plot::Curve2d([sin(3*t), cos(5*t)], t = 0..tmax)

$\mathrm{plot::Curve2d}([\sin(3\,t), \cos(5\,t)], t = 0..\mathrm{tmax})$
plot(c, p, PointSize = 3*unit::mm, LineWidth = 0.5*unit::mm)



Parameters

x

y

z

Arithmetical expressions

`x`, `y`, `z` are equivalent to the attributes Position, PositionX, PositionY, PositionZ.

a

Animation parameter, specified as `a = a`$_{min}$`..a`$_{max}$, where `a`$_{min}$ is the initial parameter value, and `a`$_{max}$ is the final parameter value.

Algorithms

For reasons of efficiency and clarity in the object browser, you should avoid generating large numbers of `plot::Point2d` and `plot::Point3d` objects. None of the domains in the plot package do. For alternatives, consider plot::PointList2d and plot::PointList3d.

See Also

plotplot::copyplot::Point2dplot::Polygon2dplot::Polygon3d

plot::PointList2d

Purpose

Finite lists of 2D points

Syntax

```
plot::PointList2d(pts, <a = a_min .. a_max>, options)
plot::PointList2d(M_2d, <a = a_min .. a_max>, options)
```

Description

`plot::PointList2d` holds lists of points in 2D.

These types are containers for a (large) finite number of points. They let you avoid constructing large numbers of objects of type plot::Point2d for two reasons. First, the point types have non-negligible overhead and constructing and plotting a large number of them (say, five thousand) takes more time than plotting the same number of points in a single container object. Second, and this may be even more important, having five thousand points in the object browser takes a significant amount of memory and is not as lucid as having a single point list displayed there.

The attribute Points2d is displayed in the inspector in the user interface only for short lists.

`plot::PointList2d, PointList3d` internally use lists for storing the points. It is therefore not advisable to add a large number of points one-by-one. See “Example 2” on page 24-569 for a better method of collecting data.

If you specify the color of one point, you must specify the colors of all other points in the list. See “Example 3” on page 24-570.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Color	the main color	RGB::MidnightBlue

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Points2d	list of 2D points	
PointSize	the size of points	1.5
PointColor	the color of points	RGB::MidnightBlue
PointStyle	the presentation style of points	FilledCircles
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0

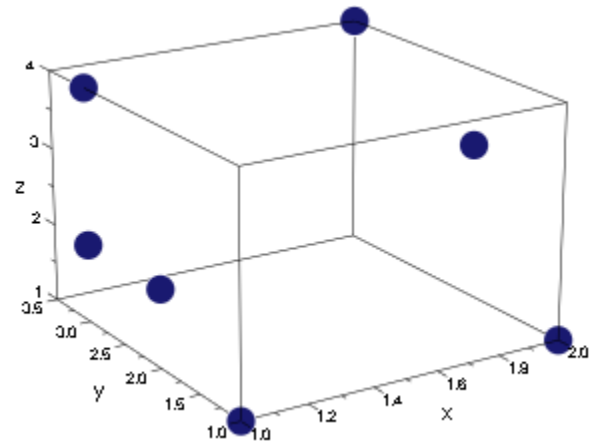
Attribute	Purpose	Default Value
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

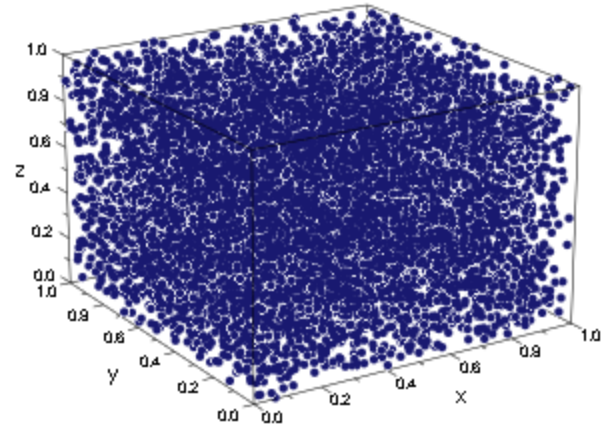
Example 1

`plot::PointList3d` provides a basic form of scatter plot:

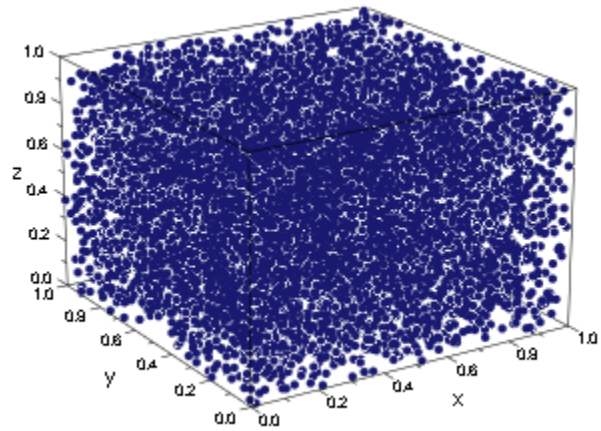
plot(plot::PointList3d([[1,1,1], [1,2,2], [1,3,2], [1,3,4], [2,1,1], [2,2,3], [2,3.5, 4]], PointSize=5))



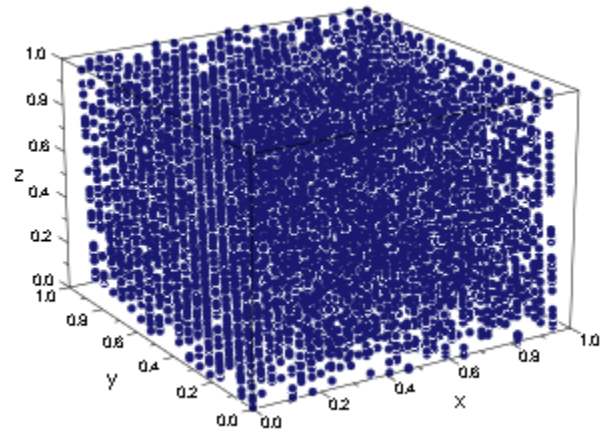
We can use this, for example, to get a visual test of random number generators:
r := frandom(0): plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000])):



r := random(10^10)*1e-10: plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000])):



frandom and random fill the cube nicely, without noticeable patterns. The following generator, however, should probably not be used: randseed := 12345: r := proc() begin randseed := (randseed * 17 + 8) mod 10^10: 1e-10 * randseed; end: plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000])):

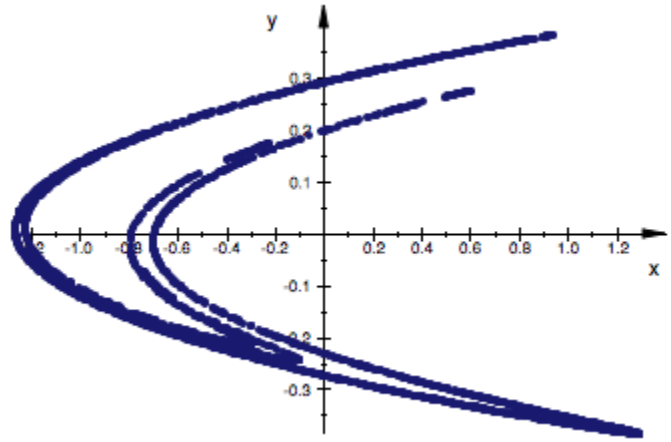


Example 2

The following iteration leads to the so-called Hénon attractor (from chaos theory):
c1 := 1.4: c2 := 0.3: henon_iter := (x, y) -> [c1*x^2+y-1, c2*x]:

We start at (0, 0), let hundred iteration cycles pass by (to only plot the attractor) and then collect the next three thousand points:
[x, y] := [0, 0]: for i from 1 to 100 do [x, y] := henon_iter(x, y); end_for:
data := {}: for i from 1 to 3000 do [x, y] := henon_iter(x, y); data := data union {[x, y]}; end_for:

Note that we collected the data in a set, because adding elements to a set is a fast operation, unlike changing the length of a list, and we don't care for the order in which points were reached. To plot the data, we must convert it to a list first:
data := coerce(data, DOM_LIST): plot(plot::PointList2d(data))

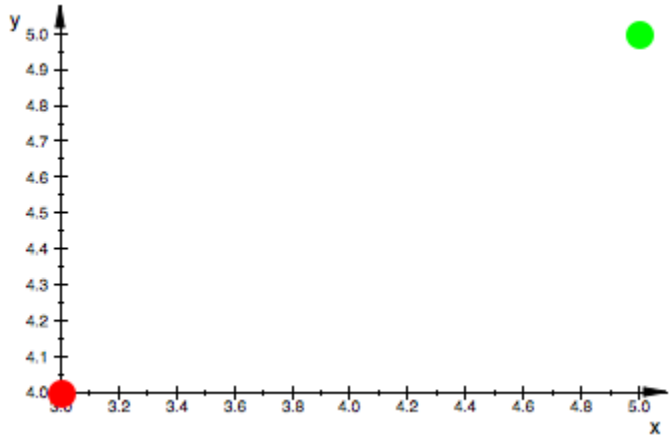


We'd like to invite you to experiment with different values of `c1` and `c2` and see how they change the resulting image.

Example 3

`plot::PointList2d` and plot::PointList3d allow you to specify the colors of the points. For example, the following list contains two points. When you plot this list, the first point appears in red, and the second point appears in green:
Coords := [[3, 4, RGB::Red], [5, 5, RGB::Green]]; plotCoords := plot::PointList2d(Coords): plot(plotCoords, PointSize=5)[[3, 4, [1.0, 0.0, 0.0]], [5, 5, [0.0, 1.0, 0.0]]]

```
[[3, 4, [1.0, 0.0, 0.0]], [5, 5, [0.0, 1.0, 0.0]]]
```



If you specify the color of one point, you must also specify the colors of all other points in the list:
Coords := [[3, 4, RGB::Red], [5, 5]]; plotCoords := plot::PointList2d(Coords)[[3, 4, [1.0, 0.0, 0.0]], [5, 5]]

[[3, 4, [1.0, 0.0, 0.0]], [5, 5]]

Error: The attribute 'Points2d' in the 'PointList2d' object must be a list of lists of two expressions and an optional color value. [plot]

Example 4

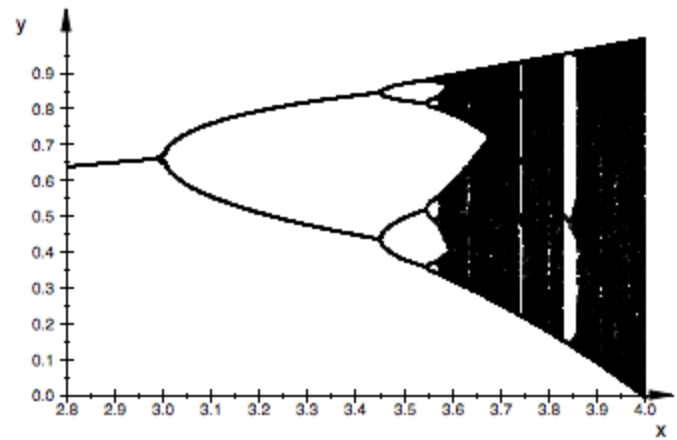
(Feigenbaum's period doubling route to chaos)

We consider the iteration $x_{n+1} = f_p(x_n)$ where funcDecl(f[p], x, p * x * (1 - x))$f_p: x \to p\,x\,(1-x)$ is the "logistic map" with a parameter p. The iteration map f_p maps the interval [0, 1] to itself for $0 \le p \le 4$. For small values of p, the sequence (x_n) has a finite number of accumulation points that are visited cyclically. Increasing p, the accumulation points split into 2 separate accumulation points for certain critical values of p ("period doubling"). For p approx _outputSequence(3.569945672, Symbol::dots)$p \approx 3.569945672\ldots$, there are infinitely many accumulation points and the sequence (x_n) behaves chaotically.

We wish to visualize the accumulation points as functions of p ("Feigenbaum diagram").

For P closely spaced values of p, we construct the sequence (x_n) starting with $x_0 = 0.5$. We ignore the first N values, expecting that the next M values cycle over the accumulation points. These points are added to a list `plotdata` that is finally fed into a `PointList2d` for plotting:

```
f:= (p, x) -> p*x*(1-x): P:= 500: // number of steps in p direction N:= 200: // transitional steps before we are close to the cycle M:= 300: // maximal number of points on the cycle pmin:= 2.8: // Consider p between pmax:= 4.0: // pmin and pmax plotdata:= [ ]: for p in [pmin + i*(pmax - pmin)/P $ i = 0..P] do // First, do N iterations to drive the // point x towards the limit cycle x:= 0.5: for i from 1 to N do x:= f(p, x): end_for: // consider the next M iterates and use them as plot data: xSequence:= table(): xSequence[1]:= x; for i from 2 to M do x:= f(p, x): if abs(x - xSequence[1]) < 10^(-5) then // We are back at the beginning of the cycle; // the points will repeat. Go to the next p. break; else xSequence[i]:= x; end_if; end_for: plotdata:= plotdata . [[p, rhs(x)] $ x in xSequence]; end_for: plot(plot::PointList2d(plotdata, PointColor = RGB::Black, PointSize = 0.5*unit::mm)):
```



```
delete f, P, N, M, pmin, pmax, plotdata, x, xSequence, i;
```

Parameters

pts

A list of points. A point must not be of type plot::Point2d or plot::Point3d, respectively. In 2D, each point must be a list of two real-valued expressions (the coordinates) and an optional RGB color. In 3D, each point mut be a list of three expressions (the coordinates) and an optional RGB or RGBa color. The lists specifying the points and the colors must all have the same length.

`pts` is equivalent to the attributes Points2d, Points3d.

M_{2d}

An array or a matrix with 2 columns. Each row provides the coordinates of one point.

M_{2d} is equivalent to the attribute Points2d.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::PointList3dplot::Listplotplot::Point2dplot::Point3dplot::Polygon2

plot::PointList3d

Purpose

Finite lists of 3D points

Syntax

```
plot::PointList3d(pts, <a = a_min .. a_max>, options)
plot::PointList3d(M_3d, <a = a_min .. a_max>, options)
```

Description

`plot::PointList3d` holds lists of points in 3D.

These types are containers for a (large) finite number of points. They let you avoid constructing large numbers of objects of type plot::Point3d, for two reasons. First, the point types have non-negligible overhead and constructing and plotting a large number of them (say, five thousand) takes more time than plotting the same number of points in a single container object. Second, and this may be even more important, having five thousand points in the object browser takes a significant amount of memory and is not as lucid as having a single point list displayed there.

The attribute Points3d is displayed in the inspector in the user interface only for short lists.

`plot::PointList2d, PointList3d` internally use lists for storing the points. It is therefore not advisable to add a large number of points one-by-one. See “Example 2” on page 24-579 for a better method of collecting data.

If you specify the color of one point, you must specify the colors of all other points in the list. See “Example 3” on page 24-580.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::MidnightBlue
Frames	the number of frames in an animation	`50`

Attribute	Purpose	Default Value
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Points3d	list of 3D points	
PointSize	the size of points	1.5
PointColor	the color of points	RGB::MidnightBlue
PointStyle	the presentation style of points	FilledCircles
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	

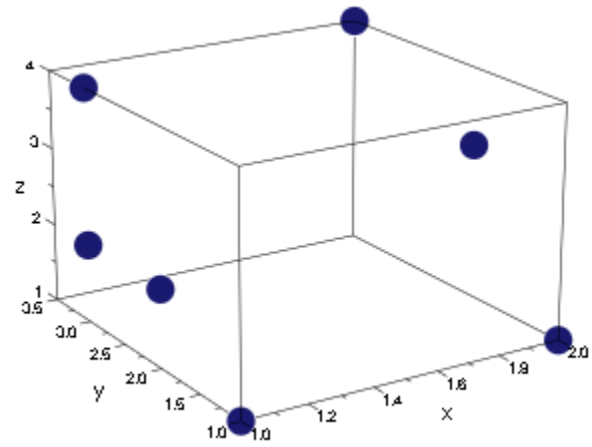
Attribute	Purpose	Default Value
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

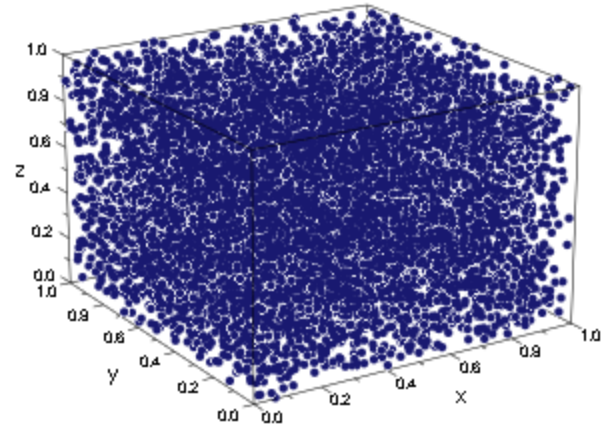
Example 1

`plot::PointList3d` provides a basic form of scatter plot:

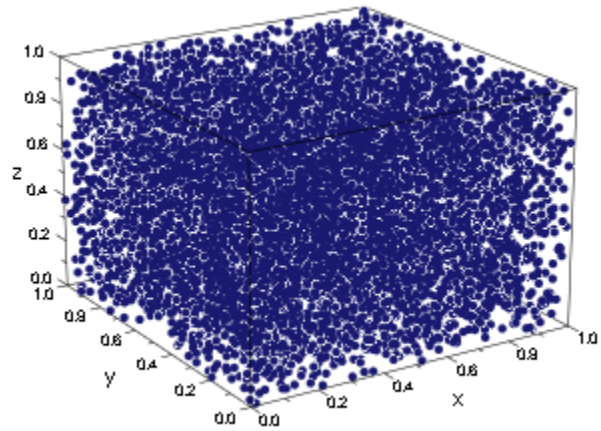
plot(plot::PointList3d([[1,1,1], [1,2,2], [1,3,2], [1,3,4], [2,1,1], [2,2,3], [2,3.5, 4]], PointSize=5))



We can use this, for example, to get a visual test of random number generators:
r := frandom(0): plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000])):

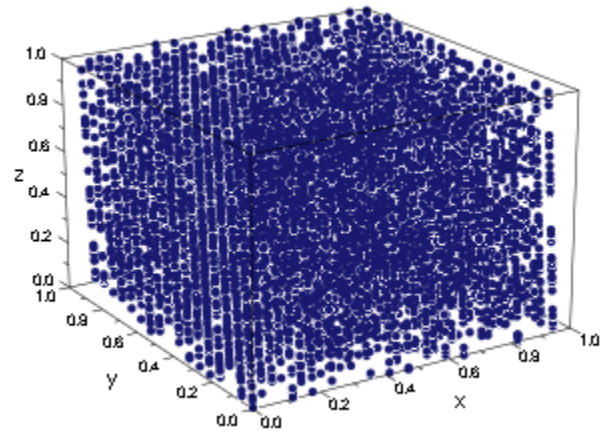


```
r := random(10^10)*1e-10: plot(plot::PointList3d([[r(), r(), r()] $
i=1..10000])):
```



frandom and random fill the cube nicely, without noticeable patterns. The following generator, however, should probably not be used:

```
randseed := 12345: r := proc() begin randseed := (randseed * 17 + 8)
mod 10^10: 1e-10 * randseed; end: plot(plot::PointList3d([[r(), r(), r()]
$ i=1..10000])):
```

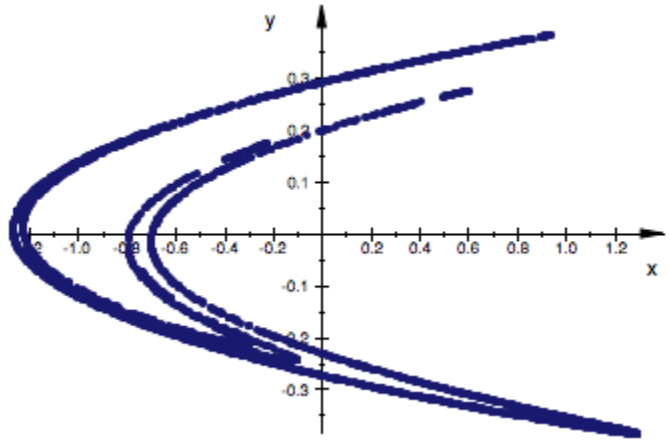


Example 2

The following iteration leads to the so-called Hénon attractor (from chaos theory):
c1 := 1.4: c2 := 0.3: henon_iter := (x, y) -> [c1*x^2+y-1, c2*x]:

We start at (0, 0), let hundred iteration cycles pass by (to only plot the attractor) and then collect the next three thousand points:
[x, y] := [0, 0]: for i from 1 to 100 do [x, y] := henon_iter(x, y); end_for:
data := {}: for i from 1 to 3000 do [x, y] := henon_iter(x, y); data := data union {[x, y]}; end_for:

Note that we collected the data in a set, because adding elements to a set is a fast operation, unlike changing the length of a list, and we don't care for the order in which points were reached. To plot the data, we must convert it to a list first:
data := coerce(data, DOM_LIST): plot(plot::PointList2d(data))

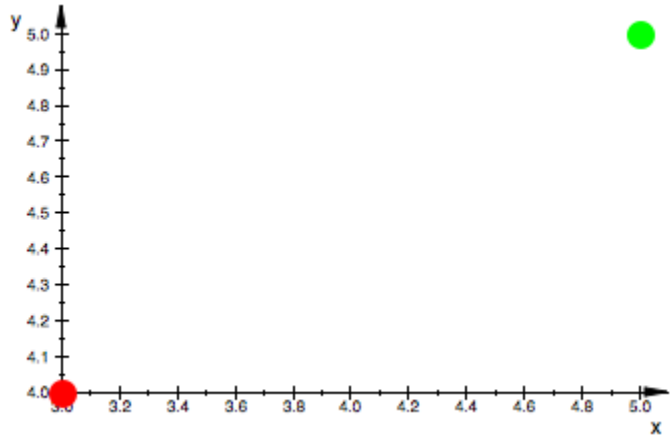


We'd like to invite you to experiment with different values of `c1` and `c2` and see how they change the resulting image.

Example 3

plot::PointList2d and `plot::PointList3d` allow you to specify the colors of the points. For example, the following list contains two points. When you plot this list, the first point appears in red, and the second point appears in green:
Coords := [[3, 4, RGB::Red], [5, 5, RGB::Green]]; plotCoords := plot::PointList2d(Coords): plot(plotCoords, PointSize=5)[[3, 4, [1.0, 0.0, 0.0]], [5, 5, [0.0, 1.0, 0.0]]]

```
[[3, 4, [1.0, 0.0, 0.0]], [5, 5, [0.0, 1.0, 0.0]]]
```



If you specify the color of one point, you must also specify the colors of all other points in the list:
Coords := [[3, 4, RGB::Red], [5, 5]]; plotCoords := plot::PointList2d(Coords)[[3, 4, [1.0, 0.0, 0.0]], [5, 5]]

[[3, 4, [1.0, 0.0, 0.0]], [5, 5]]

Error: The attribute 'Points2d' in the 'PointList2d' object must be a list of lists of two expressions and an optional color value. [plot]

Example 4

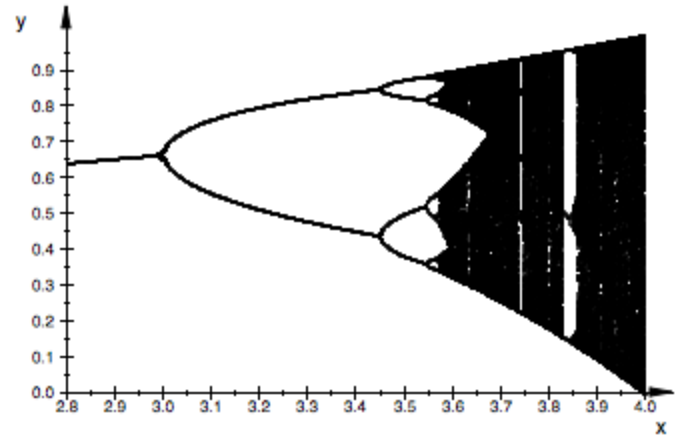
(Feigenbaum's period doubling route to chaos)

We consider the iteration $x_{n+1} = f_p(x_n)$ where funcDecl(f[p], x, p * x * (1 - x))$f_p: x \to p\,x\,(1-x)$ is the "logistic map" with a parameter p. The iteration map f_p maps the interval [0, 1] to itself for $0 \le p \le 4$. For small values of p, the sequence (x_n) has a finite number of accumulation points that are visited cyclically. Increasing p, the accumulation points split into 2 separate accumulation points for certain critical values of p ("period doubling"). For p approx _outputSequence(3.569945672, Symbol::dots)$p \approx 3.569945672\ldots$, there are infinitely many accumulation points and the sequence (x_n) behaves chaotically.

We wish to visualize the accumulation points as functions of p ("Feigenbaum diagram").

For P closely spaced values of p, we construct the sequence (x_n) starting with $x_0 = 0.5$. We ignore the first N values, expecting that the next M values cycle over the accumulation points. These points are added to a list `plotdata` that is finally fed into a `PointList2d` for plotting:

```
f:= (p, x) -> p*x*(1-x): P:= 500: // number of steps in p direction N:= 200: // transitional steps before we are close to the cycle M:= 300: // maximal number of points on the cycle pmin:= 2.8: // Consider p between pmax:= 4.0: // pmin and pmax plotdata:= [ ]: for p in [pmin + i*(pmax - pmin)/P $ i = 0..P] do // First, do N iterations to drive the // point x towards the limit cycle x:= 0.5: for i from 1 to N do x:= f(p, x): end_for: // consider the next M iterates and use them as plot data: xSequence:= table(): xSequence[1]:= x; for i from 2 to M do x:= f(p, x): if abs(x - xSequence[1]) < 10^(-5) then // We are back at the beginning of the cycle; // the points will repeat. Go to the next p. break; else xSequence[i]:= x; end_if; end_for: plotdata:= plotdata . [[p, rhs(x)] $ x in xSequence]; end_for: plot(plot::PointList2d(plotdata, PointColor = RGB::Black, PointSize = 0.5*unit::mm)):
```



```
delete f, P, N, M, pmin, pmax, plotdata, x, xSequence, i;
```

Parameters

pts

A list of points. A point must not be of type plot::Point2d or plot::Point3d, respectively. In 2D, each point must be a list of two real-valued expressions (the coordinates) and an optional RGB color. In 3D, each point mut be a list of three expressions (the coordinates) and an optional RGB or RGBa color. The lists specifying the points and the colors must all have the same length.

`pts` is equivalent to the attributes Points2d, Points3d.

M_{3d}

An array or a matrix with 3 columns. Each row provides the coordinates of one point.

M_{3d} is equivalent to the attribute Points3d.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::PointList2dplot::Listplotplot::Point2dplot::Point3dplot::Polygon2

plot::Polar

Purpose

Curves in 2D parameterized in polar coordinates

Syntax

```
plot::Polar([r,  ], u = u_min .. u_max, <a =
a_min .. a_max>, options)
```

Description

`plot::Polar` creates parameterized curves in 2D, with parametrization in polar coordinates.

`plot::Polar` creates curves in one parameter, with parametrization in polar coordinates and possibly animated (see “Example 1” on page 24-588 and “Example 2” on page 24-590). The curves may contain poles, in which case automatic clipping is used by default, see “Example 4” on page 24-593.

Polar coordinates consist of a radius and an angle. The radius of a point is its distance from the origin (0, 0), while the angle is the angle between the positive “*x*”-axis (the ordinate) and the connection between the point and the origin, measured in radians and counter-clockwise.

By default, curves are sampled at equidistant values of the parameter `t`. The attribute AdaptiveMesh can be used to change this behavior, such that a denser sampling rate is used in areas of higher curvature. Cf. “Example 3” on page 24-591.

Curves are graphical objects that can be manipulated, see the examples and the documentation of the parameters listed below for details.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	`0`
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`

Attribute	Purpose	Default Value
Color	the main color	RGB::Blue
DiscontinuitySearch	semi-symbolic search for discontinuities	`TRUE`
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`TRUE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`1`

Attribute	Purpose	Default Value
Mesh	number of sample points	121
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Submesh	density of submesh (additional sample points)	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	

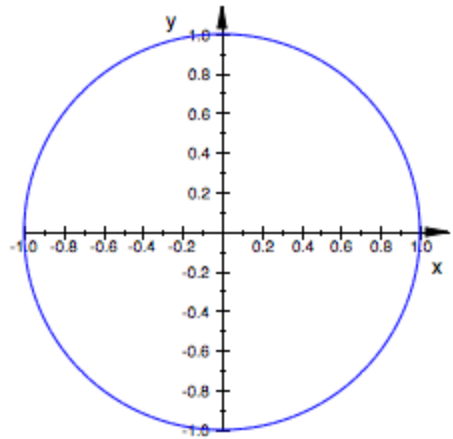
Attribute	Purpose	Default Value
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
UMax	final value of parameter “u”	
UMesh	number of sample points for parameter “u”	`121`
UMin	initial value of parameter “u”	
UName	name of parameter “u”	
URange	range of parameter “u”	
USubmesh	density of additional sample points for parameter “u”	`0`
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
YFunction	function for y values	

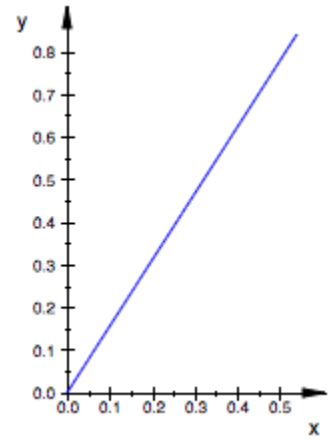
Examples

Example 1

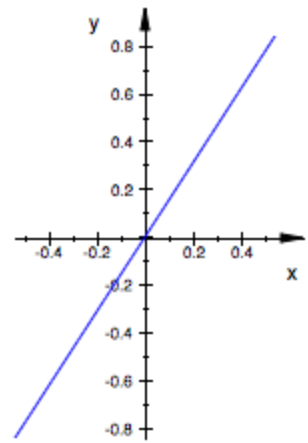
The most basic example of a curve in polar coordinates is a circle: Using a constant radius, the angle goes from 0 to 2π:
plot(plot::Polar([1, u], u = 0..2*PI))



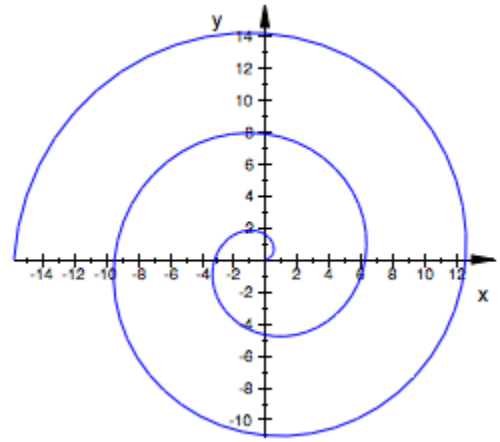
A constant angle, on the other hand, means a straight line through the origin:
plot(plot::Polar([r, 1], r = 0..1))



`plot::Polar` accepts negative radii:
plot(plot::Polar([r, 1], r = -1..1))

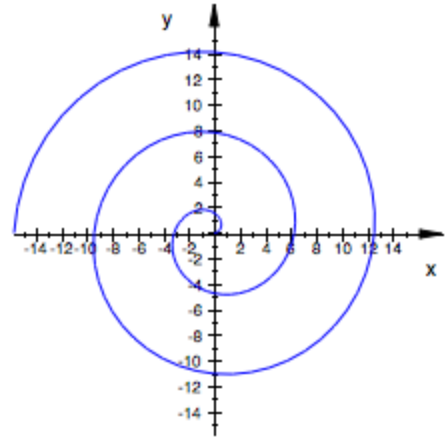


The most simple “interesting” example is probably Archimedes’ spiral:
plot(plot::Polar([r, r], r = 0..5*PI))



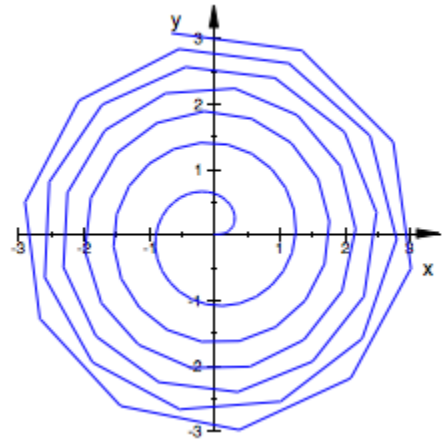
Example 2

Polar curves can be animated just like almost anything else:
plot(plot::Polar([r, a*r], r = 0..5*PI, a = -1..1))

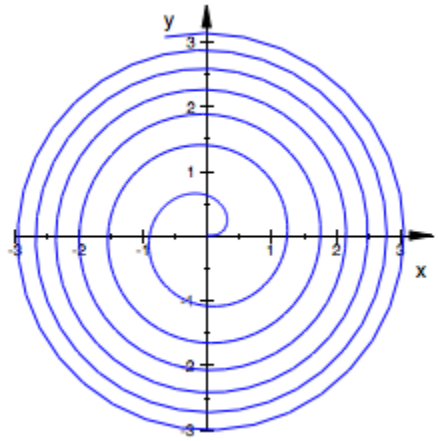


Example 3

In some cases, the default of 121 evaluations on the curve is not sufficient and causes visible artifacts:
plot(plot::Polar([r, 4*r^2], r = 0..PI))

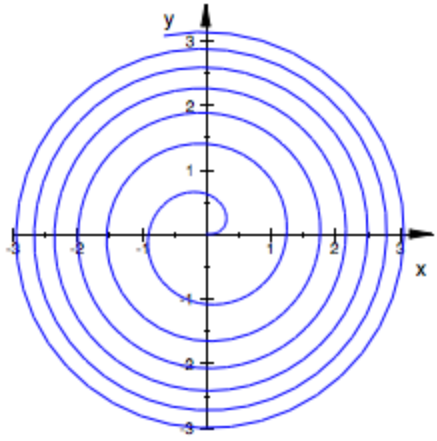


One remedy for this problem is to increase the number of evaluation points:
plot(plot::Polar([r, 4*r^2], r = 0..PI, Mesh = 400))



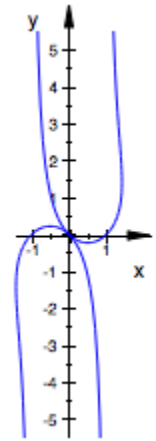
This method is, however, wasteful: Near the center, the initial density was perfectly sufficient, while on the outer edge still more points would be desirable. `plot::Polar` offers adaptive mesh refinement for exactly these situations. In the following example, we switch on adaptive mesh refinement with up to $2^4 = 16$ points introduced between each two consecutive points of the initial mesh:

```
plot(plot::Polar([r, 4*r^2], r = 0..PI, AdaptiveMesh=4))
```

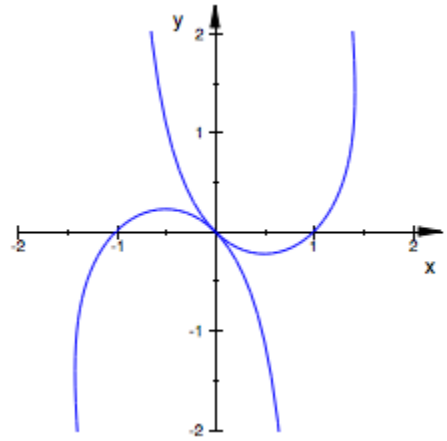


Example 4

If the curve (i.e., the radius expression/function) contains poles, `plot::Polar` will use heuristics to clip the viewing box:
plot(plot::Polar([tan(t)+1, t], t = 0..2*PI))



To select a different area, use the attribute ViewingBox:
plot(plot::Polar([tan(t)+1, t], t = 0..2*PI, ViewingBox = [-2..2, -2..2]))



Example 5

`plot::Polar` creates objects that can be manipulated interactively and/or programmatically:

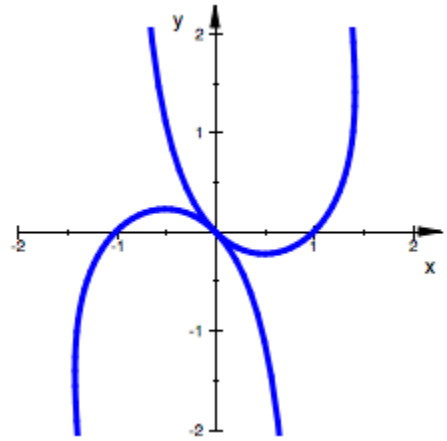
```
p := plot::Polar([tan(t)+1, t], t = 0..PI)
```

plot::Polar([tan(t) + 1, t], t = 0..PI)

```
p::UMax := 2*PI: pplot::Polar([tan(t) + 1, t], t = 0..2*PI)
```

plot::Polar([tan(t) + 1, t], t = 0..2*PI)

```
p::ViewingBox := [-2..2, -2..2]: p::LineColor := RGB::Blue: p::LineWidth
:= 1*unit::mm: plot(p)
```



Parameters

r

- The coordinate functions: arithmetical expressions or piecewise objects depending on the curve parameter *u* and the animation parameter a. Alternatively, procedures that accept 1 input parameter *u* or 2 input parameters *u*, *a* and return a real numerical value when the input parameters are numerical.

  r, are equivalent to the attributes XFunction, YFunction.

u

The curve parameter: an identifier or an indexed identifier.

u is equivalent to the attribute UName.

u_{min} .. u_{max}

The plot range for the parameter *u*: u_{min}, u_{max} must be numerical real values or expressions of the animation parameter *a*.

u_{min} .. u_{max} is equivalent to the attributes URange, UMin, UMax.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Curve2dplot::Sphericalplot::Cylindrical

plot::Polygon2d

Purpose

2D polygons

Syntax

```
plot::Polygon2d([pt2d1, pt2d2,  ], <a = amin .. amax>, options)
plot::Polygon2d(M2d, <a = amin .. amax>, options)
```

Description

`plot::Polygon2d` define polygons in 2D, by a given list of vertex points.

A polygon consists of points and edges. The edges are made up of the lines traversing from the first to the second point, the second to the third point, and so on. The last point is automatically connected with the first point if the attribute Closed = `TRUE` is specified.

Points and lines can be hidden via PointsVisible = `FALSE` and LinesVisible = `FALSE`. Per default the vertex points are hidden while the edges are visible.

All points as a whole can be manipulated via PointStyle and PointSize. The attribute LineColor sets the color for all points and all lines. Likewise all lines can be manipulated via LineStyle and LineWidth.

It is possible to vary the color of all lines and points via LineColorType. The default value is `Flat`. Specifying the values `Dichromatic` or `Rainbow`, a second color LineColor2 can be set. With `Functional`, the colors are taken from a user defined LineColorFunction. Cf. “Example 2” on page 24-602.

The area of any closed 2D polygon can be filled by specifying Filled = `TRUE`. The filled area is defined by connecting the last and the first vertex. This additional edge itself, however, is only displayed if Closed = `TRUE` is set.

A fill color and a fill pattern can be chosen by FillColor and FillPattern.

In case of a self-intersecting polygon, a FillStyle can be selected. Cf. “Example 3” on page 24-604.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Closed	open or closed polygons	`FALSE`
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	`FALSE`
FillColor	color of areas and surfaces	RGB::Red
FillStyle	definition of inside/outside	`EvenOdd`
FillPattern	type of area filling	`DiagonalLines`
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`

Attribute	Purpose	Default Value
LinesVisible	visibility of lines	`TRUE`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`1`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Points2d	list of 2D points	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`

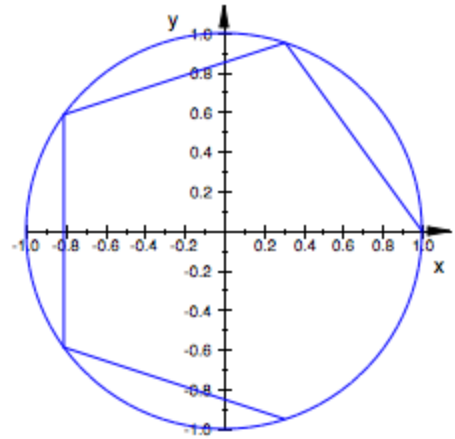
Attribute	Purpose	Default Value
PointsVisible	visibility of mesh points	`FALSE`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

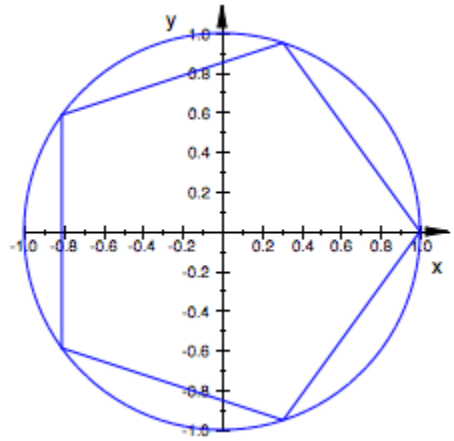
Examples

Example 1

We create a polygon with vertices located at the 5 complex 5^{th} roots of 1. The polygon consists of the 4 lines joining the 5 points in the order given:
p := plot::Polygon2d([[cos(2*PI*k/5), sin(2*PI*k/5)] $ k = 0..4]): plot(p, plot::Circle2d(1, [0, 0])):



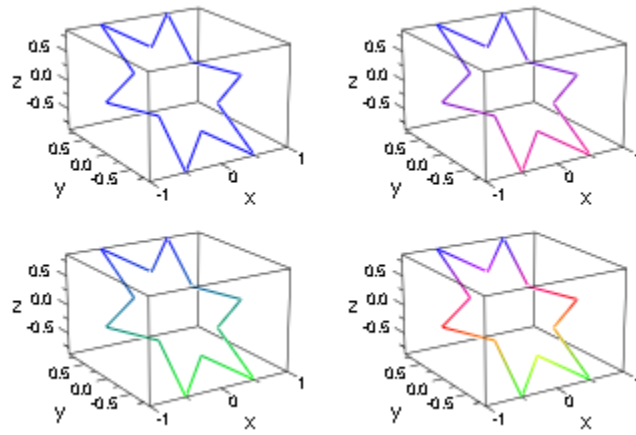
In order to include the line connecting the last with the first point, pass the attribute Closed to the polygon:
p::Closed := TRUE: plot(p, plot::Circle2d(1, [0, 0])):



delete p

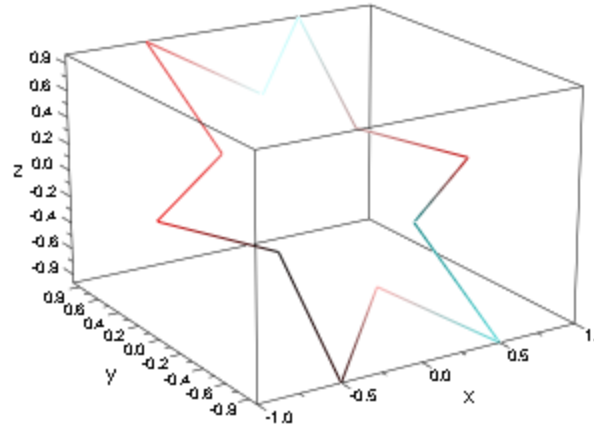
Example 2

We plot a closed star-shaped 3D polygon with various color attributes:
p := plot::Polygon3d([([cos(PI*k/3), sin(PI*k/3), sin(PI*k/3)], [cos(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2]) $k = 1..6], Closed = TRUE): S1 := plot::Scene3d(p, LineColorType = Flat): S2 := plot::Scene3d(p, LineColorType = Dichromatic): S3 := plot::Scene3d(p, LineColorType = Dichromatic, LineColor = RGB::Blue, LineColor2 = RGB::Green): S4 := plot::Scene3d(p, LineColorType = Rainbow, LineColor = RGB::Blue, LineColor2 = RGB::Green): plot(S1, S2, S3, S4)



We plot the same polygon while animating its line color using a color function. The result is a dazzling star:

```
p := plot::Polygon3d( [([cos(PI*k/3), sin(PI*k/3), sin(PI*k/3)], [cos(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2]) $k = 1..6 ], Closed = TRUE, LineColorFunction = proc(x, y, z, i, a) begin [sin(x + a*i)^2, sin(y + a*i)^2, sin(z + a*i)^2]: end_proc, a = 0..10): plot(p)
```

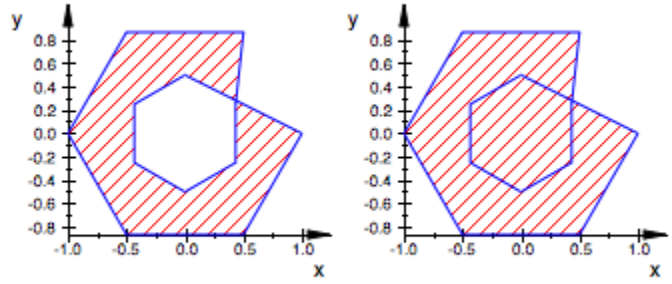


delete p, S1, S2, S3, S4

Example 3

We plot a closed 2D polygon and fill the area inside. In fact, there are two possible interpretations of what "inside" really means. In the first plot, the complement of the unbound component of the complement of the polygon is filled. In the second plot only that area is filled that contains points with non-zero winding number with respect to the polygon. Cf. FillStyle for a detailed discussion.

```
p := plot::Polygon2d( [[cos(PI*k/3), sin(PI*k/3)] $k = 1..6, [cos(PI*k/3
+ PI/6)/2, sin(PI*k/3 + PI/6)/2] $k = 1..6 ], Closed = TRUE): S1 :=
plot::Scene2d(p, Filled = TRUE): S2 := plot::Scene2d(p, Filled = TRUE,
FillStyle = Winding): plot(S1, S2, Layout = Horizontal, Axes = Frame,
Scaling = Constrained)
```



delete p, S1, S2:

Parameters

pt2d$_1$, pt2d$_2$, ...

The 2D vertices. These must not be of type plot::Point2d, but lists of two numerical real values or arithmetical expressions of the animation parameter `a` (the coordinates).

`pt2d`$_1$, `pt2d`$_2$, ... is equivalent to the attribute Points2d.

M_{2d}

An array or a matrix with 2 columns. Each row provides the coordinates of one point.

M_{2d} is equivalent to the attribute Points2d.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Polygon3dplot::Line2dplot::Line3dplot::Listplot

plot::Polygon3d

Purpose

3D polygons

Syntax

```
plot::Polygon3d([pt3d1, pt3d2,  ], <a = amin .. amax>, options)
plot::Polygon3d(M3d, <a = amin .. amax>, options)
```

Description

`plot::Polygon3d` define polygons in 3D, by a given list of vertex points.

A polygon consists of points and edges. The edges are made up of the lines traversing from the first to the second point, the second to the third point, and so on. The last point is automatically connected with the first point if the attribute Closed = `TRUE` is specified.

Points and lines can be hidden via PointsVisible = `FALSE` and LinesVisible = `FALSE`. Per default the vertex points are hidden while the edges are visible.

All points as a whole can be manipulated via PointStyle and PointSize. The attribute LineColor sets the color for all points and all lines. Likewise all lines can be manipulated via LineStyle and LineWidth.

It is possible to vary the color of all lines and points via LineColorType. The default value is `Flat`. Specifying the values `Dichromatic` or `Rainbow`, a second color LineColor2 can be set. With `Functional`, the colors are taken from a user defined LineColorFunction. Cf. “Example 2” on page 24-611.

A 3D polygon can only be filled if it is defined by 3 vertices (a triangle). The attribute Filled = `TRUE` is ignored for other 3D polygons.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Closed	open or closed polygons	`FALSE`

Attribute	Purpose	Default Value
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0

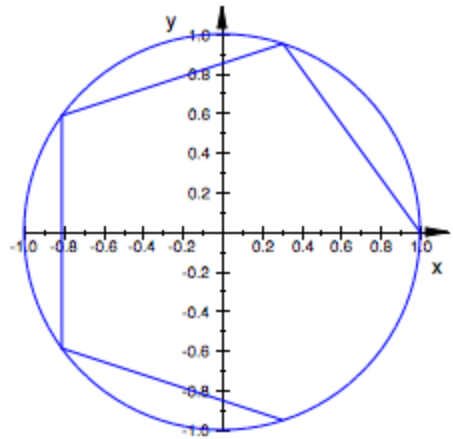
Attribute	Purpose	Default Value
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Points3d	list of 3D points	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

Attribute	Purpose	Default Value
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

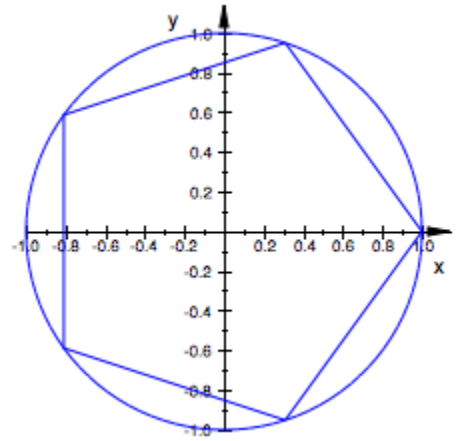
Examples

Example 1

We create a polygon with vertices located at the 5 complex 5^{th} roots of 1. The polygon consists of the 4 lines joining the 5 points in the order given:
p := plot::Polygon2d([[cos(2*PI*k/5), sin(2*PI*k/5)] $ k = 0..4]): plot(p, plot::Circle2d(1, [0, 0])):



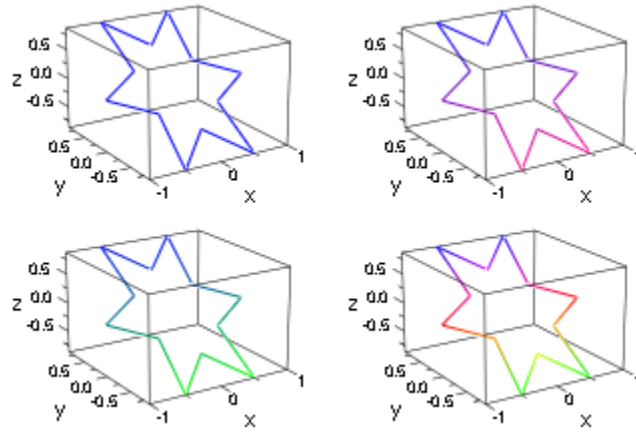
In order to include the line connecting the last with the first point, pass the attribute Closed to the polygon:
p::Closed := TRUE: plot(p, plot::Circle2d(1, [0, 0])):



delete p

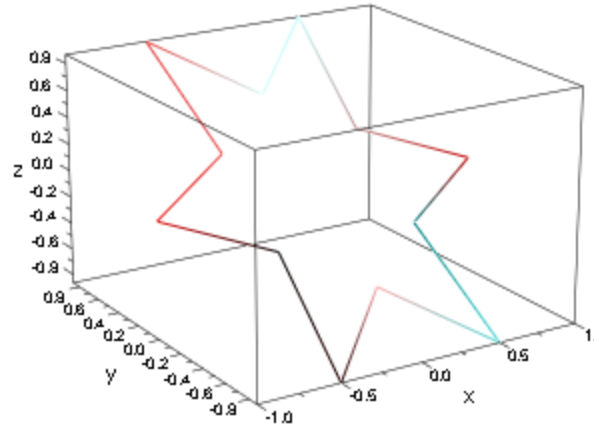
Example 2

We plot a closed star-shaped 3D polygon with various color attributes:
p := plot::Polygon3d([([cos(PI*k/3), sin(PI*k/3), sin(PI*k/3)], [cos(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2]) $k = 1..6], Closed = TRUE): S1 := plot::Scene3d(p, LineColorType = Flat): S2 := plot::Scene3d(p, LineColorType = Dichromatic): S3 := plot::Scene3d(p, LineColorType = Dichromatic, LineColor = RGB::Blue, LineColor2 = RGB::Green): S4 := plot::Scene3d(p, LineColorType = Rainbow, LineColor = RGB::Blue, LineColor2 = RGB::Green): plot(S1, S2, S3, S4)



We plot the same polygon while animating its line color using a color function. The result is a dazzling star:

```
p := plot::Polygon3d( [([cos(PI*k/3), sin(PI*k/3), sin(PI*k/3)], [cos(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2]) $k = 1..6 ], Closed = TRUE, LineColorFunction = proc(x, y, z, i, a) begin [sin(x + a*i)^2, sin(y + a*i)^2, sin(z + a*i)^2]: end_proc, a = 0..10): plot(p)
```

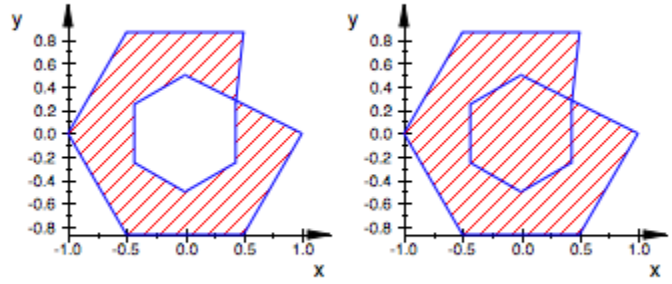


delete p, S1, S2, S3, S4

Example 3

We plot a closed 2D polygon and fill the area inside. In fact, there are two possible interpretations of what "inside" really means. In the first plot, the complement of the unbound component of the complement of the polygon is filled. In the second plot only that area is filled that contains points with non-zero winding number with respect to the polygon. Cf. FillStyle for a detailed discussion.

```
p := plot::Polygon2d( [[cos(PI*k/3), sin(PI*k/3)] $k = 1..6, [cos(PI*k/3
+ PI/6)/2, sin(PI*k/3 + PI/6)/2] $k = 1..6 ], Closed = TRUE): S1 :=
plot::Scene2d(p, Filled = TRUE): S2 := plot::Scene2d(p, Filled = TRUE,
FillStyle = Winding): plot(S1, S2, Layout = Horizontal, Axes = Frame,
Scaling = Constrained)
```



delete p, S1, S2:

Parameters

pt3d$_1$, pt3d$_2$, ...

The 3D vertices. These must not be of type plot::Point3d, but lists of three numerical real values or arithmetical expressions of the animation parameter `a` (the coordinates).

`pt3d`$_1$, `pt3d`$_2$, ... is equivalent to the attribute Points3d.

M_{3d}

An array or a matrix with 3 columns. Each row provides the coordinates of one point.

M_{3d} is equivalent to the attribute Points3d.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Prism

Purpose

Prisms

Syntax

```
plot::Prism(r, [x1, y1, z1], [x2, y2, z2], <a = amin .. amax>, options)
```

Description

`plot::Prism(r, [x1, y1, z1] , [x2, y2, z2] )` creates a prism with a regular base plane with a circumcircle of radius *r* and an axis from the point `[x1, y1, z1]` to the point `[x2, y2, z2]`.

The base center and top center of the prism can also be passed as vectors.

Note that only prisms with a regular base can be created with `plot::Prism`. For other bases, use a plot::SurfaceSet primitive.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Angle	rotation angle	`0`
Base	base center of cones, cylinders, pyramids and prisms	`[0, 0, 0]`
BaseX	x-coordinate of top center of cones, cylinders, pyramids and prisms	`0`
BaseY	y-coordinate of top center of cones, cylinders, pyramids and prisms	`0`

Attribute	Purpose	Default Value
BaseZ	z-coordinate of top center of cones, cylinders, pyramids and prisms	0
Color	the main color	RGB::Red
Edges	Number of Edges	3
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0

Attribute	Purpose	Default Value
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0

Attribute	Purpose	Default Value
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
Normal	normal vector of circles and discs, etc. in 3D	[0, 0, 0]
NormalX	normal vector of circles and discs, etc. in 3D, x-component	0
NormalY	normal vector of circles and discs, etc. in 3D, y-component	0
NormalZ	normal vector of circles and discs, etc. in 3D, z-component	0
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles

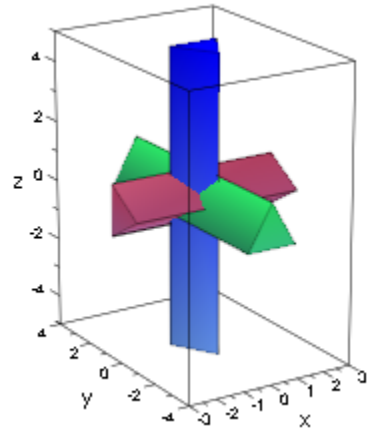
Attribute	Purpose	Default Value
PointsVisible	visibility of mesh points	`FALSE`
Radius	radius of circles, spheres etc.	`1`
Shading	smooth color blend of surfaces	`Smooth`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Top	top center of cones, cylinders, pyramids and prisms	`[0, 0, 1]`

Attribute	Purpose	Default Value
TopX	base and top center of cones, cylinders, pyramids and prisms	0
TopY	base and top center of cones, cylinders, pyramids and prisms	0
TopZ	base and top center of cones, cylinders, pyramids and prisms	1
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

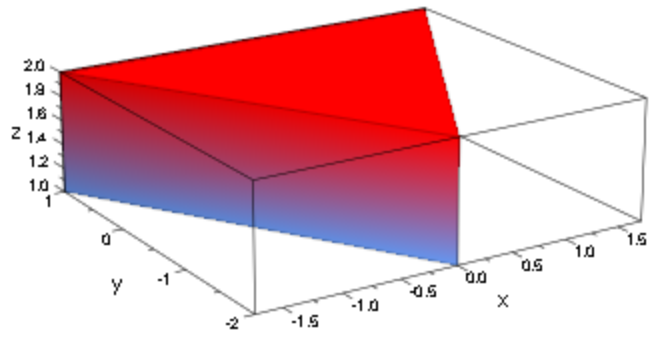
Example 1

We plot three regular prisms with axes given by the coordinate axes: plot(plot::Prism(1, [-3, 0, 0], [3, 0, 0], Color = RGB::Red), plot::Prism(1, [0, -4, 0], [0, 4, 0], Color = RGB::Green), plot::Prism(1, [0, 0, -5], [0, 0, 5], Color = RGB::Blue)):



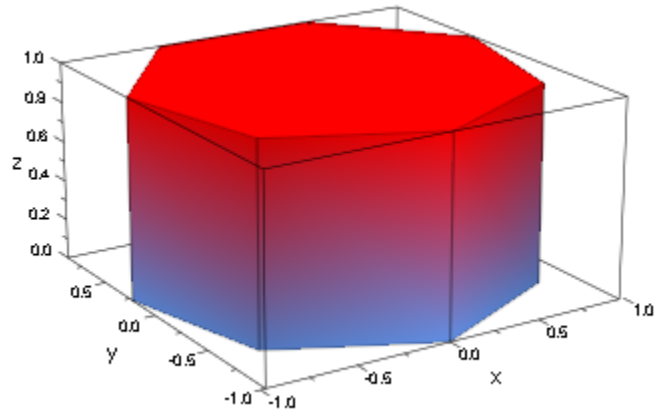
Example 2

All parameters of a prism can be animated:
plot(plot::Prism(a, [0, 0, a], [0, 0, 3-a], a = 1..2)):



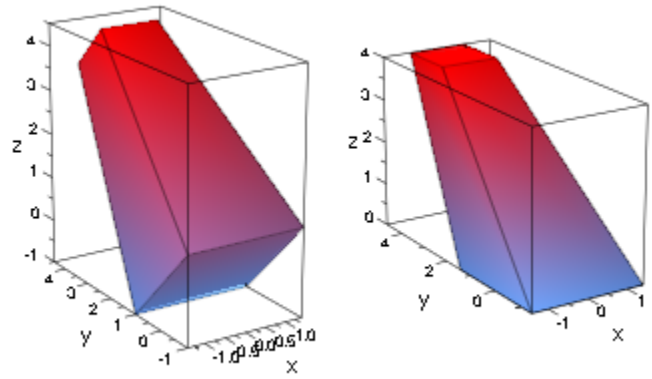
Example 3

The number of edges of the regular base plane of the prism are determined with the attribute Edges:
plot(plot::Prism(1, [0, 0, 0], [0, 0, 1], Edges = 7)):



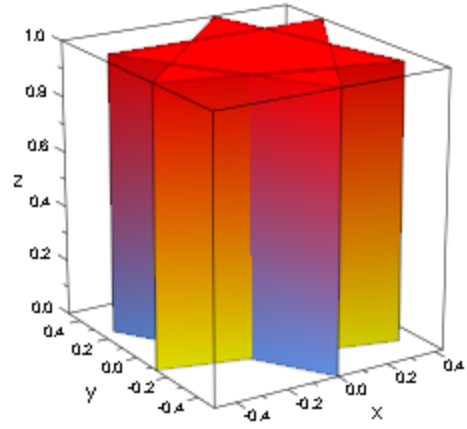
Example 4

To create a crooked regular prism, the normal vector of its base plane is specified with the attribute Normal. If this attribute is set to [0, 0, 0], the axis between Base and Top ist used as normal vector:
plot(plot::Scene3d(plot::Pyramid(2,[0,0,0],1,[0,4,4], Normal=[0,0,0])),
plot::Scene3d(plot::Pyramid(2,[0,0,0],1,[0,4,4], Normal=[0,0,1]))):



Example 5

Additionally, the orientation of the edges of the base can be changed with the rotation angle Angle:
plot(plot::Prism(1/2, Angle=0), plot::Prism(1/2, Angle=PI/4, FillColor2=RGB::Yellow))



Parameters

r

The radius of the circumcircle of the regular base plane: a real numerical value or an arithmetical expression of the animation parameter a.

r is equivalent to the attribute Radius.

x_1

y_1

z_1

Components of the base center: real numerical values or expressions of the animation parameter a.

x_1, y_1, z_1 are equivalent to the attributes BaseX, BaseY, BaseZ.

x_2

y_2

z_2

Components of the top center: real numerical values or expressions of the animation parameter a.

x_2, y_2, z_2 are equivalent to the attributes TopX, TopY, TopZ.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Pyramidplot::Cylinderplot::Cone

plot::Pyramid

Purpose

Pyramids and frustums of pyramids

Syntax

```
plot::Pyramid(br, [b_x, b_y, b_z], <tr>, [t_x, t_y, t_z],
<a = a_min .. a_max>, options)
```

Description

`plot::Pyramid(br, [ b_x, b_y, b_z], [ t_x, t_y, t_z])` creates a pyramid stretching from the regular base plane with a circumcircle of radius *br* and center `[b_x, b_y, b_z]` to the top `[t_x, t_y, t_z]`.

`plot::Pyramid(br, [ b_x, b_y, b_z], tr, [ t_x, t_y, t_z])` creates a frustum of pyramid from the base with center `[b_x, b_y, b_z]` to the top with center `[t_x, t_y, t_z]`. The radius of the circumcircle of the regular base is `br`. The radius of the circumcircle of the regular top is `tr`.

The optional "top radius" `tr` for creating a frustum may also be specified as the attribute `TopRadius = tr`.

Note that only pyramids with a regular base can be created with `plot::Pyramid`. For other bases, use a plot::SurfaceSet primitive.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Angle	rotation angle	`0`
Base	base center of cones, cylinders, pyramids and prisms	`[0, 0, 0]`
BaseX	x-coordinate of top center of cones, cylinders, pyramids and prisms	`0`

Attribute	Purpose	Default Value
BaseY	y-coordinate of top center of cones, cylinders, pyramids and prisms	0
BaseZ	z-coordinate of top center of cones, cylinders, pyramids and prisms	0
BaseRadius	base radius of cones/conical frustums and pyramids/frustums of pyramids	1
Color	the main color	RGB::Red
Edges	Number of Edges	4
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue

TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	

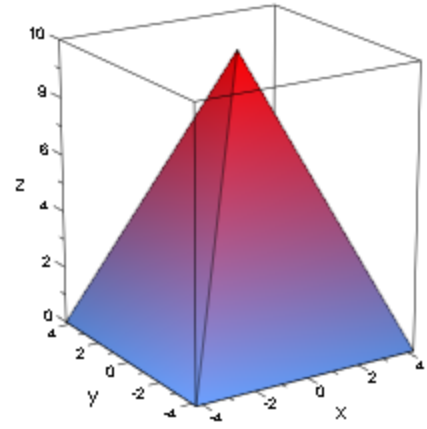
Attribute	Purpose	Default Value
TitlePositionZ	position of object titles, z component	
Top	top center of cones, cylinders, pyramids and prisms	[0, 0, 1]
TopX	base and top center of cones, cylinders, pyramids and prisms	0
TopY	base and top center of cones, cylinders, pyramids and prisms	0
TopZ	base and top center of cones, cylinders, pyramids and prisms	1
TopRadius	top radius of cones/conical frustums and pyramids/frustums of pyramids	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

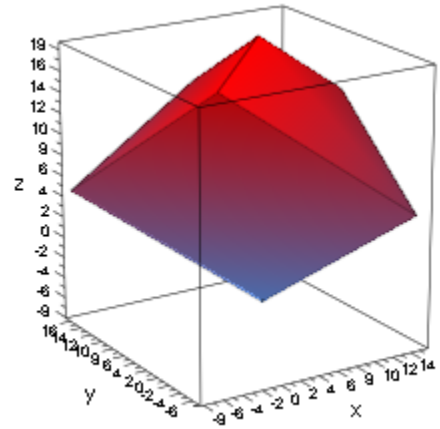
Example 1

We draw a pyramid with base radius 6:
plot(plot::Pyramid(6, [0, 0, 0], [0, 0, 10])):



Example 2

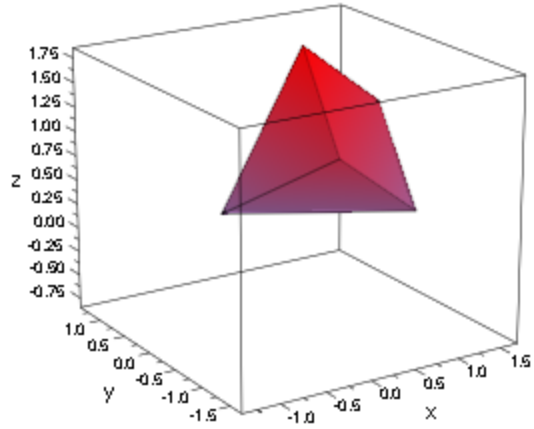
We create a frustum of pyramid by specifying a non-zero top radius:
br := 16: base := [3, 4, 5]: tr:= 7: top := [11, 12, 13]: plot(plot::Pyramid(br, base, tr, top)):



delete br, base, tr, top, n:

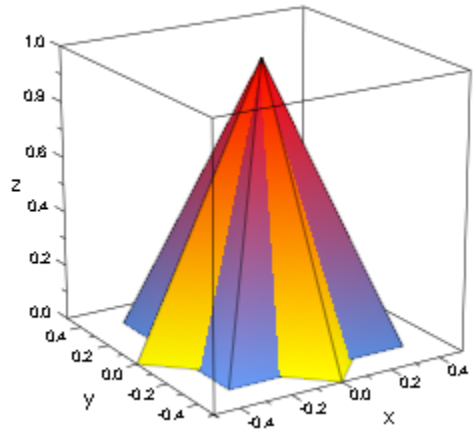
Example 3

Bottom and top radii and centers can be animated:
plot(plot::Pyramid(sin(a)^2, [sin(2*a), cos(2*a), 0], cos(a)^2, [cos(2*a), sin(2*a), 1], a = 0..PI)):



Example 4

Additionally, the orientation of the edges of the base can be changed with the rotation angle Angle:
plot(plot::Pyramid(1/2, Angle=0), plot::Pyramid(1/2, Angle=PI/4, FillColor2=RGB::Yellow))



Parameters

br

The radius of the circumcircle of the regular base. This must be a real numerical value or an arithmetical expression of the animation parameter `a`.

`br` is equivalent to the attribute BaseRadius.

b_x

b_y

b_z

The lower center point. The coordinates b_x, b_y, b_z must be real numerical values or arithmetical expressions of the animation parameter `a`.

b_x, b_y, b_z are equivalent to the attributes BaseX, BaseY, BaseZ.

tr

The radius of the circumcircle of the regular top of the frustum of pyramid. This must be a real numerical value or an arithmetical expression of the animation parameter `a`. If no top radius is specified, a pyramid with top radius *tr* = 0 is created.

`tr` is equivalent to the attribute TopRadius.

t_x

t_y

t_z

The upper center point. The coordinates t_x, t_y, t_z must be real numerical values or arithmetical expressions of the animation parameter `a`.

t_x, t_y, t_z are equivalent to the attributes TopX, TopY, TopZ.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Prismplot::Coneplot::Cylinder

plot::QQplot

Purpose

Statistical quantile-quantile plots

Syntax

```
plot::QQplot([a_1, a_2,  ], [b_1, b_2,  ], <a =
a_min .. a_max>, options)
plot::QQplot([[a_1, a_2,  ], [b_1, b_2,  ]], <a =
a_min .. a_max>, options)
plot::QQplot(A, <a = a_min .. a_max>, options)
plot::QQplot(s, <c_1, c_2>, <a = a_min .. a_max>, options)
plot::QQplot(s, <[c_1, c_2]>, <a = a_min .. a_max>, options)
```

Description

`plot::QQplot(data1, data2)` plots the quantiles of the first data set against the quantiles of the second data set.

`plot::QQplot` creates a quantile-quantile plot of two discrete data samples `[a_1, a_2,  ]` and `[b_1, b_2,  ]`. A QQ plot displays the collection of points with coordinates `[x_1, y_1]`, `[x_2, y_2]` etc., where `x_i = stats::empiricialQuantile([a_1, a_2, Symbol::dots])(i/(n - 1))` and `y_i = stats::empiricialQuantile([b_1, b_2, Symbol::dots])(i/(n - 1))` with `i` running from 0 through n - 1. The number of plot points n is set by the attribute Size = n. If no value is specified by the user, n is chosen as the minimum of the lengths of the data lists [a_1, a_2, ...] and [b_1, b_2, ...].

In addition, the diagonal reference line $y = x$ is displayed in the plot. This line can be suppressed by the attribute LinesVisible = `FALSE`.

The samples [a_1, a_2, ...] and [b_1, b_2, ...] do not need to have the same length.

A QQ plot is a graphical technique for determining if two data sets come from populations with a common distribution.

If the two sets come from a population with the same distribution, the points of the QQ plot should fall approximately along the reference line $y = x$. The greater the departure from this reference line, the greater the evidence for the conclusion that the two data sets have come from populations with different distributions.

A specialized version of the QQ plot is the “probability plot”, where the quantiles of one of the data samples are replaced with the quantiles of a theoretical distribution. You can use `plot::QQplot` for this type of plot, too, by using a reference list such as

```
[stats::normalQuantile(0, 1)(i/n) $ i = 1 ..  n-1]
```

as one of the data lists. In this particular case, data obeying a standard normal distribution should produce plot points close to the diagonal reference line $y = x$.

Cf. “Example 3” on page 24-640.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Data	the (statistical) data to plot	
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Red
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`

Attribute	Purpose	Default Value
LinesVisible	visibility of lines	`TRUE`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointColor	the color of points	RGB::Black
PointStyle	the presentation style of points	`FilledCircles`

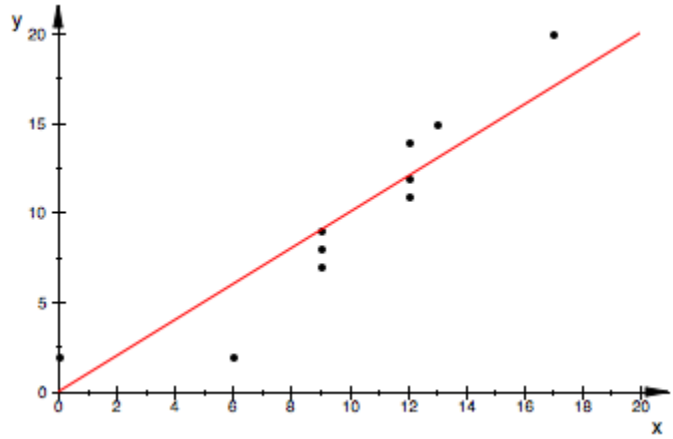
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

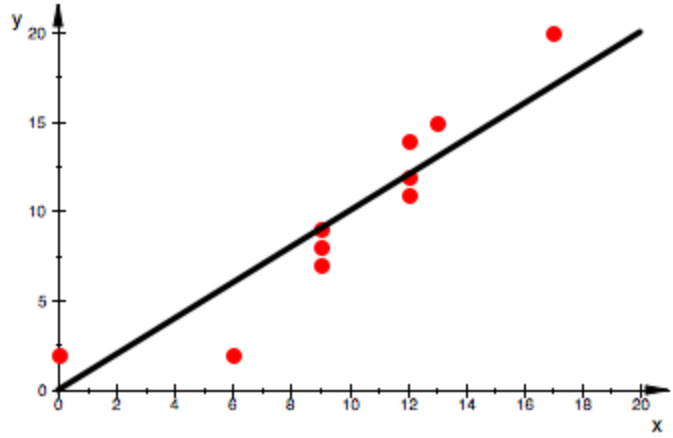
Examples

Example 1

We create a QQ plot of some data samples:
a := [6, 9, 17, 0, 13, 9, 9, 12, 12, 12]: b := [7, 8, 20, 2, 11, 8, 9, 12, 13, 15, 2, 14]: q := plot::QQplot(a, b): plot(q)



We can modify the appearance of the QQ plot in various ways: q::PointColor := RGB::Red: q::PointSize := 3*unit::mm: q::LineColor := RGB::Black: q::LineWidth := 1*unit::mm:plot(q)



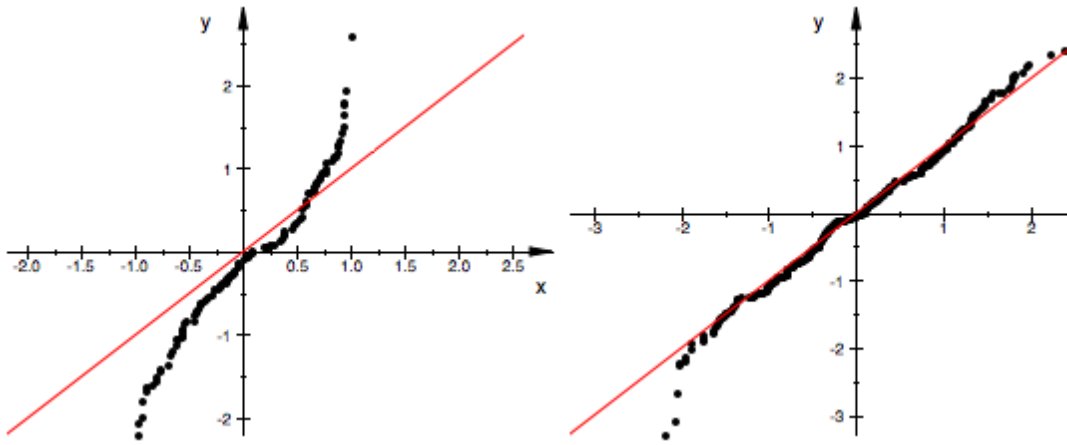
delete a, b, q:

Example 2

We create some samples:

a := [stats::uniformRandom(-1, 1)() $ k = 1..100]: b := [stats::normalRandom(0, 1)() $ k = 1..300]: c := [stats::normalRandom(0, 1)() $ k = 1..500]:

The left QQ-plot shows a clear deviation from the reference line $y = x$. The samples a and b do not seem to be chosen from the same population. The QQ plot of the samples b and c (both normally distributed with mean 0 and variance 1), however, shows data points close to the reference line:
plot(plot::Scene2d(plot::QQplot(a, b)), plot::Scene2d(plot::QQplot(b, c)), Width = 20*unit::cm, Rows = 1)



delete a, b, c:

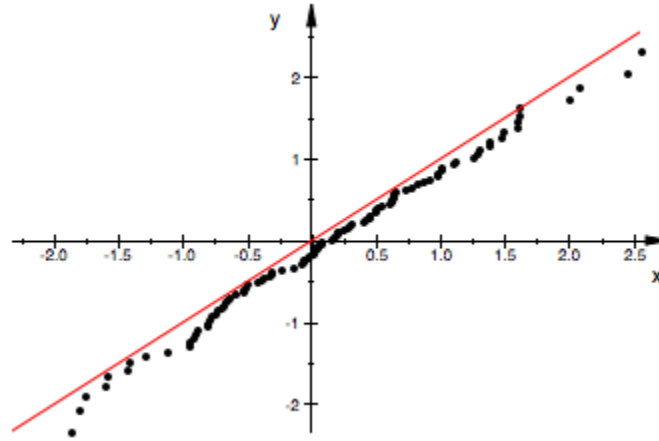
Example 3

We create a normally distributed sample:
data1 := [stats::normalRandom(0, 1)() $ k = 1..100]:

We wish to investigate whether these data can indeed be regarded as normally distributed. We create a reference sample of data that are definitely normally distributed:
n:= nops(data1): data2 := [stats::normalQuantile(0, 1)(i/n) $ i = 1 .. n-1]:

The QQ plot of the data shows plot points close to the reference line $y = x$:

plot(plot::QQplot(data1, data2))



delete data1, n, data2:

Parameters

a_1, a_2, ...

b_1, b_2, ...

The statistical data: numerical real values or arithmetical expressions of the animation parameter `a`.

a_1, a_2, ..., b_1, b_2, ... are equivalent to the attribute Data.

A

An array of domain type DOM_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) providing numerical real values or arithmetical expressions of the animation parameter `a`. The array/matrix must have 2 columns. The first column is regarded as the data set [a_1, a_2, ...] the second column is regarded as the data set [b_1, b_2, ...]. If more columns are provided, the superfluous columns are ignored.

`A` is equivalent to the attribute Data.

s

A data collection of domain type stats::sample. Two columns in s are regarded as the data lists [a_1, a_2, ...] and [b_1, b_2, ...] respectively.

s is equivalent to the attribute Data.

c_1

c_2

Column indices into s: positive integers. These indices, if given, indicate that only the specified columns in s should be used. If no column indices are specified, the first two columns in s are used as the data sets [a_1, a_2, ...] and [b_1, b_2, ...], respectively.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Boxplotplot::Bars2dplot::Bars3dplot::Histogram2dplot::Listplotplot::S

plot::Raster

Purpose

Raster plot

Syntax

```
plot::Raster(A, options)
plot::Raster(A, x = x_min .. x_max, y = y_min .. y_max,
<a = a_min .. a_max>, options)
plot::Raster(L, options)
plot::Raster(L, x = x_min .. x_max, y = y_min .. y_max,
<a = a_min .. a_max>, options)
```

Description

`plot::Raster fenced(A, x = `x_{min}`..`x_{max}`, y = `y_{min}`..`y_{max}`)` translates a matrix *A* of RGB values into a regular 2D mesh of rectangles extending from the lower left corner (x_{min}, y_{min}) to the upper right corner (x_{max}, y_{max}). The rectangles are colored according to the color entries in *A*.

`plot::Raster` serves for generating 2D raster objects such as bitmaps. External bitmap data can be imported to a MuPAD session via import::readbitmap. The resulting array of color values can be passed directly to `plot::Raster` to embed the imported bitmap in a 2D MuPAD scene.

When color values are specified by an array or a matrix *A*, the low indices correspond to the lower left corner of the graphics. The high indices correspond to the upper right corner.

Note Note that the bitmap data of most standard graphical formats are stored in the usual Western reading order: the first pixels correspond to the upper left corner, the last pixels correspond to the lower right corner. The utility import::readbitmap produces an array in which the first element corresponds to the lower left corner. Bitmap data imported this way can be passed directly to `plot::Raster`.

Arrays/matrices do not need to be indexed from 1. E.g.,

```
A = array( `i_{min}` ..  `i_{max}` , `j_{min}` ..
`j_{max}` , [..RGB values..])
```

yields a graphical array with

XMesh = j_{max} - j_{min} + 1, YMesh = i_{max} - i_{min} + 1.

If no plot range `x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}` is specified,

x_{min} = j_{min} - 1, x_{max} = j_{max}, y_{min} = i_{min} - 1, y_{max} = i_{max}

is used.

When color values are specified by a list of lists *L*, the first entries in the list correspond to the lower left corner of the graphics. The last entries correspond to the upper right corner.

If no plot range `x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}` is specified,

x_{min} = 0, x_{max} = m, y_{min} = 0, y_{max} = n

is used, where *n* is the length of *L* and *m* is the (common) length of the sublists in *L*. All sublists ("rows") must have the same length.

Animations are triggered by specifying a range a = amin .. amax for a parameter a that is different from the variables x, y. Thus, in animations, both the ranges x = `x_{min}` .. `x_{max}`, y = `y_{min}` .. `y_{max}` as well as the animation range a = `a_{min}` .. `a_{max}` must be specified.

The related plot routine plot::Density provides a similar functionality offering an automatic color scheme based on scalar density values.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`FALSE`
Color	the main color	RGB::Blue
ColorData	color values of a raster plot	
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`FALSE`
Mesh	number of sample points	`[11, 11]`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

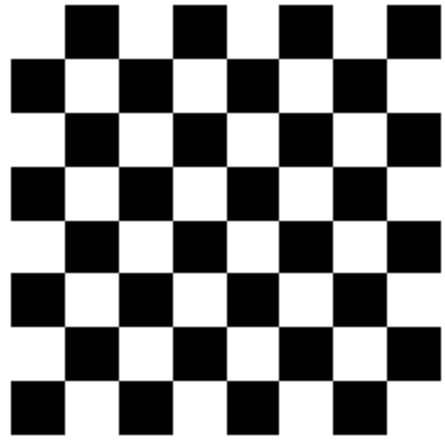
Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter “x”	
XMesh	number of sample points for parameter “x”	11
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YMax	final value of parameter “y”	
YMesh	number of sample points for parameter “y”	11
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

Examples

Example 1

We generate a raster plot:
checkerboard:= array(1..8, 1..8): for i from 1 to 8 do for j from 1 to 8 do if i + j mod 2 = 0 then checkerboard[i,j] := RGB::Black; else checkerboard[i,j] := RGB::White; end_if; end_for: end_for: p := plot::Raster(checkerboard):

The plot object is rendered:
plot(p):



delete checkerboard, p:

Example 2

We import an external bitmap file:
READPATH := READPATH, "DATA":[width, height, colordata] := import::readbitmap("Eva.jpeg"):

The array `colordata` can be passed directly to `plot::Raster`:
scenewidth:= 80*unit::mm: sceneheight:= height/width*scenewidth: plot(plot::Raster(colordata), Width = scenewidth, Height = sceneheight, Footer = "This is Eva"):

This is Eva

delete width, height, colordata, scenewidth, sceneheight:

Example 3

This is Tom:

```
READPATH := READPATH, "DATA":[widthT, heightT, Tom]
:= import::readbitmap("Tom.jpeg", ReturnType=DOM_ARRAY):
plot(plot::Raster(Tom), Width = widthT/3, Height = heightT/3):
```

This is Jerry:

```
[widthJ, heightJ, Jerry] := import::readbitmap("Jerry.jpeg",
ReturnType=DOM_ARRAY): plot(plot::Raster(Jerry), Width = widthT/3,
Height = heightT/3):
```

Although they look different, they are topologically equivalent. We demonstrate this by deforming Tom to Jerry via a smooth map $(1 - a)T + aJ$, $a \in [0, 1]$:

```
blend := (T, J, a) -> zip(T, J, (t,j) -> (1-a)*t + a*j): Tom2Jerry:=
array(1..heightT, 1..widthT): for i from 1 to heightT do for j from 1 to
widthT do Tom2Jerry[i, j]:= blend(Tom[i, j], Jerry[i, j], a): end_for:
end_for:
```

The following call produces an animated plot of the deformation. Note that x and y ranges must be specified for an animation:

```
plot(plot::Raster(Tom2Jerry, x = 1..widthT, y = 1..heightT, a = 0..1,
Frames = 10, Footer = "Tom & Jerry"), Width = widthT/3, Height =
heightT/3):
```

This is the arithmetical mean of Tom and Jerry:
plot(plot::Raster(map(subs(Tom2Jerry, a = 0.5), eval)), Footer = "(Tom + Jerry)/2", FooterFont = [12], Width = widthT/3, Height = heightT/3):

Parameters

A

An array of domain type DOM_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) providing RGB values or color expressions of the animation parameter *a*. Rows/columns of the array, respectively matrix, correspond to rows/columns of the graphical array.

A is equivalent to the attribute ColorData.

L

A list of lists RGB values or color expressions of the animation parameter *a*. Each sublist of *L* represents a row of the graphical array.

L is equivalent to the attribute ColorData.

x

Name of the horizontal variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in *x* direction.

x is equivalent to the attribute XName.

x_{min} .. x_{max}

The range of the horizontal variable: x_{min}, x_{max} must be numerical real value or expressions of the animation parameter *a*.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

y

Name of the vertical variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in *y* direction.

y is equivalent to the attribute YName.

y_{min} .. y_{max}

The range of the vertical variable: y_{min}, y_{max} must be numerical real value or expressions of the animation parameter *a*.

y_{min} .. y_{max} is equivalent to the attributes YRange, YMin, YMax.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

import::readbitmapplotplot::copyplot::Densityplot::Inequality

plot::Rectangle

Purpose

Rectangles in 2D

Syntax

```
plot::Rectangle(x_min .. x_max, y_min .. y_max, <a = a_min .. a_max>, options)
```

Description

`plot::Rectangle( `x_{min}`..`x_{max}` , `y_{min}`..`y_{max}` )` generates the 2D rectangle with the corners (x_{min}, y_{min}), (x_{min}, y_{max}), (x_{max}, y_{min}), (x_{max}, y_{max}).

`plot::Rectangle` creates a 2D rectangle with edges parallel to the coordinate axes.

With Filled = `FALSE`, the rectangle consists only of its edges. With Filled = `TRUE`, it is a filled area.

The lines can be set as desired with LineStyle, LineWidth, and LineColor. Cf. “Example 1” on page 24-657.

With `LinesVisible = FALSE`, the edges are rendered invisible.

For filled rectangles, a FillColor and a FillPattern can be selected. Cf. “Example 2” on page 24-658.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`FALSE`
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	`FALSE`
FillColor	color of areas and surfaces	RGB::Red

Attribute	Purpose	Default Value
FillPattern	type of area filling	`DiagonalLines`
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
LineColorDirection	the direction of color transitions on lines	`[0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`1`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	

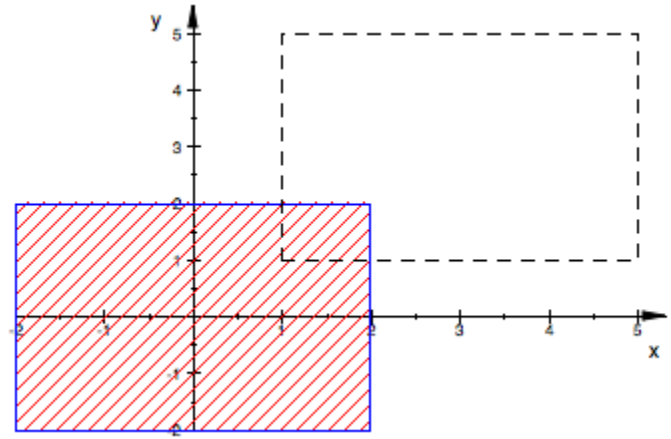
Attribute	Purpose	Default Value
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter “x”	1
XMin	initial value of parameter “x”	-1
XRange	range of parameter “x”	-1 .. 1
YMax	final value of parameter “y”	1
YMin	initial value of parameter “y”	-1
YRange	range of parameter “y”	-1 .. 1

Examples

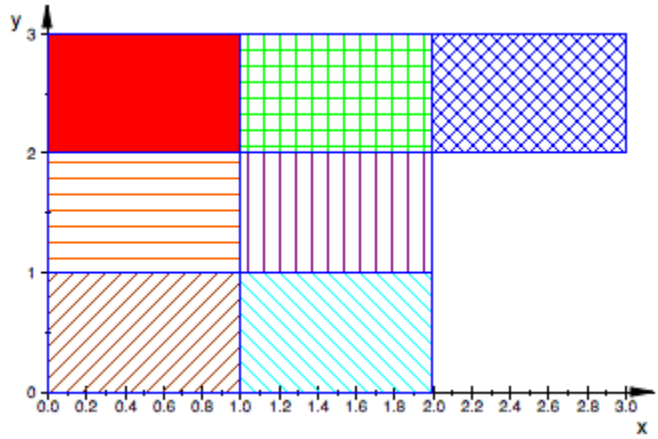
Example 1

We plot two rectangles:
plot(plot::Rectangle(-2..2, -2..2, Filled = TRUE, FillColor = RGB::Red),
plot::Rectangle(1..5, 1..5, Filled = FALSE, LineColor = RGB::Black,
LineStyle = Dashed))



Example 2

We plot rectangles with different fill patterns (FillPattern):
plot(plot::Rectangle(0..1, 2..3, Filled = TRUE, FillPattern = Solid, FillColor = RGB::Red), plot::Rectangle(1..2, 2..3, Filled = TRUE, FillPattern = CrossedLines, FillColor = RGB::Green), plot::Rectangle(2..3, 2..3, Filled = TRUE, FillPattern = XCrossedLines, FillColor = RGB::Blue), plot::Rectangle(0..1, 1..2, Filled = TRUE, FillPattern = HorizontalLines, FillColor = RGB::Orange), plot::Rectangle(1..2, 1..2, Filled = TRUE, FillPattern = VerticalLines, FillColor = RGB::Violet), plot::Rectangle(0..1, 0..1, Filled = TRUE, FillPattern = DiagonalLines, FillColor = RGB::Brown), plot::Rectangle(1..2, 0..1, Filled = TRUE, FillPattern = FDiagonalLines, FillColor = RGB::Cyan))



Parameters

x_{min} .. x_{max}

The left and right border of the rectangle: real numerical values or arithmetical expressions of the animation parameter `a`.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

y_{min} .. y_{max}

The lower and upper border of the rectangle: real numerical values or arithmetical expressions of the animation parameter `a`.

y_{min} .. y_{max} is equivalent to the attributes YRange, YMin, YMax.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Boxplot::Line2dplot::Line3dplot::Polygon2dplot::Polygon3d

plot::Rootlocus

Purpose

Curves of roots of rational expressions

Syntax

```
plot::Rootlocus(p(z, u), u = u_min .. u_max, <a =
a_min .. a_max>, options)
```

Description

`plot::Rootlocus(p(z, u), u = u_min.. u_max)` creates a 2D plot of the curves in the complex plane given by the roots of $p(z, u) = 0$ (solved for z) as the parameter u varies between u_{min} and u_{max}.

For any given value of u, `plot::Rootlocus` solves the equation $p(z, u) = 0$ for z. The solutions define points with coordinates $x = \Re(z)$, $y = \Im(z)$ in the complex plane. As the parameter u varies, the solutions form continuous curves that a depicted by `plot::Rootlocus`.

The roots of the numerator of `p(z, u)` are considered. All complex solutions of this polynomial in z are computed numerically via numeric::polyroots.

The polynomial is initially solved for some values u from the range `u = `u_{min}` .. `u_{max}``. The optional argument Mesh = n can be used to specify the number n of these initial points (the default value is 51). These points are not equally spaced, but accumulate close to the end of the range.

The routine then tries to pair up the roots for adjacent values of u by choosing those closest to each other.

Finally, the routine tries to trace out the different curves by joining up adjacent points with line segments. If adjacent line segments exhibit angles that are not close to 180 degrees, additional roots are computed for parameter values u between the values of the initial mesh. Up to m such bisectioning steps are possible, where m is specified by the optional argument AdaptiveMesh = m (the default value is 4). With AdaptiveMesh = 0, this adaptive mechanism may be switched off.

Sometimes, the matching up of the roots to continuous curves can be fooled and the result is a messy plot. In such a case, the user can take the following measures to improve the plot:

- The parameter range `u = `u_{min}` .. `u_{max}`` may be unreasonably large. Reduce this range to a reasonable size!
- Increase the size n of the initial mesh using the option Mesh = n. Note that increasing n by some factor may increase the runtime of the plot by the same factor!
- Increase the number m of possible adaptive bisectioning steps using the option AdaptiveMesh = m. Note that increasing m by 1 may increase the runtime of the plot by a factor of 2!
- Using the options `LinesVisible = FALSE` in conjunction with `PointsVisible = TRUE`, the roots are displayed as separate points without joining line segments.

Cf. "Example 2" on page 24-667.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter `a` that is different from the variables `z` and `u`. Cf. "Example 3" on page 24-669.

The curves can be colored by a user defined color scheme. Just pass the option LineColorFunction = `mycolor`, where `mycolor` is a user definied procedure that returns an RGB color value. The routine `plot::Rootlocus` calls `mycolor(u, x, y)`, where u is the parameter value and x, y are the real and imaginary parts of the root of $p(x + iy, u) = 0$. Cf. "Example 4" on page 24-670.

Attributes

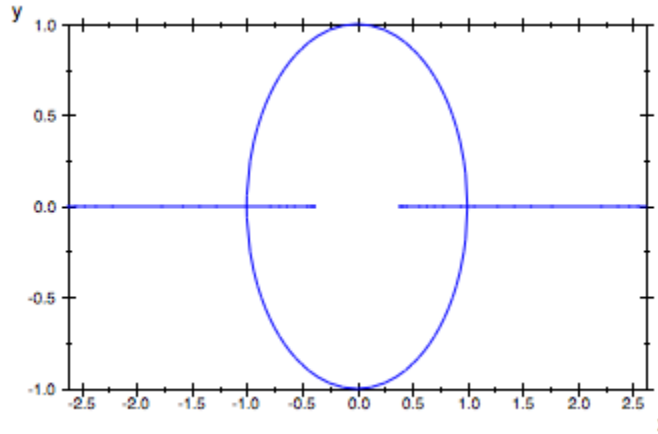
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

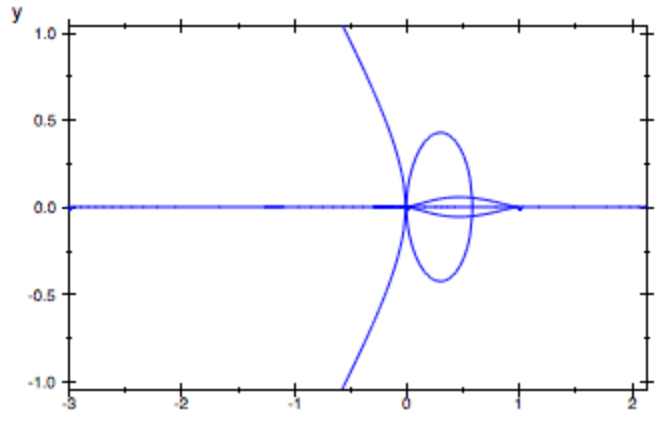
The roots of the polynomial $z^2 - 2uz + 1$ are given by z = u + sqrt(u^2 - 1) $z = u + \sqrt{u^2 - 1}$ and z = u - sqrt(u^2 - 1) $z = u - \sqrt{u^2 - 1}$. We visualise these two curves via a rootlocus plot:

```
plot(plot::Rootlocus(z^2 - 2*u*z + 1, u = -1.5..1.5))
```



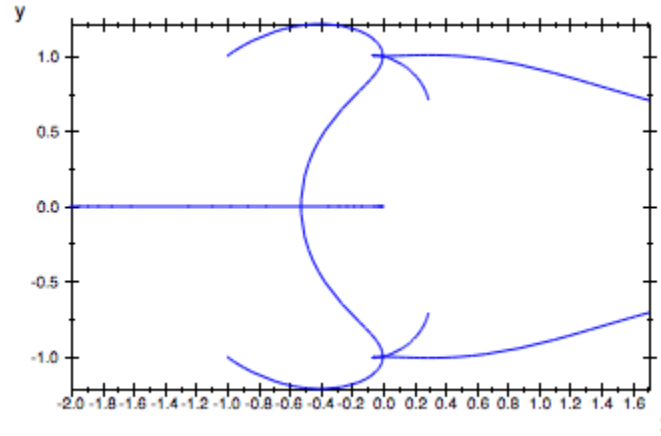
For rational expressions, the roots of the numerator are considered. The following plot displays the roots of the numerator polynomial $(z^2 - u)^2 + u(z - u)^3$:

```
plot(plot::Rootlocus(1 + u * (z - u)^3/(z^2 - u)^2, u = -1..1)):
```

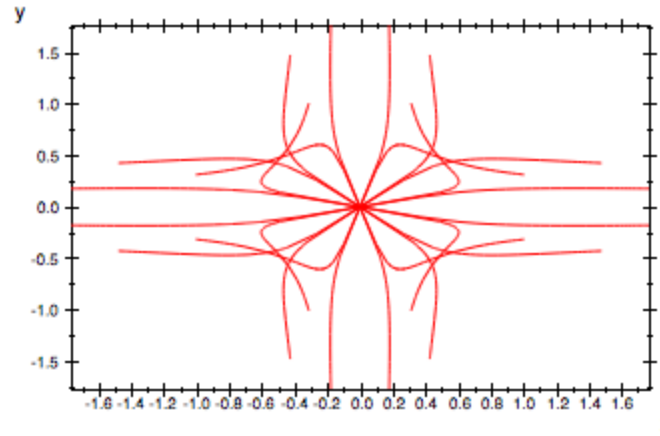


Here are various other examples:

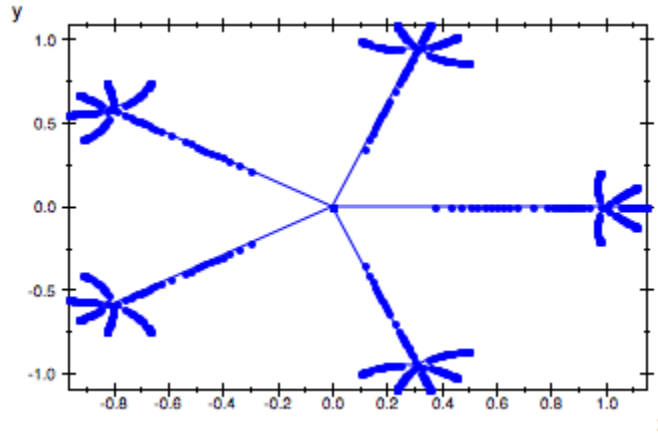
```
plot(plot::Rootlocus((z^2 - 2*u*z + 1)^2 + u, u = -1..1))
```



plot(plot::Rootlocus((z^2 - u)^6 + u^2, u = -2..2, Color = RGB::Red))

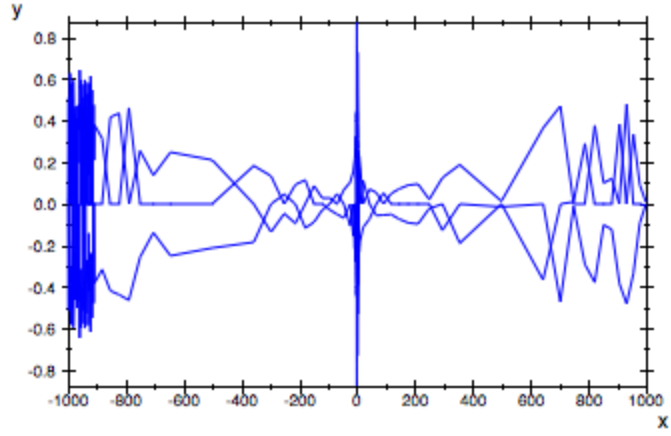


plot(plot::Rootlocus((z^5 - 1)^3 + u, u = -1..1, PointsVisible, PointSize = 1.5))

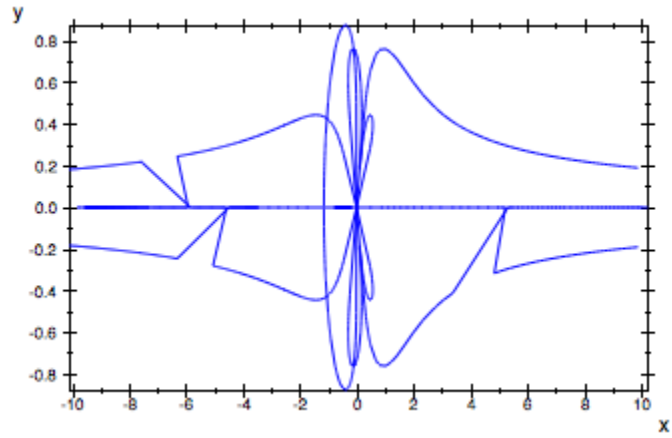


Example 2

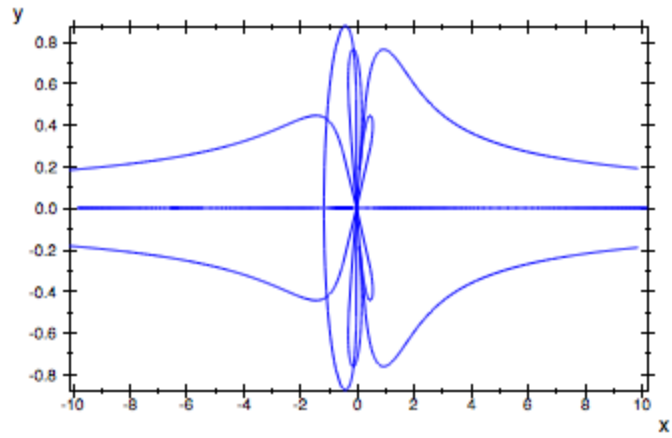
The following plot is rather messy, since the default mesh size of 51 initial points on each curve is not sufficient to obtain a good resolution:
plot(plot::Rootlocus((z-u)^3 - u/z^3, u = -10^3 .. 10^3)):



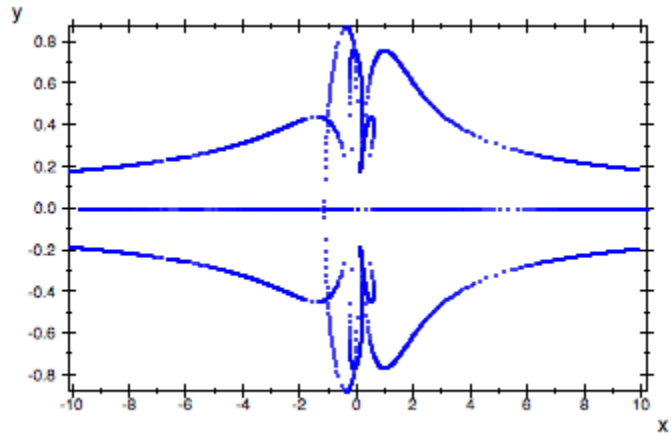
We obtain a better resolution by decreasing the range of the parameter *u* to a reasonable size. There are still a few points that are not properly matched up with the curves:
plot(plot::Rootlocus((z-u)^3 - u/z^3, u = -10 .. 10)):



We increase the mesh size to cure this problem:
plot(plot::Rootlocus((z-u)^3 - u/z^3, u = -10 .. 10, Mesh = 251)):

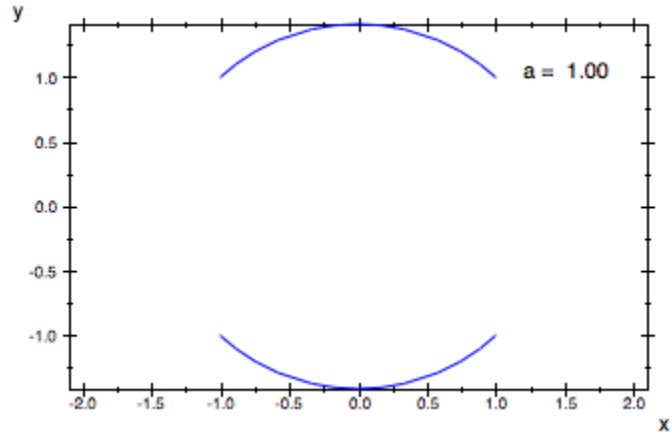


We plot the roots as separate points without displaying connecting line segments:
plot(plot::Rootlocus((z-u)^3 - u/z^3, u = -10 .. 10, Mesh = 501, LinesVisible = FALSE, PointsVisible)):

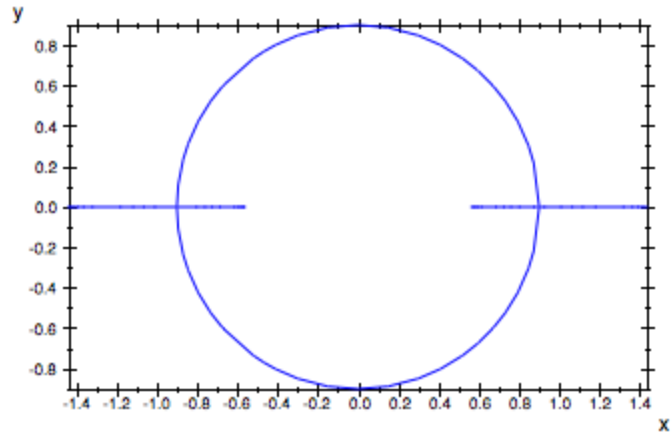


Example 3

We animate the expression whose roots are to plotted:
plot(plot::Rootlocus(z^2 - 2*u*z + a, u = -1..1, a = -0.2 .. 2, Mesh = 10), plot::Text2d(a -> "a = ".stringlib::formatf(a, 2, 5), [1.2, 1.0], a = -0.2 .. 1));



We animate the parameter range:
plot(plot::Rootlocus(z^2 - 2*u*z + 0.81, u = -1 .. a, a = -1 .. 1, Mesh = 10))



Example 4

We provide a color function: roots for small values of the parameter *u* are displayed in red, whereas roots for large parameter values are displayed in blue:

```
plot(plot::Rootlocus(z^2 - 2*u*z + 0.81, u = -1..1, LineColorFunction =
((u, x, y) -> [(1 - u)/2, 0, (1 + u)/2])))
```

Parameters

p(z, u)

An arithmetical expression in two unknowns *z* and *u* and, possibly, the animation parameter `a`. It must be a rational expression in *z*.

`p(z, u)` is equivalent to the attribute RationalExpression.

z

Name of the unknown: an identifier or an indexed identifier.

u

Name of the curve parameter: an identifier or an indexed identifier.

`u` is equivalent to the attribute UName.

u_{min} .. u_{max}

The range of the curve parameter: u_{min}, u_{max} must be numerical real values or expressions of the animation parameter *a*.

u_{min} .. u_{max} is equivalent to the attributes URange, UMin, UMax.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copynumeric::polyrootsplot::Curve2d

plot::Scatterplot

Purpose

Statistical scatter plots

Syntax

```
plot::Scatterplot([x1, x2,  ], [y1, y2,  ], <a =
amin .. amax>, options)
plot::Scatterplot([[x1, x2,  ], [y1, y2,  ]], <a
= amin .. amax>, options)
plot::Scatterplot([x1, y1], [x2, y2],  , <a =
amin .. amax>, options)
plot::Scatterplot([[x1, y1], [x2, y2],  ], <a =
amin .. amax>, options)
plot::Scatterplot(A, <a = amin .. amax>, options)
plot::Scatterplot(s, <c1, c2>, <a = amin .. amax>, options)
```

Description

`plot::Scatterplot` creates a scatter plot of two discrete data samples `[x1, x2,  ]` and `[y1, y2,  ]`. A scatter plot displays the collection of points with coordinates `[x1, y1]`, `[x2, y2]` etc.

In addition, a regression line $y = a + bx$ through the given data pairs `[x1, y1]` etc. is computed and added to the plot. The estimators a, b of the regression are computed by stats::linReg.

The regression line can be suppressed by specifying the attribute LinesVisible = `FALSE`.

The samples $[x_1, x_2, \ldots]$ and $[y_1, y_2, \ldots]$ should have the same number of elements. Otherwise, superflous elements in the longer list are ignored.

There is an ambiguity between the various input formats if only 2 data points are provided:

Note For two data points the calls `plot::Scatterplot([a, b], [c, d])` and `plot::Scatterplot([[a, b], [c, d]])` both yield plots of the two points `(x1, y1) = (a, b)` and `(x2, y2) = (c, d)`, not of the points `(x1, y1) = (a, c)` and `(x2, y2) = (b, d)`!

The routines plot::Listplot and plot::PointList2d have a similar functionality. The main additional feature of `plot::Scatterplot` is the regression line.

Scatter plots are useful to visualize the relationship between two variables x (the "predictor") and y (the "criterion").

The variable regarded as a predictor corresponds to the horizontal axis while the variable regarded as the criterion corresponds to the vertical axis. The criterion variable represents the behavior to be predicted. The predictor variable represents the activity which is believed to be associated with the criterion.

The scatter plot consists of points (x, y) where x is a predictor value and y is the corresponding value of the criterion.

If there is a linear relation $y = a + bx$ between x and y, the data points should form a line, potentially marred by statistical deviations. The regression line provided by the scatter plot allows a visual test of such a relation between x and y.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Data	the (statistical) data to plot	
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	

Attribute	Purpose	Default Value
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Red
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointColor	the color of points	RGB::Black
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	TRUE
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0

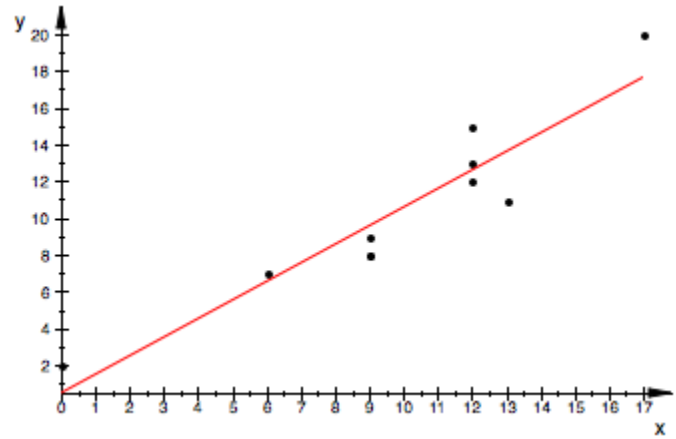
Attribute	Purpose	Default Value
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

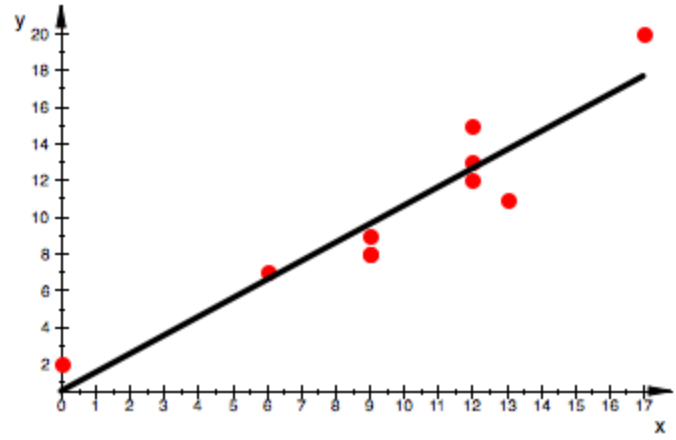
Example 1

We plot some data samples:

xdata := [6, 9, 17, 0, 13, 9, 9, 12, 12, 12]: ydata := [7, 8, 20, 2, 11, 8, 9, 12, 13, 15]: b := plot::Scatterplot(xdata, ydata): plot(b)



We can modify the appearance of the scatter plot in various ways: b::PointColor := RGB::Red: b::PointSize := 3*unit::mm: b::LineColor := RGB::Black: b::LineWidth := 1*unit::mm:plot(b)

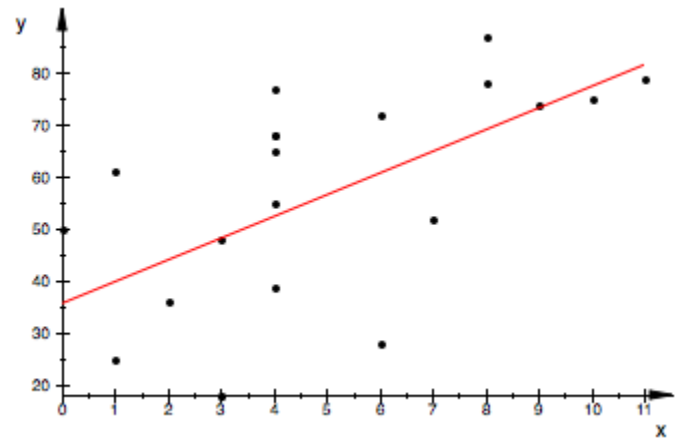


delete xdata, ydata, b:

Example 2

We analyze the relationship between the time students spent on preparing for a test and the result of the test. We collect the data in a matrix. Each row corresponds to a student. The first column describes the numbers of hours spent for the preparation, the second column contains the corresponding test score (points out of 100):
TimesAndScores := matrix([[1, 61], [10, 75], [4, 55], [3, 18], [4, 77], [6, 72], [3, 18], [1, 25], [0, 50], [4, 68], [4, 68], [8, 87], [9, 74], [11, 79], [6, 28], [4, 65], [7, 52], [8, 78], [2, 36], [3, 48], [4, 39]]):

We draw a scatter plot to identify a possible relationship between the two variables:
plot(plot::Scatterplot(TimesAndScores))



There seems to be a relationship, indeed.
delete TimesAndScores:

Parameters

x_1, y_1, x_2, y_2, ...

The statistical data: numerical real values or arithmetical expressions of the animation parameter `a`.

x_1, y_1, x_2, y_2, ... is equivalent to the attribute Data.

A

An array of domain type DOM_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) providing numerical real values or arithmetical expressions of the animation parameter `a`. The i-th row is regarded as the data point (x_i, y_i). The array/matrix must have 2 columns. If more columns are provided, the superfluous columns are ignored.

`A` is equivalent to the attribute Data.

s

A data collection of domain type stats::sample. The columns in `s` are regarded as x- and y-values, respectively.

`s` is equivalent to the attribute Data.

c_1

c_2

Column indices into `s`: positive integers. These indices, if given, indicate that only the specified columns in `s` should be used. If no column indices are specified, the first two columns in `s` are used as x and y-values, respectively.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copystats::linRegstats::correlationplot::Boxplotplot::Bars2dplot::Bars3dplo

plot::Sequence

Purpose

Sequences

Syntax

```
plot::Sequence(y, n = n_1 .. n_2, <a = a_min .. a_max>, options)
plot::Sequence(x, y, n = n_1 .. n_2, <a = a_min ..
a_max>, options)
```

Description

`plot::Sequence(y(n), n = n_1 .. n_2 )` creates the points

fenced(n_1, y(n_1)), fenced(n_1+1, y(n_1+1)), Symbol::hellip, fenced(n_2, y(n_2))

$(n_1, y(n_1)), (n_1 + 1, y(n_1 + 1)), \ldots, (n_2, y(n_2))$

`plot::Sequence(x(n), y(n), n = n_1 .. n_2 )` creates the sequence of points

fenced(x(n_1), y(n_1)), fenced(x(n_1+1), y(n_1+1)), Symbol::hellip, fenced(x(n_2), y(n_2))

$(x(n_1), y(n_1)), (x(n_1 + 1), y(n_1 + 1)), \ldots, (x(n_2), y(n_2))$

`plot::Sequence` creates graphs of sequences, i.e., functions and curves defined over (some subset of) the integers.

`plot::Sequence(y(n), n = n_1..n_2 )` is functionally equivalent to the call `plot::PointList2d([[n, y(n)] $ n = n_1..n_2 )`, and `plot::Sequence(x(n), y(n), n = n_1..n_2 )` creates the same image as `plot::PointList2d([[x(n), y(n)] $ n = n_1..n_2 )`. See “Example 2” on page 24-685 for some extra functionality.

Attributes

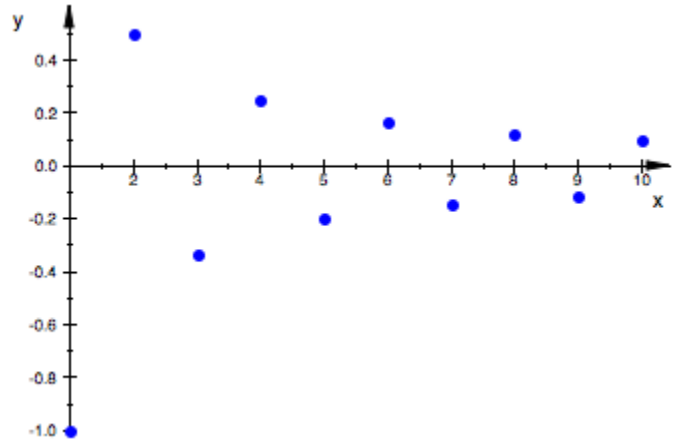
YFunction	function for y values	

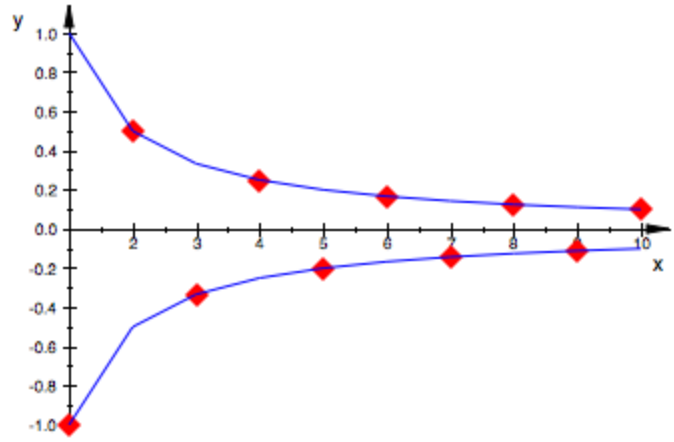
Examples

Example 1

When given one expression and a range, `plot::Sequence` plots the sequence in function style:
plot(plot::Sequence((-1)^n/n, n=1..10))

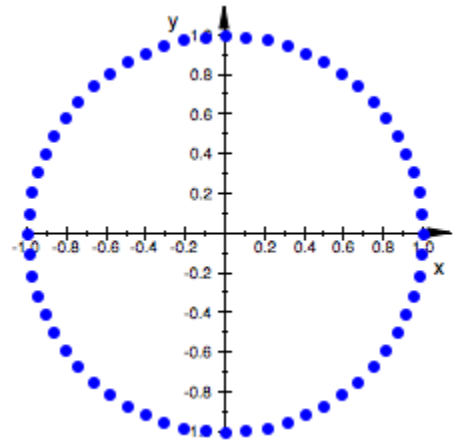


`plot::Sequence` accepts a variety of attributes to influence the appearance of the plot:
plot(plot::Sequence((-1)^n/n, n=1..10, PointStyle = FilledDiamonds, PointSize = 4*unit::mm, Color = RGB::Red), plot::Sequence(1/n, n=1..10, PointsVisible = FALSE, LinesVisible = TRUE), plot::Sequence(-1/n, n=1..10, PointsVisible = FALSE, LinesVisible = TRUE))

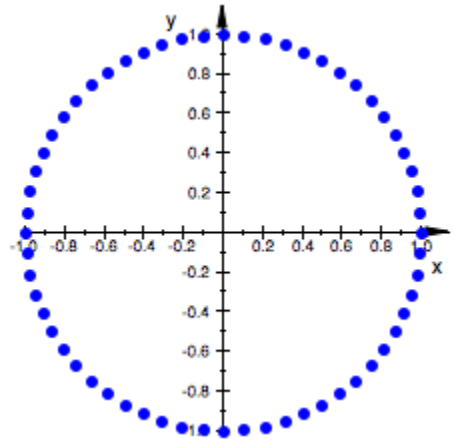


Example 2

By giving two expressions, we can make `plot::Sequence` plot a sequence of points given by two expressions, for the *x*- and *y*-coordinate:
plot(plot::Sequence(sin(2*PI*n/60), cos(2*PI*n/60), n = 1..60), Scaling=Constrained)



In contrast to the plot::PointList2d call listed above as equivalent, `plot::Sequence` allows to easily animate the number of points:
plot(plot::Sequence(sin(2*PI*n/60), cos(2*PI*n/60), n = 1..nmax, nmax = 1..60), Scaling=Constrained, Frames = 60, TimeRange = 1..60)



Example 3

By including the animation parameter in the expressions `x` and `y`, more complex animations are possible. As an example, we animate Newton iteration for different starting values. First of all, we define the iteration step which maps an approximation to its refinement:
newton := x -> x - f(x)/f'(x):

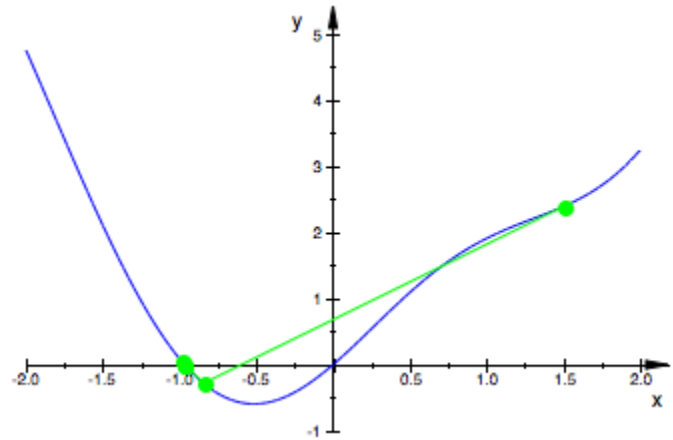
For concrete calculations, we will need to use a specific function `f`:
f := x -> sin(2*x) + x^2:

To get successive iteration steps, we will employ the function iteration operator @@. For example, the third improvement of the starting value `1.0` is calculated as follows:
(newton@@3)(1.0)-1.064963748

```
- 1.064963748
```

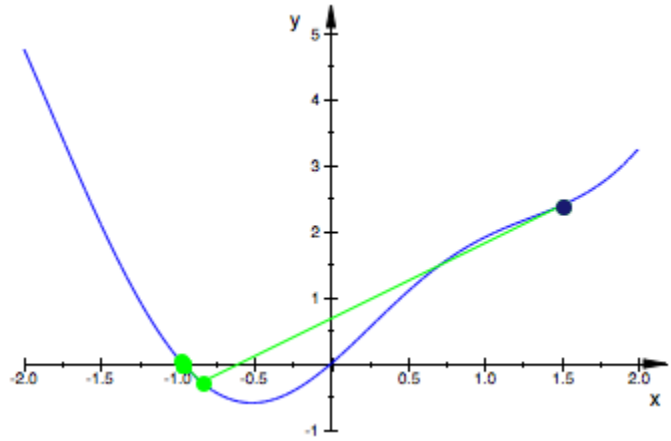
For our animation, we want to show the approximations, the corresponding function values, and the order in which the approximations are found. Additionally, we display the function itself:
function := plot::Function2d(f, x = -2..2): steps := plot::Sequence((newton@@n)(x0), f((newton@@n)(x0)), n = 0..5,

x0 = -1.25..1.5, Color = RGB::Green, LinesVisible = TRUE):
plot(function, steps, ViewingBox = [-2..2, -1..5], PointSize = 2.5)



To further increase the number of iteration steps, we should reuse previously computed approximations. To this end, we use a function with option remember:
newtonIter := proc(x0, n) option remember; begin if domtype(n) <> DOM_INT then return(procname(args())); end_if; if iszero(n) then x0 else newton(newtonIter(x0, n-1)); end_if; end_proc:

Additionally, we use plot::Point2d to display the initial point in a different color.
steps := plot::Sequence(newtonIter(x0, n), f(newtonIter(x0, n)), n = 0..10, x0 = -1.25..1.5, Color = RGB::Green, LinesVisible = TRUE): start := plot::Point2d(x0, f(x0), x0 = -1.25..1.5): plot(function, steps, start, ViewingBox = [-2..2, -1..5], PointSize = 2.5)



Since `f` was evaluated in our object definitions, we will need to reissue the corresponding commands when changing `f`.

Parameters

x

y

Real-valued arithmetical expressions in `n` and possibly the animation parameter `a`.

`x`, `y` are equivalent to the attributes XFunction, YFunction.

n

The index of the sequence: an identifier or an indexed identifier.

`n` is equivalent to the attribute UName.

n_1 .. n_2

The range of the index `n`: real-valued expressions, possibly of the animation parameter `a`.

n_1 .. n_2 is equivalent to the attributes URange, UMin, UMax.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Curve2dplot::Function2dplot::PointList2d

plot::SparseMatrixplot

Purpose

Sparsity pattern of a matrix

Syntax

```
plot::SparseMatrixplot(A, options)
plot::SparseMatrixplot(A, x = x_min .. x_max, y = y_min ..
y_max, <a = a_min .. a_max>, options)
plot::SparseMatrixplot([row_1, row_2,  ], options)
plot::SparseMatrixplot([row_1, row_2,  ], x = x_min .. x_max,
y = y_min .. y_max, <a = a_min .. a_max>, options)
```

Description

`plot::SparseMatrixplot(A)` creates a 2D plot with the axes representing the rows and columns of the matrix *A*. For each nonzero entry of *A* a point is plotted, thus displaying sparsity patterns in the matrix.

`plot::SparseMatrixplot` interprets the indices of a matrix as *x* and *y* coordinates, respectively. The indices are ordered according to the standard orientation of the axes, i.e., low matrix indices are found in the lower left corner of the plot.

If `x = `x_{min}` .. `x_{max}`` is specified, the *j*-th column of an *m n* matrix *A* corresponds to the coordinate

x=(x_min)+fenced(j-1)/fenced(n-1)*fenced((x_max-x_min))

$$x = x_{min} + \frac{(j-1)}{(n-1)} (x_{max} - x_{min})$$

If `y = `y_{min}` .. `y_{max}`` is specified, the *i*-th row corresponds to the coordinate

y=(y_min)+fenced(i-1)/fenced(m-1)*fenced((y_max-y_min))

$$y = y_{min} + \frac{(i-1)}{(m-1)} (y_{max} - y_{min})$$

If no coordinate range is specified, $x_{min} = 1$, $x_{max} = n$, and $y_{min} = 1$, $y_{max} = m$ is used, i.e., the coordinate $x = j$ corresponds to the *j*-th column, the coordinate $y = i$ corresponds to the *i*-th row.

A point is plotted for each non-zero matrix entry A_{ij}.

By default, the attribute PointColorType = `Flat` is used. The color of all points is given by PointColor.

With PointColorType = `Dichromatic`, a color blend from PointColor to PointColor2 is used to indicate the size of the non-zero matrix entries.

The color of points corresponding to small entries A_{ij} is PointColor. Large entries are colored with PointColor2.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter `a` that is different from the variables `x`, `y`. Thus, in animations, both the ranges `x = `x_{min}` .. `x_{max}``, `y = `y_{min}` .. `y_{max}`` as well as the animation range `a = `a_{min}` .. `a_{max}`` must be specified.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Color	the main color	RGB::MidnightBlue

XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	

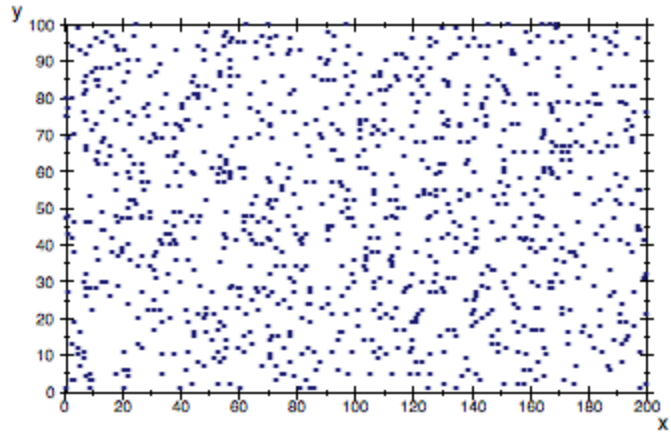
Attribute	Purpose	Default Value
YMax	final value of parameter “y”	
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

Examples

Example 1

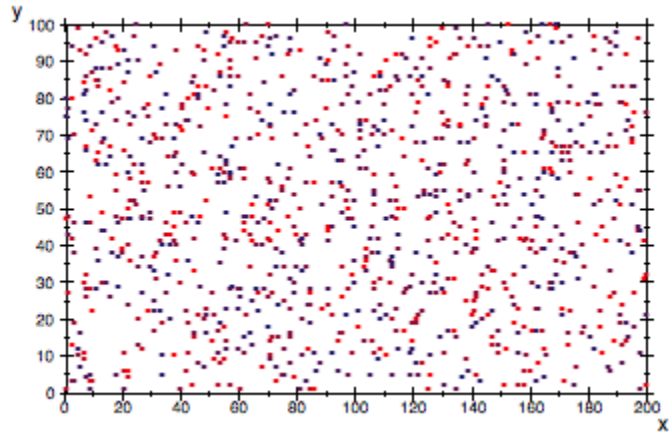
We create a random matrix of dimension 100 200 with 1000 nonzero entries:

```
A := matrix::random(100, 200, 1000, frandom):
plot(plot::SparseMatrixplot(A))
```



With PointColorType = `Dichromatic`, the color of the points indicates the size of the matrix entries:

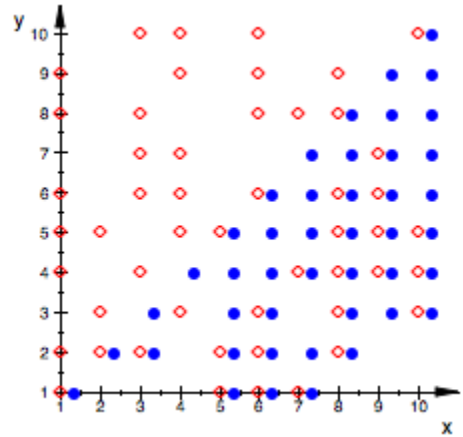
plot(plot::SparseMatrixplot(A, PointColorType = Dichromatic)):



delete A:

Example 2

Choosing appropriate coordinate ranges, we let two sparse matrix plots overlap each other. The red points correspond to a sparse 10 10 matrix with 50 random entries. The blue points indicate the corresponding upper triangular form obtained by Gaussian elimination:
A := matrix::random(10, 10, 50, random(1..5)): B := A::dom::gaussElim(A)[1]: plot(plot::SparseMatrixplot(A, x = 1..10, y = 1..10, Color = RGB::Red), plot::SparseMatrixplot(B, x = 1.3..10.3, y = 1..10, Color = RGB::Blue, PointStyle = FilledCircles), PointSize = 2*unit::mm, Scaling = Constrained, Axes = Frame)



delete A, B:

Parameters

A

A matrix of category Cat::Matrix or an array containing real numerical values or expressions of the animation parameter `a`.

`A` is equivalent to the attribute Data.

row_1, row_2, ...

The matrix rows: each row must be a list of real numerical values or expressions of the animation parameter `a`. All rows must have the same length.

row_1, row_2, ... is equivalent to the attribute Data.

x

Name of the horizontal coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in *x* direction.

`x` is equivalent to the attribute XName.

x_{min} .. x_{max}

The range of the horizontal coordinate: x_{min}, x_{max} must be numerical real value or expressions of the animation parameter *a*.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

y

Name of the vertical coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in *y* direction.

y is equivalent to the attribute YName.

y_{min} .. y_{max}

The range of the vertical coordinate: y_{min}, y_{max} must be numerical real value or expressions of the animation parameter *a*.

y_{min} .. y_{max} is equivalent to the attributes YRange, YMin, YMax.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Densityplot::Matrixplotplot::Raster

plot::Sphere

Purpose

Graphical primitive for spheres

Syntax

`plot::Sphere(r, <[`c_x`, `c_y`, `c_z`]>, <a = `a_{min}` .. `a_{max}`>, options)`

Description

`plot::Sphere(r, c)` creates a sphere of radius `r` and center `c`.

Attributes

Attribute	Purpose	Default Value

Examples

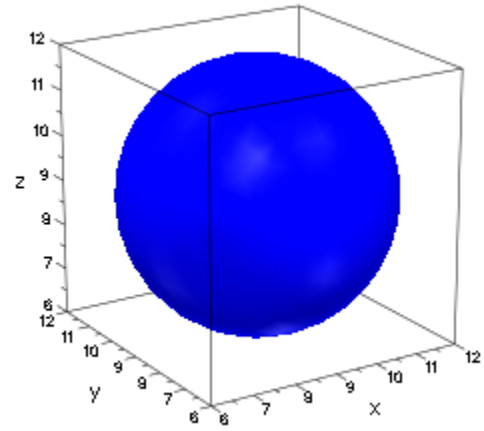
Example 1

We create a blue sphere with center (9, 9, 9) and radius 3:
s := plot::Sphere(3, [9, 9, 9], Color = RGB::Blue)plot::Sphere(3, [9, 9, 9])

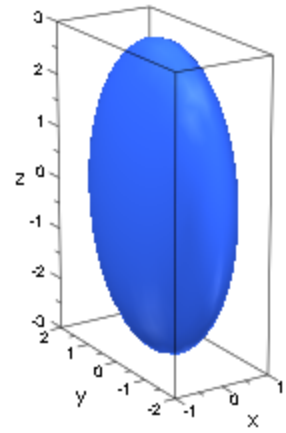
```
plot::Sphere(3, [9, 9, 9])
```

Call plot to plot the sphere:

plot(s)



Here is an ellipsoid around the origin with semi axes of lengths 1, 2, 3:
plot(plot::Ellipsoid(1, 2, 3, [0, 0, 0]))



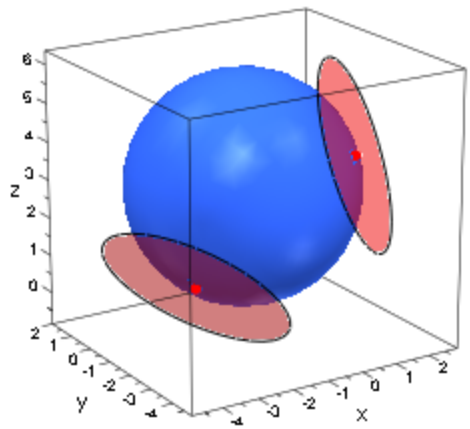
delete s:

Example 2

We create a sphere with center (- 1, - 1, 5) and radius 3. At two points on the sphere, we wish to add 3D discs indicating the tangent planes.
c := [-1, -1, 3]: s := plot::Sphere(3, c): p1 := [1, -3, 4]: p2 := [-3, -2, 1]:

The discs are created via plot::Circle3d as filled 3D circles of radius 2.5, centered at the points p_1 and p_2, respectively. The normals n_i are given by p_i - c. We compute them by subracting the center c from the points p_i via zip:
n1 := zip(p1, c, _subtract): n2 := zip(p2, c, _subtract): t1 := plot::Circle3d(2.5, p1, n1, Filled = TRUE, LineColor = RGB::Black, FillColor = RGB::Red.[0.5]): t2 := plot::Circle3d(2.5, p2, n2, Filled = TRUE, LineColor = RGB::Black, FillColor = RGB::Red.[0.5]):

Finally, we convert the points p_i to graphical points and add them to the plot:
p1 := plot::Point3d(p1, PointColor = RGB::Red, PointSize = 2*unit::mm):
p2 := plot::Point3d(p2, PointColor = RGB::Red, PointSize = 2*unit::mm):
plot(s, p1, p2, t1, t2)



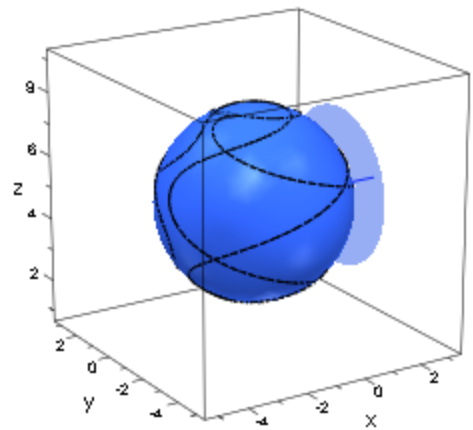
delete c, s, p1, p2, n1, n2, t1, t2:

Example 3

We consider the same sphere as in the previous example:
radius := 3: center := [-1, -1, 5]: s := plot::Sphere(radius, center):

Using spherical coordinates, we define a curve on the sphere:
phi := a -> PI*sin(7*a): thet := a -> PI/2 + 1.3*sin(5*a): x := a -> center[1] + radius*cos(phi(a))*sin(thet(a)): y := a -> center[2] + radius*sin(phi(a))*sin(thet(a)): z := a -> center[3] + radius*cos(thet(a)):

The curve *c* is defined as an object of type plot::Curve3d. Further, we define an animated point *p* that will run along the curve. An animated filled disc of type plot::Circle3d indicating the tangent plane at the point *p* as well as the corresponding normal are added to the plot:
c := plot::Curve3d([x(t), y(t), z(t)], t = 0..2*PI, Mesh = 1000, Color = RGB::Black): p := a -> [x(a), y(a), z(a)]: n := a -> zip([x(a), y(a), z(a)], center, _subtract): d := plot::Circle3d(2.5, p(a), n(a), a = 0..2*PI, Filled = TRUE, FillColor = RGB::BlueLight.[0.5], LinesVisible = FALSE): n := plot::Arrow3d(p(a), [p(a)[i] + n(a)[i]/2 $ i=1..3], a = 0..2*PI, TipLength = 0.8*unit::mm): p := plot::Point3d(p(a), a = 0..2*PI, PointColor = RGB::Black, PointSize = 2*unit::mm):plot(s, c, p, n, d, Frames = 200, TimeEnd = 50):



delete radius, center, s, phi, thet, x, y, z, c, p, n, d:

Parameters

r

The radius of the sphere: a real numerical value or an arithmetical expression of the animation parameter a.

r is equivalent to the attribute Radius.

c_x

c_y

c_z

The coordinates of the center: real numerical values or arithmetical expressions of the animation parameter a. If no center is specified, a sphere/ellipsoid centered at the orign is created.

c_x, c_y, c_z are equivalent to the attributes Center, CenterX, CenterY, CenterZ.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Ellipsoidplot::Circle3dplot::Surface

plot::Ellipsoid

Purpose

Graphical primitive for ellipsoids

Syntax

```
plot::Ellipsoid(r_x, r_y, r_z, <[c_x, c_y, c_z]>, <a = a_min .. a_max>, options)
```

Description

`plot::Ellipsoid(`r_x`, `r_y`, `r_z`, c)` creates an ellipsoid with the center `c` and symmetry axes parallel to the coordinate axes. The semi axes have the lengths r_x, r_y, r_z.

Ellipsoids with arbitrary orientations of the symmetry axes can be generated via plot::Rotate3d.

Attributes

VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

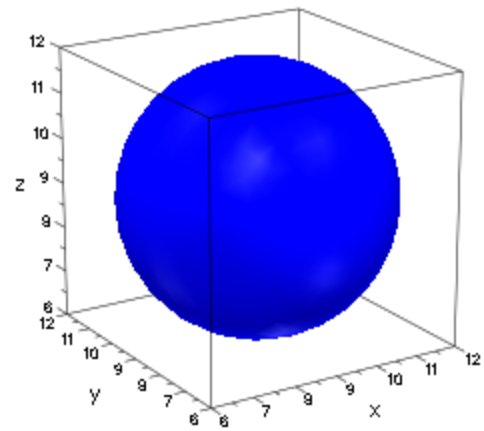
Examples

Example 1

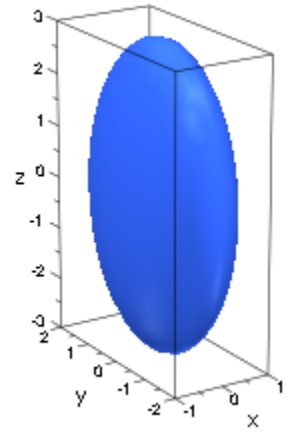
We create a blue sphere with center (9, 9, 9) and radius 3:
s := plot::Sphere(3, [9, 9, 9], Color = RGB::Blue)plot::Sphere(3, [9, 9, 9])

plot::Sphere(3, [9, 9, 9])

Call plot to plot the sphere:
plot(s)



Here is an ellipsoid around the origin with semi axes of lengths 1, 2, 3:
plot(plot::Ellipsoid(1, 2, 3, [0, 0, 0]))



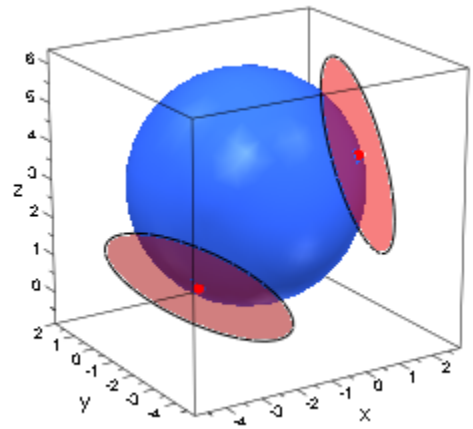
delete s:

Example 2

We create a sphere with center (- 1, - 1, 5) and radius 3. At two points on the sphere, we wish to add 3D discs indicating the tangent planes.
c := [-1, -1, 3]: s := plot::Sphere(3, c): p1 := [1, -3, 4]: p2 := [-3, -2, 1]:

The discs are created via plot::Circle3d as filled 3D circles of radius 2.5, centered at the points p_1 and p_2, respectively. The normals n_i are given by p_i - c. We compute them by subracting the center c from the points p_i via zip:
n1 := zip(p1, c, _subtract): n2 := zip(p2, c, _subtract): t1 := plot::Circle3d(2.5, p1, n1, Filled = TRUE, LineColor = RGB::Black, FillColor = RGB::Red.[0.5]): t2 := plot::Circle3d(2.5, p2, n2, Filled = TRUE, LineColor = RGB::Black, FillColor = RGB::Red.[0.5]):

Finally, we convert the points p_i to graphical points and add them to the plot:
p1 := plot::Point3d(p1, PointColor = RGB::Red, PointSize = 2*unit::mm):
p2 := plot::Point3d(p2, PointColor = RGB::Red, PointSize = 2*unit::mm):
plot(s, p1, p2, t1, t2)



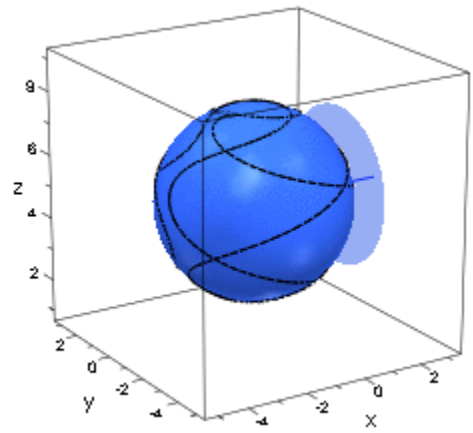
delete c, s, p1, p2, n1, n2, t1, t2:

Example 3

We consider the same sphere as in the previous example:
radius := 3: center := [-1, -1, 5]: s := plot::Sphere(radius, center):

Using spherical coordinates, we define a curve on the sphere:
phi := a -> PI*sin(7*a): thet := a -> PI/2 + 1.3*sin(5*a): x := a -> center[1] + radius*cos(phi(a))*sin(thet(a)): y := a -> center[2] + radius*sin(phi(a))*sin(thet(a)): z := a -> center[3] + radius*cos(thet(a)):

The curve *c* is defined as an object of type plot::Curve3d. Further, we define an animated point *p* that will run along the curve. An animated filled disc of type plot::Circle3d indicating the tangent plane at the point *p* as well as the corresponding normal are added to the plot:
c := plot::Curve3d([x(t), y(t), z(t)], t = 0..2*PI, Mesh = 1000, Color = RGB::Black): p := a -> [x(a), y(a), z(a)]: n := a -> zip([x(a), y(a), z(a)], center, _subtract): d := plot::Circle3d(2.5, p(a), n(a), a = 0..2*PI, Filled = TRUE, FillColor = RGB::BlueLight.[0.5], LinesVisible = FALSE): n := plot::Arrow3d(p(a), [p(a)[i] + n(a)[i]/2 $ i=1..3], a = 0..2*PI, TipLength = 0.8*unit::mm): p := plot::Point3d(p(a), a = 0..2*PI, PointColor = RGB::Black, PointSize = 2*unit::mm):plot(s, c, p, n, d, Frames = 200, TimeEnd = 50):



delete radius, center, s, phi, thet, x, y, z, c, p, n, d:

Parameters

r_x

r_y

r_z

The length of the semi axes of the ellipsoid: real numerical values or arithmetical expressions of the animation parameter `a`.

r_x, r_y, r_z are equivalent to the attributes SemiAxes, SemiAxisX, SemiAxisY, SemiAxisZ.

c_x

c_y

c_z

The coordinates of the center: real numerical values or arithmetical expressions of the animation parameter `a`. If no center is specified, a sphere/ellipsoid centered at the orign is created.

c_x, c_y, c_z are equivalent to the attributes Center, CenterX, CenterY, CenterZ.

a

Animation parameter, specified as `a = a_min..a_max`, where `a_min` is the initial parameter value, and `a_max` is the final parameter value.

plotplot::copyplot::Sphereplot::Circle3dplot::Surface

plot::Spherical

Purpose

Surfaces in 3D parameterized in spherical coordinates

Syntax

`plot::Spherical([r, , Ł], u = u_min .. u_max, v = v_min .. v_max, <a = a_min .. a_max>, options)`

Description

`plot::Spherical` creates surfaces parametrized in spherical coordinates.

The surface given by a mapping ("parametrization") (u, v) -> fenced(r(u, v), Symbol::phi(u, v), Symbol::theta(u, v))$(u, v) \to (r(u, v), \phi(u, v), \theta(u, v))$ is the set of all image points

ImageSet(matrix([r(u,v), Symbol::phi(u,v), Symbol::theta(u,v)]), u in [u_min, u_max], v in [v_min, v_max])

$$\left\{ \begin{pmatrix} r(u, v) \\ \phi(u, v) \\ \theta(u, v) \end{pmatrix} \;\middle|\; u \in [u_{min}, u_{max}],\ v \in [v_{min}, v_{max}] \right\}$$

in spherical coordinates, which translate to the usual "Cartesian" coordinates as

eqsys(x = r * cos(Symbol::phi) * sin(Symbol::theta), y = r * sin(Symbol::phi) * sin(Symbol::theta), z = r * cos(Symbol::theta))

$$x = r \cos(\phi) \sin(\theta)$$

$$y = r \sin(\phi) \sin(\theta)$$

$$z = r \cos(\theta)$$

r is referred to as "radius", φ as "azimuthal angle", and θ is known as "polar angle."

The functions r, φ, θ are evaluated on a regular equidistant mesh of sample points in the u-v plane. This mesh is determined by the

attributes UMesh, VMesh. By default, the attribute `AdaptiveMesh = 0` is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of UMesh, VMesh or USubmesh, VSubmesh, or set `AdaptiveMesh = n` with some (small) positive integer `n`. If necessary, up to 2^n - 1 additional points are placed in each direction of the u-v plane between adjacent points of the initial equidistant mesh. Cf. "Example 3" on page 24-722.

"Coordinate lines" ("parameter lines") are curves on the surface.

The phrase "`ULines`" refers to the curves $(r(u, v_0), \varphi(u, v_0), \theta(u, v_0))$ with the parameter u running from u_{min} to u_{max}, while v_0 is some fixed value from the interval $[v_{min}, v_{max}]$.

The phrase "`VLines`" refers to the curves $(r(u_0, v), \varphi(u_0, v), \theta(u_0, v))$ with the parameter v running from v_{min} to v_{max}, while u_0 is some fixed value from the interval $[u_{min}, u_{max}]$.

By default, the parameter curves are visible. They may be switched off by specifying `ULinesVisible = FALSE` and `VLinesVisible = FALSE`, respectively.

The coordinate lines controlled by `ULinesVisible = TRUE/FALSE` and `VLinesVisible = TRUE/FALSE` indicate the equidistant mesh in the u-v plane set via the UMesh, VMesh attributes. If the mesh is refined by the USubmesh, VSubmesh attributes, or by the adaptive mechanism controlled by `AdaptiveMesh = n`, no additional parameter lines are drawn.

As far as the numerical approximation of the surface is concerned, the settings

`UMesh =` n_u, `VMesh =` n_v, `USubmesh =` m_u, `VSubmesh =` m_v

and

`UMesh =` $(n_u - 1)\ (m_u + 1) + 1$, `VMesh =` $(n_v - 1)\ (m_v + 1) + 1$,

`USubmesh = 0`, `VSubmesh = 0`

are equivalent. However, in the first setting, `nu` parameter lines are visible in the *u* direction, while in the latter setting `(nu - 1)*(mu + 1) + 1` parameter lines are visible. Cf. "Example 3" on page 24-722.

Use Filled = `FALSE` to obtain a wireframe representation of the surface.

If the expression/function *r* contains singularities, it is recommended (but not strictly necessary) to use the attribute ViewingBox to set a suitable viewing box. No such precautions are necessary for φ and θ, although singularities in these functions may result in poorly rendered surfaces – in many cases setting the attributes Mesh and/or AdaptiveMesh to higher values will help. Cf. "Example 6" on page 24-726.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	`0`
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`
FillColorFunction	functional area/surface coloring	

Attribute	Purpose	Default Value
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat

Attribute	Purpose	Default Value
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	[25, 25]
MeshVisible	visibility of irregular mesh lines in 3D	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5

Attribute	Purpose	Default Value
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`FALSE`
Submesh	density of submesh (additional sample points)	`[0, 0]`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
ULinesVisible	visibility of parameter lines (u lines)	`TRUE`

Attribute	Purpose	Default Value
UMax	final value of parameter “u”	
UMesh	number of sample points for parameter “u”	25
UMin	initial value of parameter “u”	
UName	name of parameter “u”	
URange	range of parameter “u”	
USubmesh	density of additional sample points for parameter “u”	0
VLinesVisible	visibility of parameter lines (v lines)	TRUE
VMax	final value of parameter “v”	
VMesh	number of sample points for parameter “v”	25
VMin	initial value of parameter “v”	
VName	name of parameter “v”	
VRange	range of parameter “v”	

Attribute	Purpose	Default Value
VSubmesh	density of additional sample points for parameter “v”	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

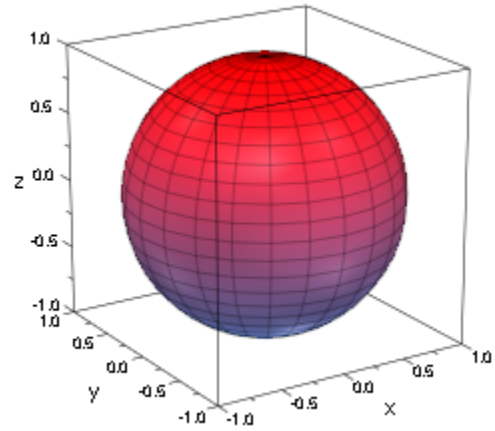
XFunction	function for x values	
YContours	contour lines at constant y values	[]
YFunction	function for y values	
ZContours	contour lines at constant z values	[]
ZFunction	function for z values	

Examples

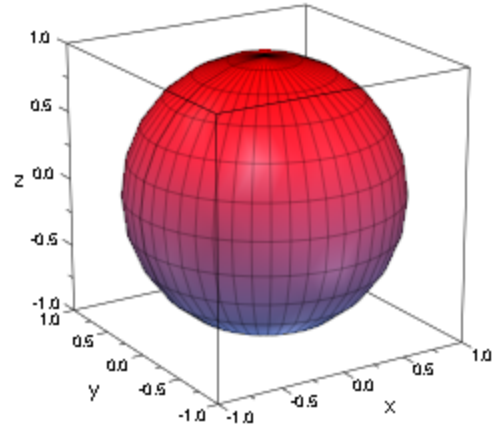
Example 1

Spherical coordinates get their name from the fact that, with a constant radius, the parameterize a sphere:

plot(plot::Spherical([1, u, v], u = 0..2*PI, v = 0..PI))



plot(plot::Spherical([1, u, v], u = 0..PI, v = 0..2*PI))



Example 2

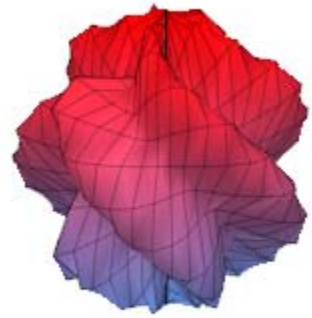
The following plot demonstrates that spherical plots can exhibit singular surface features even with differentiable parameterizations;

in this case, the rim in the middle is actually a border of both the left- and the right-hand part:
plot(plot::Spherical([(phi^2*thet), phi, thet^2], phi = -PI..PI, thet=0..0.25*PI, Mesh = [40,40], Submesh=[3,0], Color = [0.9$3], FillColorType=Flat, LineColor=[0.8$3]), Axes = None, CameraDirection = [1, 0, 0])

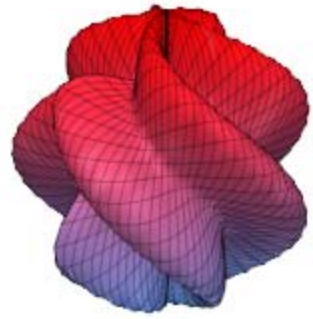
Example 3

For oscillating parameterizations or other surfaces with fine details, the default mesh may be too coarse. As stated above, the three attributes Mesh, Submesh, and AdaptiveMesh can be used for improving plots of these objects.

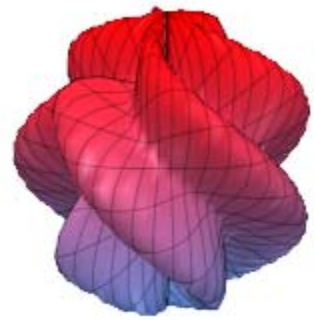
First, note that the following plot is not rendered with a sufficient resolution:
surf := plot::Spherical([4+sin(5*(u+v)), u, v], u = 0..PI, v = 0..2*PI):
plot(surf, Axes = None)



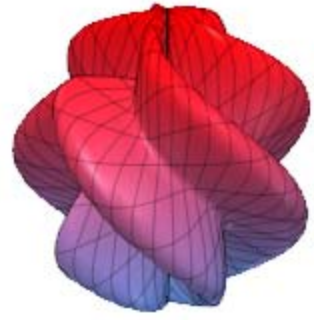
Setting `Mesh` to twice its default, we get a smoother surface with additional parameter lines:
surf::Mesh := [50, 50]: plot(surf, Axes = None)



Almost the same effect, but without the additional parameter lines, can be achieved by setting `Submesh = [1, 1]`:
delete surf::Mesh: surf::Submesh := [1, 1]: plot(surf, Axes = None)

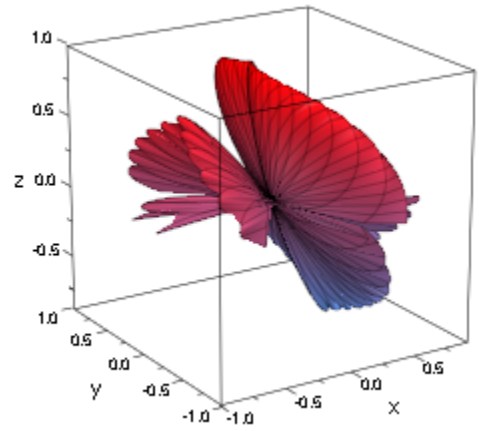


It is also possible to use adaptive mesh refinement in areas where neighboring patches have an angle of more than 10 degrees. While this option is mostly useful for surfaces which require refinement only in some parts, it is certainly feasible with a plot like this, too (but increasing `Submesh` is faster):
delete surf::Submesh: surf::AdaptiveMesh := 2: plot(surf, Axes = None)



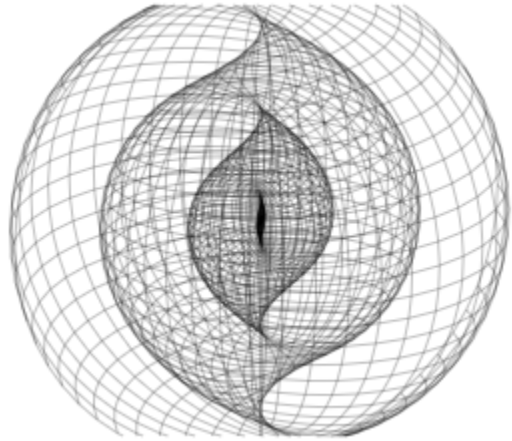
Example 4

The radius function r may also take on negative values. With radius functions of changing sign, spherical surfaces often do self-intersect:
plot(plot::Spherical([sin(phi^2*thet), phi, thet], phi = -PI..PI, thet = 0..0.5*PI, Mesh = [40, 20], Submesh=[0, 3]))



Example 5

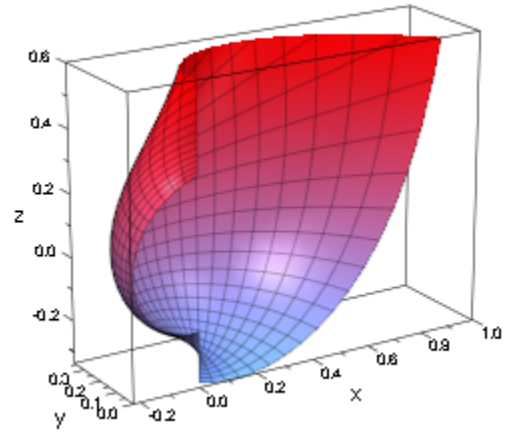
The angular functions (φ and θ) are not limited in value:
plot(plot::Spherical([r, r, thet], r = 0..9, thet = -PI..PI, Mesh = [60, 60], Filled = FALSE), Axes = None, plot::Camera([100, 100, 50], [0,0,0], 0.1))



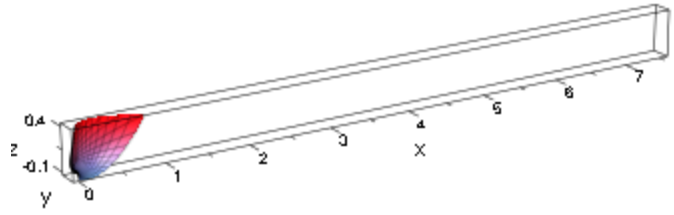
Note that we used an explicit plot::Camera object here because the automatic camera is always placed such that all of an object is visible, even when using CameraDirection. To get a “closer” look, use the interactive manipulation possibilities or an explicit camera.

Example 6

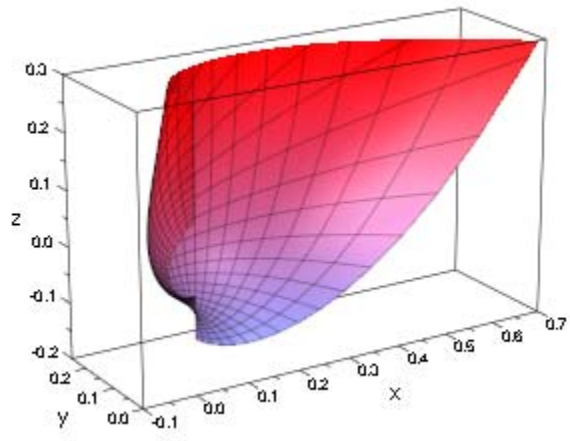
Singularities in the radius function are heuristically handled:
plot(plot::Spherical([1/(u + v), u, v], u = 0..PI, v = 0..PI))



However, the heuristics fails for some examples:
plot(plot::Spherical([1/(u + v)^2, u, v], u = 0..PI, v = 0..PI))



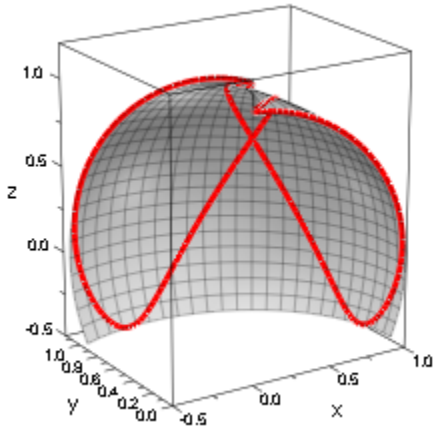
In cases like this, we recommend setting a viewing box explicitly with the attribute ViewingBox:
plot(plot::Spherical([1/(u + v)^2, u, v], u = 0..PI, v = 0..PI), ViewingBox = [-1/10..0.7, 0..1/4, -0.2..0.3])



Example 7

By setting one of the parameter ranges to a degenerate interval, it is possible to draw curves on a spherical surface:

```
f := (u, v) -> [1 + u/10, u, v]: surface := plot::Spherical(f(u,v), u =
0..2, v = 0..2, FillColor = RGB::Grey, FillColorType = Flat): curve :=
plot::Spherical(f((1 + sin(u)), (1 + sin(2*u))), u = 0..2*PI, v = 0..0, Mesh =
[200, 1], LineColor = RGB::Red, LineWidth = 1): plot(surface, curve)
```



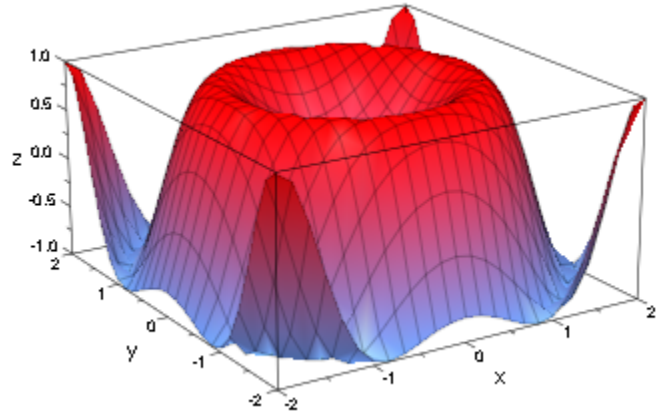
Example 8

While the transformation from spherical to Cartesian coordinates is not invertible, there are at least two ways of expressing each Cartesian point in spherical coordinates and any surface parameterizable in Cartesian coordinates can also be plotted using `plot::Spherical` (although this is probably more a curiosity than really useful):

```
trans := linalg::ogCoordTab[Spherical, InverseTransformation]: spher := trans(x, y, sin(x^2+y^2))[sqrt(x^2 + y^2 + sin(x^2 + y^2)^2), arccos(x/sqrt(x^2 + y^2)) + sign(y)*(sign(y) - 1)*(PI - arccos(x/sqrt(x^2 + y^2))), arccos(sin(x^2 + y^2)/sqrt(x^2 + y^2 + sin(x^2 + y^2)^2))]
```

```
plot(plot::Spherical(spher, x = -2..2, y = -2..2))
```

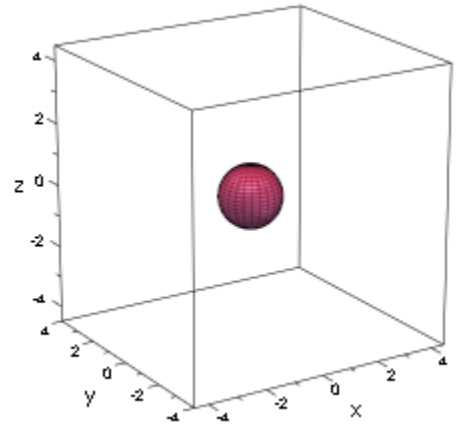
$$\left[\sqrt{x^2+y^2+\sin\left(x^2+y^2\right)^2},\ \arccos\left(\frac{x}{\sqrt{x^2+y^2}}\right)+\operatorname{sign}(y)\,(\operatorname{sign}(y)-1)\left(\pi-\arccos\left(\frac{x}{\sqrt{x^2+y^2}}\right)\right),\ \arccos\right.$$



Example 9

Last but not least we can also produce animations with the help of `plot::Spherical`. The following shows a deformation from a general spherical object to a sphere. We have used the animation parameter `a` inside of the argument for the sine function to obtain a slight rotation during the deformation process:

```
plot( plot::Spherical( [1+a*sin(3*Phi+a)*sin(2*Theta),Phi,Theta],
Theta=0..PI, Phi=0..2*PI, a=5..0 ) )
```



Parameters

r

•

The coordinate functions: arithmetical expressions or piecewise objects depending on the surface parameters *u*, *v* and the animation parameter a. Alternatively, procedures that accept 2 input parameters *u*, *v* or 3 input parameters *u*, *v*, *a* and return a real numerical value when the input parameters are numerical.

r, , Ł are equivalent to the attributes XFunction, YFunction, ZFunction.

u

The first surface parameter: an identifier or an indexed identifier.

u is equivalent to the attribute UName.

u_{min} .. u_{max}

The plot range for the parameter *u*: u_{min}, u_{max} must be numerical real values or expressions of the animation parameter *a*.

u_{min} .. u_{max} is equivalent to the attributes URange, UMin, UMax.

v

The second surface parameter: an identifier or an indexed identifier.

v is equivalent to the attribute VName.

v_{min} .. v_{max}

The plot range for the parameter *v*: v_{min}, v_{max} must be numerical real values or expressions of the animation parameter *a*.

v_{min} .. v_{max} is equivalent to the attributes VRange, VMin, VMax.

a

Animation parameter, specified as a = a_{min}..a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

linalg::ogCoordTabplotplot::copyplot::Cylindricalplot::Polarplot::Surface

plot::Streamlines2d

Purpose

Streamlines of vector fields

Syntax

```
plot::Streamlines2d([v1, v2], x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
plot::Streamlines2d(v1, v2, x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
plot::Streamlines2d(V, x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
```

Description

`plot::Streamlines2d( [v1, v2] , x = `x_{min}`..`x_{max}` , y = `y_{min}`..`y_{max}` )` creates streamlines of the vector field defined by (x, y) -> fenced(v[1](x, y), v[2](x, y)) $(x, y) \to (v_1(x, y), v_2(x, y))$ with (x, y) $[x_{min}, x_{max}]$ $[y_{min}, y_{max}]$.

A vector field is defined by a function funcDecl(f, R_^2, R_^2) $f: \mathbb{R}^2 \to \mathbb{R}^2$. `plot::Streamlines2d` displays a vector field by drawing almost evenly spaced streamlines of the vector field, i.e., curves to which the vector field is tangential at every point. The density of stream lines (and the time needed for calculation) is controlled with the attribute MinimumDistance.

As a rule of thumb: decreasing the value of `MinimumDistance` by a factor of 2 leads to an increase of the runtime by a factor of 4.

A user defined color scheme may be specified by `LineColorFunction = color`, where `color` is a MuPAD procedure accepting 6 input parameters and returning a list of RGB values. During plotting, this function is called in the form `color(x, y, v1, v2, t, l, n)`:

The values `x`, `y` are the coordinates of the current point.

The values `v1`, `v2` are the components of the vector field at the current point.

The value `t` is the "time" of the current point `(x, y)` on the current streamline. The scaling of this parameter depends on the vector field.

The value `l` is the curve length of the current streamline from its starting point the current point `(x, y)`, as a Euclidean distance. This

parameter is invariant with respect to scalar changes of the vector field (up to changing the direction of the streamline).

The integer value `n` is a count of the current streamline. Each separate streamline has a different value.

Cf. "Example 3" on page 24-740.

Attributes

Attribute	Purpose	Default Value
AbsoluteError	maximal absolute discretization error	
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Black
LineWidth	width of lines	`0.35*unit::mm`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LineColorType	line coloring types	`Flat`

Attribute	Purpose	Default Value
LineColorFunction	functional line coloring	
MinimumDistance	space between stream lines	
Name	the name of a plot object (for browser and legend)	
ODEMethod	the numerical scheme used for solving the ODE	`ABM4`
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
RelativeError	maximal relative discretization error	`1/100000`
Stepsize	set a constant step size	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`

Attribute	Purpose	Default Value
TipAngle	opening angle of arrow heads	`(2*PI)/15`
TipStyle	presentation style of arrow heads	`Filled`
TipLength	length of arrow heads	`0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`

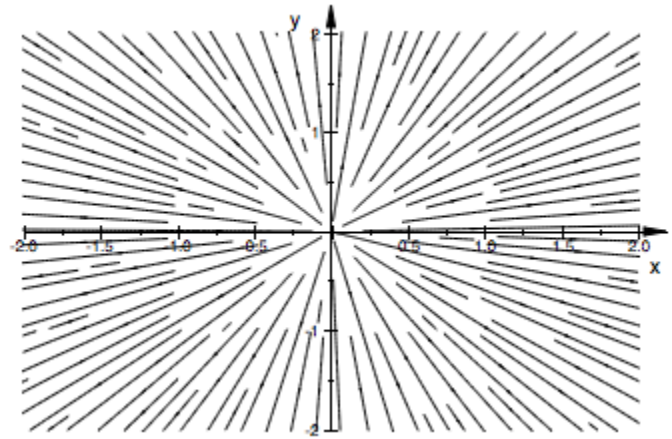
Attribute	Purpose	Default Value
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YFunction	function for y values	
YMax	final value of parameter “y”	
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

Examples

Example 1

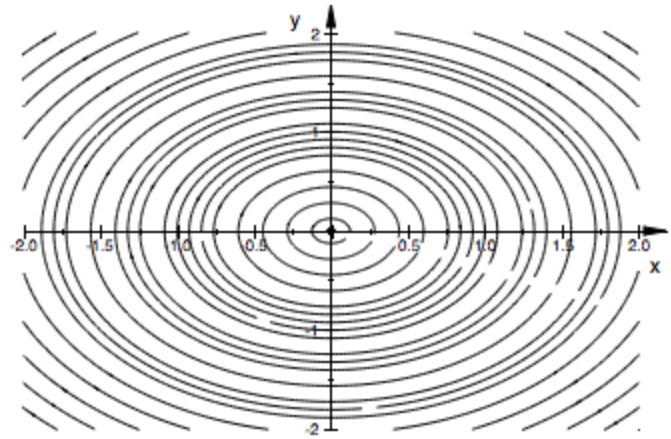
`plot::Streamlines2d` depicts vector fields by (more or less) equidistant stream lines:

```
plot(plot::Streamlines2d(-x, -y, x=-2..2, y=-2..2))
```



Note that this style of display necessarily breaks symmetries, in this case the perfect rotational symmetry of the vector field.

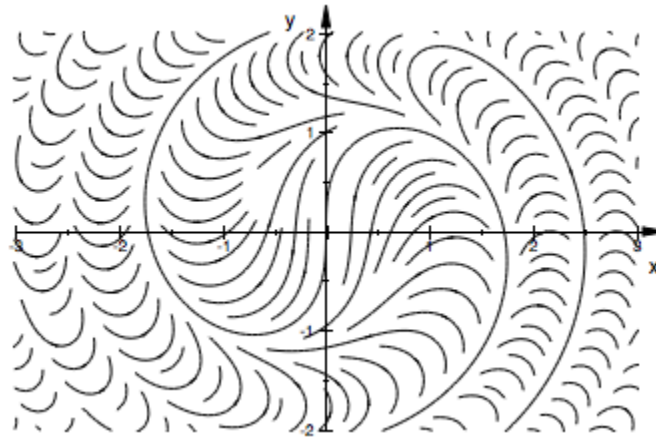
Additionally, cycles will not be closed, but leave a gap:
plot(plot::Streamlines2d(-y, x, x=-2..2, y=-2..2))



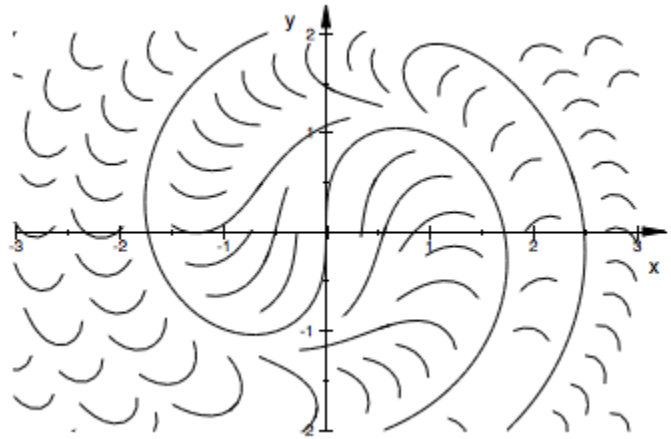
Example 2

Apart from the “usual” parameters such as parameter ranges, line color, or line width, `plot::Streamlines2d` can be controlled with the attribute MinimumDistance, which sets the minimum distance between stream lines:

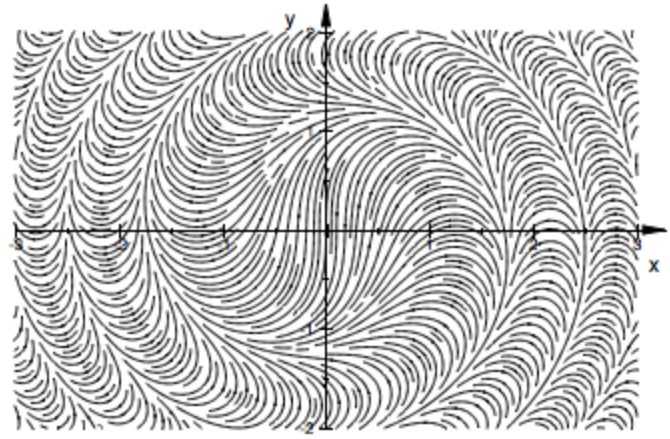
```
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2), x = -3..3, y = -2..2))
```



```
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2), x = -3..3, y = -2..2,
MinimumDistance = 0.2))
```



plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2), x = -3..3, y = -2..2, MinimumDistance = 0.05))

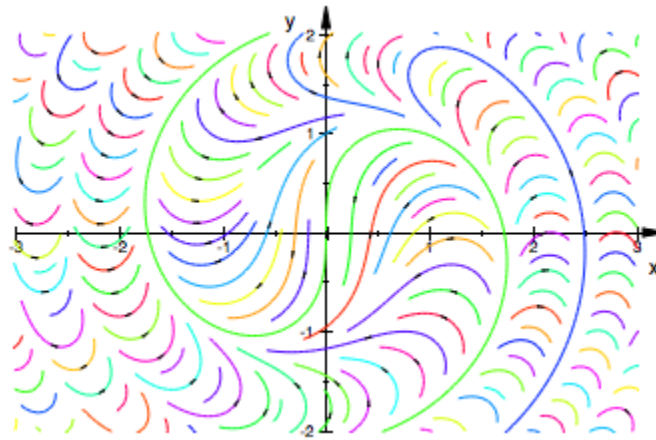


Example 3

A line color function for `plot::Streamlines2d` has access to the current coordinates, to the components of the vector field at the current point, to the current length on the curve (both in terms of the “time”

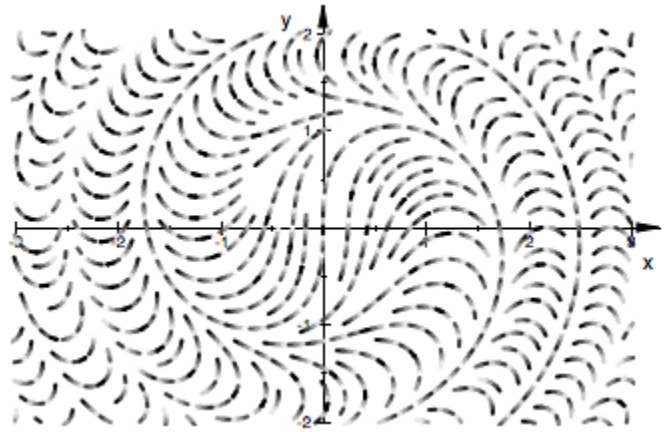
parameter and Euclidean distance) and an integer count of the current curve (which are not found in some predefined order). We use the curve number to generate a colorful display:

```
num2col := (x, y, vx, vy, t, l, n) -> RGB::fromHSV([111*n, 1, 1]):
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2), x = -3..3, y = -2..2,
LineColorFunction = num2col))
```



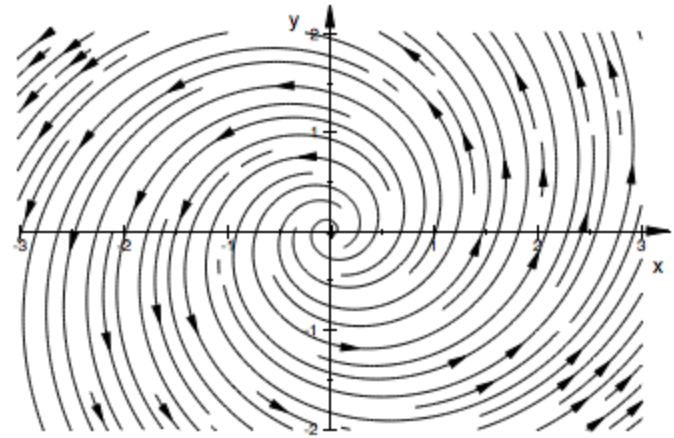
Using the curve length information allows us to include directional information in the visual display:

```
l2col := (x, y, vx, vy, t, l) -> [frac(5*l) $ 3]:
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2), x = -3..3, y = -2..2,
LineWidth = 0.75, LineColorFunction = l2col))
```



Often, an easier way of plotting the orientation of the stream lines is to activate the arrow heads `plot::Streamlines2d` plots at the middle of each sufficiently long) stream line. These are made invisible by the default tip length of 0:

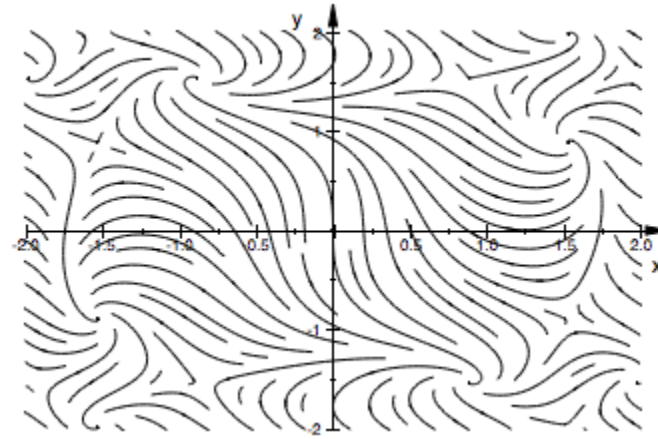
```
plot(plot::Streamlines2d(0.3*x-y, 0.3*y+x, x = -3..3, y = -2..2, TipLength = 3*unit::mm))
```



Example 4

Since the placement of stream lines is hard to predict, `plot::Streamlines2d` is not really suitable for animations. It is possible to animate `plot::Streamlines2d`, but coherence between the animation frames is less than usual:

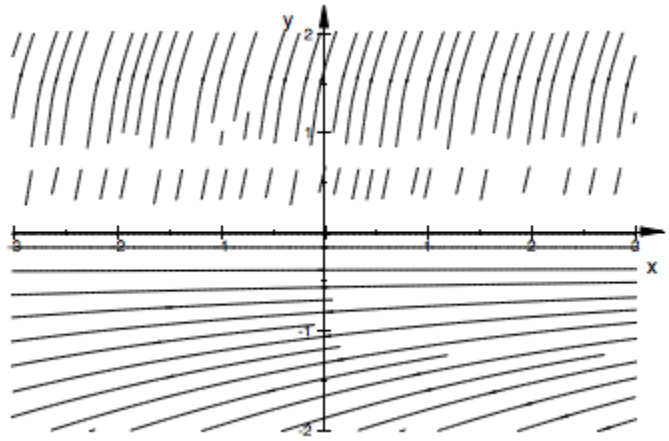
```
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2-y^2+a), x = -2..2, y =
-2..2, a = -PI..PI, MinimumDistance = 0.1, Frames=10))
```



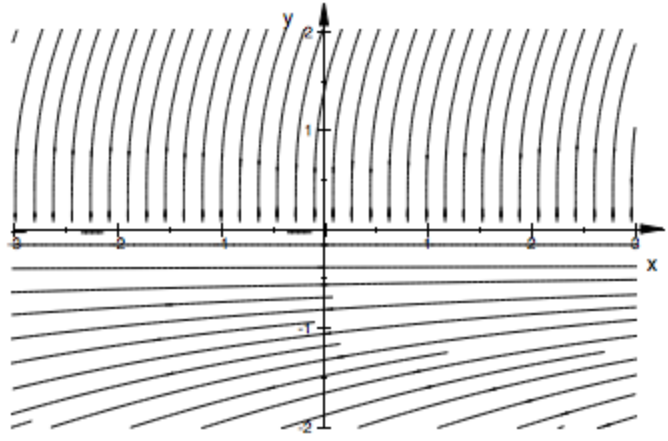
Example 5

With the default settings, `plot::Streamlines2d` is not able to plot the vector field [1, 3^(2/y)] $\left[1, 3^{2/y}\right]$ (which is not Lipschitz continous) in a satisfying way:

```
plot(plot::Streamlines2d([1, surd(3,y)^2], x=-3..3, y=-2..2))
```



By using a different numerical integrator, the problems can be overcome (at the cost of longer computation):
plot(plot::Streamlines2d([1, surd(3,y)^2], x=-3..3, y=-2..2, ODEMethod=RKF43, RelativeError=1e-3))



Parameters

v_1

v_2

The *x*- and *y*-component of the vector field: arithmetical expressions in `x`, `y`, and, possibly, the animation parameter `a`.

v_1, v_2 are equivalent to the attributes XFunction, YFunction.

V

A matrix of category Cat::Matrix with two entries that provide the components v_1, v_2 of the vector field.

x

y

Identifiers.

`x`, `y` are equivalent to the attributes XName, YName.

x_{min} .. x_{max}

y_{min} .. y_{max}

Real numerical values.

x_{min} .. x_{max}, y_{min} .. y_{max} are equivalent to the attributes XRange, YRange, XMin, XMax, YMin, YMax.

a

Animation parameter, specified as `a = `a_{min}`..`a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

Algorithms

The algorithm used in `plot::Streamlines2d` has been published in "Creating Evenly-Spaced Streamlines of Arbitrary Density" by Bruno Jobard and Wilfrid Lefer at the Eurographics Workshop in Boulogne-sur-Mer, France.

plot::Sum

Purpose

Graphical primitive for symbolic sums

Syntax

```
plot::Sum(ex, i = m .. n, <a = a_min .. a_max>, options)
plot::Sum(sum(ex, i = m .. n), <a = a_min .. a_max>, options)
```

Description

`plot::Sum(ex, i = m..n)` creates a plot of summing `ex` over the range `m..n`.

`plot::Sum` creates a visual display of partial sums over a finite interval. Mathematically, `plot::Sum(ex, i = m..n)` plots the function x -> sum(m + floor(x-m)*ex, i=m) $x \to \sum_{i=m}(m + \lfloor x - m \rfloor \, ex)$.

To ease the use of `plot::Sum` in programs, symbolic sums are accepted in the input and `plot::Sum` takes care not to evaluate these. It is highly recommended, though, not to use this syntax in interactive applications, to avoid premature evaluation.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`FALSE`
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	`FALSE`
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	`Solid`
Frames	the number of frames in an animation	`50`

Attribute	Purpose	Default Value
Function	function expression or procedure	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`1`
Name	the name of a plot object (for browser and legend)	

Attribute	Purpose	Default Value
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointColor	the color of points	RGB::MidnightBlue
PointsVisible	visibility of mesh points	`FALSE`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	

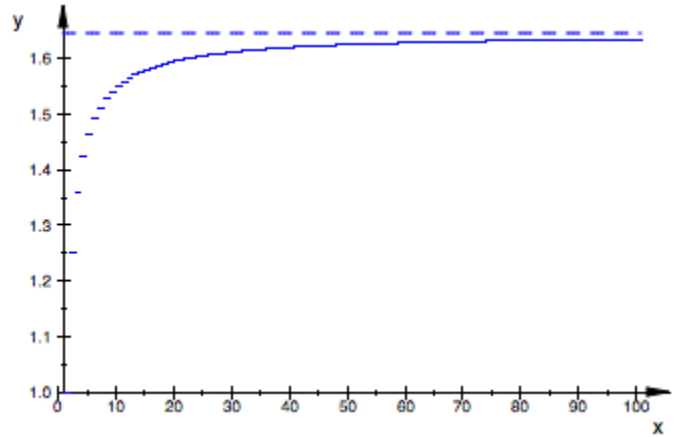
Attribute	Purpose	Default Value
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	

Examples

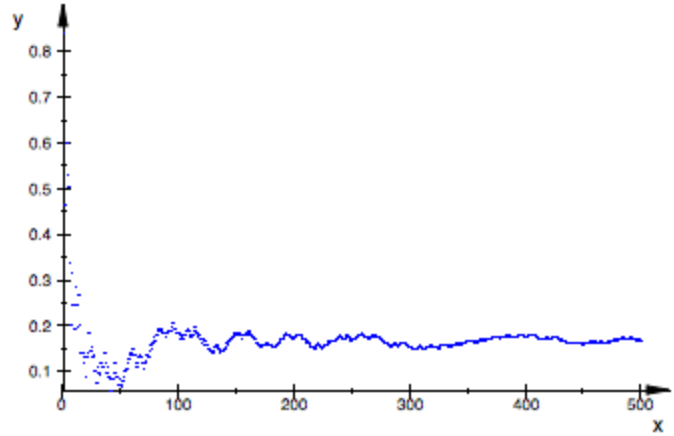
Example 1

It is well known that sum(1/j^2, j=1..infinity) = PI^2/6 $\sum_{j=1}^{\infty} \frac{1}{j^2} = \frac{\pi^2}{6}$. We use `plot::Sum` to display the first 100 partial sums:

```
plot(plot::Sum(1/j^2, j = 1..100), plot::Function2d(PI^2/6, x=1..101,
LineStyle = Dashed))
```



With more partial sums, the steps approximate points:
plot(plot::Sum(sin(j^2)/j, j=1..500))

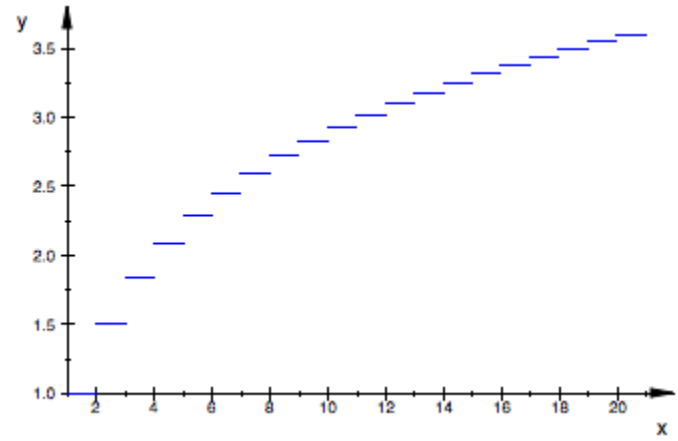


Example 2

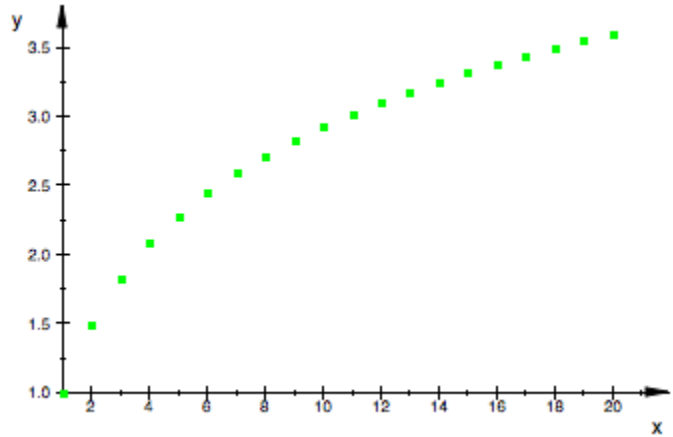
To show some of the formatting options of `plot::Sum`, we use the following sum:
s := plot::Sum(1/j, j = 1..20)plot::Sum(1/j, j = 1..20)

plot::Sum(1/i, i = 1..20)

By default, this object is displayed as follows:
plot(s)

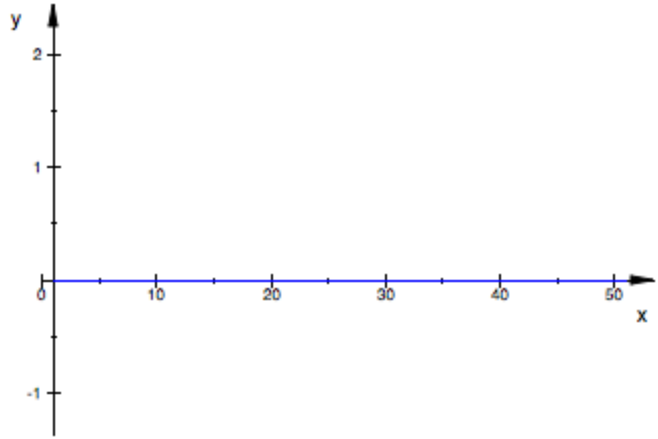


To change parameters, we can select them in the inspector and change the values, we can give other values directly in the `plot` command or we can set the new values in our object `s`:
s::PointsVisible := TRUE: s::LinesVisible := FALSE: s::PointColor := RGB::Green: plot(s)

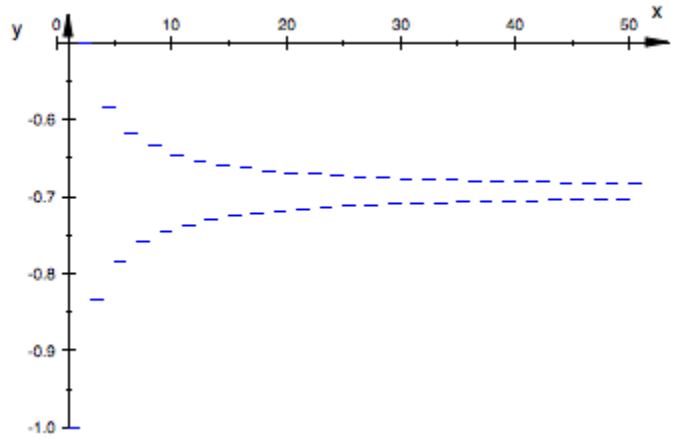


Example 3

`plot::Sum` allows animation in the usual way, for example, in the term to sum:
plot(plot::Sum(sin(a*i^2)/i, i = 1..50, a = 0..PI))



Another interesting parameter to animate is the summation range:
plot(plot::Sum((-1)^j/j, j = 1..jmax, jmax = 1..50))



Parameters

ex

Arithmetical expression in `i` and the animation parameter `a`, if that is used.

`ex` is equivalent to the attribute Function.

i

An identifier or indexed identifier.

`i` is equivalent to the attribute XName.

m .. n

The range of `i`. `m` and `n` may be expressions in the animation parameter `a`. Summation goes over `m` + integer. If `n - m` is not an integer, `n` will not be reached.

`m .. n` is equivalent to the attributes XRange, XMin, XMax.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also plotplot::copyplot::Function2dplot::PointList2d

plot::Surface

Purpose

Parametrized surfaces in 3D

Syntax

```
plot::Surface([x, y, z], u = u_min .. u_max, v = v_min ..
v_max, <a = a_min .. a_max>, options)
plot::Surface(xyz, u = u_min .. u_max, v = v_min .. v_max,
<a = a_min .. a_max>, options)
plot::Surface(A, u = u_min .. u_max, v = v_min .. v_max,
<a = a_min .. a_max>, options)
```

Description

`plot::Surface` creates a parametrized surface in 3D.

The surface given by a mapping ("parametrization") (u, v) -> fenced(x(u, v), y(u, v), z(u, v))$(u, v) \to (x(u, v), y(u, v), z(u, v))$ is the set of all image points

ImageSet(matrix([x(u,v), y(u,v), z(u,v)]), u in [u_min, u_max], v in [v_min, v_max]) in R_^3

$$\left\{ \begin{pmatrix} x(u, v) \\ y(u, v) \\ z(u, v) \end{pmatrix} \;\middle|\; u \in [u_{min}, u_{max}], v \in [v_{min}, v_{max}] \right\} \in \mathbb{R}^3$$

The expressions/functions x, y, z may have singularities in the plot range. Although a heuristics is used to find a reasonable viewing range when singularities are present, it is highly recommended to specify a viewingbox via the attribute

```
ViewingBox = [`x_{min}` ..  `x_{max}`, `y_{min}` ..
`y_{max}`, `z_{min}` ..  `z_{max}`]
```

with suitable numerical real values x_{min}, , z_{max}. See "Example 3" on page 24-764.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter a that is different from the surface parameters u, v. See "Example 5" on page 24-766.

The functions x, y, z are evaluated on a regular equidistant mesh of sample points in the u-v plane. This mesh is determined by the attributes UMesh, VMesh. By default, the attribute AdaptiveMesh = 0 is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of UMesh, VMesh or USubmesh, VSubmesh, or set AdaptiveMesh = n with some (small) positive integer n. If necessary, up to 2^n - 1 additional points are placed in each direction of the u-v plane between adjacent points of the initial equidistant mesh. See "Example 6" on page 24-767.

The "coordinate lines" ("parameter lines") are curves on the surface.

The phrase "ULines" refers to the curves $(x(u, v_0), y(u, v_0), z(u, v_0))$ with the parameter u running from u_{min} to u_{max}, while v_0 is some fixed value from the interval $[v_{min}, v_{max}]$.

The phrase "VLines" refers to the curves $(x(u_0, v), y(u_0, v), z(u_0, v))$ with the parameter v running from v_{min} to v_{max}, while u_0 is some fixed value from the interval $[u_{min}, u_{max}]$.

By default, the parameter curves are visible. They may be "switched off" by specifying ULinesVisible = FALSE and VLinesVisible = FALSE, respectively.

The coordinate lines controlled by ULinesVisible = TRUE/FALSE and VLinesVisible = TRUE/FALSE indicate the equidistant mesh in the u-v plane set via the UMesh, VMesh attributes. If the mesh is refined by the USubmesh, VSubmesh attributes, or by the adaptive mechanism controlled by AdaptiveMesh = n, no additional parameter lines are drawn.

As far as the numerical approximation of the surface is concerned, the settings UMesh = n_u, VMesh = n_v, USubmesh = m_u, VSubmesh = m_v and UMesh = $(n_u - 1)(m_u + 1) + 1$, VMesh = $(n_v - 1)(m_v + 1) + 1$, USubmesh = 0, VSubmesh = 0 are equivalent. However, in the first setting, n_u parameter lines are visible in the u direction, while in the latter setting $(n_u - 1)(m_u + 1) + 1$ parameter lines are visible. See "Example 7" on page 24-769.

Use `Filled = FALSE` to render the surface as a wireframe.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	`0`
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	`[0, 0, 1]`
FillColorDirectionX	x-component of the direction of color transitions on surfaces	`0`
FillColorDirectionY	y-component of the direction of color transitions on surfaces	`0`

Attribute	Purpose	Default Value
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0

Attribute	Purpose	Default Value
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	[25, 25]
MeshVisible	visibility of irregular mesh lines in 3D	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Shading	smooth color blend of surfaces	Smooth
Submesh	density of submesh (additional sample points)	[0, 0]

Attribute	Purpose	Default Value
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
ULinesVisible	visibility of parameter lines (u lines)	`TRUE`
UMax	final value of parameter “u”	
UMesh	number of sample points for parameter “u”	`25`
UMin	initial value of parameter “u”	

Attribute	Purpose	Default Value
UName	name of parameter “u”	
URange	range of parameter “u”	
USubmesh	density of additional sample points for parameter “u”	0
VLinesVisible	visibility of parameter lines (v lines)	TRUE
VMax	final value of parameter “v”	
VMesh	number of sample points for parameter “v”	25
VMin	initial value of parameter “v”	
VName	name of parameter “v”	
VRange	range of parameter “v”	
VSubmesh	density of additional sample points for parameter “v”	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XContours	contour lines at constant x values	[]
XFunction	function for x values	
YContours	contour lines at constant y values	[]
YFunction	function for y values	
ZContours	contour lines at constant z values	[]
ZFunction	function for z values	

Examples

Example 1

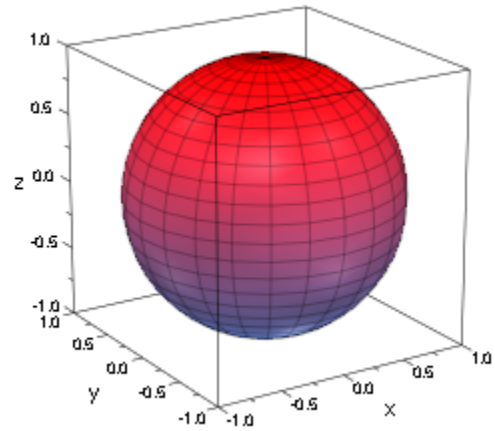
Using standard spherical coordinates, a parametrization of a sphere of radius r by the azimuth angle $u \in [0, 2\pi]$ and the polar angle $v \in [0, \pi]$ is given by:

```
x := r*cos(u)*sin(v): y := r*sin(u)*sin(v): z := r*cos(v):
```

We fix $r = 1$ and create the surface object:

```
r := 1: s := plot::Surface([x, y, z], u = 0 .. 2*PI, v = 0 .. PI)plot::Surface([cos(u)*sin(v), sin(u)*sin(v), cos(v)], u = 0..2*PI, v = 0..PI)
```

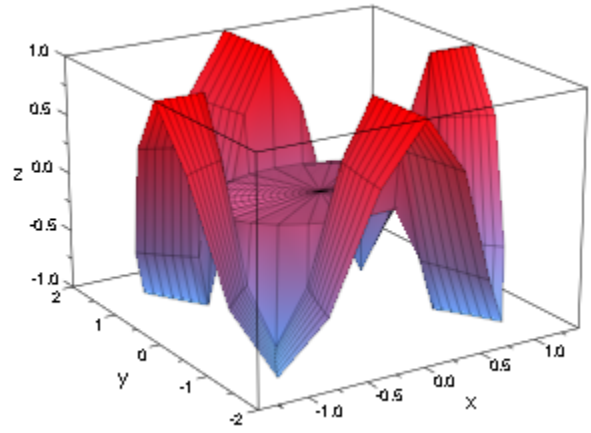
We call plot to plot the surface:
plot(s, Scaling = Constrained):



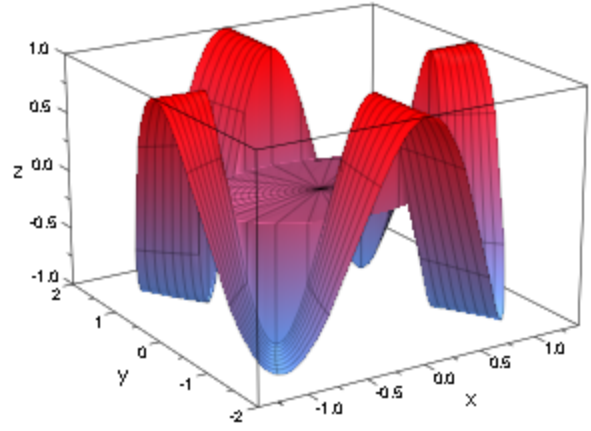
delete x, y, z, r, s:

Example 2

The parametrization can also be specified by piecewise objects or procedures:
x := u*cos(v): y := piecewise([u <= 1, u*sin(v)], [u >= 1, u^2*sin(v)]):
z := proc(u, v) begin if u <= 1 then 0 else cos(4*v) end_if: end_proc:
plot(plot::Surface([x, y, z], u = 0 .. sqrt(2), v = 0 .. 2*PI)):



We enable adaptive sampling to get a smoother graphical result: plot(plot::Surface([x, y, z], u = 0 .. sqrt(2), v = 0 .. 2*PI), AdaptiveMesh = 3):

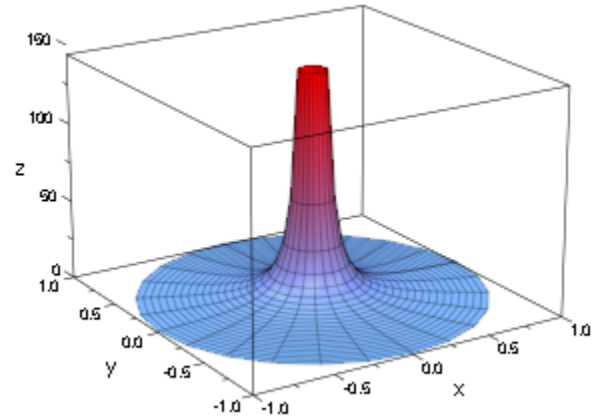


delete x, y, z, s, r:

Example 3

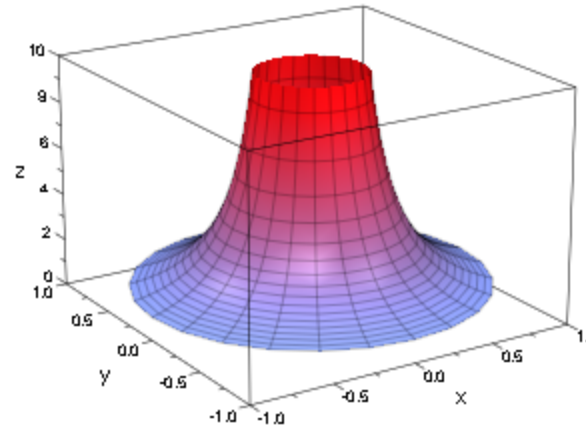
We plot a surface with singularities:

```
s := plot::Surface([u*cos(v), u*sin(v), 1/u^2], u = 0 .. 1, v = 0 .. 2*PI):
plot(s):
```



We specify an explicit viewing range for the *z* coordinate:

```
plot(s, ViewingBox = [Automatic, Automatic, 0 .. 10]):
```

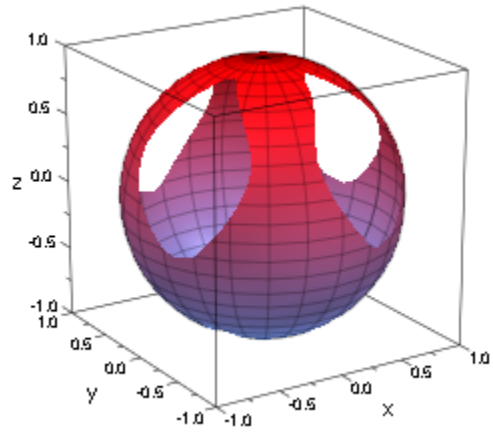


delete s:

Example 4

By introducing non-real function evaluations, we can plot surfaces with holes:

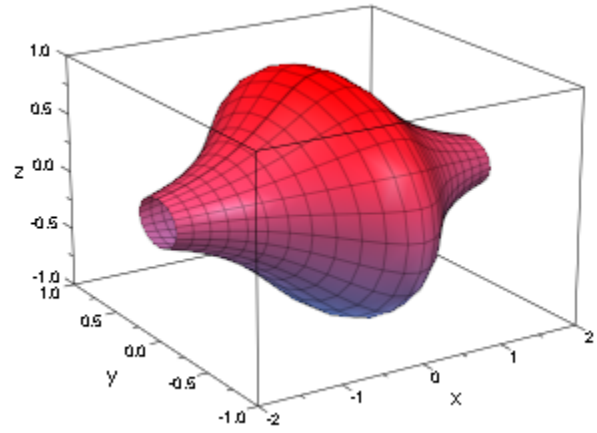
```
chi := piecewise([sin(4*u) < cos(3*v)+0.5, 1]):
plot(plot::Surface([cos(u)*sin(v), sin(u)*sin(v), chi*cos(v)], u = 0 .. 2*PI,
v = 0 .. PI, AdaptiveMesh=2), Scaling = Constrained)
```



Example 5

We generate an animation of a surface of revolution. The graph of the function f(u)=1/fenced(1+u^2) is rotated around the *x*-axis:

```
f := u -> 1/(1 + u^2): plot(plot::Surface([u, f(u)*sin(v), f(u)*cos(v)], u = -2
.. 2, v = 0 .. a*2*PI, a = 0 .. 1)):
```

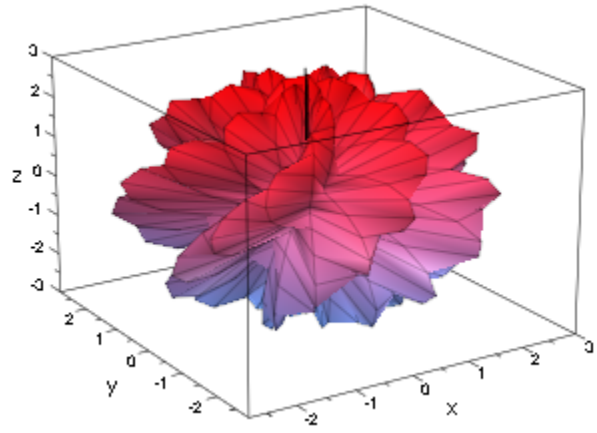


See plot::XRotate, plot::ZRotate for an alternative way to create surfaces of revolution.
delete f:

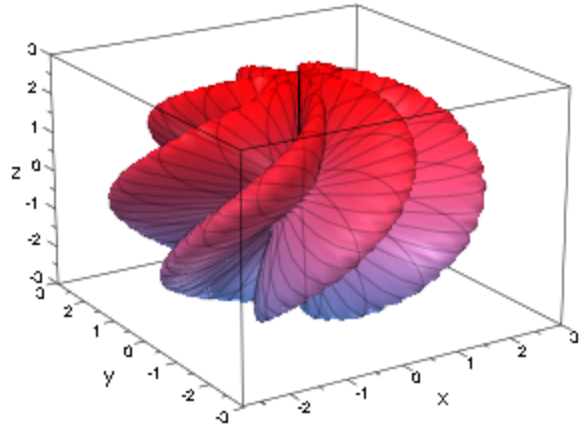
Example 6

The standard mesh for the numerical evaluation of a surface does not suffice to generate a satisfying plot in the following case:

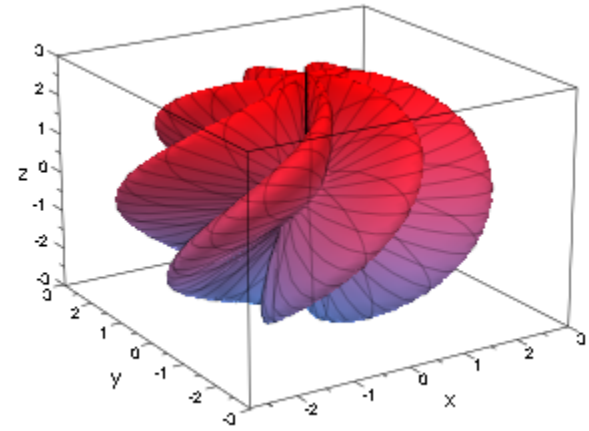
```
r := 2 + sin(7*u + 5*v): x := r*cos(u)*sin(v): y := r*sin(u)*sin(v): z:= r*cos(v): plot(plot::Surface([x, y, z], u = 0 .. 2*PI, v = 0 .. PI)):
```



We increase the number of mesh points. Here, we use USubmesh, VSubmesh to place 2 additional points in each direction between each pair of neighboring points of the default mesh. This increases the runtime for computing the plot by a factor of 9:
plot(plot::Surface([x, y, z], u = 0 .. 2*PI, v = 0 .. PI, USubmesh = 2, VSubmesh = 2)):



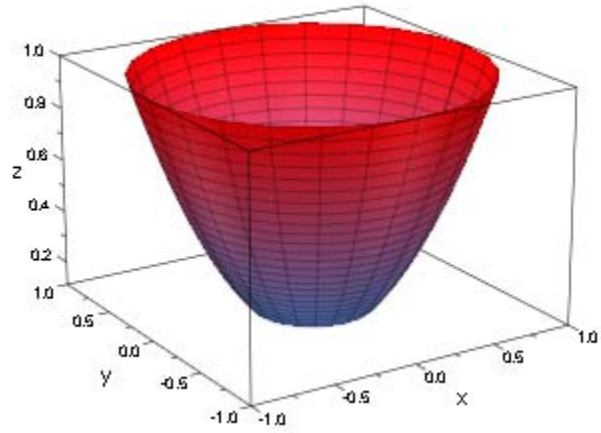
Alternatively, we enable adaptive sampling by setting the value of AdaptiveMesh to some positive value:
plot(plot::Surface([x, y, z], u = 0 .. 2*PI, v = 0 .. PI, AdaptiveMesh = 2)):



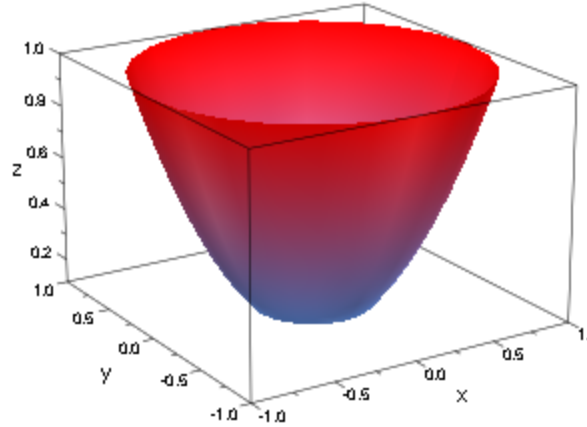
delete r, x, y, z:

Example 7

By default, the parameter lines of a parametrized surface are “switched on”:
x := r*cos(phi): y := r*sin(phi): z := r^2: plot(plot::Surface([x, y, z], r = 1/3 .. 1, phi = 0 .. 2*PI)):

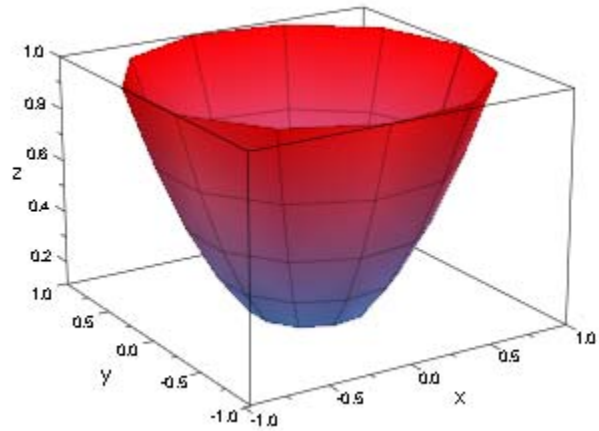


The parameter lines are “switched off”:
plot(plot::Surface([x, y, z], r = 1/3 .. 1, phi = 0 .. 2*PI, ULinesVisible = FALSE, VLinesVisible = FALSE)):

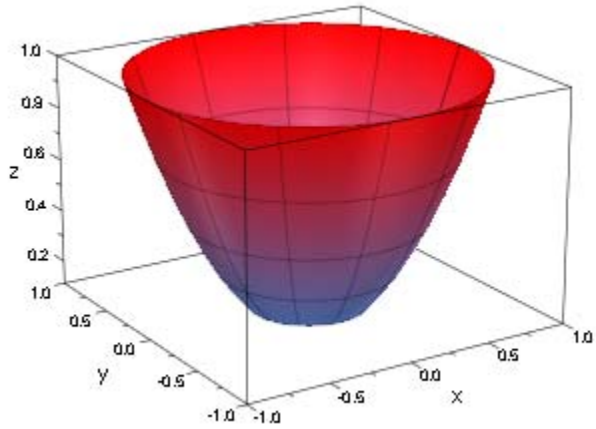


The number of parameter lines are determined by the attributes UMesh and VMesh:

plot(plot::Surface([x, y, z], r = 1/3 .. 1, phi = 0 .. 2*PI, UMesh = 5, VMesh = 12)):



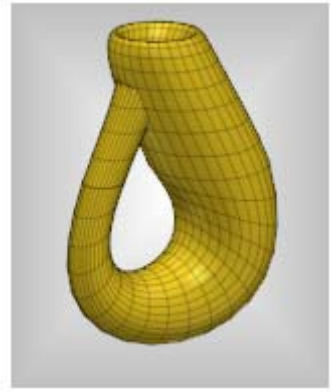
When the mesh is refined via the attributes USubmesh, VSubmesh, the numerical approximation of the surface becomes smoother. However, the number of parameter lines is determined by the values of UMesh, VMesh and is not increased:
plot(plot::Surface([x, y, z], r = 1/3 .. 1, phi = 0 .. 2*PI, UMesh = 5, VMesh = 12, USubmesh = 1, VSubmesh = 2)):



Example 8

Klein's bottle is a surface without orientation. There is no "inside" and no "outside" of the following object:

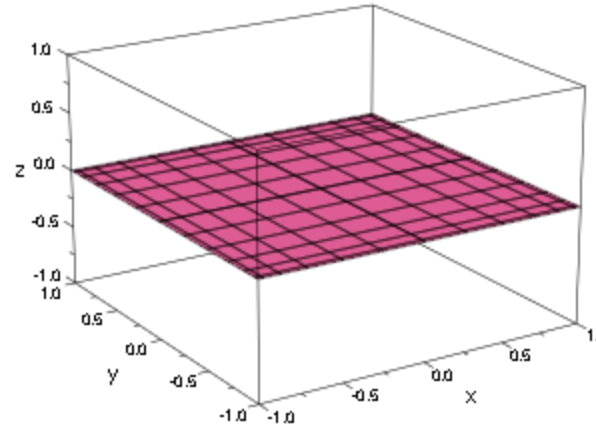
```
bx := u -> -6*cos(u)*(1 + sin(u)): by := u -> -14*sin(u): r := u -> 4 - 2*cos(u): x := (u, v) -> piecewise([u <= PI, bx(u) - r(u)*cos(u)*cos(v)], [PI < u, bx(u) + r(u)*cos(v)]): y := (u, v) -> r(u)*sin(v): z := (u, v) -> piecewise([u <= PI, by(u) - r(u)*sin(u)*cos(v)], [PI < u, by(u)]): KleinBottle:= plot::Surface( [x, y, z], u = 0 .. 2*PI, v = 0 .. 2*PI, Mesh = [35, 31], LineColor = RGB::Black.[0.2], FillColorFunction = RGB::MuPADGold): plot(KleinBottle, Axes = None, Scaling = Constrained, Width = 60*unit::mm, Height = 72*unit::mm, BackgroundStyle = Pyramid):
```



delete bx, by, r, x, y, z, KleinBottle:

Example 9

Finally we create an animated surface plot of (u, v) -> fenced(sin(u),sin(v),a*sin(u+v))$(u, v) \to (\sin(u), \sin(v), a\sin(u+v))$ where a is the animation parameter:
plot(plot::Surface([sin(u),sin(v),a*sin(u+v)], u=0..2*PI, v=0..2*PI, a=1..0, AnimationStyle = BackAndForth))



Parameters

x

y

z

The coordinate functions: arithmetical expressions or piecewise objects depending on the surface parameters u, v and the animation parameter `a`. Alternatively, procedures that accept 2 input parameters u, v or 3 input parameters u, v, a and return a numerical value when the input parameters are numerical.

`x`, `y`, `z` are equivalent to the attributes XFunction, YFunction, ZFunction.

xyz

The parametrization: a procedure that accepts 2 input parameters u, v or 3 input parameters u, v, a and returns a list of 3 numerical values $[x, y, z]$.

A

A matrix of category Cat::Matrix with three entries that provide the parametrization `x`, `y`, `z`

u

The first surface parameter: an identifier or an indexed identifier.

`u` is equivalent to the attribute UName.

u_{min} .. u_{max}

The plot range for the parameter u: u_{min}, u_{max} must be numerical real values or expressions of the animation parameter a.

u_{min} .. u_{max} is equivalent to the attributes URange, UMin, UMax.

v

The second surface parameter: an identifier or an indexed identifier.

`v` is equivalent to the attribute VName.

v_{min} .. v_{max}

The plot range for the parameter *v*: v_{min}, v_{max} must be numerical real values or expressions of the animation parameter *a*.

v_{min} .. v_{max} is equivalent to the attributes VRange, VMin, VMax.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplotfunc3dplot::Function3dplot::Matrixplot

plot::SurfaceSet

Purpose

Triangle and quad surface meshes

Syntax

```
plot::SurfaceSet(meshlist, <MeshListType = t>,
<MeshListNormals = n>, <UseNormals = b>, <a =
a_min .. a_max>, options)
```

Description

`plot::SurfaceSet(MeshList)` creates a 3D graphical object from a given list of triangle or quad coordinates.

MeshList contains coordinates of points (and optional normals) of either triangles or quads which define a mesh of a 3D surface. The points must be given homogenous: If a normal is given, it must be given for all points or facets, respectively. The attribute `MeshListType` specifies how these points are to be interpreted for plotting the surface. The attribute `MeshListNormals` specifies whether the list contains normal vectors and at which positions they located.

MeshListType specifies how the points in `MeshList` are to be interpreted for plotting the surface. See MeshList for more information about mesh list types. Cf. “Example 4” on page 24-784.

MeshListNormals specifies whether `MeshList` contains normals and at which positions they are located. See MeshList for more information about normals and facet orientation.

When setting the attribute UseNormals to FALSE the normals defined in `MeshList` are ignored when plotting the object in MuPAD. This reduces the data volume of the graphics object and the computing time as well. However, it leads to a less brilliant image.

User-defined color functions LineColorFunction and FillColorFunction will be called with the index of the current point as its first parameter, followed by the *x*, *y*, and *z* coordinate of the current point.

The transformation objects plot::Rotate3d, plot::Scale3d, plot::Translate3d and plot::Transform3d can be applied to the imported STL object. Cf. “Example 8” on page 24-793.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	`[0, 0, 1]`
FillColorDirectionX	x-component of the direction of color transitions on surfaces	`0`
FillColorDirectionY	y-component of the direction of color transitions on surfaces	`0`
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	`1`

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	`RGB::Black.[0.25]`
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`0`
LineColorDirectionZ	z-component of the direction of color transitions on lines	`1`
MeshList	triangulation data	

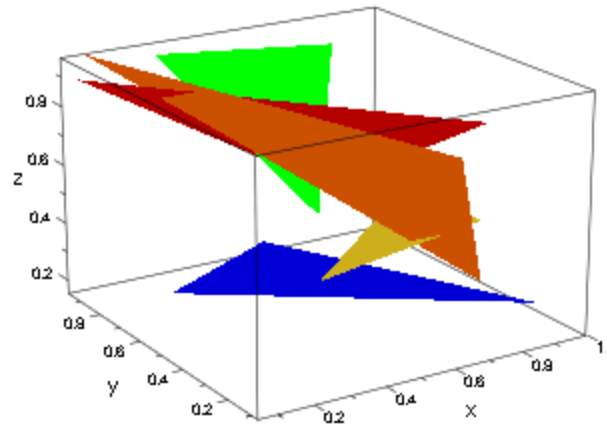
Attribute	Purpose	Default Value
MeshVisible	visibility of irregular mesh lines in 3D	`FALSE`
MeshListType	triangulation data	`Triangles`
MeshListNormals	triangulation data	`None`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`FALSE`
Shading	smooth color blend of surfaces	`Smooth`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`

Attribute	Purpose	Default Value
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
UseNormals	use pre-defined normals?	TRUE
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

When given a list of real numbers, `plot::SurfaceSet` by default considers them as the coordinates of points in 3D forming triangles. Note that we are using FillColorFunction here to make the triangles easier to see and that the number of values must be divisible by 9, since each triangle needs 9 numbers to be specified:
plot(plot::SurfaceSet([frandom() $ i = 1..9*5], FillColorFunction = (i -> RGB::ColorList[floor((i+2)/3)])));

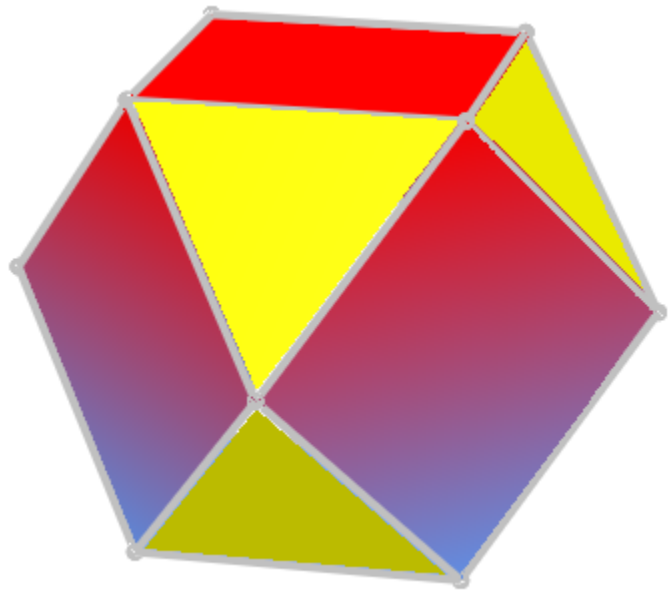


Example 2

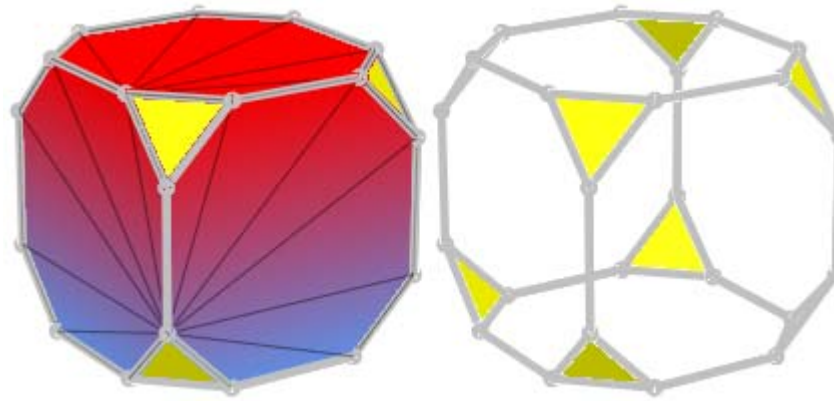
This examples demonstrates how surface sets can be created and animated in MuPAD. First we create a mesh of points:
delete cx, cy, cz, r: F:= [[[cx-r ,cy-r+a,cz+r], [cx-r+a,cy-r ,cz+r], [cx+r-a,cy-r ,cz+r], [cx+r ,cy-r+a,cz+r], [cx+r ,cy+r-a,cz+r], [cx+r-a,cy+r ,cz+r], [cx-r+a,cy+r ,cz+r], [cx-r ,cy+r-a,cz+r]], [[cx+r,cy-r ,cz-r+a], [cx+r,cy-r+a,cz-r], [cx+r,cy+r-a,cz-r], [cx+r,cy+r ,cz-r+a], [cx+r,cy+r ,cz+r-a], [cx+r,cy+r-a,cz+r], [cx+r,cy-r+a,cz+r], [cx+r,cy-r ,cz+r-a]], [[cx-r ,cy+r,cz-r+a], [cx-r+a,cy+r,cz-r], [cx+r-a,cy+r,cz-r], [cx+r ,cy+r,cz-r+a], [cx+r ,cy+r,cz+r-a], [cx+r-a,cy+r,cz+r], [cx-r+a,cy+r,cz+r], [cx-r ,cy+r,cz+r-a]]]: F:= F.[subs(F[1], cz+r=cz-r), subs(F[2], cx+r=cx-r), subs(F[3], cy+r=cy-r)]: T:= [[cx+r,cy-r+a,cz+r], [cx+r-a,cy-r,cz+r],

[cx+r,cy-r,cz+r-a]]: T:= T.subs(T, cx+r-a=cx-r+a, cx+r=cx-r): T:= T.subs(T, cy-r+a=cy+r-a, cy-r=cy+r): T:= T.subs(T, cz+r-a=cz-r+a, cz+r=cz-r):

Then we create plot objects using the mesh above:
cx := 0: cy := 0: cz := 0: r := 1: P := range -> plot::Group3d(plot::Group3d(plot::SurfaceSet(map(F[i], op), a = range, MeshListType = TriangleFan) $ i=1..6), plot::Group3d(plot::Polygon3d(F[i], a = range, Closed) $ i=1..6, LineWidth = 1.5, LineColor = RGB::Grey, PointsVisible, PointSize = 3), plot::Group3d(plot::SurfaceSet(map(T, op), a = range), FillColorType = Flat, FillColor=RGB::Yellow, Filled)):plot(P(0..r), Scaling = Constrained, Width = 120, Height = 120, Axes = None):

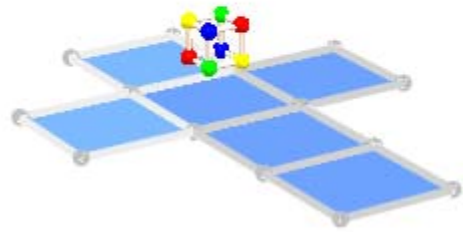


The first half of this animation is plotted again. In the left image we can see how parts of the surface set are constructed as triangle fan. In the right image parts of the surface are displayed as wireframe:
plot(plot::Scene3d(P(0..r/2), MeshVisible = TRUE), plot::Scene3d(P(0..r/2), Filled = FALSE), Scaling = Constrained, Width = 150, Height = 75, Axes = None, Layout = Horizontal):



Example 3

A second animation demonstrates the fold back of a cube:
r := 1: bottom := [[0, 0, 0], [r, 0, 0], [r, r, 0], [0, r, 0]]: left := [[0, 0, 0], [0, -r*sin(a), r*cos(a)], [r, -r*sin(a), r*cos(a)], [r, 0, 0]]: right := map(left, l -> [l[1], r-l[2], l[3]]): front := map(left, l -> [l[2], l[1], l[3]]): back := map(right, l -> [l[2], l[1], l[3]]): top := [left[3], left[2], zip(left[2], [0, -r*sin(2*a-PI/2), r*cos(2*a-PI/2)], '+'), zip(left[3], [0, -r*sin(2*a-PI/2), r*cos(2*a-PI/2)], '+')]:plot(plot::SurfaceSet(map(bottom.left.top.right.front.back, op), MeshListType = Quads, PointsVisible = TRUE, PointSize = 3, MeshVisible = TRUE, LineWidth = 1.5, LineColor = RGB::Grey, a=0..PI/2), plot::MuPADCube(Radius = r/3, Center = [r/2 $ 3]), Scaling = Constrained)

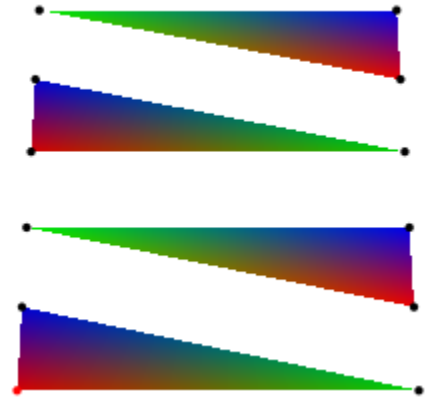


delete r, bottom, left, right, front, back, top:

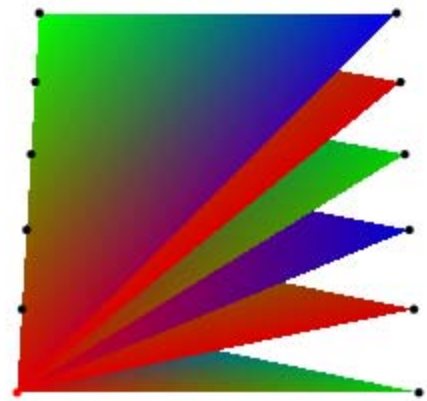
Example 4

Let's have a deeper look on the different kind of mesh types. We create a mesh of points first and then plot it using the different mesh types available. The first point will always be plotted in red color:
PL:= [((0,i,0.5-0.1*i), (1,i,0.5-0.1*i)) $ i = 0..5]: SO:= FillColorFunction = ((n,x,y,z)->[RGB::Blue,RGB::Red,RGB::Green][(n mod 3)+1]), LineColorFunction = ((n,x,y,z)-> if n=1 then RGB::Red else RGB::Black end_if), PointsVisible: VO:= plot::Camera([0.5,2.5,4.5], [0.5,2.51,0], 0.2), ViewingBox = [0..1,0..5,0..0.5], Axes = None:

We tell MuPAD to interpret the given mesh list as a set of separate triangles. The corresponding plot looks like this:
plot(plot::SurfaceSet(PL, SO, MeshListType = Triangles), VO):

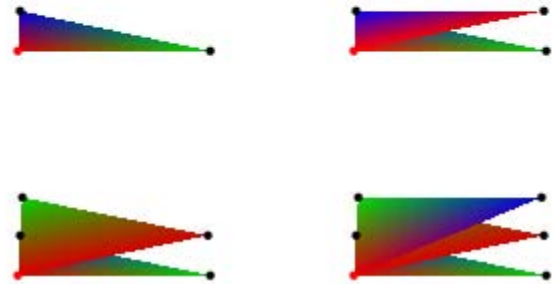


We tell MuPAD to interpret the given mesh list as a triangle fan. The corresponding plot looks like this:
plot(plot::SurfaceSet(PL, SO, MeshListType = TriangleFan), VO):

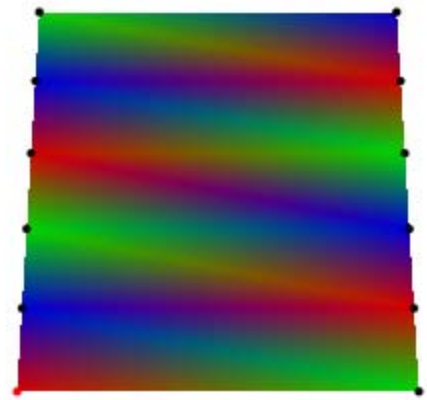


The plot above looks a little bit confusing, thus we let MuPAD plot the first four triangles step by step in order to learn how the whole fan will be created:

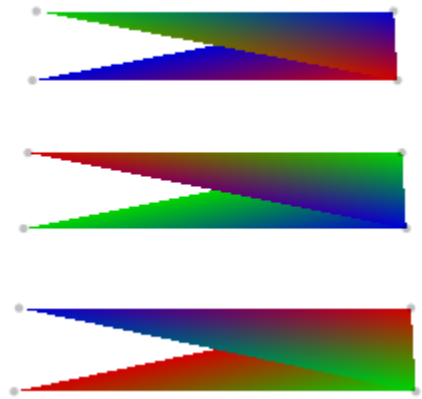
plot(plot::Scene3d(plot::SurfaceSet(PL[1..3*n], SO, MeshListType = TriangleFan), VO) $ n=3..6):



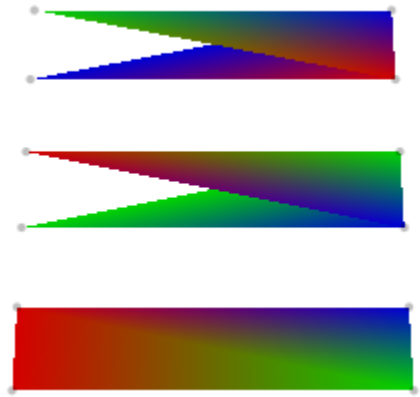
We tell MuPAD to interpret the given mesh list as a triangle strip. The corresponding plot looks like this:
plot(plot::SurfaceSet(PL, SO, MeshListType = TriangleStrip), VO):



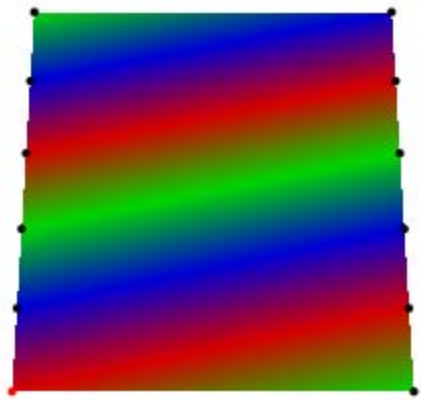
We tell MuPAD to interpret the given mesh list as a set of separate quads. The corresponding plot looks like this:
plot(plot::SurfaceSet(PL, SO, MeshListType = Quads), VO):



The reason for plotting triangles instead of (the expected) rectangles is the order of the points in the point list. Changing the order of the second and third point, we get the expected result:
PK:= PL: tmp:= PK[7]: PK[7]:= PK[10]: PK[10]:=tmp:
plot(plot::SurfaceSet(PK, SO, MeshListType = Quads), VO): delete PK, tmp:



We tell MuPAD to interpret the given mesh list as a quad strip. The corresponding plot looks like this:
plot(plot::SurfaceSet(PL, SO, MeshListType = QuadStrip), VO): delete PL, SO, VO:



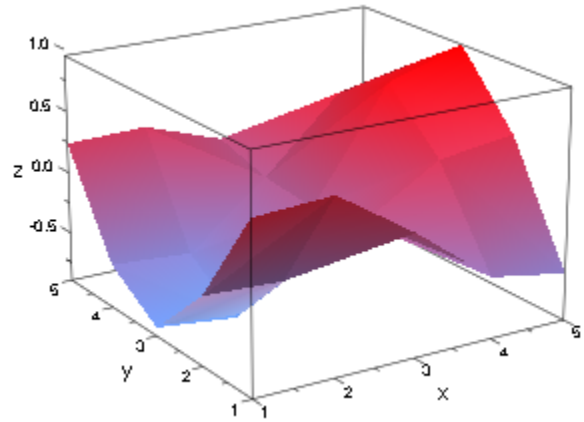
Example 5

It is possible to include normals to give smooth shading for surfaces that are not supposed to look like flat triangles. In the following example, we use a triangulation of a rectangle:

```
trias := [([x, y ], [(x+1), y], [ x ,(y+1)], [x, (y+1)], [(x+1), y], [(x+1),(y+1)]) $
x = 1..4 $ y = 1..4]:
```

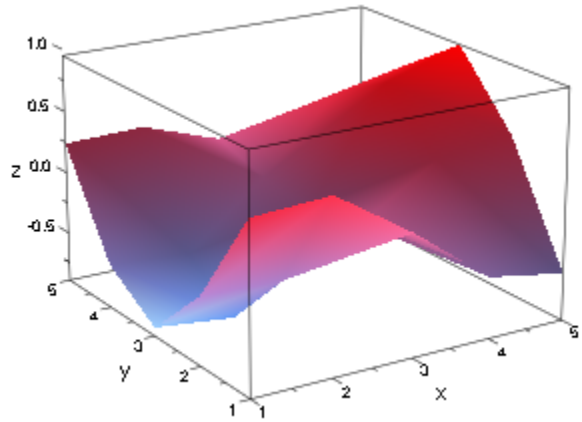
Mapping the function (x,y) -> sin(x)*cos(y) $(x, y) \to \sin(x)\cos(y)$ to these points, we get the following surface plot:

```
f := (x,y) -> sin(x)*cos(y): meshList := map(trias, l -> [l[1], l[2], f(l[1],
l[2])]): plot(plot::SurfaceSet(meshList, MeshListType = Triangles))
```



The triangulation is clearly visible. One way to reduce this would be to refine the mesh, but this may take a lot of time with more complicated functions or be completely impossible for measurement data. It is much faster to give MuPAD more information on the surface, namely, the direction of the tangent planes at the points we evaluated:

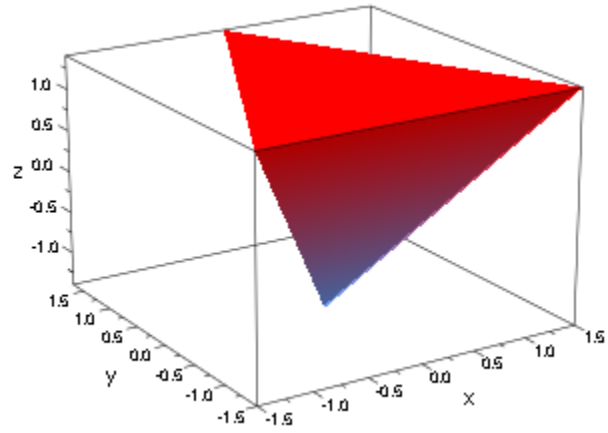
```
normals := map(trias, l -> [D([1], f)(l[1], l[2]), D([2], f)(l[1], l[2]), 1]):
plot(plot::SurfaceSet(zip(meshList, normals, _exprseq), MeshListType =
Triangles, MeshListNormals = BehindPoints))
```



As you can see (especially at the border; otherwise, switch on `LinesVisible`), MuPAD still draws the triangles at exactly the same places, but uses a color shading to create the illusion of a smooth surface.

Example 6

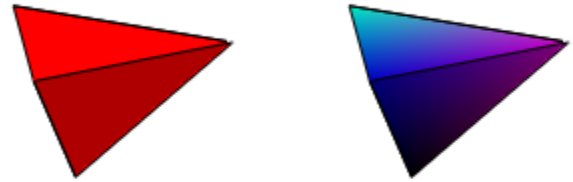
We create a triangle mesh with normals in front of each triangle and plot this object, a tetrahedron, afterwards:
meshList:= [0.0 , 0.0 , -1.0 , -1.5 , -1.5 , 1.4 , 0.0, 1.7, 1.4, 1.5, -1.5, 1.4, 0.0 , 0.88, 0.47, -1.5 , -1.5 , 1.4 , 1.5, -1.5, 1.4, 0.0, 0.0, -1.4, -0.88, -0.41, 0.25, 1.5 , -1.5 , 1.4 , 0.0, 1.7, 1.4, 0.0, 0.0, -1.4, 0.88, -0.41, 0.25, 0.0 , 1.7 , 1.4 , -1.5, -1.5, 1.4, 0.0, 0.0, -1.4]: plot(plot::SurfaceSet(meshList, MeshListType = Triangles, MeshListNormals = BeforeFacets)):



Example 7

A color function FillColorFunction can be specified. The procedure is called for each vertex: the parameters are the index of the current triangle followed by the x-, y- and z-coordinate of the current vertex:

```
plot( plot::Scene3d( plot::SurfaceSet(meshList,
MeshListNormals = BeforeFacets, MeshVisible =
TRUE, LineColor = RGB::Black, FillColorFunction = (n
->[RGB::Red,RGB::Blue,RGB::Green,RGB::Yellow] [n+2 div 3])
) ), plot::Scene3d( plot::SurfaceSet(meshList, MeshListNormals
= BeforeFacets, MeshVisible = TRUE, LineColor = RGB::Black,
FillColorFunction = ((n,x,y,z) -> [x/2,y/2,z/2]) ) ), Axes = None, Layout =
Horizontal ):
```

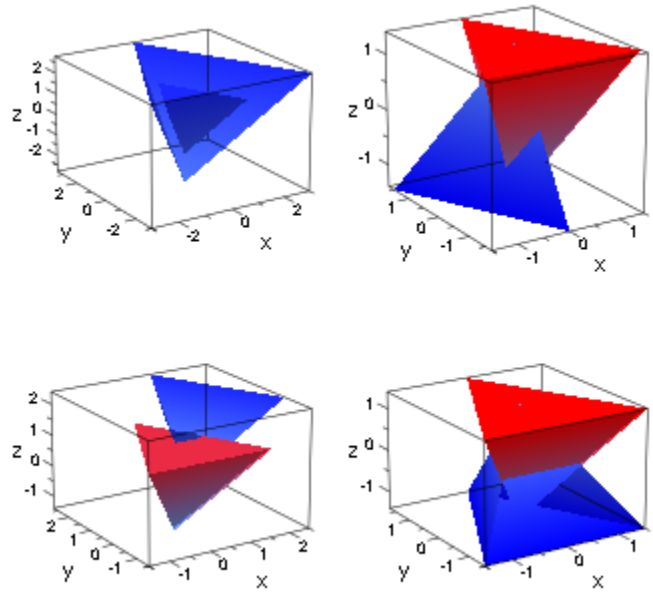


The same is true for a LineColorFunction:
plot(plot::Scene3d(plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets, MeshVisible = TRUE, PointsVisible = TRUE, Filled = FALSE, LineWidth = 2, LineColorFunction = (n -> [RGB::Red,RGB::Blue,RGB::Green,RGB::Yellow][n+2 div 3]))), plot::Scene3d(plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets, MeshVisible = TRUE, PointsVisible = TRUE, Filled = FALSE, LineWidth = 2, LineColorFunction = ((n,x,y,z) -> [x/4,y/4,z/4]))), Axes = None, Layout = Horizontal):

Example 8

Again we plot the object defined in “Example 6” on page 24-790, but now we add a rotated, scaled and translated copy of it:

```
plot( plot::Scene3d( plot::SurfaceSet(meshList, MeshListNormals
= BeforeFacets), plot::Scale3d([2,2,2], plot::SurfaceSet(meshList,
MeshListNormals = BeforeFacets, Color = RGB::Blue.[0.1]) )
), plot::Scene3d( plot::SurfaceSet(meshList, MeshListNormals
= BeforeFacets), plot::Rotate3d(PI, Axis=[1,0,0],
plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets, Color
= RGB::Blue.[0.1]) ) ), plot::Scene3d( plot::SurfaceSet(meshList,
MeshListNormals = BeforeFacets), plot::Translate3d([1,1,1],
plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets, Color
= RGB::Blue.[0.1]) ) ), plot::Scene3d( plot::SurfaceSet(meshList,
MeshListNormals = BeforeFacets), plot::Transform3d([0,0,0], [1,0,0,
0,1,0, 0,0,-1], plot::SurfaceSet(meshList, MeshListNormals =
BeforeFacets, Color = RGB::Blue.[0.1]) ) ), Width = 120, Height = 120 ):
```



Parameters

meshlist

The point list: a list of coordinates of type DOM_FLOAT.

`meshlist` is equivalent to the attribute MeshList.

a

Animation parameter, specified as `a = a`$_{min}$`..a`$_{max}$, where `a`$_{min}$ is the initial parameter value, and `a`$_{max}$ is the final parameter value.

Options

MeshListType

Option, specified as `MeshListType = t`

`t` may be `Triangles`, `TriangleFan`, `TriangleStrip`, `Quads` or `QuadStrip`. This attribute specifies the kind of surface mesh given

in `MeshList`. This means it specifies how the point coordinates in `MeshList` are to be interpreted.

MeshListNormals

Option, specified as `MeshListNormals = n`

`n` may be `None`, `BeforePoints`, `BehindPoints`, `BeforeFacets` or `BehindFacets`. This attribute specifies whether `MeshList` contains normal vectors and at which positions they are located.

UseNormals

Option, specified as `UseNormals = b`

`b` may be TRUE or FALSE. This attribute specifies whether the normals defined in the STL file are used for the MuPAD plot.

Algorithms

The normal of a facet (a triangle or quad) given in `MeshList` is used for all its vertices when plotting this object. Due to the fact that some facets may share points with other facets, these points may be specified with different normals.

readbytesplotplot::Surfaceplot::SurfaceSTLplot::Rotate3dplot::Scale3dplot::Transla

plot::SurfaceSTL

Purpose

Import of STL graphics files

Syntax

```
plot::SurfaceSTL(filename, <UseNormals = b>, <a
= a_min .. a_max>, options)
```

Description

`plot::SurfaceSTL(filename)` creates a 3D surface object from the data of a given STL graphics file named "`filename`".

Stereolithography (STL) files were introduced in software by 3D Systems of Valencia, CA, as a simple method of storing information about 3D objects.

STL files contain triangulation data of 3D surfaces. Each triangle is stored as a unit normal and three vertices. The normal and the vertices are specified by three coordinates each, so there is a total of 12 numbers stored for each triangle. Read the 'Background' section of this help page for further details.

Depending on your hardware we recommend to plot STL objects with no more than 50.000 to 150.000 facets (triangles). You should activate the option 'Accelerate OpenGL®' in the VCam options menu.

`plot::SurfaceSTL` reacts to the MuPAD environment variable READPATH. For example, after

```
>> READPATH := READPATH, "C:\\STLFILES":
```

the file '`C:\STLFILES\xyz.stl`' is found by the command

```
>> S := plot::SurfaceSTL("xyz.stl"):
```

Alternatively, the file name can be specified as an absolute pathname:

```
>> S := plot::SurfaceSTL("C:\\STLFILES\\xyz.stl"):
```

If a MuPAD notebook was saved to a file, its location is available inside the notebook as the environment variable `NOTEBOOKPATH`. If your STL file is in the same folder as the notebook, you may call

```
>> S := plot::SurfaceSTL(NOTEBOOKPATH."xyz.stl"):
```

When setting the attribute UseNormals to `FALSE`, the normals defined in the STL graphics file are ignored when plotting the object in MuPAD. This reduces the data volume of the graphics object in the MuPAD session and improves the computing time as well. However, it leads to a slightly less brilliant image. Cf. "Example 2" on page 24-802.

The STL data do not include any color information. Hence, the imported graphics reacts to the usual settings of FillColor, FillColorType etc. for MuPAD surfaces.

Also user-defined color functions LineColorFunction and FillColorFunction can be used to color the imported surface. These functions are called with the index of the current triangle as its first parameter, followed by the *x*, *y*, and *z* coordinate of the current point.

The transformation objects plot::Rotate3d, plot::Scale3d, plot::Translate3d and plot::Transform3d can be applied to the imported STL object. Cf. "Example 7" on page 24-809.

If an object of type `plot::SurfaceSTL` is to be plotted together with other objects, one needs to know the coordinates of the surface objects. To this end, an object `S := plot::SurfaceSTL(...)` provides the methods `S::center` and `S::boundingBox`.

The call `S::center()` returns a list of 3 floating-point values representing the 3D center of the STL object.

The call `S::boundingBox()` returns a list of 3 ranges of floating-point values representing the ranges for the *x*, *y*, and *z* coordinates of the STL surface.

See "Example 2" on page 24-802 and "Example 5" on page 24-807.

`plot::SurfaceSTL::center(S)` and `plot::SurfaceSTL::boundingBox(S)`, respectively, are alternative calls.

Note that the STL graphics file must be read completely for computing these data. Also note that after a first call to `S::center()` or `S::boundingBox()`, the data are not recomputed by these functions even

if the STL object `S` has changed. Use `plot::SurfaceSTL::center(S)`, `plot::SurfaceSTL::boundingBox(S)` in such a case.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	`[0, 0, 1]`
FillColorDirectionX	x-component of the direction of color transitions on surfaces	`0`
FillColorDirectionY	y-component of the direction of color transitions on surfaces	`0`

Attribute	Purpose	Default Value
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
InputFile	input file for import functions	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0

Attribute	Purpose	Default Value
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
MeshVisible	visibility of irregular mesh lines in 3D	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Shading	smooth color blend of surfaces	Smooth
TimeEnd	end time of the animation	10.0

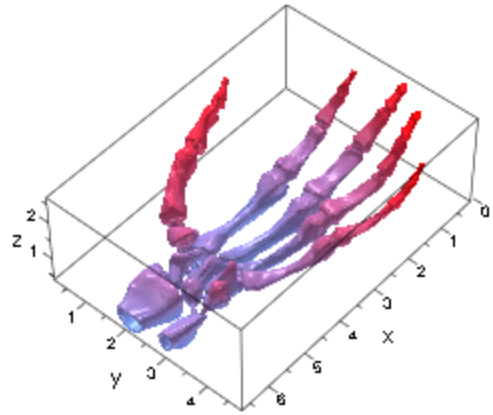
Attribute	Purpose	Default Value
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
UseNormals	use pre-defined normals?	`TRUE`
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

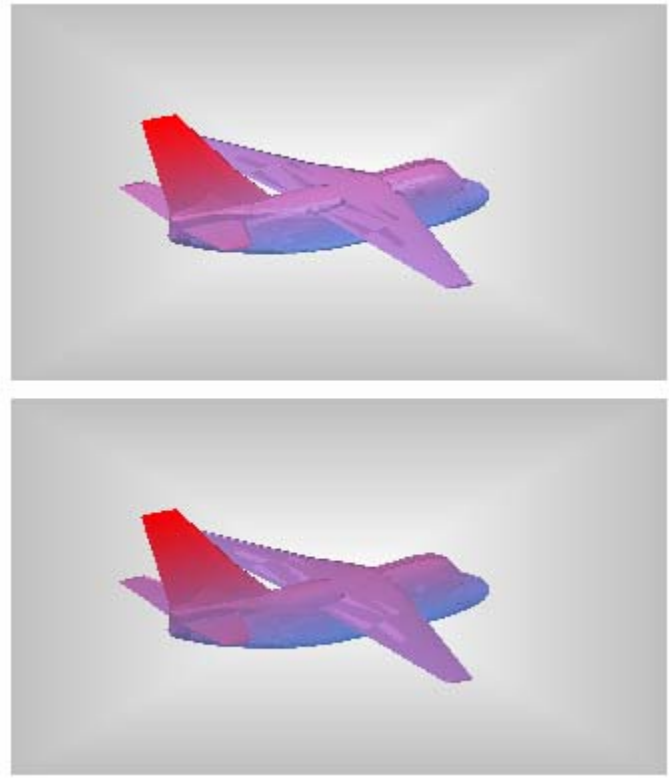
The following imported STL graphics consists of about 110.000 triangles:
plot(plot::SurfaceSTL("hand.stl"), CameraDirection = [15, 13, 22])



Example 2

By default, the normals defined in an STL graphics file are used when plotting the object in MuPAD. Suppressing the use of these normals may reduce the data volume of the graphical object and speed up plotting. However, in general, this leads to slightly less brilliant

images. For comparison, the following STL graphics is plotted with and without using its normals:
S1 := plot::SurfaceSTL("skin.stl"): S2 := plot::SurfaceSTL("skin.stl", UseNormals = FALSE): plot(plot::Scene3d(S1), plot::Scene3d(S2), Layout = Vertical, Width = 120*unit::mm, Height = 140*unit::mm, Axes = None, BackgroundStyle = Pyramid):



We compute the center and the bounding box of the surface:
S1::center()[-422.035, 0.0, 282.1]

[-422.035, 0.0, 282.1]

S1::boundingBox()[-738.07..-106.0, -401.5..401.5, 156.0..408.2]

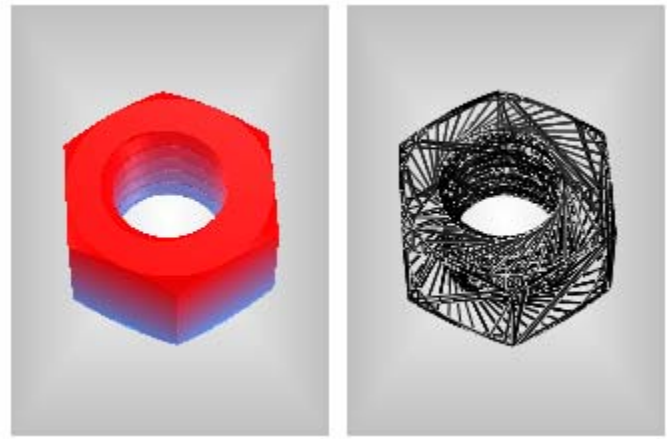
[-738.07..-106.0, -401.5..401.5, 156.0..408.2]

We rotate the object around its center:
plot(plot::Rotate3d(a, S1::center(), [0, 0, 1], S1, a = 0..2*PI), Axes = None)

delete S1, S2:

Example 3

The following STL graphics is displayed as a surface model and as a wireframe model:
nut := plot::SurfaceSTL("nut.stl"): plot(plot::Scene3d(nut, CameraDirection = [10, 15, 30]), plot::Scene3d(nut, CameraDirection = [10, 15, 30], MeshVisible = TRUE, Filled = FALSE, LineColor = RGB::Black), Axes = None, Layout = Horizontal, BackgroundStyle = Pyramid):

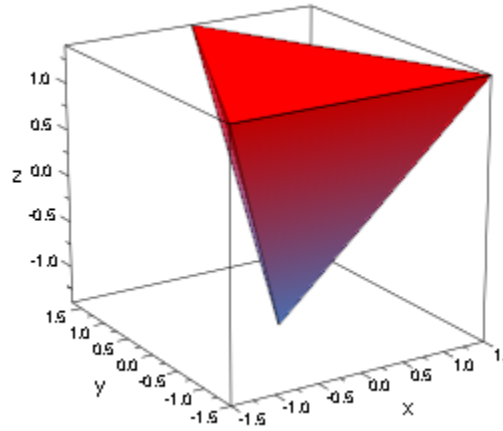


delete nut:

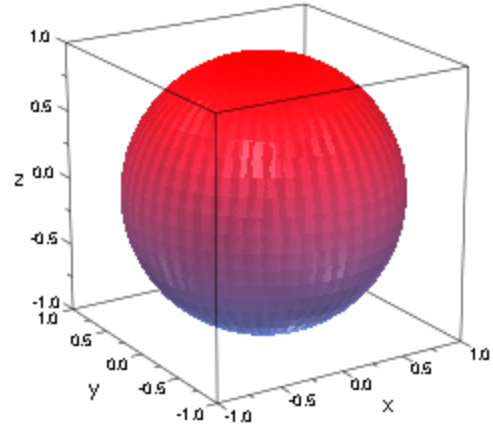
Example 4

For demonstrating further features of STL file import, we first create our own STL graphics file which defines a tetrahedron:
if sysname() = "MSDOS" then stlFile:= "C:\\sample.stl"; else stlFile:= "/tmp/sample.stl": end_if:stdlib::gprof(NIL, stlFile):stlFile := "demo.stl":fprint(Unquoted, Text, stlFile, "SOLID TRI FACET NORMAL 0.0 0.0 -1.0 OUTER LOOP VERTEX -1.5 -1.5 1.4 VERTEX 0.0 1.7 1.4 VERTEX 1.5 -1.5 1.4 ENDLOOP ENDFACET FACET NORMAL 0.0 0.88148 0.472221 OUTER LOOP VERTEX -1.5 -1.5 1.4 VERTEX 1.5 -1.5 1.4 VERTEX 0.0 0.0 -1.4 ENDLOOP ENDFACET FACET NORMAL -0.876814 -0.411007 0.24954 OUTER LOOP VERTEX 1.5 -1.5 1.4 VERTEX 0.0 1.7 1.4 VERTEX 0.0 0.0 -1.4 ENDLOOP ENDFACET FACET NORMAL 0.876814 -0.411007 0.24954 OUTER LOOP VERTEX 0.0 1.7 1.4 VERTEX -1.5 -1.5 1.4 VERTEX 0.0 0.0 -1.4 ENDLOOP ENDFACET ENDSOLID TRI")

This STL graphics file is imported as a MuPAD plot object and rendered:
plot(plot::SurfaceSTL(stlFile, MeshVisible = TRUE)):



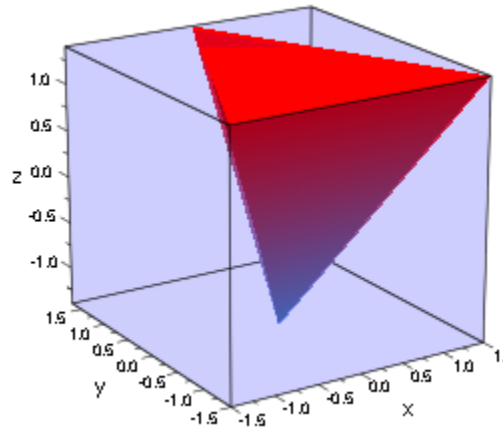
We create another STL file using export::stl. It contains a sphere of radius 1 parametrized by spherical coordinates:
export::stl("sphere.stl", [cos(u)*sin(v), sin(u)*sin(v), cos(v)], u = 0 .. 2*PI, v = 0 .. 2*PI, Mesh = [50, 50], Scaling = Constrained, OutputBox = [-1 .. 1, -1 .. 1, -1 .. 1]):plot(plot::SurfaceSTL("sphere.stl", Scaling = Constrained)):



stdlib::gprof(NIL, "sphere.stl"):

Example 5

We plot the object defined in the STL graphics file of “Example 4” on page 24-805 with its bounding box:
if sysname() = "MSDOS" then stlFile:= "C:\\sample.stl"; else stlFile:= "/tmp/sample.stl": end_if:S := plot::SurfaceSTL(stlFile): plot(S, plot::Box(op(S::boundingBox()), Color = RGB::Blue.[0.1])):



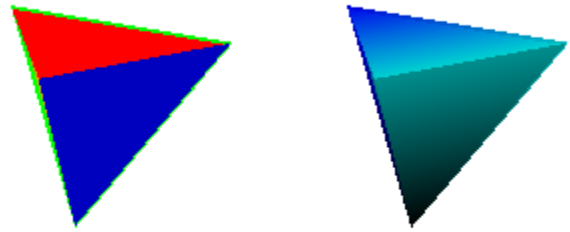
delete S:

Example 6

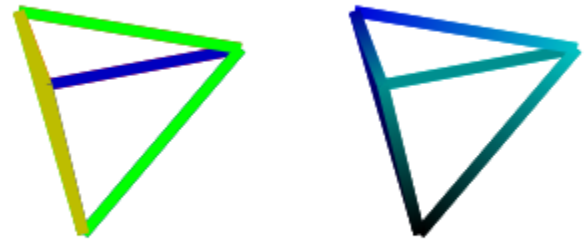
A color function FillColorFunction can be specified. This will be called with the index of the current facet as its first parameter followed by the x-, y- and z-coordinate of the current point.

We use the object defined in the STL graphics file of “Example 4” on page 24-805:
if sysname() = "MSDOS" then stlFile:= "C:\\sample.stl"; else stlFile:= "/tmp/sample.stl": end_if:mycolorlist:= [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]: plot(plot::Scene3d(plot::SurfaceSTL(stlFile, FillColorFunction = proc(n, x, y, z) begin mycolorlist[n] end_proc)), plot::Scene3d(plot::SurfaceSTL(stlFile, FillColorFunction = proc(n, x, y,

z) begin [abs(x)/2, abs(y)/2, abs(z)/2] end_proc)), Axes = None, Layout = Horizontal):



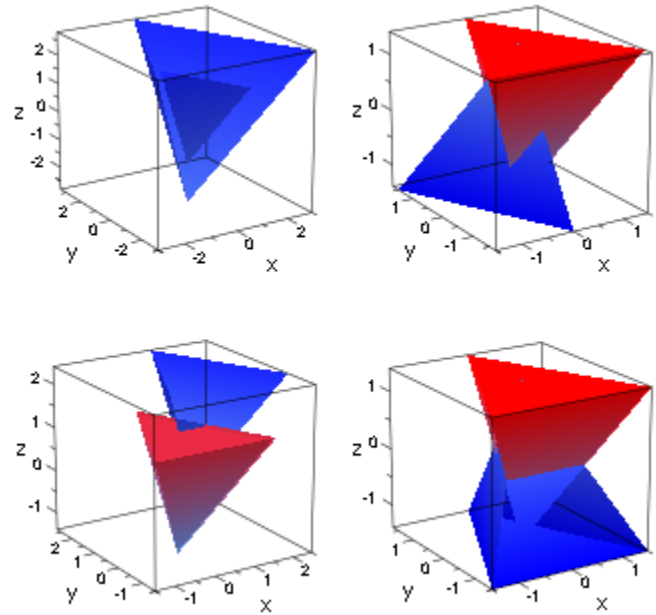
We define a LineColorFunction:
plot(plot::Scene3d(plot::SurfaceSTL(stlFile, LineColorFunction = proc(n, x, y, z) begin mycolorlist[n] end_proc)), plot::Scene3d(plot::SurfaceSTL(stlFile, LineColorFunction = proc(n, x, y, z) begin [abs(x)/2, abs(y)/2, abs(z)/2] end_proc)), Axes = None, Filled = FALSE, MeshVisible = TRUE, LineWidth = 2*unit::mm, Layout = Horizontal):



delete mycolorlist:

Example 7

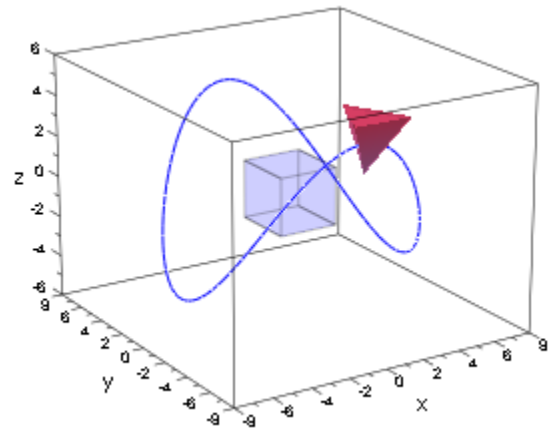
Again, we plot the object of the STL graphics file defined in “Example 4” on page 24-805. Here, we add rotated, scaled and translated copies:
if sysname() = "MSDOS" then stlFile:= "C:\\sample.stl"; else stlFile:= "/tmp/sample.stl": end_if:plot(plot::Scene3d(plot::SurfaceSTL(stlFile), plot::Scale3d([2, 2, 2], plot::SurfaceSTL(stlFile, Color = RGB::Blue.[0.1]))), plot::Scene3d(plot::SurfaceSTL(stlFile), plot::Rotate3d(PI, Axis = [1, 0, 0], plot::SurfaceSTL(stlFile, Color = RGB::Blue.[0.1]))), plot::Scene3d(plot::SurfaceSTL(stlFile), plot::Translate3d([1, 1, 1], plot::SurfaceSTL(stlFile, Color = RGB::Blue.[0.1]))), plot::Scene3d(plot::SurfaceSTL(stlFile), plot::Transform3d([0, 0, 0], [1, 0, 0, 0, 1, 0, 0, 0, -1], plot::SurfaceSTL(stlFile, Color = RGB::Blue.[0.1]))), Width = 120*unit::mm, Height = 120*unit::mm):



Example 8

STL objects can be animated. The tetrahedron defined in “Example 4” on page 24-805 moves around a box:

```
if sysname() = "MSDOS" then stlFile:= "C:\\sample.stl"; else stlFile:=
"/tmp/sample.stl": end_if:SO := plot::SurfaceSTL(stlFile): BO :=
plot::Box(op(SO::boundingBox(SO)), Color = RGB::Blue.[0.1]): GO :=
[6*sin(a), -6*cos(a), 4*cos(2*a)], a = 0..2*PI: CU := plot::Curve3d(GO):
plot(BO, CU, plot::Translate3d(GO, SO), ViewingBox = [-8..8, -8..8,
-6..6]):
```



Below, the color function FillColorFunction of an STL object is animated:
plot(plot::SurfaceSTL(stlFile, MeshVisible = TRUE, LineColor = RGB::Black, FillColorFunction = proc(n, x, y, z) begin [sin(x + a)^2 ,sin(y + a)^2, sin(z + a)^2] end_proc, a = 0..2*PI, TimeRange = 1..4), Axes = None, Layout = Horizontal)

stdlib::gprof(NIL, stlFile): delete stlFile:delete SO, BO, GO, CU, stlFile:

Parameters

filename

The file name: a character string of type DOM_STRING.

`filename` is equivalent to the attribute InputFile.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

Options

UseNormals

Option, specified as `UseNormals = b`

`b` may be TRUE or FALSE. This attribute specifies whether the normals defined in the STL file are used for the MuPAD plot.

Algorithms

The STL sample files presented on this help page were taken from the ftp site of the Clemson University, South Carolina, USA:

ftp.vr.clemson.edu/pub/rp/STL_objects.

There are two storage formats available for STL files, which are ASCII and BINARY. ASCII files are human-readable while BINARY files are smaller and faster to process. Both formats can be read by `plot::SurfaceSTL`. A typical ASCII STL file looks like this:

```
solid sample
 facet normal -4.470293E-02 7.003503E-01 -7.123981E-01
  outer loop
   vertex -2.812284E+00 2.298693E+01 0.000000E+00
   vertex -2.812284E+00 2.296699E+01 -1.960784E-02
   vertex -3.124760E+00 2.296699E+01 0.000000E+00
  endloop
 endfacet
 ...
endsolid sample
```

STL BINARY files have the following format:

```
Bytes  Type   Description
80     ASCII  header, no data significance
4      uint   number of facets in file

4      float  normal  x - start of facet
4      float  normal  y
4      float  normal  z
4      float  vertex1 x
4      float  vertex1 y
4      float  vertex1 z
4      float  vertex2 x
4      float  vertex2 y
4      float  vertex2 z
4      float  vertex3 x
4      float  vertex3 y
4      float  vertex3 z
2      byte   not used  - end of facet
       ...
```

Facet orientation: The facets define the surface of a 3D object. As such, each facet is part of the boundary between the interior and the exterior of the object. The orientation of the facets (which way is "out" and which way is "in") is specified redundantly in two ways which should be consistent. First, the direction of the normal is outward. Second, which is most commonly used nowadays, the facet vertices are listed in counterclockwise order when looking at the object from the outside (right-hand rule).

Vertex-to-vertex rule: Each triangle must share two vertices with each of its adjacent triangles. In other words, a vertex of one triangle cannot lie on the side of another.

Axes: The format specifies that all vertex coordinates must be strictly positive numbers. However, it seems that — with a few exceptions —

most software used today (MuPAD included) allow negative coordinates as well.

Units: The STL file does not contain any scale information; the coordinates may be interpreted in arbitrary units.

Further details about the STL file format are available in the web, e.g., at:

- www.ennex.com/fabbers/StL.asp,
- www.math.iastate.edu/burkardt/data/stl/stl.html and
- rpdrc.ic.polyu.edu.hk/content/stl/stl_introduction.htm.

Collections of STL sample files can be found in the web, e.g., at:

- www.wohlersassociates.com/Software-for-Rapid-Prototyping.html and
- www.cs.duke.edu/~edels/Tubes.

Information about rapid prototyping technologies is available in the web, e.g., at:

www.cs.hut.fi/~ado/rp/rp.html.

Note that MuPAD only accepts the following notations for the keywords "`facet`" and "`vertex`" in STL ASCII files: `facet`, `FACET`, `Facet` and `vertex`, `VERTEX`, `Vertex`, respectively.

The normal of a facet defined in an STL file is used for all its vertices when plotting this object. Due to the fact that some facets (triangles) share points with other ones, these points are plotted with different normals.

plot::Sweep

Purpose

Sweep surface from the deformation of a 3D curve

Syntax

```
plot::Sweep([x_1, y_1, z_1], <Ground = g>, u = u_min ..
u_max, <a = a_min .. a_max>, options)
plot::Sweep(A_1, <Ground = g>, u = u_min .. u_max, <a
= a_min .. a_max>, options)
plot::Sweep(C_1, <Ground = g>, options)
plot::Sweep([x_1, y_1, z_1], [x_2, y_2, z_2], u = u_min ..
u_max, <a = a_min .. a_max>, options)
plot::Sweep(A_1, A_2, u = u_min .. u_max, <a = a_min ..
a_max>, options)
plot::Sweep(C_1, C_2, options)
```

Description

`plot::Sweep([x_1(u), y_1(u), z_1(u)], u = `u_{min}`..`u_{max}`)` creates the surface swept out by the (linear) deformation of the parameterized curve $(x_1(u), y_1(u), z_1(u))$ to its projection $(x_1(u), y_1(u), 0)$ to the x-y-plane.

`plot::Sweep([x_1(u), y_1(u), z_1(u)], [x_2(u), y_2(u), z_2(u)], u = `u_{min}`..`u_{max}`)` creates the surface swept out by the (linear) deformation of the parameterized curve $(x_1(u), y_1(u), z_1(u))$ to the parameterized curve $(x_2(u), y_2(u), z_2(u))$.

`plot::Sweep` creates the parametrized surface

eqsys(x(u, v)=x_1(u)+v*fenced(x_2(u)-x_1(u)), y(u, v)=y_1(u)+v*fenced(y_2(u)-y_1(u)), z(u, v)=z_1(u)+v*fenced(z_2(u)-z_1(u)))

$$x(u, v) = x_1(u) + v\,(x_2(u) - x_1(u))$$

$$y(u, v) = y_1(u) + v\,(y_2(u) - y_1(u))$$

$$z(u, v) = z_1(u) + v\,(z_2(u) - z_1(u))$$

with the two surface parameters u (ranging from u_{min} to u_{max}) and v (ranging from 0 to 1). This is the linear deformation of the curve $(x_1(u),$

$y_1(u)$, $z_1(u)$) defining one border of the surface to the curve ($x_2(u)$, $y_2(u)$, $z_2(u)$) defining the other border of the surface.

If no "target curve" ($x_2(u)$, $y_2(u)$, $z_2(u)$) is specified, the projection $x_2(u) = x_1(u)$, $y_2(u) = y_1(u)$, $z_2(u) = g$ of the "source curve" ($x_1(u)$, $y_1(u)$, $z_1(u)$) to the x-y-plane with constant value $z = g$ is used. The value g is set by the attribute Ground = `g`. The default value is `g = 0`.

When a target curve [$x_2(u)$, $y_2(u)$, $z_2(u)$] is specified, the Ground attribute does not have any effect.

If the curves are specified by objects C_1, C_2 of type plot::Curve3d, the graphical attributes of the object created by `plot::Sweep` are copied from C_1. The parametrization of C_2 is automatically rewritten in terms of the curve parameter used in the definition of C_1. This, however, will only work if the parametrization of C_2 is defined by symbolic expressions.

Note If the parametrization of C_2 is defined by procedures, make sure that the parameter ranges of C_1 and C_2 coincide!

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	`0`
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Color	the main color	`RGB::Black.[0.25]`
DiscontinuitySearch	semi-symbolic search for discontinuities	`TRUE`
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red

Attribute	Purpose	Default Value
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	`[0, 0, 1]`
FillColorDirectionX	x-component of the direction of color transitions on surfaces	`0`
FillColorDirectionY	y-component of the direction of color transitions on surfaces	`0`
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	`1`
Frames	the number of frames in an animation	`50`
Ground	base value	`0`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`TRUE`

Attribute	Purpose	Default Value
LineColor	color of lines	`RGB::Black.[0.25]`
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`0`
LineColorDirectionZ	z-component of the direction of color transitions on lines	`1`
Mesh	number of sample points	`25`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	

Attribute	Purpose	Default Value
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`FALSE`
Submesh	density of submesh (additional sample points)	`4`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	

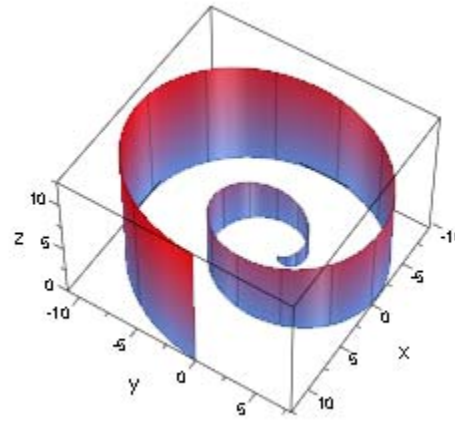
Attribute	Purpose	Default Value
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
ULinesVisible	visibility of parameter lines (u lines)	TRUE
UMax	final value of parameter “u”	
UMesh	number of sample points for parameter “u”	25
UMin	initial value of parameter “u”	
UName	name of parameter “u”	
URange	range of parameter “u”	
USubmesh	density of additional sample points for parameter “u”	4
VLinesVisible	visibility of parameter lines (v lines)	TRUE
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction1	parametrization of the curves in sweep surfaces	
XFunction2	parametrization of the curves in sweep surfaces	
YFunction1	parametrization of the curves in sweep surfaces	
YFunction2	parametrization of the curves in sweep surfaces	
ZFunction1	parametrization of the curves in sweep surfaces	
ZFunction2	parametrization of the curves in sweep surfaces	

Examples

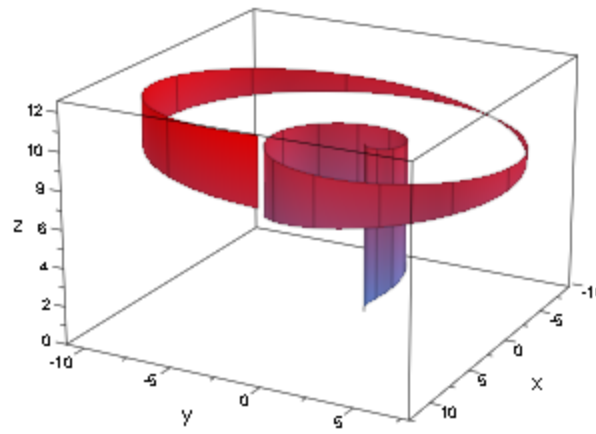
Example 1

We deform a 3D spiral to its projection to the *x*-*y*-plane:
plot(plot::Sweep([u*cos(u), u*sin(u), u], u = 0..4*PI), CameraDirection = [90, 50, 120])



We use the Ground attribute to project the spiral to the *x*-*y*-plane with *z* = 9:

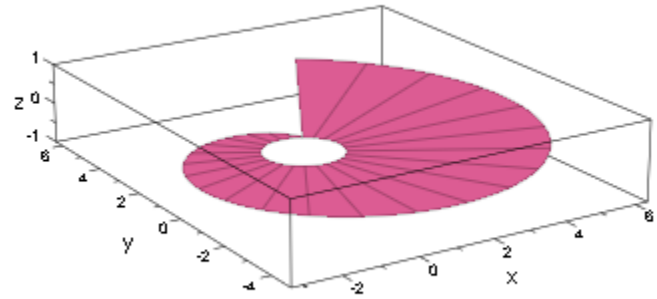
```
plot(plot::Sweep([u*cos(u), u*sin(u), u], u = 0..4*PI, Ground = 9),
CameraDirection = [130, 60, 45])
```



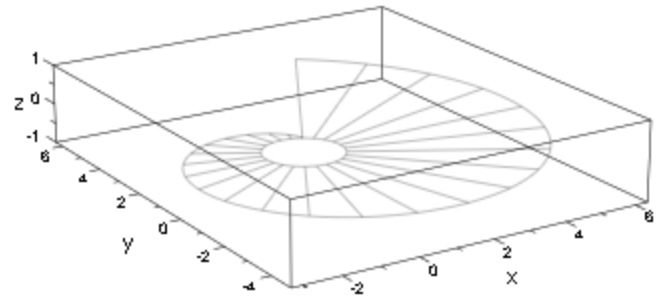
Example 2

We deform a circle in the *x*-*y*-plane to a planar spiral:

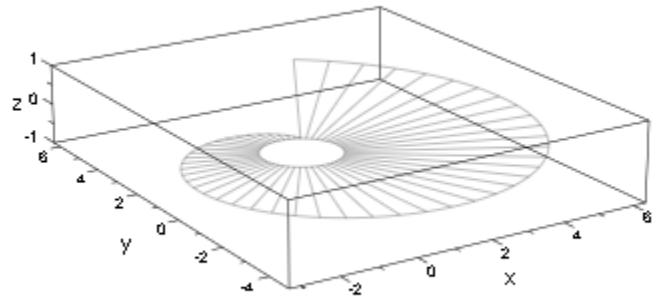
plot(plot::Sweep([cos(u), sin(u), 0], [u*cos(u), u*sin(u), 0], u = PI/3..7/3*PI), Scaling = Constrained)



With Filled = FALSE, only the lines are visible along which the mesh points of the curves are moved:
plot(plot::Sweep([cos(u), sin(u), 0], [u*cos(u), u*sin(u), 0], u = PI/3..7/3*PI), Scaling = Constrained, Filled = FALSE)

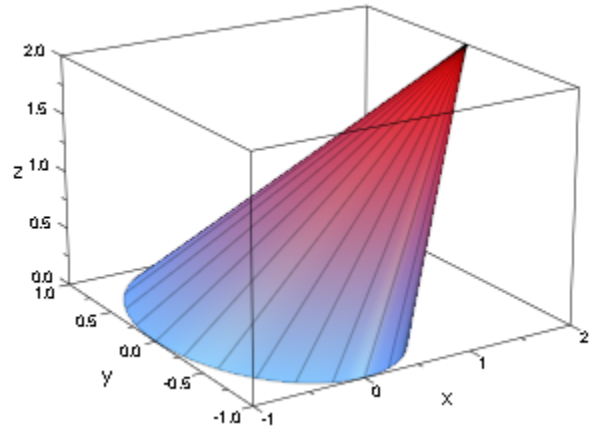


We increase the number of mesh points:
plot(plot::Sweep([cos(u), sin(u), 0], [u*cos(u), u*sin(u), 0], u = PI/3..7/3*PI, Mesh = 50), Scaling = Constrained, Filled = FALSE)



Example 3

We deform a circle to an animated point. The resulting sweep surface is an animated cone:
plot(plot::Sweep([cos(u), sin(u), 0], [a, 0, a], u = 0..2*PI, a = 0..2))



Parameters

x_1

y_1

z_1

The parametrization of the initial 3D curve: real-valued expressions in u (and possibly the animation parameter).

x_1, y_1, z_1 are equivalent to the attributes XFunction1, YFunction1, ZFunction1.

x_2

y_2

z_2

The parametrization of the "target curve": real-valued expressions in u (and possibly the animation parameter).

x_2, y_2, z_2 are equivalent to the attributes XFunction2, YFunction2, ZFunction2.

u

The curve parameter: an identifier or an indexed identifier.

u is equivalent to the attribute UName.

u_{min}

u_{max}

Real-valued expressions (possibly in the animation parameter).

u_{min}, u_{max} are equivalent to the attributes UMin, UMax.

g

Real-valued expression (possibly in the animation parameter).

g is equivalent to the attribute Ground.

A_1

A_2

matrices of category Cat::Matrix with three entries that provide the parametrizations x_1, y_1, z_1 and x_2, y_2, z_2, respectively.

C_1

C_2

Curves of type plot::Curve3d. C_1 provides the "initial curve" $[x_1, y_1, z_1]$, C_2 provides the "target curve" $[x_2, y_2, z_2]$.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::Curve3dplot::Polygon3dplot::Surfaceplot::Hatch

plot::Tetrahedron

Purpose

Regular Tetrahedra

Syntax

```
plot::Tetrahedron(<a = a_min .. a_max>, options)
```

Description

`plot::Tetrahedron()` creates regular polyhedra.

Per default, all polyhedra are centered at the origin. The attribute Center allows to choose a different center. This is helpful to align the polyhedra relative to other objects in the graphical scene. Cf. “Example 1” on page 24-832.

All polyhedra fit into a box extending from -1 to 1 in all coordinate directions. Their size can be changed by the attribute Radius. In case of a hexahedron (a box), this attribute represents the radius of the inscribed sphere. For the other polyhedra, it is the radius of the circumscribed sphere.

The default value of Radius is 1 for all polyhedra.

Further to the attributes Center and Radius, you can modify the polyhedra by applying transformation objects of type plot::Rotate3d, plot::Scale3d, plot::Translate3d , and plot::Transform3d. Cf. “Example 3” on page 24-834.

User-defined color functions (LineColorFunction, FillColorFunction) are called with the index of the current facet as its first parameter, followed by the *x*, *y*, and *z* coordinate of the current point, followed by the current value of the animation parameter (if animated). Cf. “Example 4” on page 24-835.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Center	center of objects, rotation center	`[0, 0, 0]`

Attribute	Purpose	Default Value
CenterX	center of objects, rotation center, x-component	`0`
CenterY	center of objects, rotation center, y-component	`0`
CenterZ	center of objects, rotation center, z-component	`0`
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	`[0, 0, 1]`
FillColorDirectionX	x-component of the direction of color transitions on surfaces	`0`

Attribute	Purpose	Default Value
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend

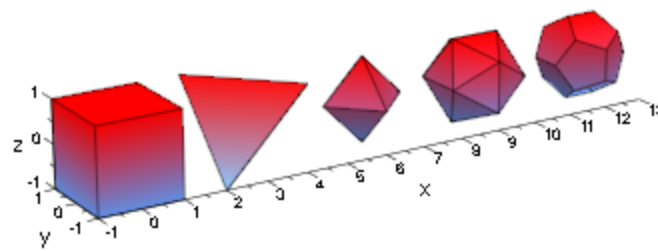
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

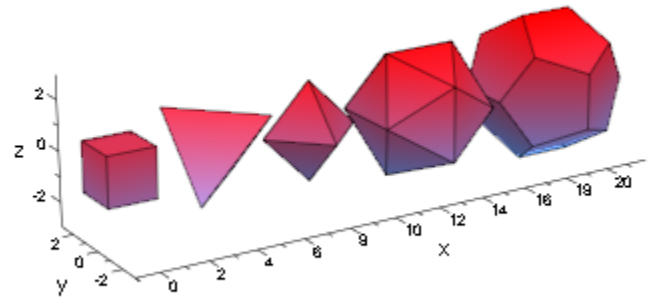
Example 1

Using different Centers, the five regular polyhedra are placed side by side:
plot(plot::Hexahedron (Center = [0, 0, 0]), plot::Tetrahedron (Center = [3, 0, 0]), plot::Octahedron (Center = [6, 0, 0]), plot::Icosahedron (Center = [9, 0, 0]), plot::Dodecahedron(Center = [12, 0, 0]), Axes = Frame);



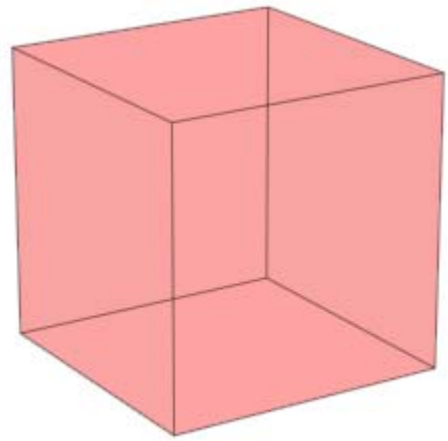
With the attribut Radius, the size of the polyhydra can be changed:
plot(plot::Hexahedron (Radius = 1.0, Center = [0, 0, 0]), plot::Tetrahedron (Radius = 1.5, Center = [4, 0, 0]), plot::Octahedron (Radius = 2.0, Center = [8, 0, 0]), plot::Icosahedron (Radius = 2.5,

Center = [13, 0, 0]), plot::Dodecahedron(Radius = 3.0, Center = [19, 0, 0]), Axes = Frame);



Example 2

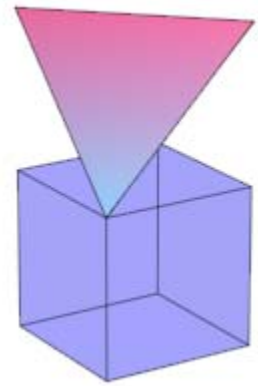
A tetrahedron and an octahedron are embedded in a hexahedron:
plot(plot::Hexahedron (FillColorFunction = RGB::Red.[0.2], VisibleFromTo = 0..8), plot::Tetrahedron(FillColorFunction = RGB::Green.[0.2], VisibleFromTo = 1..5), plot::Octahedron (FillColorFunction = RGB::Blue.[0.2], VisibleFromTo = 3..7), Axes = None)



Example 3

Transformation objects can be applied to polyhedra as demonstrated below:

```
H := plot::Hexahedron(Color = RGB::Blue.[0.2], FillColorType = Flat):
T := plot::Tetrahedron(Color = RGB::Red): plot(plot::Rotate3d(a, [0,
0, 0], [0, 0, 1], a = 0..2*PI, H, plot::Translate3d([0, 0, a], T, a = 0..2)
), Axes = None)
```

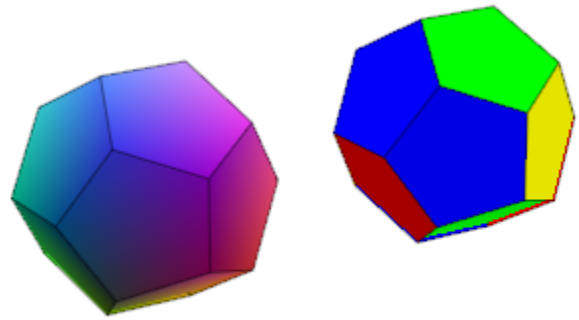


delete T, H:

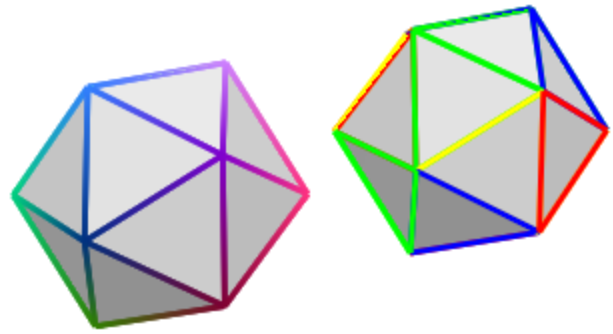
Example 4

A FillColorFunction can be specified. This will be called with the index of the current facet as its first parameter, followed by the *x*-, *y*- and *z*-coordinate of the current point:

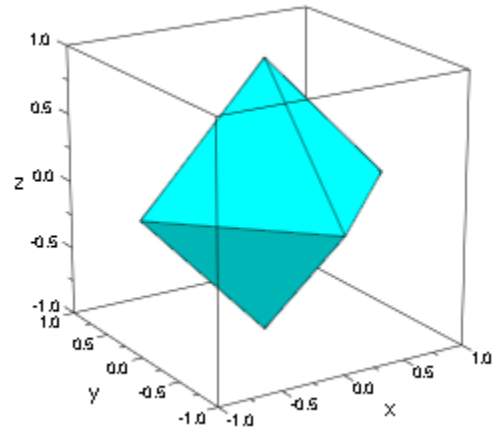
```
mycolorlist := [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]:
plot(plot::Dodecahedron(Center = [0, 0, 0], FillColorFunction =
proc(n, x, y, z) begin [(1 + x)/2, (1 + y)/2, (1 + z)/2] end_proc),
plot::Dodecahedron(Center = [3, 0, 0], FillColorFunction = proc(n, x, y,
z) begin mycolorlist[(n mod 4)+1] end_proc), Axes = None):
```



The same holds true for a LineColorFunction:
plot(plot::Icosahedron(Center = [0, 0, 0], LineColorFunction =
proc(n, x, y, z) begin [(1 + x)/2, (1 + y)/2, (1 + z)/2] end_proc),
plot::Icosahedron(Center = [3, 0, 0], LineColorFunction = proc(n, x, y, z)
begin mycolorlist[(n mod 4)+1] end_proc), Axes = None, LineWidth =
1.0*unit::mm, FillColor = RGB::Grey80, FillColorType = Flat):



If the polyhedron is animated, the color functions are called with an additional argument: the current value of the animation parameter:
plot(plot::Octahedron(FillColorFunction = proc(n, x, y, z, a) begin [sin(n*a)^2, cos(n*a)^2, 1]: end_proc, a = 0..2*PI))



delete mycolorlist:

Algorithms

A polyhedron is called regular if all its facets consist of the same regular polygon and each vertex has the same number of coincidence polygons.

Since Plato we know that only five regular polyhedrons exist:

- the tetrahedron with 4 (greek *tetra*) triangles,
- the hexahedron with 6 (greek *hexa*) squares,
- the octahedron with 8 (greek *okta*) triangles,
- the dodecahedron with 12 (greek *dodeka*) pentagons and
- the icosahedron with 20 (greek *eikosi*) triangles.

The following table lists some important geometrical data of the polyhedra with the edge length a. Where R is the radius of the outer

spherem r the radius of the inner sphere, A the surface area and V the volume:

	tetra-	hexa-	octa-	dodeca-	icosahedron
R/a	(1)/(4)*sqrt(6)	(1)/(2)*sqrt(3)	(1)/(2)*sqrt(2)	(1)/(4)*sqrt(3)*fenced(1+sqrt(5))	(1)/(4)*sqrt(10+2*sqrt(5))
r/a	(1)/(12)*sqrt(6)	(1)/(2)	(1)/(6)*sqrt(6)	(1)/(20)*sqrt(250+110*sqrt(5))	(1)/(12)*sqrt(3)*fenced(3+s
A/a^2	sqrt(3)	6	2*sqrt(3)	3*sqrt(25+10*sqrt(5))	5*sqrt(3)
V/a^3	(1)/(12)*sqrt(2)	1	(1)/(3)*sqrt(2)	(1)/(4)*fenced(15+7*sqrt(5))	(5)/(12)*fenced(3+sqrt(5))

plot::Hexahedron

Purpose

Regular Hexahedra

Syntax

```
plot::Hexahedron(<a = a_min .. a_max>, options)
```

Description

`plot::Hexahedron()` creates regular polyhedra.

Per default, all polyhedra are centered at the origin. The attribute Center allows to choose a different center. This is helpful to align the polyhedra relative to other objects in the graphical scene. Cf. “Example 1” on page 24-844.

All polyhedra fit into a box extending from -1 to 1 in all coordinate directions. Their size can be changed by the attribute Radius. In case of a hexahedron (a box), this attribute represents the radius of the inscribed sphere. For the other polyhedra, it is the radius of the circumscribed sphere.

The default value of Radius is 1 for all polyhedra.

Further to the attributes Center and Radius, you can modify the polyhedra by applying transformation objects of type plot::Rotate3d, plot::Scale3d, plot::Translate3d , and plot::Transform3d. Cf. “Example 3” on page 24-846.

User-defined color functions (LineColorFunction, FillColorFunction) are called with the index of the current facet as its first parameter, followed by the *x*, *y*, and *z* coordinate of the current point, followed by the current value of the animation parameter (if animated). Cf. “Example 4” on page 24-847.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`

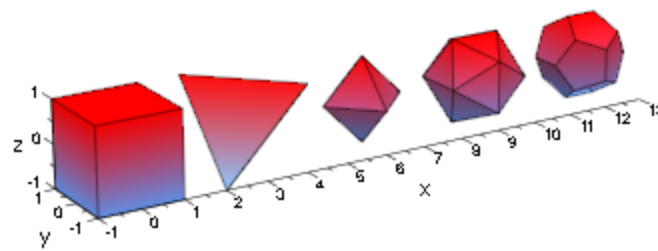
Examples

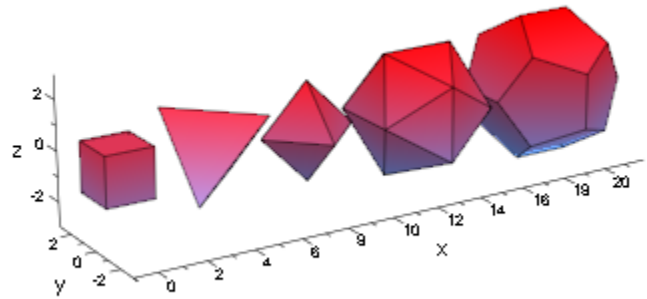
Example 1

Using different Centers, the five regular polyhedra are placed side by side:
plot(plot::Hexahedron (Center = [0, 0, 0]), plot::Tetrahedron (Center = [3, 0, 0]), plot::Octahedron (Center = [6, 0, 0]), plot::Icosahedron (Center = [9, 0, 0]), plot::Dodecahedron(Center = [12, 0, 0]), Axes = Frame);



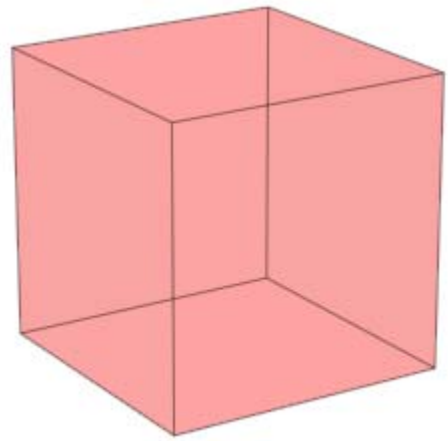
With the attribut Radius, the size of the polyhydra can be changed:
plot(plot::Hexahedron (Radius = 1.0, Center = [0, 0, 0]), plot::Tetrahedron (Radius = 1.5, Center = [4, 0, 0]), plot::Octahedron (Radius = 2.0, Center = [8, 0, 0]), plot::Icosahedron (Radius = 2.5,

Center = [13, 0, 0]), plot::Dodecahedron(Radius = 3.0, Center = [19, 0, 0]), Axes = Frame);



Example 2

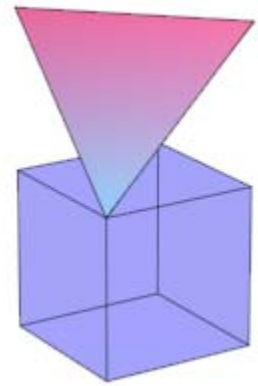
A tetrahedron and an octahedron are embedded in a hexahedron:
plot(plot::Hexahedron (FillColorFunction = RGB::Red.[0.2], VisibleFromTo = 0..8), plot::Tetrahedron(FillColorFunction = RGB::Green.[0.2], VisibleFromTo = 1..5), plot::Octahedron (FillColorFunction = RGB::Blue.[0.2], VisibleFromTo = 3..7), Axes = None)



Example 3

Transformation objects can be applied to polyhedra as demonstrated below:

```
H := plot::Hexahedron(Color = RGB::Blue.[0.2], FillColorType = Flat):
T := plot::Tetrahedron(Color = RGB::Red): plot(plot::Rotate3d(a, [0,
0, 0], [0, 0, 1], a = 0..2*PI, H, plot::Translate3d([0, 0, a], T, a = 0..2)
), Axes = None)
```

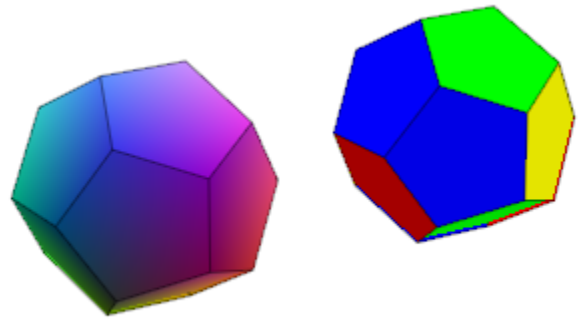


delete T, H:

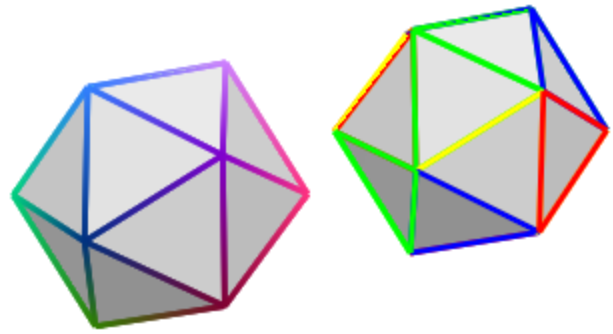
Example 4

A FillColorFunction can be specified. This will be called with the index of the current facet as its first parameter, followed by the *x*-, *y*- and *z*-coordinate of the current point:

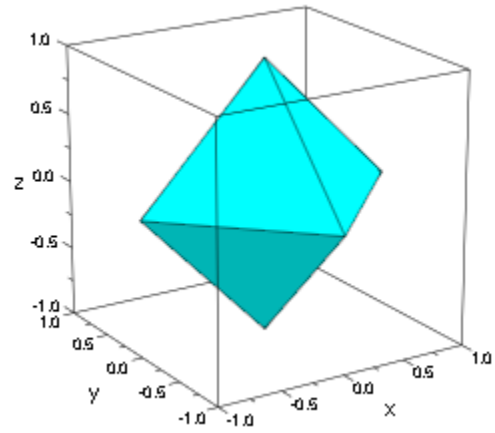
```
mycolorlist := [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]:
plot(plot::Dodecahedron(Center = [0, 0, 0], FillColorFunction =
proc(n, x, y, z) begin [(1 + x)/2, (1 + y)/2, (1 + z)/2] end_proc),
plot::Dodecahedron(Center = [3, 0, 0], FillColorFunction = proc(n, x, y,
z) begin mycolorlist[(n mod 4)+1] end_proc), Axes = None):
```



The same holds true for a LineColorFunction:
plot(plot::Icosahedron(Center = [0, 0, 0], LineColorFunction =
proc(n, x, y, z) begin [(1 + x)/2, (1 + y)/2, (1 + z)/2] end_proc),
plot::Icosahedron(Center = [3, 0, 0], LineColorFunction = proc(n, x, y, z)
begin mycolorlist[(n mod 4)+1] end_proc), Axes = None, LineWidth =
1.0*unit::mm, FillColor = RGB::Grey80, FillColorType = Flat):



If the polyhedron is animated, the color functions are called with an additional argument: the current value of the animation parameter:
plot(plot::Octahedron(FillColorFunction = proc(n, x, y, z, a) begin [sin(n*a)^2, cos(n*a)^2, 1]: end_proc, a = 0..2*PI))



delete mycolorlist:

Algorithms

A polyhedron is called regular if all its facets consist of the same regular polygon and each vertex has the same number of coincidence polygons.

Since Plato we know that only five regular polyhedrons exist:

- the tetrahedron with 4 (greek *tetra*) triangles,
- the hexahedron with 6 (greek *hexa*) squares,
- the octahedron with 8 (greek *okta*) triangles,
- the dodecahedron with 12 (greek *dodeka*) pentagons and
- the icosahedron with 20 (greek *eikosi*) triangles.

The following table lists some important geometrical data of the polyhedra with the edge length a. Where R is the radius of the outer

spherem r the radius of the inner sphere, A the surface area and V the volume:

	tetra-	hexa-	octa-	dodeca-	icosahedron
R/a	(1)/(4)*sqrt(6)	1	(1)/(2)*sqrt(2)	(1)/(4)*sqrt(3)*fenced(1+sqrt(5))	(1)/(4)*sqrt(10+2*sqrt(5))
r/a	(1)/(12)*sqrt(6)	(1)/(2)	(1)/(6)*sqrt(6)	(1)/(20)*sqrt(250+110*sqrt(5))	(1)/(12)*sqrt(3)*fenced(3+s
A/a^2	sqrt(3)	6	2*sqrt(3)	3*sqrt(25+10*sqrt(5))	5*sqrt(3)
V/a^3	(1)/(12)*sqrt(2)	1	(1)/(3)*sqrt(2)	(1)/(4)*fenced(7+3*sqrt(5))	(5)/(12)*fenced(3+sqrt(5))

plotplot::Tetrahedronplot::Octahedronplot::Dodecahedronplot::Icosahedronplot::Boxplot

plot::Octahedron

Purpose

Regular Octahedra

Syntax

`plot::Octahedron(<a = a_min .. a_max>, options)`

Description

`plot::Octahedron()` creates regular polyhedra.

Per default, all polyhedra are centered at the origin. The attribute Center allows to choose a different center. This is helpful to align the polyhedra relative to other objects in the graphical scene. Cf. “Example 1” on page 24-856.

All polyhedra fit into a box extending from -1 to 1 in all coordinate directions. Their size can be changed by the attribute Radius. In case of a hexahedron (a box), this attribute represents the radius of the inscribed sphere. For the other polyhedra, it is the radius of the circumscribed sphere.

The default value of Radius is 1 for all polyhedra.

Further to the attributes Center and Radius, you can modify the polyhedra by applying transformation objects of type plot::Rotate3d, plot::Scale3d, plot::Translate3d , and plot::Transform3d. Cf. “Example 3” on page 24-858.

User-defined color functions (LineColorFunction, FillColorFunction) are called with the index of the current facet as its first parameter, followed by the *x*, *y*, and *z* coordinate of the current point, followed by the current value of the animation parameter (if animated). Cf. “Example 4” on page 24-859.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Center	center of objects, rotation center	`[0, 0, 0]`

Attribute	Purpose	Default Value
CenterX	center of objects, rotation center, x-component	`0`
CenterY	center of objects, rotation center, y-component	`0`
CenterZ	center of objects, rotation center, z-component	`0`
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	`[0, 0, 1]`
FillColorDirectionX	x-component of the direction of color transitions on surfaces	`0`

Attribute	Purpose	Default Value
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]

Attribute	Purpose	Default Value
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Radius	radius of circles, spheres etc.	1
Shading	smooth color blend of surfaces	Smooth

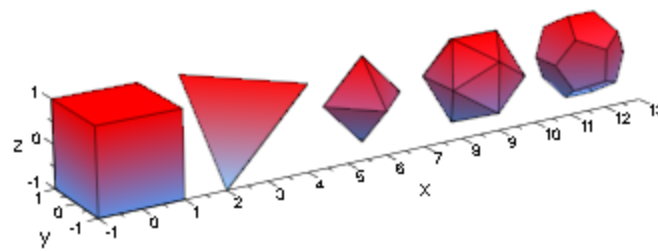
Attribute	Purpose	Default Value
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

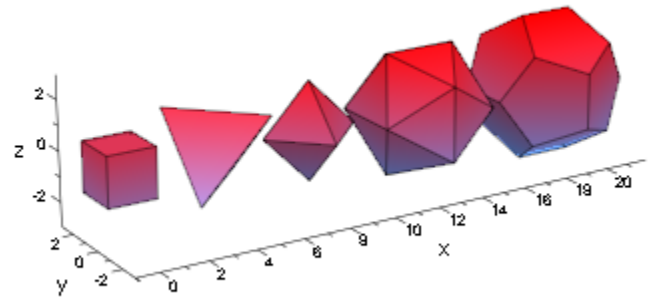
Example 1

Using different Centers, the five regular polyhedra are placed side by side:
plot(plot::Hexahedron (Center = [0, 0, 0]), plot::Tetrahedron (Center = [3, 0, 0]), plot::Octahedron (Center = [6, 0, 0]), plot::Icosahedron (Center = [9, 0, 0]), plot::Dodecahedron(Center = [12, 0, 0]), Axes = Frame);



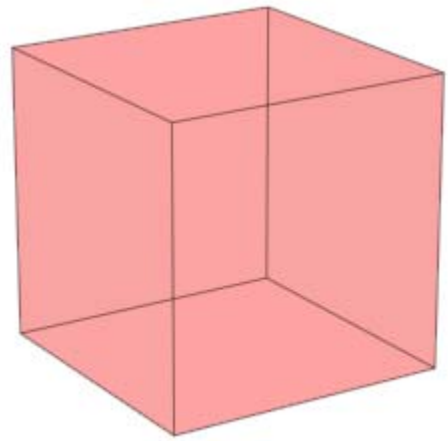
With the attribut Radius, the size of the polyhydra can be changed:
plot(plot::Hexahedron (Radius = 1.0, Center = [0, 0, 0]), plot::Tetrahedron (Radius = 1.5, Center = [4, 0, 0]), plot::Octahedron (Radius = 2.0, Center = [8, 0, 0]), plot::Icosahedron (Radius = 2.5,

Center = [13, 0, 0]), plot::Dodecahedron(Radius = 3.0, Center = [19, 0, 0]), Axes = Frame);



Example 2

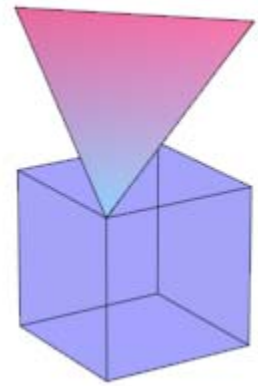
A tetrahedron and an octahedron are embedded in a hexahedron:
plot(plot::Hexahedron (FillColorFunction = RGB::Red.[0.2], VisibleFromTo = 0..8), plot::Tetrahedron(FillColorFunction = RGB::Green.[0.2], VisibleFromTo = 1..5), plot::Octahedron (FillColorFunction = RGB::Blue.[0.2], VisibleFromTo = 3..7), Axes = None)



Example 3

Transformation objects can be applied to polyhedra as demonstrated below:

```
H := plot::Hexahedron(Color = RGB::Blue.[0.2], FillColorType = Flat):
T := plot::Tetrahedron(Color = RGB::Red): plot(plot::Rotate3d(a, [0,
0, 0], [0, 0, 1], a = 0..2*PI, H, plot::Translate3d([0, 0, a], T, a = 0..2)
), Axes = None)
```

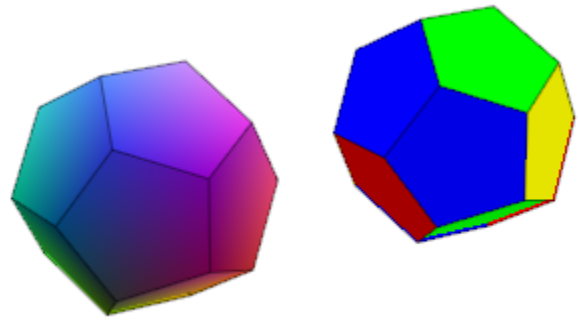


delete T, H:

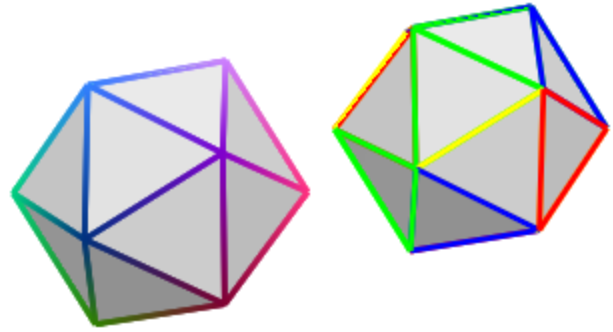
Example 4

A FillColorFunction can be specified. This will be called with the index of the current facet as its first parameter, followed by the *x*-, *y*- and *z*-coordinate of the current point:

```
mycolorlist := [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]:
plot(plot::Dodecahedron(Center = [0, 0, 0], FillColorFunction =
proc(n, x, y, z) begin [(1 + x)/2, (1 + y)/2, (1 + z)/2] end_proc),
plot::Dodecahedron(Center = [3, 0, 0], FillColorFunction = proc(n, x, y,
z) begin mycolorlist[(n mod 4)+1] end_proc), Axes = None):
```



The same holds true for a LineColorFunction:
plot(plot::Icosahedron(Center = [0, 0, 0], LineColorFunction =
proc(n, x, y, z) begin [(1 + x)/2, (1 + y)/2, (1 + z)/2] end_proc),
plot::Icosahedron(Center = [3, 0, 0], LineColorFunction = proc(n, x, y, z)
begin mycolorlist[(n mod 4)+1] end_proc), Axes = None, LineWidth =
1.0*unit::mm, FillColor = RGB::Grey80, FillColorType = Flat):



If the polyhedron is animated, the color functions are called with an additional argument: the current value of the animation parameter:
plot(plot::Octahedron(FillColorFunction = proc(n, x, y, z, a) begin [sin(n*a)^2, cos(n*a)^2, 1]: end_proc, a = 0..2*PI))

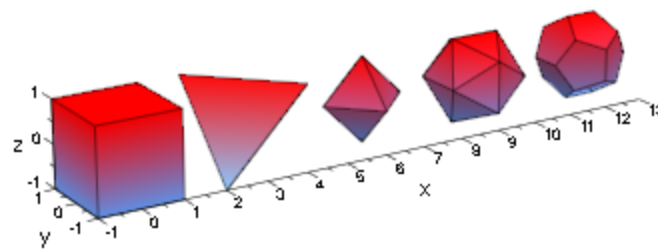
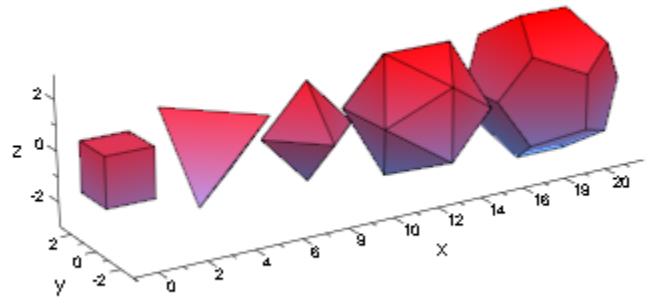
Example 1

Using different Centers, the five regular polyhedra are placed side by side:
plot(plot::Hexahedron (Center = [0, 0, 0]), plot::Tetrahedron (Center = [3, 0, 0]), plot::Octahedron (Center = [6, 0, 0]), plot::Icosahedron (Center = [9, 0, 0]), plot::Dodecahedron(Center = [12, 0, 0]), Axes = Frame);



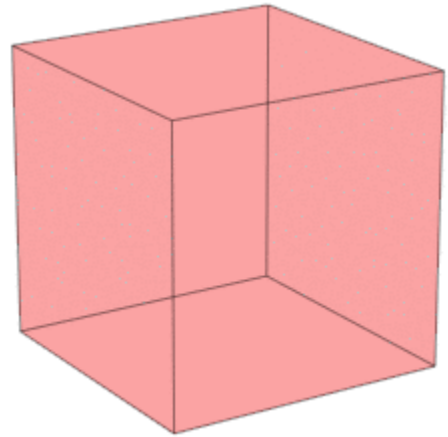
With the attribut Radius, the size of the polyhydra can be changed:
plot(plot::Hexahedron (Radius = 1.0, Center = [0, 0, 0]), plot::Tetrahedron (Radius = 1.5, Center = [4, 0, 0]), plot::Octahedron (Radius = 2.0, Center = [8, 0, 0]), plot::Icosahedron (Radius = 2.5,

Center = [13, 0, 0]), plot::Dodecahedron(Radius = 3.0, Center = [19, 0, 0]), Axes = Frame);



Example 2

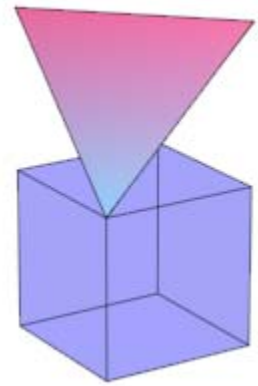
A tetrahedron and an octahedron are embedded in a hexahedron:
plot(plot::Hexahedron (FillColorFunction = RGB::Red.[0.2], VisibleFromTo = 0..8), plot::Tetrahedron(FillColorFunction = RGB::Green.[0.2], VisibleFromTo = 1..5), plot::Octahedron (FillColorFunction = RGB::Blue.[0.2], VisibleFromTo = 3..7), Axes = None)



Example 3

Transformation objects can be applied to polyhedra as demonstrated below:

```
H := plot::Hexahedron(Color = RGB::Blue.[0.2], FillColorType = Flat):
T := plot::Tetrahedron(Color = RGB::Red): plot(plot::Rotate3d(a, [0,
0, 0], [0, 0, 1], a = 0..2*PI, H, plot::Translate3d([0, 0, a], T, a = 0..2)
), Axes = None)
```

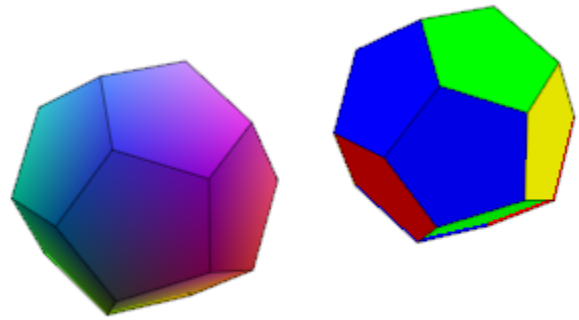


delete T, H:

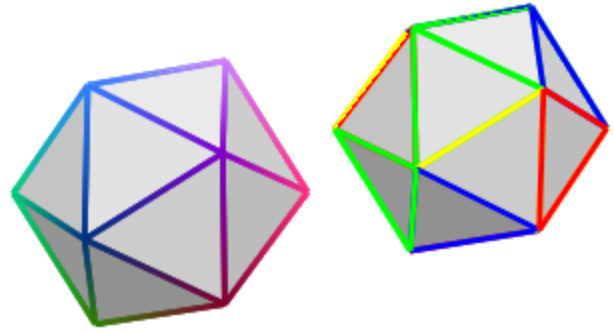
Example 4

A FillColorFunction can be specified. This will be called with the index of the current facet as its first parameter, followed by the *x*-, *y*- and *z*-coordinate of the current point:

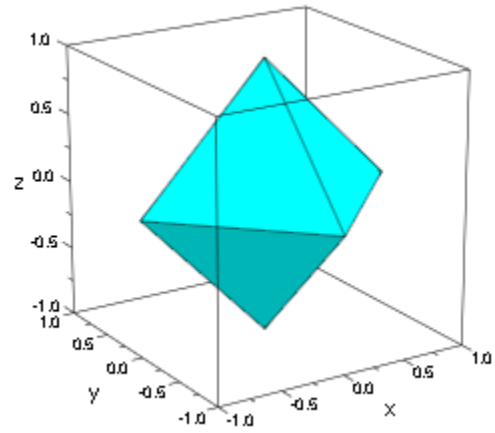
```
mycolorlist := [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]:
plot(plot::Dodecahedron(Center = [0, 0, 0], FillColorFunction =
proc(n, x, y, z) begin [(1 + x)/2, (1 + y)/2, (1 + z)/2] end_proc),
plot::Dodecahedron(Center = [3, 0, 0], FillColorFunction = proc(n, x, y,
z) begin mycolorlist[(n mod 4)+1] end_proc), Axes = None):
```



The same holds true for a LineColorFunction:
plot(plot::Icosahedron(Center = [0, 0, 0], LineColorFunction =
proc(n, x, y, z) begin [(1 + x)/2, (1 + y)/2, (1 + z)/2] end_proc),
plot::Icosahedron(Center = [3, 0, 0], LineColorFunction = proc(n, x, y, z)
begin mycolorlist[(n mod 4)+1] end_proc), Axes = None, LineWidth =
1.0*unit::mm, FillColor = RGB::Grey80, FillColorType = Flat):



If the polyhedron is animated, the color functions are called with an additional argument: the current value of the animation parameter:
plot(plot::Octahedron(FillColorFunction = proc(n, x, y, z, a) begin [sin(n*a)^2, cos(n*a)^2, 1]: end_proc, a = 0..2*PI))



delete mycolorlist:

Algorithms

A polyhedron is called regular if all its facets consist of the same regular polygon and each vertex has the same number of coincidence polygons.

Since Plato we know that only five regular polyhedrons exist:

- the tetrahedron with 4 (greek *tetra*) triangles,
- the hexahedron with 6 (greek *hexa*) squares,
- the octahedron with 8 (greek *okta*) triangles,
- the dodecahedron with 12 (greek *dodeka*) pentagons and
- the icosahedron with 20 (greek *eikosi*) triangles.

The following table lists some important geometrical data of the polyhedra with the edge length a. Where R is the radius of the outer

sphere, *r* the radius of the inner sphere, *A* the surface area and *V* the volume:

	tetra-	hexa-	octa-	dodeca-	icosahedron
R/a	(1)/(4)*sqrt(6)	(1)/(2)*sqrt(3)	(1)/(2)*sqrt(2)	(1)/(4)*sqrt(3)*fenced(1+sqrt(5))	(1)/(4)*sqrt(10+2*sqrt(5))
r/a	(1)/(12)*sqrt(6)	(1)/(2)	(1)/(6)*sqrt(6)	(1)/(20)*sqrt(250+110*sqrt(5))	(1)/(12)*sqrt(3)*fenced(3+s
A/a^2	sqrt(3)	6	2*sqrt(3)	3*sqrt(25+10*sqrt(5))	5*sqrt(3)
V/a^3	(1)/(12)*sqrt(2)	1	(1)/(3)*sqrt(2)	(1)/(4)*fenced(15+7*sqrt(5))	(5)/(12)*fenced(3+sqrt(5))

plot::Text2d

Purpose

2D text

Syntax

```
plot::Text2d(text, [x, y], <a = a_min .. a_max>, options)
```

Description

`plot::Text2d` draws a text at a given position (*x*, *y*) (the "anchor point"). The attributes VerticalAlignment and HorizontalAlignment determine the alignment of the text w.r.t. its anchor.

Size, text color, font type etc. are controlled by the attribute TextFont.

A text may consist of several lines. The newline character in MuPAD strings ist `\n`. For example: `"first line\nsecond line"`.

The attribute TextRotation allows to rotate the text on the screen.

The text of a text object can be animated if it is passed as a procedure that returns the text string during runtime. Cf. "Example 5" on page 24-892.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Frames	the number of frames in an animation	`50`
HorizontalAlignment	horizontal alignment of text objects w.r.t. their coordinates	`Left`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`

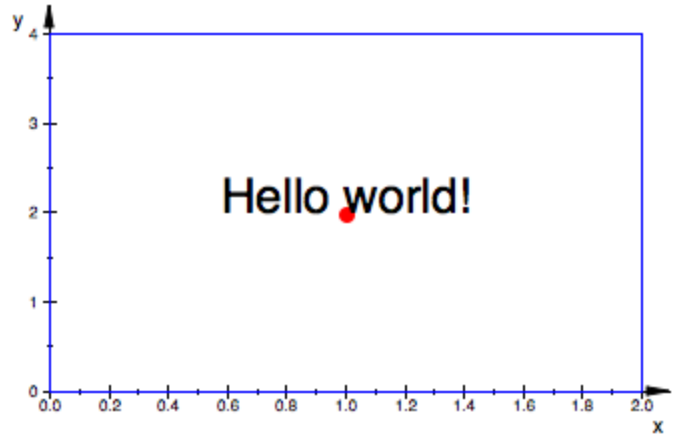
Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Position	positions of cameras, lights, and text objects	
PositionX	x-positions of cameras, lights, and text objects	
PositionY	y-positions of cameras, lights, and text objects	
Text	the text of a text object	
TextFont	font of text objects	`[" sans-serif ", 11]`
TextRotation	rotation of a 2D text	`0`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`

Attribute	Purpose	Default Value
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
VerticalAlignment	vertical alignment of text objects w.r.t. their coordinates	`BaseLine`
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

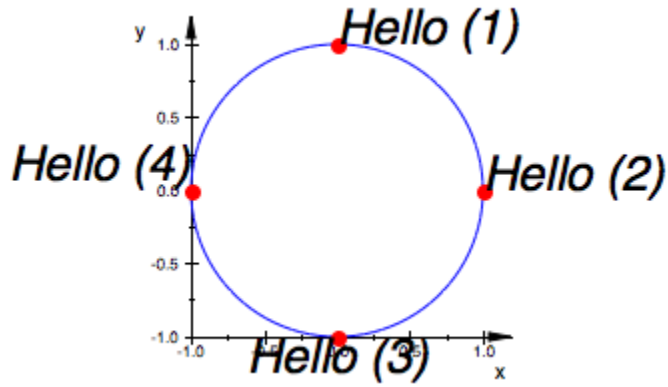
Example 1

We draw the text string ‘Hello world!’ at the anchor point (1, 2) which is indicated by a red dot:
plot(plot::Rectangle(0..2, 0..4), plot::Point2d([1, 2]), plot::Text2d("Hello world!", [1, 2], HorizontalAlignment = Center), Axes = Frame, TextFont = [24], PointColor = RGB::Red, PointSize = 3*unit::mm)



Example 2

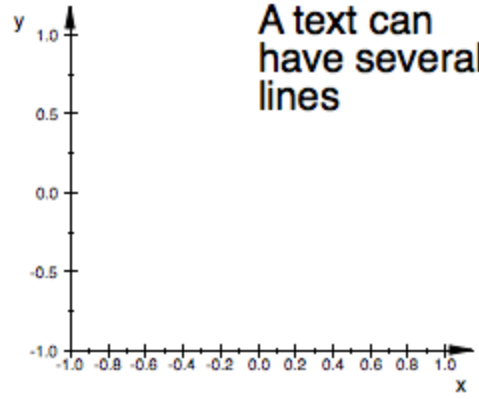
We animate the anchor points of the following texts and demonstrate various alignment possibilities:
plot(plot::Circle2d(1), plot::Point2d([sin(a), cos(a)], a = 0..2*PI), plot::Point2d([cos(a), -sin(a)], a = 0..2*PI), plot::Point2d([-sin(a), -cos(a)], a = 0..2*PI), plot::Point2d([-cos(a), sin(a)], a = 0..2*PI), PointColor = RGB::Red, PointSize = 3*unit::mm, plot::Text2d("Hello (1)", [sin(a), cos(a)], a = 0..2*PI), plot::Text2d("Hello (2)", [cos(a), -sin(a)], a = 0..2*PI, HorizontalAlignment = Left, VerticalAlignment = BaseLine), plot::Text2d("Hello (3)", [-sin(a), -cos(a)], a = 0..2*PI, HorizontalAlignment = Center, VerticalAlignment = Top), plot::Text2d("Hello (4)", [-cos(a), sin(a)], a = 0..2*PI, HorizontalAlignment = Right, VerticalAlignment = Bottom), TextFont = [Italic, 24], Axes = Frame)



Example 3

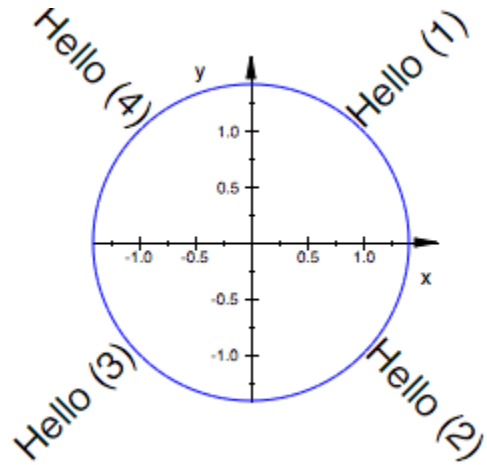
A text may consist of several lines. The newline character in MuPAD strings is \n:

```
plot(plot::Text2d("A text can\nhave several\nlines", [sin(a), cos(a)], a = 0..2*PI), Axes = Frame, TextFont = [20])
```



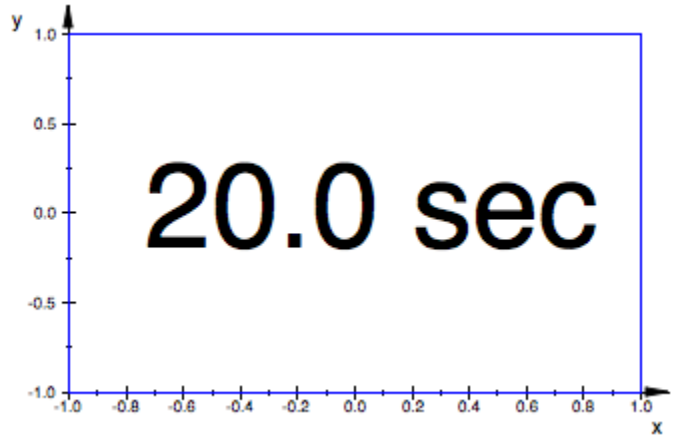
Example 4

The attribute TextRotation allows to rotate a 2D text on the screen:
plot(plot::Circle2d(sqrt(2)), plot::Text2d("Hello (1)", [1, 1], HorizontalAlignment = Left, TextRotation = PI/4), plot::Text2d("Hello (2)", [1,-1], HorizontalAlignment = Left, TextRotation = -PI/4), plot::Text2d("Hello (3)", [-1,-1], HorizontalAlignment = Right, TextRotation = PI/4), plot::Text2d("Hello (4)", [-1, 1], HorizontalAlignment = Right, TextRotation = -PI/4), HorizontalAlignment = Left, TextFont = [20])



Example 5

The text of a text object can be animated if the text string is provided by a procedure. We use stringlib::formatf to format the animation parameter that is passed to the procedure as a floating-point number for each frame of the animation:
plot(plot::Rectangle(-1..1, -1..1), plot::Text2d(a -> stringlib::formatf(a, 2, 5)." sec", [0, 0], a = 0..20), TextFont = [60], HorizontalAlignment = Center, VerticalAlignment = Center, Axes = Frame, Frames = 201, TimeRange = 0..20)



Parameters

text

The text: a string. Alternatively, a procedure that accepts one input parameter *a* (the animation parameter) and returns a string.

`text` is equivalent to the attribute Text.

x

y

The position of the text. The coordinates `x` and `y` must be real numerical values or arithmetical expressions of the animation parameter `a`.

`x`, `y` are equivalent to the attributes Position, PositionX, PositionY.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copystringlib::formatfplot::Text3d

plot::Text3d

Purpose

3D text

Syntax

```
plot::Text3d(text, [x, y, z], <a = a_min .. a_max>, options)
```

Description

`plot::Text3d` draws a text at a given position (*x*, *y*, *z*) (the "anchor point"). The attributes VerticalAlignment and HorizontalAlignment determine the alignment of the text w.r.t. its anchor.

Size, text color, font type etc. are controlled by the attribute TextFont.

In contrast to plot::Text2d, a 3D text cannot consist of several lines. The newline character `\n` in MuPAD strings does not have an effect.

By default, a 3D text uses Billboarding = `TRUE`, i.e., the text is automatically oriented such that it is readable by the observer. When setting Billboarding = `FALSE`, the attribute TextOrientation allows to fix the orientation of the text arbitrarily in space. See the help page of TextOrientation for details.

The text of a text object can be animated if it is passed as a procedure that returns the text string during runtime. Cf. "Example 5" on page 24-901.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Billboarding	text orientation in space or towards observer	`TRUE`
Frames	the number of frames in an animation	`50`

Attribute	Purpose	Default Value
HorizontalAlignment	horizontal alignment of text objects w.r.t. their coordinates	`Left`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Position	positions of cameras, lights, and text objects	
PositionX	x-positions of cameras, lights, and text objects	
PositionY	y-positions of cameras, lights, and text objects	

Attribute	Purpose	Default Value
PositionZ	z-positions of cameras, lights, and text objects	
Text	the text of a text object	
TextFont	font of text objects	[" sans-serif ", 11]
TextOrientation	orientation of a 3D text	[1, 0, 0, 0, 0, 1]
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	

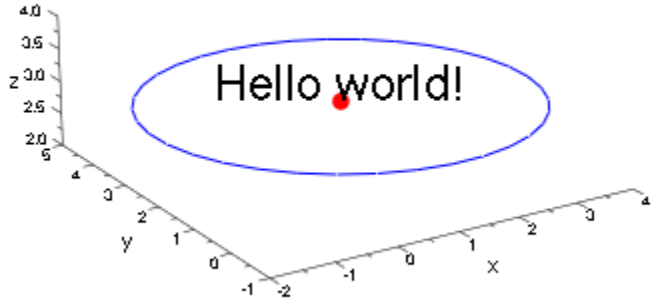
Attribute	Purpose	Default Value
VerticalAlignment	vertical alignment of text objects w.r.t. their coordinates	`BaseLine`
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`

Examples

Example 1

We draw the text string 'Hello world' at the anchor point (1, 2, 3) which is indicated by a red dot:

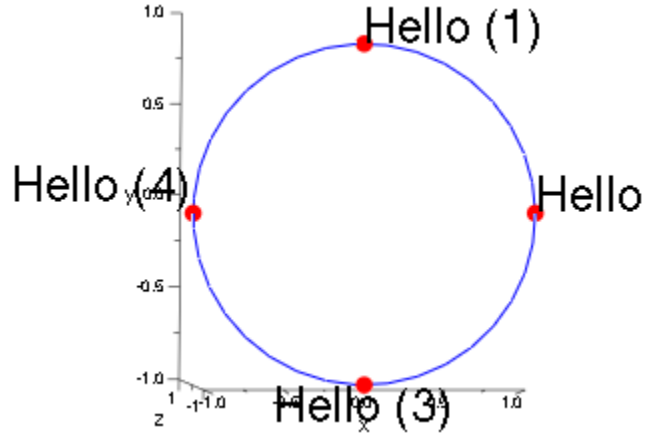
```
plot(plot::Circle3d(3, [1, 2, 3], [0, 0, 1]), plot::Point3d([1, 2, 3]),
plot::Text3d("Hello world!", [1, 2, 3], HorizontalAlignment = Center),
Axes = Frame, TextFont = [24], PointColor = RGB::Red, PointSize
= 3*unit::mm)
```



Example 2

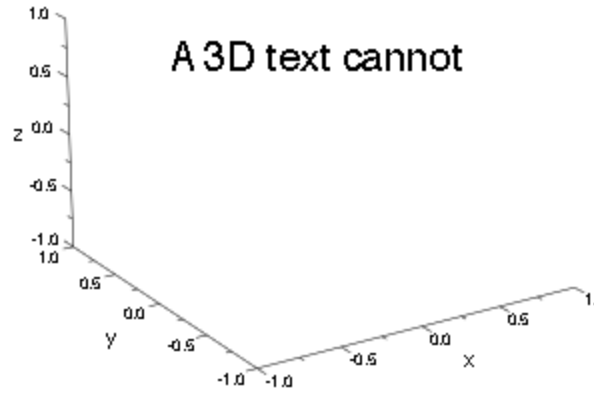
We animate the anchor points of the following texts and demonstrate various alignment possibilities:

```
plot(plot::Circle3d(1, [0, 0, 0], [0, 0, 1]), plot::Point3d([sin(a),
cos(a), 0], a = 0..2*PI), plot::Point3d([cos(a), -sin(a), 0], a
= 0..2*PI), plot::Point3d([-sin(a), -cos(a), 0], a = 0..2*PI),
plot::Point3d([-cos(a), sin(a), 0], a = 0..2*PI), PointColor =
RGB::Red, PointSize = 3*unit::mm, plot::Text3d("Hello (1)", [sin(a),
cos(a), 0], a = 0..2*PI), plot::Text3d("Hello (2)", [cos(a), -sin(a),
0], a = 0..2*PI, HorizontalAlignment = Left, VerticalAlignment
= BaseLine), plot::Text3d("Hello (3)", [-sin(a), -cos(a), 0], a =
0..2*PI, HorizontalAlignment = Center, VerticalAlignment =
Top), plot::Text3d("Hello (4)", [-cos(a), sin(a), 0], a = 0..2*PI,
HorizontalAlignment = Right, VerticalAlignment = Bottom), TextFont =
[Italic, 24], Axes = Frame, CameraDirection = [0, -1, 10])
```



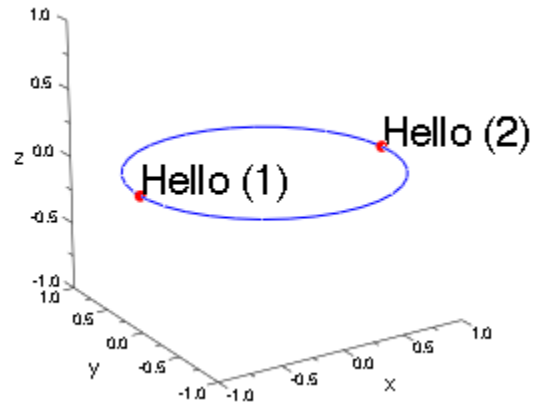
Example 3

In contrast to plot::Text2d, a 3D text may not consist of several lines. The newline character \n in MuPAD strings does not have any effect:
plot(plot::Text3d("A 3D text cannot \nhave several\nlines", HorizontalAlignment = Center, [0, 0, 0]), Axes = Frame, TextFont = [20])

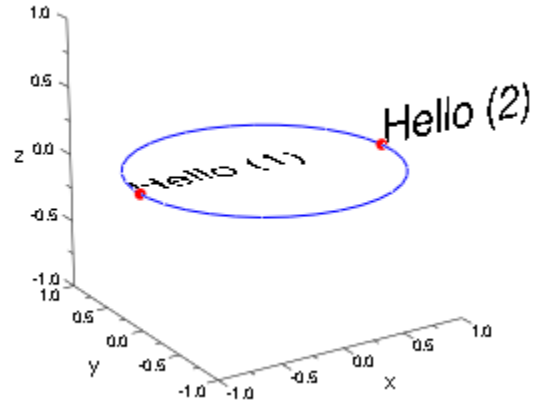


Example 4

Per default, the attribute Billboarding = TRUE is set. The text always faces the observer:
plot(plot::Circle3d(1, [0, 0, 0], [0, 0, 1]), plot::Point3d([-cos(a), -sin(a), 0], a = 0 .. 2*PI), plot::Point3d([cos(a), sin(a), 0], a = 0 .. 2*PI), plot::Text3d("Hello (1)", [-cos(a), -sin(a), 0], a = 0 .. 2*PI), plot::Text3d("Hello (2)", [cos(a), sin(a), 0], a = 0 .. 2*PI), Axes = Frame, TextFont = [20], PointColor = RGB::Red, PointSize = 2*unit::mm)

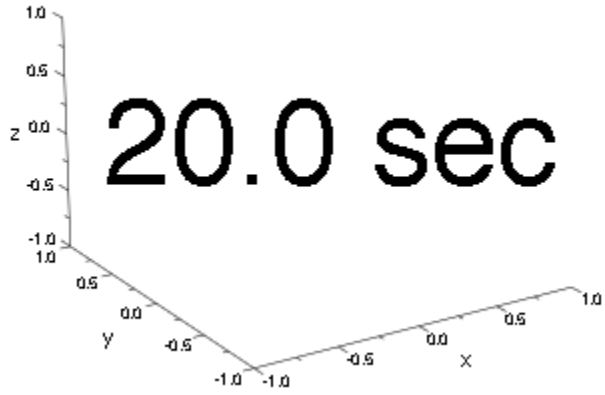


We use TextOrientation to fix the orientation of the texts in space. The first text lies in a plane parallel to the *x*-*y* plane, the second text is parallel to the *x*-*z* plane. Note that we have to specify Billboarding = FALSE for TextOrientation to have an effect:
plot(plot::Circle3d(1, [0, 0, 0], [0, 0, 1]), plot::Point3d([-cos(a), -sin(a), 0], a = 0 .. 2*PI), plot::Point3d([cos(a), sin(a), 0], a = 0 .. 2*PI), PointColor = RGB::Red, PointSize = 2*unit::mm, plot::Text3d("Hello (1)", [-cos(a), -sin(a), 0], a = 0 .. 2*PI, TextOrientation = [1, 0, 0, 0, 1, 0]), plot::Text3d("Hello (2)", [cos(a), sin(a), 0], a = 0 .. 2*PI, TextOrientation = [1, 0, 0, 0, 0, 1]), Billboarding = FALSE, TextFont = [20], Axes = Frame)



Example 5

The text of a text object can be animated if the text string is provided by a procedure. We use stringlib::formatf to format the animation parameter that is passed to the procedure as a floating-point number for each frame of the animation:
plot(plot::Text3d(a -> stringlib::formatf(a, 2, 5)." sec", [0, 0, 0], a = 0..20), TextFont = [60], HorizontalAlignment = Center, VerticalAlignment = Center, Axes = Frame, Frames = 201, TimeRange = 0..20)



Parameters

text

The text: a string. Alternatively, a procedure that accepts one input parameter a (the animation parameter) and returns a string.

`text` is equivalent to the attribute Text.

x

y

z

The position of the text. The coordinates `x`, `y`, `z` must be real numerical values or arithmetical expressions of the animation parameter `a`.

`x`, `y`, `z` are equivalent to the attributes Position, PositionX, PositionY, PositionZ.

a

Animation parameter, specified as `a = a`$_{min}$`..a`$_{max}$, where `a`$_{min}$ is the initial parameter value, and `a`$_{max}$ is the final parameter value.

See Also plotplot::copystringlib::formatfplot::Text2d

plot::Tube

Purpose

Generalized tubular plots (canal surfaces)

Syntax

```
plot::Tube([x, y, z], <r>, t = t_min .. t_max, <a = a_min .. a_max>, options)
```

Description

`plot::Tube` creates generalized tubular plots, known as “canal surfaces”, with special cases known as “tube surface”, “pipe surface” or “tubular surfaces.”

Intuitively, canal surfaces are space curves with thickness. More formally, a canal surface `plot::Tube([x(t), y(t), z(t)], r(t), t = t_min..t_max)` is the envelope of spheres with center [$x(t)$, $y(t)$, $z(t)$] and radius $r(t)$, i.e., the thickness of the curve can vary with the curve parameter t.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AngleEnd	end of angle range	`2*PI`
AngleBegin	begin of angle range	`0`
AngleRange	angle range	`0 .. 2*PI`
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Dichromatic`

Attribute	Purpose	Default Value
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineColorType	line coloring types	Flat

Attribute	Purpose	Default Value
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	[60, 11]
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointsVisible	visibility of mesh points	FALSE
RadiusFunction	radius of a tube plot	1/10

Attribute	Purpose	Default Value
Shading	smooth color blend of surfaces	`Smooth`
Submesh	density of submesh (additional sample points)	`[0, 1]`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
ULinesVisible	visibility of parameter lines (u lines)	`TRUE`
UMax	final value of parameter “u”	

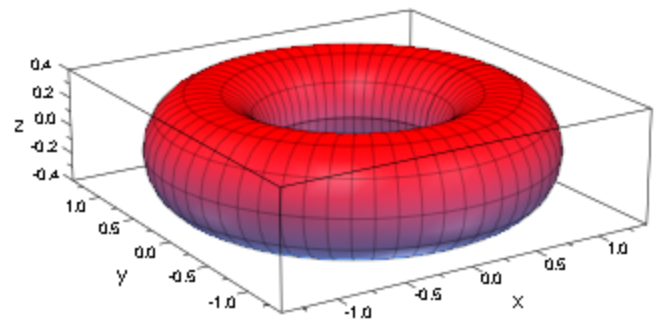
Attribute	Purpose	Default Value
UMesh	number of sample points for parameter “u”	60
UMin	initial value of parameter “u”	
UName	name of parameter “u”	
URange	range of parameter “u”	
USubmesh	density of additional sample points for parameter “u”	0
VLinesVisible	visibility of parameter lines (v lines)	TRUE
VMesh	number of sample points for parameter “v”	11
VSubmesh	density of additional sample points for parameter “v”	1
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
YFunction	function for y values	
ZFunction	function for z values	

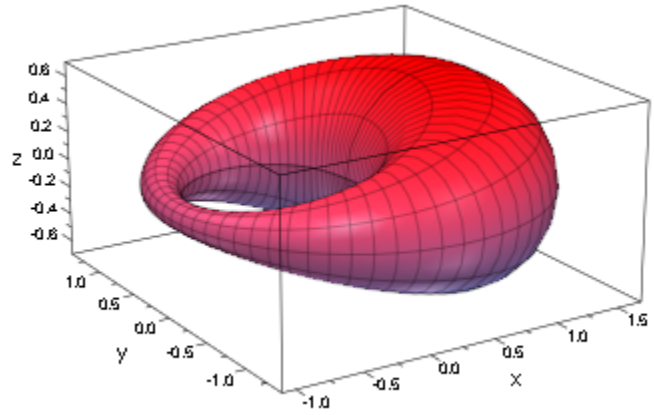
Examples

Example 1

A torus can be drawn as a tube around a circle:
plot(plot::Tube([cos(t), sin(t), 0], 0.4, t = 0..2*PI))

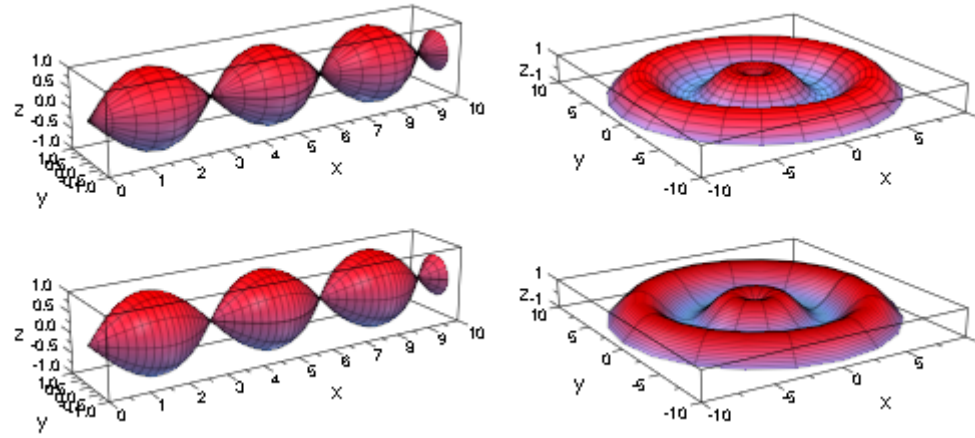


Varying the diameter of the tube, we deform the torus into a cyclide:
plot(plot::Tube([cos(t), sin(t), 0], 0.4 + 0.3*cos(t), t = 0..2*PI))

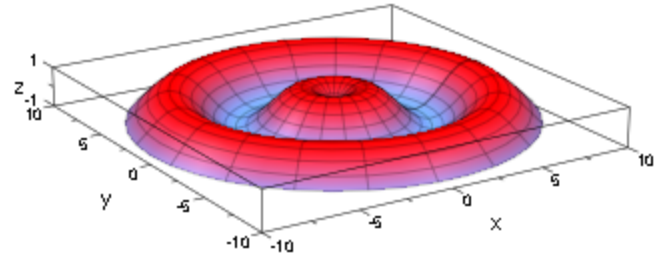


Example 2

All surfaces of revolution are special cases of canal surfaces:
plot(plot::Scene3d(plot::XRotate(sin(u), u = 0..10)),
plot::Scene3d(plot::ZRotate(sin(u), u = 0..10)),
plot::Scene3d(plot::Tube([u, 0, 0], sin(u), u = 0..10)),
plot::Scene3d(plot::Tube([0, 0, sin(u)], u, u = 0..10)), Width = 180
* unit::mm)



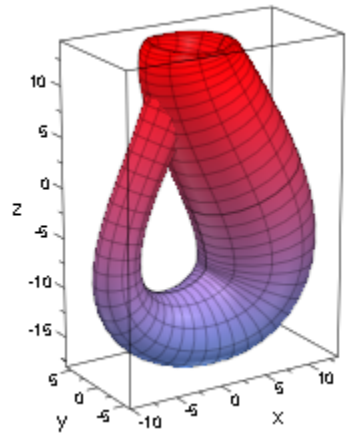
The last image shows that the defaults for the mesh are not always adequate and should be changed:
plot(plot::Tube([0, 0, sin(u)], u, u = 0..10, Mesh = [20, 20]))



Example 3

The famous Klein bottle can be obtained from a “drop silhouette” by using an appropriate radius parametrization:

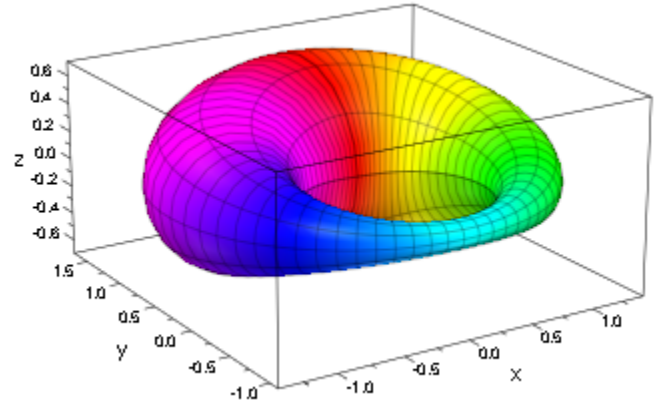
```
plot(plot::Tube([6*cos(u)*(sin(u) - 1), 0, 14*sin(u)], 4 - 2*cos(u), u =
-PI..PI))
```



Example 4

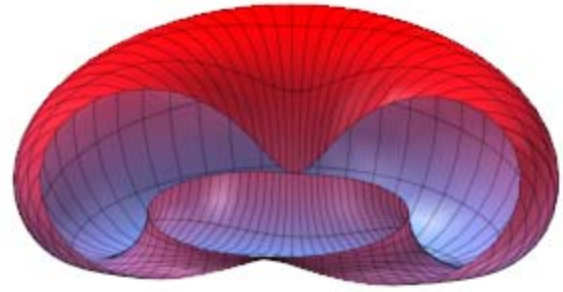
Re-using the cyclide from above, we demonstrate coloring a canal surface:

```
color := (t, phi) -> RGB::fromHSV([(t+sin(4*phi))*180/PI, 1,
1]): plot(plot::Tube([sin(t), cos(t), 0], 0.4 + 0.3*cos(t), t=0..2*PI,
FillColorFunction = color))
```



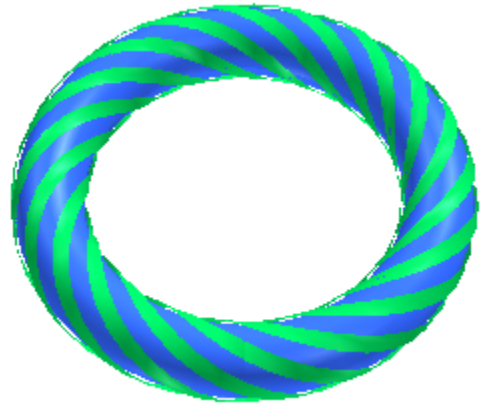
Example 5

Yet another variation of the cyclide, we use a non-constant AngleRange to “slice” it:
plot(plot::Tube([sin(t), cos(t), 0], 0.4 - 0.3*sin(t), t=0..2*PI, AngleRange = 0 .. 2*PI*sin(abs(t-PI/2)/2)), Axes = None, CameraDirection = [14, 1, 5])



Combining more than one tubular plot with identical spine curves but different angle ranges, we can achieve a braid-like effect:

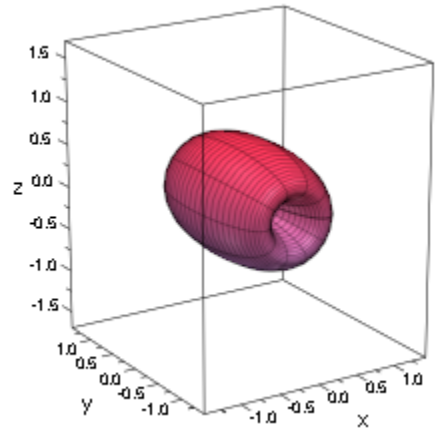
```
braid := i -> plot::Tube([sin(u), cos(u), 0], 0.2, u=0..2*PI, AngleRange = i*PI/3 + 3*u .. i*PI/3 + 3*u + 1/2, Color = RGB::EmeraldGreen, Mesh = [60, 2]): torus := plot::Tube([sin(u), cos(u), 0], 0.18, u=0..2*PI, Color = RGB::BlueLight, Name = "Torus"): plot(braid(i) $ i = 0..5, torus, ULinesVisible = FALSE, VLinesVisible = FALSE, FillColorType = Flat, Axes = None, CameraDirection = [0, 7, 10])braid := i -> plot::Tube([sin(u), cos(u), 0], 0.2, u=0..2*PI, AngleRange = i*PI/3 + 3*u .. i*PI/3 + 3*u + 1/2, Color = RGB::EmeraldGreen, Mesh = [60, 2]): torus := plot::Tube([sin(u), cos(u), 0], 0.18, u=0..2*PI, Color = RGB::BlueLight, Name = "Torus"): plot(braid(i) $ i = 0..5, torus, ULinesVisible = FALSE, VLinesVisible = FALSE, FillColorType = Flat, Axes = None, CameraDirection = [0, 7, 10])
```



Example 6

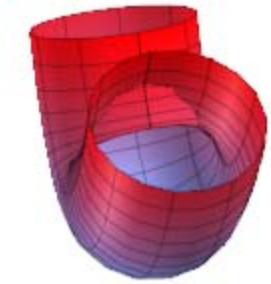
The spine curve, the radius function, color functions etc. can be animated as usual:

```
plot(plot::Tube([sin(t)*sin(a), cos(t)*cos(a), sin(a)], 0.4 - 0.3*sin(t-a), t = 0..2*PI, a = 0..2*PI, Frames = 20, TimeRange = 0..5))
```

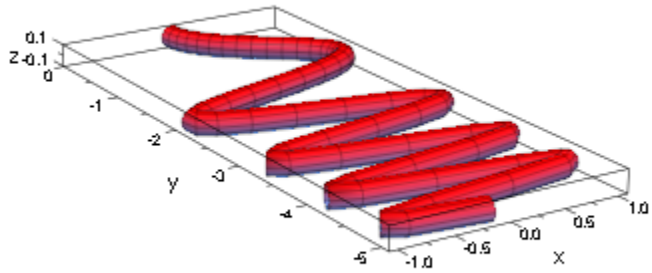


Example 7

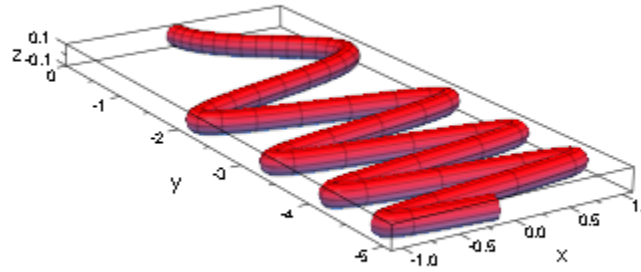
Note that in the presence of a sharp bend (in relation to the tube diameter), the surface plotted my `plot::Tube` may self-intersect: plot(plot::Tube([x, 0, x^2], 1.2, x = -1.4..1.4, Mesh = [20, 10]), Axes = None, CameraDirection = [-3, 1, 2])



This effect is unavoidable. Sharp bends also cause another effect which can be avoided by increasing the mesh density: The tube might not follow the curve quickly enough:
plot(plot::Tube([sin(x^2), x, 0], x = -5..0))



In this situation, you can set USubmesh to a positive value to request additional function evaluations:
plot(plot::Tube([sin(x^2), x, 0], x = -5..0, USubmesh = 5))



Parameters

x

y

z

The spine curve coordinates: real-valued expressions in `t` and the animation parameter.

`x`, `y`, `z` are equivalent to the attributes XFunction, YFunction, ZFunction.

r

The tube radius: a real-valued expression in `t` and the animation parameter. Default is the constant $1/10$.

`r` is equivalent to the attribute RadiusFunction.

t

The curve parameter: an (indexed) identifier.

`t` is equivalent to the attribute UName.

t_{min} .. t_{max}

The range of the curve parameter: real-valued expressions in the animation parameter.

t_{min} .. t_{max} is equivalent to the attributes URange, UMin, UMax.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Turtle

Purpose

"turtle graphics" (imperative drawings)

Syntax

`plot::Turtle(commands, <a = a_min .. a_max>, options)`

Description

Turtle graphics define a line drawing by a sequence of commands to an abstract robot.

`plot::Turtle` defines a graphic by sending movement commands to an abstract robot. This robot starts heading up and standing at the origin, with its pen ready for drawing ("down") and the line color taken from the attribute `LineColor`.

The following commands are known to the robot:

- `Left(Æ)`

  Turn left by the angle a (in radians).

- `Right(Æ)`

  Turn right by the angle a (in radians).

- `Forward(d)`

  Move forward distance d.

- `Up`

  Lift the "pen", i.e., subsequent movement commands do not draw lines.

- `Down`

  Lower the "pen", i.e., subsequent movement commands do draw lines.

- `Push`

  Remember the current state (position, angle, line color).

- `Pop`

  Restore the last remembered state and remove it from the list of remembered states.

- `Noop`

  This command is ignored.

- `LineColor(c)`

  Set the line color to the color`c`.

The commands not taking an argument may also be entered with empty parentheses `()` after, e.g., `Push()`.

A `plot::Turtle`-object can be manipulated dynamically by calling its methods `left`, `right`, `forward`, `penUp`, `penDown`, `push`, `pop`, and `setLineColor`, with the obvious connections to the commands above. These methods append a new command to the end of the list. Cf. "Example 3" on page 24-926.

Note For long command sequences, it is highly recommended to give the commands directly using the syntax above or by setting the `CommandList` attribute directly.

Both angles and distances can be animated. Colors can not.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
Color	the main color	RGB::Blue
CommandList	turtle movement commands	[]

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.35`
LineStyle	solid, dashed or dotted lines?	`Solid`
LinesVisible	visibility of lines	`TRUE`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`FALSE`

Attribute	Purpose	Default Value
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

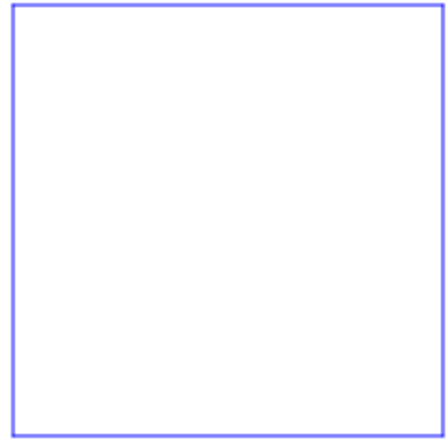
Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

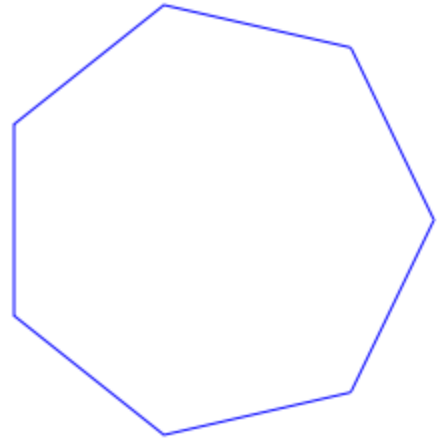
Example 1

A square can be drawn by four times moving forward, each time turning right 90°:
plot(plot::Turtle([Forward(1), Right(PI/2), Forward(1), Right(PI/2), Forward(1), Right(PI/2), Forward(1), Right(PI/2)]))

Using the $ operator, this command list can be written much shorter:
plot(plot::Turtle([(Forward(1), Right(PI/2))$4]))



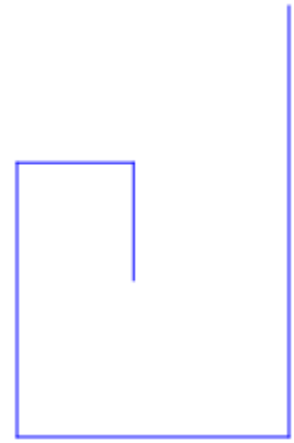
In the same fashion, we can draw any regular *n*-sided polygon:
n := 7: plot(plot::Turtle([(Forward(1), Right(2*PI/n)) $ n]))



Example 2

The distance to move may contain an animation parameter:

plot(plot::Turtle([Forward(1+a), Right(PI/2), Forward(1-2*a), Right(PI/2), Forward(1+3*a), Right(PI/2), Forward(1-4*a), Right(PI/2), Forward(1+5*a)], a=0..2))



Likewise, the angle can be animated:
plot(plot::Turtle([(Forward(1), Right(a))$10], a = 0.25..2.5))

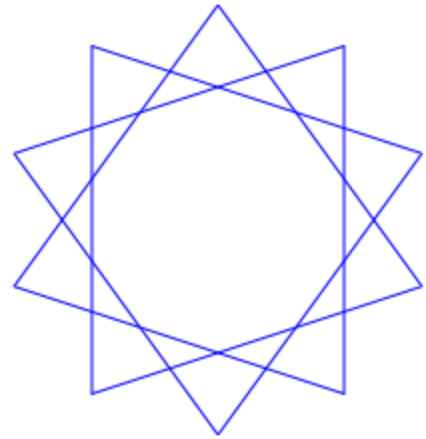
Example 3

It is also possible to successively append commands to the list:
t := plot::Turtle()plot::Turtle([])

plot::Turtle([])
t::forward(1)plot::Turtle([Forward(1)])

plot::Turtle([Forward(1)])
for i from 1 to 9 do t::left(3*PI/5); t::forward(1);
end_for‘plot::Turtle([Forward(1), Left((3*PI)/...5), Forward(1)])‘

plot::Turtle([Forward(1), Left((3*PI)/...5), Forward(1)])
plot(t)

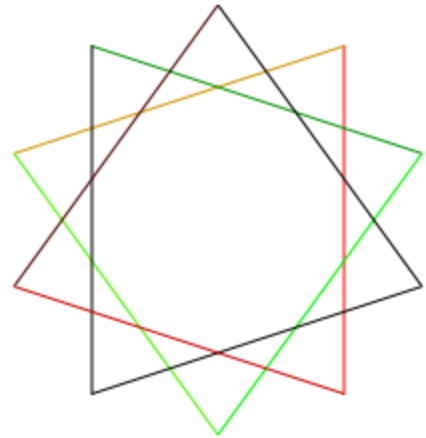


Example 4

As an extension to the original turtle model, the line color may be changed while plotting:
t := plot::Turtle(): t::setLineColor(RGB::Red): t::forward(1):
p := float(PI/5): for i from 1 to 9 do t::left(108*PI/180);

```
t::setLineColor([cos(i*p), sin(i*p), 0.0]); t::forward(1);
end_for;'plot::Turtle([LineColor([1.0, 0.0, 0.0...]), Forward(1)])'

plot::Turtle([LineColor([1.0, 0.0, 0.0...]), Forward(1)])
plot(t)
```

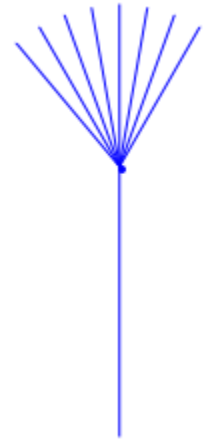


Note that the color within one line segment is constant.

Example 5

Another extension to the turtle model is that `plot::Turtle` supports a stack of saved states, enabling the robot to return to previous positions:

```
t := plot::Turtle(): t::forward(5): for i from -3 to 4 do t::push();
t::left(PI/18*i); t::forward(3); t::pop(); end_for: plot(t)
```



Example 6

Using small steps, it is possible to create appealing curves with `plot::Turtle`:

```
t := plot::Turtle(LineColor = RGB::Green): t::forward(2): for
dir in [-1, 1] do t::push(); t::left(dir*PI/30); for i from 1 to 10 do
t::forward(0.2); t::left(dir*PI/30); end_for; t::left(dir*2/3*PI); for i from
1 to 10 do t::forward(0.2); t::left(dir*PI/30); end_for; t::pop() end_for:
t::forward(3): t::setLineColor(RGB::Red): for dir from -5 to 5 do t::push();
t::left(dir*2*PI/11); for i from 1 to 10 do t::forward(0.1); t::left(PI/30);
end_for; t::left(2*PI/3); for i from 1 to 10 do t::forward(0.1); t::left(PI/30);
end_for; t::pop() end_for: plot(t)
```

Parameters

commands

A list of commands. See below for command definitions.

`commands` is equivalent to the attribute CommandList.

a

Animation parameter, specified as `a = a`$_{min}$`..a`$_{max}$, where `a`$_{min}$ is the initial parameter value, and `a`$_{max}$ is the final parameter value.

plotplot::copyplot::Lsys

plot::VectorField2d

Purpose

2D vector field

Syntax

```
plot::VectorField2d([v1, v2], x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
plot::VectorField2d(v1, v2, x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
```

Description

`plot::VectorField2d([v_1, v_2], x = `x_{min}`..`x_{max}`, y = `y_{min}`..`y_{max}`)` represents a plot of the vector field defined by (x, y) -> fenced(v[1](x, y), v[2](x, y))$(x, y) \to (v_1(x, y), v_2(x, y))$ with (x, y) $[x_min, x_max]$ $[y_min, y_max]$.

A vector field is defined by a function funcDecl(f, R_^2, R_^2)$f: \mathbb{R}^2 \to \mathbb{R}^2$. `plot::VectorField2d` displays a vector field by placing arrows at regular intervals with the arrow at (x, y) pointing in direction $f(x, y)$.

The length of the arrows depend on $|f(x, y)|$ and the setting of the attribute ArrowLength: By default, arrow lengths are proportional to the magnitude of f, but can be set to be of fixed length or to scale logarithmically.

The density of arrows placed can be controlled with the attributes XMesh, YMesh, and Mesh. See the examples below.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AntiAliased	antialiased lines and points?	`TRUE`
ArrowLength	scaling of arrows in a vector field	`Proportional`
Color	the main color	RGB::Blue

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Mesh	number of sample points	[11, 11]
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
TipAngle	opening angle of arrow heads	`0.6283185307`
TipStyle	presentation style of arrow heads	`Open`
TipLength	length of arrow heads	`1.5`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	

Attribute	Purpose	Default Value
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
XMax	final value of parameter “x”	
XMesh	number of sample points for parameter “x”	11
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YFunction	function for y values	
YMax	final value of parameter “y”	

Attribute	Purpose	Default Value
YMesh	number of sample points for parameter "y"	11
YMin	initial value of parameter "y"	
YName	name of parameter "y"	
YRange	range of parameter "y"	

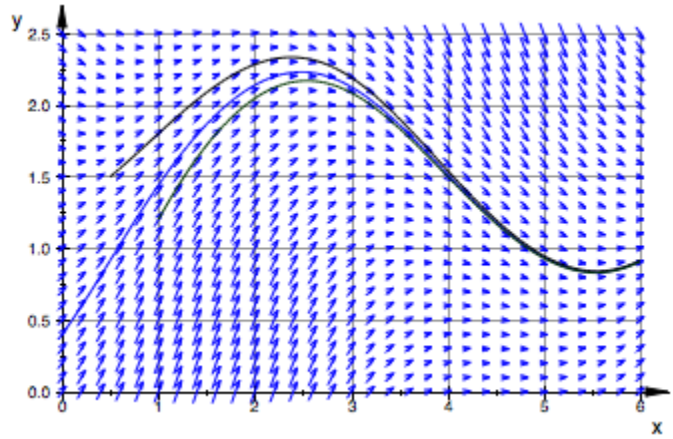
Examples

Example 1

We demonstrate a plot of the vector field $v(x, y) = (1, sin(x) + cos(y))$:
field := plot::VectorField2d([1, sin(x) + cos(y)], x = 0..6, y = 0..2.5, Mesh = [31, 26]):

It is the directional field associated with the ode y'(x)=sin(x)+cos(y)$y'(x) = \sin(x) + \cos(y)$. We insert curves representing numerical solutions of this ode into this plot. We use numeric::odesolve2 to compute the numerical solutions for the initial values $y(0) = 0.4$, $y(0.5) = 1.5$, and $y(1) = 1.2$:
f := (x, y) -> [sin(x) + cos(y[1])]: solution1 := numeric::odesolve2(f, 0, [0.4]): curve1 := plot::Function2d(solution1(x)[1], x = 0 .. 6, LineColor = RGB::Blue): solution2 := numeric::odesolve2(f, 0.5, [1.5]): curve2 := plot::Function2d(solution2(x)[1], x = 0.5 .. 6, LineColor = RGB::Black): solution3 := numeric::odesolve2(f, 1, [1.2]): curve3 := plot::Function2d(solution3(x)[1], x = 1 .. 6, LineColor = RGB::GreenDark):

We plot the three objects in a single graphical scene:
plot(field, curve1, curve2, curve3, GridVisible = TRUE):

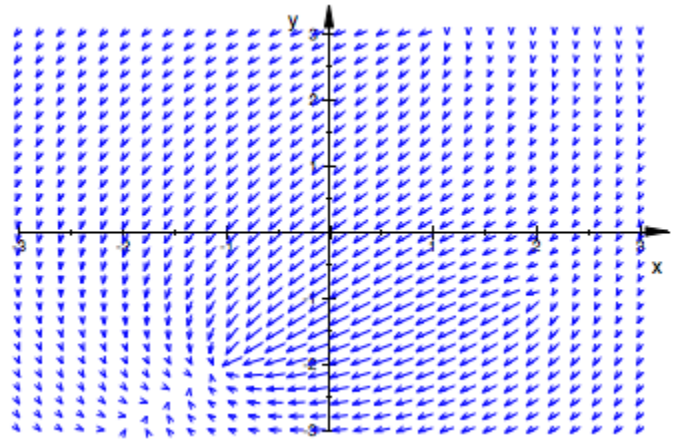


delete field, curve1, curve2, curve3:

Example 2

Assume you want to plot an electrostatic potential field. The following routine generates the necessary formula in a format accepted by `plot::VectorField2d`:

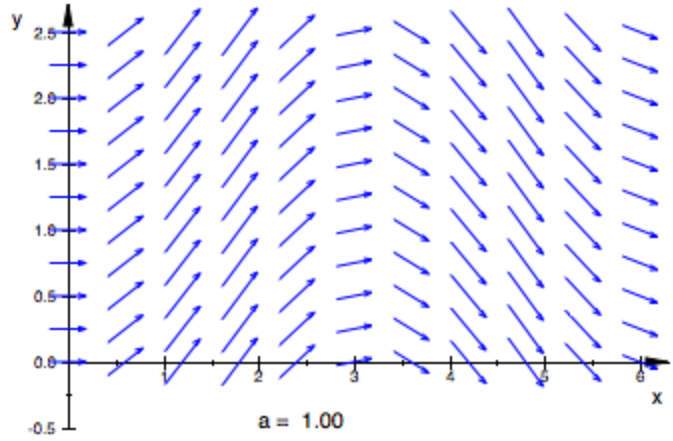
```
potentialE := proc(l) local p, x0, y0, f0, fx, fy, dist; begin fx := 0; fy := 0;
for p in [args()] do [x0, y0, f0] := p; dist := sqrt((x-x0)^2 + (y-y0)^2);
fx := fx + f0*(x-x0)/dist; fy := fy + f0*(y-y0)/dist; end_for; [fx, fy];
end_proc:plot(plot::VectorField2d(potentialE([-1, -2, -1 ], [ 1, 3, 0.5], [ 2,
-1, 0.5]), x = -3..3, y = -3..3, XMesh = 30, YMesh = 30)):
```



Example 3

Like most other objects, `plot::VectorField2d` can be animated by supplying an extra parameter:

```
field := plot::VectorField2d([1, a*sin(x) + (a-1)*cos(y)], x = 0..6, y = 0..2.5,
a=-1..1): text := plot::Text2d(a -> "a = ".stringlib::formatf(a, 2, 5), [2,
-0.5], a = -1..1, HorizontalAlignment = Left): plot(field, text)
```



delete field, text:

Parameters

v_1

v_2

The *x*- and *y*-component of the vector field: arithmetical expressions in `x`, `y`, and, possibly, the animation parameter `a`.

v_1, v_2 are equivalent to the attributes XFunction, YFunction.

x

y

Identifiers.

`x`, `y` are equivalent to the attributes XName, YName.

x_{min} .. x_{max}

y_{min} .. y_{max}

Real numerical values.

x_{min} .. x_{max}, y_{min} .. y_{max} are equivalent to the attributes XRange, YRange, XMin, XMax, YMin, YMax.

a

Animation parameter, specified as `a = `a_{min}`..`a_{max}, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::VectorField3d

Purpose

3D vector field

Syntax

```
plot::VectorField3d([v1, v2, v3], x = xmin .. xmax, y = ymin ..
ymax, z = zmin .. zmax, <a = amin .. amax>, options)
plot::VectorField3d(v1, v2, v3, x = xmin .. xmax, y = ymin ..
ymax, z = zmin .. zmax, <a = amin .. amax>, options)
```

Description

`plot::VectorField3d([v_1, v_2, v_3], x = `x_{min}`..`x_{max}`, y = `y_{min}`..`y_{max}`, z = `z_{min}`..`z_{max}`)` represents a plot of the vector field defined by

(x, y, z) -> fenced(v[1](x, y, z), v[2](x, y, z), v[3](x, y, z))

$(x, y, z) \to (v_1(x, y, z), v_2(x, y, z), v_3(x, y, z))$

with (x, y, z) $[x_min, x_max]$ $[y_min, y_max]$ $[z_min, z_max]$.

A vector field is defined by a function funcDecl(f, R_^3, R_^3)$f: \mathbb{R}^3 \to \mathbb{R}^3$. `plot::VectorField3d` displays a vector field by placing arrows at regular intervals with the arrow at (x, y, z) pointing in the direction $f(x, y, z)$.

The length of the arrows depend on $|f(x, y, z)|$ and the setting of the attribute ArrowLength: By default, arrow lengths are proportional to the magnitude of f, but can be set to be of fixed length or to scale logarithmically.

The density of arrows placed can be controlled with the attributes XMesh, YMesh, ZMesh, and Mesh. See the examples below.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
ArrowLength	scaling of arrows in a vector field	`Proportional`
Color	the main color	RGB::Blue
Frames	the number of frames in an animation	`50`
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`FALSE`
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	`0.1`
LineColor2	color of lines	RGB::DeepPink
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`0`

Attribute	Purpose	Default Value
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	[7, 7, 7]
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	TRUE
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0

Title	object title	

Attribute	Purpose	Default Value
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	`TRUE`
VisibleBeforeBegin	object visible before its animation time starts?	`TRUE`
XFunction	function for x values	
XMax	final value of parameter “x”	

Attribute	Purpose	Default Value
XMesh	number of sample points for parameter “x”	7
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YFunction	function for y values	
YMax	final value of parameter “y”	
YMesh	number of sample points for parameter “y”	7
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	
ZFunction	function for z values	
ZMax	final value of parameter “z”	
ZMesh	number of sample points for parameter “z”	7
ZMin	initial value of parameter “z”	

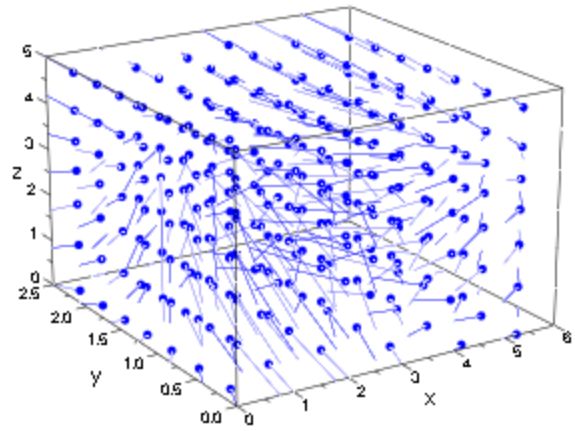
Attribute	Purpose	Default Value
ZName	name of parameter "z"	
ZRange	range of parameter "z"	

Examples

Example 1

We demonstrate a plot of the vector field $v(x, y, z) = (1, sin(x) + cos(y), sin(z))$:

```
field := plot::VectorField3d([1, sin(x) + cos(y), sin(z)], x = 0..6, y = 0..2.5,
z = 0..5, Mesh = [7, 7, 7]): plot(field):
```



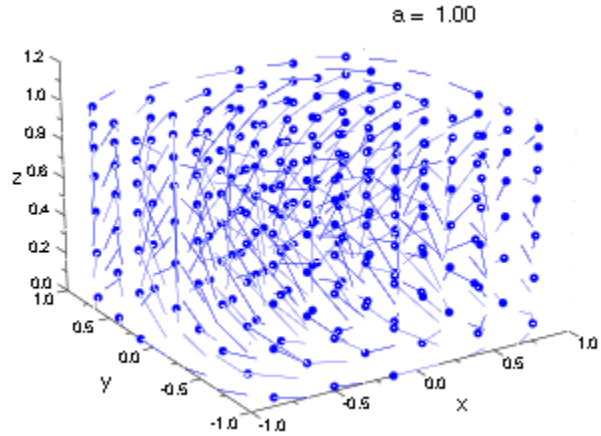
delete field:

Example 2

Like most other objects, `plot::VectorField3d` can be animated by supplying an extra parameter:

```
mycolor := (x, y, z, vx, vy, vz, a) -> [a, a*z, 1 - a]: field :=
plot::VectorField3d([ a*y + (1-a)*x , -a*x + (1-a)*y, a*sin(PI*z)], x = -1..1,
y = -1..1, z = 0..1, LineColorFunction = mycolor, Mesh = [7, 7, 7], a =
```

0..1): text := plot::Text3d(a -> "a = ".stringlib::formatf(a, 2, 5), [1, 0.7, 1.2], a = 0..1): plot(field, text, Axes = Frame)



delete field, text:

Parameters

v_1

v_2

v_3

The *x*-, *y*-, and *z*-component of the vector field: arithmetical expressions in `x`, `y`, `z` and, possibly, the animation parameter `a`.

v_1, v_2, v_3 are equivalent to the attributes XFunction, YFunction, ZFunction.

x

y

z

Identifiers.

`x`, `y`, `z` are equivalent to the attributes XName, YName, ZName.

x_{min} .. x_{max}

y_{min} .. y_{max}

z_{min} .. z_{max}

Real numerical values.

x_{min} .. x_{max}, y_{min} .. y_{max}, z_{min} .. z_{max} are equivalent to the attributes XRange, YRange, ZRange, XMin, XMax, YMin, YMax, ZMin, ZMax.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Ode2dplot::Ode3dplot::VectorField2d

plot::Waterman

Purpose

Waterman polyhedra

Syntax

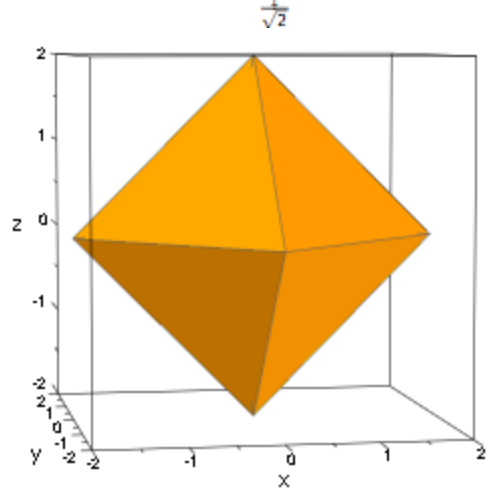
`plot::Waterman(r, <a = a_min .. a_max>, options)`

Description

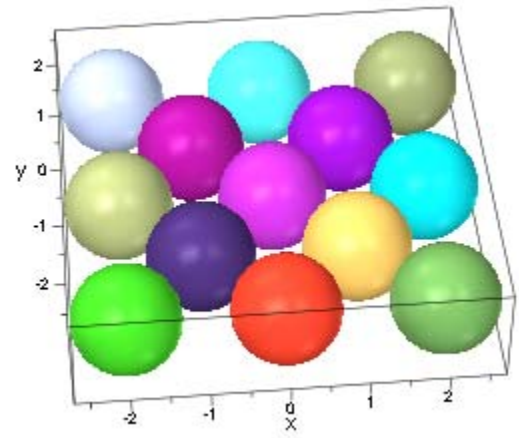
`plot::Waterman(r)` creates the Waterman polyhedron of radius *r*.

Waterman polyhedra, invented around 1990 by Steve Waterman, form a vast family of polyhedra. Some of them have a number of nice properties like multiple symmetries, or very interesting and regular shapes. Some other are just a bunch of faces formed out of irregular convex polygons.

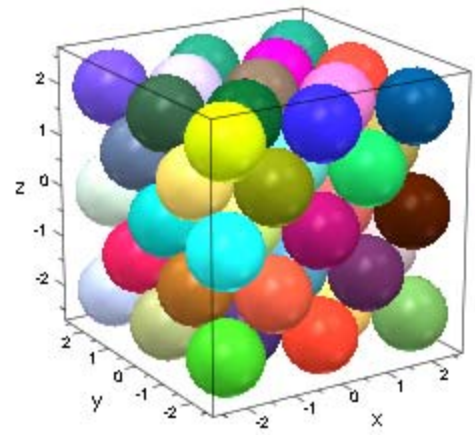
Waterman polyhedra result from the examination of balls in face-centered cubic close packing (which is one of the two densest packings of equally sized balls in 3D space, according to the Kepler Conjecture, proofed by Hales and Ferguson, 1997-2005). A single layer of spheres (of radius 1/sqrt(2) $\frac{1}{\sqrt{2}}$) in this packing looks like this:



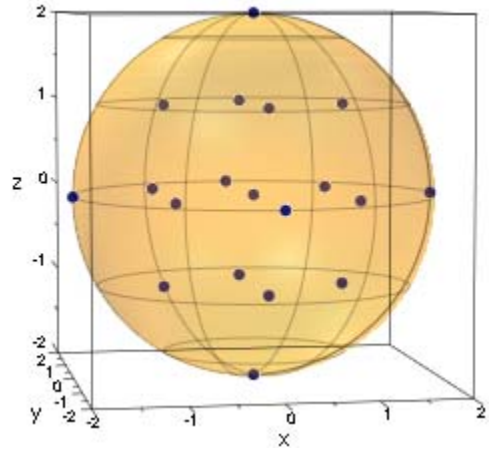
The close packing results from placing several of these layers over one another, shifted to optimally fill the gaps (in very much the same way your grocery store puts apples and oranges on display):



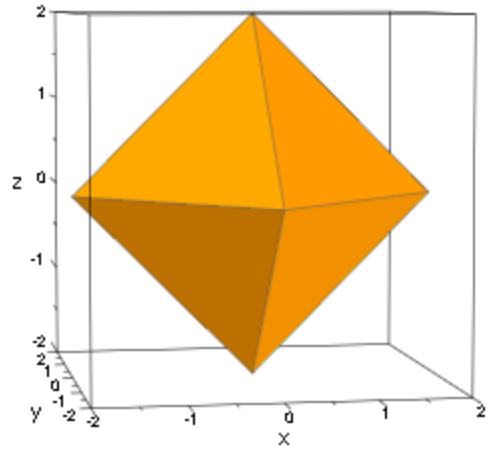
Given a radius *r* and a center *c* (which we let default to [0, 0, 0]), now consider all those centers of spheres in this packing which fall into the sphere of radius *r* around *c*:



The convex hull of these points is the Waterman polyhedron of the given radius and center:



plot(plot::Waterman(2), CameraDirection=[-2,-12,1])



Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Center	center of objects, rotation center	`[0, 0, 0]`
CenterX	center of objects, rotation center, x-component	`0`
CenterY	center of objects, rotation center, y-component	`0`
CenterZ	center of objects, rotation center, z-component	`0`
Color	the main color	RGB::SafetyOrange
Filled	filled or transparent areas and surfaces	`TRUE`
FillColor	color of areas and surfaces	RGB::SafetyOrange
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	`Flat`
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	`[0, 0, 1]`

Attribute	Purpose	Default Value
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Grey40.[0.4]
LineWidth	width of lines	0.25
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	

Attribute	Purpose	Default Value
LineColorDirection	the direction of color transitions on lines	[0, 1, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Radius	radius of circles, spheres etc.	

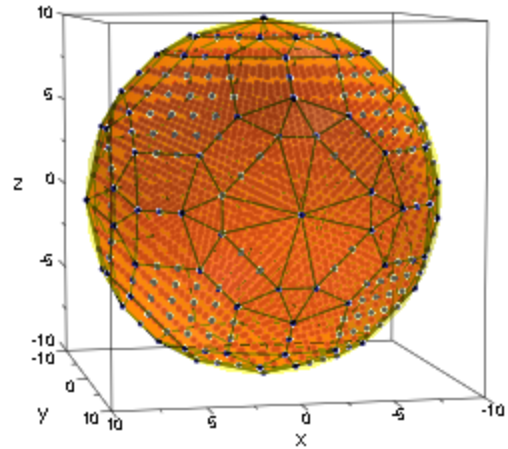
Attribute	Purpose	Default Value
Shading	smooth color blend of surfaces	`Smooth`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	`TRUE`
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

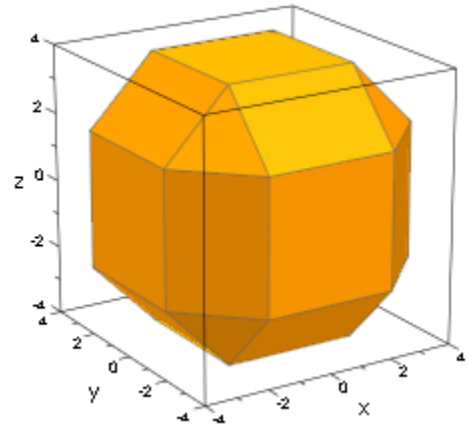
Example 1

With increasing radius, Waterman polyhedra get ever closer to spheres:
plot(plot::Waterman(r, r=0..10, PointsVisible, PointSize=1, LineColor=RGB::Black, Color=RGB::Red.[0.75]), plot::Sphere(r, [0,0,0], r=0..10, Color=RGB::Yellow.[0.3]), CameraDirection=[2,10,1])

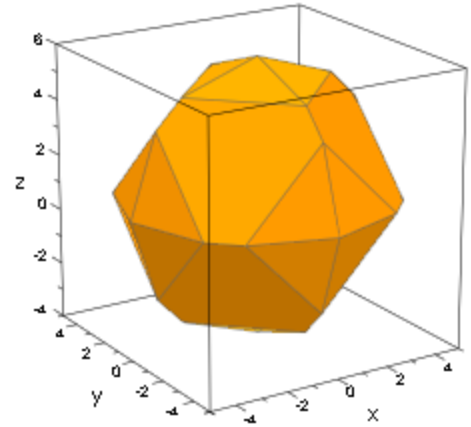


Example 2

Waterman polyhedra have a rather general definition and can be made from spheres centered anywhere:
plot(plot::Waterman(5, Center=[0,0,0]))

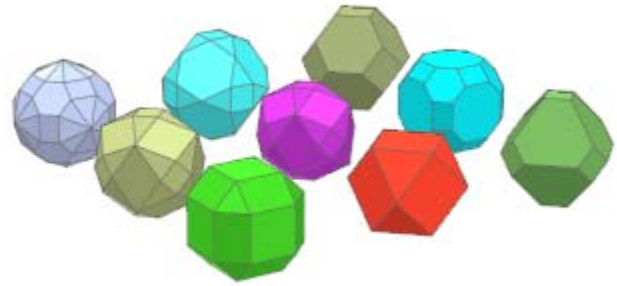


plot(plot::Waterman(5, Center=[0,0,1]))



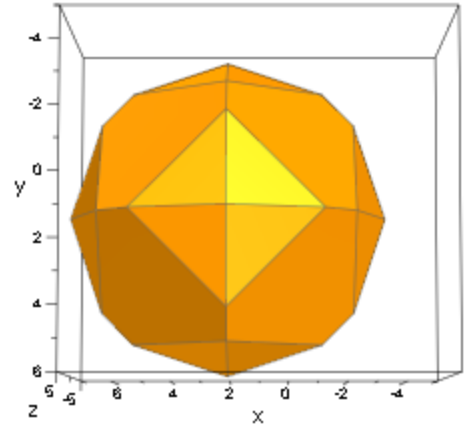
To translate or scale a Waterman polyhedron, use plot::Translate3d and plot::Scale3d:

```
n := 3: r := i -> 3/2+sqrt(i+1): plot(plot::Translate3d([i mod
n, i div n, 0], plot::Scale3d([1/(3*r(i)) $ 3], plot::Waterman(r(i),
Color=RGB::random()))) $ i = 0..n^2-1, Axes=None)
```



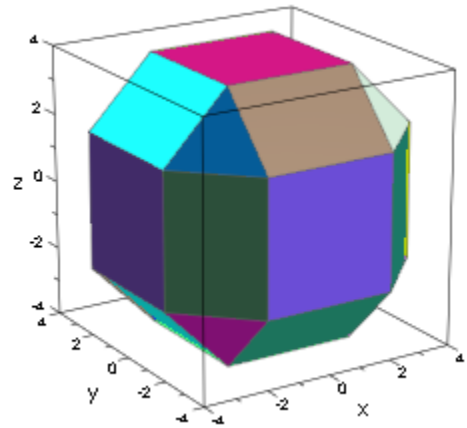
Example 3

As usual, many attributes can be animated, although by the nature of Waterman polyhedra, the resulting animation will not be smooth:
plot(plot::Waterman(5, Center=[a/PI, cos(a), 0], a=0..2*PI), AnimationStyle=BackAndForth, CameraDirection=[0,0.1,1])

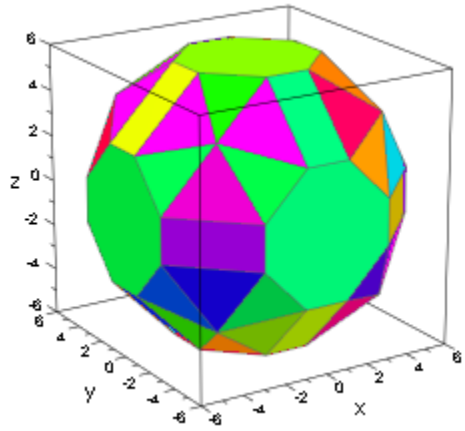


Example 4

The LineColorFunction and FillColorFunction attributes can be set to functions which get indices of the currently painted surfacepolygon and its current vertex as fourth and fifth argument, repectively. This allows to color the polygons individually:
colors := [RGB::random() $ i = 1..42]: plot(plot::Waterman(5, FillColorFunction=((x,y,z,i) -> colors[i])))



Another way of getting random colors which remain constant for each polygon is to use a procedure with option remember:
col := proc(n) option remember; begin RGB::fromHSV([360*frandom(), 1, 1]); end: plot(plot::Waterman(7, FillColorFunction=((x,y,z,i) -> col(i))))



Parameters

r

An arithmetical expression: the radius of the polyhedron (see below for details).

`r` is equivalent to the attribute Radius.

a

Animation parameter, specified as `a = a_min..a_max`, where `a_min` is the initial parameter value, and `a_max` is the final parameter value.

Algorithms

`plot::Waterman` uses plot::hull (and therefore, the Geometry Centre's qhull code) to compute the convex hull of the coordinates. Most of the remaining code has been contributed by Mirek Majewski.

plot::XRotate

Purpose

Surfaces of revolution around x-axis

Syntax

```
plot::XRotate(f, x = x_min .. x_max, <a = a_min .. a_max>, options)
```

Description

`plot::XRotate(f, x = `x_{min}`..xmax)` creates a surface of revolution by rotating the function graph $y = f(x)$ with x $[x_min, x_max]$ around the x-axis.

`plot::XRotate` rotates the graph of the function $y = f(x)$ around the x-axis, creating a surface of revolution. The slice of the surface parallel to the y-z plane at a point x is a circle of radius $f(x)$.

The range of the rotation can be restricted with the attributes AngleBegin, AngleEnd, AngleRange. The surface of revolution will only span over the given range of the rotation angle.

Surfaces of revolution are parametrized surfaces. The first surface parameter is x, the second is the rotation angle. Surfaces of revolution react to most of the graphical attributes that surfaces of type plot::Surface react to. For example, use Mesh, Submesh to control the numerical mesh or use ULinesVisible, VLinesVisible to switch the parameter lines on/off.

Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	`0`
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
AngleEnd	end of angle range	`2*PI`
AngleBegin	begin of angle range	`0`
AngleRange	angle range	`0 .. 2*PI`
Color	the main color	RGB::Red

Attribute	Purpose	Default Value
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Function	function expression or procedure	
Legend	makes a legend entry	

Attribute	Purpose	Default Value
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	`TRUE`
LineColor	color of lines	`RGB::Black.[0.25]`
LineWidth	width of lines	`0.35`
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	`Solid`
LineColorType	line coloring types	`Flat`
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	`[0, 0, 1]`
LineColorDirectionX	x-component of the direction of color transitions on lines	`0`
LineColorDirectionY	y-component of the direction of color transitions on lines	`0`
LineColorDirectionZ	z-component of the direction of color transitions on lines	`1`
Mesh	number of sample points	`[25, 25]`
MeshVisible	visibility of irregular mesh lines in 3D	`FALSE`

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	`1.5`
PointStyle	the presentation style of points	`FilledCircles`
PointsVisible	visibility of mesh points	`FALSE`
Shading	smooth color blend of surfaces	`Smooth`
Submesh	density of submesh (additional sample points)	`[0, 0]`
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Title	object title	

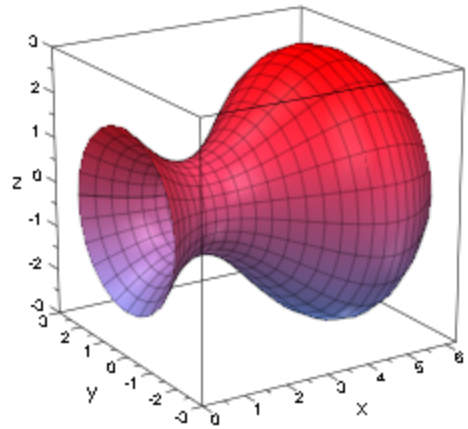
Attribute	Purpose	Default Value
TitleFont	font of object titles	`[" sans-serif ", 11]`
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	`Center`
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
ULinesVisible	visibility of parameter lines (u lines)	`TRUE`
UMesh	number of sample points for parameter “u”	`25`
USubmesh	density of additional sample points for parameter “u”	`0`
VLinesVisible	visibility of parameter lines (v lines)	`TRUE`
VMesh	number of sample points for parameter “v”	`25`
VSubmesh	density of additional sample points for parameter “v”	`0`

Attribute	Purpose	Default Value
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XContours	contour lines at constant x values	[]
XMax	final value of parameter “x”	5
XMin	initial value of parameter “x”	-5
XName	name of parameter “x”	
XRange	range of parameter “x”	-5 .. 5
YContours	contour lines at constant y values	[]
ZContours	contour lines at constant z values	[]

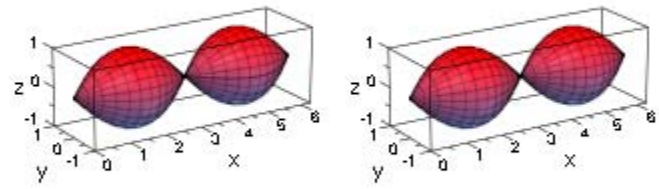
Examples

Example 1

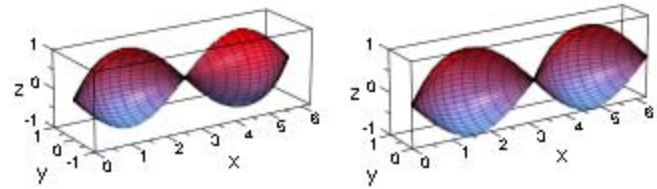
By default, `plot::XRotate` displays a complete revolution, just as if an object was created on a lathe:
plot(plot::XRotate(2 - sin(x), x = 0..2*PI))



This rotation is insensitive to negative values: The surfaces of revolution of $f(x)$ and $|f(x)|$ are identical:
plot(plot::Scene3d(plot::XRotate(sin(x), x = 0..2*PI)), plot::Scene3d(plot::XRotate(abs(sin(x)), x = 0..2*PI)), Layout = Horizontal)

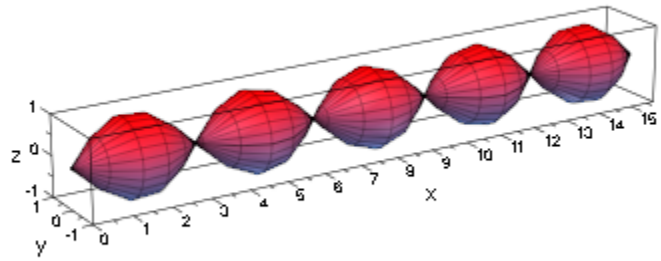


This symmetry is broken when not performing a whole revolution: plot(plot::Scene3d(plot::XRotate(sin(x), x = 0..2*PI, AngleRange = -PI/2..PI/2)), plot::Scene3d(plot::XRotate(abs(sin(x)), x = 0..2*PI, AngleRange = -PI/2..PI/2)), Layout = Horizontal)



`plot::XRotate` can be animated, like almost every plot object:

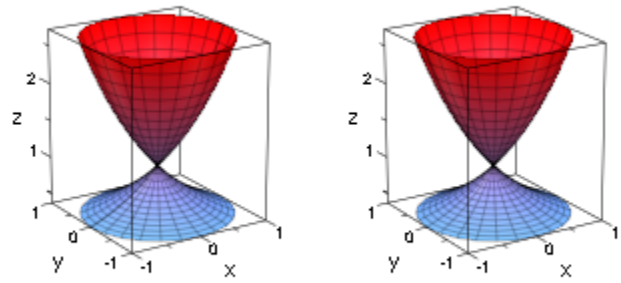
```
plot(plot::XRotate(sin(x + a), x = 0 .. 2*a + PI, AngleRange = 0 .. PI
+ a/2, a = 0..2*PI))
```



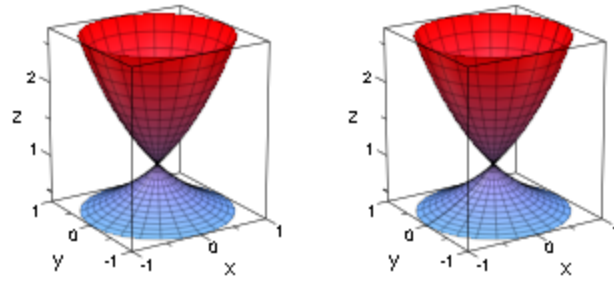
Example 2

As for `plot::ZRotate`, most of the points from above hold here, too. Obviously, the symmetry for a whole revolution is now with respect to the *x* values, not the function values:

```
plot(plot::Scene3d(plot::ZRotate(exp(x), x = -1..1)),
plot::Scene3d(plot::ZRotate(exp(-x), x = -1..1)), Layout =
Horizontal)
```



plot(plot::Scene3d(plot::ZRotate(exp(x), x = -1..1, AngleRange = -a..a, a = 0..PI)), plot::Scene3d(plot::ZRotate(exp(-x), x = -1..1, AngleRange = -a..a, a = 0..PI)), Layout = Horizontal)



Parameters

f

The function: an arithmetical expression or a piecewise object in the independent variable *x* and the animation parameter *a*. Alternatively, a procedure that accepts 1 input parameter *x* or 2 input parameters *x*, *a* and returns a real numerical value when the input parameters are numerical.

`f` is equivalent to the attribute Function.

x

The independent variable: an identifier or an indexed identifier.

`x` is equivalent to the attribute XName.

x_{min} .. x_{max}

The plot range: x_{min}, x_{max} must be numerical real values or expressions of the animation parameter *a*.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::ZRotate

Purpose

Surfaces of revolution around z-axis

Syntax

```
plot::ZRotate(f, x = x_min .. x_max, <a = a_min .. a_max>, options)
```

Description

`plot::ZRotate(f, x = `x_{min}`..xmax)` creates a surface of revolution by rotating the function graph $z = f(x)$ with x $[x_min, x_max]$ around the z-axis.

`plot::ZRotate` rotates the graph of the given function $z = f(x)$ around the z-axis, creating another surface of revolution. The slice of the surface parallel to the x-y plane at a point z consists of circles with radii $|x_i|$ given by the solutions of $f(x) = z$.

The range of the rotation can be restricted with the attributes AngleBegin, AngleEnd, AngleRange. The surface of revolution will only span over the given range of the rotation angle.

Surfaces of revolution are parametrized surfaces. The first surface parameter is x, the second is the rotation angle. Surfaces of revolution react to most of the graphical attributes that surfaces of type plot::Surface react to. For example, use Mesh, Submesh to control the numerical mesh or use ULinesVisible, VLinesVisible to switch the parameter lines on/off.

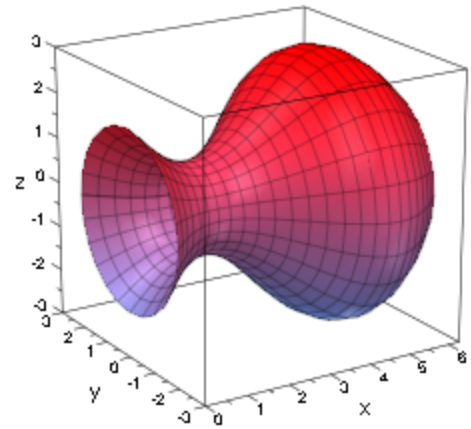
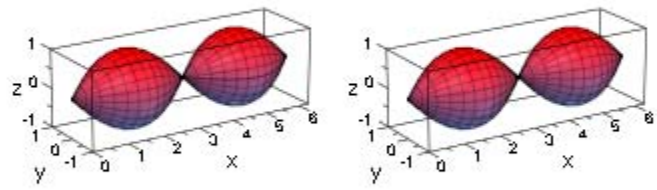
Examples

Example 1

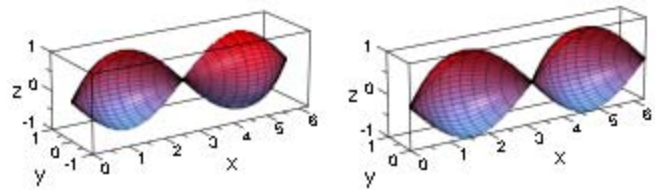
By default, `plot::XRotate` displays a complete revolution, just as if an object was created on a lathe:
plot(plot::XRotate(2 - sin(x), x = 0..2*PI))



This rotation is insensitive to negative values: The surfaces of revolution of $f(x)$ and $|f(x)|$ are identical:
plot(plot::Scene3d(plot::XRotate(sin(x), x = 0..2*PI)), plot::Scene3d(plot::XRotate(abs(sin(x)), x = 0..2*PI)), Layout = Horizontal)

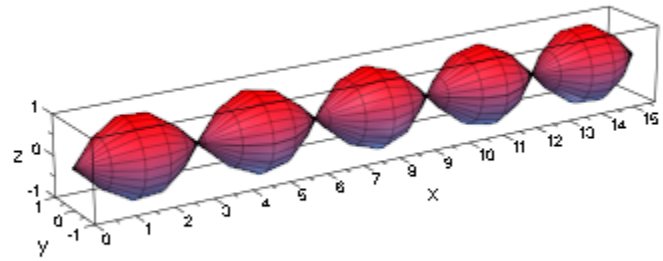


This symmetry is broken when not performing a whole revolution:
plot(plot::Scene3d(plot::XRotate(sin(x), x = 0..2*PI, AngleRange = -PI/2..PI/2)), plot::Scene3d(plot::XRotate(abs(sin(x)), x = 0..2*PI, AngleRange = -PI/2..PI/2)), Layout = Horizontal)



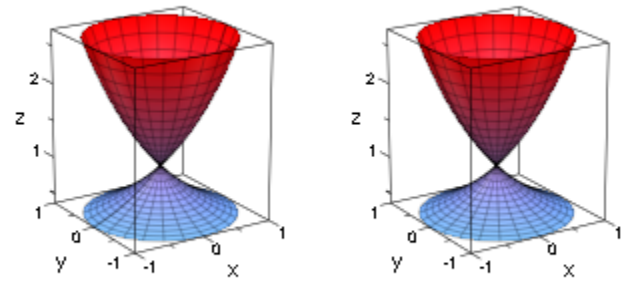
`plot::XRotate` can be animated, like almost every plot object:

plot(plot::XRotate(sin(x + a), x = 0 .. 2*a + PI, AngleRange = 0 .. PI + a/2, a = 0..2*PI))

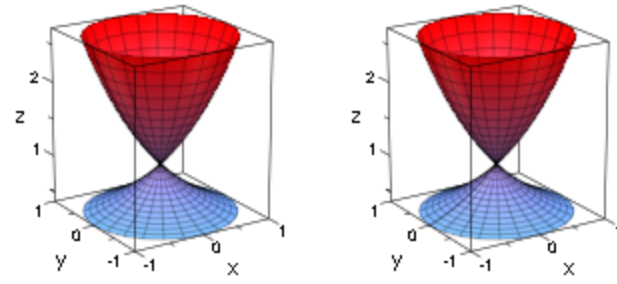


Example 2

As for `plot::ZRotate`, most of the points from above hold here, too. Obviously, the symmetry for a whole revolution is now with respect to the *x* values, not the function values:
plot(plot::Scene3d(plot::ZRotate(exp(x), x = -1..1)), plot::Scene3d(plot::ZRotate(exp(-x), x = -1..1)), Layout = Horizontal)



plot(plot::Scene3d(plot::ZRotate(exp(x), x = -1..1, AngleRange = -a..a, a = 0..PI)), plot::Scene3d(plot::ZRotate(exp(-x), x = -1..1, AngleRange = -a..a, a = 0..PI)), Layout = Horizontal)



Parameters

f

The function: an arithmetical expression or a piecewise object in the independent variable *x* and the animation parameter *a*. Alternatively, a procedure that accepts 1 input parameter *x* or 2 input parameters *x*, *a* and returns a real numerical value when the input parameters are numerical.

`f` is equivalent to the attribute Function.

x

The independent variable: an identifier or an indexed identifier.

`x` is equivalent to the attribute XName.

x_{min} .. x_{max}

The plot range: x_{min}, x_{max} must be numerical real values or expressions of the animation parameter *a*.

x_{min} .. x_{max} is equivalent to the attributes XRange, XMin, XMax.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Canvas

Purpose

Drawing area

Syntax

`plot::Canvas(object`$_1$`, object`$_2$`, , <a = a`$_{min}$ `.. a`$_{max}$`>, options)`

Description

`plot::Canvas` is the top level element of the hierachy of graphical objects. It represents the 2 dimensional drawing area into which 2D and 3D plots are painted.

The user does not need to create a canvas object explicitly, because a `plot` command such as `plot(object`$_1$`, object`$_2$`, )` implicitly creates a default canvas object to display the graphical objects in.

Strictly speaking, a canvas object is a container for scenes of type plot::Scene2d or plot::Scene3d, respectively. The user, however, does not have to bother about this technicality, because a suitable default scene is created internally, when graphical primitives are passed to `plot::Canvas`.

A canvas can display several scenes simultaneously. However, all scenes must be of the same dimension. A mixture of 2D and 3D is not supported!

See the help page of the canvas attribute Layout for details on the layout of a canvas containing several scenes.

The canvas object is always visible in the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). It can contain one or more scenes as its children. When the canvas object is selected, it provides access to a variety of attributes that are associated with the canves. The canvas attributes allow to

- set Height and Width of the plot,
- set a Header and/or a Footer,
- control the layout (Layout, Rows, Columns),

- set various style parameters such as BorderWidth, BorderColor, BackgroundColor etc.

A complete listing of the attributes associated with a canvas is given below. Follow the links to the help pages of the attributes to find more detailed information.

Apart from these attributes of the canvas object, also attributes for scenes, coordinate systems and graphical objects inside the canvas can be specified when generating a canvas object. These attribute values are inherited to the objects inside the canvas as new default values.

Attributes

Attribute	Purpose	Default Value
AnimationStyle	behaviour of the animation toolbar	`RunOnce`
AutoPlay	start animations automatically	`TRUE`
BackgroundColor	background color	RGB::White
BorderColor	color of frame/border around canvas and scenes	RGB::Grey50
BorderWidth	width of frame/border around canvas and scenes	`0`
BottomMargin	bottom margin width	`1`
Columns	number of columns of scenes	`0`
Footer	footer text	
FooterFont	font of footers (scene and canvas)	`[" sans-serif ", 12]`

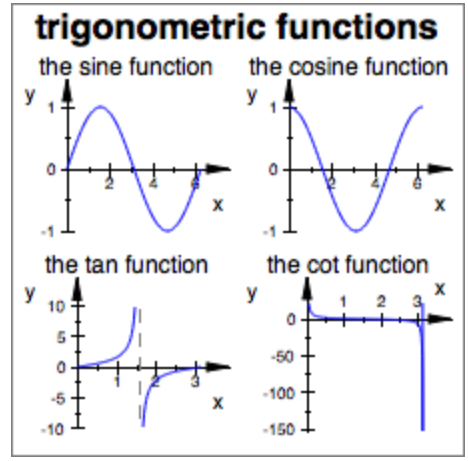
Attribute	Purpose	Default Value
FooterAlignment	alignment of footer of canvas and scenes	`Center`
Header	header text	
HeaderFont	font of headers (scene and canvas)	`[" sans-serif ", 12]`
HeaderAlignment	alignment of header of canvas and scenes	`Center`
Height	heights of canvas/scenes	`80`
InitialTime	initial time of the animation slider	
Layout	arrangement/layout of several scenes in a canvas	`Tabular`
LeftMargin	left margin width	`1`
Margin	margins around canvas and scenes	`1`
Name	the name of a plot object (for browser and legend)	
OutputUnits	the physical length unit used by the inspector	`unit::mm`
RightMargin	right margin width	`1`
Rows	number of rows of scenes	`0`
Spacing	space between scenes	`1.0`

Attribute	Purpose	Default Value
TopMargin	top margin width	1
Width	widths of canvas/scenes	120

Examples

Example 1

We diplay several scenes in a canvas. Various canvas attributes are passed when creating the canvas object:
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0..2*PI), Header = "the sine function"): S2 := plot::Scene2d(plot::Function2d(cos(x), x = 0..2*PI), Header = "the cosine function"): S3 := plot::Scene2d(plot::Function2d(tan(x), x = 0..PI), Header = "the tan function"): S4 := plot::Scene2d(plot::Function2d(cot(x), x = 0..PI), Header = "the cot function"): C := plot::Canvas(S1, S2, S3, S4, Width = 80*unit::mm, Height = 80*unit::mm, BorderWidth = 0.5*unit::mm, Header = "trigonometric functions", HeaderFont = ["Times New Roman", Bold, 18]): plot(C)



delete S1, S2, S3, S4, C:

Parameters **object$_1$, object$_2$, ...**

Graphical objects

See Also plotplot::copyplot::Scene2dplot::Scene3dplot::CoordinateSystem2dplot::CoordinateSyste

plot::CoordinateSystem2d

Purpose

Coordinate system to display 2D objects in

Syntax

```
plot::CoordinateSystem2d(object1, object2,  , <a
= amin .. amax>, options)
```

Description

`plot::CoordinateSystem2d` is a container to display graphical 2D objects within. Usually, the user does not need to create such an object explicitly, because a `plot` command such as `plot(object1, object2, )` creates a default object of type `plot::CoordinateSystem2d` implicitly to display the graphical objects in.

The `plot::CoordinateSystem2d` object is always visible in the interactive object browser of the MuPAD graphics tool (see Viewer, Browser, and Inspector: Interactive Manipulation of this document). It contains the graphical objects as its children. When the coordinate system object is selected, it provides access to a variety of attributes that are associated with the coordinate system. These attributes allow to manipulate:

- the CoordinateType (linear vs. logarithmic coordinates),
- the ViewingBox (visibility range),
- the coordinate axes (axes titles, visibility, alignment, type, tips etc.),
- the ticks along the coodinate axes (number of tick marks, visibility, tick labels etc.),
- the coordinate grid (visibility, color, line width etc.),
- the scaling ratios of the coordinate directions (`Constrained` vs. `UnConstrained`).

A complete listing of the attributes associated with the coordinate system is given below. Follow the links to the help pages of the attributes to find more detailed information.

Apart from these attributes of the coordinate system, also attributes for the graphical objects inside the coordinate system can be specified

when generating an object of type `plot::CoordinateSystem2d`. These attribute values are inherited to the graphical objects as new default values.

A graphical scene may contain more than one coordinate system. Each coordinate system provides separate coordinate axes, ticks, grid lines etc.

In such a case, separate `plot::CoordinateSystem2d` containers must be created explicitly by the user and passed to a `plot` command (or inserted into a scene of type plot::Scene2d). Cf. "Example 2" on page 24-993.

Attributes

Attribute	Purpose	Default Value
Axes	type of the coordinate axes	`Automatic`
AxesTips	arrow tips at the coordinate axes?	`TRUE`
AxesOrigin	crosspoint of the coordinate axes	`[0, 0]`
AxesTitles	titles for the coordinate axes	`[" x ", " y "]`
AxesInFront	coordinate axes in front of or behind graphical objects?	`FALSE`
AxesOriginX	crosspoint of the coordinate axes, x-coordinate	`0`
AxesOriginY	crosspoint of the coordinate axes, y-coordinate	`0`
AxesVisible	display coordinate axes?	`TRUE`

Attribute	Purpose	Default Value
AxesLineColor	color of the coordinate axes	RGB::Black
AxesLineWidth	width of the coordinate axes	`0.18`
AxesTitleFont	font of axes titles	`[" sans-serif ", 10]`
AxesTitleAlignment	alignment of axes titles	`End`
CoordinateType	linear versus logarithmic plots in 2D	`LinLin`
GridInFront	coordinate grid in front of or behind graphical objects?	`FALSE`
GridVisible	display a coordinate grid?	`FALSE`
GridLineColor	line color of the coordinate grid	RGB::Grey60
GridLineWidth	width of coordinate grid lines	`0.1`
GridLineStyle	line style of the coordinate grid	`Solid`
Name	the name of a plot object (for browser and legend)	
Scaling	scaling ratios	`Unconstrained`
SubgridVisible	display a coordinate subgrid?	`FALSE`
SubgridLineColor	line color of the coordinate subgrid	RGB::Grey80

Attribute	Purpose	Default Value
SubgridLineWidth	width of coordinate subgrid lines	`0.1`
SubgridLineStyle	line style of the coordinate subgrid	`Solid`
TicksAt	special axes tick marks	
TicksAnchor	user defined start of axes tick marks	`0`
TicksLength	length of axes tick marks	`2`
TicksNumber	number of axes tick marks	`Normal`
TicksBetween	number of minor (unlabeled) axes tick marks between major (labeled) axes tick marks	`1`
TicksVisible	display axes tick marks?	`TRUE`
TicksDistance	user defined axes tick mark distance	`0`
TicksLabelFont	font of tick labels	`[" sans-serif ", 8]`
TicksLabelStyle	display style of axes tick labels	`Horizontal`
TicksLabelsVisible	display axes tick labels?	`TRUE`

Attribute	Purpose	Default Value
ViewingBox	the visible coordinate range	[Automatic .. Automatic, Automatic .. Automatic]
ViewingBoxXMin	the smallest visible x-values	Automatic
ViewingBoxYMin	the smallest visible y-values	Automatic
ViewingBoxXMax	the largest visible x-values	Automatic
ViewingBoxYMax	the largest visible y-values	Automatic
ViewingBoxXRange	the range of x-values visible	Automatic .. Automatic
ViewingBoxYRange	the range of y-values visible	Automatic .. Automatic
XAxisTitle	title for the x axis	" x "
XAxisVisible	display x axis?	TRUE
XAxisTitleAlignment	alignment of x axis title	End
XGridVisible	display a coordinate grid in x-direction?	FALSE
XSubgridVisible	display a coordinate subgrid in x-direction?	FALSE
XTicksAt	special x axis tick marks	
XTicksAnchor	user defined start of x axis tick marks	0

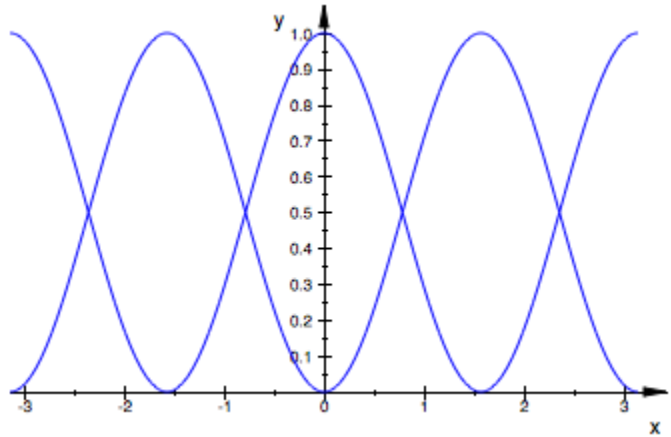
Attribute	Purpose	Default Value
XTicksNumber	number of x axis tick marks	`Normal`
XTicksBetween	number of minor (unlabeled) x axis tick marks between major (labeled) x axis tick marks	`1`
XTicksVisible	display x axis tick marks?	`TRUE`
XTicksDistance	distance of tick marks on x axis	`0`
XTicksLabelStyle	display style of x axis tick labels	`Horizontal`
XTicksLabelsVisible	display x axis tick labels?	`TRUE`
YAxisTitle	title for the y axis	`" y "`
YAxisVisible	display y axis?	`TRUE`
YAxisTitleAlignment	alignment of y axis title	`End`
YAxisTitleOrientation	orientation of the vertical axis title in 2D	`Horizontal`
YGridVisible	display a coordinate grid in y-direction?	`FALSE`
YSubgridVisible	display a coordinate subgrid in y-direction?	`FALSE`
YTicksAt	special y axis tick marks	

Attribute	Purpose	Default Value
YTicksAnchor	user defined start of y axis tick marks	`0`
YTicksNumber	number of y axis tick marks	`Normal`
YTicksBetween	number of minor (unlabeled) y axis tick marks between major (labeled) y axis tick marks	`1`
YTicksVisible	display y axis tick marks?	`TRUE`
YTicksDistance	distance of tick marks on y axis	`0`
YTicksLabelStyle	display style of y axis tick labels	`Horizontal`
YTicksLabelsVisible	display y axis tick labels?	`TRUE`

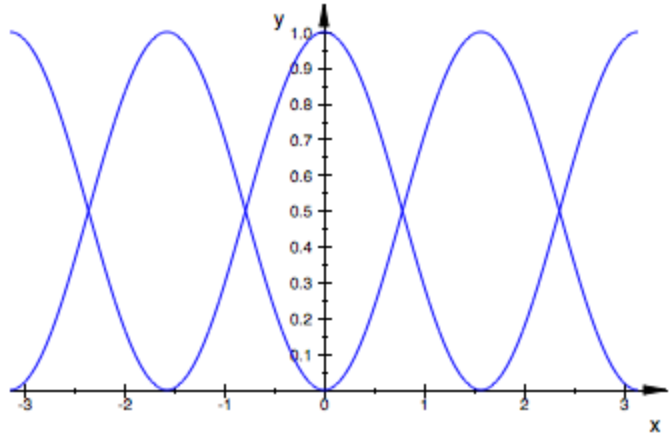
Examples

Example 1

When executing a plot command, a default `plot::CoordinateSystem2d` is created implicitly which contains the specified graphical objects:
f := plot::Function2d(sin(x)^2, x = -PI..PI): g := plot::Function2d(cos(x)^2, x = -PI..PI): plot(f, g)



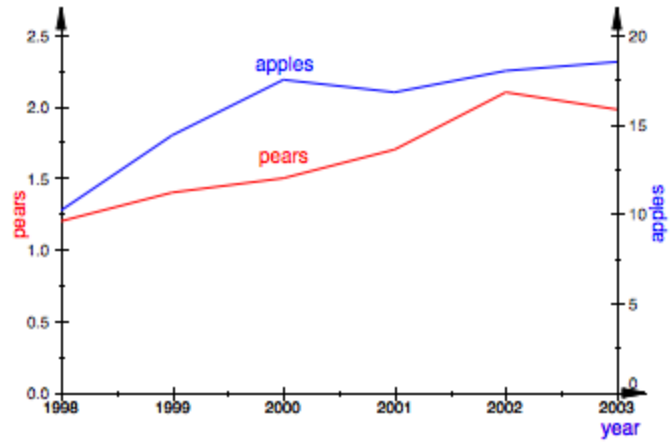
We can also create the coordinate system explicitly. The result is the same:
plot(plot::CoordinateSystem2d(f, g))



delete f, g:

Example 2

We present the yearly sales of pears and apples in one scene. Different coordinate systems are used to obtain separate axes. We set various attributes to determine the positioning of the axes and their titles: pears := plot::Polygon2d([[1998, 1.2], [1999, 1.4], [2000, 1.5], [2001, 1.7], [2002, 2.1], [2003, 1.98]], Color = RGB::Red, Title = "pears", TitlePosition = [2000, 1.6], TitleFont = [RGB::Red]): apples := plot::Polygon2d([[1998, 10.2], [1999, 14.4], [2000, 17.5], [2001, 16.8], [2002, 18.0], [2003, 18.5]], Color = RGB::Blue, Title = "apples", TitlePosition = [2000, 18.0], TitleFont = [RGB::Blue]): CS1 := plot::CoordinateSystem2d(pears): CS1::AxesOriginX := 1998: CS1::ViewingBox := [1998..2003, 0..2.5]: CS1::AxesTitleFont := [RGB::Red]: CS1::XAxisTitle := "year": CS1::YAxisTitle := "pears": CS2 := plot::CoordinateSystem2d(apples): CS2::AxesOriginX := 2003: CS2::ViewingBox := [1998..2003, 0..20]: CS2::AxesTitleFont := [RGB::Blue]: CS2::XAxisTitle := "year": CS2::YAxisTitle := "apples": plot(CS1, CS2, Axes = Origin, YAxisTitleAlignment = Center, YAxisTitleOrientation = Vertical)



delete pears, apples, CS1, CS2:

Parameters

object$_1$, object$_2$, ...

Graphical 2D objects

See Also plotplot::copyplot::Canvasplot::CoordinateSystem2dplot::Scene2d

plot::CoordinateSystem3d

Purpose

Coordinate system to display 3D objects in

Syntax

```
plot::CoordinateSystem3d(object1, object2,  , <a
= amin .. amax>, options)
```

Description

`plot::CoordinateSystem3d` is a container to display graphical 3D objects within. Usually, the user does not need to create such an object explicitly, because a `plot` command such as `plot(object1, object2, )` creates a default object of type `plot::CoordinateSystem3d` implicitly to display the graphical objects in.

The `plot::CoordinateSystem3d` object is always visible in the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). It contains the graphical objects as its children. When the coordinate system object is selected, it provides access to a variety of attributes that are associated with the coordinate system. These attributes allow to manipulate:

- the CoordinateType (linear vs. logarithmic coordinates),
- the ViewingBox (visibility range),
- the coordinate axes (axes titles, visibility, alignment, type, tips etc.),
- the ticks along the coodinate axes (number of tick marks, visibility, tick labels etc.),
- the coordinate grid (visibility, color, line width etc.),
- the scaling ratios of the coordinate directions (`Constrained` vs. `UnConstrained`).

A complete listing of the attributes associated with the coordinate system is given below. Follow the links to the help pages of the attributes to find more detailed information.

Apart from these attributes of the coordinate system, also attributes for the graphical objects inside the coordinate system can be specified

when generating an object of type `plot::CoordinateSystem3d`. These attribute values are inherited to the graphical objects as new default values.

A graphical scene may contain more than one coordinate system. Each coordinate system provides separate coordinate axes, ticks, grid lines etc.

In such a case, separate `plot::CoordinateSystem3d` containers must be created explicitly by the user and passed to a `plot` command (or inserted into a scene of type plot::Scene3d). Cf. "Example 2" on page 24-1004.

Attributes

Attribute	Purpose	Default Value
Axes	type of the coordinate axes	`Boxed`
AxesTips	arrow tips at the coordinate axes?	`FALSE`
AxesOrigin	crosspoint of the coordinate axes	`[0, 0, 0]`
AxesTitles	titles for the coordinate axes	`[" x "," y "," z "]`
AxesOriginX	crosspoint of the coordinate axes, x-coordinate	`0`
AxesOriginY	crosspoint of the coordinate axes, y-coordinate	`0`
AxesOriginZ	crosspoint of the coordinate axes, z-coordinate	`0`
AxesVisible	display coordinate axes?	`TRUE`

Attribute	Purpose	Default Value
AxesLineColor	color of the coordinate axes	RGB::Black
AxesLineWidth	width of the coordinate axes	`0.18`
AxesTitleFont	font of axes titles	`[" sans-serif ", 10]`
AxesTitleAlignment	alignment of axes titles	`Center`
GridVisible	display a coordinate grid?	`FALSE`
GridLineColor	line color of the coordinate grid	RGB::Grey60
GridLineWidth	width of coordinate grid lines	`0.1`
GridLineStyle	line style of the coordinate grid	`Solid`
Name	the name of a plot object (for browser and legend)	
Scaling	scaling ratios	`Unconstrained`
SubgridVisible	display a coordinate subgrid?	`FALSE`
SubgridLineColor	line color of the coordinate subgrid	RGB::Grey80
SubgridLineWidth	width of coordinate subgrid lines	`0.1`
SubgridLineStyle	line style of the coordinate subgrid	`Solid`

Attribute	Purpose	Default Value
TicksAt	special axes tick marks	
TicksAnchor	user defined start of axes tick marks	`0`
TicksLength	length of axes tick marks	`2`
TicksNumber	number of axes tick marks	`Normal`
TicksBetween	number of minor (unlabeled) axes tick marks between major (labeled) axes tick marks	`1`
TicksVisible	display axes tick marks?	`TRUE`
TicksDistance	user defined axes tick mark distance	`0`
TicksLabelFont	font of tick labels	`[" sans-serif ", 8]`
TicksLabelStyle	display style of axes tick labels	`Horizontal`
TicksLabelsVisible	display axes tick labels?	`TRUE`
ViewingBox	the visible coordinate range	`[Automatic .. Automatic, Automatic .. Automatic, Automatic .. Automatic]`
ViewingBoxXMin	the smallest visible x-values	`Automatic`

Attribute	Purpose	Default Value
ViewingBoxYMin	the smallest visible y-values	`Automatic`
ViewingBoxXMax	the largest visible x-values	`Automatic`
ViewingBoxZMin	the smallest visible z-values	`Automatic`
ViewingBoxYMax	the largest visible y-values	`Automatic`
ViewingBoxZMax	the largest visible z-values	`Automatic`
ViewingBoxXRange	the range of x-values visible	`Automatic .. Automatic`
ViewingBoxYRange	the range of y-values visible	`Automatic .. Automatic`
ViewingBoxZRange	the range of z-values visible	`Automatic .. Automatic`
XAxisTitle	title for the x axis	`" x "`
XAxisVisible	display x axis?	`TRUE`
XAxisTitleAlignment	alignment of x axis title	`Center`
XGridVisible	display a coordinate grid in x-direction?	`FALSE`
XSubgridVisible	display a coordinate subgrid in x-direction?	`FALSE`
XTicksAt	special x axis tick marks	

Attribute	Purpose	Default Value
XTicksAnchor	user defined start of x axis tick marks	0
XTicksNumber	number of x axis tick marks	Normal
XTicksBetween	number of minor (unlabeled) x axis tick marks between major (labeled) x axis tick marks	1
XTicksVisible	display x axis tick marks?	TRUE
XTicksDistance	distance of tick marks on x axis	0
XTicksLabelStyle	display style of x axis tick labels	Horizontal
XTicksLabelsVisible	display x axis tick labels?	TRUE
YAxisTitle	title for the y axis	" y "
YAxisVisible	display y axis?	TRUE
YAxisTitleAlignment	alignment of y axis title	Center
YGridVisible	display a coordinate grid in y-direction?	FALSE
YSubgridVisible	display a coordinate subgrid in y-direction?	FALSE
YTicksAt	special y axis tick marks	

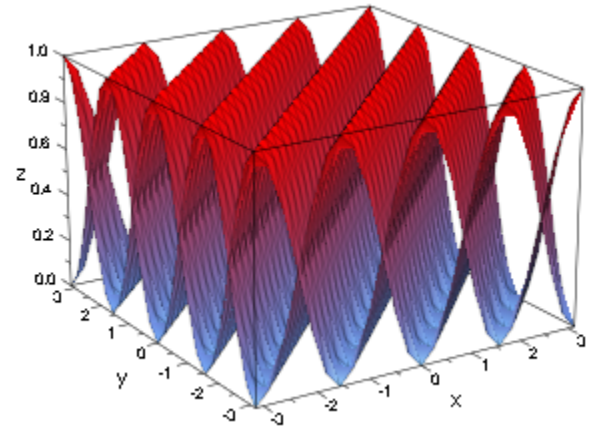
Attribute	Purpose	Default Value
YTicksAnchor	user defined start of y axis tick marks	0
YTicksNumber	number of y axis tick marks	Normal
YTicksBetween	number of minor (unlabeled) y axis tick marks between major (labeled) y axis tick marks	1
YTicksVisible	display y axis tick marks?	TRUE
YTicksDistance	distance of tick marks on y axis	0
YTicksLabelStyle	display style of y axis tick labels	Horizontal
YTicksLabelsVisible	display y axis tick labels?	TRUE
ZAxisTitle	title for the z axis	" z "
ZAxisVisible	display z axis?	TRUE
ZAxisTitleAlignment	alignment of z axis title	Center
ZGridVisible	display a coordinate grid in z-direction?	FALSE
ZSubgridVisible	display a coordinate subgrid in z-direction?	FALSE
ZTicksAt	special z axis tick marks	

Attribute	Purpose	Default Value
ZTicksAnchor	user defined start of z axis tick marks	`0`
ZTicksNumber	number of z axis tick marks	`Normal`
ZTicksBetween	number of minor (unlabeled) z axis tick marks between major (labeled) z axis tick marks	`1`
ZTicksVisible	display z axis tick marks?	`TRUE`
ZTicksDistance	distance of tick marks on z axis	`0`
ZTicksLabelStyle	display style of z axis tick labels	`Horizontal`
ZTicksLabelsVisible	display z axis tick labels?	`TRUE`

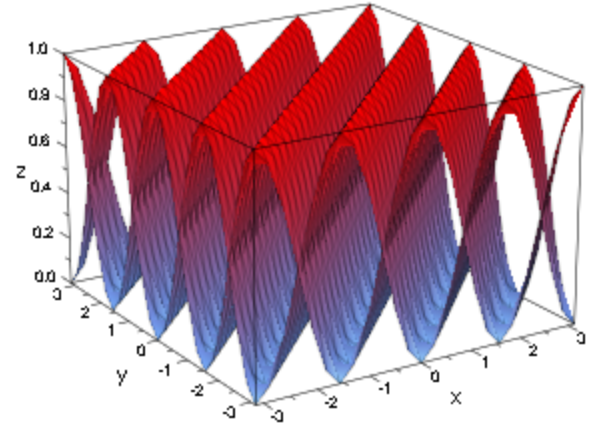
Examples

Example 1

When executing a plot command, a default `plot::CoordinateSystem3d` is created implicitly which contains the specified graphical objects:
f := plot::Function3d(sin(x - y)^2, x = -PI..PI, y = -PI..PI): g := plot::Function3d(cos(x - y)^2, x = -PI..PI, y = -PI..PI): plot(f, g)



We can also create the coordinate system explicitly. The result is the same:
plot(plot::CoordinateSystem3d(f, g))



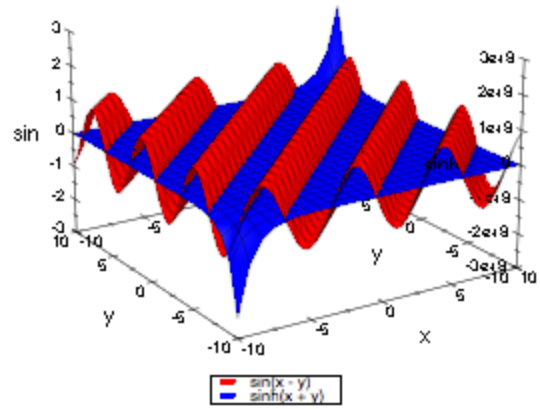
delete f, g:

Example 2

The functions $f_1 = sin(x - y)$ and $f_2 = sin(h)(x + y)$ cannot be plotted simultaneously in one coordinate system over the range $x \in [-10, 10]$, $y \in [-10, 10]$, because they produce function values of different orders of magnitude. To plot them together, we use two different coordinate systems. We request explicit vertical ranges for the (rather different) viewing boxes by the attribute ViewingBoxZRange.

We set various attributes of the coordinate systems to determine the positioning of the axes and their titles:

```
f1 := plot::Function3d(sin(x - y), x = -10..10, y = -10..10, Submesh = [2,
2], Color = RGB::Red, FillColorType = Flat, Legend = "sin(x - y)"): CS1
:= plot::CoordinateSystem3d(f1): CS1::Axes := Origin: CS1::AxesOrigin
:= [-10, 10, -3]: CS1::ViewingBoxZRange := -3..3: CS1::ZAxisTitle :=
"sin": f2 := plot::Function3d(sinh(x + y), x = -10..10, y = -10..10, Color
= RGB::Blue, FillColorType = Flat, Legend = "sinh(x + y)"): CS2 :=
plot::CoordinateSystem3d(f2): CS2::Axes := Origin: CS2::AxesOrigin
:= [10, -10, -3*10^8]: CS2::ViewingBoxZRange := -3*10^8..3*10^8:
CS2::ZAxisTitle := "sinh": plot(CS1, CS2):
```



delete f1, CS1, f2, CS2:

Parameters

$object_1$, $object_2$, ...

Graphical 3D objects

See Also

plotplot::copyplot::Canvasplot::CoordinateSystem3dplot::Scene3d

plot::Group2d

Purpose

Groups of 2D objects

Syntax

```
plot::Group2d(object2d1, object2d2,  , <a =
amin .. amax>, options)
```

Description

`plot::Group2d` forms a group of any number of graphical 2D objects.

Grouping together a larger number of graphical objects and accessing the group as a whole simplifies their handling. In particular, the main purpose of a group is to inherit graphical attributes that are shared by all members of the group.

If you wish to change the inherited attributes interactively, you should not select the group itself in the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). Underneath the group object, you find 'defaults' branches for the objects in the group. Select the 'defaults' branch for the object type that you wish to set attributes for.

A group may again contain groups.

Note When working with groups of points, it is more efficient to use the specialized grouping constructs plot::PointList2d and plot::PointList3d instead of generic groups of points!

Attributes

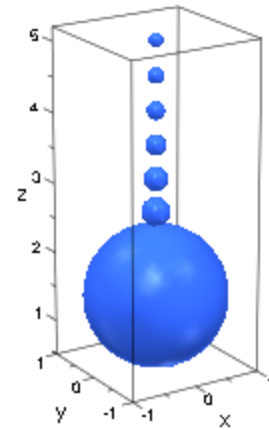
Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
Visible	visibility	TRUE

Examples

Example 1

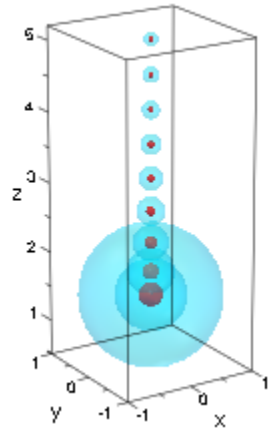
We plot two groups of bubbles. Some bubbles are not visible as they are inside larger bubbles:

```
G1 := plot::Group3d(plot::Sphere(1/n, [0, 0, n/2 + 1/n] ) $ n = 1..10): G2 := plot::Group3d(plot::Sphere(1/(3*n), [0, 0, n/2 + 1/n] ) $ n = 2..10): plot(G1, G2)
```



We wish to increase transparency of all bubbles in the first group, but keep the bubbles in the second group opaque. Since the bubbles are grouped, it is easy to set different attribute values for the two groups:

```
G1::Color := RGB::SkyBlue.[0.25]: G2::Color := RGB::Red: plot(G1, G2)
```

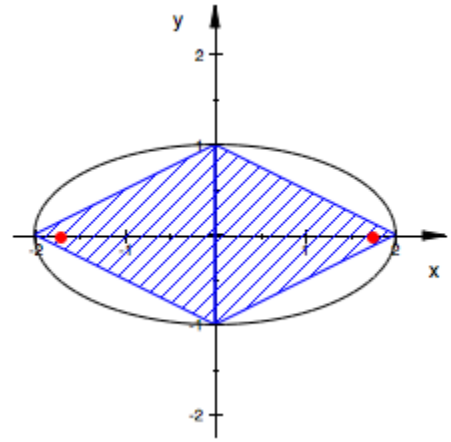


delete G1, G2:

Example 2

Consider a group `G1` consisting of two triangles inscribed in an ellipse. We form a new group `G2` consisting of the group `G1`, the ellipse and its focal points. The entire figure given by the group `G2` is rotated by an animated plot::Rotate2d:

```
G1 := plot::Group2d( plot::Polygon2d([[0, -1], [0, 1], [-2, 0]]),
plot::Polygon2d([[0, -1], [0, 1], [ 2, 0]]), Closed = TRUE, Filled = TRUE,
Color = RGB::Blue): G2 := plot::Group2d( G1, plot::Ellipse2d(2, 1,[0, 0]),
plot::PointList2d([[-sqrt(3), 0], [sqrt(3), 0]]), PointSize = 2*unit::mm,
PointColor = RGB::Red, LineColor = RGB::Black): plot(plot::Rotate2d(a,
[0, 0], a = 0..2*PI, G2))
```



delete G1, G2:

plot::Scene2d

Purpose

2D scenes

Syntax

```
plot::Scene2d(object2d1, object2d2,  , <a =
amin .. amax>, options)
```

Description

`plot::Scene2d` is a container to display one or more coordinate systems containing graphical objects. Scene objects must be created when several graphical scenes are to be displayed simultaneously in a plot.

Usually, you do not need to create a scene object explicitly, because a `plot` command such as `plot(object1, object2,  )` creates a default scene object implicitly to display the graphical objects in.

The need for creating scene objects explicitly arises only when several scenes are to be displayed simultaneously in one plot.

The MuPAD graphics makes a clear division between 2D and 3D. Scene objects of type `plot::Scene2d` do not accept 3D objects and `plot::Scene3d` objects do not accept 2D objects. When several scenes are displayed simultaneously in a single plot, all scenes must be of the same dimension.

Strictly speaking, a 2D scene object is a container for coordinate systems of type plot::CoordinateSystem2d. However, you do not have to bother about this technicality because a suitable default coordinate system is created internally, when graphical primitives are passed to `plot::Scene2d`.

Scene objects are always visible in the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). Each scene contains one or more coordinate systems as its children. When the scene object is selected, it provides access to a variety of attributes that are associated with scenes. The scene attributes allow to

- set annotations (Header, Footer) and control the Legend,

- set layout parameters such as height and width (if the canvas attribute Layout is set to `Absolute` or `Relative`),
- set various style parameters such as BackgroundColor etc.

A complete listing of the attributes associated with a 2D scene is given below. Follow the links to the help pages of the attributes to find more detailed information.

Apart from these attributes of the scene object, also attributes for the coordinate system and the graphical objects inside the scene can be specified when generating a scene object. These attribute values are inherited to the coordinate system and the graphical objects as new default values.

A plot may contain more than one graphical scene. In such a case, separate scene objects must be created explicitly by the user and passed to a `plot` command (or inserted into an object of type plot::Canvas). For details on the layout of scenes inside the drawing area ("canvas"), see the help page of the canvas attribute Layout.

See "Example 1" on page 24-1017.

Attributes

Attribute	Purpose	Default Value
BackgroundColor	background color	RGB::White
BackgroundTransparent	plot a scene on a transparent background	`FALSE`
BorderColor	color of frame/border around canvas and scenes	RGB::Grey50
BorderWidth	width of frame/border around canvas and scenes	`0`

Attribute	Purpose	Default Value
Bottom	distance of bottom of scene to bottom of canvas	`0`
BottomMargin	bottom margin width	`1`
Footer	footer text	
FooterFont	font of footers (scene and canvas)	`[" sans-serif ", 12]`
FooterAlignment	alignment of footer of canvas and scenes	`Center`
Header	header text	
HeaderFont	font of headers (scene and canvas)	`[" sans-serif ", 12]`
HeaderAlignment	alignment of header of canvas and scenes	`Center`
Height	heights of canvas/scenes	`80`
Left	distance of left of scene to left of canvas	`0`
LeftMargin	left margin width	`1`
LegendFont	font of legend entries	`[" sans-serif ", 8]`
LegendVisible	switch legend on/off	`FALSE`
LegendPlacement	legend above or below	`Bottom`
LegendAlignment	legend at left, center, or right	`Center`
Margin	margins around canvas and scenes	`1`

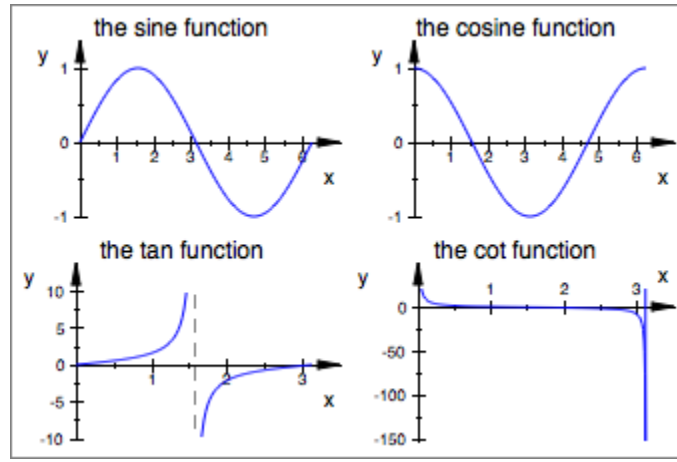
Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
RightMargin	right margin width	1
TopMargin	top margin width	1
Width	widths of canvas/scenes	120

Examples

Example 1

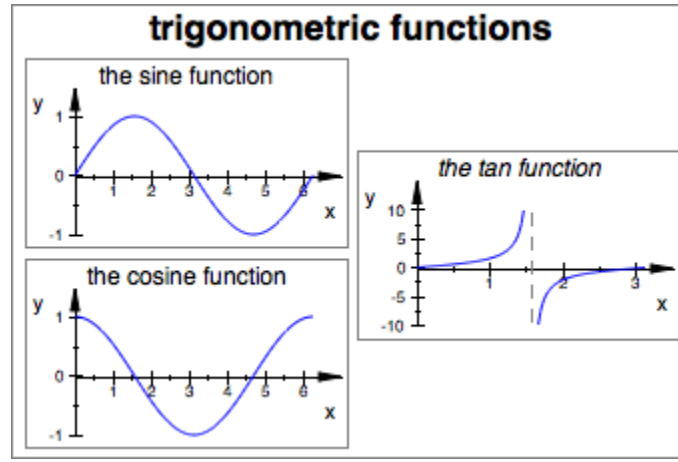
Scene objects have to be created explicitly only when several scenes are to be displayed simultaneously in one plot. The following call uses the automatic layout of several scenes in a canvas:

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0..2*PI), Header = "the
sine function"): S2 := plot::Scene2d(plot::Function2d(cos(x),
x = 0..2*PI), Header = "the cosine function"): S3 :=
plot::Scene2d(plot::Function2d(tan(x), x = 0..PI), Header =
"the tan function"): S4 := plot::Scene2d(plot::Function2d(cot(x), x =
0..PI), Header = "the cot function"): plot(S1, S2, S3, S4, BorderWidth
= 0.5*unit::mm)
```



We use the canvas attribute Layout = `Relative` to position 3 of these scenes in the canvas. The size of the scenes is set with the attributes Width and Height, specifying multiples of the canvas' width and height. The bottom left corner of each scene is positioned with the scene attributes Bottom and Left:

```
S1::Width := 0.475: S1::Height := 0.42: S2::Width := 0.475: S2::Height
:= 0.42: S3::Width := 0.475: S3::Height := 0.42: S1::Bottom := 0.46:
S1::Left := 0.02: S2::Bottom := 0.02: S2::Left := 0.02: S3::Bottom :=
0.26: S3::Left := 0.51: S3::HeaderFont := ["Times New Roman", Italic,
12]: plot(S1, S2, S3, Layout = Relative, BorderWidth = 0.5*unit::mm,
plot::Scene2d::BorderWidth = 0.2*unit::mm, Header = "trigonometric
functions", HeaderFont = ["Times New Roman", Bold, 18]):
```

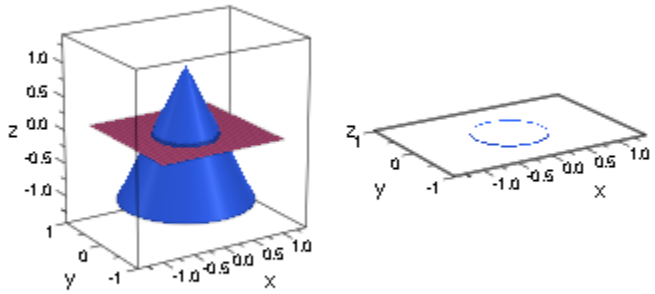


delete S1, S2, S3, S4:

Example 2

Conic sections are the curves that you get when intersecting a cone and a plane. The first scene displays a plane and a rotating cone, the second the corresponding conic section:

```
c := plot::Cone(1, [-sin(a), 0, -cos(a)], [sin(a), 0, cos(a)], a = 0..2*PI): s := plot::Surface([x, y, 0], x = -1..1, y = -1..1): S1 := plot::Scene3d(c, s): S2 := plot::Scene3d(c, ViewingBoxZRange = -0.01 .. 0.01): plot(S1, S2, Layout = Horizontal)
```



delete c, s, S1, S2:

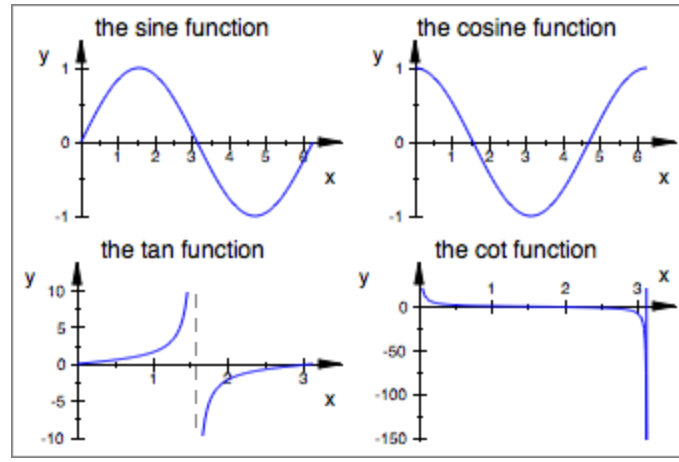
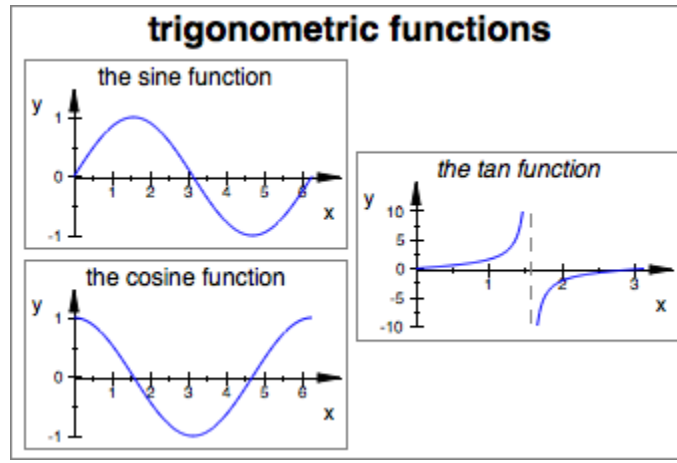
0..PI), Header = "the cot function"): plot(S1, S2, S3, S4, BorderWidth
= 0.5*unit::mm)
```



We use the canvas attribute Layout = `Relative` to position 3 of these scenes in the canvas. The size of the scenes is set with the attributes Width and Height, specifying multiples of the canvas' width and height. The bottom left corner of each scene is positioned with the scene attributes Bottom and Left:

```
S1::Width := 0.475: S1::Height := 0.42: S2::Width := 0.475: S2::Height
:= 0.42: S3::Width := 0.475: S3::Height := 0.42: S1::Bottom := 0.46:
S1::Left := 0.02: S2::Bottom := 0.02: S2::Left := 0.02: S3::Bottom :=
0.26: S3::Left := 0.51: S3::HeaderFont := ["Times New Roman", Italic,
12]: plot(S1, S2, S3, Layout = Relative, BorderWidth = 0.5*unit::mm,
```

plot::Scene2d::BorderWidth = 0.2*unit::mm, Header = "trigonometric functions", HeaderFont = ["Times New Roman", Bold, 18]):

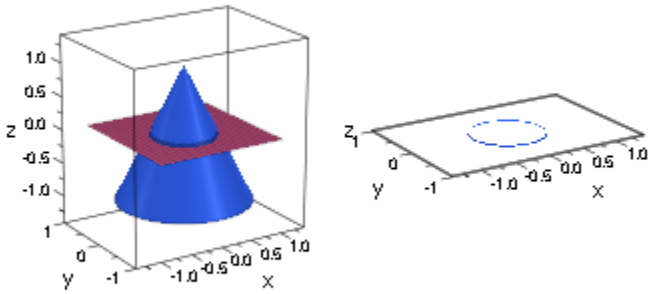


delete S1, S2, S3, S4:

Example 2

Conic sections are the curves that you get when intersecting a cone and a plane. The first scene displays a plane and a rotating cone, the second the corresponding conic section:

```
c := plot::Cone(1, [-sin(a), 0, -cos(a)], [sin(a), 0, cos(a)], a = 0..2*PI): s := plot::Surface([x, y, 0], x = -1..1, y = -1..1): S1 := plot::Scene3d(c, s): S2 := plot::Scene3d(c, ViewingBoxZRange = -0.01 .. 0.01): plot(S1, S2, Layout = Horizontal)
```



delete c, s, S1, S2:

Parameters

object3d$_1$, object3d$_2$, ...

3D coordinate systems or graphical 3D objects

See Also

plotplot::copyplot::Scene2dplot::Canvasplot::CoordinateSystem2dplot::CoordinateSy

plot::ClippingBox

Purpose

Clipping of 3D objects

Syntax

```
plot::ClippingBox(x_min .. x_max, y_min .. y_max, z_min ..
z_max, <a = a_min .. a_max>, options)
```

Description

A `plot::ClippingBox` defines a cubic box with edges parallel to the coordinate axes. When a clipping box is inserted in a 3D scene, only the parts of the graphical objects in the scene are visible that lie inside the coordinate range defined by the clipping box.

Inserting a `plot::ClippingBox` into a 3D scene has a similar effect as specifying a viewing box for the scene by the attribute ViewingBox.

However, the specified viewing box fills the entire drawing region of the plot, whereas a `plot::ClippingBox` preserves the space in the drawing region that the invisible parts would fill if no clipping box was used.

Moreover, in contrast to `plot::ClippingBox`, the visibility range defined by the ViewingBox cannot be animated.

In fact, the main purpose of `plot::ClippingBox` is to provide an animated version of the ViewingBox.

Size and location of the ViewingBox remain unaffected by the presence of a clipping box. Also coordinate axes are not clipped.

Only one single `plot::ClippingBox` should be used inside a 3D scene.

Attributes

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
Name	the name of a plot object (for browser and legend)	

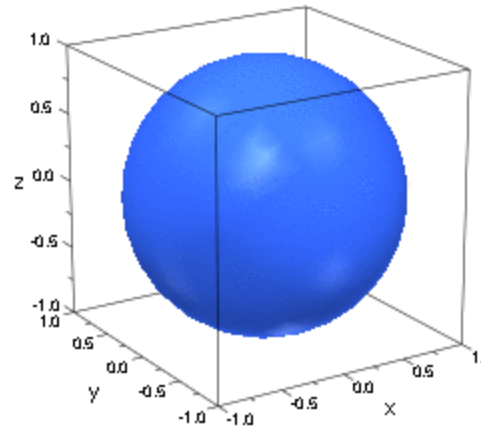
Attribute	Purpose	Default Value
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Visible	visibility	`TRUE`
XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XRange	range of parameter “x”	
YMax	final value of parameter “y”	
YMin	initial value of parameter “y”	
YRange	range of parameter “y”	

Attribute	Purpose	Default Value
ZMax	final value of parameter “z”	
ZMin	initial value of parameter “z”	
ZRange	range of parameter “z”	

Examples

Example 1

We plot a full sphere yet rendering only a part of it visible. This is done by passing a suitable animated `plot::ClippingBox` to the `plot` command. Note that the viewing box remains unaffected:
plot(plot::Sphere(1, [0, 0, 0]), plot::ClippingBox(-1 + a .. 1 - a, -1 + a .. 1 - a, -1 .. 1, a = 0..1))



Example 2

We plot a Klein bottle. By chopping off the upper parts, one can have a look inside:

```
KleinBottle := plot::Tube([6*cos(u)*(sin(u)-1), 0, 14*sin(u)], 4 - 2*cos(u),
u = -PI..PI): C := plot::ClippingBox(-15..15, -10..10, -20.. a, a = 15 .. -20):
plot(KleinBottle, C, Axes = None)
```

```
delete KleinBottle, C:
```

Parameters

x_{min}

x_{max}

The borders of the visible range of the *x* coordinate: numerical real values or arithmetical expressions of the animation parameter `a`.

x_{min}, x_{max} are equivalent to the attributes XMin, XMax.

y_{min}

y_{max}

The borders of the visible range of the *y* coordinate: numerical real values or arithmetical expressions of the animation parameter `a`.

y_{min}, y_{max} are equivalent to the attributes YMin, YMax.

z_{min}

z_{max}

The borders of the visible range of the *z* coordinate: numerical real values or arithmetical expressions of the animation parameter `a`.

z_{min}, z_{max} are equivalent to the attributes ZMin, ZMax.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::CoordinateSystem3d

plot::Reflect2d

Purpose

Reflection about a 2D point or a line

Syntax

```
plot::Reflect2d([x1, y1], <[x2, y2]>, obj1, obj2,  ,
<a = amin .. amax>, options)
```

Description

`plot::Reflect2d([ x1, y1], object)` reflects a 2D object about the point (x_1, y_1).

`plot::Reflect2d([ x1, y1], [ x2, y2], object)` reflects a 2D object about the line through the points (x_1, y_1) and (x_2, y_2).

Reflections are transformation objects that mirror their contents about a straight line (in 2D) or a plane (in 3D). In the degenerate case where both points on the line coincide, or the normal vector is given as `[0, 0, 0]`, or if only one point is specified, they reflect about a point.

Like all transformation objects, reflections may contain any number of objects of the appropriate dimension. Plotting the reflection object renders the reflections of all graphical objects inside.

Reflections can be animated. If the contained objects are animated, too, the animations will run simultaneously.

Animated reflection objects are rather "cheap" concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated reflection object than to redefine the object for each frame.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Frames	the number of frames in an animation	`50`

Attribute	Purpose	Default Value
From	starting point of arrows and lines	
FromX	starting point of arrows and lines, x-coordinate	
FromY	starting point of arrows and lines, y-coordinate	
Name	the name of a plot object (for browser and legend)

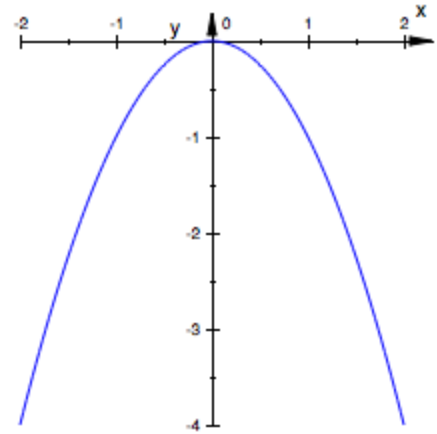
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
To	end point of arrows and lines	

Attribute	Purpose	Default Value
ToX	end point of arrows and lines, x-coordinate	
ToY	end point of arrows and lines, y-coordinate	

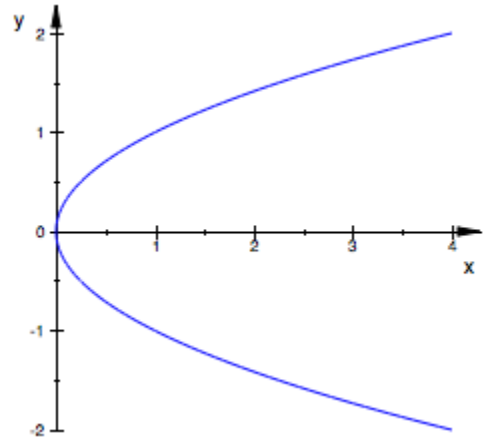
Examples

Example 1

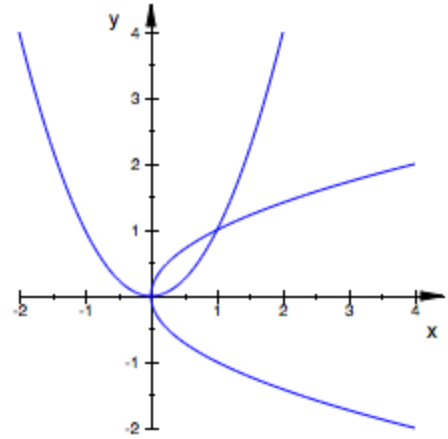
We plot the reflection of a function graph about the origin:
plot(plot::Reflect2d([0, 0], plot::Function2d(x^2, x=-2..2)))



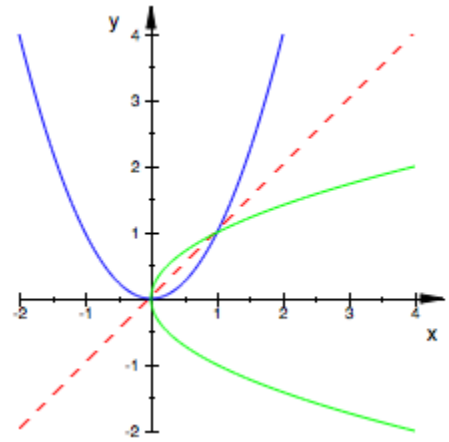
Reflecting a function about the main diagonal (the line through the origin and the point (1, 1) shows the (multivalued) inverse function:
plot(plot::Reflect2d([0, 0], [1, 1], plot::Function2d(x^2, x=-2..2)))



To display both an object and its mirror image, assign the object to some variable and plot both:
f := plot::Function2d(x^2, x=-2..2, LineWidth = 0.5): plot(f, plot::Reflect2d([0, 0], [1, 1], f))

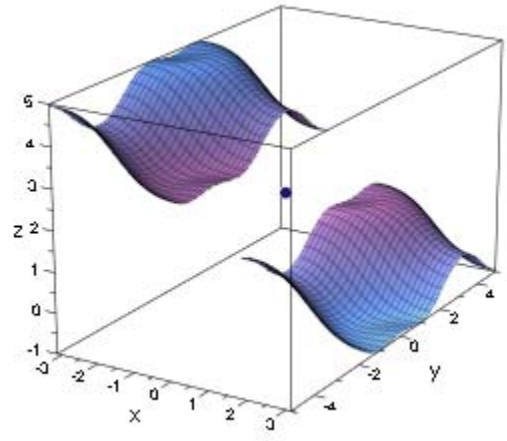


The following command shows two more useful variations: First, we use plot::Line2d to display the line of reflection. Second, we employ plot::modify to change the line color of the mirrored function graph: g := plot::Line2d([0, 0], [1, 1], Color = RGB::Red, LineStyle = Dashed, Extension = Infinite): f1 := plot::Reflect2d([0, 0], [1, 1], plot::modify(f, LineColor = RGB::Green)): plot(f, g, f1)



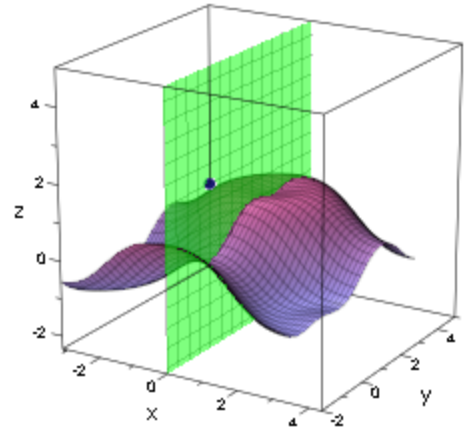
Example 2

A 3D function graph and its reflection about the point (0, 0, 2): f := plot::Function3d(sin(cos(x) - cos(y)), x = 0..PI, y = -2..5): p := plot::Point3d([0 , 0, 2], PointSize=2): plot(f, plot::Reflect3d([0, 0, 2], f), p, CameraDirection=[30, -50, 20])



The same function graph and its reflection at a plane through the point (0, 0, 2) with an animated normal vector:

```
pl := plot::Plane([0, 0, 2], [a, 0, 1-a], a=0..1, Color=RGB::Green.[0.5]):
plot(f, plot::Reflect3d([0, 0, 2], [a, 0, 1-a], a=0..1, f), p, pl,
CameraDirection=[30, -50, 20])
```



Parameters

x_1

y_1

x_2

y_2

The coordinates of two points on a line: real numerical values or arithmetical expressions of the animation parameter `a`.

x_1, y_1, x_2, y_2 are equivalent to the attributes From, To, FromX, FromY, ToX, ToY.

obj1, obj2, ...

Arbitrary plot objects of the appropriate dimension

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plot::Reflect3d

Purpose

Reflection about a 3D point or a plane

Syntax

```
plot::Reflect3d([x, y, z], <[n_x, n_y, n_z]>, obj1, obj2,
 , <a = a_min .. a_max>, options)
```

Description

`plot::Reflect3d([x, y, z], object)` reflects a 3D object about the point (*x*, *y*, *z*).

`plot::Reflect3d([x, y, z], [n_x, n_y, n_z], object)` reflects a 3D object about the plane through the point (*x*, *y*, *z*) with normal (n_x, n_y, n_z).

Reflections are transformation objects that mirror their contents about a straight line (in 2D) or a plane (in 3D). In the degenerate case where both points on the line coincide, or the normal vector is given as `[0, 0, 0]`, or if only one point is specified, they reflect about a point.

Like all transformation objects, reflections may contain any number of objects of the appropriate dimension. Plotting the reflection object renders the reflections of all graphical objects inside.

Reflections can be animated. If the contained objects are animated, too, the animations will run simultaneously.

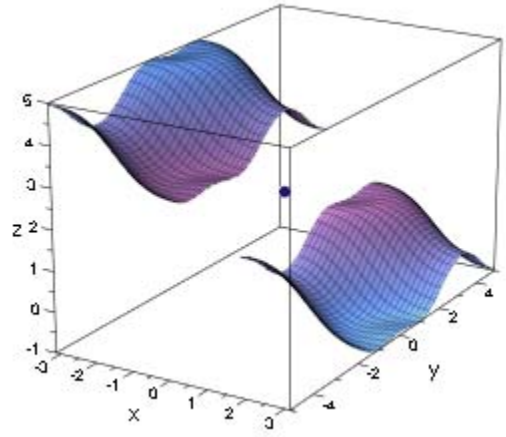
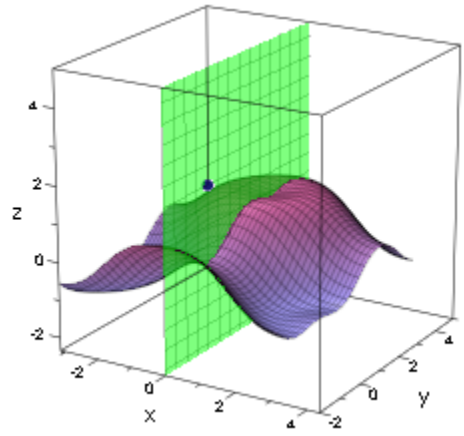
Example 2

A 3D function graph and its reflection about the point (0, 0, 2):
f := plot::Function3d(sin(cos(x) - cos(y)), x = 0..PI, y = -2..5): p := plot::Point3d([0 , 0, 2], PointSize=2): plot(f, plot::Reflect3d([0, 0, 2], f), p, CameraDirection=[30, -50, 20])



The same function graph and its reflection at a plane through the point (0, 0, 2) with an animated normal vector:
pl := plot::Plane([0, 0, 2], [a, 0, 1-a], a=0..1, Color=RGB::Green.[0.5]): plot(f, plot::Reflect3d([0, 0, 2], [a, 0, 1-a], a=0..1, f), p, pl, CameraDirection=[30, -50, 20])



Parameters

x

y

z

The coordinates of the mirror point or a point on the mirror plane, respectively: real numerical values or arithmetical expressions of the animation parameter `a`.

`x`, `y`, `z` are equivalent to the attributes Position, PositionX, PositionY, PositionZ.

n_x

n_y

n_z

The coordinates of the normal of the mirror plane: real numerical values or arithmetical expressions of the animation parameter `a`.

n_x, n_y, n_z are equivalent to the attributes Normal, NormalX, NormalY, NormalZ.

obj1, obj2, ...

Arbitrary plot objects of the appropriate dimension

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plotplot::copyplot::Reflect2dplot::Line2dplot::Planeplot::Transform2dplot::Transforr

plot::Rotate2d

Purpose

Rotations of 2D objects

Syntax

```
plot::Rotate2d(angle, <[c_x, c_y]>, obj_1, <obj_2,  >,
<a = a_min .. a_max>, options)
```

Description

`plot::Rotate2d(angle, [c_x, c_y], object)` rotates a 2D object counter clockwise by the given angle around the rotation center `[c_x, c_y]`.

In 2D, the direction of the rotation is counter clock wise. Use negative angles to rotate clock wise.

Rotate objects can rotate several graphical objects simultaneously. Plotting the rotate object renders all graphical objects inside.

Rotated objects have a tendency to overestimate their ViewingBox. Cf. the help page of ViewingBox. In such a case, you should specify a suitable ViewingBox explicitly.

Transformation objects can be used inside rotate objects. If they are animated, the animations run simultaneously.

Animated rotate objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated rotate object than to redefine the object for each frame.

The function op allows to extract the graphical objects inside a rotate object.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Angle	rotation angle	`0`

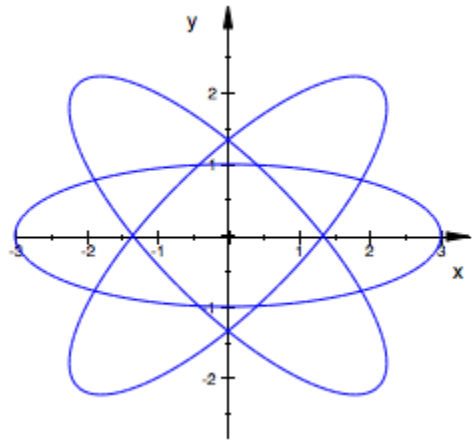
Attribute	Purpose	Default Value
Center	center of objects, rotation center	[0, 0]
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
Frames	the number of frames in an animation	50
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

Examples

Example 1

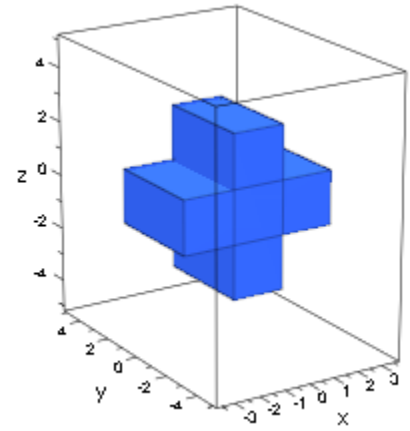
Ellipses of type plot::Ellipse2d have symmetry axes parallel to the coordinate axes. You can use `plot::Rotate2d` to obtain ellipses with other orientations:

```
e0 := plot::Ellipse2d(3, 1, [0, 0]): e1 := plot::Rotate2d(PI/4, [0, 0], e0): e2
:= plot::Rotate2d(-PI/4, [0, 0], e0): plot(e0, e1, e2):
```



Similarly, 3D boxes with arbitrary orientation can be generated via `plot::Rotate3d`. We use several animated rotation objects:

```
b0 := plot::Box(-3..3, -2..2, -1..1): b1 := plot::Rotate3d(a, [0, 0, 0], [0, 0, 1],
b0, a = 0..PI/2, TimeRange = 0..3): b2 := plot::Rotate3d(a, [0, 0, 0], [0, 1,
0], b1, a = 0..PI/2, TimeRange = 3..6): b3 := plot::Rotate3d(a, [0, 0, 0], [1,
0, 0], b2, a = 0..PI/2, TimeRange = 6..9): plot(b0, b3):
```

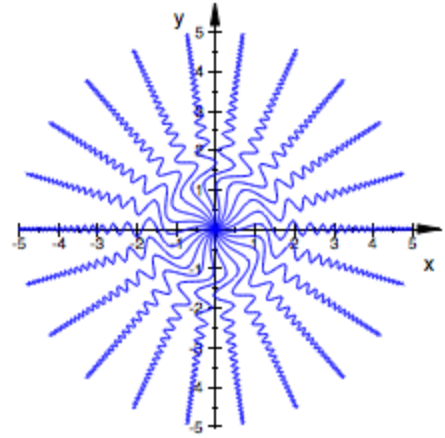


delete e0, e1, e2, b0, b1, b2, b3:

Example 2

We plot several copies of a function plot, rotated by different angles:

```
f := plot::Function2d(sin(x^3)/(x^2+1), x = -5..5, Mesh = 300):
plot(plot::Rotate2d(f, Angle = PI/11*a) $ a = 0..10):
```

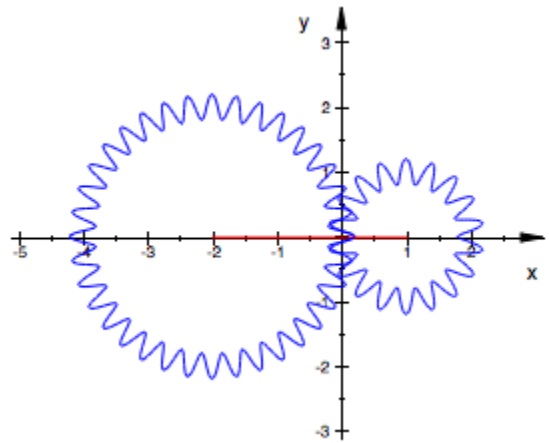


delete f:

Example 3

We plot turning cogs. Each animated rotate object rotates a curve and a line simultaneously:

```
r1 := 2: x1 := -r1: y1:= 0: r2 := 1: x2 := r2: y2:= 0: dr := 0.2:
cog1 := plot::Curve2d([x1 + (r1 + dr*cos(36*u))*cos(u), y1 + (r1 +
dr*cos(36*u))*sin(u)], u = 0..2*PI, Mesh = 360): cog2 := plot::Curve2d([x2
+ (r2 - dr*cos(18*u))*cos(u), y2 + (r2 - dr*cos(18*u))*sin(u)], u = 0..2*PI,
Mesh = 360): line1 := plot::Line2d([x1, y1], [x1 + r1 + dr, y1], Color
= RGB::Red): line2 := plot::Line2d([x2, y2], [x2 - r2 + dr, y2], Color =
RGB::Red): Cog1 := plot::Rotate2d(-a, [x1, y1], cog1, line1, a = 0..2*PI,
Frames = 180): Cog2 := plot::Rotate2d(2*a, [x2, y2], cog2, line2, a =
0..2*PI, Frames = 180): plot(Cog1, Cog2, Scaling = Constrained):
```

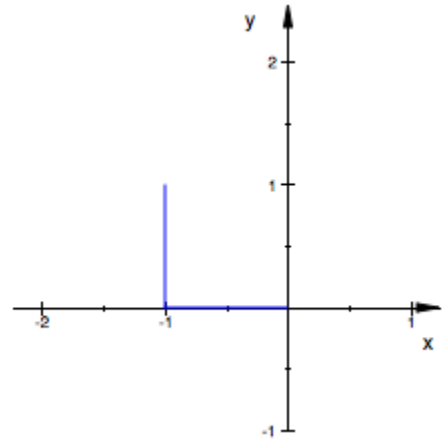


```
delete r1, x1, y1, r2, x2, y2, dr, cog1, cog2, line1, line2, Cog1, Cog2:
```

Example 4

We use an animated rotation inside another animated rotation:

```
L1 := plot::Line2d([0, 0], [0, 1]): L2 := plot::Rotate2d(a, [0, 1], a =
0..2*PI, plot::Line2d([0, 1], [1, 1])): plot(plot::Rotate2d(a, [0, 0], L1, L2, a
= 0..PI/2)):
```



delete L1, L2:

Parameters

angle

The rotation angle in radians: a numerical real value or an arithmetical expression of the animation parameter `a`.

`angle` is equivalent to the attribute Angle.

c_x

c_y

The components of the rotation center: numerical real values or arithmetical expressions of the animation parameter `a`. If no rotation center is specified, the center `[0, 0, 0]` is used.

c_x, c_y are equivalent to the attributes Center, CenterX, CenterY.

obj_1, obj_2, ...

Arbitrary plot objects of the appropriate dimension

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also plotplot::copyplot::Rotate3dplot::Scale2dplot::Scale3dplot::Translate2dplot::Translate3d

plot::Rotate3d

Purpose

Rotations of 3D objects

Syntax

```
plot::Rotate3d(angle, <[c_x, c_y, c_z], [d_x, d_y, d_z]>, obj_1,
<obj_2,  >, <a = a_min .. a_max>, options)
```

Description

`plot::Rotate3d(angle, [c_x, c_y, c_z], [d_x, d_y, d_z], object)` rotates a 3D object by the given angle around the rotation axis defined by the point `[c_x, c_y, c_z]` and the direction `[d_x, d_y, d_z]`.

In 3D, the rotation is implemented following the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation.

Use negative angles to rotate in the opposite direction.

Rotate objects can rotate several graphical objects simultaneously. Plotting the rotate object renders all graphical objects inside.

Rotated objects have a tendency to overestimate their ViewingBox. Cf. the help page of ViewingBox. In such a case, you should specify a suitable ViewingBox explicitly.

Transformation objects can be used inside rotate objects. If they are animated, the animations run simultaneously.

Animated rotate objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated rotate object than to redefine the object for each frame.

The function op allows to extract the graphical objects inside a rotate object.

d_x, d_y, d_z are equivalent to the attributes Axis, AxisX, AxisY, AxisZ.

obj_1, obj_2, ...

Arbitrary plot objects of the appropriate dimension

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also plotplot::copyplot::Rotate2dplot::Scale2dplot::Scale3dplot::Translate2dplot::Translate3d

plot::Scale2d

Purpose

Scaling of 2D objects

Syntax

```
plot::Scale2d([s_x, s_y], obj_1, <obj_2,  >, <a =
a_min .. a_max>, options)
```

Description

`plot::Scale2d([s_x, s_y], objects)` applies the scaling transformation (x) -> A*x $x \to Ax$ with the diagonal matrix $A = diag(s_x, s_y)$ to 2D objects.

Scale objects can scale several graphical objects simultaneously. Plotting the scale object renders all graphical objects inside.

Transformation objects can be used inside scale objects. If they are animated, the animations run simultaneously.

Animated scale objects are rather "cheap" concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated scale object than to redefine the object for each frame.

The function op allows to extract the graphical objects inside a scale object.

Attributes

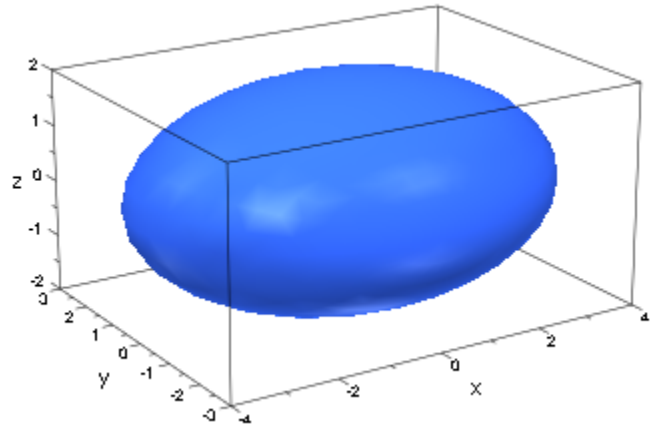
Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Frames	the number of frames in an animation	`50`
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Scale	scaling factors	[1, 1]
ScaleX	scaling factor in x-direction	1
ScaleY	scaling factor in y-direction	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

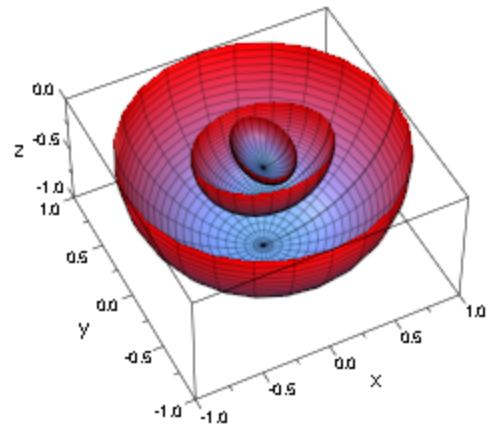
Examples

Example 1

A scaling transformation turns a sphere into an ellipsoid:
plot(plot::Scale3d([1 + 3*a, 1 + 2*a, 1 + a], plot::Sphere(1, [0, 0, 0]), a = 0..1))



We plot a (southern) hemisphere and two scaled copies:
A0 := plot::Spherical([1, u, v], u = 0..2*PI, v = PI/2 .. PI): A1 := plot::Scale3d([0.5, 0.4, 0.5], A0): A2 := plot::Scale3d([0.2, 0.3, 0.2], A0): plot(A0, A1, A2, CameraDirection = [-1, -2, 2.5]):



delete A0, A1, A2:

Parameters

s_x

s_y

The scaling factors: numerical real values or arithmetical expressions of the animation parameter `a`.

s_x, s_y are equivalent to the attributes Scale, ScaleX, ScaleY.

obj_1, obj_2, ...

Arbitrary plot objects of the appropriate dimension

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Transform2d

Purpose

Affine linear transformation of 2D objects

Syntax

```
plot::Transform2d(<b_2d>, A_2d, obj_1, <obj_2,  >, <a
= a_min .. a_max>, options)
```

Description

`plot::Transform2d(b, A, objects)` with a vector b and a matrix A applies the affine linear transformation (x) -> A*x+b $x \to A\,x + b$ to 2D objects.

The transformation matrix `A` can be specified by a list of lists

`[[A_1,1, A_1,2,  ], [A_2,1, A_2,2,  ],  ]`

with the sublists representing the rows.

A plain list

`[A_1,1, A_1,2, A_2,1, A_2,2]`

represents the matrix row by row in 2D.

Transform objects can transform several graphical objects simultaneously. Plotting the transform object renders all graphical objects inside.

Transformed objects have a tendency to overestimate their ViewingBox. Cf. the help page of ViewingBox. In such a case, you should specify a suitable ViewingBox explicitly.

Transformation objects can be used inside transformation objects. If they are animated, the animations run simultaneously.

Animated transform objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated transform object than to redefine the object for each frame.

The function op allows to extract the graphical objects inside a transformation object.

Attributes

Attribute	Purpose	Default Value

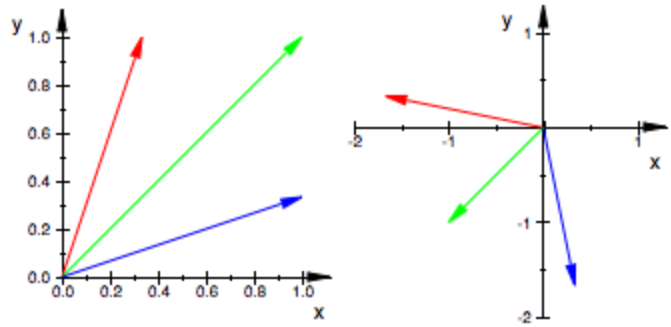
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`

Examples

Example 1

We visualize a linear transformation (x) -> A*x$_{x \to A\,x}$ without shift:
x1 := plot::Arrow2d([0, 0], [1/3, 1], Color = RGB::Red): x2 := plot::Arrow2d([0, 0], [1, 1], Color = RGB::Green): x3 := plot::Arrow2d([0, 0], [1, 1/3], Color = RGB::Blue): A := matrix([[1, -2], [-2, 1]]):
plot(plot::Scene2d(x1, x2, x3), plot::Scene2d(plot::Transform2d(A, x1, x2, x3)), Scaling = Constrained, Layout = Horizontal):

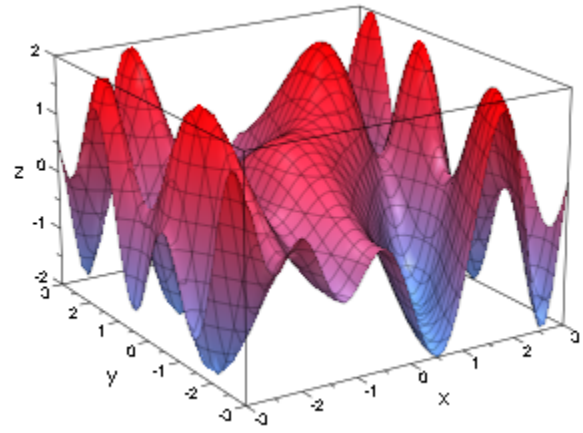


delete x1, x2, x3, A:

Example 2

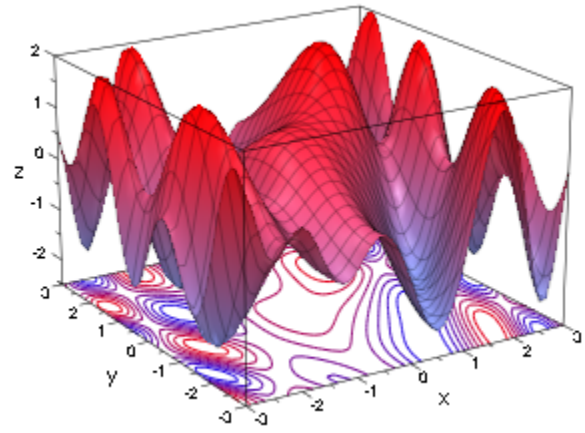
For some applications, it is very popular to plot a function in 3D together with a projection of its contour lines onto the lower or upper bounding plane. MuPAD has no direct option for this, but with `plot::Transform3d`, it is possible to achieve the same effect. Assume you have the function under consideration in a plot::Function3d object:
f := plot::Function3d(sin(x*y)+cos(x^2-y), x=-3..3, y=-3..3, Submesh=[1,1]):

To plot contour lines at all, we use the attribute ZContours. Since we don't want to change our `f`, we create a modified *copy* using plot::modify:
plot(plot::modify(f, ZContours = [Automatic, 10]))



To only get contour lines, we have to change a few more parameters: We need to switch off the surface and the parameter lines. Then, we add height coloring to our lines and use `plot::Transform3d` to *project* them onto the plane $z = -2.5$. Finally, we plot these lines together with the original function:

```
plot(f, plot::Transform3d([0, 0, -2.5], // shift vector [1, 0, 0, // transformation matrix 0, 1, 0, 0, 0, 0], plot::modify(f, Filled = FALSE, XLinesVisible = FALSE, YLinesVisible = FALSE, ZContours = [Automatic, 10], LineColorFunction = // height coloring ((x, y, z) -> [(z+2)/4, 0, (2-z)/4])))
```



Parameters

b_{2d}

The 2D shift vector: a list with 2 entries. Also vectors generated by matrix and arrays are accepted. The entries must be numerical values or arithmetical expressions of the animation paramater a.

b_{2d} is equivalent to the attribute Shift.

A_{2d}

The 2D transformation matrix: a 2 2 matrix, a 2 2 array, a list of 2 lists, or a plain list with 4 entries. The entries must be numerical values or arithmetical expressions of the animation paramater a.

A_{2d} is equivalent to the attribute Matrix2d.

obj1, obj2, ...

Plot objects of the appropriate dimension

a

Animation parameter, specified as $a = a_{min}..a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Translate2d

Purpose

Translation of 2D objects

Syntax

```
plot::Translate2d([d_x, d_y], obj_1, <obj_2,  >, <a =
a_min .. a_max>, options)
```

Description

`plot::Translate2d([d_x, d_y], object)` shifts a 2D object by d_x units along the x-axis and d_y units along the y-axis.

Translate objects can translate several graphical objects simultaneously. Plotting the translate object renders all graphical objects inside.

Transformation objects can be used inside translation objects. If they are animated, the animations run simultaneously.

Animated translate objects are rather "cheap" concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated translate object than to redefine the object for each frame.

The function op allows to extract the graphical objects inside a translate object.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the `ViewingBox` of a scene	`TRUE`
Frames	the number of frames in an animation	`50`

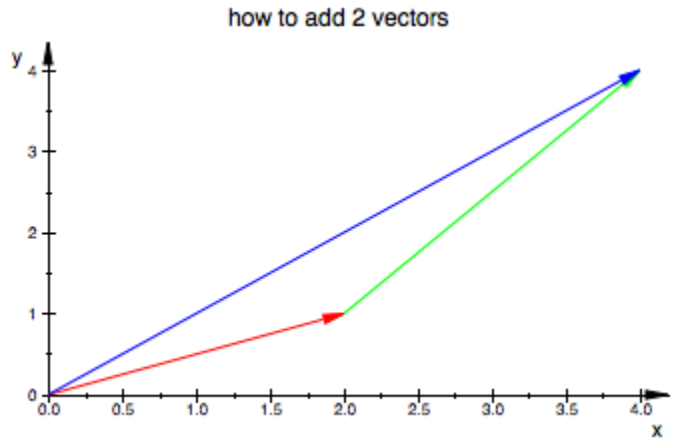
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

Examples

Example 1

We use an animated translation object to shift a vector to the tip of another vector:

```
A1 := plot::Arrow2d([0, 0], [2, 1], Color = RGB::Red): A2 :=
plot::Arrow2d([0, 0], [2, 3], Color = RGB::Green): plot(A1,
plot::Translate2d([2*a, a], A2, a = 0..1, TimeRange = 0..4),
plot::Arrow2d([0, 0], [4, 4], Color = RGB::Blue, VisibleFromTo = 4..6),
Header = "how to add 2 vectors"):
```

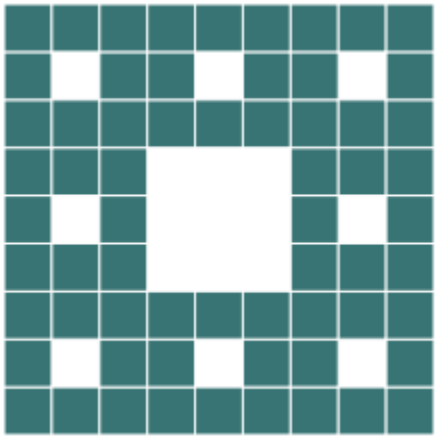


delete A1, A2:

Example 2

Note that `plot::Translate2d` and `plot::Translate3d` do not actually change the objects translated, so it is possible to use the same object in different places in the same plot. As an example, we show an intuitive way of constructing the Sierpinski carpet, a flat version of the Menger sponge.

The Sierpinski carpet is a fractal with the general shape of a square and the property that the following operation maps it onto itself: Take eight copies, scale them by $1/3 = \frac{1}{3}$, and arrange them in a square with the middle left unfilled. Now, this can be directly written in MuPAD code: Carpet := proc(iter) local square; begin if iter <= 1 then return(plot::Polygon2d([[0,0], [0,1], [1,1], [1,0]], Closed, Filled, FillPattern = Solid, FillColor = [0.2234, 0.4563, 0.4568], LinesVisible, LineColor = RGB::White, Scaling = Constrained, Axes = None)); else square := plot::Scale2d([1/3, 1/3], Carpet(iter-1)); return(plot::Group2d(plot::Translate2d([0, 0], square), plot::Translate2d([0, 1/3], square), plot::Translate2d([0, 2/3], square), plot::Translate2d([1/3, 0], square), // plot::Translate2d([1/3, 1/3], square), plot::Translate2d([1/3, 2/3], square), plot::Translate2d([2/3, 0], square), plot::Translate2d([2/3, 1/3], square), plot::Translate2d([2/3, 2/3], square))); end_if; end_proc:plot(Carpet(3))



Parameters

d_x

d_y

The components of the shift vector: numerical real values or arithmetical expressions of the animation parameter `a`.

d_x, d_y are equivalent to the attribute Shift.

obj_1, obj_2, ...

Arbitrary plot objects of the appropriate dimension

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::AmbientLight

Purpose

Ambient light

Syntax

`plot::AmbientLight(<intensity>, <a = a_min .. a_max>, options)`

Description

`plot::AmbientLight(intensity)` generates undirected ambient light of the given intensity.

Each 3D scene is illuminated by several light sources that are set automatically and cannot be controlled by the user. Cf. the help page of Lighting.

If special light effects are desired, the user can create alternative light sources of various types such as `plot::AmbientLight`, plot::DistantLight, plot::PointLight, and plot::SpotLight.

If at least one user defined light source is inserted into the scene (e.g., by simply passing the light objects as input parameters to the plot command), the automatic lights are switched off and the user defined lights are used to illuminate the scene.

While directed lights such as plot::DistantLight etc. create shading effects that add depth to the picture, a certain amount of undirected ambient light is usually needed.

`plot::AmbientLight(intensity)` creates ambient light whose intensity is given by the parameter `intensity`. When the intensity is 1, the ambient light dominates all other light sources.

By default, white light is created. Other colours can be chosen by the attribute LightColor.

It does not make sense to have more than one ambient light object in a scene.

Attributes

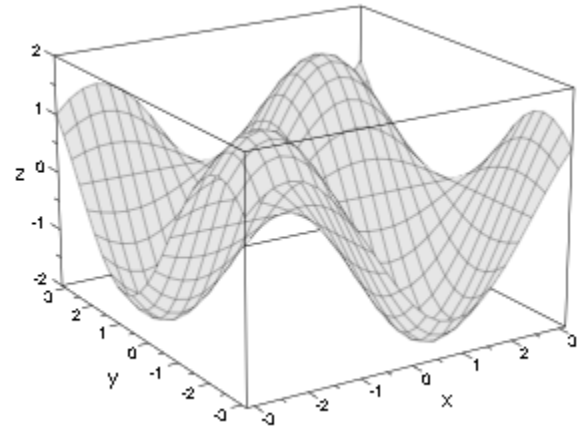
Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
LightColor	the color of light	RGB::White
LightIntensity	intensity of light	1.0
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Visible	visibility	TRUE

Examples

Example 1

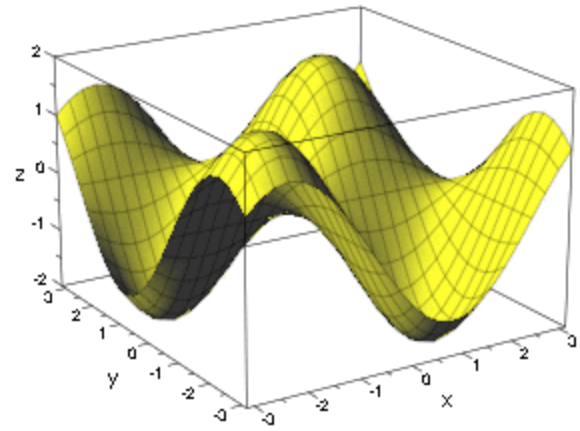
We create a 3D function graph in flat white and use ambient white light to illuminate it:

```
f := plot::Function3d(sin(x + y) + cos(x - y), x = -PI..PI, y = -PI..PI,
FillColorType = Flat, Color = RGB::White): ambientlight :=
plot::AmbientLight(0.7): plot(f, ambientlight):
```

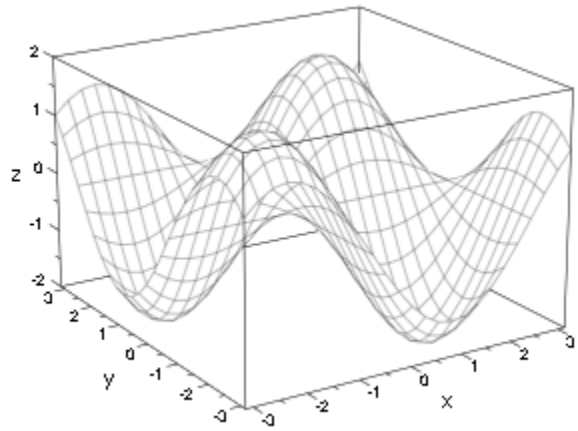


We create another ambient light with animated intensity:

```
ambientlight := plot::AmbientLight(a, a = 0..1): plot(f, ambientlight)
```



We add directed yellow light to the scene and study the mixture between the “sunlight” and an increasing amount of ambient light. When the ambient light is at full intensity, it dominates the directed light completely:
sunlight := plot::DistantLight([0, 0, 0], [5, 1, -3], 1, LightColor = RGB::Yellow): plot(f, ambientlight, sunlight)



delete f, ambientlight, sunlight:

Parameters

intensity

The intensity of the light: a numerical value between 0 and 1 or an arithmetical expression of the animation parameter `a`.

`intensity` is equivalent to the attribute LightIntensity.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::PointLightplot::DistantLightplot::SpotLight

plot::Camera

Purpose

Camera

Syntax

```
plot::Camera([p_x, p_y, p_z], [f_x, f_y, f_z], angle, <a
= a_min .. a_max>, options)
```

Description

`plot::Camera([p_x, p_y, p_z], [f_x, f_y, f_z], angle)` creates a camera at the position `[p_x, p_y, p_z]` pointing towards the focal point `[f_x, f_y, f_z]`. The opening angle of its lense is given by `angle`.

When creating a 3D scene, an "automatic camera" is used. Its location can be controlled by the attribute CameraDirection, but there are now further means of manipulating its parameters.

If the automatic camera does not suffice for your purposes, you may define your own camera by `plot::Camera`. Inserting such a camera object in your scene (for example, just by passing the camera as an argument to the plot command), the automatic camera is switched off and the new camera determines the view.

A camera of type `plot::Camera` allows to set all parameters determining the view and its perspective. Further, all parameters can be animated such that an animated "flight" through a 3D scene can be realized.

The first argument `[p_x, p_y, p_z]` in the call generating a camera is the Position of the camera in 3-space. The second argument `[f_x, f_y, f_z]` is the point the camera is aimed at (FocalPoint).

The optical axis is given by the vector `FocalPoint - Position`.

Together with the opening angle of the zoom lense (ViewingAngle), these parameters determine the view of the scene.

The `FocalPoint` vector can be replaced by any other point on the optical axes without changing the view. (`FocalPoint` and `Position` should not coincide, though.)

By default, the *z*-direction in 3-space corresponds to the vertical direction of the final picture. If this is not desired, the camera can be rotated around its optical axes using the attribute UpVector.

Depending on the distance of the camera to the graphical scene and the opening angle of the lense, the scene may fill only a small portion of the viewing area if the camera is too far away. If the camera is too close, only some parts of the scene may be visible

Just as for a real camera, you will have to move closer to or farther away from the scene to make it fill the drawing area as desired. Alternatively, you may keep the camera position fixed and use the zoom lense by choosing an appropriate ViewingAngle.

As in real life, you have to find appropriate parameters experimentally by looking at the picture and changing the parameters interactively.

Alternatively, you may define the camera with the attribute OrthogonalProjection = `TRUE`. This has the same effect as positioning the camera at a large distance from the scene using a powerful tele lense.

In this case, the camera ignores the ViewingAngle and the Position in 3-space. It is moved along the optical axis FocalPoint - Position to infinity and chooses an infinitesimal small viewing angle such that the scene fills the drawing area optimally.

Several cameras can be present simultaneously in a graphical scene. The first camera specified in the plot command determines the views.

One may switch between the cameras by clicking on the corresponding camera in the interactive “object browser” of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document).

You may place your own light sources in the scene. When specifying the attribute CameraCoordinates = `TRUE` in the definition of the lights, they are attached to the camera and move automatically, when the camera is moved.

Attributes

Attribute	Purpose	Default Value
FocalPoint	the focal point of a camera	
FocalPointX	the focal point of a camera, x-coordinate	
FocalPointY	the focal point of a camera, y-coordinate	
FocalPointZ	the focal point of a camera, z-coordinate	
Frames	the number of frames in an animation	50
KeepUpVector	keep the UpVector constant when moving the camera?	TRUE
Name	the name of a plot object (for browser and legend)	
OrthogonalProjection	parallel projection without perspective distortion	FALSE
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	

Attribute	Purpose	Default Value
Position	positions of cameras, lights, and text objects	
PositionX	x-positions of cameras, lights, and text objects	
PositionY	y-positions of cameras, lights, and text objects	
PositionZ	z-positions of cameras, lights, and text objects	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
UpVector	“up direction” of a camera	[`0.0`, `0.0`, `1.0`]
UpVectorX	x-component of the “up vector” of the camera	`0.0`
UpVectorY	y-component of the “up vector” of the camera	`0.0`
UpVectorZ	z-component of the “up vector” of the camera	`1.0`

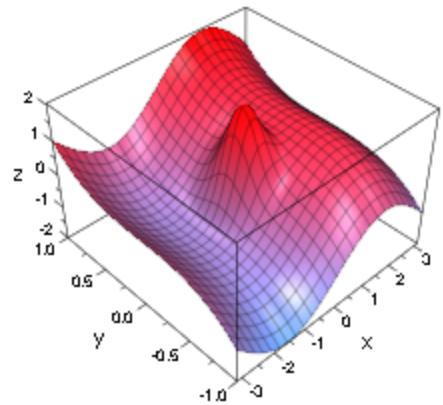
Attribute	Purpose	Default Value
ViewingAngle	opening angle of the camera lense	
Visible	visibility	TRUE

Examples

Example 1

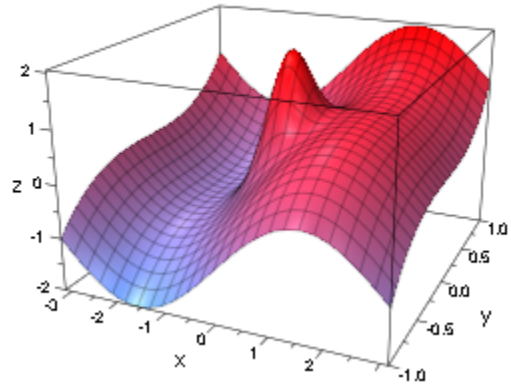
We use our own camera to view the 3D graph of a function:

```
f := plot::Function3d(sin(x) + y^3 + 2*exp(-3*x^2 - 20*y^2), x = -PI..PI, y = -1 .. 1, Submesh = [2, 2]): camera := plot::Camera([-12, -4, 14], [0, 0, 0], PI/7): plot(f, camera):
```

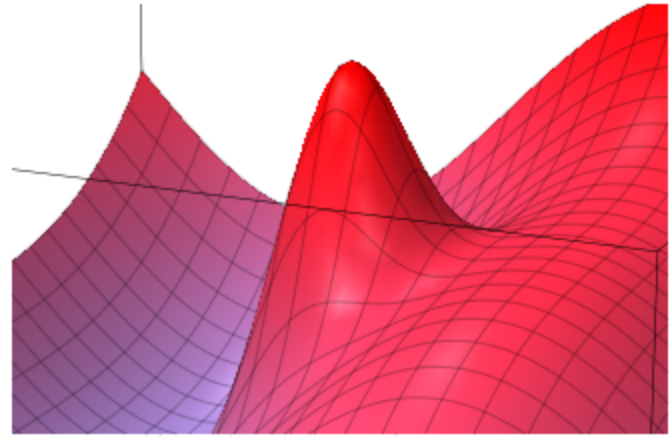


We move the camera to another position:

```
camera::Position := [7, -5, 6]: plot(f, camera):
```

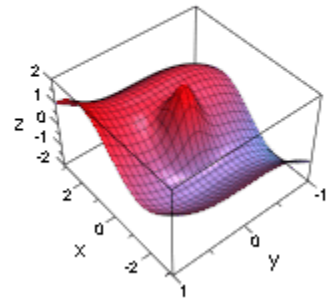


We turn the camera towards the central peak and zoom in by decreasing the openening angle of the zoom lense:
camera::FocalPoint := [0, 0, 1]: camera::ViewingAngle := PI/20: plot(f, camera):



We create an animated camera and fly through the scene:

```
camera := plot::Camera([-15 + 3*a, 4 - a, 3 + (a - 4)^2], [0, 0, 1.5], PI/6, a
= 0..8, Frames = 100, TimeRange = 0..20): plot(f, camera):
```



```
delete f, camera:
```

Parameters

p_x

p_y

p_z

Coordinates of the camera position: numerical real values or arithmetical expressions of the animation parameter `a`.

p_x, p_y, p_z are equivalent to the attributes PositionX, PositionY, PositionZ.

f_x

f_y

f_z

Coordinates of the the focal point: numerical real values or arithmetical expressions of the animation parameter `a`.

f_x, f_y, f_z are equivalent to the attributes FocalPointX, FocalPointY, FocalPointZ.

angle

The opening angle of the lense in radians: a numerical real value or an arithmetical expression of the animation parameter `a` representing a value between 0 and π.

`angle` is equivalent to the attribute ViewingAngle.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

Concepts

- "Cameras in 3D"

plot::DistantLight

Purpose

Directed distant light (“sunlight”)

Syntax

```
plot::DistantLight([p_x, p_y, p_z], [t_x, t_y, t_z], <intensity>,
<a = a_min .. a_max>, options)
```

Description

`plot::DistantLight([p_x, p_y, p_z], [t_x, t_y, t_z], intensity)` creates a distant light source emitting parallel light shining into the direction $[t_x - p_x, t_y - p_y, t_z - p_z]$

Each 3D scene is illuminated by several light sources that are set automatically and cannot be controlled by the user. Cf. the help page of Lighting.

If special light effects are desired, the user can create alternative light sources of various types such as plot::AmbientLight, `plot::DistantLight`, plot::PointLight, and plot::SpotLight.

If at least one user defined light source is inserted into the scene (e.g., by simply passing the light objects as input parameters to the plot command), the automatic lights are switched off and the user defined lights are used to illuminate the scene.

Note The vector $[p_x, p_y, p_z]$ does *not* represent the position of a distant light in space. The light source is infinitely far away.

When using $[t_x, t_y, t_z] = [0, 0, 0]$, you may think of $[p_x, p_y, p_z]$ as the *direction* where the light source is located.

When using $[p_x, p_y, p_z] = [0, 0, 0]$, you may think of $[t_x, t_y, t_z]$ as the *direction* into which the light is shining.

By default, white light is created. Other colors can be chosen by the attribute LightColor.

When using the attribute CameraCoordinates = `TRUE`, the light source is fixed to the camera. It moves automatically, when the camera is moved.

Directed light such as `plot::DistantLight` create shading effects that add depth to the picture. Usually, a certain amount of undirected ambient light of type plot::AmbientLight enhances the picture.

Attributes

Attribute	Purpose	Default Value
CameraCoordinates	position of light sources relative to the camera?	FALSE
Frames	the number of frames in an animation	50
LightColor	the color of light	RGB::White
LightIntensity	intensity of light	1.0
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Position	positions of cameras, lights, and text objects	
PositionX	x-positions of cameras, lights, and text objects	

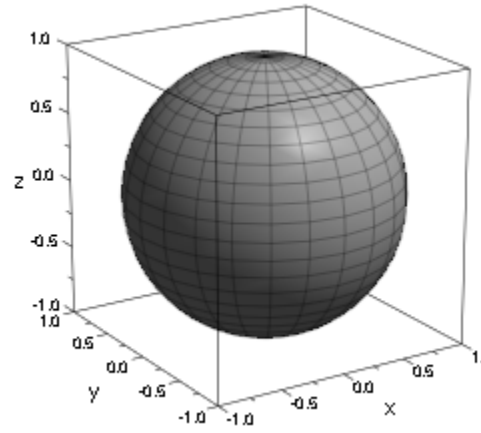
Attribute	Purpose	Default Value
PositionY	y-positions of cameras, lights, and text objects	
PositionZ	z-positions of cameras, lights, and text objects	
Target	the target point of a light	
TargetX	the target point of a light, x component	
TargetY	the target point of a light, y component	
TargetZ	the target point of a light, z component	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Visible	visibility	`TRUE`

Examples

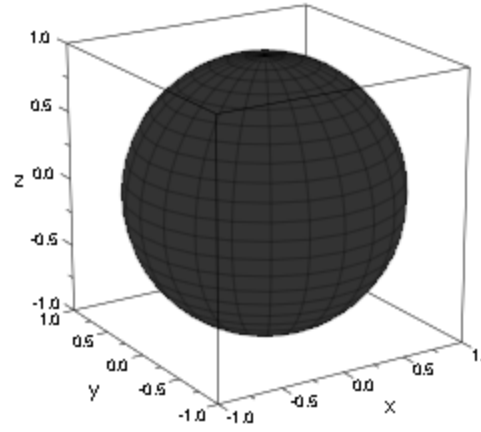
Example 1

We create a white sphere and use a single directed white light to illuminate it:

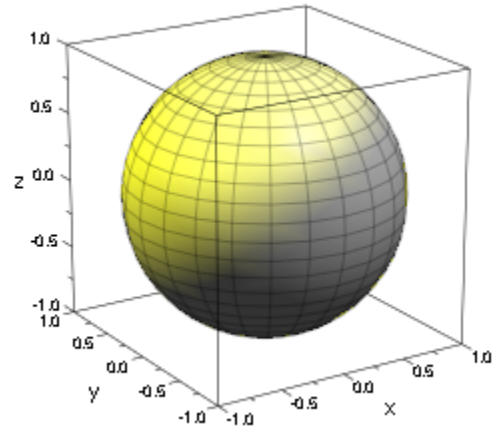
```
f := plot::Surface( [cos(u)*sin(v), sin(u)*sin(v), cos(v)], u = 0..2*PI, v = 0..PI, FillColorType = Flat, FillColorFunction = RGB::White, Scaling = Constrained): sunlight1 := plot::DistantLight([1, -2, 3], [0, 0, 0], 1/2): plot(f, sunlight1):
```



We create another distant light source shining from another direction, of yellow color and with animated intensity:
sunlight2 := plot::DistantLight([-2, 1, 3], [0, 0, 0], a, LightColor = RGB::Yellow, a = 0..1): plot(f, sunlight2)



We use both lights simultaneously:
plot(f, sunlight1, sunlight2)



delete f, sunlight1, sunlight2:

Parameters

p_x

p_y

p_z

The coordinates of the sun's "position": numerical values or arithmetical expressions of the animation parameter `a`.

p_x, p_y, p_z are equivalent to the attributes PositionX, PositionY, PositionZ.

t_x

t_y

t_z

The coordinates of the point the light is shining to: numerical values or arithmetical expressions of the animation parameter `a`.

t_x, t_y, t_z are equivalent to the attributes TargetX, TargetY, TargetZ.

intensity

The intensity of the light: a numerical value between 0 and 1 or an arithmetical expression of the animation parameter `a`.

`intensity` is equivalent to the attribute LightIntensity.

`a`

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::AmbientLightplot::PointLightplot::SpotLight

plot::PointLight

Purpose

Point light

Syntax

```
plot::PointLight([x, y, z], <intensity>, <a =
a_min .. a_max>, options)
```

Description

`plot::PointLight([x, y, z], intensity))` generates a point light at the position (*x*, *y*, *z*).

Each 3D scene is illuminated by several light sources that are set automatically and cannot be controlled by the user. Cf. the help page of Lighting.

If special light effects are desired, the user can create alternative light sources of various types such as plot::AmbientLight, plot::DistantLight, `plot::PointLight`, and plot::SpotLight.

If at least one user defined light source is inserted into the scene (e.g., by simply passing the light objects as input parameters to the plot command), the automatic lights are switched off and the user defined lights are used to illuminate the scene.

`plot::PointLight([x, y, z], intensity)` creates a point light at the position (*x*, *y*, *z*). It emits light into all directions.

Unlike in real life, the light flux of a point light does not decrease with the distance to the light source.

By default, white light is created. Other colors can be chosen by the attribute LightColor.

When using the attribute CameraCoordinates = `TRUE`, the light source is fixed to the camera. It moves automatically, when the camera is moved.

Light sources such as `plot::PointLight` create shading effects that add depth to the picture.

Usually, you will use point lights to highlight special details of the scene. For the illumination of the entire scene you will usually need additional undirected ambient light of type plot::AmbientLight, too.

Note that all light sources create a homogeneous lighting effect for a 3D triangle. Thus, realistic shading effects can only be achieved for surfaces with a sufficiently fine triangulation. For function graphs (plot::Function3d) and parametrized surfaces (plot::Surface), a fine triangulation is created by sufficiently high values of XMesh, YMesh or UMesh, VMesh, respectively.

Attributes

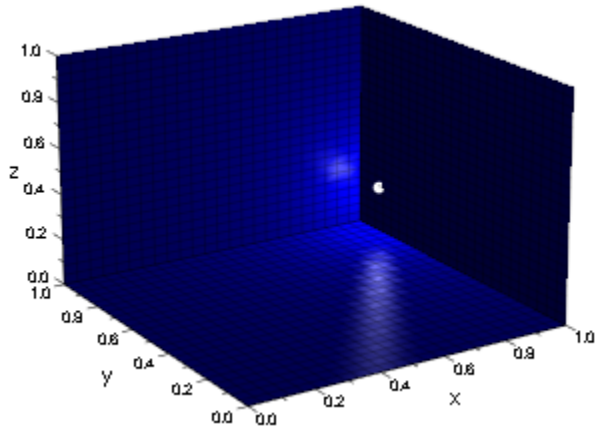
Attribute	Purpose	Default Value
CameraCoordinates	position of light sources relative to the camera?	FALSE
Frames	the number of frames in an animation	50
LightColor	the color of light	RGB::White
LightIntensity	intensity of light	1.0
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Position	positions of cameras, lights, and text objects	

Attribute	Purpose	Default Value
PositionX	x-positions of cameras, lights, and text objects	
PositionY	y-positions of cameras, lights, and text objects	
PositionZ	z-positions of cameras, lights, and text objects	
TimeEnd	end time of the animation	`10.0`
TimeBegin	start time of the animation	`0.0`
TimeRange	the real time span of an animation	`0.0 .. 10.0`
Visible	visibility	`TRUE`

Examples

Example 1

We create three blue surfaces and illuminate them by an animated point light. The position of the point light is indicated by a white point: s1 := plot::Surface([1, y, z], y = 0..1, z = 0..1): s2 := plot::Surface([x, 1, z], x = 0..1, z = 0..1): s3 := plot::Surface([x, y, 0], x = 0..1, y = 0..1): p := plot::Point3d([a, 0.9, 0.2], a = 0..1, PointSize = 2.0*unit::mm, PointColor = RGB::White): light := plot::PointLight([a, 0.9, 0.2], 1, a = 0..1): plot(s1, s2, s3, p, light, Axes = Frame, FillColor = RGB::Blue, FillColorType = Flat):



delete s1, s2, s3, p, light:

Parameters

x

y

z

The coordinates of the point light: numerical values or arithmetical expressions of the animation parameter `a`.

`x`, `y`, `z` are equivalent to the attributes Position, PositionX, PositionY, PositionZ.

intensity

The intensity of the light: a numerical value between 0 and 1 or an arithmetical expression of the animation parameter `a`.

`intensity` is equivalent to the attribute LightIntensity.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also plotplot::copyplot::AmbientLightplot::DistantLightplot::SpotLight

plot::SpotLight

Purpose

Spot light

Syntax

```
plot::SpotLight([p_x, p_y, p_z], [t_x, t_y, t_z], angle,
<intensity>, <a = a_min .. a_max>, options)
```

Description

`plot::SpotLight([`p_x`, `p_y`, `p_z`], [`t_x`, `t_y`, `t_z`], angle, intensity)` generates a spot light at the position p_x, p_y, p_z, aimed at the point t_x, t_y, t_z. The opening angle of the light cone is given by `angle`.

Each 3D scene is illuminated by several light sources that are set automatically and cannot be controlled by the user. Cf. the help page of Lighting.

If special light effects are desired, the user can create alternative light sources of various types such as plot::AmbientLight, plot::DistantLight, plot::PointLight, and `plot::SpotLight`.

If at least one user defined light source is inserted into the scene (e.g., by simply passing the light objects as input parameters to the plot command), the automatic lights are switched off and the user defined lights are used to illuminate the scene.

`plot::SpotLight([`p_x`, `p_y`, `p_z`], [`t_x`, `t_y`, `t_z`], angle)` creates a spot light source at the point [p_x, p_y, p_z] emitting a light cone towards the point [t_x, t_y, t_z]. In contrast to real life, the light flux of a spot light does not decrease with the distance to the light source.

By default, white light is created. Other colours can be chosen by the attribute LightColor.

When using the attribute CameraCoordinates = `TRUE`, the light source is fixed to the camera. It moves automatically, when the camera is moved.

Directed light such as `plot::SpotLight` create shading effects that add depth to the picture.

Usually, you will use spot lights to highlight special details of the scene. For the illumination of the entire scene you will usually need additional undirected ambient light of type plot::AmbientLight, too.

Note that all light sources create a homogeneous lighing effect for a 3D triangle. Thus, realistic shading effects can only be achieved for surfaces with a sufficiently fine triangulation. For function graphs (plot::Function3d) and parametrized surfaces (plot::Surface), a fine triangulation is created by sufficiently high values of XMesh, YMesh or UMesh, VMesh, respectively.

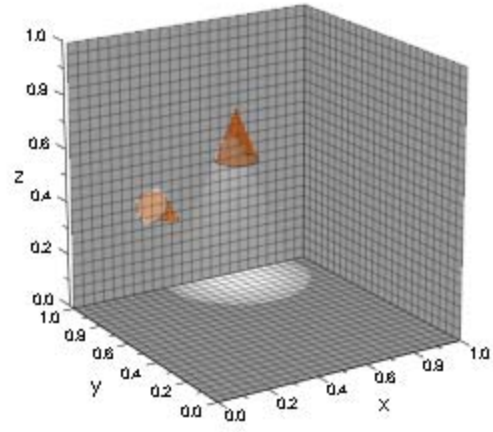
Examples

Example 1

We create three white surfaces and illuminate them by two animated white spot lights and some ambient light. The spot lights are indicated by little cones:

```
s1 := plot::Surface([1, y, z], y = 0..1, z = 0..1): s2 := plot::Surface([x, 1, z], x = 0..1, z = 0..1, Submesh = [2, 2]): s3 := plot::Surface([x, y, 0], x = 0..1, y = 0..1, Submesh = [2, 2]): ambientlight:= plot::AmbientLight(0.4): spotlight1 := plot::SpotLight([1/3, a, 1/3], [1/3, 1, 1/3], PI/5, a = 0..0.8): c1 := plot::Cone(0, [1/3, a, 1/3], 0.2*tan(PI/10), [1/3, a + 0.2, 1/3], a = 0..0.8, Color = RGB::Orange.[0.5]): spotlight2 := plot::SpotLight([2/3, a, 2/3], [2/3, a, 0], PI/4, a = 0.15..0.95): c2 := plot::Cone(0, [2/3, a, 2/3], 0.2*tan(PI/8), [2/3, a, 2/3 - 0.2], a = 0.15..0.95, Color = RGB::Orange.[0.5]): plot(s1, s2, s3, FillColor = RGB::White, FillColorType = Flat, ambientlight, c1, spotlight1, c2, spotlight2, Axes = Frame):
```



```
delete s1, s2, s3, c1, c2, ambientlight, spotlight1, spotlight2:
```

Parameters

p_x

p_y

p_z

The coordinates of the position: numerical values or arithmetical expressions of the animation parameter `a`.

p_x, p_y, p_z are equivalent to the attributes Position, PositionX, PositionY, PositionZ.

t_x

t_y

t_z

The coordinates of the point the light is shining to: numerical values or arithmetical expressions of the animation parameter `a`.

t_x, t_y, t_z are equivalent to the attributes Target, TargetX, TargetY, TargetZ.

angle

The opening angle of the light cone in radians: a numerical value between 0 and π or an arithmetical expression of the animation parameter `a`.

`angle` is equivalent to the attribute SpotAngle.

intensity

The intensity of the light: a numerical value between 0 and 1 or an arithmetical expression of the animation parameter `a`.

`intensity` is equivalent to the attribute LightIntensity.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

See Also

plotplot::copyplot::AmbientLightplot::PointLightplot::DistantLight

OutputFileOutputOptions

Purpose

File name to plot into

Value Summary

`OutputFile`, `OutputOptions`	Optional	See below

Description

The attribute `OutputFile` allows to specify a file name to direct the plot output into an external file instead of rendering the plot on the screen. The extension of the file name indicates the export format.

The available formats include `.xvz` and `.xvc` (the MuPAD proprietary XML format) as well as various standard bitmap formats such as `.bmp`, `.gif`, `.jpg` etc. and vector formats such as`.eps`, `.svg` etc. Animated MuPAD graphics can be exported to `.avi` format.

Some of the export formats allow to specify certain parameters such as "resolution," "quality" etc. Such parameters may be specified by the attribute `OutputOptions`.

MuPAD plots can be saved in "batch mode" by specifying the attribute `OutputFile = filename` in a `plot` call or in plotfunc2d, plotfunc3d. The file name must be a MuPAD string. For example:

```
plot(..graphical objects.., OutputFile = "mypicture.xvz"):
```

(Here, the extension `.xvz` of the file name `"mypicture.xvz"` indicates that the MuPAD XML data are to be written).

If the MuPAD environment variable WRITEPATH does not have a value, the previous call creates the file in the directory where MuPAD is running. (On Windows and Macintosh systems, this is, by default, the directory where it is installed).

After setting `WRITEPATH` to the absolute path of a folder, the file is created in that folder. For example, after
WRITEPATH := "C:\\Documents":

the command

plot(..graphical objects.., OutputFile = "mypicture.xvz"):

stores the plot data in the file "`C:\Documents\mypicture.xvz`." Alternatively, the file name can be specified as an absolute pathname: plot(..objects.., OutputFile = "C:\\Documents\\mypicture.xvz"):

If a MuPAD notebook was saved to a file, its location is available inside the notebook as the environment variable `NOTEBOOKPATH`. If you wish to save your plot in the same folder as the notebook, you may call plot(..objects.., OutputFile = NOTEBOOKPATH."mypicture.xvz"):

The plot data can be stored in various formats indicated by the extension of the file name. In particular, there are the MuPAD proprietary XML formats. The file extension `.xvz` indicates that XML data are to be written and, finally, the file is to be compressed. Alternatively, the extension `.xvc` may be used to write the XML data without final compression (the resulting text file can be read with any text editor). Files in both formats can be inserted into a MuPAD notebook and freely manipulated.

Apart from saving files as XML data, MuPAD pictures can also be saved in a variety of standard bitmap formats such as `.bmp`, `.gif`, `.jpg` etc. Also `.svg` and `.eps` export is available. Just use an appropriate extension of the file name indicating the format.

Note Only XML files `.xvz` and `.xvc` retain the information necessary for interactive manipulation in a MuPAD notebook. All other formats are intended for exporting graphics to other programs.

If no file extension is specified in the file name, the default extension `.xvz` is used, i.e., XML data are written.

Animated MuPAD plots can be exported to `.avi` format. Cf. "Example 2" on page 24-1122.

In addition to `OutputFile`, there is the attribute `OutputOptions` to specify parameters for some of the export formats. The admissible value for this attribute is a list of equations:

```
OutputOptions = [          <ReduceTo256Colors = b >,
                           <DotsPerInch = n1>, <Quality
                           = n2>, <JPEGMode = n3>,
                           <EPSMode = n4>, <AVIMode
                           = n5>, <WMFMode = n6>,
                           <FramesPerSecond = n7>,
                           <PlotAt = l1>]
```

Each entry of the list is optional. The parameters are:

`b`	–	`TRUE` or `FALSE`. Has an effect for export to some raster formats only. With `TRUE`, only 256 different colors are stored in the raster file. The default value is `FALSE`.
n_1	–	a positive integer setting the resolution in DPI (dots per inch). Has an effect for export to raster formats only. The default value depends on the hardware.
n_2	–	one of the integers 1, 2, ..., 100. This integer represents a percentage value determining the quality of the export. Has an effect for JPG, 3D EPS, 3D WMF and AVI export only. The default value is `75`.
n_3	–	`0`, `1`, or `2`. Has an effect for JPG export only. The flag `0` represents the JPG mode 'Baseline Sequential', `1` represents 'Progressive', `2` represents 'Sequential Optimized'. The default value is `0`.
n_4	–	`0` or `1`. Has an effect for EPS export only. The flag `0` represents the EPS mode 'Painter's Algorithm', `1` represents 'BSP Tree Algorithm'. The default value is `0`.
n_5	–	`0`, `1` or `2`. Has an effect for AVI export only. With `0`, the 'Microsoft Video 1 Codec' is used. With `1`, the 'Uncompressed Single Frame Codec' is used. With `2`, the 'Radius Cinepak Codec' is used. The default value is `0`.

n_6	–	0, 1 or 2. Has an effect for WMF export only. With 0, the 'Painter's Algorithm' is used. With 1, the 'BSP Tree Algorithm' is used. With 2, a 'embedded bitmap' is created. The default value is 0.
n_7	–	a positive integer setting the frames per second for the AVI to be generated. Has an effect for AVI and animated GIF export only. The default value is 15.
l_1	–	a list of real values between TimeBegin and TimeEnd which determines the times at which pictures should be saved from an animation.

Examples

Example 1

The following commands save the plot in four different files in JPG, EPS, SVG, and BMP format, respectively:
f1 := plot::Function2d(sin(x), x = 0..PI, Color = RGB::Red): f2 := plot::Function2d(cos(x), x = 0..PI, Color = RGB::Blue): plot(f1, f2, OutputFile = "mypicture.jpg"): plot(f1, f2, OutputFile = "mypicture.eps"): plot(f1, f2, OutputFile = "mypicture.svg"): plot(f1, f2, OutputFile = "mypicture.bmp"):

If no file extension is specified in the file name, the default extension `.xvz` is used, i.e., XML data are written. The following command creates the file `mypicture.xvz`:
plot(f1, f2, OutputFile = "mypicture"):

Example 2

An animated MuPAD plot can be exported to `.avi` format:
plotfunc2d(sin(x - a), x = 0 .. 2*PI, a = 0 .. 5, OutputFile = "myanimation.avi"):

Example 3

An animated MuPAD plot can be exported to serveral single images at given times:
plotfunc2d(sin(x - a), x = 0 .. 2*PI, a = 0 .. 5, OutputFile = "someName.png", OutputOptions=[PlotAt = [i $ i = 0..10 step 0.5]]):

Description

`AffectViewingBox` determines whether the ViewingBox of an object should be taken into account for the total `ViewingBox` of the graphical scene.

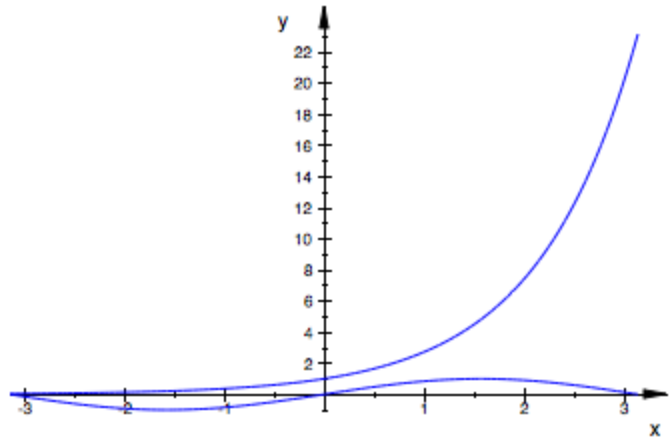
Usually, the visible area/volume of a graphical scene is automatically chosen as the smallest box containing all objects of the scene. Objects

with `AffectViewingBox = FALSE` are ignored in the computation of this box.

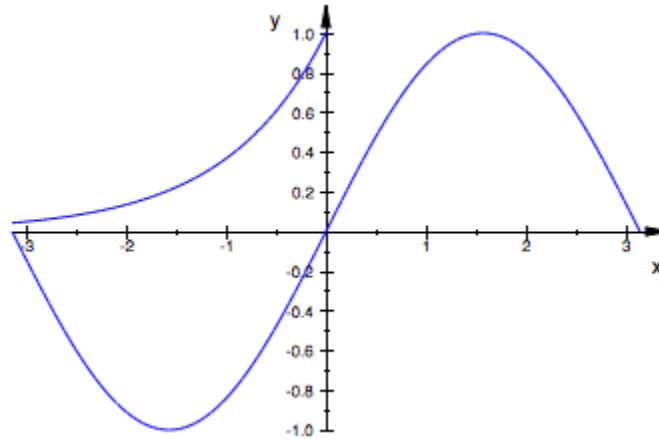
Examples

Example 1

We plot the sine and the exponential function in one scene:
plot(plot::Function2d(sin(x), x = -PI..PI), plot::Function2d(exp(x), x = -PI..PI))



The exponential function dominates the sine. We set `AffectViewingBox = FALSE` for exp. Now, only the sine function determines the visible area and `exp` is only visible where it is in the ViewingBox of the sine function:
plot(plot::Function2d(sin(x), x = -PI..PI), plot::Function2d(exp(x), x = -PI..PI, AffectViewingBox = FALSE))



See Also ViewingBox

numlib::Omega

Purpose

Angle

Rotation angle

Value Summary

Optional	MuPAD expression

Graphics Primitives

Objects	Angle Default Values
plot::Arc2d, plot::Arc3d, plot::Prism, plot::Pyramid, plot::Rotate2d, plot::Rotate3d	0

Description

`Angle` determines the rotation angle in transformation objects of type plot::Rotate2d and plot::Rotate3d, respectively, and other graphical objects. The angle has to be specified in radians.

In 2D, the direction of the rotation is counter clock wise. Use negative angles to rotate clock wise.

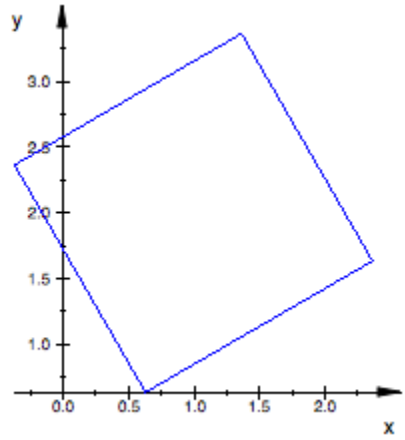
In 3D, the rotation is implemented following the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation. Use negative angles to rotate in the opposite direction.

Examples

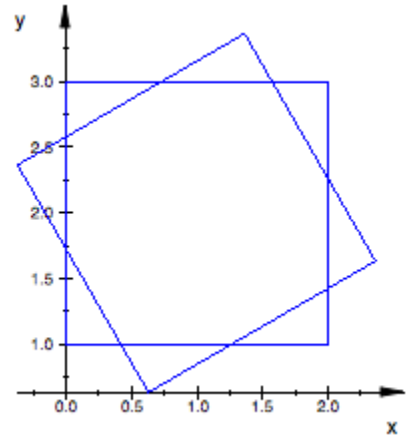
Example 1

Rectangles of type plot::Rectangle are always parallel to the coordinate axes. To have one with a different orientation, we must rotate it:
r0 := plot::Rectangle(0..2, 1..3): r1 := plot::Rotate2d(r0, Center = [1, 2], Angle = PI/6)plot::Rotate2d(PI/6, Center = [1, 2], plot::Rectangle(0..2, 1..3))

As you can see in the output above, the rotate object *contains* the rotated object and acts as a grouping construct. This means that we only need to plot `r1` to see the rotated object:
plot(r1)



Plotting both `r0` and `r1` yields a plot showing the rotated rectangle together with the unrotated one:
plot(r0, r1)

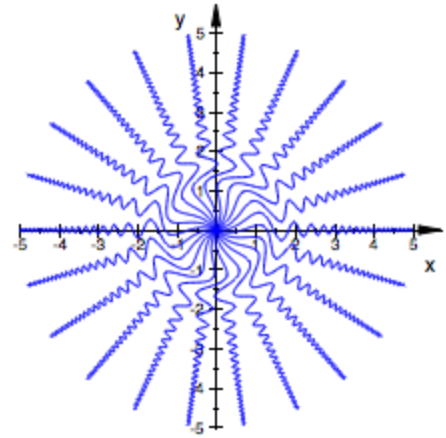


delete r0, r1:

Example 2

Using plot::Rotate2d, we plot several copies of a function plot, rotated at different angles:

```
f := plot::Function2d(sin(x^3)/(x^2+1), x = -5..5, Mesh = 300):
plot(plot::Rotate2d(f, Angle = PI/11*a) $ a = 0..10):
```

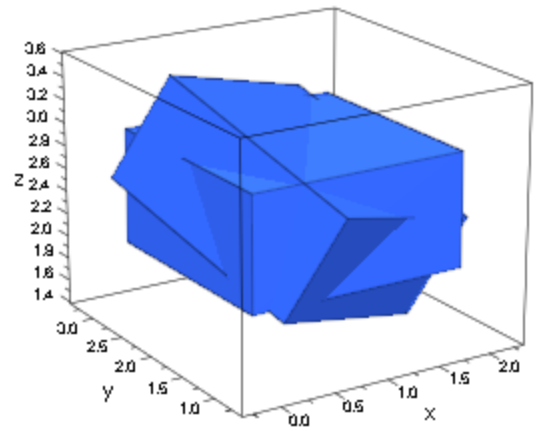


delete f:

Example 3

The rotation angle can be animated. We use an animated plot::Rotate2d object to rotate a square around a center that moves along a circle around the origin:

```
p := plot::Point2d([cos(a), sin(a)], a = 0..2*PI, Frames = 100): r := plot::Rotate2d(plot::Rectangle(0..2, -1..1), Angle = a, Center = [0, 0], a = 0..2*PI): q := plot::Rotate2d(r, Angle = 4*a, Center = [cos(a), sin(a)], a = 0..2*PI, Frames = 200): plot(p, q)
```



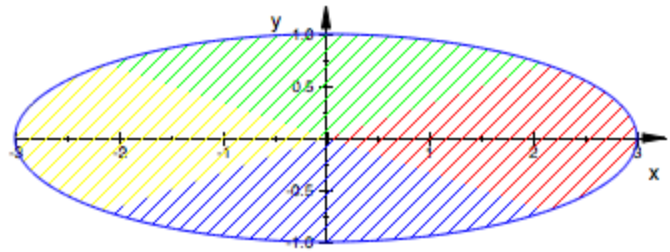
delete p, r, q:

Example 4

This is the 3D analogue of “Example 1” on page 24-1128. Boxes of type plot::Box are always parallel to the coordinate axes. To have one with a different orientation, we must rotate it:

```
b0 := plot::Box(0..2, 1..3, 2..3): b1 := plot::Rotate3d(b0, Center = [1, 2, 2.5], Axis = [1, 1, 1], Angle = PI/5)plot::Rotate3d(PI/5, Center = [1, 2, 2.5], Axis = [1, 1, 1], plot::Box(0..2, 1..3, 2..3))
```

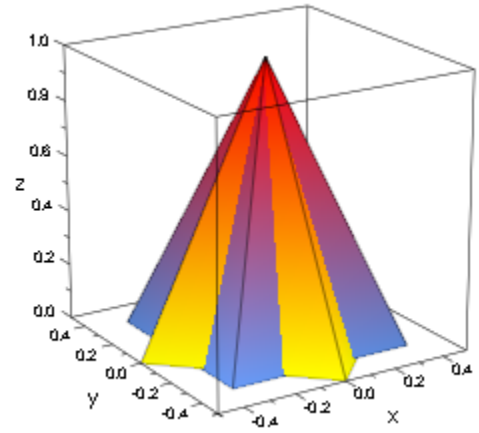
plot(b0, b1);



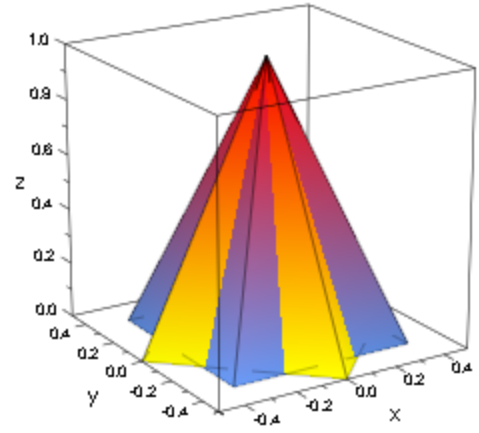
delete b0, b1:

Example 5

Some graphic objects, e.g. plot::Arc2d and plot::Pyramid, also accept a rotation angle:
arc:= [3, 1], [0, 0], -PI/4..PI/4, Filled: plot(plot::Arc2d(arc, Angle=0, FillColor=RGB::Red), plot::Arc2d(arc, Angle=1/2*PI, FillColor=RGB::Green), plot::Arc2d(arc, Angle=PI, FillColor=RGB::Yellow), plot::Arc2d(arc, Angle=3/2*PI, FillColor=RGB::Blue))



plot(plot::Pyramid(1/2, Angle=0), plot::Pyramid(1/2, Angle=PI/4, FillColor2=RGB::Yellow))



delete arc:

AxisCenter

AngleRangeAngleBeginAngleEnd

Purpose

Angle range

Value Summary

`AngleRange`	[AngleBegin .. AngleEnd]	Range of arithmetical expressions
`AngleBegin`, `AngleEnd`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values

plot::Tube, plot::XRotate, plot::ZRotate	`AngleRange: 0 .. 2*PI`
	`AngleBegin: 0`
	`AngleEnd: 2*PI`

plot::Arc2d, plot::Arc3d	`AngleRange: 0 .. PI/2`
	`AngleBegin: 0`
	`AngleEnd: PI/2`

Description

`AngleRange`, AngleBegin, AngleEnd define a range for the angle in circular arcs and surfaces of revolution.

For circular arcs of type plot::Arc2d, the attributes `AngleBegin` and `AngleEnd` define the starting point and the end point of the arc. The values are the usual polar angles measuring the angle to the positive *x*-axis in radians.

For surfaces of revolution of type plot::XRotate or plot::ZRotate, respectively, the attributes `AngleBegin` and `AngleEnd` define the starting point and the end point of the revolution.

For plot::XRotate, the values are the polar angles to the positive *y*-axis, specified in radians.

For plot::ZRotate, the values are the usual angles to the positive *x*-axis in radians, known from cylindrical coordinates.

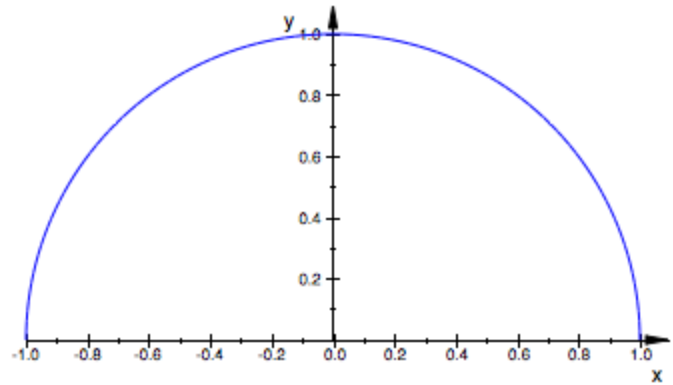
Values for `AngleBegin` and `AngleEnd` may depend on the animation parameter and must evaluate to real numbers for any given time stamp.

`AngleRange` provides a shortcut for setting `AngleBegin` and `AngleEnd`. The attribute `AngleRange = a_1..a_2` is equivalent to `AngleBegin = a_1`, `AngleEnd = a_2`.

Examples

Example 1

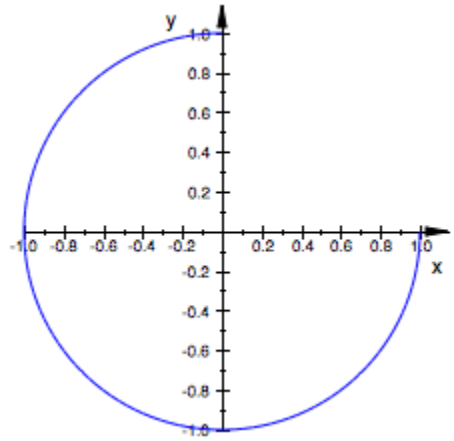
We define a semi-circle as a circular arc with a range of the polar angle from 0 to 180 degrees (i.e., π in radians):
arc := plot::Arc2d(1, 0 .. PI): plot(arc)



The range is stored as the attribute `AngleRange` in the object and can be accessed and changed:
arc::AngleBegin, arc::AngleEnd, arc::AngleRange0, PI, 0..PI

0, π, 0..π

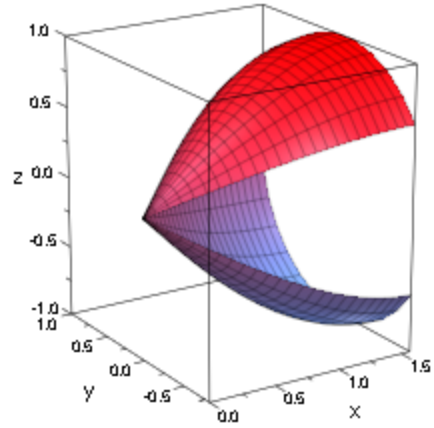
arc::AngleRange := PI/2 .. 2*PI: plot(arc)



delete arc:

Example 2

We leave gaps in the following surfaces of revolution by restricting the revolution angle:
plot(plot::XRotate(sin(x), x = 0 .. PI/2, AngleRange = -0.8*PI .. 0.8*PI)):



plot(plot::ZRotate(sin(x), x = 0 .. PI/2, AngleRange = 0.3*PI .. 2*PI)):

Area

Purpose

Area of a histogram plot

Value Summary

Optional	Non-negative real number

Graphics Primitives

Objects	Area Default Values
plot::Histogram2d	0

Description

`Area` determines whether bars of a histogram plot are scaled with respect to their heights or with respect to their areas, and by how much.

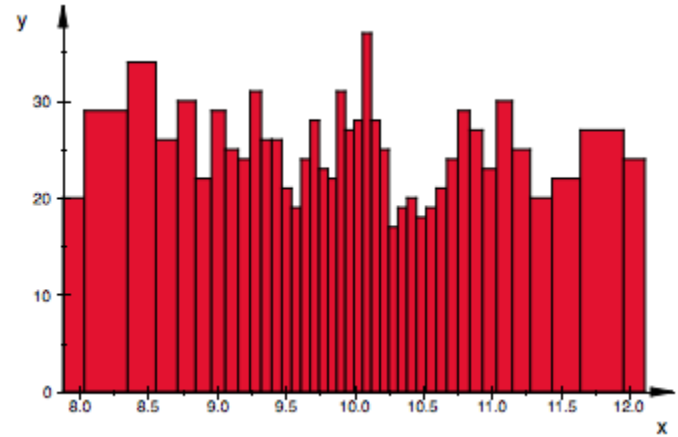
By default, the bars of a histogram plot use a height that is equal to the absolute number of data points in he corresponding cell. Using `Area`, the user can change this behavior to make the *areas* of the bars proportional to this number.

Examples

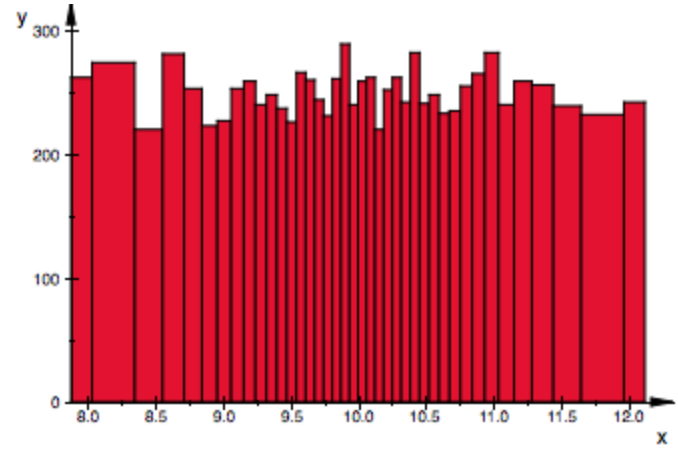
Example 1

For any distribution with a continuous quantile, we can define, using stats::equiprobableCells, a list of n cells where each cell is "hit" with the same probability, $1/n$. By the law of large numbers, we expect the number of elements in each cell to be approximating N/n for large values of N, the number of samples:

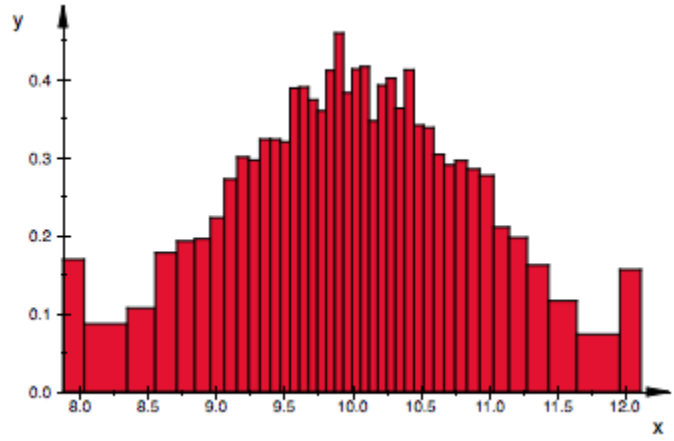
```
X := stats::normalRandom(10, 1): cells := stats::equiprobableCells(40,
stats::normalQuantile(10, 1)):N := 1000: data := [X() $ i = 1..N]:
plot(plot::Histogram2d(data, Cells = cells))
```



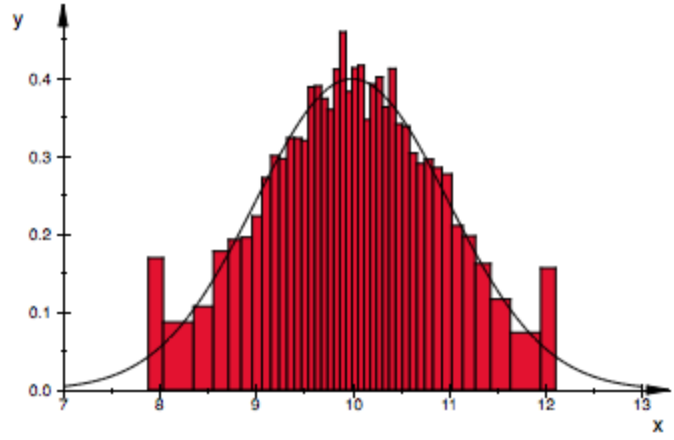
N := 10000: data := [X() $ i = 1..N]: plot(plot::Histogram2d(data, Cells = cells))



On the other hand, if we want to display a histogram as an approximation to the probability distribution, we want not the height, but rather the area of the rectangles to correspond to our measurements. Moreover, the sum of all areas should be 1, so we set `Area` to this value: plot(plot::Histogram2d(data, Cells = cells, Area = 1))



plot(plot::Histogram2d(data, Cells = cells, Area = 1), plot::Function2d(stats::normalPDF(10,1)(x), x = 7..13, Color = RGB::Black, LineWidth = 0.5))



See Also Cells

Averaged

Purpose

Mode for computing quantile lines in box plots

Value Summary

Optional	TRUE or FALSE

Graphics Primitives

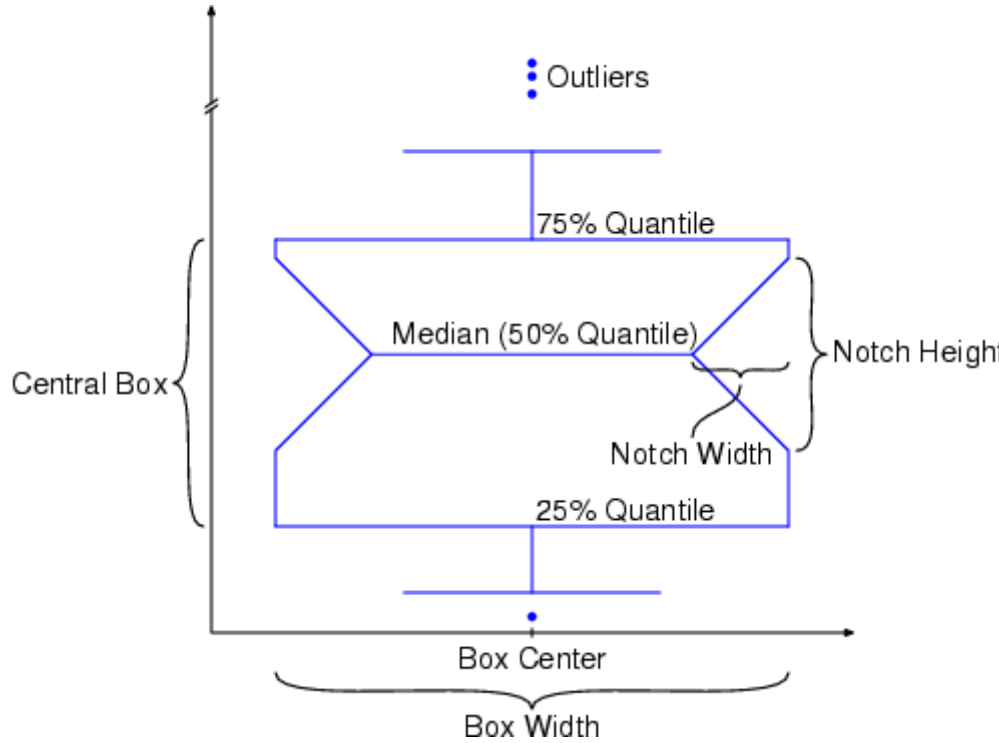
Objects	Averaged Default Values
plot::Boxplot	TRUE

Description

Statistical box plots indicate the 25%/50%/75% quantiles of data samples by horizontal lines. With the default `Averaged = TRUE`, the quantile lines are computed using stats::empiricalQuantile using the option `Averaged`.

A plot of type plot::Boxplot serves for visualizing and comparing statistical data samples. The plot reduces the data to few simple descriptive parameters.

A typical notched box looks like this:



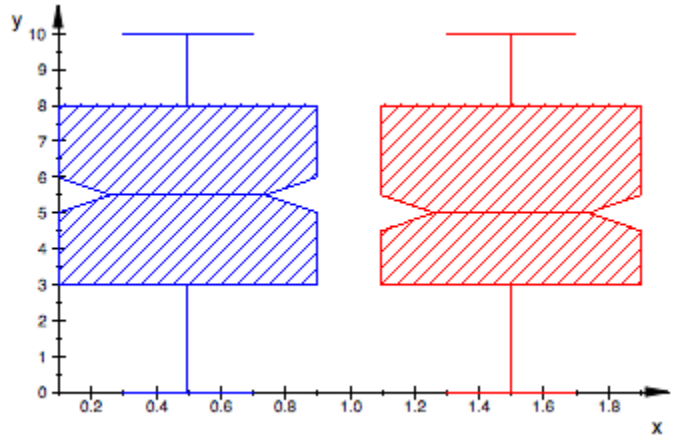
The location of the 25%/50%/75% quantile lines are computed internally via stats::empiricalQuantile. When using `Averaged = TRUE` in the box plot, the quantile function is called with the option `Averaged` (see the help page of stats::empiricalQuantile for details).

Examples

Example 1

By default, the quantile lines of the boxes are computed with the option `Averaged`. When using `Averaged = FALSE`, the quantiles are computed without this option:

```
r := random(0..10): SEED := 123: data := [r() $ k = 1..250]:
plot(plot::Boxplot(data, Averaged = TRUE, BoxCenters = 0.5, Color
= RGB::Blue, Notched), plot::Boxplot(data, Averaged = FALSE,
BoxCenters = 1.5, Color = RGB::Red, Notched) ):
```



delete r, SEED, data:

numlib::Omega

Purpose

AxisAxisXAxisYAxisZ

Rotation axis

Value Summary

`Axis`	Library wrapper for "[AxisX, AxisY, AxisZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`AxisX`, `AxisY`, `AxisZ`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Rotate3d	`Axis`: [0, 0, 1] `AxisX`, `AxisY`: 0 `AxisZ`: 1

Description

`Axis` is a vector determining the direction of the rotation axis in rotation objects of type plot::Rotate3d. It is given by a list of 3 components.

`AxisX` etc. refer to the *x*, *y*, *z* components of this vector.

A rotation in 3D is determined by a line around which is rotated. The line is given by a point on the line (the Center) and a direction vector (the `Axis`). The rotation angle is given by the attribute Angle.

The length of the `Axis` vector is of no relevance. However, it should not be zero.

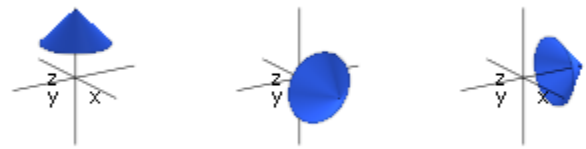
The rotation is implemented following the "right hand rule": Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation. Use negative angles to rotate in the opposite direction or replace the `Axis` vector by its negative.

Examples

Example 1

A cone is first rotated around the *x*-axis. The rotated cone is then rotated around the *z*-axis:

```
c0 := plot::Cone(1, [0, 0, 1], [0, 0, 2]): c1 := plot::Rotate3d(c0, Center =
[0, 0, 0], Axis = [1, 0, 0], Angle = PI/2): c2 := plot::Rotate3d(c1, Center
= [0, 0, 0], Axis = [0, 0, 1], Angle = PI/2): plot(plot::Scene3d(c0, Axes
= Origin, ViewingBox = [-2..2, -2..2, -2..2]), plot::Scene3d(c1, Axes =
Origin, ViewingBox = [-2..2, -2..2, -2..2]), plot::Scene3d(c2, Axes =
Origin, ViewingBox = [-2..2, -2..2, -2..2]), TicksNumber = None, Width =
120*unit::mm, Height = 40*unit::mm, Layout = Horizontal):
```

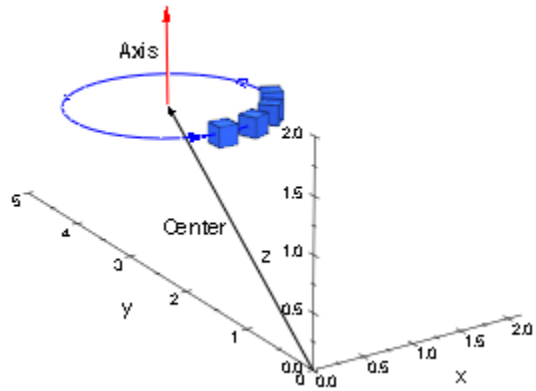


```
delete c0, c1, c2:
```

Example 2

We illustrate the “right hand rule”. A small box `b0` is rotated. The rotated copies `b1`, `b2`, `b3` are plotted together with the original box:

```
center := [1, 4, 1]: axis := [0, 0, 1]: b0 := plot::Box(0.9..1.1, 2.9 .. 3.1,
0.9 .. 1.1): b1 := plot::Rotate3d(b0, Center = center, Axis = axis, Angle
= PI/8): b2 := plot::Rotate3d(b1, Center = center, Axis = axis, Angle =
PI/8): b3 := plot::Rotate3d(b2, Center = center, Axis = axis, Angle =
PI/8): centerplusaxis := [center[i] + axis[i] $ i = 1..3]: plot(b0, b1, b2, b3,
plot::Arrow3d([0, 0, 0], center, Color = RGB::Black, Title = "Center",
TitlePosition = [0.1, 2, 0.5]), plot::Arrow3d(center, centerplusaxis, Title
= "Axis", Color = RGB::Red, TitlePosition = [0.7, 4, 1.5]), plot::Circle3d(1,
center, axis), plot::Rotate3d(plot::Arrow3d([0, 4, 1], [0, 3.9, 1], Color =
RGB::Blue), Axis = axis, Center = center, Angle = 0.43*PI + a*2*PI/3) $
a = 1..3, Axes = Origin ):
```



delete center, axis, b0, b1, b2, b3, centerplusaxis:

See Also AngleCenter

BaseTopBaseXTopXBaseYTopYBaseZTopZ

Purpose

Base center of cones, cylinders, pyramids and prisms

Value Summary

`Base`	Library wrapper for "[BaseX, BaseY]" (2D), "[BaseX, BaseY, BaseZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`Top`	Library wrapper for "[TopX, TopY]" (2D), "[TopX, TopY, TopZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`BaseX`, `BaseY`, `BaseZ`, `TopX`, `TopY`, `TopZ`	Mandatory	MuPAD expression

Graphics Primitives

Objects	Default Values

plot::Cone, plot::Cylinder, plot::Prism, plot::Pyramid	`Base`: `[0, 0, 0]`
	`Top`: `[0, 0, 1]`
	`BaseX`, `TopX`, `BaseY`, `TopY`, `BaseZ`: `0`
	`TopZ`: `1`

Description

`Base` is a vector determining the position of the base center of cones/conical frustums, cylinders, pyramids/frustums of pyramids and prisms. It is given by a list or vector of 3 components.

`BaseX` etc. refer to the *x*, *y*, *z* components of this vector.

`Top` is a vector determining the position of the top center of cones/conical frustums, cylinders, pyramids/frustums of pyramids and prisms. For a cone, this is the tip. The vector is given by a list or vector of 3 components.

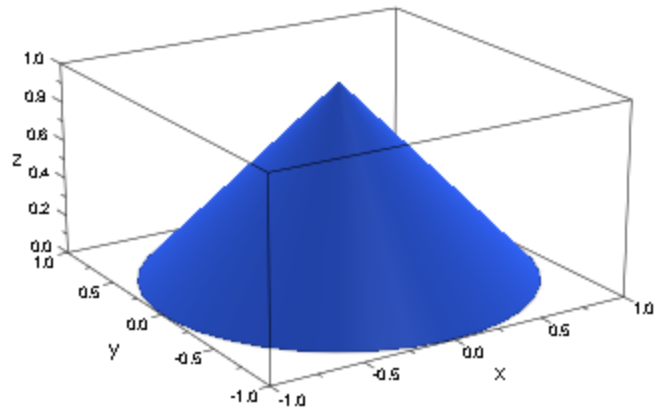
`TopX` etc. refer to the x, y, z components of this vector.

The values of these attributes can be animated.

Examples

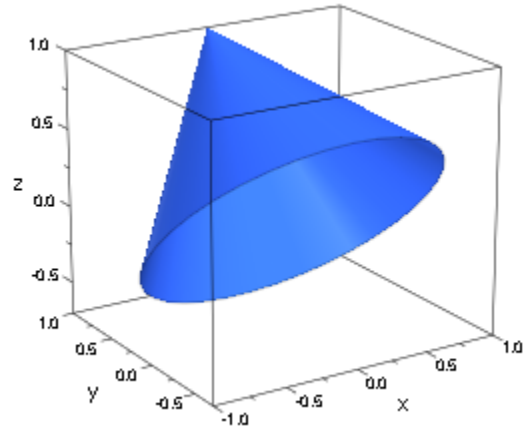
Example 1

We define a cone:
`c := plot::Cone(1, [0, 0, 0], [0, 0, 1]): plot(c)`



The second and third argument are the base center and the top center, respectively. Internally, they are stored as the attributes `Bottom` and `Top`. We can access the object's attributes and change them:
`c::Base, c::Top`
[0, 0, 0], [0, 0, 1]

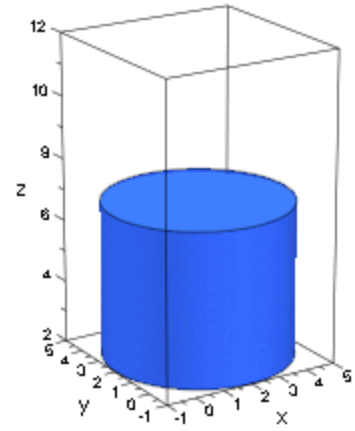
`c::Top := [0, 1, 1]: plot(c):`



delete c:

Example 2

The values of `Bottom` and `Top` can be animated:
plot(plot::Cylinder(3, [2, 2, 2], [2, 2, a], a = 7..12)):



See Also BaseRadiusTopRadius

Purpose

BaseRadiusTopRadius

Base and top radius of cones/conical frustums and pyramids/frustums of pyramids

Value Summary

`BaseRadius`, `TopRadius`	Mandatory	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Cone, plot::Pyramid	`BaseRadius: 1` `TopRadius: 0`

Description

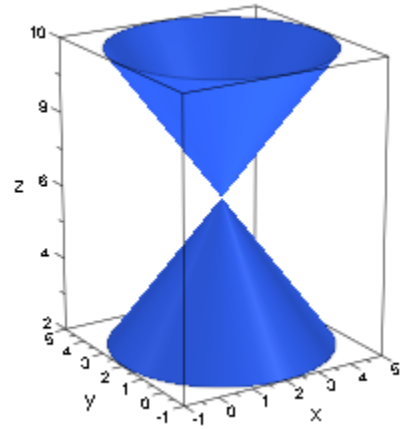
`BaseRadius` defines the radius of the base of a cone or the radius of the circumcircle of the regular base of a pyramid. `TopRadius` defines the radius r of the top of a conical frustum and the radius of the circumcircle of the top of a frustum of pyramid. With the default $r = 0$, a cone or pyramid, respectively, is created. You get a frustum for $r > 0$.

The values of these attributes can be animated.

Examples

Example 1

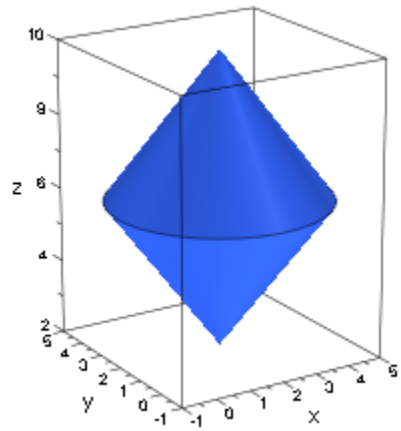
We draw two cones forming an hour glass:
c := plot::Cone(3, [2, 2, 2], [2, 2, 6]): d := plot::Cone(3, [2, 2, 10], [2, 2, 6]): plot(c, d)



The first argument is the base radius of the cone. Internally, is is stored as the attribute `BaseRadius`. We can access the objects' attributes and change them:
c::BaseRadius, d::TopRadius3, 0

3, 0

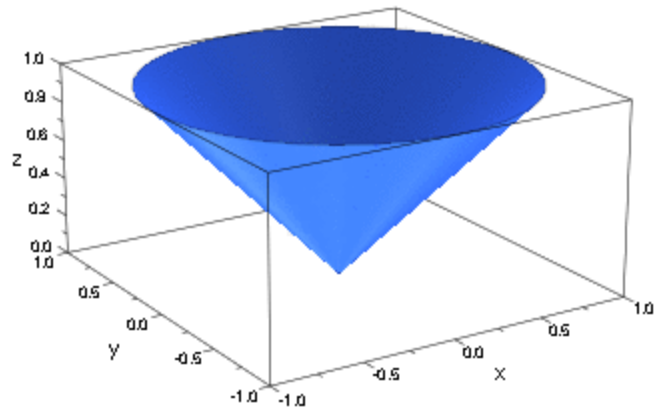
c::BaseRadius := 0: c::TopRadius := 3: d::BaseRadius := 0: d::TopRadius := 3: plot(c, d):



delete c, d:

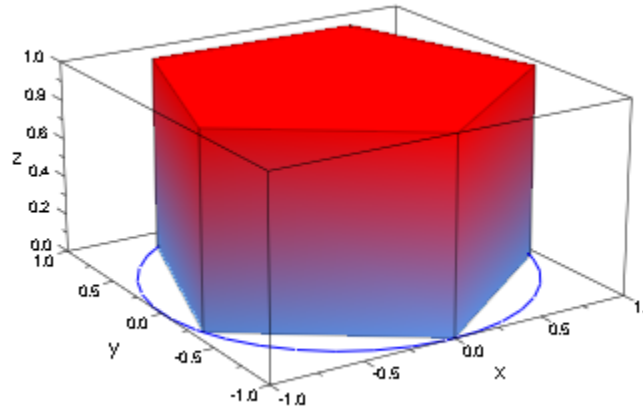
Example 2

The values of `BaseRadius` and `TopRadius` can be animated:
plot(plot::Cone(a, [0, 0, 0], 1 - a, [0, 0, 1], a = 0..1)):



Example 3

For a pyramid and a frustum of pyramid, the attributes `BaseRadius` and `TopRadius` determine the radius of the circumcircle of its regular base and top:
plot(plot::Prism(1,Edges=5), plot::Circle3d(1)):



See Also BaseTop

Cells

Purpose

Classes of histogram plots

Value Summary

Mandatory		List of arithmetical expressions

Graphics Primitives

Objects	Cells Default Values
plot::Histogram2d	[7]

Description

`Cells` determines the number and position of the classes used in a histogram.

`Cells` accepts either a single positive integer (or, equivalently, a list of one positive integer) or a list of cells given as ranges or lists of two elements.

A single integer n in the specification `Cells = n` or `Cells = [n]` is interpreted as "subdivide the range of data into n cells of equal size."

The number n can be animated. In this case, n may be a symbolic expression of the animation parameter.

The cells may be specified directly as in `Cells = [[a_1, b_1], [a_2, b_2], ]` or `Cells = [a_1..b_1, a_2..b_2, Symbol::dots]`.

Note The i-th cell is the semi-open interval Interval(a_i,[b_i]) $(a_i, b_i]$, i.e., a datum x is tallied into the i-th cell if $a_i < x \le b_i$ is satisfied.

The cell boundaries must satisfy $a_1 < b_1 \le a_2 < b_2 \le a_3 < \ldots$. In most applications, $b_1 = a_2$, $b_2 = a_3$ etc. is appropriate.

If giving cells directly, the leftmost border may be `- infinity` and the rightmost border may be infinity. These rectangles will then be

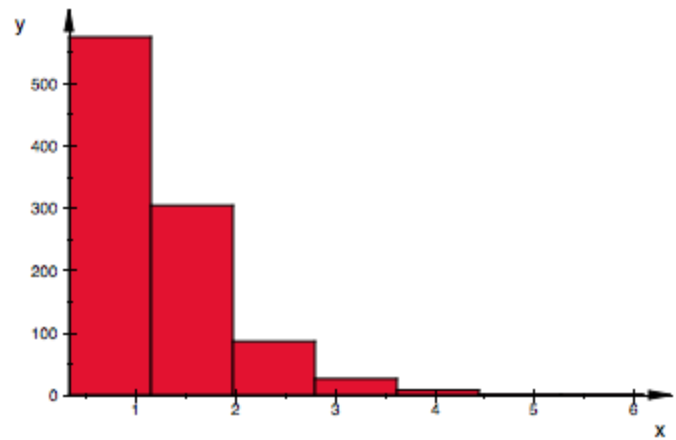
adjusted according to the average widths of the other rectangles for display purposes.

With the attribute CellsClosed = `Left`, the cells `[a_1..b_1, a_2..b_2, Symbol::dots]` are interpreted as the semi-open intervals Interval([a_i],b_i) $[a_i, b_i)$.

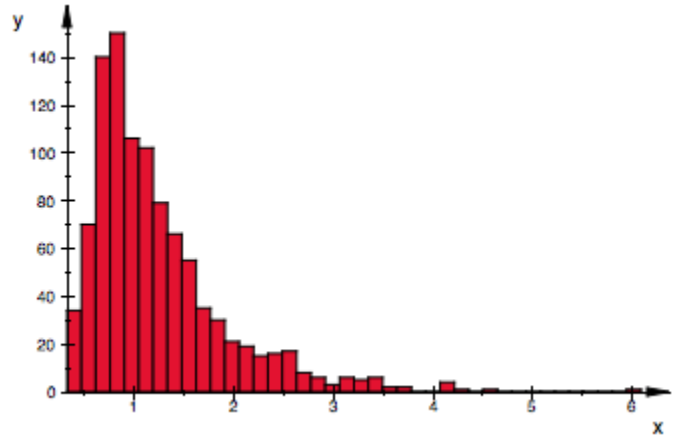
Examples

Example 1

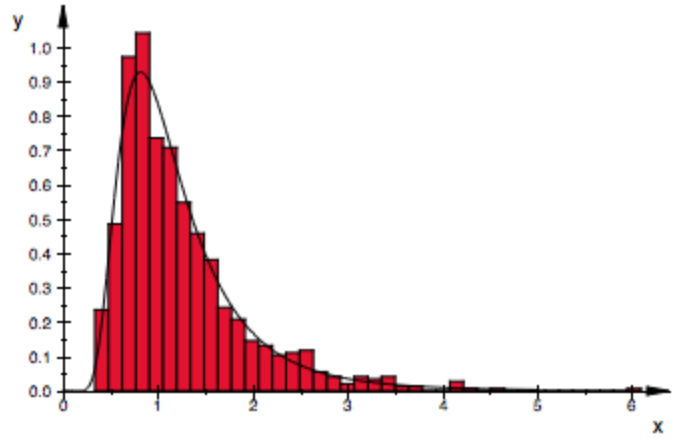
We create a sample of 1000 data points and plot a histogram of them:
X := stats::fRandom(100, 10): data := [X() $ i = 1..1000]:
plot(plot::Histogram2d(data))



The shape of the distribution becomes much better visible when we increase the number of cells:
plot(plot::Histogram2d(data, Cells = 40))



plot(plot::Histogram2d(data, Cells = [40], Area = 1), plot::Function2d(stats::fPDF(100,10)(x), x = 0 .. 5, Color = RGB::Black))



With cells of different widths, setting Area to a positive value is highly recommended, to still have the histogram follow the probability distribution:

```
cells := stats::equiprobableCells(50, stats::fQuantile(100, 10))[[0.0,
0.4426691843], [0.4426691843, 0.4977732095], [0.4977732095,

See Also AreaCellsClosed

Purpose

CellsClosedClassesClosed

Interpretation of the classes in histogram plots

Value Summary

`CellsClosed`	Optional	Left, or `Right`
`ClassesClosed`	[[`CellsClosed`]]	See below

Graphics Primitives

Objects	Default Values
plot::Histogram2d	`CellsClosed`, `ClassesClosed`: `Right`

Description

`CellsClosed` determines whether the classes used in a histogram are intepreted as semi-open intervals that are closed at the left or the right boundary.

The graphical primitive plot::Histogram2d tallies numerical data into cells ("classes") that are defined by the attribute Cells = `[a_1 .. b_1, a_2 .. b_2, dots]`. By default, these classes are interpreted as a collection of semi-open intervals Interval(a[i], [b[i]])$_{(a_i,\ b_i]}$ that are closed at the right boundary. A data item `x` is tallied into the i-th cell if it satisfies a_i < x $\leq$ b_i. With the option CellsClosed = `Left` or the equivalent `ClassesClosed` = `Left` the classes are interpreted as the semi-open intervals Interval([a[i]], b[i])$_{[a_i,\ b_i)}$ that are closed at the left boundary.

Examples

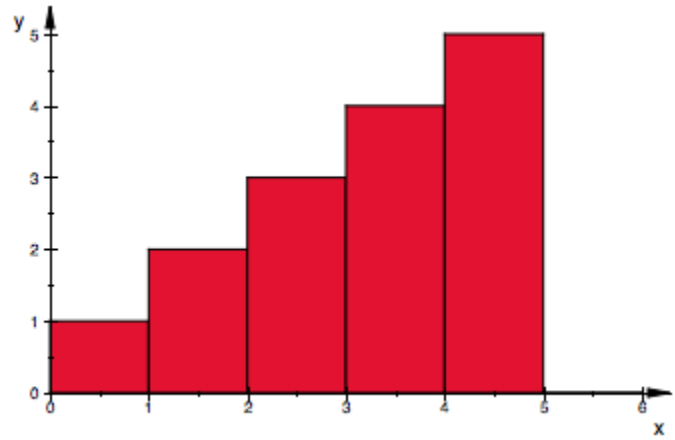
Example 1

We create a sample of 15 data points:
data := [1, 2, 2, 3, 3, 3, 4, 4, 4, 4, 5, 5, 5, 5, 5]:

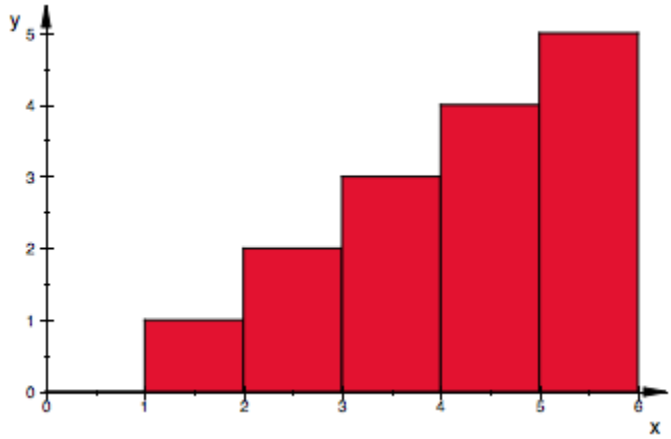
These data are to be tallied into the following cells (classes):
cells := [0 .. 1, 1 .. 2, 2 .. 3, 3 .. 4, 4 .. 5, 5 .. 6]:

With the default setting CellsClosed = `Right`, the 6 classes are the intervals Interval(0, [1])$_{(0,\ 1]}$, Interval(1, [2])$_{(1,\ 2]}$ Interval(2, [3])$_{(2,\ 3]}$

etc. The interval Interval(0, [1])$_{(0,\ 1]}$ contains one of the data items, the interval Interval(1, [2])$_{(1,\ 2]}$ contains two, etc.:
plot(plot::Histogram2d(data, Cells = cells))



Using CellsClosed = `Left`, the 6 classes are interpreted as the intervals Interval([0], 1)$_{[0,\ 1)}$, Interval([1], 2)$_{[1,\ 2)}$ Interval([2], 3)$_{[2,\ 3)}$ etc. Now, the first class Interval([0], 1)$_{[0,\ 1)}$ contains none of the data items, the second class Interval([1], 2)$_{[1,\ 2)}$ contains one item, etc.:
plot(plot::Histogram2d(data, Cells = cells, CellsClosed = Left))



delete data, cells:

See Also AreaCells

CenterCenterXCenterYCenterZ

Purpose

Center of objects, rotation center

Value Summary

`Center`	Library wrapper for "[CenterX, CenterY]" (2D), "[CenterX, CenterY, CenterZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`CenterX`, `CenterY`, `CenterZ`	Mandatory	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Arc3d, plot::Circle3d, plot::Dodecahedron, plot::Ellipse3d, plot::Ellipsoid, plot::Hexahedron, plot::Icosahedron, plot::MuPADCube, plot::Octahedron, plot::Parallelogram3d, plot::Piechart3d, plot::Rotate3d, plot::Sphere, plot::Tetrahedron, plot::Waterman	`Center`: `[0, 0, 0]` `CenterX`, `CenterY`, `CenterZ`: `0`
plot::Arc2d, plot::Circle2d, plot::Ellipse2d, plot::Parallelogram2d, plot::Piechart2d, plot::Rotate2d	`Center`: `[0, 0]` `CenterX`, `CenterY`: `0`

Description

The vector `Center` determines the center of various objects such a circles, spheres, pie charts etc. In rotation objects, it refers to the center of rotation.

Depending on the dimension of the object, it is given by a list or vector of 2 or 3 components.

`CenterX` etc. refer to the x, y, z components of this vector.

`Center`, `CenterX` etc. also denotes the rotation center in rotation objects of type plot::Rotate2d or plot::Rotate3d.

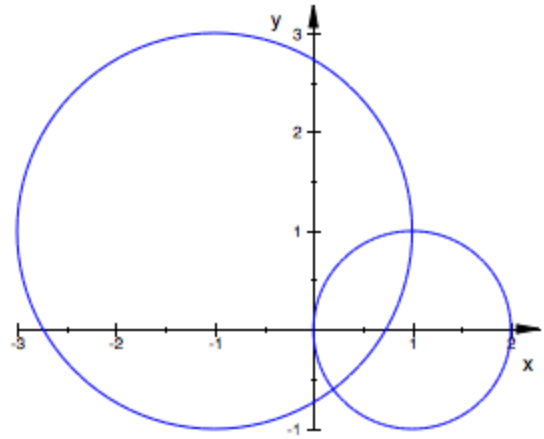
The values of these attributes can be animated.

Examples

Example 1

We create circles around the origin:
c1 := plot::Circle2d(1, [0, 0]): c2 := plot::Circle2d(2, [0, 0]):

The second argument in plot::Circle2d is the center. Internally, it is stored as the attribute `Center` and can be changed by assigning a new value:
c1::Center := [1, 0]: c2::Center := [-1, 1]: plot(c1, c2):

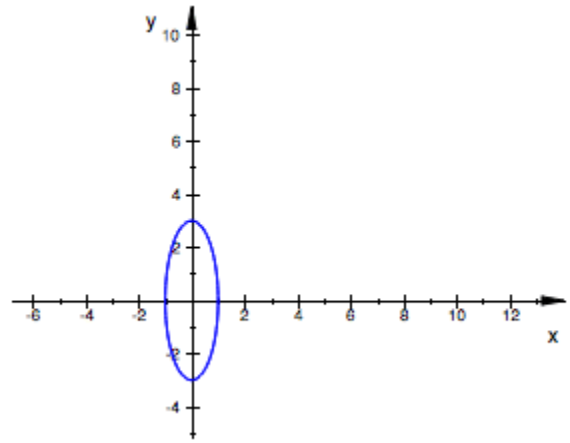


delete c1, c2:

Example 2

We create an ellipse with an animated center. A copy of it is rotated around this center:

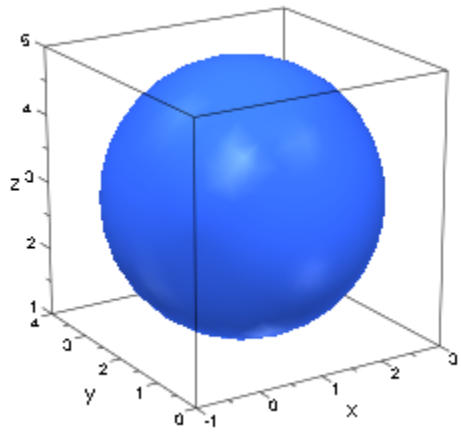
e1 := plot::Ellipse2d(1, 3, Center = [a, a], a = 0..5): e2 := plot::Rotate2d(e1, Angle = a*PI/2, Center = e1::Center, a = 0..5): plot(e1, e2)



delete e1, e2:

Example 3

We create a sphere of radius 2 and change the default center `[0, 0, 0]` to `[1, 2, 3]`:
s := plot::Sphere(2): s::Center := [1, 2, 3]: plot(s)



delete s:

See Also RadiusSemiAxes

Closed

Purpose

Open or closed polygons

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Closed Default Values
plot::Arc2d, plot::Arc3d, plot::Polygon2d, plot::Polygon3d	FALSE

Description

`Closed` switches between open and closed polygons.

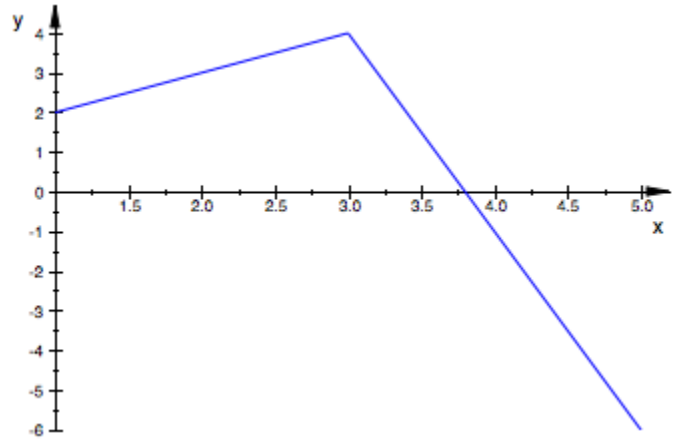
`Closed` determines whether objects of type plot::Polygon2d and plot::Polygon3d are drawn as "real" polygons (i.e., closed) or as broken lines (open polygons).

Open polygons can be filled, too. The filled area is exactly the same as if the polygon were closed.

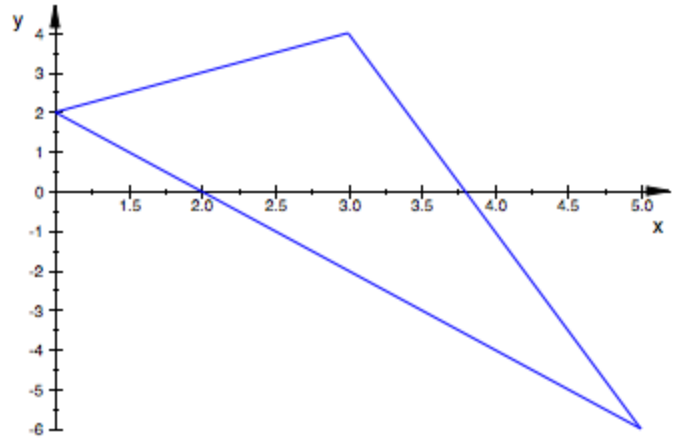
Examples

Example 1

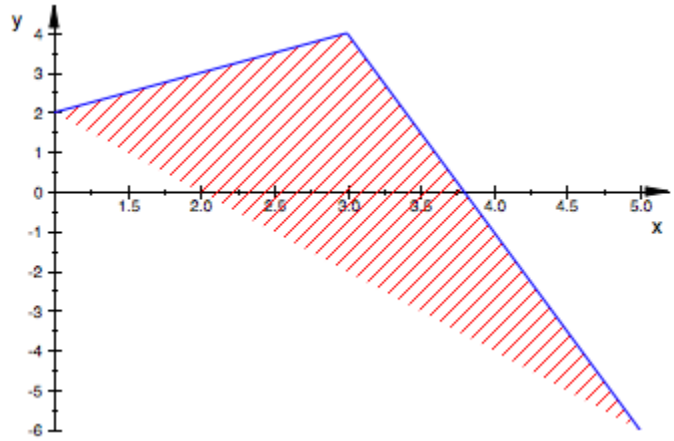
By default, polygons are not closed automatically:
p := plot::Polygon2d([[1, 2], [3, 4], [5, -6]]): plot(p)



p := plot::Polygon2d([[1, 2], [3, 4], [5, -6]], Closed = TRUE): plot(p)



Note that `Filled` and `Closed` are independent:
p::Closed := FALSE: p::Filled := TRUE: plot(p)



delete p:

Filled

ColorData

Purpose

Color values of a raster plot

Value Summary

Mandatory	List of arithmetical expressions

Graphics Primitives

Objects	ColorData Default Values
plot::Raster	

Description

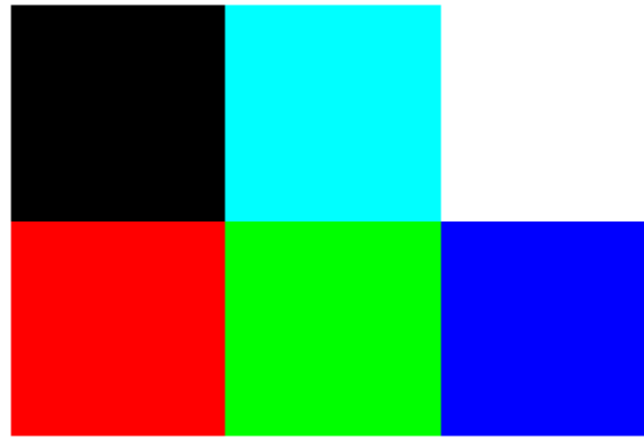
`ColorData` is a nested list of RGB color values visualized by a plot::Raster object.

The internal reresentation of the `ColorData` entry of a plot::Raster object is a list of lists of color values. Also a matrix or a 2-dimensional array of color values can be assigned to this entry: they are converted to a list of lists.

Examples

Example 1

We create a raster plot object:
colordata := [[RGB::Red, RGB::Green, RGB::Blue], [RGB::Black, RGB::Cyan, RGB::White]]: r := plot::Raster(colordata, x = 0..3, y = 0..2): plot(r):



The color data of the raster object can be accessed via the `ColorData` slot:

```
colordata := r::ColorData[[[1.0, 0.0, 0.0], [0.0, 1.0, 0.0], [0.0, 0.0, 1.0]],
[[0.0, 0.0, 0.0], [0.0, 1.0, 1.0], [1.0, 1.0, 1.0]]]
```

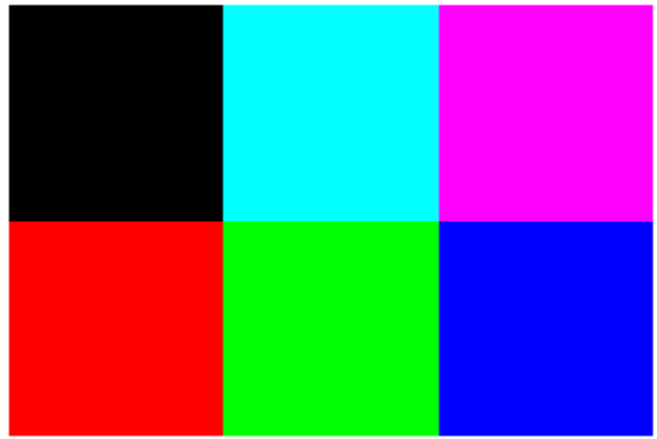
```
[[[1.0, 0.0, 0.0], [0.0, 1.0, 0.0], [0.0, 0.0, 1.0]], [[0.0, 0.0, 0.0], [0.0, 1.0, 1.0], [1.0, 1.0, 1.0]]]
```

The list of list of color values is turned into an array. After changing one entry, the new colors are written back into the raster object:

```
colordata := array(1..2, 1..3, colordata): colordata[2, 3] := RGB::Magenta:
colordataarray(1..2, 1..3, [[[1.0, 0.0, 0.0], [0.0, 1.0, 0.0], [0.0, 0.0, 1.0]],
[[0.0, 0.0, 0.0], [0.0, 1.0, 1.0], [1.0, 0.0, 1.0]]])
```

```
⎛ [1.0, 0.0, 0.0]  [0.0, 1.0, 0.0]  [0.0, 0.0, 1.0] ⎞
⎝ [0.0, 0.0, 0.0]  [0.0, 1.0, 1.0]  [1.0, 0.0, 1.0] ⎠
```

```
r::ColorData := colordata: plot(r)
```



Although the color values were assigned as an array, they are internally stored as a list of lists:
r::ColorData[[[1.0, 0.0, 0.0], [0.0, 1.0, 0.0], [0.0, 0.0, 1.0]], [[0.0, 0.0, 0.0], [0.0, 1.0, 1.0], [1.0, 0.0, 1.0]]]

[[[1.0, 0.0, 0.0], [0.0, 1.0, 0.0], [0.0, 0.0, 1.0]], [[0.0, 0.0, 0.0], [0.0, 1.0, 1.0], [1.0, 0.0, 1.0]]]
delete colordata, r:

CommandList

Purpose

Turtle movement commands

Value Summary

Mandatory	List of arithmetical expressions

Graphics Primitives

Objects	CommandList Default Values
plot::Turtle	[]

Description

`CommandList` stores the command sequence of a plot::Turtle. See the documentation of plot::Turtle for admissible commands and examples.

Contours

Purpose

Contours of an implicit function

Value Summary

Mandatory	List of arithmetical expressions

Graphics Primitives

Objects	Contours Default Values
plot::Implicit2d, plot::Implicit3d	[0]

Description

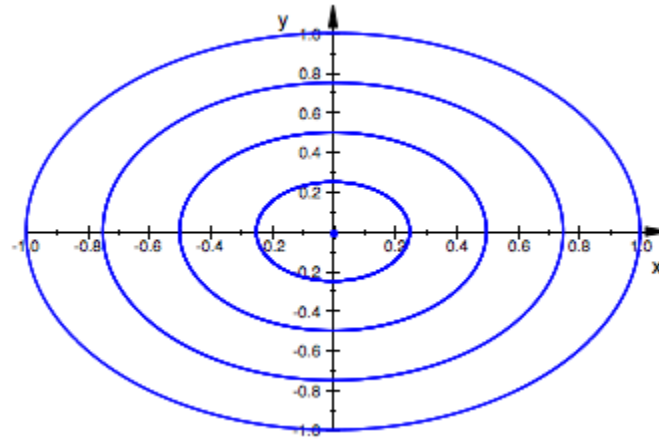
With `Contours`, you can set the contour(s) of an implicit function.

By default, plot::Implicit2d and plot::Implicit3d plot the set _outputSequence(invMatrix(f), fenced(0))=ImageSet(x , f(x)=0)$f^{-1}(0) = \{x \mid f(x) = 0\}$. Using `Contours`, you can instead plot the set _outputSequence(invMatrix(f), fenced(c))$f^{-1}(c)$ for any real *c* or for a sequence of such values.

Examples

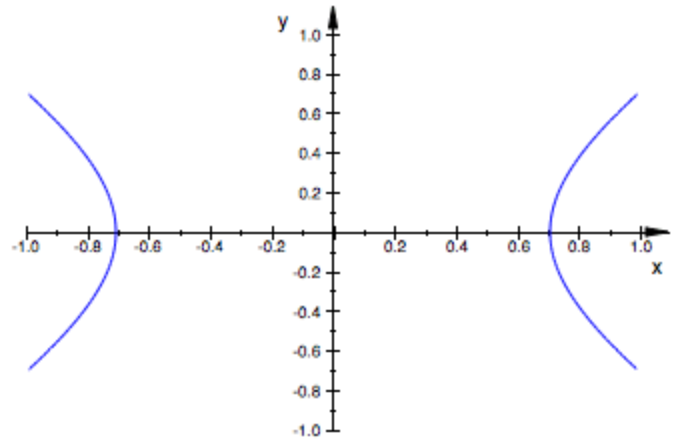
Example 1

The following command plots a series of cuts through a sphere:
plot(plot::Implicit2d(x^2+y^2, x = -1..1, y = -1..1, Contours = [0, 0.25^2, 0.5^2, 0.75^2, 1.0])):



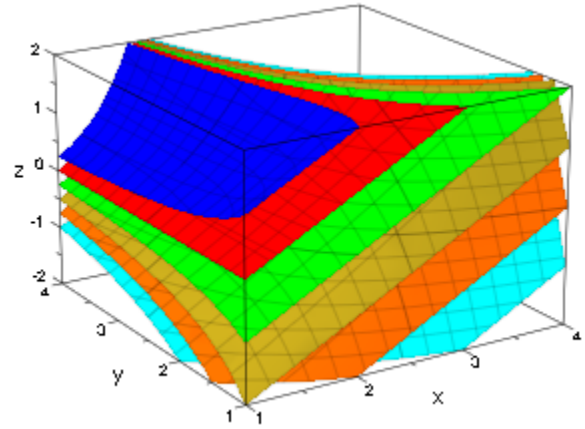
Example 2

Being an expression attribute, `Contours` can be animated:
plot(plot::Implicit2d(x^2-y^2, x = -1..1, y = -1..1, Contours = [1/2*cos(a)], a=0..2*PI)):



Example 3

The contour currently plotted is passed to the color functions and can be used to distinguish them visually:
plot(plot::Implicit3d(x^y - y*z, x=1..4, y=1..4, z=-2..2, Contours = [$0..5], FillColorFunction = ((x,y,z,dx,dy,dz,c) -> RGB::ColorList[round(c)+1]))



Purpose

CoordinateType

Linear versus logarithmic plots in 2D

Value Summary

Inherited		See below

Graphics Primitives

Objects	CoordinateType Default Values
plot::CoordinateSystem2d	`LinLin`

Description

`CoordinateType` allows to switch between linear and logarithmic 2D plots.

By default, a linear (Cartesian) scaling of all coordinate axes is used in 2D. This corresponds to `CoordinateType = LinLin`. Logarithmic plots are created by choosing a `CoordinateType` different from `LinLin`.

In 2D, the following coordinate types are available:

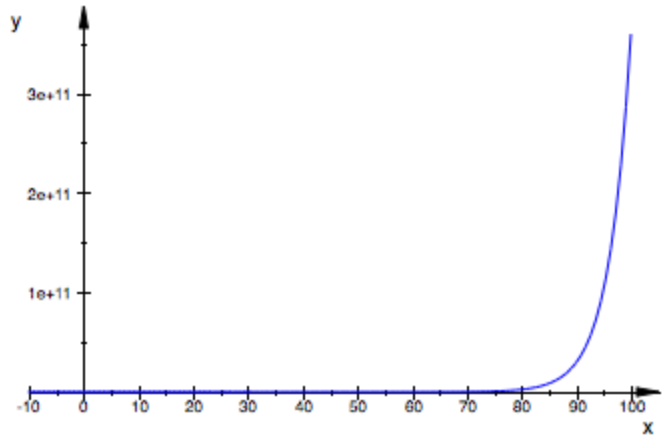
- `LinLin`: Straight lines given by $y = c_1 x + c_2$ are rendered as straight lines on the screen.
- `LinLog`: Linear coordinates are plotted along the horizontal axis, logarithmic coordinates along the vertical axis. The curves y=exp(c_1*x+c_2)$y = e^{c_1 x + c_2}$ are rendered as straight lines on the screen.
- `LogLin`: Logarithmic coordinates are plotted along the horizontal axis, linear coordinates along the vertical axis. The curves $y = c_1 ln(x) + c_2$ are rendered as straight lines on the screen.
- `LogLog`: Logarithmic coordinates are plotted along both axes. The curves $y = c_1 x^{c_2}$ are rendered as straight lines on the screen.

The objects to be plotted must have strictly positive coordinate values in “logarithmic directions”.

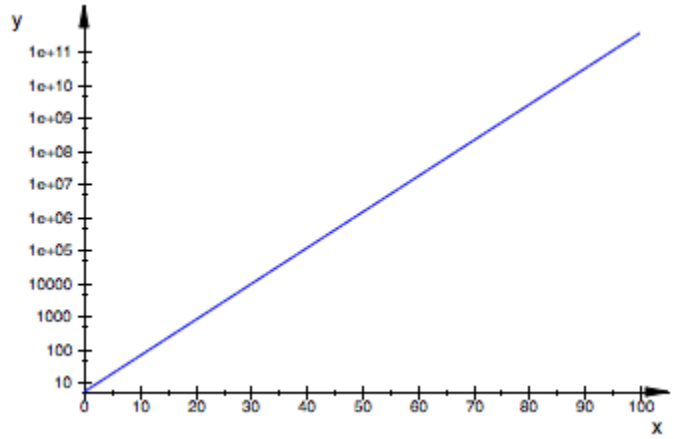
Examples

Example 1

We consider an exponential function:
plot(plot::Function2d(5*exp(x/4), x = -10 .. 100), CoordinateType = LinLin):

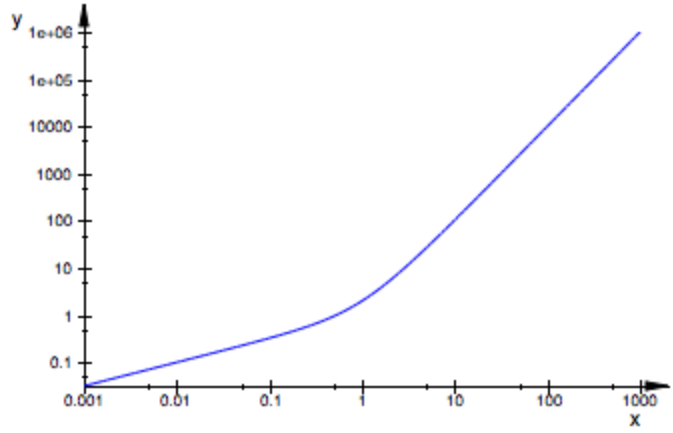


In a singly logarithmic plot, the graph is a straight line:
plot(plot::Function2d(5*exp(x/4), x = 0 .. 100), CoordinateType = LinLog):



Example 2

We render the function y=sqrt(x)+x^2$y = \sqrt{x} + x^2$ in a log-log plot: plot(plot::Function2d(sqrt(x) + x^2, x = 10^(-3) .. 10^3), CoordinateType = LogLog):



Purpose

Data

The (statistical) data to plot

Value Summary

Mandatory	List of arithmetical expressions

Graphics Primitives

Objects	Data Default Values
plot::Bars2d, plot::Bars3d, plot::Boxplot, plot::Histogram2d, plot::Listplot, plot::Matrixplot, plot::QQplot, plot::Scatterplot, plot::SparseMatrixplot	
plot::Piechart2d, plot::Piechart3d	[1]

Description

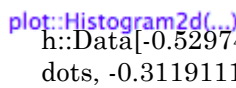
`Data` is used internally to store the statistical data displayed, for example, in a pie-chart diagram. While it is possible to manipulate this data (as shown in “Example 2” on page 24-1181), `Data` is mostly seen as a storage space irrelevant to the user.

For speed and clarity, `Data` will be displayed in the object inspector only if the amount of data is small. This may cause problems when using the “recalculate” feature. In such a case, the remedy is to assign the plot object in question to an identifier before plotting.

Examples

Example 1

All object types listed above store the data given in `Data`:
X := stats::normalRandom(0, 1): h := plot::Histogram2d([X() $ i = 1..30])‘plot::Histogram2d(...)‘

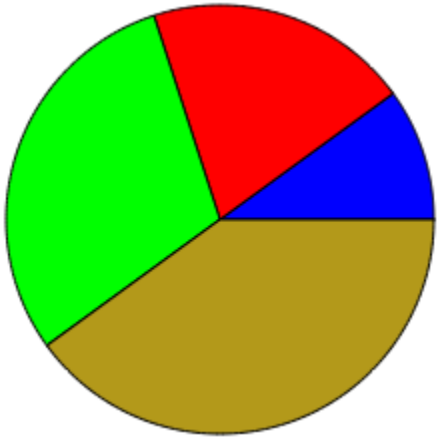


h::Data[-0.5297400457, -0.5694234147, -0.5161446272, -1.090814471, dots, -0.3119111074, 0.1868437371, -0.7818045527]

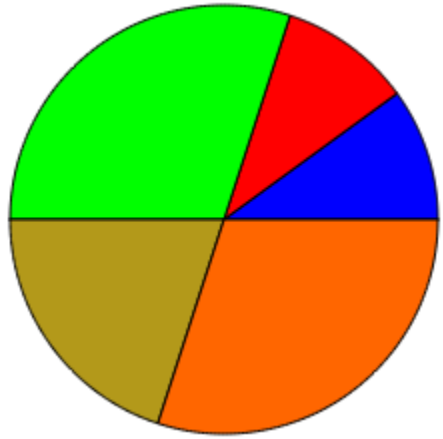
[-0.5297400457, -0.5694234147, -0.5161446272, -1.090814471,
1.782520584, 0.6370330472, 0.6902346071, 0.3399758858, ..., -0.3119111074, 0.186
1.177699186, -0.5970692982, -1.386247581, -0.9783222199,
-0.7891413081, 0.2090732178, 0.2186783746, -0.7392138209,
0.6496128588, 0.6258699055, 3.606896706, -0.3319378999,
0.4727169669, 0.4443759372, 0.1735552584, -0.1748302292,
-1.468420962, -0.6711676724, 0.6600121852, -0.3119111074,
0.1868437371, -0.7818045527]

Example 2

It is possible to change the data in an object using `Data`:
p := plot::Piechart2d([1, 2, 3, 4]): plot(p)



p::Data := [1, 1, 3, 2, 3]: plot(p)



See Also Cells

DensityDataDensityFunction

Purpose

Density values for a density plot

Value Summary

`DensityData`, `DensityFunction`	Optional	List of arithmetical expressions

Graphics Primitives

Objects	Default Values
plot::Density	

Description

`DensityData` is a nested list of "density values" visualized by a plot::Density object.

`DensityFunction` is a symbolic expression or a procedure defining the "density values" of a plot::Density object.

Density objects of type plot::Density can be defined either by discrete density data or by a density function. In the first case, the object has the slot `DensityData`. In the latter case, the function describing the densities is stored in the slot `DensityFunction`.

The internal representation of the `DensityData` entry of a plot::Density object is a list of lists of density values. Also a matrix or a 2-dimensional array of density values can be assigned to this entry: they are converted to a list of lists.

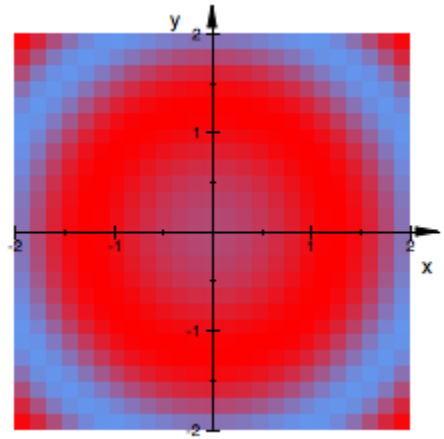
The `DensityFunction` of a density object can be a symbolic expression, a procedure or a piecewise object.

Assigning a value to the `DensityData` entry deletes an existing `DensityFunction` entry and vice versa.

Examples

Example 1

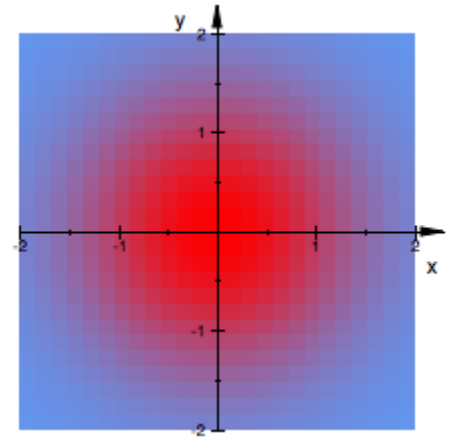
We create a density plot object defined by a density function:
d := plot::Density(sin(x^2 + y^2), x = -2..2, y = -2..2): plot(d, Scaling = Constrained):



The density function of this object can be accessed via the `DensityFunction` slot:
d::DensityFunctionsin(x^2 + y^2)

$$\sin\left(x^2 + y^2\right)$$

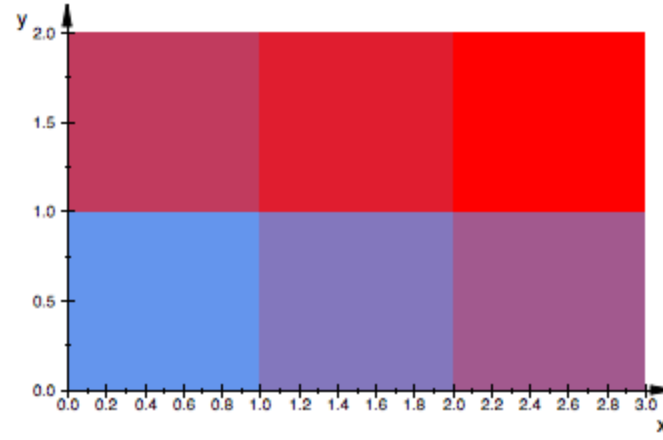
We change the density function by assigning a new value to the `DensityFunction` slot:
d::DensityFunction := exp(-(x^2 + y^2)/2): plot(d, Scaling = Constrained)



delete d:

Example 2

We create a density plot object defined by discrete density data: densitydata := [[0.1, 0.2, 0.3], [0.4, 0.5, 0.6]]: d := plot::Density(densitydata, x = 0..3, y = 0..2): plot(d):



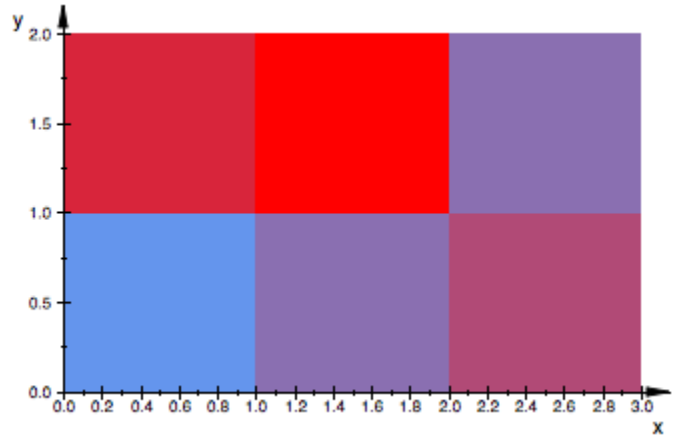
The density data of the density object can be accessed via the `DensityData` slot:
densitydata := d::DensityData[[0.1, 0.2, 0.3], [0.4, 0.5, 0.6]]

```
[[0.1, 0.2, 0.3], [0.4, 0.5, 0.6]]
```

The list of list of density values is turned into a matrix. After changing one entry, the new density values are written back into the density object:
densitydata := matrix(densitydata): densitydata[2, 3] := 0.2:
densitydatamatrix([[0.1, 0.2, 0.3], [0.4, 0.5, 0.2]])

```
( 0.1  0.2  0.3 )
( 0.4  0.5  0.6 )
```

d::DensityData := densitydata: plot(d)



Although the density values were assigned as a matrix, they are internally stored as a list of lists:
d::DensityData[[0.1, 0.2, 0.3], [0.4, 0.5, 0.2]]

```
[[0.1, 0.2, 0.3], [0.4, 0.5, 0.2]]
```

```
delete densitydata, d:
```

Purpose

Edges
Number of Edges

Value Summary

Mandatory	MuPAD expression

Graphics Primitives

Objects	Edges Default Values
plot::Pyramid	4
plot::Prism	3

Description

`Edges` determines the number of edges for the regular base plane of a prism or pyramid. `Edges` is a positive integer number.

Examples

Example 1

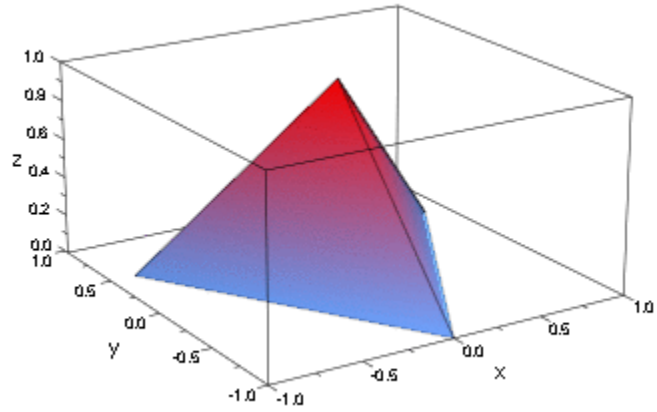
The default values for the attribute `Edges` are:
plot::Prism(); plot::Pyramid();plot::Prism(1, [0, 0, 0], [0, 0, 1], Edges = 3)

plot::Prism(1, [0, 0, 0], [0, 0, 1], Edges = 3)
plot::Pyramid(1, [0, 0, 0], 0, [0, 0, 1], Edges = 4)

plot::Pyramid(1, [0, 0, 0], 0, [0, 0, 1], Edges = 4)

Example 2

The attribute `Edges` can be animated:
plot(plot::Pyramid(Edges=a, a=3..13)):



1.0
0.8
0.6

Purpose

Extension

Line extensions

Value Summary

Inherited	`Finite`, `Infinite`, or `SemiInfinite`

Graphics Primitives

Objects	Extension Default Values
plot::Line2d, plot::Line3d	`Finite`

Description

`Extension` allows to extent a line segment to an infinite ray or an infinite line.

Lines of type plot::Line2d and plot::Line3d are defined by specifying two points through which the line passes. For example: `plot::Line2d([`x_1`, `y_1`], [`x_2`, `y_2`])`. The first point `[`x_1`, `y_1`]` corresponds to the attribute From, the second point `[`x_2`, `y_2`]` corresponds to the attribute To.

With `Extension` = `Finite`, a line segment from From to To is drawn.

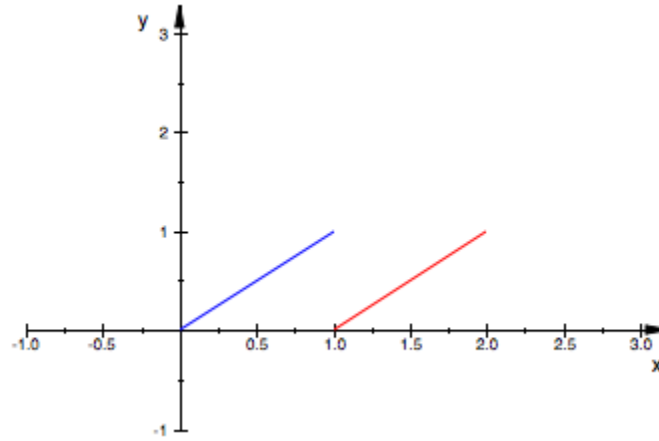
With `Extension` = `SemiInfinite`, an infinite ray is drawn starting at From passing through To. The ray extends to the border of the ViewingBox.

With `Extension` = `Infinite`, an infinite line is drawn passing through From and To. The line extends in both directions to the border of the ViewingBox.

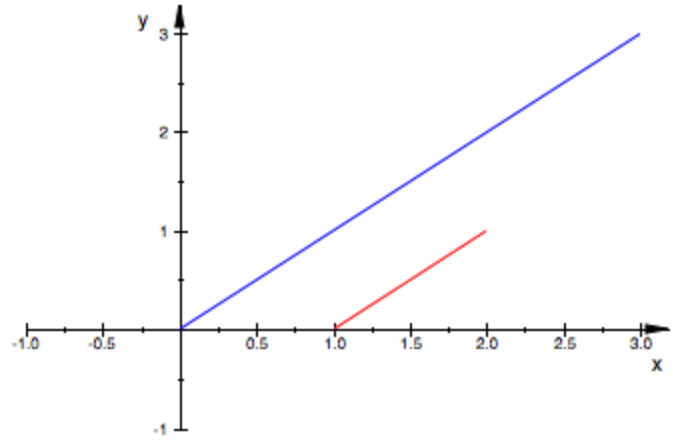
Examples

Example 1

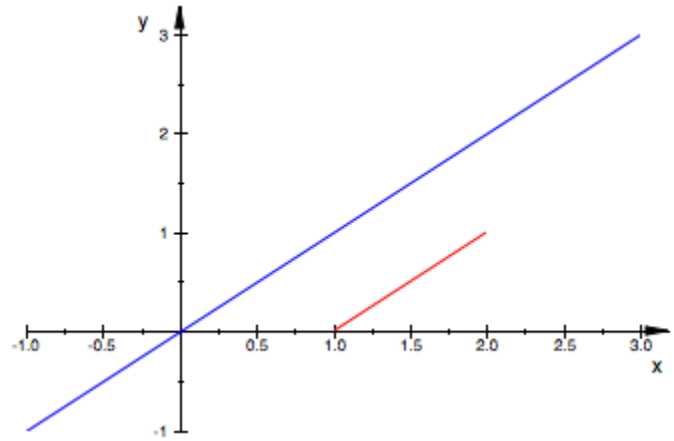
We plot two lines with the default value `Extension` = `Finite`: plot(plot::Line2d([0, 0], [1, 1], Color = RGB::Blue), plot::Line2d([1, 0], [2, 1], Color = RGB::Red), ViewingBox = [-1..3, -1..3])



Now, with `Extension` = `SemiInfinite`, the blue line becomes a ray extending to the ViewingBox in one direction:
plot(plot::Line2d([0, 0], [1, 1], Color = RGB::Blue, Extension = SemiInfinite), plot::Line2d([1, 0], [2, 1], Color = RGB::Red), ViewingBox = [-1..3, -1..3])

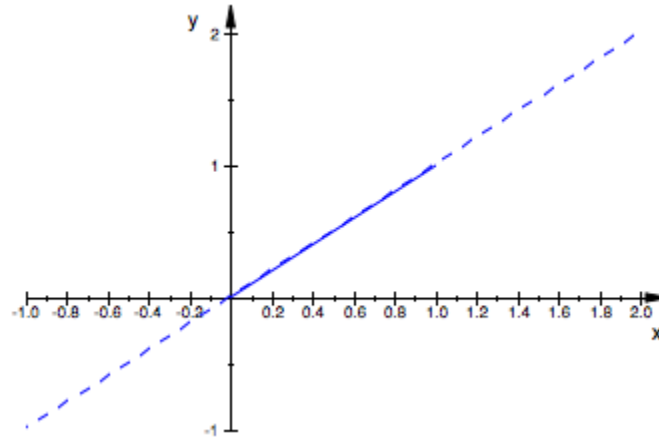


With `Extension` = `Infinite`, the blue line extends to the ViewingBox in both directions:
plot(plot::Line2d([0, 0], [1, 1], Color = RGB::Blue, Extension = Infinite), plot::Line2d([1, 0], [2, 1], Color = RGB::Red), ViewingBox = [-1..3, -1..3])



Example 2

Here we define a finite line segment and use plot::modify to create an extended copy. It is drawn as an infinite dashed line:
line := plot::Line2d([0, 0], [1, 1]): plot(plot::modify(line, Extension = Infinite, LineStyle = Dashed), line, ViewingBox = [-1..2, -1..2]):



delete line:

	`To`: `[1, 0, 0]`
	`FromX`, `FromY`, `FromZ`, `ToY`, `ToZ`: `0`
	`ToX`: `1`

plot::Reflect2d	

Description

The vectors `From` and `To` determine the starting point and the end point, respectively, of arrows and lines.

`From` is a vector determining the position of the starting point of arrows and lines. Depending on the dimension, it is given by a list or vector of 2 or 3 components.

`FromX` etc. refer to the x, y, z components of this vector.

`To` is a vector determining the position of the end point of arrows and lines. Depending on the dimension, it is given by a list or vector of 2 or 3 components.

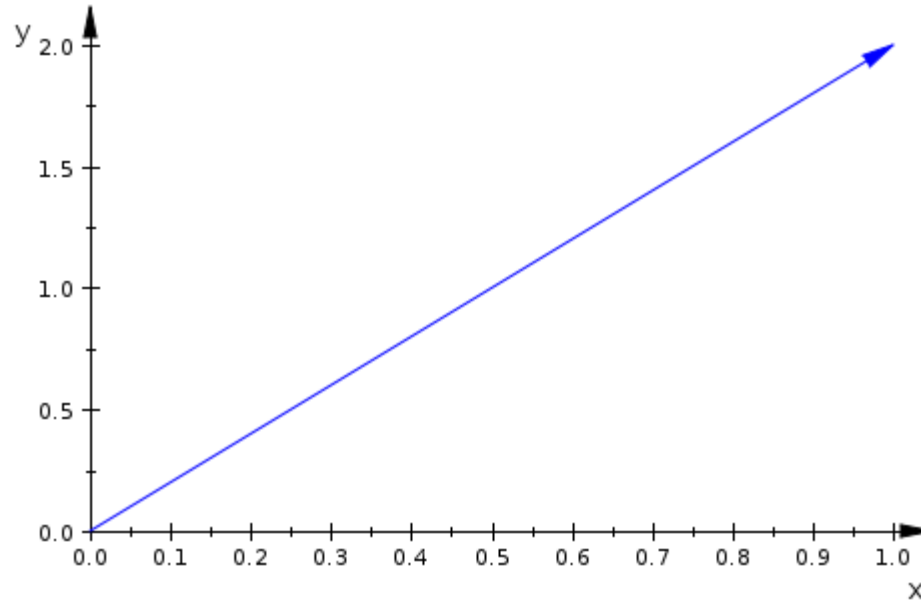
`To` etc. refer to the x, y, z components of this vector.

The values of these attributes can be animated.

Examples

Example 1

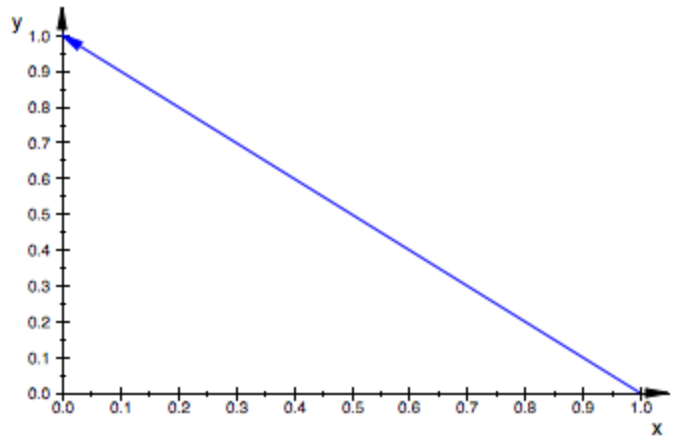
We define an arrow:
p := plot::Arrow2d([0, 0], [1, 2]): plot(p):



The arguments are the starting point and the end point of the arrow. Internally, they are stored as the attributes `From` and `To`. We can access the object's attributes and change them:
p::From, p::To[0, 0], [1, 2]

```
[0, 0], [1, 2]
```

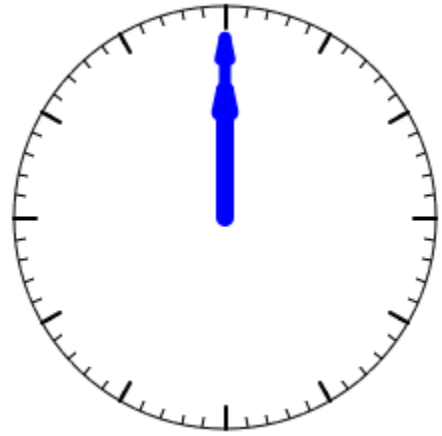
p::From := [1, 0]: p::To := [0, 1]: plot(p):



delete p:

Example 2

The values of `From` and `To` can be animated. Here is a simple clock:
plot(plot::Circle2d(1, [0, 0], Color = RGB::Black), plot::Line2d([0.9*cos(a*PI/6), 0.9*sin(a*PI/6)], [1.0*cos(a*PI/6), 1.0*sin(a*PI/6)], Color = RGB::Black, LineWidth = 0.8*unit::mm) $ a = 0 .. 11, plot::Line2d([0.95*cos(a*PI/30), 0.95*sin(a*PI/30)], [1.0*cos(a*PI/30), 1.0*sin(a*PI/30)], Color = RGB::Black, LineWidth = 0.5*unit::mm) $ a = 0 .. 59, plot::Arrow2d([0, 0], [0.85*sin(12*a), 0.85*cos(12*a)], a = 0 .. 2*PI, LineWidth = 2*unit::mm), plot::Arrow2d([0, 0], [0.6*sin(a), 0.6*cos(a)], a = 0 .. 2*PI, LineWidth = 3*unit::mm), Axes = None, Frames = 600, TimeRange = 0..120):



Purpose

FunctionXFunctionYFunctionZFunction
Function expression or procedure

Value Summary

`Function`, `XFunction`, `YFunction`, `ZFunction`	Mandatory	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylindrical, plot::Function2d, plot::Function3d, plot::Implicit2d, plot::Implicit3d, plot::Iteration, plot::Ode2d, plot::Ode3d, plot::Polar, plot::Sequence, plot::Spherical, plot::Streamlines2d, plot::Sum, plot::Surface, plot::Tube, plot::VectorField2d, plot::VectorField3d, plot::XRotate, plot::ZRotate	

Description

`Function`, XFunction, YFunction, ZFunction correspond to function expressions or procedures in various plot objects given by a mathematical function.

The attribute `Function` is used for graphs of functions in 2D and 3D, implicit plots, conformal plots etc. which are characterized by a single function.

The attributes `XFunction` etc. refer to the parametrization of the x, y or z-coordinate of parametrized curves and surfaces. In vector field plots they correspond to the components of the vector field.

When defining a graphical primitive such as a function plot, the mathematical expression defining the function is passed directly to the plot routine generating this object. E.g., one calls `plot::Function2d(x*sin(x), x = -5 .. 5)` to define the graph of $f(x) = x\sin(x)$. Internally, the attribute `Function = x*sin(x)` is associated with the graphical object.

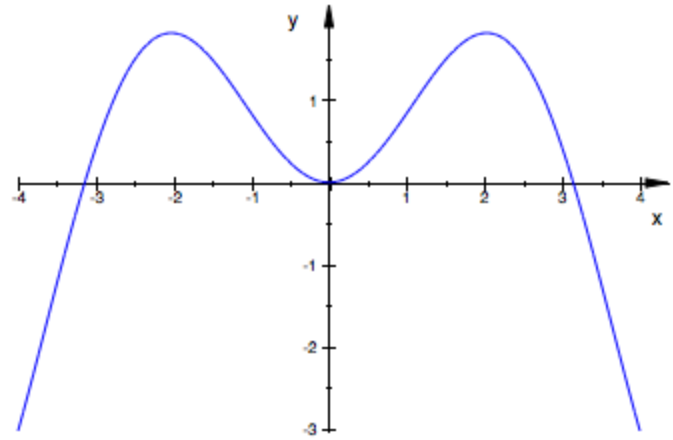
Wherever function expressions are expected, also piecewise objects or MuPAD procedures can be used. E.g., the calls `plot::Function2d(sin(x), x = 0..PI)` and `plot::Function2d(x -> sin(x), x = 0..PI)` are equivalent and associate the attributes `Function = sin(x)` or `Function = x -> sin(x)`, respectively, with the plot objects.

Examples

Example 1

We define an object of type plot::Function2d representing the graph of $f(x) = x\sin(x)$:

```
f := plot::Function2d(x*sin(x), x = -4 .. 4): plot(f)
```

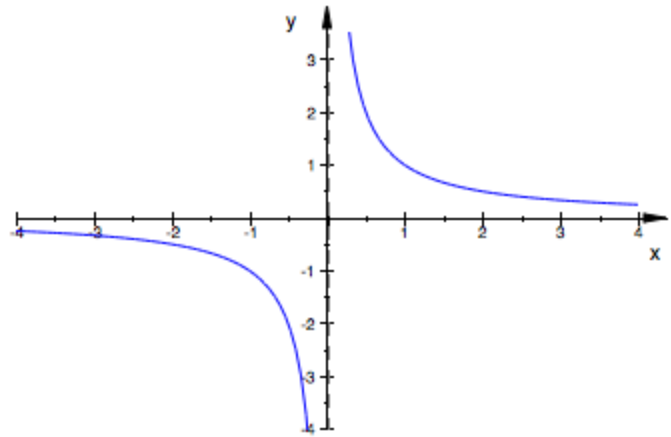


Internally, the expression defining the function is turned into the attribute `Function = x*sin(x)`. It is accessible via a corresponding slot of the object:

f::Functionx*sin(x)

$x \sin(x)$

One can change the object by reassigning a new value to this attribute:
f::Function := 1/x: plot(f):



delete f:

Example 2

For implicit plots as produced by plot::Implicit2d and plot::Implicit3d, the attribute `Function` refers to the function whose zero set is to be plotted:
p := plot::Implicit2d(y*sin(x) - x*cos(y), x=-5..5, y=-5..5):

Internally, the expression defining the function is turned into the attribute `Function = y*sin(x) - x*cos(y)`. It is accessible via a corresponding slot of the object:
p::Functiony*sin(x) - x*cos(y)

$y \sin(x) - x \cos(y)$

delete p:

Example 3

For parametrized curves and surfaces, the attributes `XFunction`, `YFunction` etc. correspond to the parametrization of the coordinates x, y etc:

```
c2 := plot::Curve2d([u*cos(u), u*sin(u)], u = 0..5*PI): c2::XFunction, c2::YFunctionu*cos(u), u*sin(u)
```

$$u\cos(u),\ u\sin(u)$$

```
c3 := plot::Curve3d([u*cos(u), u*sin(u), u^2], u = 0..5*PI): c3::XFunction, c3::YFunction, c3::ZFunctionu*cos(u), u*sin(u), u^2
```

$$u\cos(u),\ u\sin(u),\ u^2$$

```
s := plot::Surface([u*cos(v), u*sin(v), u^2*sin(2*v)], u = 0..1, v = 0..2*PI): s::XFunction, s::YFunction, s::ZFunctionu*cos(v), u*sin(v), u^2*sin(2*v)
```

$$u\cos(v),\ u\sin(v),\ u^2\sin(2\,v)$$

```
delete c2, c3, s:
```

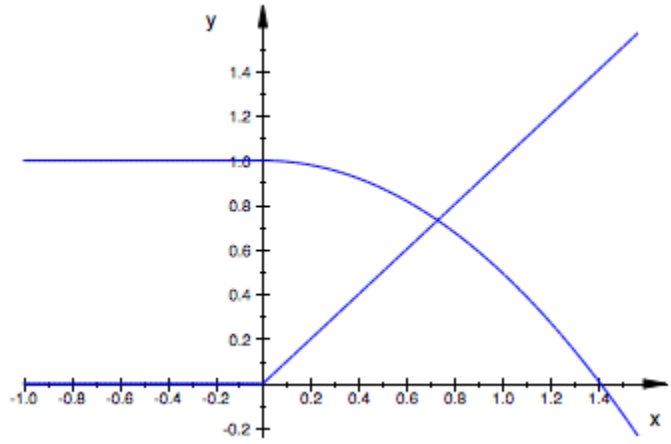
Example 4

Wherever a function expression is expected, also a piecewise object or a procedure can be used:

```
f1 := piecewise([x < 0, 0], [x >= 0, x]): f2 := proc(x) begin if x < 0 then 1 else 1 - x^2/2 end_if; end_proc: F1 := plot::Function2d(f1, x = -1..PI/2): F2 := plot::Function2d(f2, x = -1..PI/2): F1::Function, F2::Functionpiecewise([x < 0, 0], [0 <= x, x]), ‘proc f2(x) ... end‘
```

$$\begin{cases} 0 & \text{if } x < 0 \\ x & \text{if } 0 \le x \end{cases},\quad \text{proc f2(x) ... end}$$

```
plot(F1, F2)
```



delete f1, f2, F1, F2:

See Also Function1Function2

Function1Function2Baseline

Purpose

First function/curve delimiting hatch

Value Summary

`Baseline`, `Function1`, `Function2`	Mandatory	Text string

Graphics Primitives

Objects	Default Values
plot::Hatch, plot::Integral	

Description

`Function1` and `Function2` refer to the functions that define the borders of a hatched 2D region of type plot::Hatch.

`Baseline` is the *y* value of a straight horizontal border line of a hatch.

`Function1`, `Function2` are very technical attributes that a user will hardly ever use.

If f_1, f_2 are function objects of type plot::Function2d, the hatch object `h := plot::Hatch(`f_1`, `f_2`)` stores references to the objects f_1, f_2 as the slots `h::Function1`, `h::Function2`. These are text references (i.e., strings) by which the function objects f_1, f_2 can be identified, but not the function objects themselves.

`Function1` points to a function object of type plot::Function2d or a curve object of type plot::Curve2d.

`Function1` is usually set implicitly by plot::Hatch to the Name attribute of its first argument.

When `Function1` refers to a curve of type plot::Curve2d, `Function2` and `Baseline` are ignored.

`Function2` is the (optional) second border function of a hatch. In the plot, the hatched area is bounded by the two functions refered to by `Function1` and `Function2`.

If `Function2` is given, `Function1` must refer to a function graph of type plot::Function2d, too.

`Function2` is usually set implicitly by plot::Hatch to the Name attribute of its second argument.

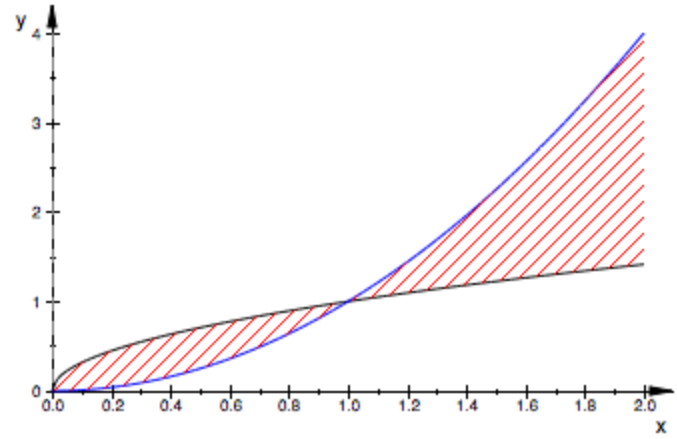
`Baseline` is an alternative second delimiter of a hatch. It defines a horizontal border line of the hatch with a y-value given by `Baseline`. The `Baseline` expression may be animated.

Examples

Example 1

We hatch the area between the functions sqrt(x) $\sqrt{x}$ and x^2:

```
f1 := plot::Function2d(sqrt(x), x = 0..2, Color = RGB::Black): f2 :=
plot::Function2d(x^2, x = 0..2, Color = RGB::Blue): h := plot::Hatch(f1,
f2): plot(f1, f2, h)
```



The references to the border functions are stored a strings in the hatch object `h`:

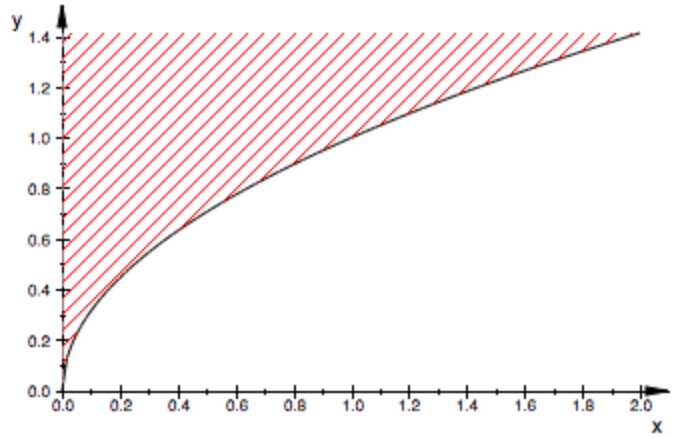
```
h::Function1, h::Function2"Function2d(LineColor = [0.0, 0.0, 0.0], XMin
= 0, XMax = 2, XName = x, Function = x^(1/2), XAxisTitle = \"x\")",
"Function2d(LineColor = [0.0, 0.0, 1.0], XMin = 0, XMax = 2, XName =
x, Function = x^2, XAxisTitle = \"x\")"
```

`Baseline` serves as an alternative for the special case of a constant border function. The `Baseline` value can be animated:

```
h := plot::Hatch(f1, sqrt(2)*a, a = 0..1): h::Baseline := sqrt(2)*a
```

$\sqrt{2}\,a$

```
plot(f1, h)
```

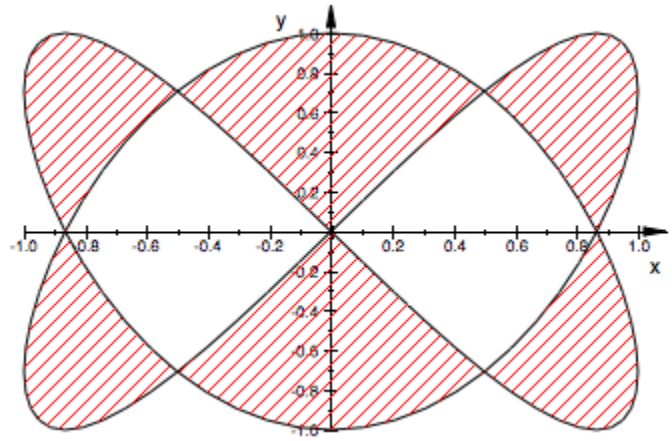


A (closed) curve of type plot::Curve2d may be used as the boundary of the hatch:

```
f1 := plot::Curve2d([sin(2*x), cos(3*x)], x = 0..2*PI, Color = RGB::Black):
h := plot::Hatch(f1): h::Function1"Curve2d(LineColor = [0.0, 0.0, 0.0],
UMin = 0, UMax = 2*PI, UName = x, XFunction = sin(2*x), YFunction
= cos(3*x))"
```

```
"Curve2d(LineColor = [0.0, 0.0, 0.0], UMin = 0, UMax = 2*PI, UNa
  YFunction = cos(3*x))"
```

plot(f1, h)



delete f1, f2, h, c:

See Also Name

Purpose

InitialConditionsTimeMesh

Initial conditions of the ODE

Value Summary

`InitialConditions`, `TimeMesh`	Mandatory	List of arithmetical expressions

Graphics Primitives

Objects	Default Values
plot::Ode2d, plot::Ode3d	

Description

`InitialConditions = [`$y_1(t_0)$`, `$y_2(t_0)$`, ]` sets the initial conditions for the initial value problem

diff(matrix([[y_1(t)], [y_2(t)], [‘.’],[‘.’],[‘.’]]), t)=matrix([[f_1(t, y_1(t), y_2(t), Symbol::hellip)], [f_2(t, y_1(t), y_2(t), Symbol::hellip)], [‘.’],[‘.’],[‘.’]])

$$\frac{\partial}{\partial t}\begin{pmatrix} y_1(t) \\ y_2(t) \\ \vdots \end{pmatrix} = \begin{pmatrix} f_1(t, y_1(t), y_2(t), \ldots) \\ f_2(t, y_1(t), y_2(t), \ldots) \\ \vdots \end{pmatrix}$$

`TimeMesh = [`t_0`, `t_1`, `t_2`, ]` sets the values of the independent variable t (the “time”) of the ODE at which graphical points of the solution curve are plotted. The first entry t_0 is the initial time for which initial conditions are set by `InitialConditions`.

Internally, plot::Ode2d and plot::Ode3d call the routine numeric::odesolve for solving the given ODE numerically.

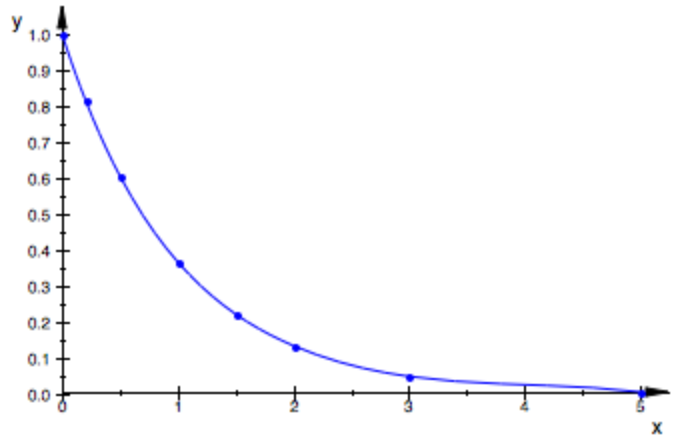
The list of initial conditions set by `InitialConditions` is forwarded to numeric::odesolve. See the corresponding help page for further details.

Examples

Example 1

We solve the initial value problem y'(t)=-y(t), y(0)=1 $y'(t) = -y(t),\ y(0) = 1$ numerically:

```
f := (t, Y) -> [-Y[1]]: Y0 := [1]: timemesh:= [0, 0.2, 0.5, 1, 1.5, 2, 3, 5]:
plot(plot::Ode2d(f, InitialConditions = Y0, TimeMesh = timemesh))
```



delete f, Y0, timemesh:

IntMethod

Method for integral approximation

Value Summary

Optional	`Exact`, `RiemannLeft`, `RiemannRight`, `RiemannLower`, `RiemannUpper`, `RiemannMiddle`, `RiemannLowerAbs`, `RiemannUpperAbs`, `Simpson`, or `Trapezoid`

Graphics Primitives

Objects	IntMethod Default Values
plot::Integral	`Exact`

Description

`IntMethod` determines the method of the visualization of plot::Integral objects.

Following methods are implemented:

- Exact

  the area between x-axis and function graph is colored

- RiemannLower

  display boxes between x-axis and function graph using the smallest value of the function in each subinterval

- RiemannLowerAbs

  display boxes between x-axis and function graph using the smallest absolut value of the function in each subinterval

- RiemannUpper

  display boxes between x-axis and function graph using the greatest value of the function in each subinterval

- RiemannUpperAbs

display boxes between x-axis and function graph using the greatest absolut value of the function in each subinterval

- RiemannLeft

  display boxes between x-axis and function graph using the function value of the left border in each subinterval

- RiemannMiddle

  display boxes between x-axis and function graph using the function value of the middle in each subinterval

- RiemannRight

  display boxes between x-axis and function graph using the function value of the right border in each subinterval

- Trapezoid

  display an approximation of the integral using the Trapezoidal rule

- Simpson

  interpolate the graph of the function using Simpsons rule

Purpose

GenerationsRotationAngleIterationRulesStartRuleStepLengthTurtleRules
Number of iterations of L-system rules

Value Summary

`Generations`, `IterationRules`, `RotationAngle`, `StartRule`, `StepLength`, `TurtleRules`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Lsys	`Generations`: `5` `StepLength`: `1.0`

Description

`Generations`, RotationAngle, IterationRules, StartRule, StepLength, and TurtleRules define a Lindenmayer system. The attribute meanings and examples of their use can be found in the documentation of plot::Lsys.

Purpose

Base value

Value Summary

Optional | MuPAD expression

Graphics Primitives

Objects	Ground Default Values
plot::Bars3d, plot::Sweep	0

Description

In bar charts, the attribute `Ground = g` determines the vertical coordinate value of one end of the bars. Data values $m > g$ are displayed as bars stretching in the vertical direction from the lower end `g` up to the upper end `m`. Data values $m < g$ are displayed as bars stretching in the vertical direction from the upper end `g` down to the lower end `m`.

In sweep surfaces of type plot::Sweep, a parametrized space curve ($x(u)$, $y(u)$, $z(u)$) is projected to the x-y-plane with constant $z = g$, where g is set by the `Ground` attribute.

The parameter `g` has to be a numerical real value or an expression of the animation parameter.

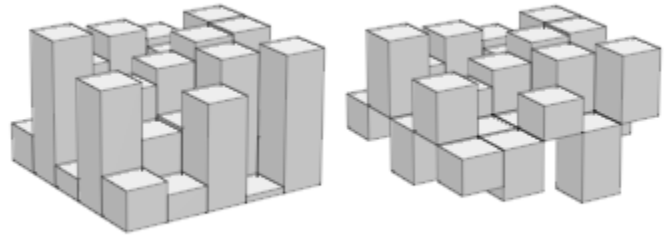
If the attribute `Ground = g` is not specified, the default value `g = 0` is used.

Examples

Example 1

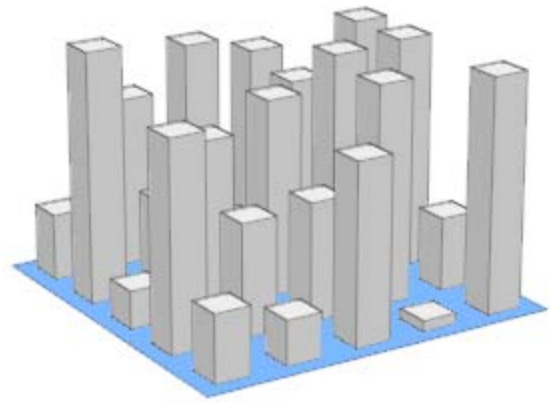
We plot the same data with different `Ground` values:

```
A := matrix::random(5, 5, frandom): plot(plot::Scene3d(plot::Bars3d(A, Ground = 0, Color = RGB::Grey)), plot::Scene3d(plot::Bars3d(A, Ground = 0.5, Color = RGB::Grey)), Layout = Horizontal):
```



In the next call, the ground level is animated. Note that in animations one must specify ranges for the *x* and *y* coordinates. We include a transparent plane visualizing the ground level:

```
plot(plot::Bars3d(A, x = 0 .. 1, y = 0 .. 1, a = 0 .. PI, Color = RGB::Grey,
Gap = [0.5, 0.5], Ground = sin(a)), plot::Surface([x, y, sin(a) + 0.001], x =
0 .. 1, y = 0 .. 1, a = 0 .. PI, Mesh = [2, 2], Color = RGB::Blue.[0.5]) ):
```

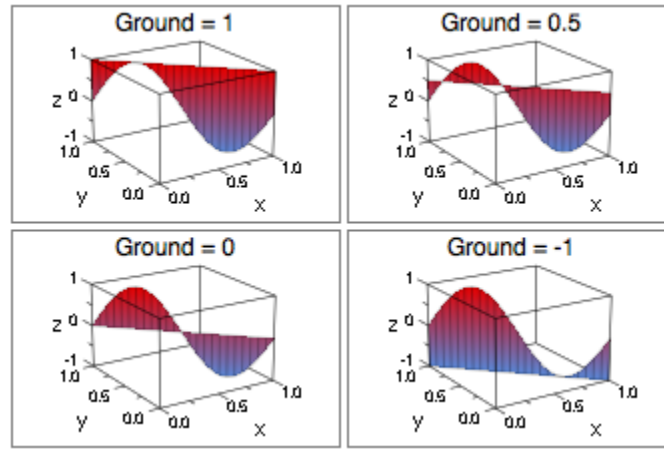


delete A:

Example 2

We use different `Ground` values to project a space curve to the *x*-*y*-plane:

```
plot(plot::Scene3d(plot::Sweep([u, 1-u, sin(2*PI*u)], u = 0..1, Ground
= 1), Header = "Ground = 1"), plot::Scene3d(plot::Sweep([u, 1-u,
sin(2*PI*u)], u = 0..1, Ground = 0.5), Header = "Ground = 0.5"),
plot::Scene3d(plot::Sweep([u, 1-u, sin(2*PI*u)], u = 0..1, Ground
= 0), Header = "Ground = 0"), plot::Scene3d(plot::Sweep([u, 1-u,
sin(2*PI*u)], u = 0..1, Ground = -1), Header = "Ground = -1"),
plot::Scene3d::BorderWidth = 0.5*unit::mm, Layout = Tabular, Rows
= 2)
```



Purpose

HeightsMoves

Heights of pieces in pie charts

Value Summary

`Heights`, `Moves`	Optional	List of arithmetical expressions

Graphics Primitives

Objects	Default Values
plot::Piechart3d	`Heights`: [0.3] `Moves`: [0]
plot::Piechart2d	`Moves`: [0]

Description

`Heights`, Moves determine the heights and displacements of the single pieces in a pie chart.

`Heights` determines the heights of the pieces in a plot::Piechart3d. If no height value is given for a piece, 0.3 is used. The given values have to be real numbers or expressions of the animation parameter.

`Moves` determines the movements of pieces away from the pie chart center. If no move value is given for a piece, 0 is used. The given values have to be non-negative real numbers or expressions of the animation parameter. The values are fractions of the Radius of the pie chart. A value of 1 means a full pie chart radius, 0.5 half the radius of the pie chart etc.

`Heights`, Moves accept its input in two formats:

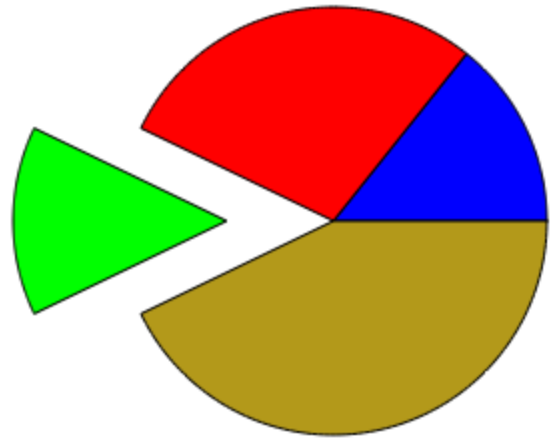
- The values can be given as a flat list of values with entries of the type specified above. The first list entry will be used for the first piece etc. If the list contains less values than the data set of the pie chart, the last value is repeated. Superfluous entries are ignored.

- The values can be given as a list of equations with positive integers on the left hand side and values – as specified above – on the right hand side. The integers are interpreted as indices of the pieces.

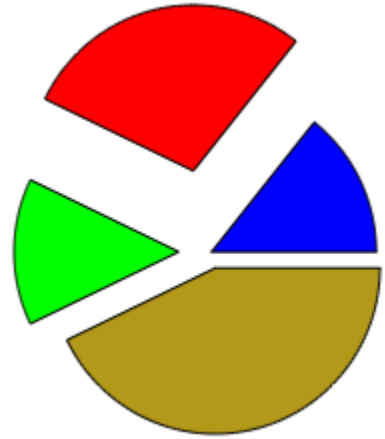
Examples

Example 1

We move the third piece of the following pie chart away from the center by half the radius of the pie chart:
plot(plot::Piechart2d([1, 2, 1, 3], Moves = [3 = 0.5]))

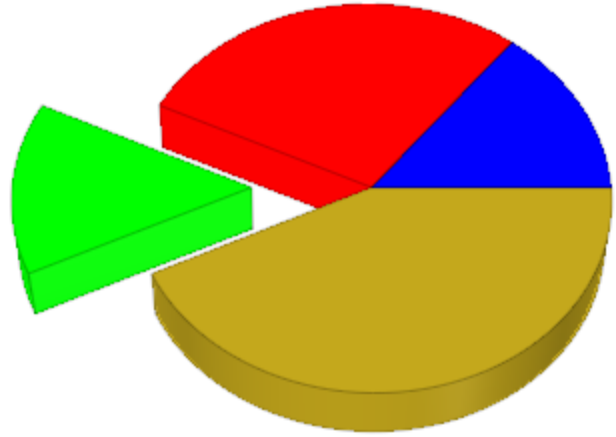


The pieces are moved away from the center by different amounts:
plot(plot::Piechart2d([1, 2, 1, 3], Moves = [0, 0.5, 0.2, 0.1]))

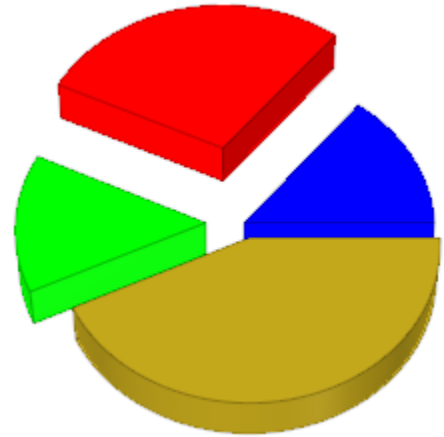


Example 2

We plot an analogeous 3D pie chart:
plot(plot::Piechart3d([1, 2, 1, 3], Moves = [3 = 0.5]))



The pieces are moved away from the center by different amounts:
plot(plot::Piechart3d([1, 2, 1, 3], Moves = [0, 0.5, 0.2, 0.1]))



In 3D, the pieces of a pie chart can have different heights:
plot(plot::Piechart3d([1, 2, 1, 3], Heights = [0.4, 0.5, 0.2, 0.1]))

Example 3

Here is a plot::Piechart3d with animated `Heights`, `Moves`, and Radius:
plot(plot::Piechart3d([4, 3, 2, 1], Radius = 3 + sin(a), Heights = [cos(a)^2, cos(2*a)^2, cos(3*a)^2, cos(4*a)^2], Moves = [0.3*sin(a)^2], a = 0..PI)):

Ground

See Also DataRadius

Inequalities

Purpose

Inequalities displayed in inequality plots

Value Summary

Mandatory	List of arithmetical expressions

Graphics Primitives

Objects	Inequalities Default Values
plot::Inequality	

Description

`Inequalities` is the attribute used by plot::Inequality to store the inequalities to plot.

plot::Inequality is used to plot the areas where one or more inequalities are fulfilled. `Inequalities` is the internal attribute where the inequalities are stored. Most users will never access this attribute directly; it exists for technical reasons only.

InputFile

Purpose

Input file for import functions

Value Summary

Mandatory	Text string

Graphics Primitives

Objects	InputFile Default Values
plot::SurfaceSTL	

Description

`InputFile` specifies the name of the input file for import functions.

`InputFile` can either be an absolute pathname or a pathname relative to the current working directory or one of the directories specified by the MuPAD variable READPATH.

Note that some MuPAD functions do not react to the MuPAD variable READPATH. In this case it might be necessary to specify `InputFile` as an absolute pathname.

Note that the current working directory of a MuPAD session may depend on how and from where MuPAD has been started. Be careful when making assumptions about this.

See plot::SurfaceSTL for examples.

See Also

OutputFile

Purpose

IterationsStartingPoint

Number of iterations in plot::Iteration

Value Summary

`Iterations`, `StartingPoint`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Iteration	`Iterations`: 10

Description

`Iterations` and `StartingPoints` are special attributes for iteration objects of type plot::Iteration. `StartingPoint` sets the starting point, `Iterations` sets the number of iteration steps.

The call `it := plot::Iteration(f, x_0, n, x = `x_{min}`..`x_{max}`)` yields a visualization of the iteration $x_i = f(x_{i-1})$ of the starting point x_0 with $i = 1, \ldots, n$. The values x_0 and `n` are stored as the attributes `StartingPoint` = x_0 and `Iterations` = `n` in the iteration object `it`. The values can be accessed and changed as the slots `it::StartingPoint` and `it::Iterations`, respectively.

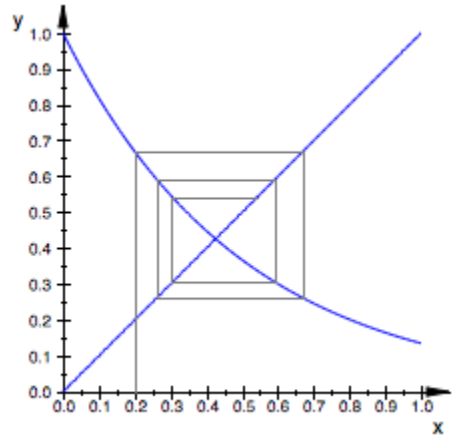
These attributes can be animated.

Examples

Example 1

We define and plot an iteration object:

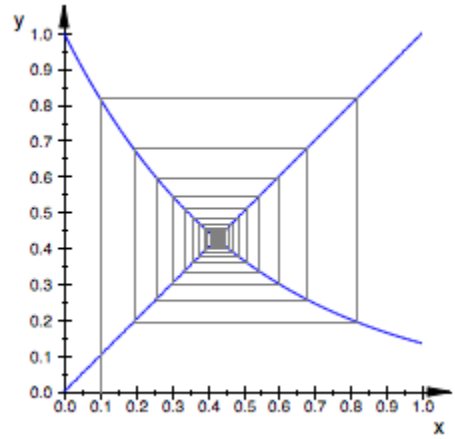
```
f := plot::Function2d(exp(-2*x), x = 0..1): g := plot::Function2d(x, x = 0..1): it := plot::Iteration(exp(-2*x), 0.2, 5, x = 0..1): plot(f, g, it)
```



The starting point $x_0 = 0.2$ and the number of iteration steps 5 are stored inside the iteration object:
it::StartingPoint, it::Iterations0.2, 5

0.2, 5

We change these values:
it::StartingPoint := 0.1: it::Iterations := 30: plot(f, g, it)



delete f, g, it:

Ground

Purpose

LineColorFunctionFillColorFunction

Functional line coloring

Value Summary

`FillColorFunction`, `LineColorFunction`	Optional	Color function (see below)

Graphics Primitives

Objects	Default Values
plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylindrical, plot::Density, plot::Dodecahedron, plot::Function2d, plot::Function3d, plot::Hexahedron, plot::Icosahedron, plot::Implicit2d, plot::Implicit3d, plot::Integral, plot::Listplot, plot::Matrixplot, plot::Octahedron, plot::Polar, plot::Polygon2d, plot::Polygon3d, plot::Prism, plot::Pyramid, plot::Rootlocus, plot::Sequence, plot::Spherical, plot::Streamlines2d, plot::Sum, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::VectorField2d, plot::VectorField3d, plot::Waterman, plot::XRotate, plot::ZRotate	

Description

These options accept functions that define the color of a plot at arbitrary points.

Using FillColorType and LineColorType, the user can control the color of many graphical objects. The setting providing the most detailed (and most complicated) control is `Functional`. In this case, a *color function* must be provided using one of `LineColorFunction`, FillColorFunction.

A color function can be a list of three or four expressions.

If three expressions are given, they specify RGB colors. If four expressions are given, they specify RGBA colors. See the introduction for more details on color specifications.

The expressions may contain the identifiers bound in the corresponding object. For example, in a `plot::Function2d(sin(x), x=0..PI)`, the color function may refer to `x`. More formally, the expressions may contain the identifiers found in the attributes XName, YName, ZName, UName, VName, and ParameterName of the plot object they are found in.

All of these expressions must, for values in the given ranges, evaluate to real numbers in the range $0..1_{0..1}$. Real values outside this range do not yield errors, they are simply clipped.

See also “Example 1” on page 24-1229.

Alternatively, a color function can be a procedure or function environment.

A procedure (or a function environment) used as a color function must return lists of three or four real numbers in the range $0..1_{0..1}$. Real values outside this range are clipped. (If this function ever returns a list of four numbers, it must always do so.) A list of three numbers is interpreted as an RGB color, while a list of four values is interpreted as an RGBA color. See the introduction for more details on color specifications.

The number and meaning of arguments a color function is called with depends on the object type. Informally, we have:

type (abbreviated)	parameters
`Conformal(f(z))`	`z`, `Re(f((z))`, `Im(f((z))`, `flag` (with `flag = 1` or `flag = 2`)
`Curve2d(x(u),y(u))`	`u`, `x(u)`, `y(u)`
`Curve3d(x(u),y(u),z(u))`	`u`, `x(u)`, `y(u)`, `z(u)`
`Cylindrical(r(u,v),phi(u,v),z(u,v))`	`u`, `v`, `r(u,v)`, `phi(u,v)`, `z(u,v)`, `x(u)`, `y(u)`, `z(u)`
`Density(f(x,y))`	`x`, `y`, `f(x,y)`

Icosahedron	see below
`Implicit2d(f(x,y), Contours=[c])`	`x`, `y`, `D([1],f)(x,y)`, `D([2],f)(x,y)`, `c`
`Implicit3d(f(x,y,z), Contours=[c])`	`x`, `y`, `z`, `D([1],f)(x,y,z)`, `D([2],f)(x,y,z)`, `D([3],f)(x,y,z)`, `c`
Matrixplot	`x`, `y`, `z`
Octahedron	see below
`Polar([r(t),phi(t)])`	`t`, `r(t)`, `phi(t)`, `x(t)`, `y(t)`
`Polygon2d([..,[xi,yi],..])`	`xi`, `yi`, `i`
`Polygon3d([..,[xi,yi,zi],..])`	`xi`, `yi`, `zi`, `i`
`Rootlocus(p(z, u))`	`u`, `Re(z)`, `Im(z)`
`Spherical(r(u,v),phi(u,v),thet(u,v))`	`u`, `v`, `r(u,v)`, `phi(u,v)`, `thet(u,v)`, `x`, `y`, `z`
`Streamlines2d(v(x,y), w(x, y))`	`x`, `y`, `v(x,y)`, `w(x,y)`, `t`, `l`, `n`

type (abbreviated)	parameters
`Surface(x(u,v),y(u,v),z(u,v))`	`u`, `v`, `x(u,v)`, `y(u,v)`, `z(u,v)`
SurfaceSTL	see below
SurfaceSet	see below
Tetrahedron	see below
Tube	see below
`VectorField2d(v(x,y),w(x,y))`	`x`, `y`, `v(x,y)`, `w(x,y)`
`XRotate(f(x))`	`x`, `phi`, `x`, `y(x,phi)`, `z(x,phi)`
`ZRotate(f(t))`	`t`, `phi`, `x(t,phi)`, `y(t,phi)`, `f(t)(=z(t,phi))`

Additionally, for animated objects, the current value of the animation parameter is provided.

Dodecahedron, Hexahedron, Icosahedron, SurfaceSTL, SurfaceSet, and Tetrahedron are built from triangles; the color functions are called once for each vertex of these triangles and are passed the number of the triangle (an integer count starting at 1), the coordinates of the vertex and the animation parameter, if that is used.

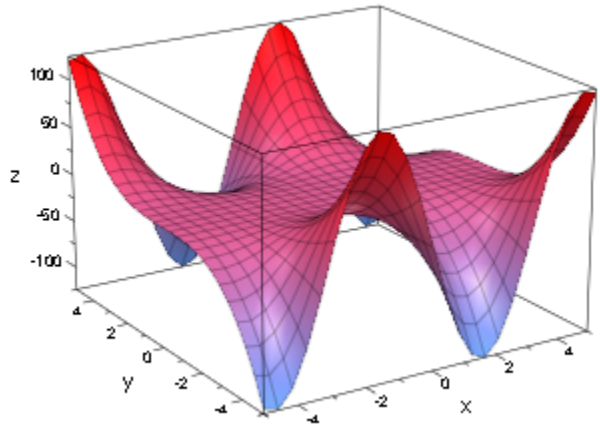
For plot::Tube, the color functions are given the coordinates of the currently visited point on the central curve, followed by the coordinates of the point on the surface, followed by the animation parameter, if any. (That makes seven arguments altogether.)

The examples below show different usage environments of color functions for some of the object types listed above.

Examples

Example 1

By default, most 3D-objects in MuPAD get “height coloring”:
plot(plot::Function3d(sin(x)*y^3))

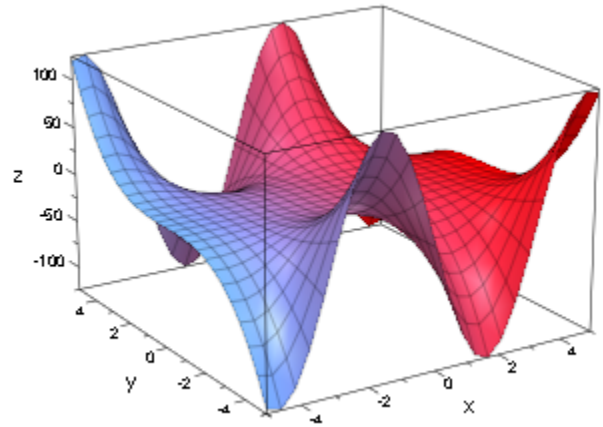


To change the direction of this color, you can use `FillColorFunction`:

```
xmin := -5: xmax := 5: color := zip(RGB::Red, RGB::CornflowerBlue, (a, b) -> (x-xmin)/(xmax-xmin)*a +(xmax-x)/(xmax-xmin)*b)[0.0607807*x + 0.6960965, 0.2921535 - 0.0584307*x, 0.4646975 - 0.0929395*x]
```

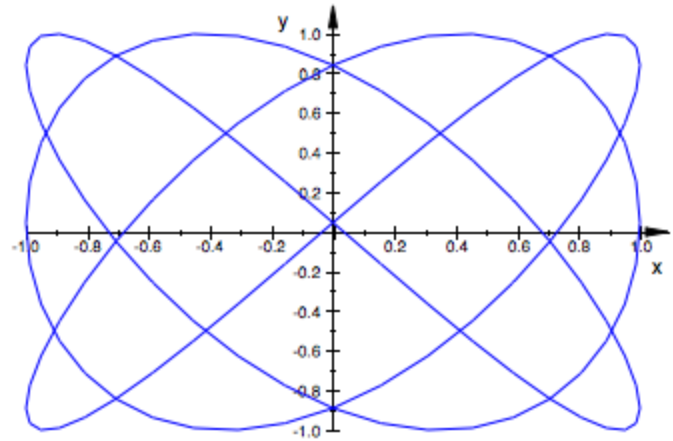
$$[0.0607807\,x + 0.6960965,\ 0.2921535 - 0.0584307\,x,\ 0.4646975 - 0.0929395\,x]$$

```
plot(plot::Function3d(sin(x)*y^3, FillColorFunction = color))
```

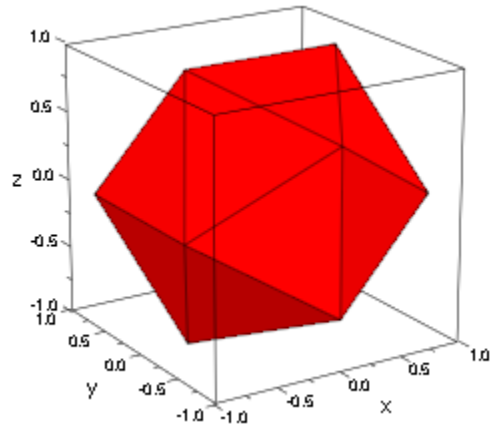


Example 2

Animated color functions can be combined with static objects:
plot(plot::Curve2d([sin(3*x), sin(4*x+1)], x=0..2*PI, LineColorFunction = ((u, x, y, a) -> [(u-a)/5, (u-a)/5, 1]), a = -5..6))

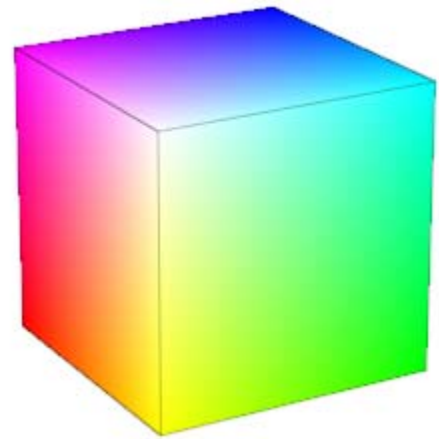


cf := (i, x, y, z, a) -> [RGB::Red, RGB::Green, RGB::Blue][(floor(a*i) mod 3) + 1]: plot(plot::Icosahedron(FillColorFunction = cf, a = 0..9))



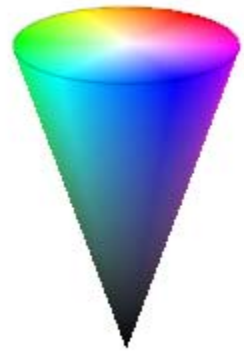
Example 3

A color function should generate values in RGB color space. Since a plot::Box does not allow a `FillColorFunction`, we use six (trivial) Surface objects to show the outside of this color space:
rgb := (u, v, x, y, z) -> [x, y, z]: plot(plot::Surface(formula, u = 0..1, v = 0..1, FillColorFunction = rgb) $ formula in [[0, u, v], [1, u, v], [u, 0, v], [u, 1, v], [u, v, 0], [u, v, 1]], plot::Box(0..1, 0..1, 0..1, Filled = FALSE, LineColor = RGB::Black.[0.25]), Scaling = Constrained, Axes = None, ULinesVisible = FALSE, VLinesVisible = FALSE, Lighting = None, CameraDirection = [4, 7, 3])



RGB colors are a very technical way of defining a color. The HSV color space is more popular with designers, since there the “hue” (i.e., the perceived color type) is not a combination of three numbers but rather one of the numbers making up a color:

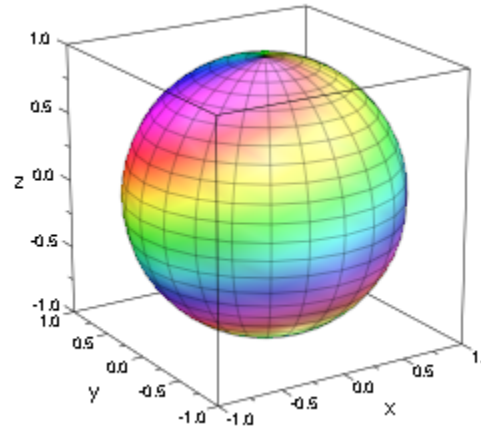
```
hsv := (u, v, r, phi, z) -> RGB::fromHSV([180/PI*phi, r, z]):
plot(plot::Cylindrical([z, phi, z], z = 0..1, phi = 0..2*PI, FillColorFunction
= hsv), plot::Cylindrical([r, phi, 1], r = 0..1, phi = 0..2*PI,
FillColorFunction = hsv), plot::Circle3d(1, [0, 0, 1], [0, 0, 1], Color =
RGB::Black.[0.25]), ZXRatio = 1.5, Scaling = Unconstrained, Axes =
None, Lighting = None, ULinesVisible = FALSE, VLinesVisible =
FALSE, CameraDirection = [-17, -12, 3])
```



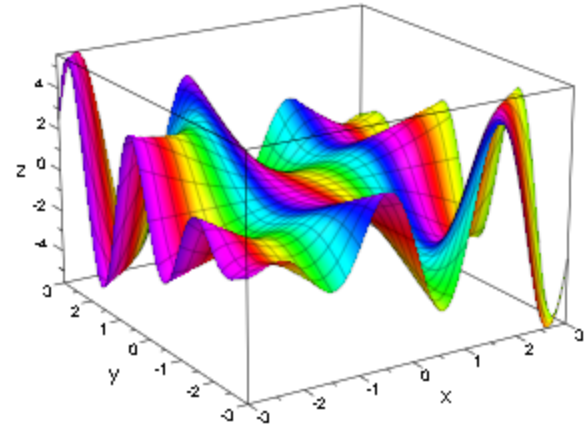
Example 4

HSV color space is especially suitable for quick coloring of cylindrical,polar, or spherical plots, due to its circular nature:

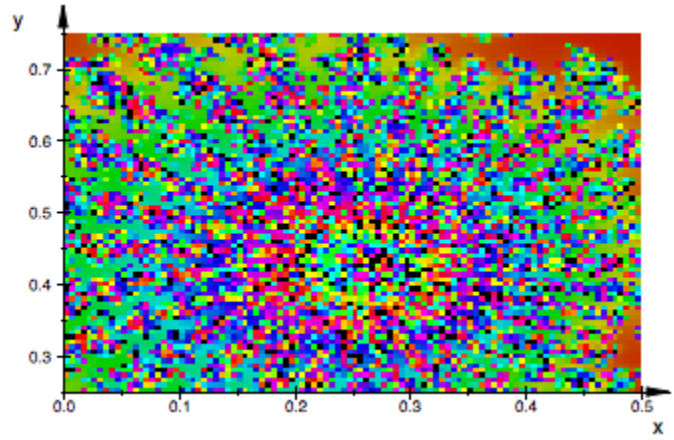
```
hsv := (u, v, r, phi,thet) ->
RGB::fromHSV([180/PI*(phi+(thet+2)^3/PI^2), 3/4+sin(u)/4, 1]):
plot(plot::Spherical([1, u, v], u = 0..2*PI, v = 0..PI, FillColorFunction
= hsv))
```



There are other examples, where the cyclic nature comes in handy, too:
hsv := (x, y, z) -> RGB::fromHSV([150*z, 1, 1]):
plot(plot::Function3d(sin(x*y)*(x-y), x = -3..3, y = -3..3, Submesh = [2, 2], FillColorFunction = hsv))



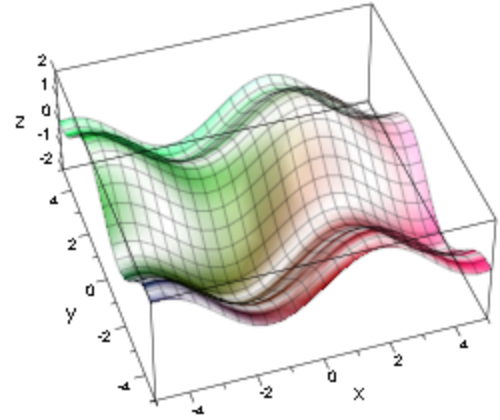
The following example takes a long time to compute. Reducing the values set for Mesh results in a shorter computation, while higher values lead to an image with finer details:
c := 0.377+0.2*I: julia := proc(x, y) local i, z; begin i := 0; z := float(x + I*y); while i < 1000 and abs(z) < 4 do z := z^2 + c; i := i + 1; end_while; i; end_proc: Jcol := (x, y, i) -> if i >= 1000 then RGB::Black else RGB::fromHSV([i, 1, 3/4+i/2000]) end: plot(plot::Density(julia, x = 0..0.5, y=0.25..0.75, FillColorFunction = Jcol, Mesh = [100,75]))



Example 5

Another way of getting a smooth color transition is to use a periodic function in between, for example trigonometric ones (note the `(1+sin(a))/2`: we need values between 0 and 1):
plot(plot::Polar([r*surd(r, 3), r], r = -4*PI..4*PI, AdaptiveMesh = 2, LineColorFunction = [(sin(r)+1)/2, (cos(r/2)+1)/2, 1/3], LineWidth = 1*unit::mm))

This also applies for cyclic colors in terms of time:
plot(plot::Function3d(sin(x)+sin(y), x = -5..5, y = -5..5, FillColorFunction = [(x+5)/10, (y+5)/10, abs(x+y+5*cos(a))/15, (1+cos(x+y^2-a))/2], a = 0..2*PI), CameraDirection = [-1, -3, 3], Scaling = Constrained)



Algorithms

Animation is handled by the general framework, not the individual objects. Therefore, the framework also supplies the animation parameter to the color functions.

Purpose

Matrix2dMatrix3d

Transformation matrices

Value Summary

`Matrix2d`, `Matrix3d`	Optional	List of four real-valued expressions

Description

`Matrix2d`, Matrix3d represent the transformation matrices of transformation objects.

The general transformation objects plot::Transform2d and plot::Transform3d allow to apply the affine-linear transformation (x) -> A*x+b$x \to A\,x + b$ to 2D and 3D objects, respectively. Depending on the dimension, the transformation matrix *A* can be accessed and changed via the attributes `Matrix2d`, `Matrix3d`, of the transformation object. The shift vector *b* can be accessed and changed via the attribute Shift.

When setting the matrix attribute, matrices, arrays, lists of lists, and plain lists are accepted. Internally, however, the matrix data are always stored as a plain list

$[A_{1,1}, A_{1,2}, A_{2,1}, A_{2,2}]$

in 2D or

$[A_{1,1}, A_{1,2}, \ , A_{3,2}, A_{3,3}]$

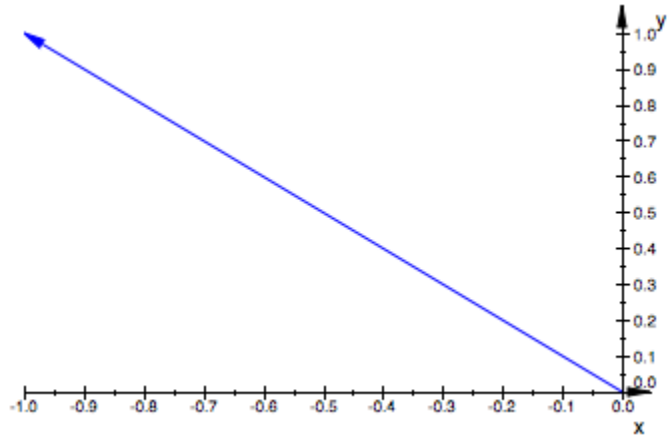
in 3D, respectively, representing the matrix row by row. When reading the matrix by a slot access, this plain list is returned.

The entries of `Matrix2d`, Matrix3d can be animated.

Examples

Example 1

We apply a linear transformation to an arrow:
A := matrix([[1, -1], [1, 1]]): g := plot::Transform2d(A, plot::Arrow2d([0, 0], [0, 1])): plot(g)



The `Matrix2d` corresponding to the transformation is stored as a plain list in the corresponding slot of `g`:
g::Matrix2d[1.0, -1.0, 1.0, 1.0]

```
[1.0, -1.0, 1.0, 1.0]
```

delete f, g:

Purpose

MeshListMeshListTypeMeshListNormals
Triangulation data

Value Summary

`MeshList`	Mandatory	List of arithmetical expressions
`MeshListType`	Optional	`ColorQuads`, `Quads`, `QuadStrip`, `Triangles`, `TriangleFan`, or `TriangleStrip`
`MeshListNormals`	Optional	`BeforeFacets`, `BeforePoints`, `BehindFacets`, `BehindPoints`, or `None`

Graphics Primitives

Objects	Default Values
plot::SurfaceSet	`MeshListType: Triangles` `MeshListNormals: None`

Description

`MeshList` is a list of data defining the triangulation of a 3D surface of type plot::SurfaceSet.

`MeshListType` specifies how the data in the list `MeshList` are to be interpreted.

`MeshListNormals` specifies which of the data in the list `MeshList` are to be interpreted as normals.

`MeshList` contains coordinates of points (and optional normals) of either triangles or quads which define a mesh of a 3D surface. The points must be given homogenous: If a normal is given, it must be given for all points or facets, respectively. The attribute `MeshListType` specifies how these points are to be interpreted for plotting the surface. The attribute `MeshListNormals` specifies whether the list contains normal vectors and at which positions they located.

About normals and facet orientation: The facets (triangles or quads) define the surface of a 3D object. As such, each facet is part of the

boundary between the interior and the exterior of the object. The orientation of the facets (which way is "out" and which way is "in") is specified redundantly in two ways which should be consistent: First, the direction of the normal is outward. Second, which is most commonly used now-a-day, the facet vertices are listed in counter-clockwise order when looking at the object from the outside (right-hand rule). Normals must be given as unit vectors.

`MeshList` must not contain color values. Use the color functions LineColorFunction and FillColorFunction instead.

`MeshListType` specifies how the points in `MeshList` are to be interpreted. Supported mesh list types are:

Value	*Info*	*Description*
`Triangles`	a set of separate triangles	Each tuple of three points define one new triangle.
`TriangleFan`	a triangle fan	The first triangle is defined by the first three points. The next triangles are defined by the first point, the previous point and the current point.
`TriangleStrip`	a triangle strip	The first triangle is defined by the first three points. The next triangles are defined by the two previous points and the current point.
`Quads`	a set of separate quads	Each tuple of four points define one new quad.
`QuadStrip`	a strip of quads	The first quad is defined by the first four points. The next quads are defined by the two previous points and the next two points.

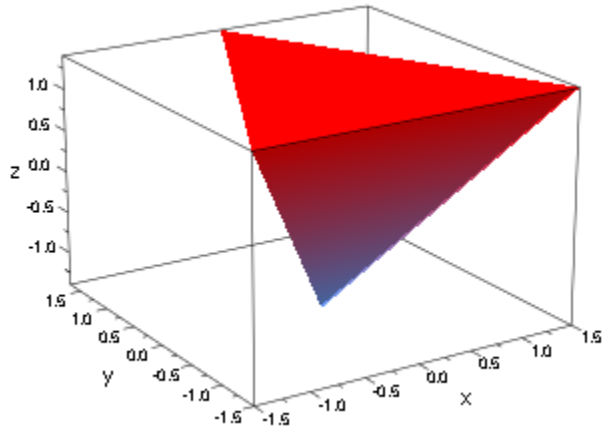
`MeshListNormals` specifies whether `MeshList` contains normal vectors and at which positions they are located. Valid options are:

Value	*Description*
`None`	No normals are specified.
`BeforePoints`	A normal is given before each point.
`BehindPoints`	A normal is given behind each point.
`BeforeFacets`	A normal is given before each triangle or quad, respectively. This option is only valid for `MeshListType = Triangles` and `MeshListType = Quads`.
`BehindFacets`	A normal is given behind each triangle or quad, respectively. This option is only valid for `MeshListType = Triangles` and `MeshListType = Quads`.

Examples

Example 1

We create a triangle set with normals in front of each triangle and plot this object, a tetrahedron, afterwards:
meshList:= [0.0 , 0.0 , -1.0 , -1.5 , -1.5 , 1.4 , 0.0, 1.7, 1.4, 1.5, -1.5, 1.4, 0.0 , 0.88, 0.47, -1.5 , -1.5 , 1.4 , 1.5, -1.5, 1.4, 0.0, 0.0, -1.4, -0.88, -0.41, 0.25, 1.5 , -1.5 , 1.4 , 0.0, 1.7, 1.4, 0.0, 0.0, -1.4, 0.88, -0.41, 0.25, 0.0 , 1.7 , 1.4 , -1.5, -1.5, 1.4, 0.0, 0.0, -1.4]: plot(plot::SurfaceSet(meshList, MeshListType = Triangles, MeshListNormals = BeforeFacets)):



delete meshList:

Example 2

See plot::SurfaceSet for further examples.

The object is displayed by this name in the legend and the interactive object browser of the graphics tool.

Description

Giving a name to a graphical object has no significance whatsoever for the graphical appearance of the object. The main purpose of the name is to make it easier to identify the object in the interactive “object browser” of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document).

If no name is specified, the type of the object is diplayed in the object browser.

If the legend is “switched on” by setting LegendVisible to `TRUE`, the name slot of an object is used (if if exists), unless the object has a specific LegendText.

Note has special semantics for objects of type plot::Hatch. The bounding function or curves of the hatch are referenced via the name slot. If the bounding function or curve has no name slot, it is implicitly set to the output of expr2text of the function. Cf. “Example 2” on page 24-1247Example 2.

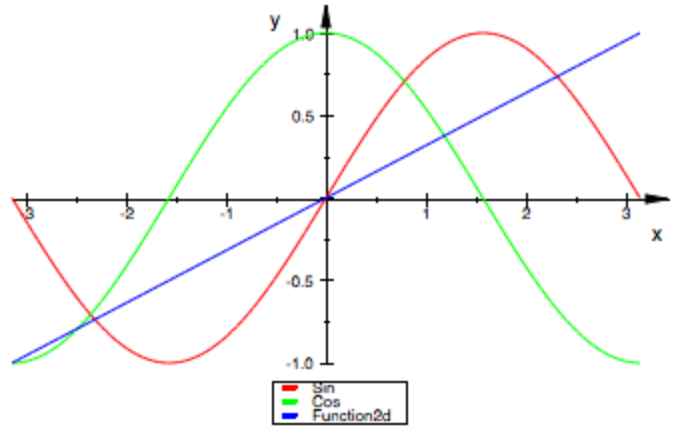
Examples

Example 1

The first two of the following function objects are given the names `Sin` and `Cos`, respectively. Generate the graphics and doubleclick on the plot. The two function objects are visible under their names in the object browser. The third function is just labeled as a ’Function2d’ object. Also the legend uses this labeling:

```
plot(plot::Function2d(sin(x), x = -PI..PI, Name = "Sin", Color =
RGB::Red), plot::Function2d(cos(x), x = -PI..PI, Name = "Cos", Color =
```

Objects	Name Default Values
RGB::Green, plot::Function2d(x/PI, x = -PI..PI, Color = RGB::Blue), Legend = TRUE)	



Example 2

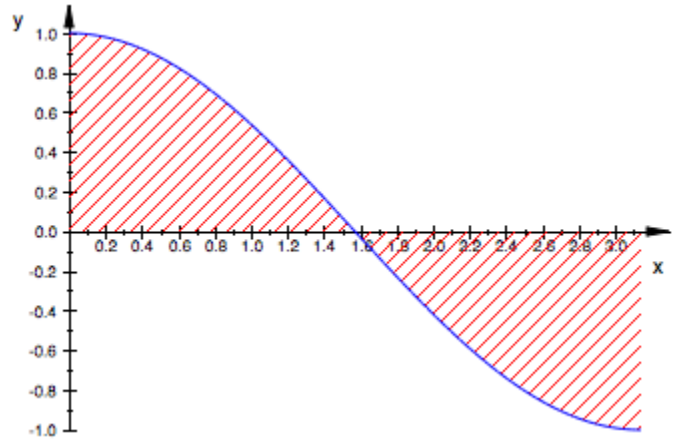
By default, an object does not have a `Name` entry:
f := plot::Function2d(cos(x), x=0..PI): f::NameFAIL

FAIL

When creating a plot::Hatch object, the `Name` slot is set implicitly for the border function(s):
h := plot::Hatch(f): f::Name"Function2d(XMin = 0, XMax = PI, XName = x, Function = cos(x), XAxisTitle = \"x\")"

"Function2d(XMin = 0, XMax = PI, XName = x, Function = cos(x), XAxisTitle = "x")"

We plot the hatch with its bounding function:
plot(h, f)



Doubleclick on the graphics and observe the way the objects are labeled in the object inspector.
delete f, h:

See Also Function1Function2LegendTextTitle

Nodes

Purpose

Number of subintervals or list of x-values for subintervals

Value Summary

Optional	List of arithmetical expressions

Graphics Primitives

Objects	Nodes Default Values
plot::Integral	[10]

Description

`Nodes` is a positive number of subintervals for numeric approximation of integrals. The given interval for approximation is divided into the given number of subintervals, all of the same width.

Otherwise, `Nodes` can be a list of x-values for dividing the given interval. The interval is divided into subintervals at the given x-values.

When a number is given for `Nodes`, the number can be given as a list with this one number, too.

When a list with x-values is given, the left and right border of the whole (approximation) interval can be omitted. In this case, the number of subintervals is the number of given x-values plus one.

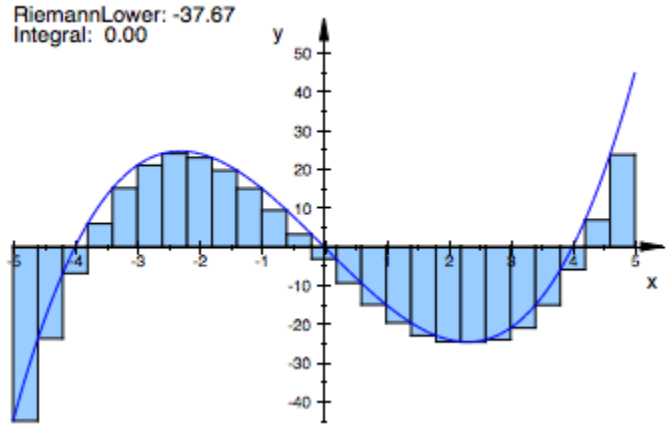
Nodes outside the approximation interval are ignored. Duplicate values are ignored.

The nodes need not be ordered.

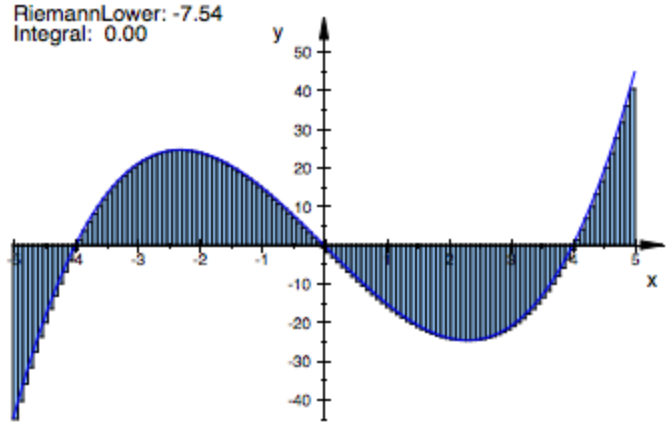
Examples

Example 1

`Nodes` determines the number of rectangles for Riemann sums:
f := plot::Function2d(x*(x+4)*(x-4)): plot(plot::Integral(f, Nodes = 25, IntMethod = RiemannLower), f)



Increasing of `Nodes` decreases the error or the approximation:
plot(plot::Integral(f, Nodes = 125, IntMethod = RiemannLower), f)

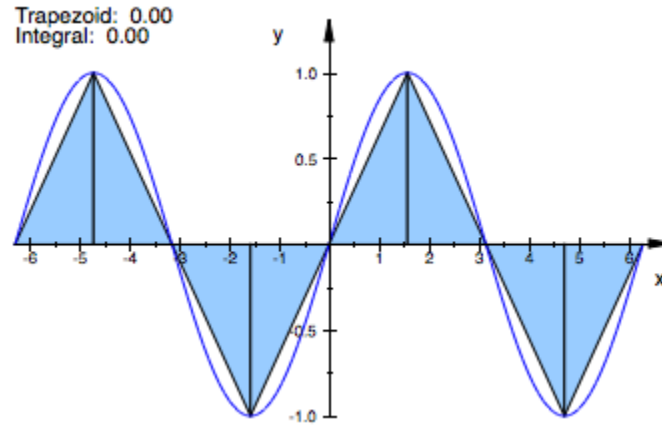


delete f:

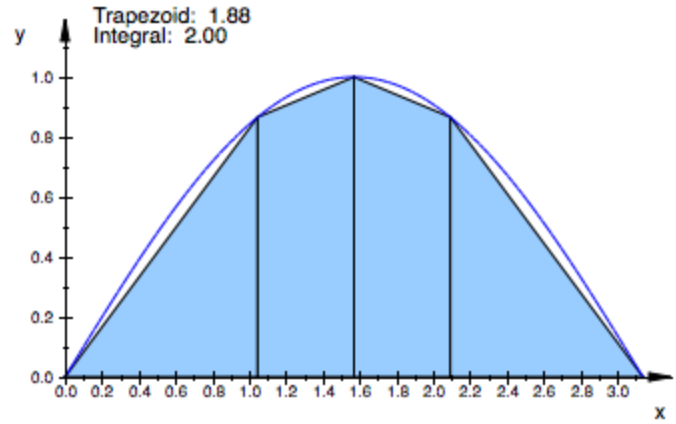
Example 2

We request a specific division into subintervals:

f := plot::Function2d(sin(x), x = -2*PI..2*PI): plot(plot::Integral(f, Nodes = [i*PI/2 $ i = -4..4], IntMethod = Trapezoid), f)



The subintervals do not need to be of equal width:
f := plot::Function2d(sin(x), x = 0..PI): plot(plot::Integral(f, [PI/3, PI/2, 2*PI/3], IntMethod = Trapezoid), f)



delete f:

See Also IntMethod

NormalNormalXNormalYNormalZ

Purpose

Normal vector of circles and discs, etc. in 3D

Value Summary

`Normal`	Library wrapper for "[NormalX, NormalY]" (2D), "[NormalX, NormalY, NormalZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`NormalX`, `NormalY`, `NormalZ`	Mandatory	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Prism, plot::Pyramid	`Normal`: [0, 0, 0] `NormalX`, `NormalY`, `NormalZ`: 0
plot::Arc3d, plot::Circle3d, plot::Ellipse3d, plot::Plane, plot::Reflect3d	`Normal`: [0, 0, 1] `NormalX`, `NormalY`: 0 `NormalZ`: 1

Description

`Normal` determines the normal vector of the plane of the 3D circle, prism or pyramid. It is given by a list or vector of 3 components.

`NormalX` etc. refer to the *x*, *y*, *z* components of this vector.

The values of these attributes can be animated.

With Filled = `TRUE`, a circle becomes a disc.

Examples

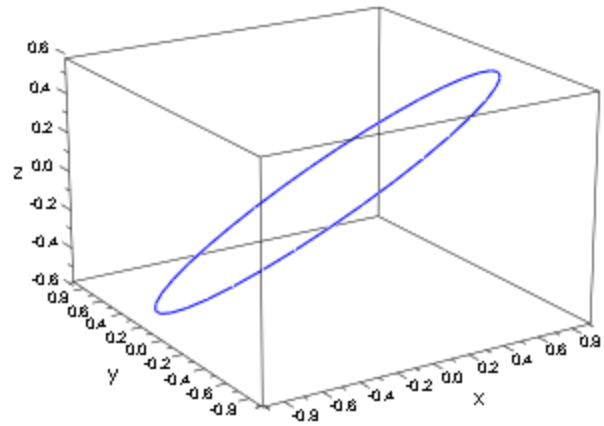
Example 1

We create a circle around the origin lying in the *x*-*y* plane:

```
c := plot::Circle3d(1, [0, 0, 0], [0, 0, 1])plot::Circle3d(1, [0, 0, 0], [0, 0, 1])
```

```
plot::Circle3d(1, [0, 0, 0], [0, 0, 1])
```

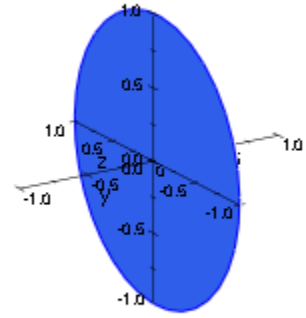
The second argument in plot::Circle3d is the center, the third argument is the normal. Internally, these vectors are stored as the attributes `Center` and `Normal` and can be changed by assigning a new value:
c::Normal := [-0.5, 0.5, 1]: plot(c):



delete c:

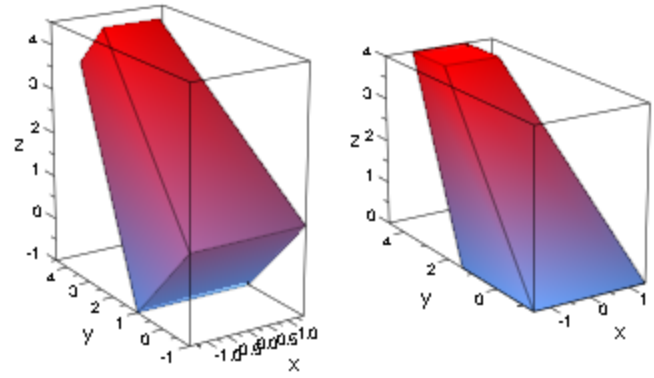
Example 2

`Normal` can be animated:
plot(plot::Circle3d(1, [0, 0, 0], [cos(a), sin(a), 0], a = 0 .. 2*PI, Filled = TRUE), Axes = Origin):



Example 3

`Normal` can be used to create crooked prisms, pyramids and frustums of pyramids. If this attribute is set to [0, 0, 0], the axis between Base and Top ist used as normal vector:
plot(plot::Scene3d(plot::Pyramid(2,[0,0,0],1,[0,4,4], Normal=[0,0,0])),
plot::Scene3d(plot::Pyramid(2,[0,0,0],1,[0,4,4], Normal=[0,0,1]))):



Purpose

ParameterNameParameterBeginParameterEndParameterRange
Name of the animation parameter

Value Summary

`ParameterBegin`, `ParameterEnd`, `ParameterName`	Optional	MuPAD expression
`ParameterRange`	[ParameterBegin .. ParameterEnd]	Range of arithmetical expressions

Description

Typically, animations are triggered by passing an equation of the form `a = `a_{min}`..`a_{max}`` in the definition of an object.

This is equivalent to passing the attributes `ParameterName = a`, `ParameterBegin = a`$_{min}$, and `ParameterEnd = a`$_{max}$ in the definition of the object.

The attribute `ParamterRange = `a_{min}`..`a_{max}`` is equivalent to setting both `ParameterBegin = a`$_{min}$ and `ParameterEnd = a`$_{max}$.

Animations are defined object by object, not frame by frame.

In most cases, the user will define animations by passing an equation of the form `a = `a_{min}`..`a_{max}`` in the definition of an object. Any equation of this form that is not essential for the definition of a static version of the object is interpreted as an animation parameter and an animation range.

Passing such an equation is equivalent to setting the three attributes

`ParameterName = a`, `ParameterBegin = a`$_{min}$, `ParameterEnd = a`$_{max}$.

The attribute `ParamterRange = `a_{min}`..`a_{max}`` serves as a short cut for setting both `ParameterBegin = a`$_{min}$ and `ParameterEnd = a`$_{max}$.

The values `a`$_{min}$ and `a`$_{max}$ are the parameter values at the beginning and the end of the real time range in which an object is animated. This time range is set by the attributes TimeBegin and TimeEnd, respectively.

The parameter range `a_{min}`..`a_{max}` is mapped linearly to this time interval.

The name of the animation parameter may be an identifier or an indexed identifier. This parameter is a 'global variable' that may be present in other quantities or attributes defining the object.

The definition of an object may involve procedures rather than symbolic expressions. E.g., a 2D function plot may be defined by `plot::Function2d(f, x = x_0..x_1)`, where *f* is a procedure accepting one numerical argument *x* from the plot range between x_0 und *x1*.

In an animated version `plot::Function2d(f, x = x_0..x_1, a = `a_{min}`..`a_{max}`)`, the function *f* will be called with two arguments *x* and *a*. Thus, *f* may be defined as a function accepting two parameters *x*, *a* or as a function with one parameter *x*, using the animation parameter *a* as a global variable.

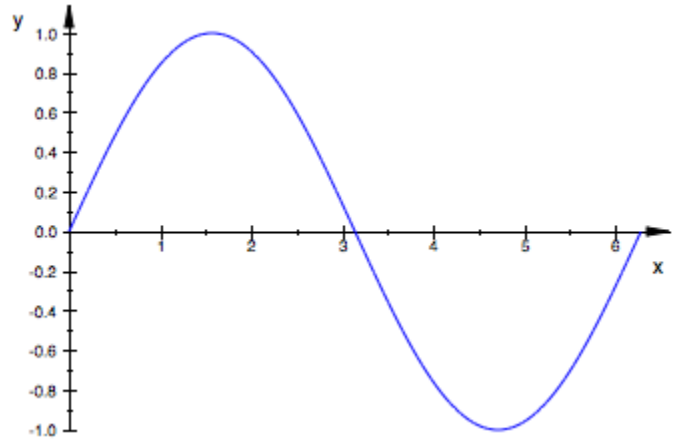
Each animated object has its own animation parameter and range `a_{min}`..`a_{max}`. It is not necessary that several animated objects in a scene use the same parameter name. It is not used to synchronize the animations.

The synchronization is determined uniquely by the linear correspondence between the animation range `a_{min}`..`a_{max}` and the real time span of the animation set by the attributes TimeBegin and TimeEnd of the object.

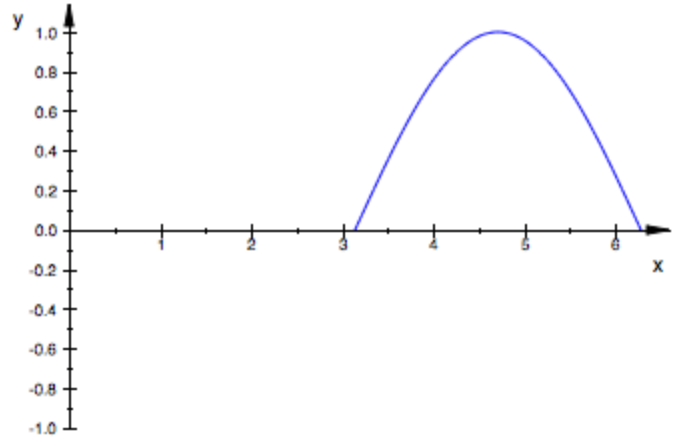
Examples

Example 1

The definition of a static 2D function plot involves the specification of one range (for the *x* variable):
plot(plot::Function2d(sin(x), x = 0 .. 2*PI))

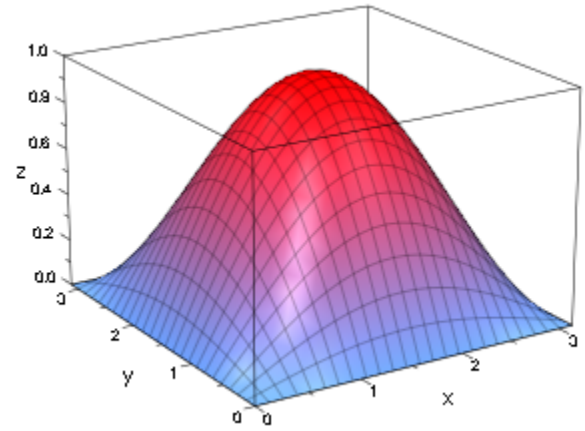


When a "surplus equation" `a = `a_{min}`..`a_{max}`` is passed, this is interpreted as a call to animate the function. The animation parameter may turn up in the expression defining the function: plot(plot::Function2d(sin(x + a), x = a .. 2*PI, a = 0..PI))

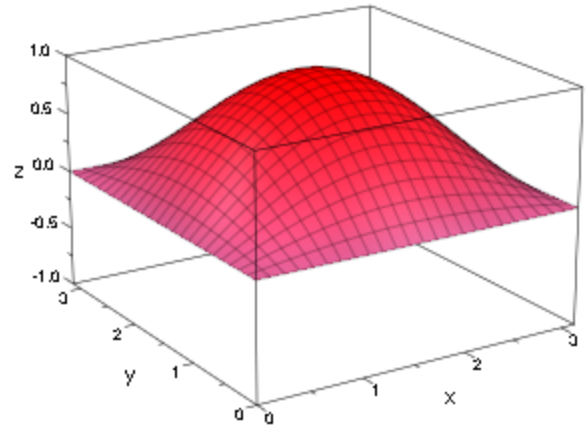


A static function plot in 3D requires two ranges (for the *x* and the *y* variable):

plot(plot::Function3d(sin(x)*sin(y), x = 0 .. PI, y = 0..PI))

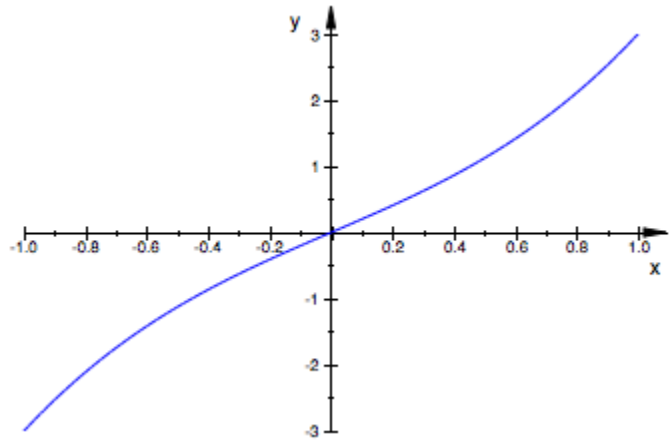


Now, a third equation `a = `a_{min}`..`a_{max}`` triggers an animation:
plot(plot::Function3d(sin(x + a)*sin(y - a), x = 0 .. PI, y = 0..PI, a = 0..PI))



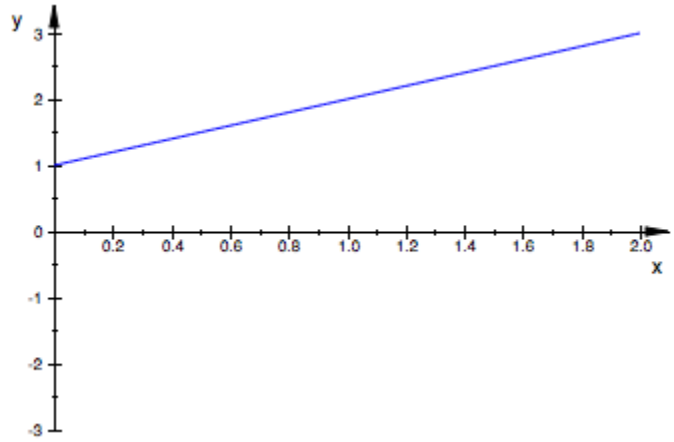
Example 2

We define an animated 2D function plot:
f := plot::Function2d(x^3 + a*x, x = -1..1, a = 0..2): plot(f):



We swap the role of the independent variable x and the animation parameter a:
[f::XName, f::ParameterName] := [f::ParameterName, f::XName]:
[f::XRange, f::ParameterRange] := [f::ParameterRange, f::XRange]:

The function now is drawn as a function of a for various values of the "time" x:
plot(f)



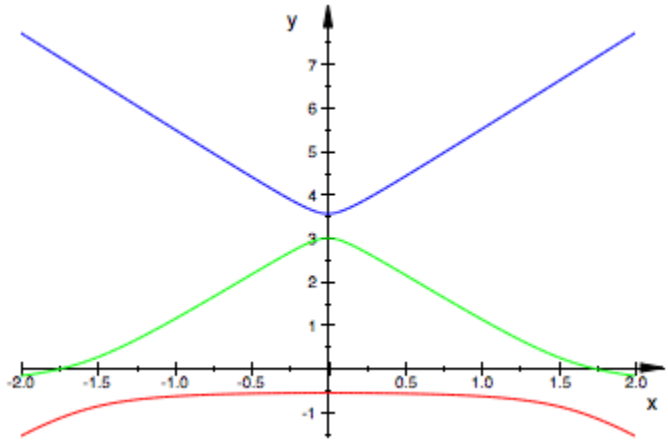
delete f:

Example 3

We demonstrate the use of procedures in the definition of animated functions.

We wish to plot the eigenvalues of a matrix that depends on two parameters x and a. The eigenvalues are computed numerically in the procedure `eigenvals`. This procedure uses option remember, because it is called thrice with the same arguments by the procedures f_1, f_2, f_3 that produce the smallest, the middle, and the largest eigenvalue, respectively, as functions of the parameters x and a:

```
eigenvals := proc(x, a) option remember; local A; begin A:= matrix([[1, a, x ], [a, 2, a*x], [x, a*x, 3 ]]): sort(numeric::eigenvalues(A)): end_proc: f1:= (x, a) -> eigenvals(x, a)[1]: f2:= (x, a) -> eigenvals(x, a)[2]: f3:= (x, a) -> eigenvals(x, a)[3]:plot(plot::Function2d(f1, x = -2..2, a = 0..2, Color = RGB::Red), plot::Function2d(f2, x = -2..2, a = 0..2, Color = RGB::Green), plot::Function2d(f3, x = -2..2, a = 0..2, Color = RGB::Blue)):
```



delete eigenvals, f1, f2, f3:

Concepts

- "The Number of Frames and the Time Range"

Points2dPoints3d

Purpose

List of 2D points

Value Summary

`Points2d`, `Points3d`	Mandatory	List of 2D points

Graphics Primitives

Objects	Default Values
plot::PointList2d, plot::PointList3d, plot::Polygon2d, plot::Polygon3d	

Description

`Points2d` is the list of 2D points in objects of type plot::PointList2d and plot::Polygon2d, respectively.

`Points3d` is the list of 3D points in objects of type plot::PointList3d and plot::Polygon3d, respectively.

One usually defines such an object `p`, say, via

`p := plot::PointList2d([[`x_1`, `y_1`], [`x_2`, `y_2`], ])` or

`p := plot::Polygon2d([[`x_1`, `y_1`], [`x_2`, `y_2`], ])`, respectively.

Internally, the points are stored as the attribute

`Points2d = [[`x_1`, `y_1`], [`x_2`, `y_2`], ]`

and can be accessed via the slot call `p::Points2d`. Assigning a new list to `p::Points2d` changes the object `p` accordingly.

The corresponding statements hold for 3D point lists and polygons.

The points in the list `Points2d` may consist of lists with 2 elements (the *x* and *y* coordinates) or of lists with 3 elements (the *x* and *y* coordinates and the RGB color of the point).

The points in the list `Points3d` may consist of lists with 3 elements (the *x*, *y*, and *z* coordinates) or of lists with 4 elements (the *x*, *y*, *z* coordinates and the RGB/RGBa color of the point).

If you specify the color of one point, you must specify the colors of all other points in the list. See “Example 2” on page 24-1265.

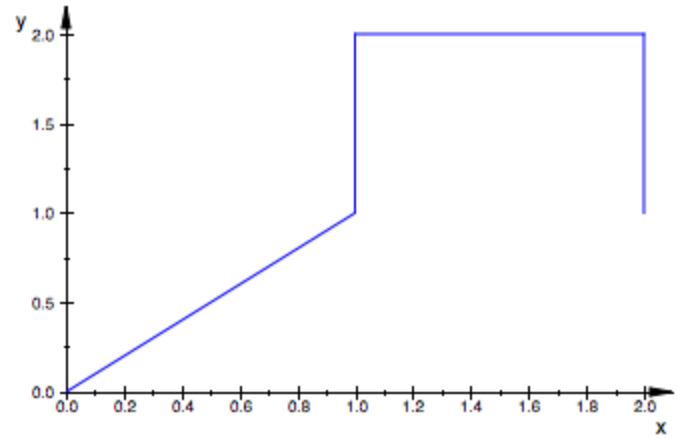
The points in the lists `Points2d` and `Points3d` can be animated.

Examples

Example 1

We define a 2D polygon with 5 points:

```
p := plot::Polygon2d([[0, 0], [1, 1], [1, 2], [2, 2], [2, 1]]): plot(p):
```



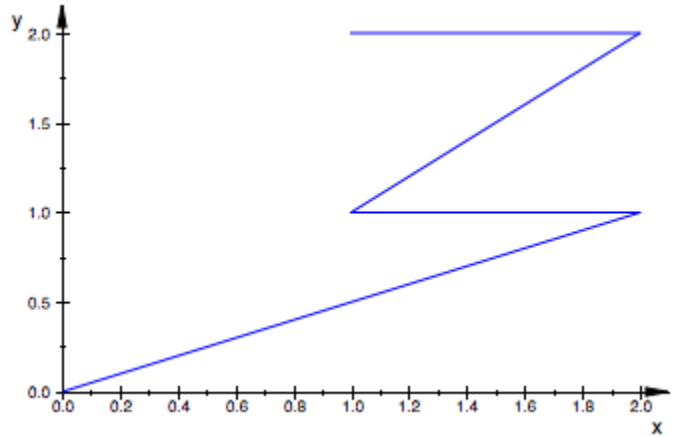
The points in the polygon can be accessed as the `Points2d` attribute:

```
pts := p::Points2d[[0, 0], [1, 1], [1, 2], [2, 2], [2, 1]]
```

```
[[0, 0], [1, 1], [1, 2], [2, 2], [2, 1]]
```

We change the polygon be assigning a new point list:

```
p::Points2d := [pts[1], pts[5], pts[2], pts[4], pts[3]]: plot(p):
```

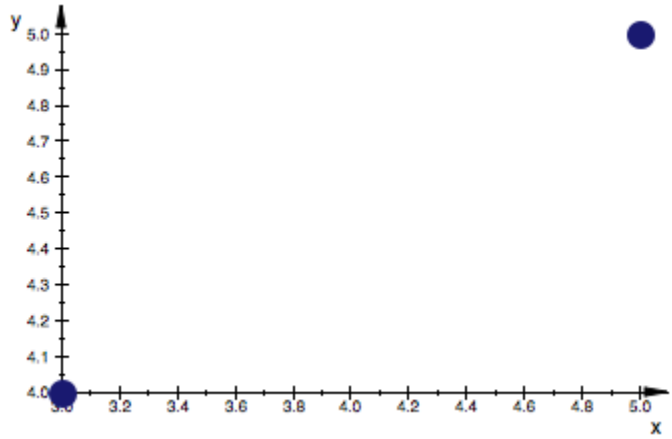


delete p, pts:

Example 2

`Points2d` and Points3d allow you to specify the colors of the points. For example, the following list contains two points. The plot function uses the default color for both points on the plot:
Coords := [[3, 4], [5, 5]]; plotCoords := plot::PointList2d(Coords):
plot(plotCoords, PointSize = 5)[[3, 4], [5, 5]]

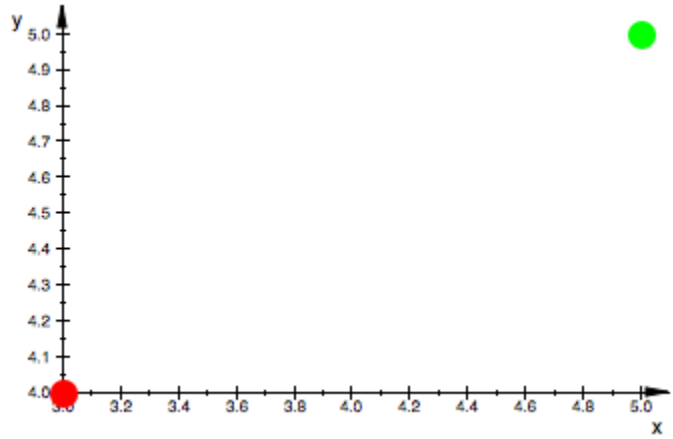
[[3, 4], [5, 5]]



To access and modify the list of points, use `Points2d`. For example, include the color of each point in the list:
plotCoords::Points2d := [[3, 4, RGB::Red], [5, 5, RGB::Green]][[3, 4, [1.0, 0.0, 0.0]], [5, 5, [0.0, 1.0, 0.0]]]

```
[[3, 4, [1.0, 0.0, 0.0]], [5, 5, [0.0, 1.0, 0.0]]]
```

Now the first point appears in red, and the second point appears in green:
plot(plotCoords, PointSize = 5)



If you specify the color of one point, you must also specify the colors of all other points in the list:
plotCoords::Points2d := [[3, 4, RGB::Red], [5, 5]] Error: The attribute 'Points2d' in the 'PointList2d' object must be a list of lists of two expressions and an optional color value. [plot]

Purpose

PositionPositionXPositionYPositionZ

Positions of cameras, lights, and text objects

Value Summary

`Position`	Library wrapper for "[PositionX, PositionY]" (2D), "[PositionX, PositionY, PositionZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`PositionX`, `PositionY`, `PositionZ`	Mandatory	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Camera, plot::DistantLight, plot::PointLight, plot::SpotLight, plot::Text2d, plot::Text3d	
plot::Point2d	`Position`: [0, 0] `PositionX`, `PositionY`: 0
plot::Plane, plot::Point3d, plot::Reflect3d	`Position`: [0, 0, 0] `PositionX`, `PositionY`, `PositionZ`: 0

Description

`Position` determines the positions of cameras, lights, and text objects.

`PositionX` etc. refer to the single coordinate values of the position.

The attribute `Position` refers to the location of a camera taking pictures of a 3D scene. Its a value is a list or vector of coordinates.

Also the position of light sources illuminating the 3D scene is set by `Position`.

Further, `Position` determines the coordinates where text objects are to be placed.

These attributes can be animated. Animating a camera position one can realize a flight through a 3D scene.

By default, the position of lights is given in model coordinates that have nothing to do with the camera that is used to view the scene.

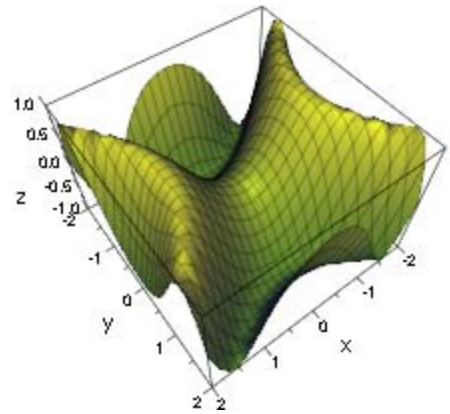
The attribute CameraCoordinates also allows to position a light relative to the camera. In particular, the light moves automatically, when the camera is moved.

Examples

Example 1

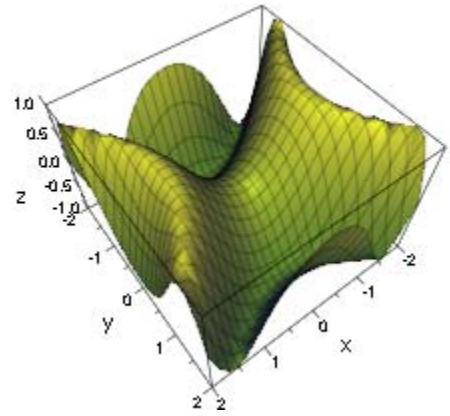
We define a 3D scene consisting of a function, a distant light, and a camera. The light shines from the direction of the camera:

```
f := plot::Function3d(sin(x^2 - y^2), x = -2..2, y = -2..2, Color =
RGB::White): light := plot::DistantLight([3, 4, 5], [0, 0, 0], 0.75, Color
= RGB::Yellow): camera := plot::Camera([3, 4, 5], [0, 0, 0], 0.25*PI):
plot(f, light, camera)
```

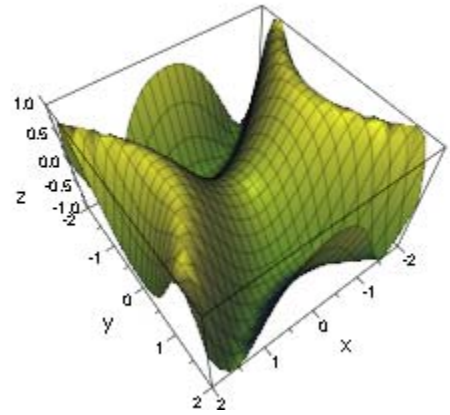


We animate the camera position but keep the light position fixed:

camera::Position := [3*sqrt(2)*cos(a + PI/4), 4*sqrt(2)*sin(a + PI/4), 5*(0.7 + 0.3*cos(2*a))]: camera::ParameterName := a: camera::ParameterRange := 0..2*PI: plot(f, light, camera)



Using the same objects, we fix the camera and animate the light position:
camera::Position := [3, 4, 5]: camera::Frames := 1: light::Position := [3*sqrt(2)*cos(a + PI/4), 4*sqrt(2)*sin(a + PI/4), 5]: light::ParameterName := a: light::ParameterRange := 0..2*PI: plot(f, light, camera)



delete f, light, camera:

See Also CameraCoordinatesCameraDirectionFocalPointSpotAngleTargetViewingAngle

Ground

Radius

Purpose

Radius of circles, spheres etc.

Value Summary

Mandatory	MuPAD expression

Graphics Primitives

Objects	Radius Default Values
plot::Circle2d, plot::Circle3d, plot::Cylinder, plot::Dodecahedron, plot::Hexahedron, plot::Icosahedron, plot::MuPADCube, plot::Octahedron, plot::Piechart2d, plot::Piechart3d, plot::Prism, plot::Sphere, plot::Tetrahedron	1
plot::Waterman	

Description

`Radius` defines the radius of circles (plot::Circle2d and plot::Circle3d, respectively), spheres (plot::Sphere), cylinders (plot::Cylinder), circumcircles of regular bases of prisms (plot::Prism) and pie charts (plot::Piechart2d and plot::Piechart3d, respectively). Also polyhedra such as plot::Dodecahedron use this attribute to set their size.

Examples

Example 1

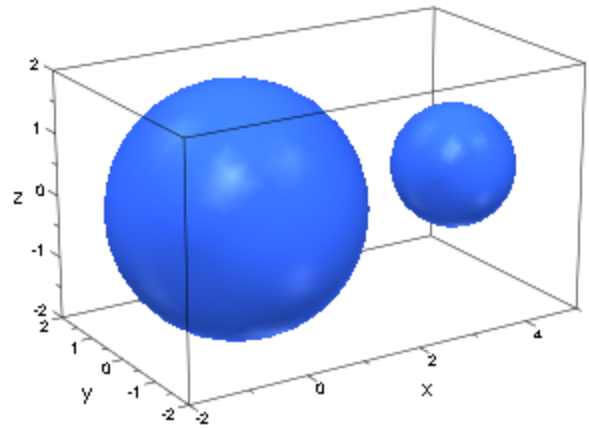
We generate a sphere around the origin with radius 2:

```
s := plot::Sphere(2, [0, 0, 0])plot::Sphere(2, [0, 0, 0])
```

```
plot::Sphere(2, [0, 0, 0])
```

The first argument in plot::Sphere is the radius, the second argument is the center. Internally, these values are stored as the attributes `Radius` and Center, respectively. We can access the objects' attributes and change them:
s::Radius, s::Center2, [0, 0, 0]

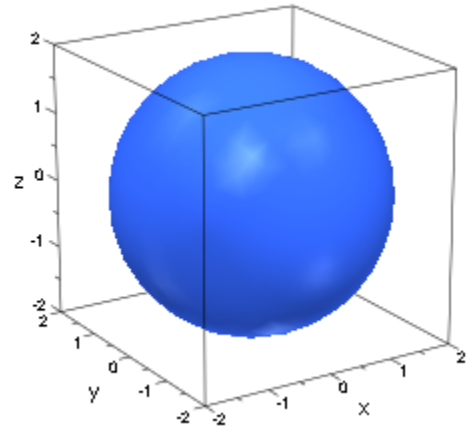
2, [0, 0, 0]
s2 := plot::copy(s): s2::Center := [4, 0, 0]: s2::Radius := 1: plot(s, s2):



delete s, s2:

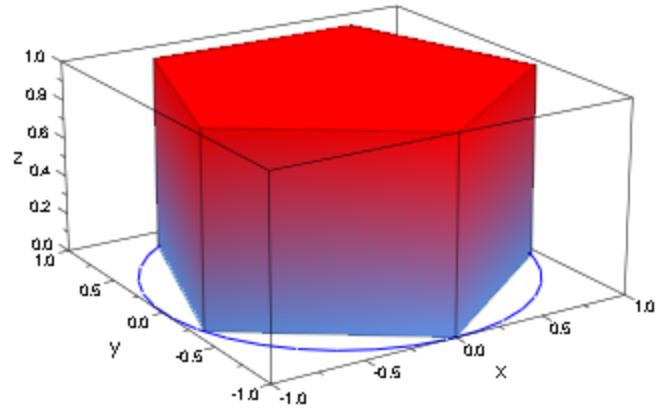
Example 2

The attribute `Radius` can be animated:
plot(plot::Sphere(a, [0, 0, 0], a = 1..2)):



Example 3

For a prism, the attribute `Radius` determines the radius of the circumcircle of its regular bases:
plot(plot::Prism(1,Edges=5), plot::Circle3d(1)):



See Also BaseCenterNormalSemiAxesTop

RadiusFunction

Purpose

Radius of a tube plot

Value Summary

Mandatory	Arithmetical expression or function

Graphics Primitives

Objects	RadiusFunction Default Values
plot::Tube	1/10

Description

`RadiusFunction` is the internal name of the radius function in plot::Tube.

With `RadiusFunction = r(t)`, plot::Tube will draw (part of) a circle of radius `r(t)` at the point $(x(t), y(t), z(t))$ around the central curve.

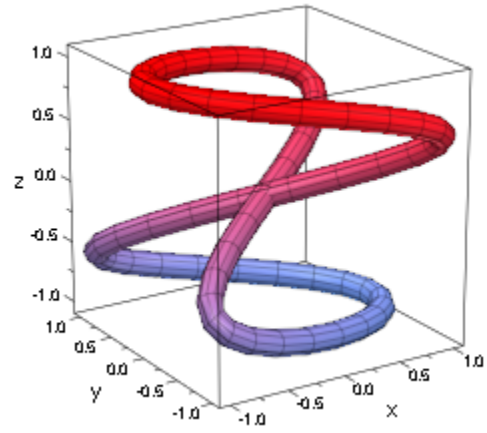
Usually, a user will have no need to access `RadiusFunction` directly, since it is set by plot::Tube directly.

Examples

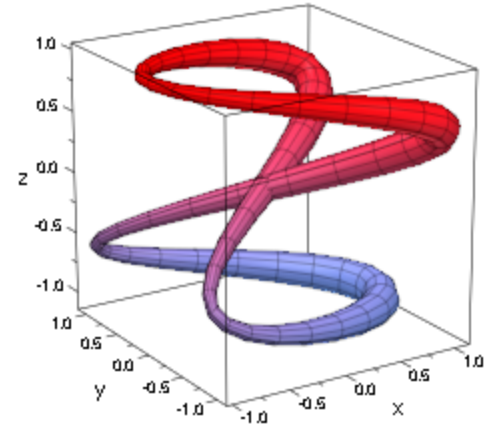
Example 1

By default, plot::Tube uses a constant radius of 1/10:

```
t := plot::Tube([sin(3*x), sin(2*x), sin(x)], x = 0..2*PI): plot(t)
```



To change this default, either set some other radius when creating the tube plot (see the documentation of plot::Tube for this) or set `RadiusFunction`:
t::RadiusFunction := (1+sin(3*x)/2)/10: plot(t)



RationalExpression

Purpose

Rational expression in a rootlocus plot

Value Summary

Mandatory	MuPAD expression

Graphics Primitives

Objects	RationalExpression Default Values
plot::Rootlocus	

Description

`RationalExpression` is the internal name of the expression whose roots are depicted by plot::Rootlocus.

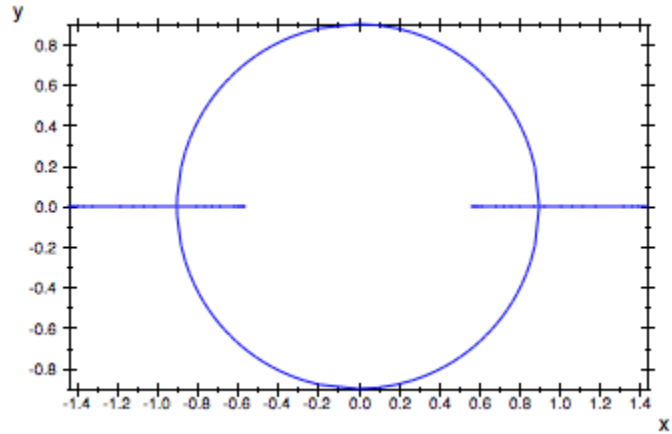
A rootlocus plot depicts the roots of a rational function `p(z, u)` in the complex plane, depending on a parameter `u`. The expression `p(z, u)` is stored as the attribute `RationalExpression` in the rootlocus object.

Usually, a user will have no need to access the attribute `RationalExpression`, since it is set by plot::Rootlocus directly.

Examples

Example 1

We define a rootlocus plot:
r:= plot::Rootlocus(z^2 - 2*u*z + 0.81, u = -1..1): plot(r)



The function z^2 - $2uz$ + 0.81 is stored as the attribute `r::RationalExpression` in the object `r`:
r::RationalExpressionz^2 - 2*u*z + 0.81

$$z^2 - 2\,u\,z + 0.81$$

We can redefine this attribute:
r::RationalExpression:= z^3 - 2*u*z + 0.81: plot(r)

Purpose

ScaleScaleXScaleYScaleZ

Scaling factors

Value Summary

`Scale`	Library wrapper for "[ScaleX, ScaleY]" (2D), "[ScaleX, ScaleY, ScaleZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`ScaleX`, `ScaleY`, `ScaleZ`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Scale2d	`Scale`: [1, 1] `ScaleX`, `ScaleY`: 1
plot::Scale3d	`Scale`: [1, 1, 1] `ScaleX`, `ScaleY`, `ScaleZ`: 1

Description

`Scale` defines the scaling factors used by plot::Scale2d and plot::Scale3d.

`ScaleX` etc. correspond to the factors in the single coordinate directions.

The scaling objects plot::Scale2d and plot::Scale3d apply the scaling transformation (x) -> A*x$_{x \to Ax}$ with the matrix $A = diag(s_x, s_y)$ in 2D and $A = diag(s_x, s_y, s_z)$ in 3D, repectively.

`Scale` is the list `[`s_x`, `s_y`]` resp. `[`s_x`, `s_y`, `s_z`]` of the scaling factors. The attributes `ScaleX` etc. correspond to s_x etc.

These attributes can be animated.

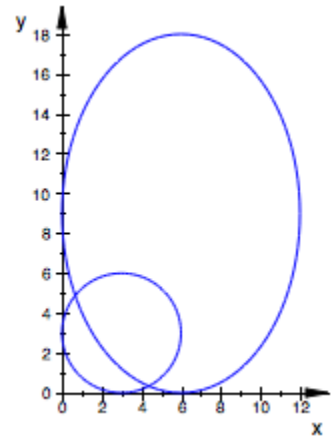
Examples

Example 1

We start with a 2D circle:

```
c := plot::Circle2d(3, [3, 3]):
```

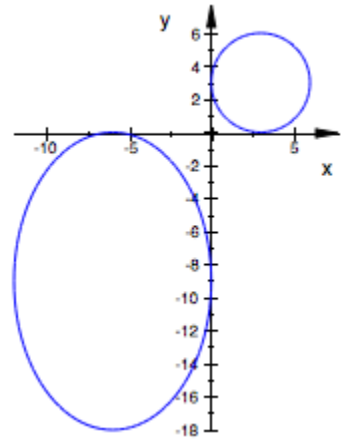
We apply a scaling transformation:
S := plot::Scale2d([2, 3], c): plot(c, S):



The scaling factors are stored as the `Scale` attribute in the scaling object `S`:
S::Scale, S::ScaleX, S::ScaleY[2, 3], 2, 3

[2, 3], 2, 3

We change the scaling factors:
S::Scale := [-2, -3]: plot(c, S):



delete c, S:

See Also ShiftMatrix2dMatrix3d

Purpose

SemiAxesSemiAxisXSemiAxisYSemiAxisZ

Semi axes of ellipses and ellipsods

Value Summary

`SemiAxes`	Library wrapper for "[SemiAxisX, SemiAxisY]" (2D), "[SemiAxisX, SemiAxisY, SemiAxisZ]" (3D)	List of two or three real-valued expressions
`SemiAxisX`, `SemiAxisY`, `SemiAxisZ`	Mandatory	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Ellipsoid	`SemiAxes`: [1, 2, 3] `SemiAxisX`: 1 `SemiAxisY`: 2 `SemiAxisZ`: 3
plot::Ellipse2d	`SemiAxes`: [2, 1] `SemiAxisX`: 2 `SemiAxisY`: 1
plot::Ellipse3d	`SemiAxisX`: 2 `SemiAxisY`: 1
plot::Arc2d	`SemiAxes`: [1, 1] `SemiAxisX`, `SemiAxisY`: 1
plot::Arc3d	`SemiAxisX`, `SemiAxisY`: 1

Description

`SemiAxes` determines the lengths of the semi axes of ellipses in 2D and ellipsoids in 3D.

`SemiAxes = [`r_x`, `r_y`]` sets the lengths r_x, r_y of the semi axes of an ellipse in 2D.

`SemiAxes = [`r_x`, `r_y`, `r_z`]` sets the lengths r_x, r_y, r_z of the semi axes of an ellipsoid in 3D.

`SemiAxisX = `r_x, `SemiAxisY = `r_y, `SemiAxisZ = `r_z refer to the semi axis in the x, y, and z direction, respectively.

The values of these attributes can be animated.

Examples

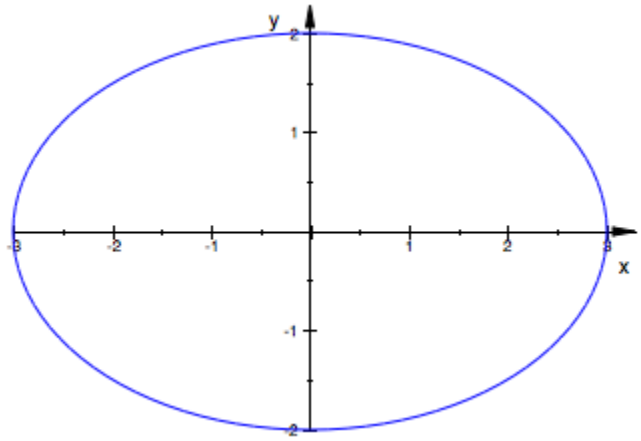
Example 1

We create an ellipse around the origin with semi axes 1 and 2:
e := plot::Ellipse2d(1, 2, [0, 0]):

The first two arguments in plot::Ellipse2d are the semi axes. Internally, they are stored as the attributes `SemiAxisX` and `SemiAxisY` and can be changed by assigning new values:
e::SemiAxisX, e::SemiAxisY, e::SemiAxes1, 2, [1, 2]

1, 2, [1, 2]

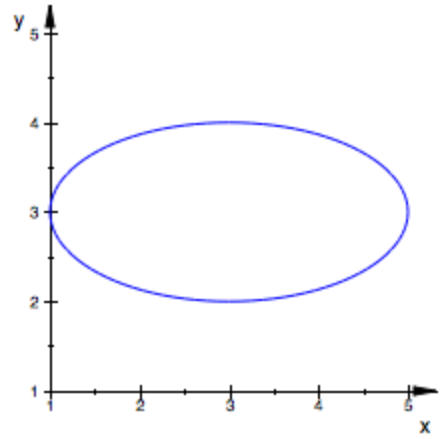
e::SemiAxes := [3, 2]: plot(e):



delete e:

Example 2

`SemiAxes` can be animated:
plot(plot::Ellipse2d(a, 3 - a, [3, 3], a = 1..2)):



See Also

Radius

Purpose

ShiftShiftXShiftYShiftZ

Shift vector

Value Summary

`Shift`	Library wrapper for "[ShiftX, ShiftY]" (2D), "[ShiftX, ShiftY, ShiftZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`ShiftX`, `ShiftY`, `ShiftZ`	Optional	MuPAD expression

Description

`Shift` is the shift vector in transformation objects. `ShiftX` etc. refer to the single components of this vector.

The general transformation objects plot::Transform2d and plot::Transform3d allow to apply the affine-linear transformation (x) -> A*x+b$x \to A\,x + b$ to 2D and 3D objects, respectively. The shift vector b can be accessed and changed via the attribute `Shift`.

Special transformation objects such as plot::Translate2d, plot::Translate3d correspond to special matrices A and shifts b. They also allow to access and change the shift vector by the attribute `Shift`.

When setting the `Shift` attribute, matrices, arrays, and lists with 2 or 3 elements are accepted. Internally, however, the shift data are always stored as the list `[b1, b2]` in 2D or `[b1, b2, b3]` in 3D, respectively. When reading the vector by a slot access, this list is returned.

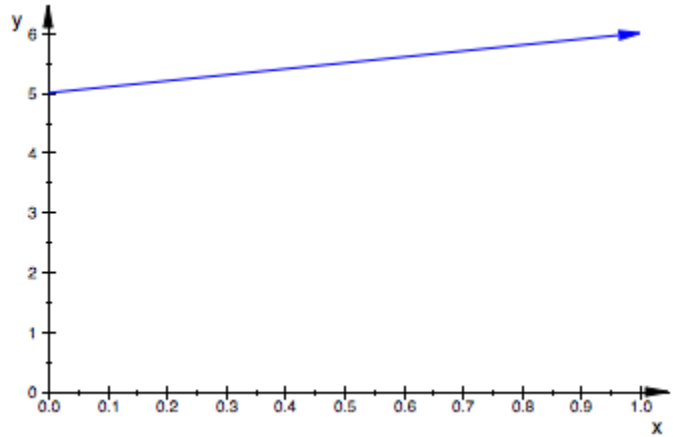
The entries of `Shift` can be animated.

Examples

Example 1

We move an arrow along the y-axis:

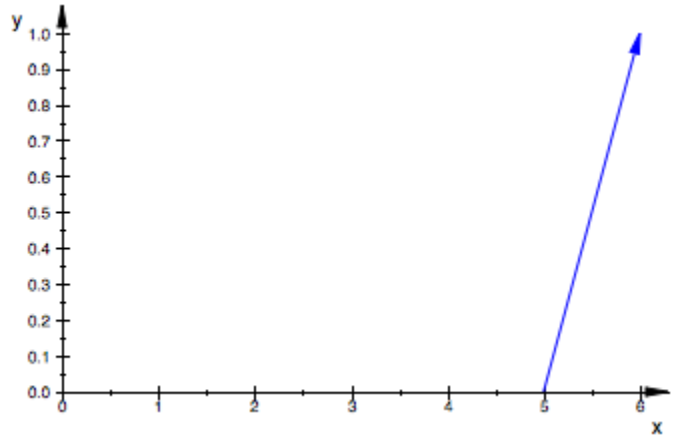
```
T := plot::Translate2d([0, a], a = 0..5, plot::Arrow2d([0, 0], [1, 1])): plot(T)
```



The `Shift` vector is the first argument in the call above. It is stored in the corresponding slot of the translation object `T`:
T::Shift[0, a]

[0, *a*]

We change the shift vector:
T::Shift := [a, 0]: plot(T)



delete T:

See Also Matrix2dMatrix3dScale

Size

Purpose

Size of a point list

Value Summary

Optional | MuPAD expression

Graphics Primitives

Objects	Size Default Values
plot::QQplot	

Description

`Size` represents the number of plot points in a plot::QQplot.

A plot::QQplot accepts two data lists, displaying a set of plot points with coordinate values given by quantile values of the data. By default, the number of plot points is chosen as the minimum of the sizes of the two data lists. In principle, however, the number of plot points can be chosen independently of the data sizes. With `Size` = *n*, the number of plot points of the QQ plot can be set to any positive integer value *n*.

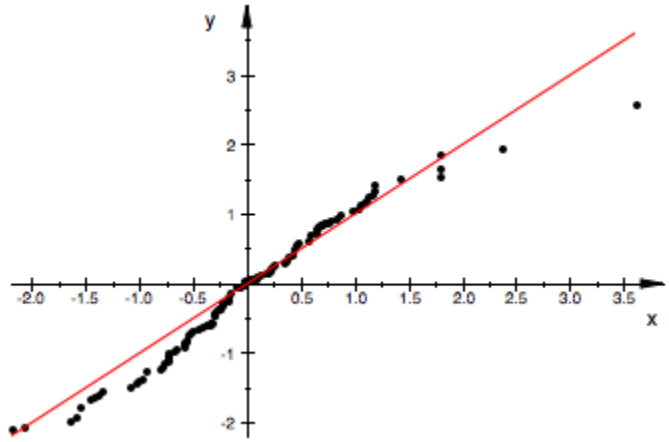
The value of `Size` can be animated.

Examples

Example 1

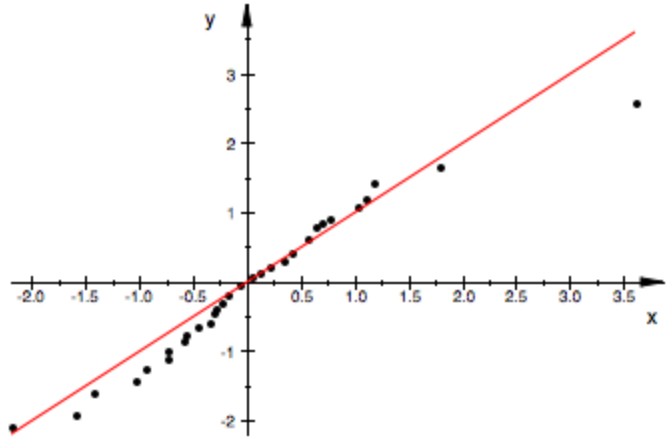
We create a QQ plot:

```
data1 := [stats::normalRandom(0, 1)() $ k = 1..100]: data2 := [stats::normalRandom(0, 1)() $ k = 1..200]: qq := plot::QQplot(data1, data2): plot(qq)
```



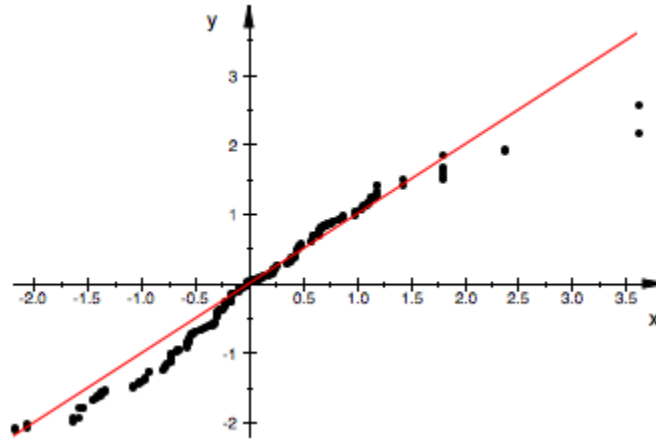
By default, the minimum of the data sizes is chosen as the number of plot points in the plot (i.e., `Size` = 100 in this case). We reduce the number of plot points by setting the value of `Size` explicitly:

```
qq::Size := 30: plot(qq)
```



The number of plot points can also be specified directly by passing the attribute `Size` = *n*. In the following graphics, this value is animated:

```
plot(plot::QQplot(data1, data2, Size = n, n = 10..200));
```



delete data1, data2, qq:

Purpose

Tangent1Tangent1XTangent1YTangent1ZTangent2Tangent2XTangent2YTangent2Z
First vector spanning parallelograms

Value Summary

`Tangent1`	Library wrapper for "[Tangent1X, Tangent1Y]" (2D), "[Tangent1X, Tangent1Y, Tangent1Z]" (3D)	List of 2 or 3 expressions, depending on the dimension
`Tangent1X`, `Tangent1Y`, `Tangent1Z`, `Tangent2X`, `Tangent2Y`, `Tangent2Z`	Mandatory	MuPAD expression
`Tangent2`	Library wrapper for "[Tangent2X, Tangent2Y]" (2D), "[Tangent2X, Tangent2Y, Tangent2Z]" (3D)	List of 2 or 3 expressions, depending on the dimension

Graphics Primitives

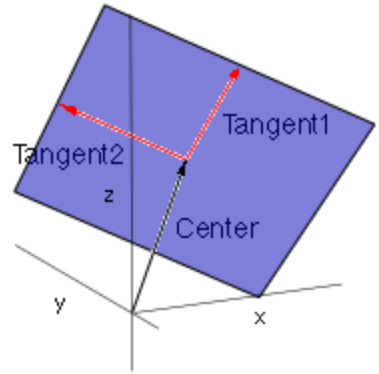
Objects	Default Values
plot::Parallelogram3d	`Tangent1`: [0, 1, 0] `Tangent1X`, `Tangent1Z`, `Tangent2Y`, `Tangent2Z`: 0 `Tangent1Y`, `Tangent2X`: 1 `Tangent2`: [1, 0, 0]
plot::Parallelogram2d	`Tangent1`: [0, 1] `Tangent1X`, `Tangent2Y`: 0

Objects	Default Values
	Tangent1Y, Tangent2X: 1 Tangent1Z, Tangent2Z: 0

Description

Tangent1 and Tangent2 determine the vectors spanning the parallelograms created by plot::Parallelogram2d and plot::Parallelogram3d.

Parallelograms created by plot::Parallelogram2d and plot::Parallelogram3d are specified by a vector defining the Center and two vectors Tangent1 and Tangent2 which span the plane of the parallelogram. The lengths of the “tangent” vectors are half the side lengths of the parallelogram:
plot(plot::Arrow3d([0, 0, 0], [2, 2, 2], Color = RGB::Black, Title = "Center", TitlePosition = [2.1, 1, 0.8], TitleFont = [14]), plot::Arrow3d([2, 2, 2], [2, 0, 4], Color = RGB::Red, Title = "Tangent1", TitlePosition = [3.3, 1, 2.5], TitleFont = [14]), plot::Arrow3d([2, 2, 2], [0, 3, 3],Color = RGB::Red, Title = "Tangent2", TitlePosition = [0, 2.5, 2.0], TitleFont = [14]), plot::Parallelogram3d([2, 2, 2],[0,-2, 2], [-2, 1, 1], LineColor = RGB::Black, Filled = TRUE, FillColor = RGB::Blue.[0.5]), CameraDirection = [-10, -20, 5], Axes = Origin, TicksNumber = None, Scaling = Constrained):



Depending on the dimension, the vectors `Tangent1`, `Tangent2` are given by lists or vectors of two or three components.

The attributes `Tangent1X` etc. represent the x, y, z coordinates of these vectors.

The values of these attributes can be animated.

Examples

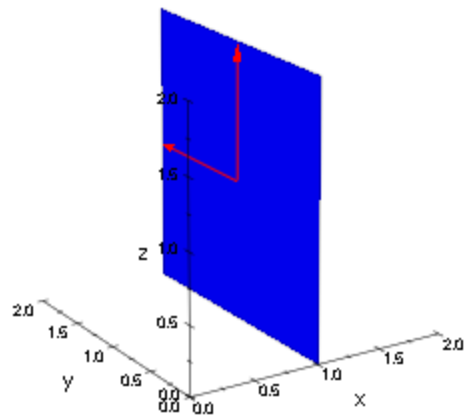
Example 1

The "tangent vectors" of a parallelogram are accessible via the slots `Tangent1` and `Tangent2`:

```
p := plot::Parallelogram3d([1, 1, 1], [0, 1, 0], [0, 0, 1], Color = RGB::Blue):
p::Tangent1, p::Tangent2[0, 1, 0], [0, 0, 1]
```

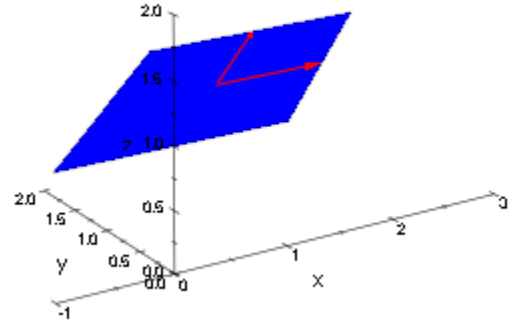
[0, 1, 0], [0, 0, 1]

```
plot(p, plot::Arrow3d([1, 1, 1], [1, 2, 1], Color = RGB::Red),
plot::Arrow3d([1, 1, 1], [1, 1, 2], Color = RGB::Red), Axes = Origin,
Scaling = Constrained):
```



We change the "tangent vectors":

p::Tangent1 := [1, 0, 0]: p::Tangent2 := [1, 1, 0]: plot(p, plot::Arrow3d([1, 1, 1], [2, 1, 1], Color = RGB::Red), plot::Arrow3d([1, 1, 1], [2, 2, 1], Color = RGB::Red), Axes = Origin, Scaling = Constrained):



delete p:

See Also

Center

Text

Purpose

Text of a text object

Value Summary

Mandatory	String or function

Graphics Primitives

Objects	Text Default Values
plot::Text2d, plot::Text3d	

Description

The attribute `Text` represents the text of a text object. It may be a text string or a function generating a text string at runtime.

The `Text` attribute represents the text in text objects of type plot::Text2d and plot::Text3d. When creating a text object such as

```
t := plot::Text2d("hello world", [0, 0]),
```

the text is the first argument. Internally, it is stored as the attribute `Text = "hello world"` and can be accessed and changed via a slot call `t::Text`.

In most cases, the text is given as a string.

Note Note that this string has to be quoted when changing it in the "property inspector" of the interactive graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). If the string contains white space and the quotes are removed, the recalculation following the change will produce a syntax error!

A text given by a fixed string cannot be animated. Use a procedure to create animated texts.

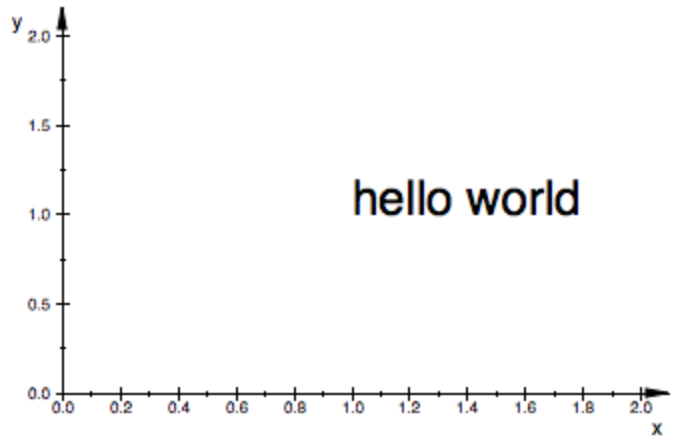
The attribute `Text` can be a procedure that is called at runtime with the animation parameter as the only input parameter. The return

value is used as the text of the text object in the corresponding frame of the animation. If the result is not a string, expr2text is applied to the return value.

Examples

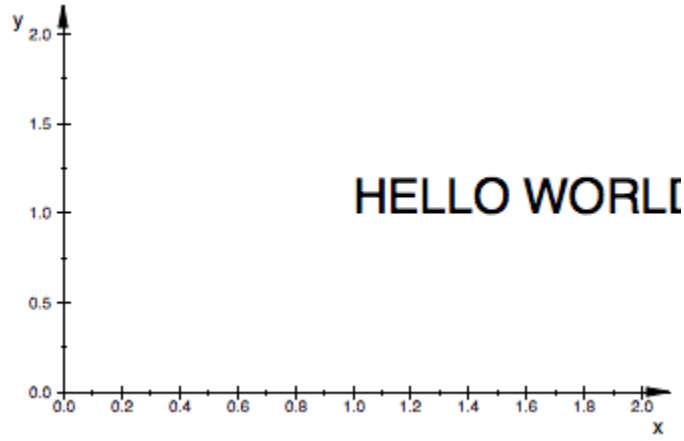
Example 1

Usually, a text is given by a string:
t := plot::Text2d("hello world", [1, 1], TextFont = [24]): plot(t)

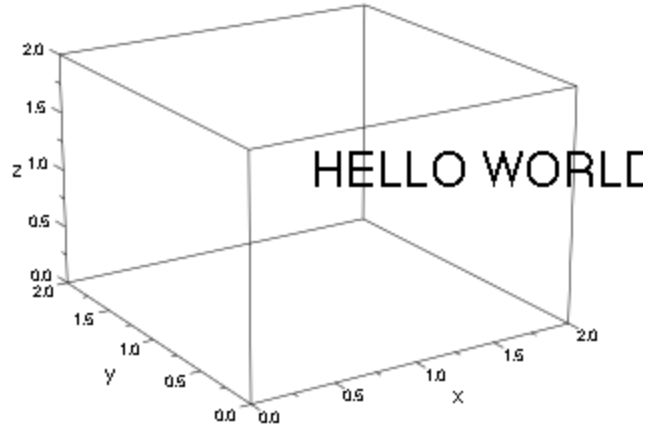


We access and change the text:
t::Text"hello world"

"hello world"
t::Text := "HELLO WORLD": plot(t)



The same message in 3D:
plot(plot::Text3d("HELLO WORLD", [1, 1, 1], TextFont = [24]))

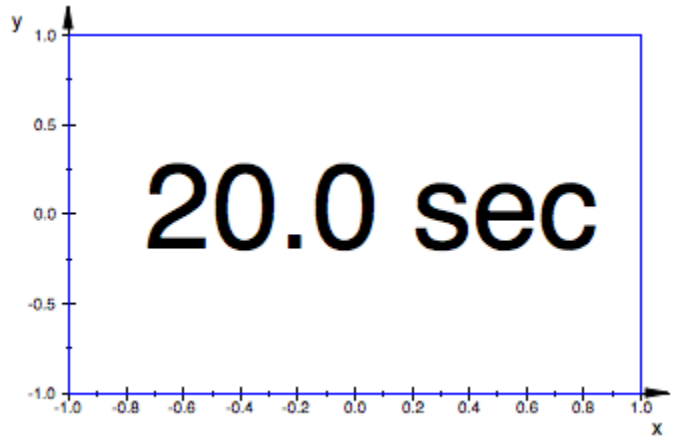


delete t:

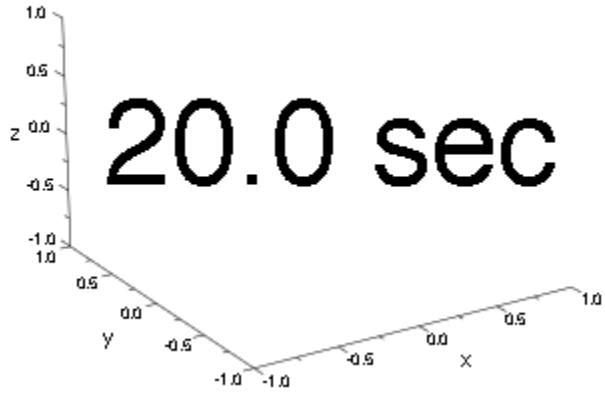
Example 2

The text of a text object can be animated if the text string is provided by a procedure. We use stringlib::formatf to format the animation

parameter that is passed to the procedure as a floating-point number for each frame of the animation:
plot(plot::Rectangle(-1..1, -1..1), plot::Text2d(a -> stringlib::formatf(a, 2, 5)." sec", [0, 0], a = 0..20, TextFont = [60], HorizontalAlignment = Center, VerticalAlignment = Center), Axes = Frame, Frames = 201, TimeRange = 0..20)



Here is the corresponding example in 3D:
plot(plot::Text3d(a -> stringlib::formatf(a, 2, 5)." sec", [0, 0, 0], a = 0..20, TextFont = [60], HorizontalAlignment = Center, VerticalAlignment = Center), Axes = Frame, Frames = 201, TimeRange = 0..20)



See Also BillboardingHorizontalAlignmentTextFontVerticalAlignmentstringlib::formatf

Purpose

TextOrientation

Orientation of a 3D text

Value Summary

Optional	List of six real-valued expressions

Graphics Primitives

Objects	TextOrientation Default Values
plot::Text3d	[1, 0, 0, 0, 0, 1]

Description

`TextOrientation` defines the orientation of a text object of type plot::Text3d. Its orientation in 3 space is given by 2 directions. There is the “writing direction” from the first character of the text to the last. The direction from the bottom of the characters to their top shall be referred to as the “up direction”.

Together with the anchor point of the text (the attribute Position of a plot::Text3d object), these two directions define a 2 dimensional plane in 3D. You may regard this plane as the sheet onto which the text is written.

The value of `TextOrientation` has to be a list of 6 numerical values or expressions of the animation parameter. The first 3 components of this list define the “writing direction”, the last 3 components the “up direction”.

The length of these two vectors is irrelevant, only their directions matter. The lengths should not be zero, though.

Further, the “up direction” should be orthogonal to the “writing direction”. If this is not the case, the “up direction” is automatically replaced by the vector orthogonal to the “writing direction” that lies in the plane given by the original directions.

“Writing direction” and “up direction” should not be parallel.

Note `TextOrientation` only has an effect in conjunction with the attribute `Billboarding = FALSE`.

`TextOrientation` can be animated.

The effect of `TextOrientation` is independent of the HorizontalAlignment and VerticalAlignment of the text relative to its anchor point (Position).

While `TextOrientation` is used for orienting 3D texts, TextRotation is used for rotating a 2D text of type plot::Text2d.

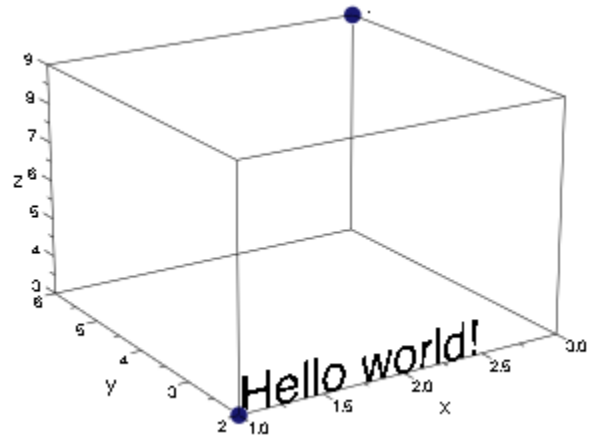
Examples

Example 1

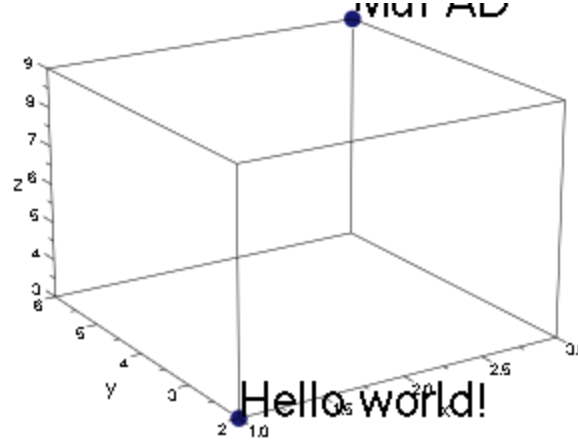
The "writing direction" of the text object `text1` is rotated around an axis parallel to the *z*-axis. The "up direction" of its characters is the *z* direction.

The "writing direction" of the text object `text2` is parallel to the *x* axis. The animated "up direction" is rotated around an axis pointing into the *x* direction:

```
p1 := plot::Point3d([1, 2, 3], PointSize = 3*unit::mm): text1 :=
plot::Text3d("Hello world!", [1, 2, 3], TextOrientation = [cos(a), sin(a),
0, 0, 0, 1], a = 0..2*PI, TextFont = [24], Billboarding = FALSE):
p2 := plot::Point3d([3, 6, 9], PointSize = 3*unit::mm): text2 :=
plot::Text3d("MuPAD", [3, 6, 9], TextOrientation = [1, 0, 0, 0, sin(a),
cos(a)], a = 0..2*PI, TextFont = [24], Billboarding = FALSE): plot(p1,
text1, p2, text2)
```



When Billboarding is set to `TRUE`, `TextOrientation` does not have any effect:
text1::Billboarding := TRUE: text2::Billboarding := TRUE: plot(p1, text1, p2, text2)



delete p1, text1, p2, text2:

See Also TextRotation

TextRotation

Purpose

Rotation of a 2D text

Value Summary

Optional	Real-valued expression (interpreted in radians)

Graphics Primitives

Objects	TextRotation Default Values
plot::Integral, plot::Text2d	0

Description

`TextRotation` sets the rotation angle of a 2D text object relative to the horizontal axis.

`TextRotation` rotates a text object of type plot::Text2d. around its anchor point (the attribute Position of a plot::Text2d object). Note that a plot::Text2d allows different alignments (HorizontalAlignment, VerticalAlignment) relative to this point.

The rotation angle in `TextRotation = angle` has to be entered in radians. If positive, the rotation is counterclockwise.

The rotation of the text refers to 'rotation on the screen'. It is invariant w.r.t. rescaling of the canvas, aspect ratio etc.

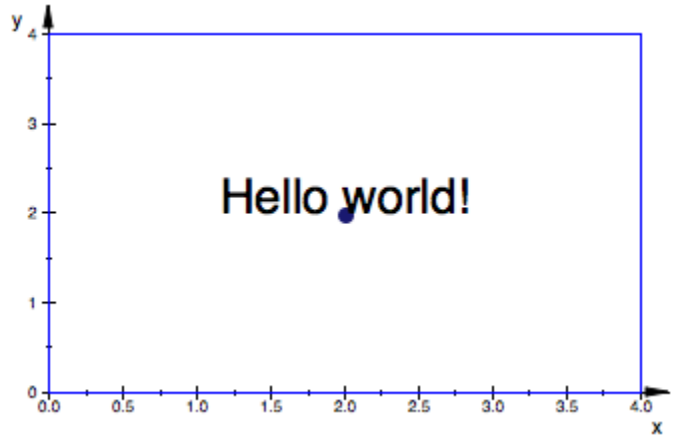
While `TextRotation` is used for rotating 2D texts, TextOrientation is used for rotating a 3D text of type plot::Text3d.

`TextRotation` can be animated.

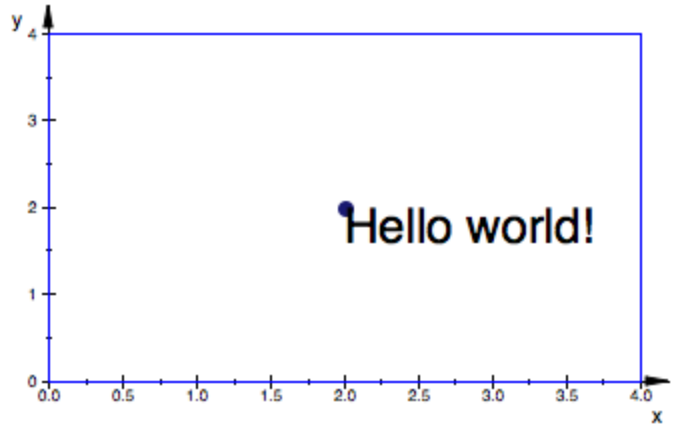
Examples

Example 1

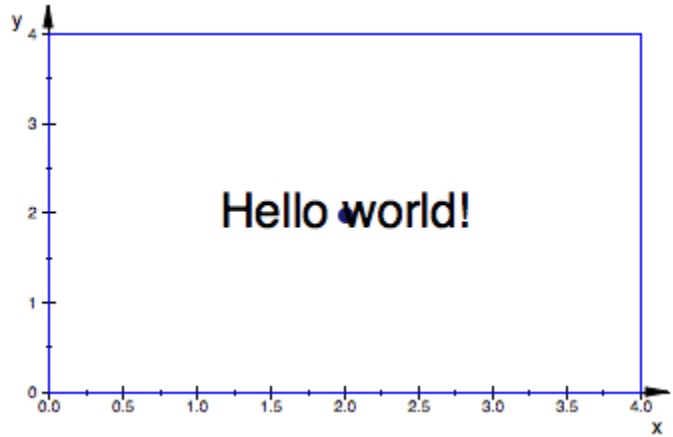
We draw a rectangle and a rotating text inside:
r := plot::Rectangle(0..4, 0..4): p := plot::Point2d([2, 2], PointSize = 3*unit::mm): text := plot::Text2d("Hello world!", [2, 2], HorizontalAlignment = Center, TextRotation = a, a = 0..2*PI, TextFont = [24]): plot(r, p, text):



We change the alignment of the text w.r.t. its anchor point [2, 2]: text:: HorizontalAlignment := Left: text:: VerticalAlignment := Top: plot(r, p, text):



text:: HorizontalAlignment := Center: text:: VerticalAlignment := Center: plot(r, p, text):



delete r, p, text:

	`XMax, YMax: 1`

plot::Hatch	`XRange: -infinity .. infinity`
	`XMin: -infinity`
	`XMax: infinity`

Description

`UName, VName, XName, YName, ZName` specify the names of parameters defining parametrized objects such as functions, curves and surfaces.

`UMin, UMax, VMin, VMax, XMin, XMax, YMin, YMax, ZMin, ZMax` specify the minimal and maximal values of the range of the parameters.

`URange, VRange, XRange, YRange, ZRange` serve as shortcuts for setting `UMin`, `UMax` etc.

In most cases, the user has no need for using these attributes explicitly, because parameter ranges are set implicitly during creation of plot objects. For example, the definition

```
f := plot::Function2d(sin(x), x = 0 ..  2*PI)
```

sets the attribute values `XName = x`, `XMin = 0`, `XMax = 2*PI` automatically for the function object `f`. In fact, you can define `f` by the equivalent call

```
f := plot::Function2d(sin(x), XName = x, XMin = 0, XMax =
2*PI).
```

In the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document), you will not see a specification such as `x = 0 .. 2*PI`, but you find separate entries for `XName`, `XMin`, `XMax`.

The use of 'X', 'Y', 'Z' as opposed to 'U', 'V' depends on the type of the object.

Functions of type plot::Function2d refer to the independent variable ("the parameter") as `XName`.

Functions of type plot::Function3d refer to the two independent variables as `XName`, `YName`.

Parametrized curve of type plot::Curve2d or plot::Curve3d refer to the curve parameter as `UName`.

Parametrized surfaces of type plot::Surface, plot::XRotate etc. refer to the two surface parameters as `UName`, `VName`.

Various other plot objects of type plot::Implicit2d, plot::VectorField2d etc. also use the attributes `XName` etc. Here, the ranges from `XMin` to `XMax` etc. denote the coordinate range in which the objects are placed.

After a definition such as `f := plot::Function2d(sin(x), x = 0 .. 2*PI)`, the parameter and its range can be accessed as the slots `f::XName`, `f::XMin`, `f::XMax`.

The slot `f::XRange` yields the range `0 .. 2*PI` consisting of the values of `XMin` and `XMax`. Setting the attribute `XRange` is a short cut for setting `XMin` and `XMax` simultaneously. For example, setting `f::XRange := -PI .. PI` is equivalent to setting `f::XMin := -PI` and `f::XMax := PI`.

Of course, the analogous statements hold for `YRange`, `ZRange`, `URange`, `VRange`, too.

Examples

Example 1

We define a function object:
f1 := plot::Function2d(sin(x), x = 0.. 2*PI)plot::Function2d(sin(x), x = 0..2*PI)

plot::Function2d(sin(x), x = 0..2 π)

This is equivalent to:
f2 := plot::Function2d(sin(x), XName = x, XMin = 0, XMax = 2*PI)plot::Function2d(sin(x), x = 0..2*PI)

plot::Function2d(sin(x), x = 0..2 π)

The objects `f1` and `f2` have the same entries for the parameter `x`:
f1::XName = f1::XMin .. f1::XMax, f2::XName = f2::XRangex = 0..2*PI, x = 0..2*PI

x = 0..2 π, x = 0..2 π

Changing the *x* range via `XRange` is equivalent to changing `XMin` and `XMax` separately:
f1::XRange := -PI..PI: f2::XMin := -PI: f2::XMax := PI: f1, f2plot::Function2d(sin(x), x = -PI..PI), plot::Function2d(sin(x), x = -PI..PI)

plot::Function2d(sin(x), x = −π..π), plot::Function2d(sin(x), x = −π..π)

delete f1, f2:

plot::CoordinateSystem2d	`ViewingBox`: [`Automatic` .. `Automatic`, `Automatic` .. `Automatic`]
	`ViewingBoxXMin`, `ViewingBoxXMax`, `ViewingBoxYMin`, `ViewingBoxYMax`: `Automatic`
	`ViewingBoxXRange`, `ViewingBoxYRange`: `Automatic` .. `Automatic`

plot::CoordinateSystem3d	`ViewingBox`: [`Automatic` .. `Automatic`, `Automatic` .. `Automatic`, `Automatic` .. `Automatic`]
	`ViewingBoxXMin`, `ViewingBoxXMax`, `ViewingBoxYMin`, `ViewingBoxYMax`, `ViewingBoxZMin`, `ViewingBoxZMax`: `Automatic`
	`ViewingBoxXRange`, `ViewingBoxYRange`, `ViewingBoxZRange`: `Automatic` .. `Automatic`

Description

The `ViewingBox` attributes set the coordinate range that is visible in a plot.

`ViewingBoxXMin` = x_{min}, `ViewingBoxXMax` = x_{max}, equivalent to `ViewingBoxXRange` = x_{min} `..` x_{max}, restricts the visibility to x values between x_{min} and x_{max}. `ViewingBoxYMin` etc. work analogously.

Setting `ViewingBox` = [x_{min} .. x_{max}, y_{min} .. y_{max}] in 2D and `ViewingBox` = [x_{min} .. x_{max}, y_{min} .. y_{max}, z_{min} .. z_{max}] in 3D

respectively, serves as a short cut for setting the single entries `ViewingBoxXMin` etc.

The `ViewingBox` of a plot is computed automatically by default. It is chosen as the smallest box containing all graphical objects in the coordinate system.

The values x_{min} etc. of the `ViewingBox` attributes must be real numerical expressions or the special flag `Automatic`. With `Automatic`, the system chooses appropriate values automatically.

When plotting a function or a curve with singularities, a heuristics is used to set a "reasonable" restricted viewing box for the plot. This heuristics sometimes fails to produce a pleasing picture. We recommended to request an explicit `ViewingBox` in such a case.

When using plot::Rotate2d or plot::Rotate3d, the `ViewingBox` may be larger than necessary. Its size is computed by rotating the common viewing box of all objects in the rotation object. See "Example 4" on page 24-1320.

The `ViewingBox` of an animation is automatically chosen as the union of all viewing boxes of the frames of the animation.

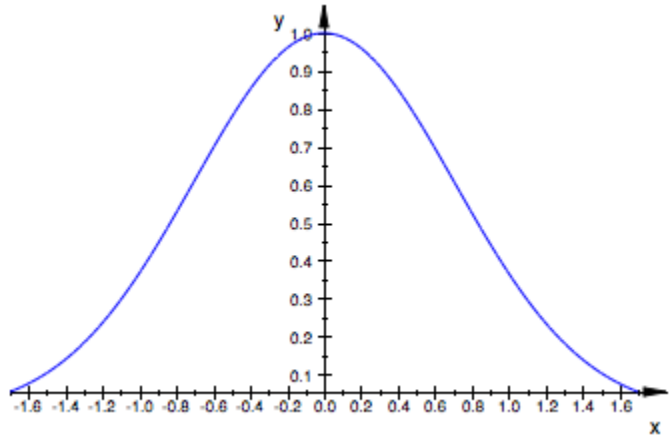
The `ViewingBox` itself cannot be animated. However, the object plot::ClippingBox may be used to implement animated visibility regions.

Examples

Example 1

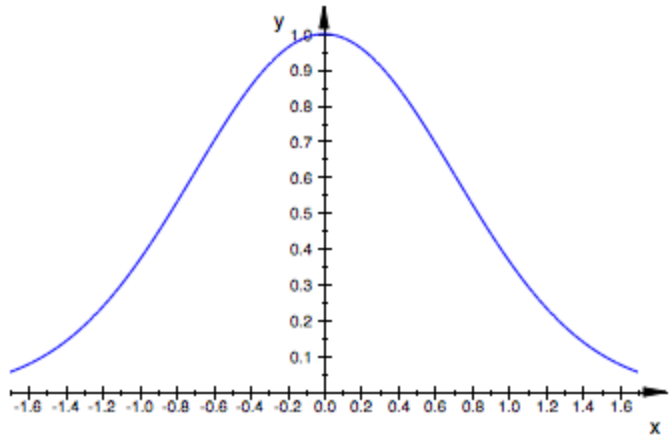
In the following plot, the horizontal axis is placed at the minmal *y*-value produced by the function:

```
f := plot::Function2d(exp(-x^2), x = -1.7 .. 1.7): plot(f)
```



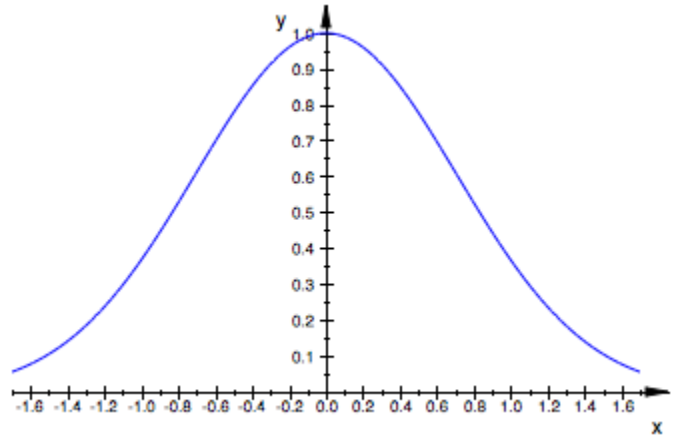
We wish to make the x-axis appear at $y = 0$. To this end, we request the y range to start with $y = 0$ and use `Automatic` to let MuPAD find the maximal y-value automatically:

```
plot(f, ViewingBoxYRange = 0..Automatic)
```



The previous command is equivalent to:

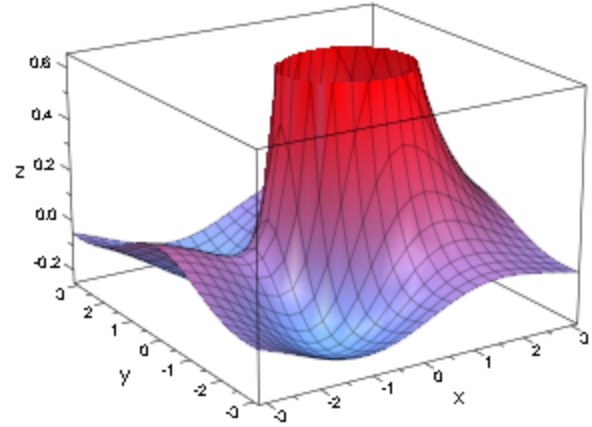
```
plot(f, ViewingBoxYMin = 0)
```



delete f:

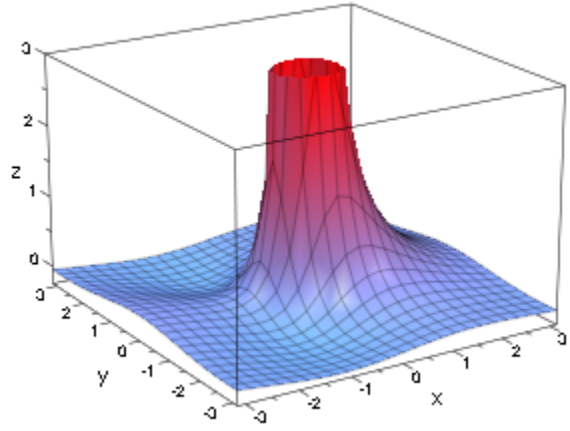
Example 2

Here is a 3D plot of a singular function:
f := plot::Function3d((sin(x) + cos(y))/(x^2 + y^2), x = -PI..PI, y = -PI..PI):
plot(f)



We specify the upper *z* value of the visible volume:

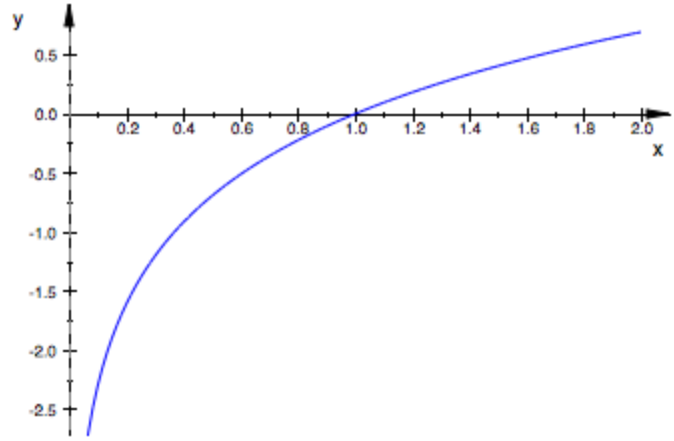
plot(f, ViewingBoxZRange = Automatic..3)



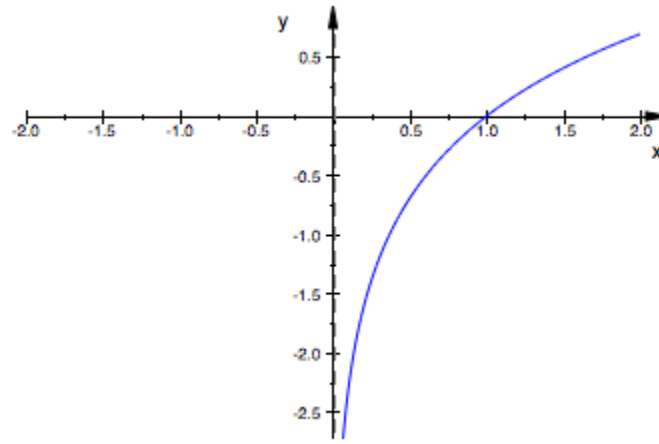
delete f:

Example 3

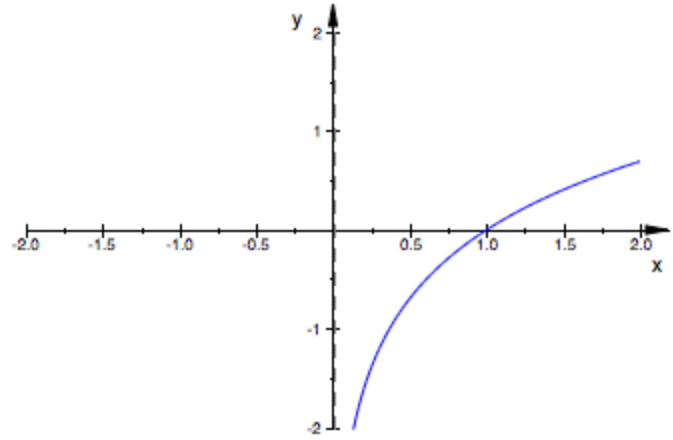
Usually, a plot uses the whole drawing aera:
f := plot::Function2d(ln(x), x = 0..2): plot(f)



We extend the viewing box in x direction to make it symmetric w.r.t. x:
plot(f, ViewingBoxXRange = -2..2)



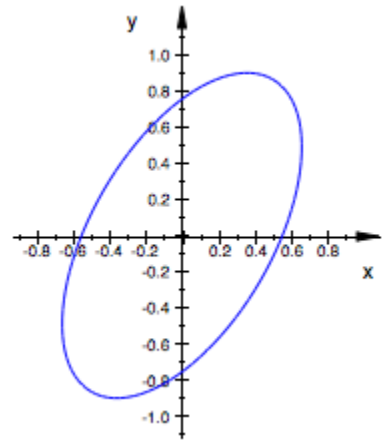
We specify the viewing box both in x and y direction:
plot(f, ViewingBox = [-2..2, -2..2])



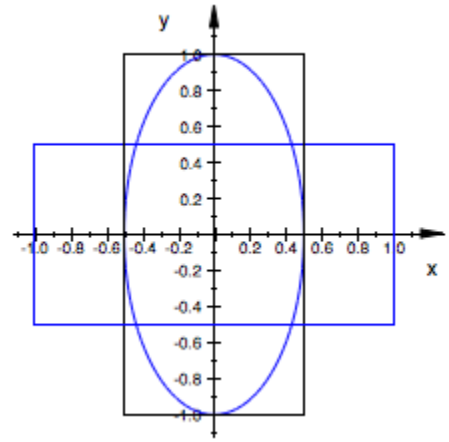
delete f:

Example 4

The following viewing box is larger than expected:
c := plot::Ellipse2d(1, 0.5, [0, 0]): r := plot::Rotate2d(c, PI/3): plot(r)



The reason is how the viewing box of the rotation is computed. The blue rectangle is the viewing box of the ellipse. The rotated viewing box is the black rectangle. The viewing box of the rotation is the smallest rectangle containing the rotated viewing box of the ellipse (the dashed black rectangle):
rect1 := plot::Rectangle(-1..1, -0.5..0.5, Color = RGB::Black): rect2 := plot::modify(rect1, Color = RGB::Blue): r := plot::Rotate2d(c, rect1, a, a = 0..PI/2): X := cos(a) + 0.5*sin(a): Y := 0.5*cos(a) + sin(a): rect3 := plot::Rectangle(-X..X, -Y..Y, a = 0..PI/2, Color = RGB::Black, LineStyle = Dashed): plot(r, rect2, rect3)



delete c, r, rect1, rect2, rect3, X, Y:

Example 5

The *x*-range from - π to π is generated by *all* frames of the following animation and does not change from frame to frame:
plot(plot::Function2d(sin(x), x = -PI + a .. a, a = 0 .. PI)):

Visible = FALSE makes an object invisible.

All graphical objects react to the attribute Visible. With Visible = FALSE, an object is made invisible. This attribute can be set in the property inspector of the interactive viewer (see section Viewer, Browser, and Inspector: Interactive Manipulation in this document) to make a selected object disappear without needing to change and re-execute the plot call.

Invisible objects do not influence the viewing box of their coordinate system.

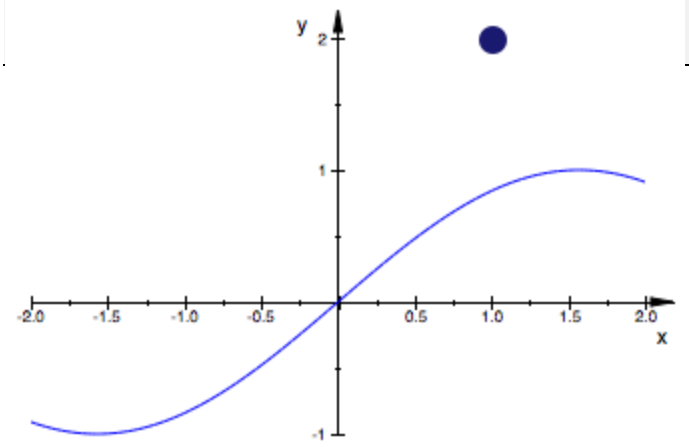
Visible cannot be animated. However, the attributes VisibleBefore, VisibleBeforeBegin, VisibleAfter, and VisibleAfterEnd serve for some form of animated visibility. See section Frame by Frame Animations in this document for further details and examples.

Examples

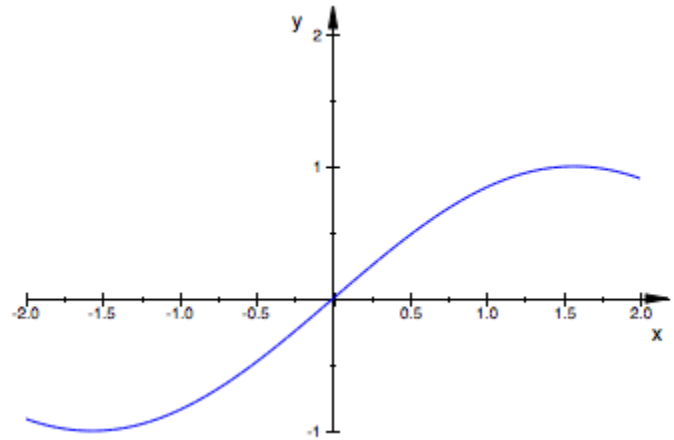
Example 1

Consider the following scene:

```
plot(plot::Point2d(sin(x), x = -2..2), plot::Point2d([1, 2], PointSize = 3*unit::mm))
```



Obviously, the point influences the visible region of the coordinates. This region is not affected by making the point invisible:
plot(plot::Function2d(sin(x), x=-2..2), plot::Point2d([1, 2], PointSize = 5*unit::mm, Visible = FALSE))



See Also VisibleAfterVisibleAfterEndVisibleBeforeVisibleBeforeBegin

Purpose

XFunction1YFunction1ZFunction1XFunction2YFunction2ZFunction2
Parametrization of the curves in sweep surfaces

Value Summary

`XFunction1`, `XFunction2`, `YFunction1`, `YFunction2`, `ZFunction1`, `ZFunction2`	Mandatory	Arithmetical expression or function

Graphics Primitives

Objects	Default Values
plot::Sweep	

Description

`XFunction1` etc. are the parametrization functions of the curves delimiting a surface of type plot::Sweep.

In most cases, the user passes parametrizations `[x1(u), y1(u), z1(u)]` and `[x2(u), y2(u), z2(u)]` as expressions of a curve parameter *u* directly to plot::Sweep. Internally, these expressions are stored as the attributes `XFunction1 = x1(u)`, ..., `ZFunction2 = z2(u)` in the sweep object. They can be accessed and changed via the corresponding slots `"XFunction1"` etc. of the sweep object.

The attributes `XFunction1` etc. can also be defined by procedures instead of symbolic expressions.

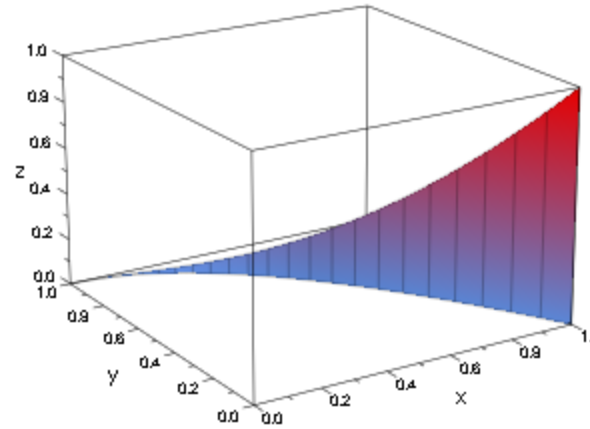
Examples

Example 1

Typically, the user sets the parametrization of the bounding curves directly by passing lists of corresponding expressions to plot::Sweep. Here, `XFunction1 = u`, `YFunction1 = 1 - u^2`, `ZFunction1 = u^3`, `XFunction2 = u`, `YFunction2 = 1 - u^2`, `ZFunction2 = 0`:
s := plot::Sweep([u, 1 - u^2, u^3], [u, 1 - u^2, 0], u = 0..1)plot::Sweep([u, 1 - u^2, u^3], [u, 1 - u^2, 0], u = 0..1)

plot::Sweep([u, 1 - u^2, u^3], [u, 1 - u^2, 0], u = 0..1)

plot(s):



s::XFunction1, s::YFunction1, s::ZFunction1u, 1 - u^2, u^3

u, 1 - u^2, u^3

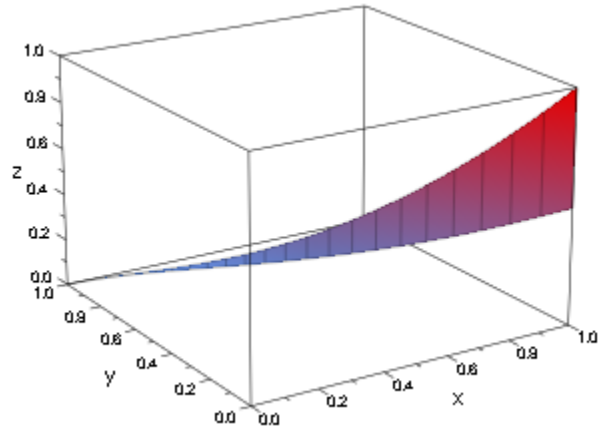
s::XFunction2, s::YFunction2, s::ZFunction2u, 1 - u^2, 0

u, 1 - u^2, 0

We change the *z*-component of the "target curve":
s::ZFunction2 := s::ZFunction1 / 2: splot::Sweep([u, 1 - u^2, u^3], [u, 1 - u^2, u^3/2], u = 0..1)

plot::Sweep([u, 1 - u^2, u^3], [u, 1 - u^2, u^3/2], u = 0..1)

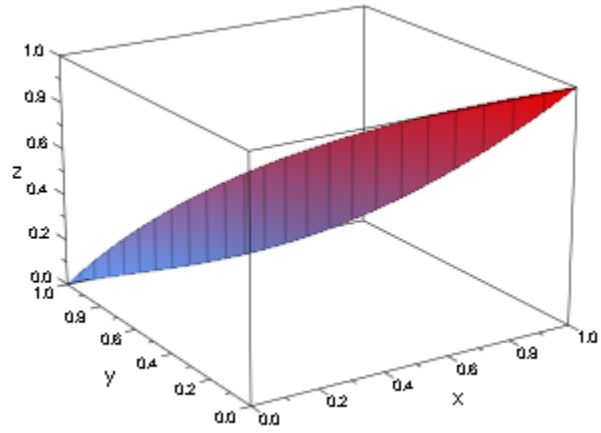
plot(s)



Instead of expressions, the attributes `XFunction1` etc. can be defined by procedures:
s::ZFunction2 := u -> u: splot::Sweep([u, 1 - u^2, u^3], [u, 1 - u^2, u -> u], u = 0..1)

$$\text{plot::Sweep}\left([u,\ 1-u^2,\ u^3],\ [u,\ 1-u^2,\ u \to u],\ u = 0..1\right)$$

plot(s)



delete s:

Ground

Purpose

Axes

Type of the coordinate axes

Value Summary

Inherited	`Automatic`, `Boxed`, `Frame`, `None`, or `Origin`

Graphics Primitives

Objects	Axes Default Values
plot::CoordinateSystem2d	`Automatic`
plot::CoordinateSystem3d	`Boxed`

Description

`Axes` determines the type of the coordinate axes.

The following types of coordinate axes are available:

- `Automatic`: The axes are displayed as a coordinate cross. The cross point is not taken from the attribute AxesOrigin, but is chosen automatically.
- `Origin`: The axes are displayed as a coordinate cross. The cross point is set by the attribute AxesOrigin. If AxesOrigin is not set, the origin of the coordinate system is used as the default cross point. If the AxesOrigin is not inside the "viewing box" of the scene, parts of the axes may not be visible (cf. "Example 4" on page 24-1334).
- `Boxed`: The axes are displayed as a box around the graphical scene. It corresponds to the "viewing box" of the scene and may be set explicitly by the attribute ViewingBox.
- `Frame`: As with `Axes = Boxed`, the edges of the "viewing box" are used. However, only the labeled edges are displayed.
- `None`: No coordinate axes are displayed.

As an alternative to `Axes = None`, you may also "switch the axes off" by setting AxesVisible = `FALSE` in the `plot` command or via the interactive

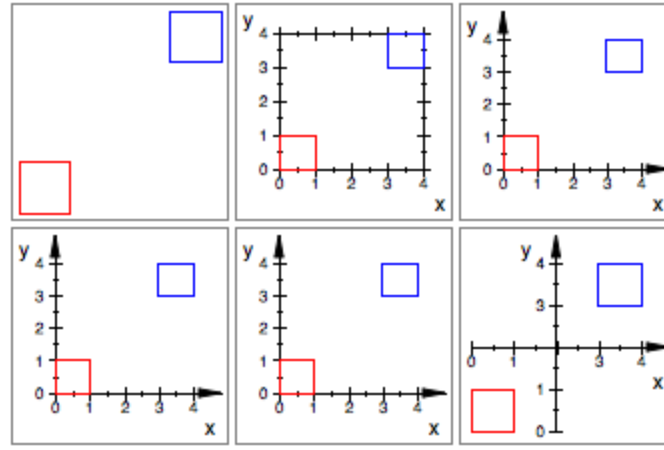
object inspector (see Viewer, Browser, and Inspector: Interactive Manipulation in this document).

Single coordinate axes can also be “switched off” separately via XAxisVisible = FALSE etc.

Examples

Example 1

We demonstrate the axes styles in 2D:
b1 := plot::Rectangle(0..1, 0..1, Color = RGB::Red): b2 := plot::Rectangle(3..4, 3..4, Color = RGB::Blue): plot(plot::Scene2d(b1, b2, Axes = None), plot::Scene2d(b1, b2, Axes = Boxed), plot::Scene2d(b1, b2, Axes = Frame), plot::Scene2d(b1, b2, Axes = Automatic), plot::Scene2d(b1, b2, Axes = Origin), plot::Scene2d(b1, b2, Axes = Origin, AxesOrigin = [2, 2]), plot::Scene2d::BorderWidth = 0.5*unit::mm, Rows = 2):

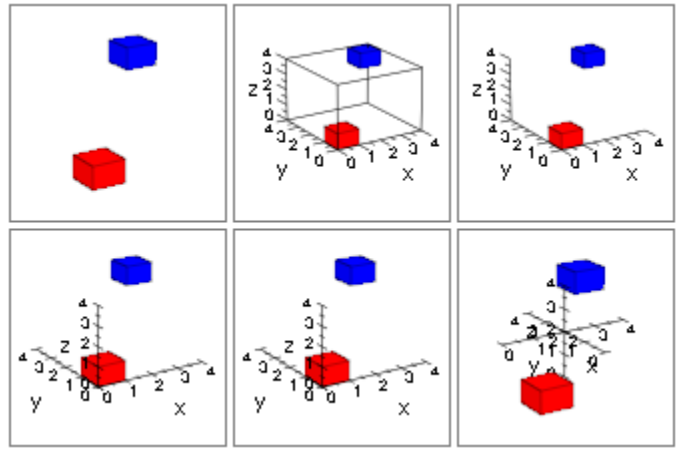


delete b1, b2:

Example 2

We demonstrate the axes styles in 3D:
b1 := plot::Box(0..1, 0..1, 0..1, Color = RGB::Red): b2 := plot::Box(3..4, 3..4, 3..4, Color = RGB::Blue): plot(plot::Scene3d(b1, b2, Axes = None),

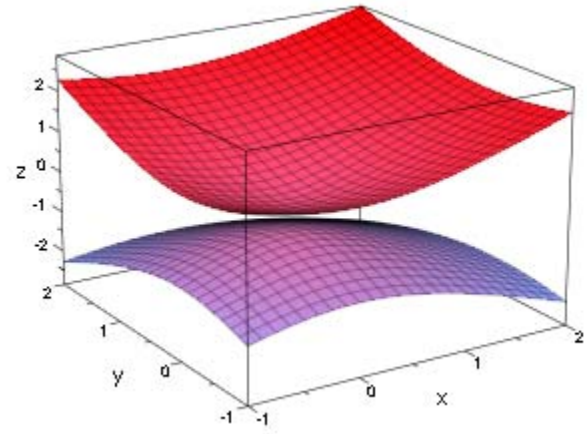
plot::Scene3d(b1, b2, Axes = Boxed), plot::Scene3d(b1, b2, Axes = Frame), plot::Scene3d(b1, b2, Axes = Automatic), plot::Scene3d(b1, b2, Axes = Origin), plot::Scene3d(b1, b2, Axes = Origin, AxesOrigin = [2, 2, 2]), plot::Scene3d::BorderWidth = 0.5*unit::mm, Rows = 2):



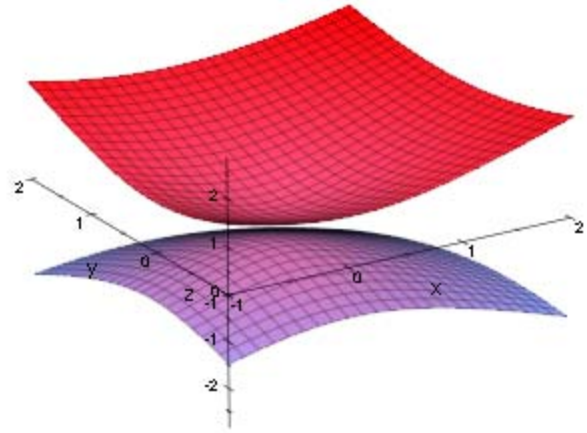
delete b1, b2:

Example 3

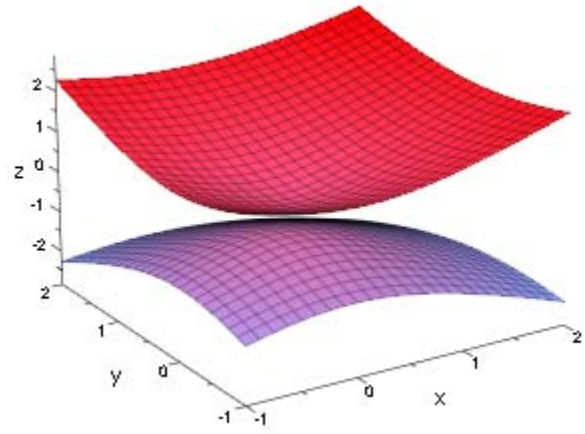
Here is a hyperboloid with various axes:
f1 := plot::Function3d(sqrt(0.2 + x^2 + y^2), x = -1..2, y = -1..2): f2 := plot::Function3d(-sqrt(0.2 + x^2 + y^2), x = -1..2, y = -1..2): plot(f1, f2):



plot(f1, f2, Axes = Origin, AxesOrigin = [-1, -1, 0]):



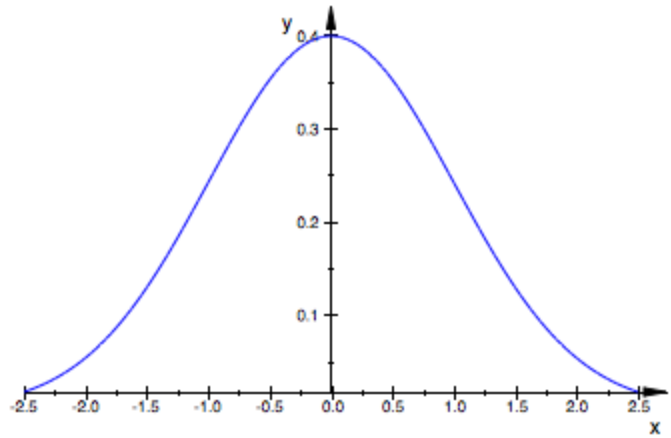
plot(f1, f2, Axes = Frame):



delete f1, f2:

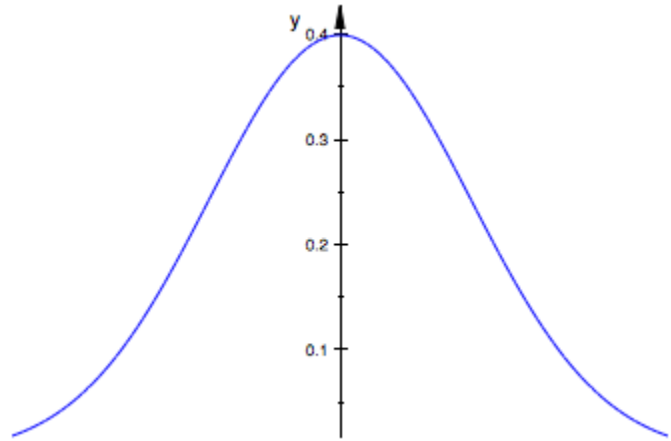
Example 4

We draw a portion of the normal distribution density:
F := plot::Function2d(stats::normalPDF(0, 1)(x), x = -2.5 .. 2.5): plot(F)

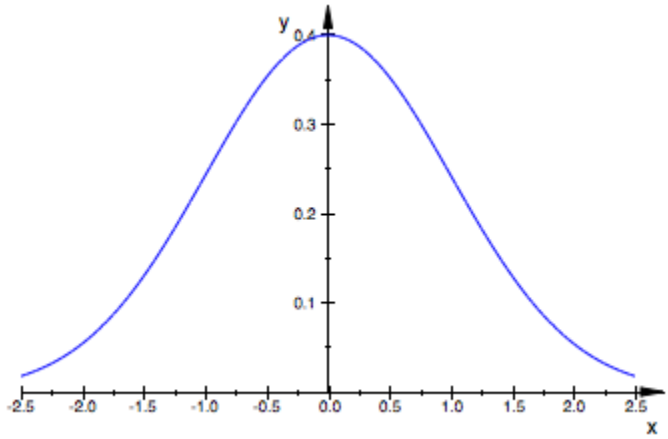


Note that with the default setting `Axes = Automatic`, the *x*-axis does not pass through the origin but is shifted along the *y*-axis to fit into the viewing box of the scene.

With `Axes = Origin`, the *x*-axis passes through the origin, but is outside the viewing box:
plot(F, Axes = Origin)



We extend the viewing box in the *y* direction:
plot(F, Axes = Origin, ViewingBoxYRange = 0 .. Automatic):



delete F:

See Also AxesInFrontAxesLineColorAxesLineWidthAxesOriginAxesTipsAxesTitleAlignmentAxesTitlel

AxesInFront

Purpose

Coordinate axes in front of or behind graphical objects?

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	AxesInFront Default Values
plot::CoordinateSystem2d	FALSE

Description

`AxesInFront = TRUE` versus `AxesInFront = FALSE` places 2D axes in front of or behind the graphical objects in the scene.

By default, the coordinate axes are plotted behind the graphical objects in a scene. Consequently, the objects may cover the axes. If only line objects and points are present in a 2D scene, this is desirable in most cases.

However, if there are filled areas such as filled polygons in the scene, the view to the axes, tick marks, and tick labels may be totally blocked. In such a situation, you may want to draw the axes in front of the objects to guarantee visibility of the axes.

Although the default setting is `AxesInFront = FALSE`, some objects which create filled areas send `AxesInFront = TRUE` as a "hint" (see the section Primitives Requesting Special Scene Attributes: "Hints" of this documentation).

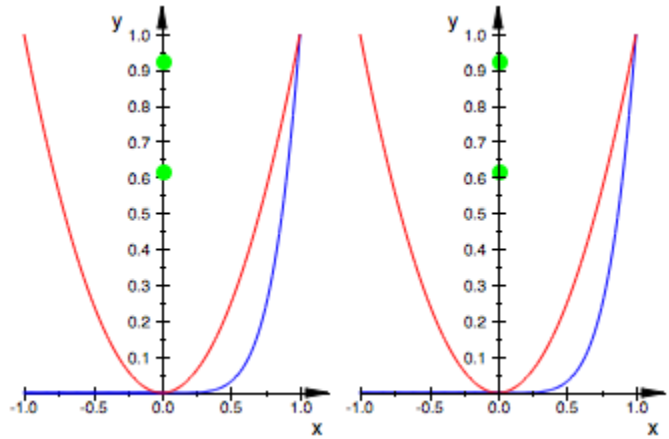
This attribute is available only in 2D.

Examples

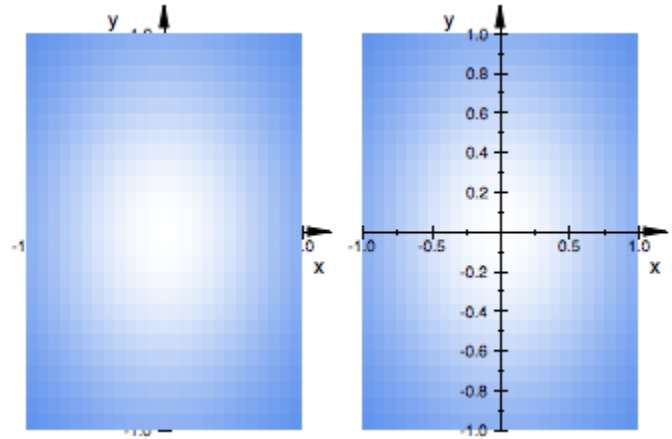
Example 1

It is usually desirable to let line objects and points cover the axes: p1 := plot::Point2d(0, 0.62, PointSize = 3*unit::mm, Color = RGB::Green): p2 := plot::Point2d(0, 0.93, PointSize = 3*unit::mm, Color = RGB::Green): f1 := plot::Function2d(x^5*heaviside(x), x = -1 .. 1, Color = RGB::Blue): f2 := plot::Function2d(x^2, x = -1 .. 1, Color =

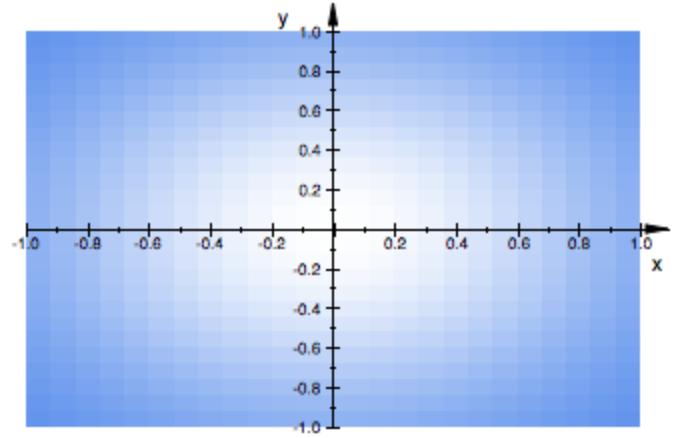
RGB::Red): plot(plot::Scene2d(p1, p2, f1, f2, AxesInFront = FALSE), plot::Scene2d(p1, p2, f1, f2, AxesInFront = TRUE)):



However, you probably want to have the axes visible in front of the following density plot:
d := plot::Density(exp(-x^2 - y^2), x = -1..1, y = -1 ..1, FillColor = RGB::White): plot(plot::Scene2d(d, AxesInFront = FALSE), plot::Scene2d(d, AxesInFront = TRUE), Layout = Horizontal):



Note that density objects of type plot::Density automatically send the "hint" `AxesInFront = TRUE`, so there is no need to set this attribute explicitly:
plot(d):



delete p1, p2, f1, f2, d:

See Also AxesAxesLineColorAxesLineWidthAxesOriginAxesTipsAxesTitleAlignmentAxesTitleFontAxe

AxesLineColor

Purpose

Color of the coordinate axes

Value Summary

Inherited	Color

Graphics Primitives

Objects	AxesLineColor Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	RGB::Black

Description

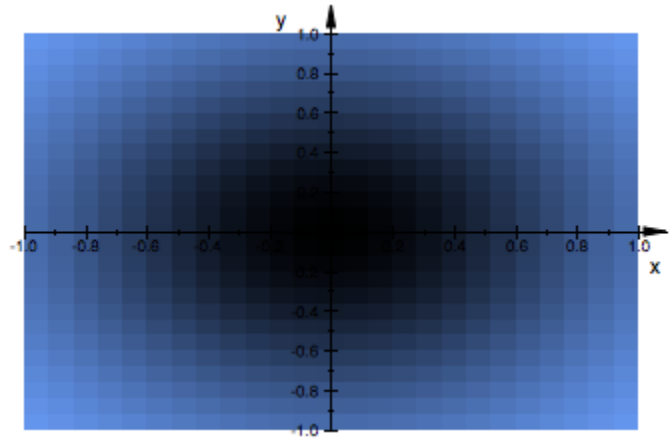
`AxesLineColor` sets the RGB color for the coordinate axes and the tick marks.

The color of the axes titles and the tick labels are *not* set by `AxesLineColor`. Choose an appropriate color for the corresponding fonts via the attributes AxesTitleFont and TicksLabelFont.

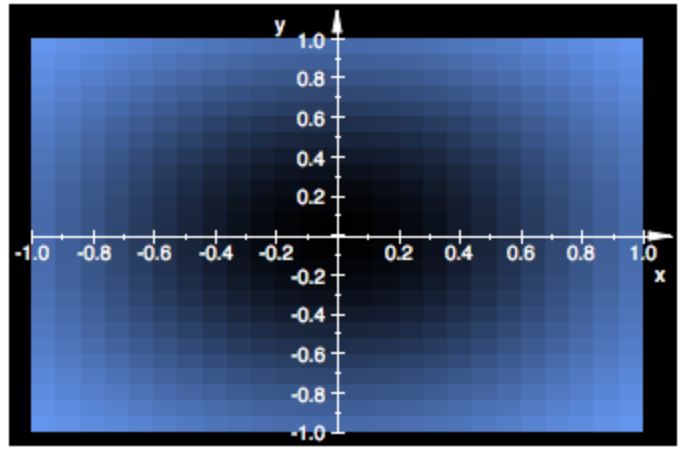
Examples

Example 1

The black axes are not appropriate for the following density graphics: d := plot::Density(exp(-x^2 - y^2), x = -1..1, y = -1 ..1, FillColor = RGB::Black): plot(d)



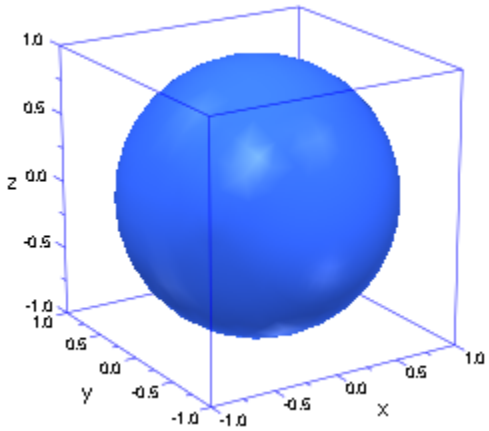
We change the axes color to 'white' via `AxesLineColor`. The titles and the tick labels along the axes do not turn white, automatically, so we choose white font colors as well:
plot(d, AxesLineColor = RGB::White, AxesTitleFont = [RGB::White], TicksLabelFont = [RGB::White], plot::Scene2d::BackgroundColor = RGB::Black)



delete d:

Example 2

We display the axes as a blue box:
plot(plot::Sphere(1, [0, 0, 0]), AxesLineColor = RGB::Blue):



See Also AxesAxesInFrontAxesLineWidthAxesOriginAxesTipsAxesTitleAlignmentAxesTitleFontA

Purpose

AxesLineWidth

Width of the coordinate axes

Value Summary

Inherited	Positive output size

Graphics Primitives

Objects	AxesLineWidth Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	`0.18`

Description

`AxesLineWidth` sets the width for the coordinate axes, the ticks, and the AxesTips. The value should be specified as an absolute physical length including a length unit such as `AxesLineWidth = 0.5*unit::mm`. Numbers without a physical unit give the size in mm.

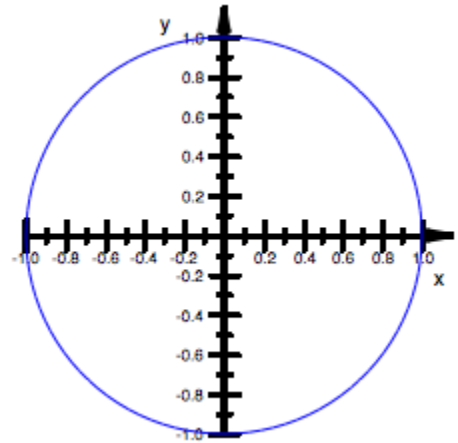
The length of the ticks is not affected by `AxesLineWidth` and can be set separately via TicksLength.

Note that the graphics cannot always react to small changes of the line width because of the discretization into pixels.

Examples

Example 1

We create a graticule with “thick” wiring. Note that LineWidth refers to the circles, whereas `AxesLineWidth` relates to the coordinate axes: plot(plot::Circle2d(1, [0, 0]), TicksDistance = 0.2, TicksLength = 5*unit::mm, LineWidth = 0.5*unit::mm, AxesLineWidth = 1*unit::mm):



See Also AxesAxesInFrontAxesLineColorAxesOriginAxesTipsAxesTitleAlignmentAxesTitleFontAx

Purpose

AxesOriginAxesOriginXAxesOriginYAxesOriginZ

Crosspoint of the coordinate axes

Value Summary

`AxesOrigin`	Library wrapper for "[AxesOriginX, AxesOriginY]" (2D), "[AxesOriginX, AxesOriginY, AxesOriginZ]" (3D)	See below
`AxesOriginX`, `AxesOriginY`, `AxesOriginZ`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`AxesOrigin`: `[0, 0]` `AxesOriginX`, `AxesOriginY`: `0`
plot::CoordinateSystem3d	`AxesOrigin`: `[0, 0, 0]` `AxesOriginX`, `AxesOriginY`, `AxesOriginZ`: `0`

Description

`AxesOrigin` determines the crosspoint of the coordinate axes.

These attributes only have an effect with Axes = `Origin`. The coordinate axes are displayed as a cross.

The vector `AxesOrigin` determines the point where the coordinate axes cross. Depending on the dimension of the scene, it is given by a list of 2 or 3 components.

`AxesOriginX` etc. refer to the x, y, z components of this point.

Note If the crosspoint of the axes is not inside the "viewing box" of the scene, parts of the axes may not be visible.

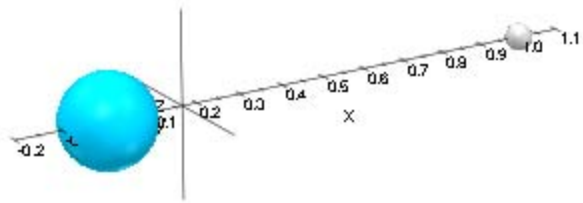
The viewing box may be set explicitly via the attribute ViewingBox. With Axes = `Automatic`, the point given by `AxesOrigin` is ignored; the crosspoint of the axes is chosen automatically inside the viewing box.

Examples

Example 1

We plot two spheres representing a planet with a moon. The coordinate axes cross at their common center of gravity:

```
m1 := 1: x1 := 0: x2 := 1: m2 := 0.2: earth := plot::Sphere(0.1, [x1, 0, 0], FillColor = RGB::SkyBlue): moon := plot::Sphere(0.03, [x2, 0, 0], FillColor = RGB::Grey): plot(earth, moon, Axes = Origin, YTicksNumber = None, ZTicksNumber = None, AxesOrigin = [(m1*x1 + m2*x2)/(m1 + m2), 0, 0], ViewingBox = [-0.2 .. 1.1, -0.2..0.2, -0.2..0.2]):
```



delete m1, m2, x1, x2, earth, moon:

See Also

AxesAxesInFrontAxesLineColorAxesLineWidthAxesTipsAxesTitleAlignmentAxesTitleFor

AxesTips

Purpose

Arrow tips at the coordinate axes?

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	AxesTips Default Values
plot::CoordinateSystem2d	TRUE
plot::CoordinateSystem3d	FALSE

Description

With `AxesTips` = `TRUE`, the coordinate axes are drawn with arrow tips.

This attribute only has an effect with Axes = `Automatic` or Axes = `Origin`. In both cases the coordinate axes are displayed as a cross.

With `AxesTips = TRUE`, little arrows are drawn on the end of the coordinate axes pointing into the positive direction.

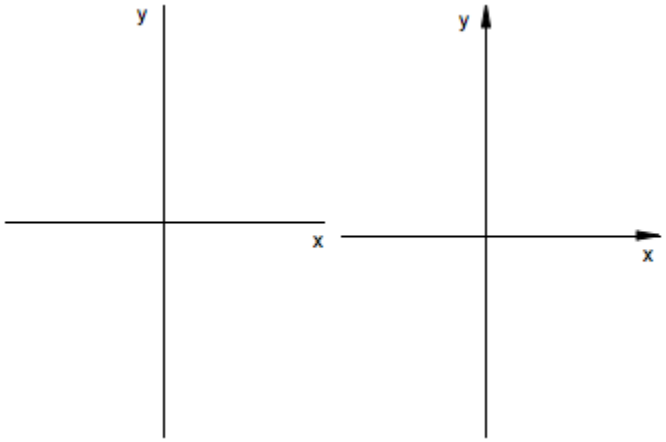
The size of the arrow tips that are displayed as lines is controlled by AxesLineWidth.

`AxesTips = FALSE` suppresses any coordinate axes tips.

Examples

Example 1

In order to emphasize on `AxesTips`, we plot empty scenes. The tick marks are "switched off" via TicksNumber = `None`:
S1 := plot::Scene2d(AxesTips = FALSE): S2 := plot::Scene2d(AxesTips = TRUE): plot(S1, S2, TicksNumber = None, Layout = Horizontal):



S1 := plot::Scene3d(AxesTips = FALSE): S2 := plot::Scene3d(AxesTips = TRUE): plot(S1, S2, Axes = Origin, TicksNumber = None, Layout = Horizontal):

See Also AxesAxesInFrontAxesLineColorAxesLineWidthAxesOriginAxesTitleAlignmentAxesTitleF

Ground

Purpose

AxesTitleAlignmentXAxisTitleAlignmentYAxisTitleAlignmentZAxisTitleAlignment
Alignment of axes titles

Value Summary

`AxesTitleAlignment`	Library wrapper for "{XAxisTitleAlignment, YAxisTitleAlignment}" (2D), "{XAxisTitleAlignment, YAxisTitleAlignment, ZAxisTitleAlignment}" (3D)	See below
`XAxisTitleAlignment`, `YAxisTitleAlignment`, `ZAxisTitleAlignment`	Inherited	`Begin`, Center, or `End`

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`AxesTitleAlignment`, `XAxisTitleAlignment`, `YAxisTitleAlignment`: `End`
plot::CoordinateSystem3d	`AxesTitleAlignment`, `XAxisTitleAlignment`, `YAxisTitleAlignment`, `ZAxisTitleAlignment`: `Center`

Description

`AxesTitleAlginment` governs the alignment of axes titles along the coordinate axes.

With `AxesTitleAlignment = End`, titles for all coordinate axes are displayed at that end of the axes with higher coordinate values.

With `AxesTitleAlignment = Begin`, titles are displayed at that end of the axes with lower coordinate values.

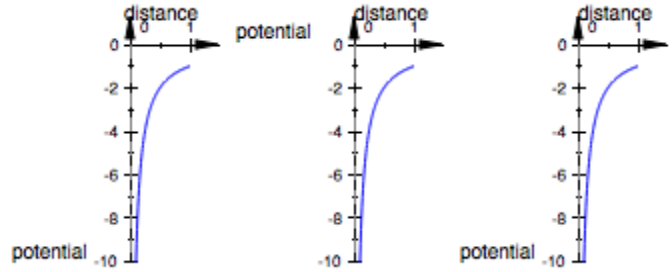
With `AxesTitleAlignment = Center`, titles are centered along the axes.

`XAxisTitleAlignment` etc. allow to set the title alignments separately for each single axis.

Examples

Example 1

We plot the Coulomb potential of a charged particle:
F := plot::Function2d(-1/r, r = 0..1, ViewingBoxYRange = -10..0):
S1 := plot::Scene2d(F, AxesTitles = ["distance", "potential"], XAxisTitleAlignment = Center, YAxisTitleAlignment = Begin):
S2 := plot::Scene2d(F, AxesTitles = ["distance", "potential"], XAxisTitleAlignment = Begin, YAxisTitleAlignment = End):
S3 := plot::Scene2d(F, AxesTitles = ["distance", "potential"], XAxisTitleAlignment = Begin, YAxisTitleAlignment = Begin): plot(S1, S2, S3, Layout = Horizontal, Width = 120*unit::mm, Height = 50*unit::mm):

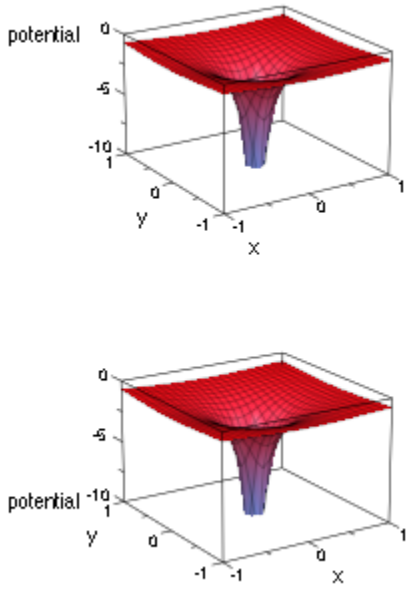


delete F, S1, S2, S3:

Example 2

We use the 3D analogue of the previous example to demonstrate the alignment of axes titles in 3D: :
F := plot::Function3d(-1/sqrt(x^2 + y^2), x = -1..1, y = -1..1, ViewingBoxZRange = -10 .. 0): S1 := plot::Scene3d(F, AxesTitles = ["x", "y", "potential"], XAxisTitleAlignment = Begin, YAxisTitleAlignment = Center, ZAxisTitleAlignment = End): S2 := plot::Scene3d(F, AxesTitles = ["x", "y", "potential"], XAxisTitleAlignment = Center,

YAxisTitleAlignment = End, ZAxisTitleAlignment = Begin): plot(S1, S2, Layout = Vertical, Width = 80*unit::mm, Height = 120*unit::mm):



delete F, S1, S2:

Graphics Primitives

Objects	Default Values

plot::CoordinateSystem2d	`AxesTitles`: `[" x ", " y "]`
	`XAxisTitle`: `" x "`
	`YAxisTitle`: `" y "`

plot::CoordinateSystem3d	`AxesTitles`: `[" x ", " y ", " z "]`
	`XAxisTitle`: `" x "`
	`YAxisTitle`: `" y "`
	`ZAxisTitle`: `" z "`

Description

`AxesTitles` sets the titles attached to the coordinate axes.

Depending on the dimension of the coordinate system, the value of the attribute `AxisTitles` must be a list with two or three strings.

Per default, the coordinate axes titles are `["x", "y"]` in 2D and `["x", "y", "z"]` in 3D regardless of the names of involved parameters.
Cf. “Example 1” on page 24-1354.

Using `AxesTitles`, axes titles can be edited as desired.

With `XAxisTitle` etc., the titles can be edited separately for the different coordinate directions.

Set empty strings `AxesTitles = ["",""]` in 2D or `AxesTitles = ["","",""]` in 3D, respectively, if no axes titles shall be displayed.

Some objects in the MuPAD `plot` library override the default setting via the "hint mechanism" (see the section Primitives Requesting Special Scene Attributes: "Hints" in this document). Whenever such an object is plotted in a scene, the axes titles chosen by the object are used. A complete list of these objects is given further up on this help page.

You can still override these titles via `AxesTitles` etc.

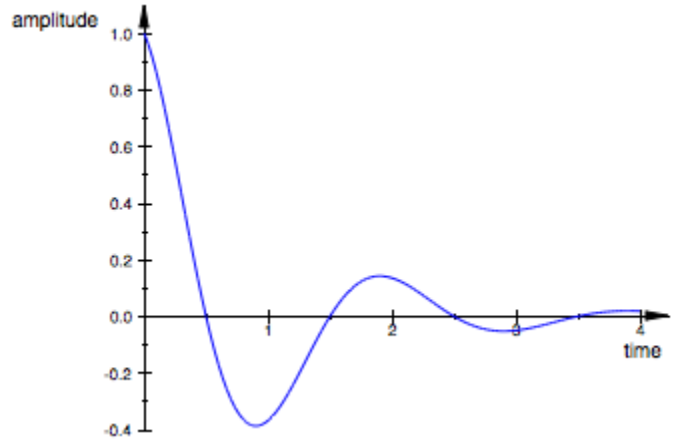
The attribute AxesTitleAlignment can be used to change the default alignment of the titles along the axes.

The attribute YAxisTitleOrientation can be used in 2D to rotate the title of the vertical axis.

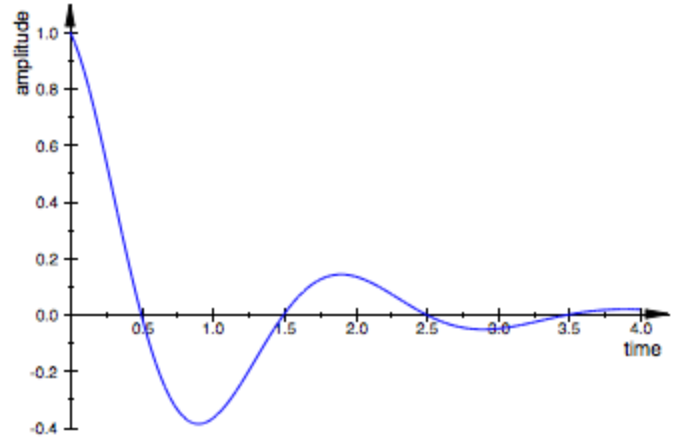
Examples

Example 1

We set appropriate axes titles for a damped vibration given by a plot of the "amplitude over time":
F := plot::Function2d(exp(-t)*cos(PI*t), t = 0 .. 4): plot(F, AxesTitles = ["time", "amplitude"]):



It might be desirable to use the attribute YAxisTitleOrientation to twist the title for the vertical axis:
plot(F, AxesTitles = ["time", "amplitude"], YAxisTitleOrientation = Vertical):



See Also AxesAxesInFrontAxesLineColorAxesLineWidthAxesOriginAxesTipsAxesTitleAlignmentA

Purpose

AxesVisibleXAxisVisibleYAxisVisibleZAxisVisible

Display coordinate axes?

Value Summary

`AxesVisible`	Library wrapper for "{XAxisVisible, YAxisVisible}" (2D), "{XAxisVisible, YAxisVisible, ZAxisVisible}" (3D)	`TRUE`, `FALSE`, or list of 2 or 3 of these, depending on the dimension
`XAxisVisible`, `YAxisVisible`, `ZAxisVisible`	Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`AxesVisible`, `XAxisVisible`, `YAxisVisible`: `TRUE`
plot::CoordinateSystem3d	`AxesVisible`, `XAxisVisible`, `YAxisVisible`, `ZAxisVisible`: `TRUE`

Description

With `AxesVisible` = `TRUE` versus `AxesVisible` = `FALSE` all coordinate axes are "switched on" or "off".

With `XAxisVisible` etc., the coordinate axes in the different coordinate directions can be switched on and off, separately.

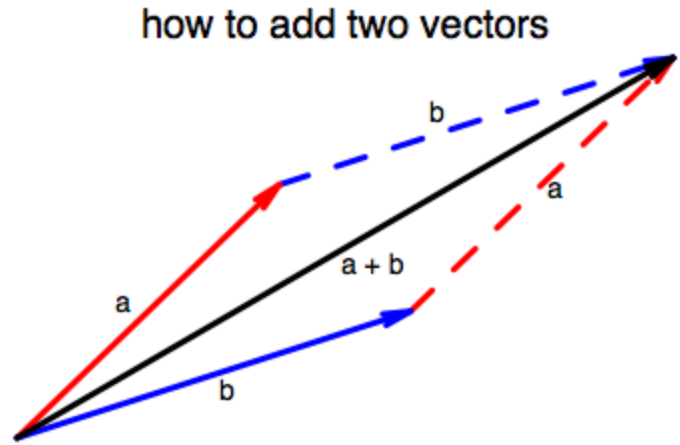
With Axes = `Box`, the coordinate axes are displayed as a box about the scene. With `XAxisVisible = FALSE` etc., the four edges of this box parallel to the respective axis are suppressed.

Alternatively to `AxesVisible = FALSE`, you may switch the axes off by setting Axes = `None`, too.

Examples

Example 1

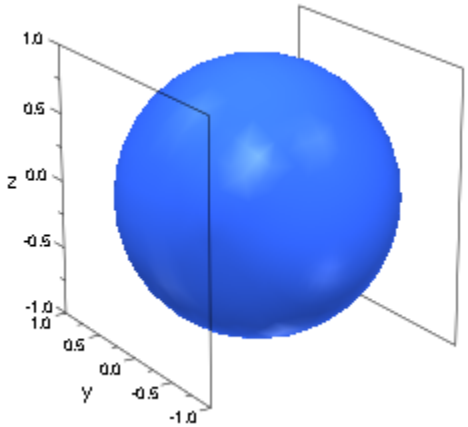
In the following illustration, you probably do not want any axes:
plot(plot::Arrow2d([1.5, 1], [2.5, 3], Title = "a", TitlePosition = [2.05, 1.9], LineStyle = Dashed, Color = RGB::Red), plot::Arrow2d([1, 2], [2.5, 3], Title = "b", TitlePosition = [1.6, 2.5], LineStyle = Dashed, Color = RGB::Blue), plot::Arrow2d([0, 0], [1, 2], Color = RGB::Red, Title = "a", TitlePosition = [0.4, 1.0]), plot::Arrow2d([0, 0], [1.5, 1], Color = RGB::Blue, Title = "b", TitlePosition = [0.8, 0.3]), plot::Arrow2d([0, 0], [2.5, 3], Color = RGB::Black, Title = "a + b", TitlePosition = [1.35, 1.3]), AxesVisible = FALSE, TitleFont = [14], TipLength = 5.0*unit::mm, LineWidth = 1.0*unit::mm, HeaderFont = [20], Header = "how to add two vectors")



Example 2

Using the default axes style Axes = `Box` in 3D, we suppress all parts of the axes box in the *x* direction:
plot(plot::Sphere(1, [0, 0, 0]), XAxisVisible = FALSE):

Ground



See Also AxesAxesInFrontAxesLineColorAxesLineWidthAxesOriginAxesTipsAxesTitleAlignmentAxes

YAxisTitleOrientation

Purpose

Orientation of the vertical axis title in 2D

Value Summary

Inherited	`Horizontal`, or `Vertical`

Graphics Primitives

Objects	YAxisTitleOrientation Default Values
plot::CoordinateSystem2d	`Horizontal`

Description

`YAxisTitleOrientation` determines whether the title of the vertical axis in 2D is plotted horizontally or vertically.

If the title of the vertical axis in 2D is long, it uses up a lot of horizontal space when rendered from left to right with `YAxisTitleOrientation` = Horizontal. This space may be taken away from the drawing region for the graphical objects. In such a case it might be desirable to use `YAxisTitleOrientation = Vertical` to let the title be rendered from bottom to top instead, parallel to the vertical axis.

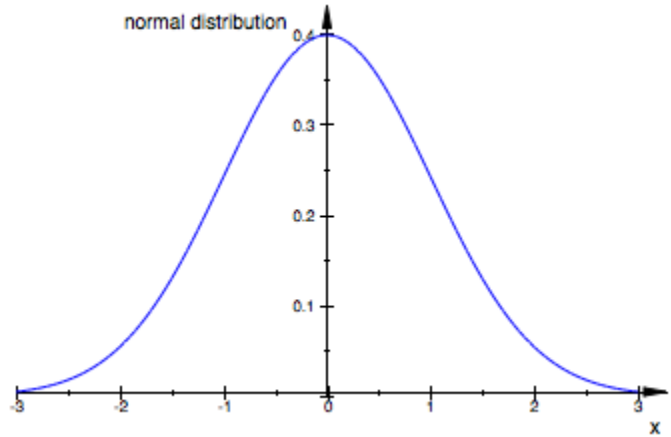
This attribute is ignored in 3D.

Examples

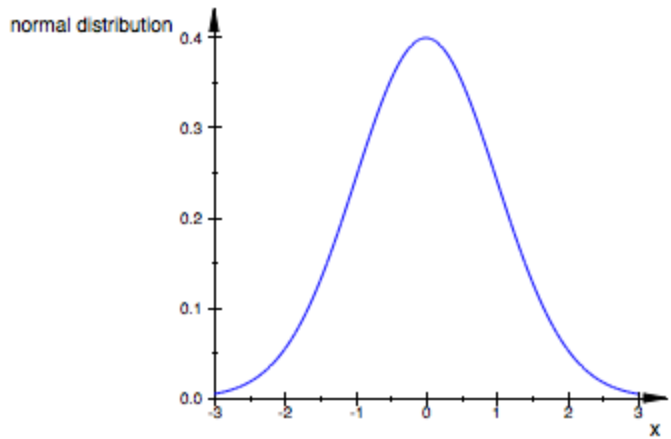
Example 1

We plot the density of the normal distribution function:

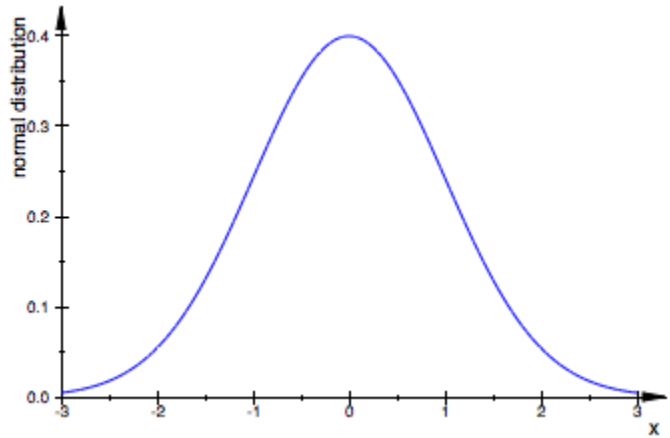
```
f := plot::Function2d(stats::normalPDF(0, 1)(x), x = -3 .. 3): plot(f,
Axes = Automatic, AxesTitles = ["x", "normal distribution"],
YAxisTitleOrientation = Horizontal):
```



There is plenty of room to draw the long title `"normal distribution"`, because the vertical axis is placed in the middle of the plot. In the next plot, however, the vertical axis is flushed left and a lot of space is "wasted" for the axis title:
plot(f, Axes = Frame, AxesTitles = ["x", "normal distribution"], YAxisTitleOrientation = Horizontal):



You make better use of the drawing area by plotting the title of the vertical axis parallel to this axis:
plot(f, Axes = Frame, AxesTitles = ["x", "normal distribution"], YAxisTitleOrientation = Vertical):



delete f:

See Also AxesAxesInFrontAxesLineColorAxesLineWidthAxesOriginAxesTipsAxesTitleAlignmentA

TicksAnchorXTicksAnchorYTicksAnchorZTicksAnchor

Purpose

User defined start of axes tick marks

Value Summary

`TicksAnchor`	Library wrapper for "{XTicksAnchor, YTicksAnchor}" (2D), "{XTicksAnchor, YTicksAnchor, ZTicksAnchor}" (3D)	MuPAD expression
`XTicksAnchor`, `YTicksAnchor`, `ZTicksAnchor`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`TicksAnchor`, `XTicksAnchor`, `YTicksAnchor`: `0`
plot::CoordinateSystem3d	`TicksAnchor`, `XTicksAnchor`, `YTicksAnchor`, `ZTicksAnchor`: `0`

Description

With `TicksAnchor` = t_0, TicksDistance = `d`, the automatic ticks along the coordinate axes are switched off and replaced by equidistant ticks with distance `d` at the positions $t_j = t_0 + jd, j$.

With `TicksAnchor` = t_0, TicksDistance = `d`, these ticks are used for all coordinate axes.

With `XTicksAnchor` = t_0, XTicksDistance = `d` etc., these ticks may be defined separately for each single coordinate axis.

When executing a plot command, per default a "reasonable" placing for tick marks on coordinate axes is automatically computed. Through this process tick marks may not come to lie on desired positions. The attributes `TicksAnchor` and TicksDistance allow to generate an alternative mesh of equidistant tick marks.

Note The attributes `TicksAnchor`, `XTicksAnchor` etc. only have an effect when a positive distance $d > 0$ between major ticks marks is set explicitly via TicksDistance = `d`, XTicksDistance = `d` etc.

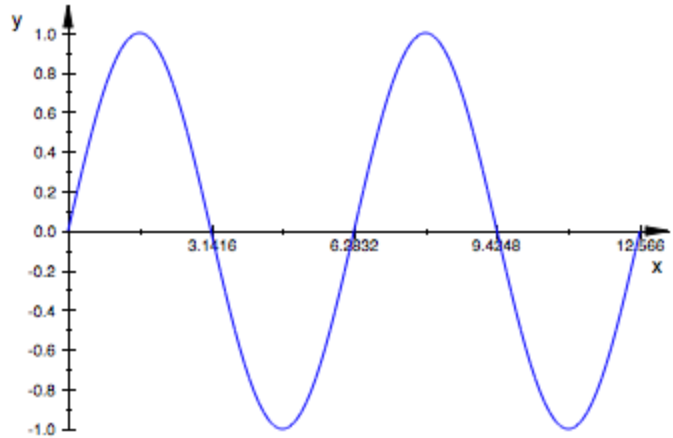
The ticks set by `TicksAnchor` and `TicksDistance` are "major" tick marks bearing labels. Depending on the value of TicksBetween, there may be additional "minor" ticks without labels between each pair of major tick marks.

Additional tick marks at specific positions can be inserted with TicksAt.

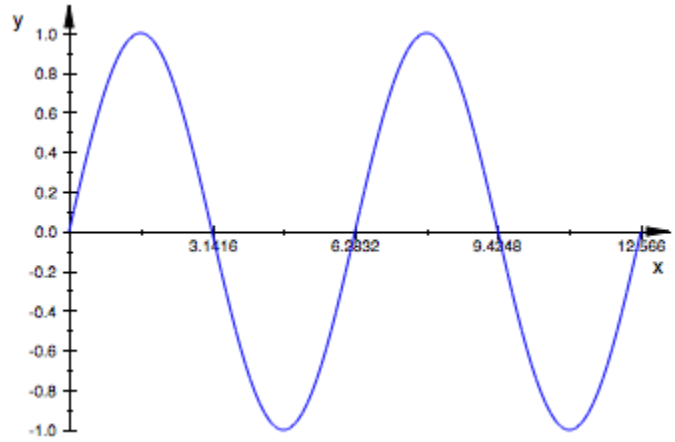
Examples

Example 1

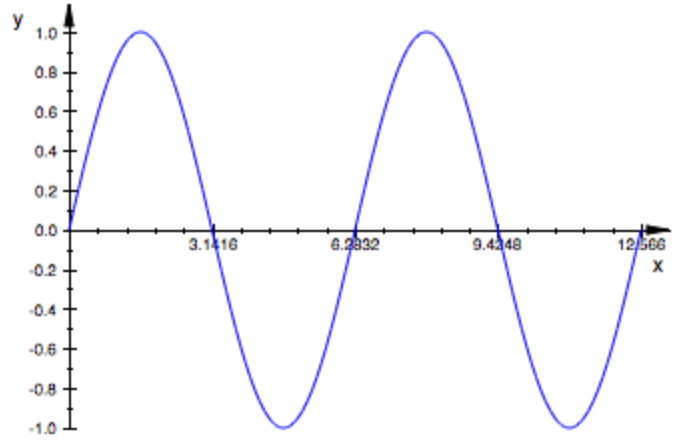
For the following plot of the sine function, the tick marks along the x-axis are chosen to match the period:
plot(plot::Function2d(sin(x), x = 0..4*PI), XTicksAnchor = 0, XTicksDistance = PI):



The ticks along the y-axis are re-defined with a distance of 0.2:
plot(plot::Function2d(sin(x), x = 0..4*PI), XTicksAnchor = 0, XTicksDistance = PI, YTicksAnchor = 0, YTicksDistance = 0.2):



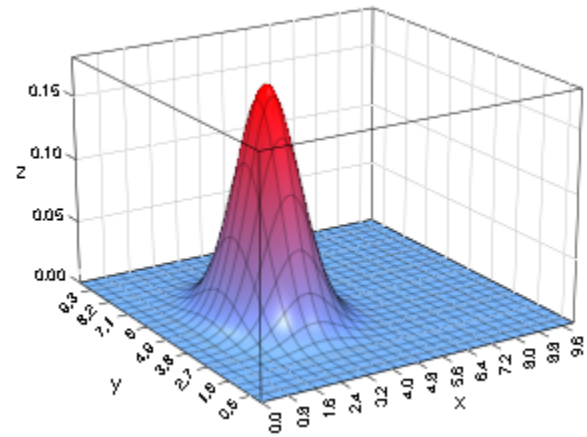
We increase the number of "minor" ticks along the *x*-axis: plot(plot::Function2d(sin(x), x = 0..4*PI), XTicksAnchor = 0, XTicksDistance = PI, XTicksBetween = 4, YTicksAnchor = 0, YTicksDistance = 0.2):



Example 2

We plot the two-dimensional normal distribution centered around the mean (m_1, m_2) = (3.2, 4.9). This point is used as the anchor for the tick marks along the x-axis and the y-axis, respectively. Ticks are positioned at distances that are integer multiples of the standard deviations (s_1, s_2) = (0.8, 1.2):

```
m1:= 3.2: s1 := 0.8: m2:= 4.9: s2 := 1.1: plot(plot::Function3d(
stats::normalPDF(m1, s1^2)(x) *stats::normalPDF(m2, s2^2)(y), x = 0
.. 10, y = 0 .. 10, Submesh = [3, 3]), TicksBetween = 0, XTicksAnchor
= m1, XTicksDistance = s1, YTicksAnchor = m2, YTicksDistance = s2,
XTicksLabelStyle = Vertical, YTicksLabelStyle = Diagonal, GridVisible
= TRUE):
```



delete m1, s1, m2, s2:

See Also TicksAtTicksBetweenTicksDistanceTicksLabelFontTicksLabelStyleTicksLabelsVisibleTic

Purpose

TicksAtXTicksAtYTicksAtZTicksAt

Special axes tick marks

Value Summary

`TicksAt`	Library wrapper for "[XTicksAt, YTicksAt]" (2D), "[XTicksAt, YTicksAt, ZTicksAt]" (3D)	See below
`XTicksAt`, `YTicksAt`, `ZTicksAt`	Optional	See below

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	

Description

`XTicksAt = [`x_1`, `x_2`, ]` allows to set additional tick marks on the *x*-axis at the positions x_1, x_2 etc. With `XTicksAt = [`x_1` = `L_1`, `x_2` = `L_2`, ]`, the special tick marks at the positions x_1, x_2 etc. are labeled with the strings L_1, L_2 etc.

`YTicksAt`, `ZTicksAt` work analogously for the other coordinate directions.

`TicksAt = [[`x_1`, `x_2`, ], [`y_1`, `y_2`, ]]` in 2D and `TicksAt = [[`x_1`, `x_2`, ], [`y_1`, `y_2`, ], [`z_1`, `z_2`, ]]` in 3D serve as shortcuts for setting `XTicksAt`, `YTicksAt` etc.

Per default, equidistant tick marks along the coordinate axes are chosen automatically.

With `XTicksAt = [`x_1`, `x_2`, ]`, *additional* tick marks are inserted along the *x*-axis at arbitrary positions x_1, x_2 etc. These values must be numbers or exact numerical expressions such as PI or `sqrt(2)` that can be converted to floating-point numbers via float.

The special ticks set by `XTicksAt` are labeled automatically by floating-point numbers approximating x_1, x_2 etc.

Special labels for these ticks may be requested by replacing the coordinate values x_1, x_2 etc. by equations $x_1 = L_1$, $x_2 = L_2$ etc., where L_1, L_2 etc. are strings to be used as the labels. Note that MuPAD strings have to be enclosed by the string delimiters `"`. For example, `XTicksAt = [3.14 = "pi"]` adds a single tick as the position $x = 3.14$ with the label `pi`. Cf. "Example 1" on page 24-1367.

With `YTicksAt = [`y_1`, `y_2`, ]` or `YTicksAt = [`$y_1 = L_1$`, `$y_2 = L_2$`, ]` etc., special ticks can be inserted along the y-axis.

In 3D, `ZTicksAt` allows to insert special ticks along the z-axis.

If no automatic tick marks are desired, set TicksNumber = `None` or XTicksNumber = `None` etc. to switch them off on all coordinate axes or on single coordinate axes, respectively.

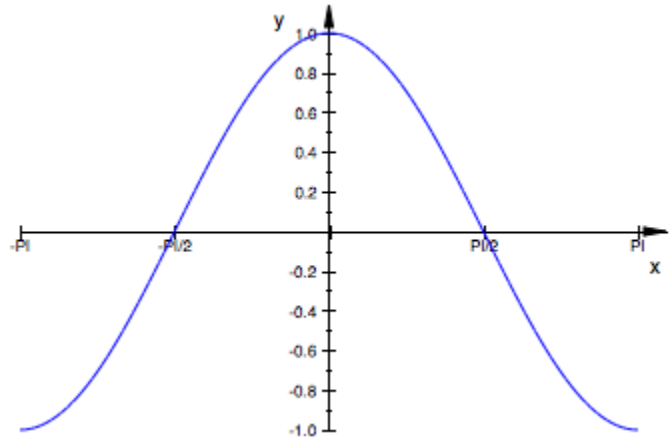
Use `TicksAt`, `XTicksAt` etc. to set alternative tick marks.

Examples

Example 1

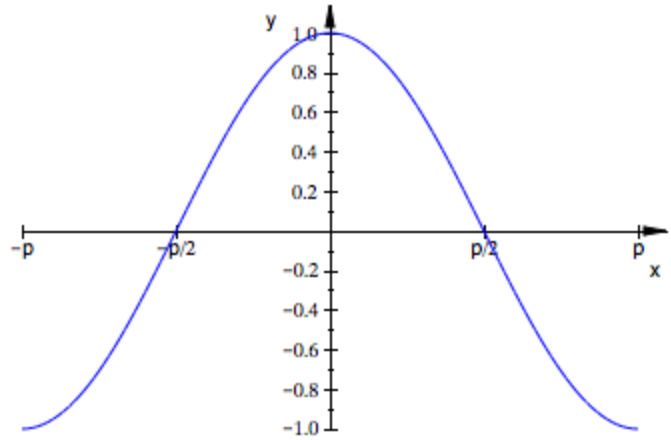
We plot the cosine function. The automatic tick marks along the x-axis are suppressed via XTicksNumber = `None`. Points of special interest such as the extrema and the zeroes of the function are set as special tick marks:

```
plot(plot::Function2d(cos(x), x = -PI..PI), XTicksNumber = None,
XTicksAt = [-PI = "-PI", -PI/2 = "-PI/2", 0 = "0", PI/2 = "PI/2", PI = "PI"])
```



We improve the labeling of the tick marks by using the font `Symbol`. This font allows to typeset Greek characters such as π, addressed by the character `"p"`:

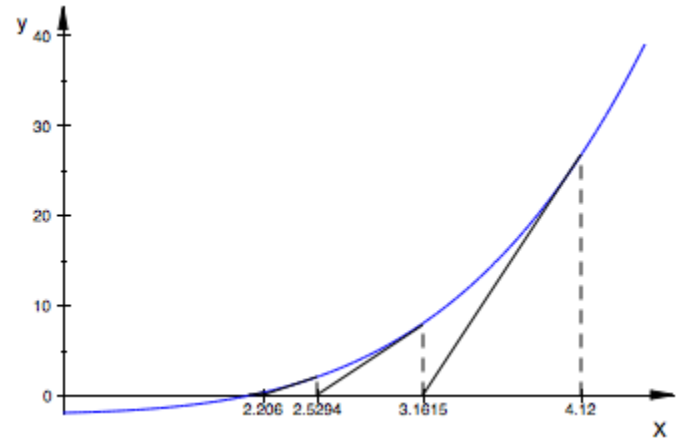
```
plot(plot::Function2d(cos(x), x = -PI..PI), XTicksNumber = None,
TicksLabelFont = ["Symbol"], XTicksAt = [-PI = "-p", -PI/2 = "-p/2", 0 =
"0", PI/2 = "p/2", PI = "p"]):
```



Example 2

The Newton iteration x[(i+1)]=x[i]-f(x[i])/f'(x[i]) $x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)}$ finds successive approximations to a zero of a function $f(x)$. We switch the automtic ticks along the x-axis off via XTicksNumber = `None` and display some elements of the Newton sequence as tick marks:

```
f := x -> x^4/10 - 2: x[0] := 4.12: for i from 0 to 3 do x[i + 1] :=
x[i] - f(x[i])/f'(x[i]); end_for: plot(plot::Function2d(f(X), X = 1..4.5),
plot::Line2d([x[i], f(x[i])], [x[i+1], 0], Color = RGB::Black) $ i = 0..3,
plot::Line2d([x[i], 0], [x[i], f(x[i])], Color = RGB::Black, LineStyle =
Dashed) $ i = 0..4, XTicksNumber = None, XTicksAt = [x[i] $ i = 0..3])
```



delete f, x, i:

See Also TicksAnchorTicksBetweenTicksDistanceTicksLabelFontTicksLabelStyleTicksLabelsVisib

Purpose

TicksBetweenXTicksBetweenYTicksBetweenZTicksBetween

Number of minor (unlabeled) axes tick marks between major (labeled) axes tick marks

Value Summary

`TicksBetween`	Library wrapper for "{XTicksBetween, YTicksBetween}" (2D), "{XTicksBetween, YTicksBetween, ZTicksBetween}" (3D)	Non-negative integer
`XTicksBetween`, `YTicksBetween`, `ZTicksBetween`	Inherited	Non-negative integer

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`TicksBetween`, `XTicksBetween`, `YTicksBetween`: `1`
plot::CoordinateSystem3d	`TicksBetween`, `XTicksBetween`, `YTicksBetween`, `ZTicksBetween`: `1`

Description

The tick marks along the coordinate axes consist of "major" tick marks bearing labels and of "minor" tick marks without labels.

`TicksBetween` sets the number of minor ticks between each pair of major ticks for all coordinate axes.

With `XTicksBetween` etc., the number of minor ticks may be set separately for each single coordinate axis.

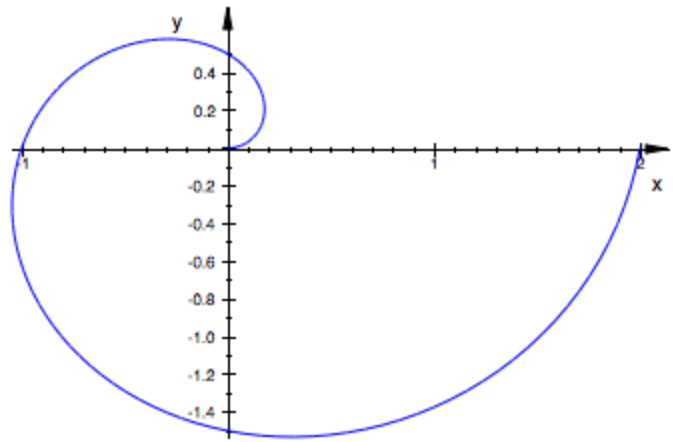
Per default between every two major tick marks one minor tick mark is rendered. Via `TicksBetween` this number can be increased or set to zero. In contrast to major tick marks, minor tick marks are never labelled.

Minor tick marks are rendered always with half the length of the major tick marks. Cf. TicksLength.

Examples

Example 1

We request few "major" tick marks in the *x* direction and place 9 "minor" tick marks between each pair. The ticks in *y* direction are chosen automatically:
plot(plot::Curve2d([u*cos(u*PI), u*sin(u*PI)], u = 0..2), XTicksNumber = Low, XTicksBetween = 9)



Example 2

We request few "major" tick marks in all directions. In the horizontal directions, we place 4 "minor" tick marks between each pair. The ticks in *z* direction consist of the the labeled ticks only:
plot(plot::Function3d(exp(-x^2 - y^2), x = -3..3, y = -3..3, Submesh = [2, 2]), TicksNumber = Low, XTicksBetween = 4, YTicksBetween = 4, ZTicksBetween = 0, GridVisible = TRUE)

Ground

Purpose

TicksDistanceXTicksDistanceYTicksDistanceZTicksDistance

User defined axes tick mark distance

Value Summary

`TicksDistance`	Library wrapper for "{XTicksDistance, YTicksDistance}" (2D), "{XTicksDistance, YTicksDistance, ZTicksDistance}" (3D)	MuPAD expression
`XTicksDistance`, `YTicksDistance`, `ZTicksDistance`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`TicksDistance`, `XTicksDistance`, `YTicksDistance`: `0`
plot::CoordinateSystem3d	`TicksDistance`, `XTicksDistance`, `YTicksDistance`, `ZTicksDistance`: `0`

Description

With `TicksAnchor = t0`, `TicksDistance = d`, the automatic ticks along the coordinate axes are switched off and replaced by equidistant ticks with distance `d` at the positions $t_j = t_0 + jd, j$.

With `TicksAnchor = t0`, `TicksDistance = d`, these ticks are used for all coordinate axes.

With `XTicksAnchor = t0`, `XTicksDistance = d` etc., these ticks may be defined separately for each single coordinate axis.

When executing a plot command, per default a “reasonable” placing for tick marks on coordinate axes is automatically computed. Through this process tick marks may not come to lie on desired positions. The attributes TicksAnchor and `TicksDistance` allow to generate an alternative mesh of equidistant tick marks.

Note The attributes TicksAnchor, XTicksAnchor etc. only have an effect when a positive distance $d > 0$ between major ticks marks is set explicitly via `TicksDistance = d`, `XTicksDistance = d` etc.

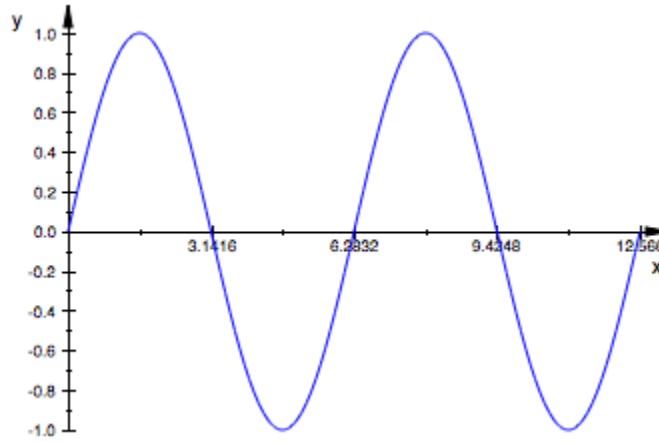
The ticks set by TicksAnchor and `TicksDistance` are “major” tick marks bearing labels. Depending on the value of TicksBetween, there may be additional “minor” ticks without labels between each pair of major tick marks.

Additional tick marks at specific positions can be inserted with TicksAt.

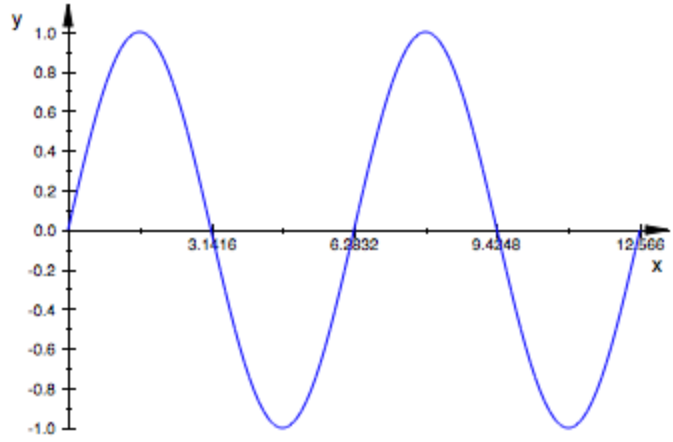
Examples

Example 1

For the following plot of the sine function, the tick marks along the x-axis are chosen to match the period:
plot(plot::Function2d(sin(x), x = 0..4*PI), XTicksAnchor = 0, XTicksDistance = PI):

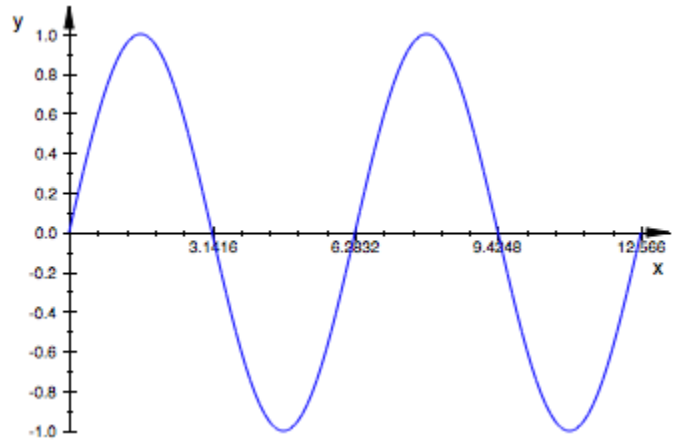


The ticks along the *y*-axis are re-defined with a distance of 0.2:
plot(plot::Function2d(sin(x), x = 0..4*PI), XTicksAnchor = 0,
XTicksDistance = PI, YTicksAnchor = 0, YTicksDistance = 0.2):



We increase the number of “minor” ticks along the *x*-axis:

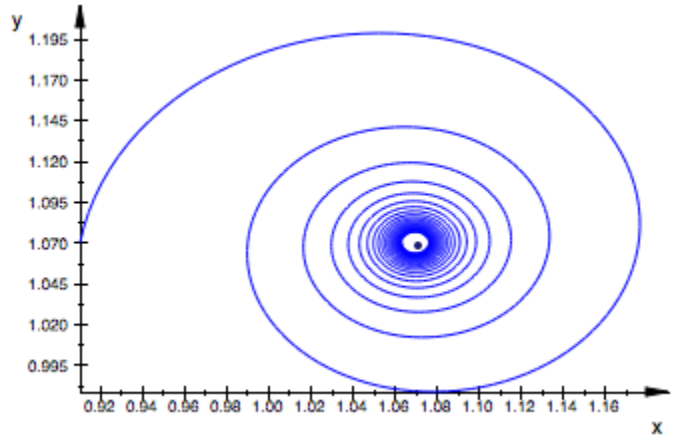
plot(plot::Function2d(sin(x), x = 0..4*PI), XTicksAnchor = 0, XTicksDistance = PI, XTicksBetween = 4, YTicksAnchor = 0, YTicksDistance = 0.2):



Example 2

We plot a hyperbolic spiral about the point `(1.07, 1.07)` which is not included in the automatic tick marks. We increase the number of ticks along the vertical axis and position the ticks relative to this point. Note that the tick marks along the horizontal axis miss the center of the spiral:

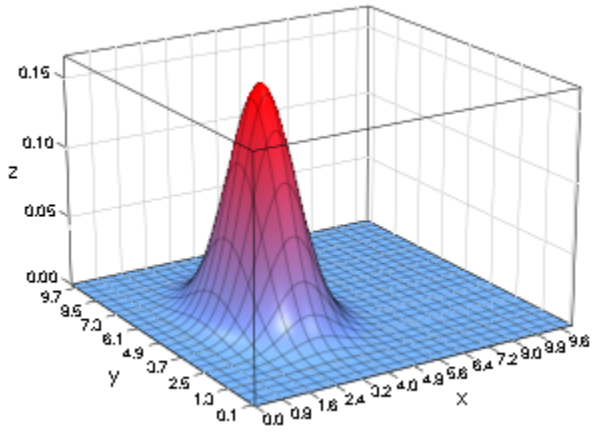
plot(plot::Point2d(1.07, 1.07), plot::Curve2d([1.07 - cos(t)/t, 1.07 + sin(t)/t], t = 2*PI..50*PI, Submesh = 20), YTicksDistance = 0.025, YTicksAnchor = 1.07)



Example 3

We plot the two-dimensional normal distribution centered around the mean $(m_1, m_2) = (3.2, 4.9)$. This point is used as the anchor for the tick marks along the x-axis and the y-axis, respectively. Ticks are positioned at distances that are integer multiples of the standard deviations $(s_1, s_2) = (0.8, 1.2)$:

```
m1:= 3.2: s1 := 0.8: m2:= 4.9: s2 := 1.2: plot(plot::Function3d(
stats::normalPDF(m1, s1^2)(x) *stats::normalPDF(m2, s2^2)(y), x = 0 ..
10, y = 0 .. 10, Submesh = [3, 3]), XTicksAnchor = m1, XTicksDistance
= s1, YTicksAnchor = m2, YTicksDistance = s2, TicksBetween = 0,
GridVisible = TRUE):
```



delete m1, s1, m2, s2:

See Also TicksAnchorTicksAtTicksBetweenTicksLabelFontTicksLabelStyleTicksLabelsVisibleTicksLen

Purpose

TicksLabelStyleXTicksLabelStyleYTicksLabelStyleZTicksLabelStyle
Display style of axes tick labels

Value Summary

`TicksLabelStyle`	Library wrapper for "{XTicksLabelStyle, YTicksLabelStyle}" (2D), "{XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle}" (3D)	See below
`XTicksLabelStyle`, `YTicksLabelStyle`, `ZTicksLabelStyle`	Inherited	`Diagonal`, `Horizontal`, `Shifted`, or `Vertical`

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`TicksLabelStyle`, `XTicksLabelStyle`, `YTicksLabelStyle`: `Horizontal`
plot::CoordinateSystem3d	`TicksLabelStyle`, `XTicksLabelStyle`, `YTicksLabelStyle`, `ZTicksLabelStyle`: `Horizontal`

Description

`TicksLabelStyle` allows to modify the display style of the tick labels on all coordinate axes.

`XTicksLabelStyle` etc. allow to set the label styles separately for each single coordinate axis.

It may occur that tick labels overlap if too many tick marks along the coordinate axes are requested. The following styles for the tick labels are available to deal with this problem:

`Horizontal`: The labels are displayed in the usual horizontal reading order from left to right.

`Vertical`: The labels are tilted 90 degrees counter clockwise, i.e., they have to be read from bottom to top.

`Diagonal`: The labels are tilted 45 degrees counter clockwise.

`Shifted`: Each second label is shifted to avoid overlapping.

Note that also in 3D the orientation `Horizontal`, `Diagonal`, `Vertical` refers to the screen output irrespectively of the 3D orientation of the corresponding axis.

`TicksLabelStyle` sets the display style for the ticks labels along *all* coordinate axes.

With `XTicksLabelStyle` etc. the style may be set separately for each single axis.

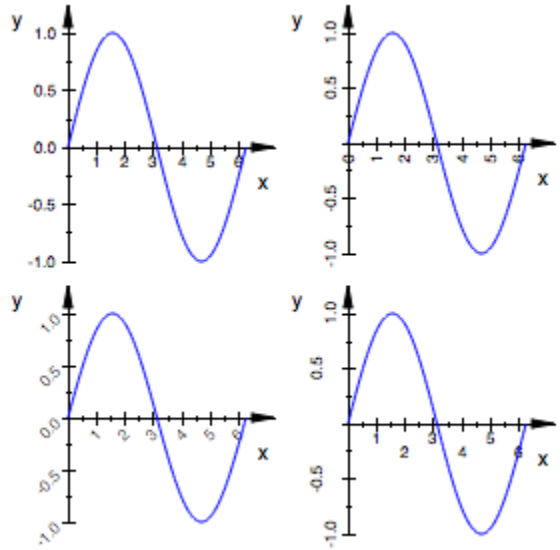
Independently from `TicksLabelStyle`, the titles of the axes are rendered horizontally. In 2D, the attribute YAxisTitleOrientation is available to tilt the title of the vertical axis by 90 degrees.

Examples

Example 1

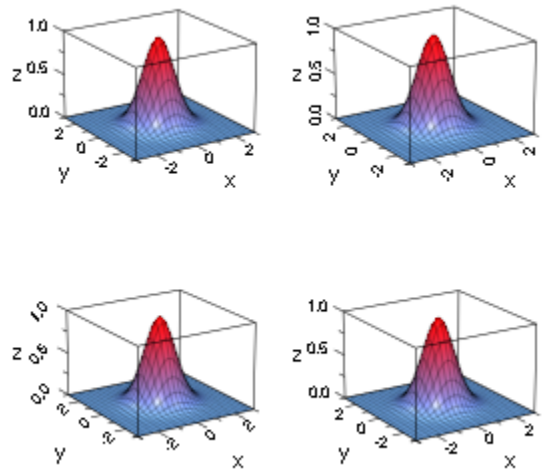
We demonstrate the styles for the ticks labels:

```
f := plot::Function2d(sin(x), x = 0 .. 2*PI): S1 := plot::Scene2d(f, TicksLabelStyle = Horizontal): S2 := plot::Scene2d(f, TicksLabelStyle = Vertical): S3 := plot::Scene2d(f, TicksLabelStyle = Diagonal): S4 := plot::Scene2d(f, TicksLabelStyle = Shifted): plot(S1, S2, S3, S4, Height = 10*unit::cm, Width = 10*unit::cm):
```



Here is a corresponding picture in 3D:

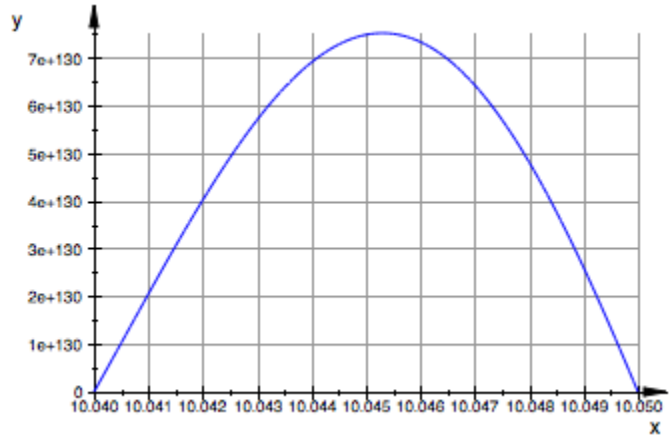
```
f := plot::Function3d(exp(-x^2 - y^2), x = -3..3, y = -3..3, Submesh =
[2, 2]): S1 := plot::Scene3d(f, TicksLabelStyle = Horizontal): S2 :=
plot::Scene3d(f, TicksLabelStyle = Vertical): S3 := plot::Scene3d(f,
TicksLabelStyle = Diagonal): S4 := plot::Scene3d(f, TicksLabelStyle
= Shifted): plot(S1, S2, S3, S4, Height = 10*unit::cm, Width =
10*unit::cm):
```



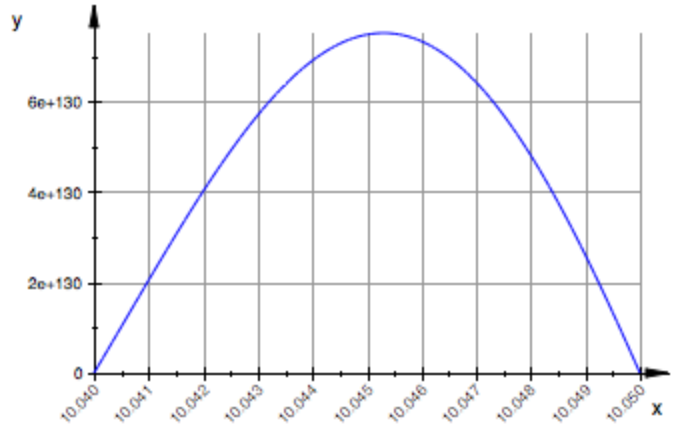
delete f, S1, S2, S3, S4:

Example 2

The tick labels along the *x*-axis nearly collide in the following plot:
f := plot::Function2d(exp(30*x)*sin(x*100*PI), x = 10.04 .. 10.05): plot(f, GridVisible = TRUE, XTicksNumber = High):



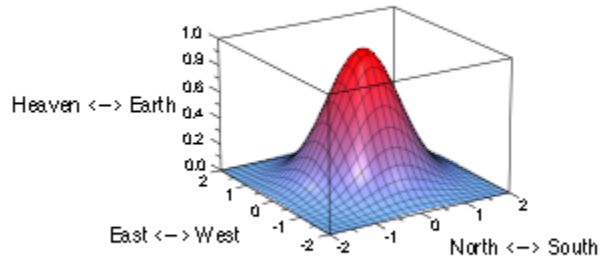
Tilting the labels yields a more tidy looking graphics:
plot(f, GridVisible = TRUE, XTicksNumber = High, XTicksLabelStyle = Diagonal):



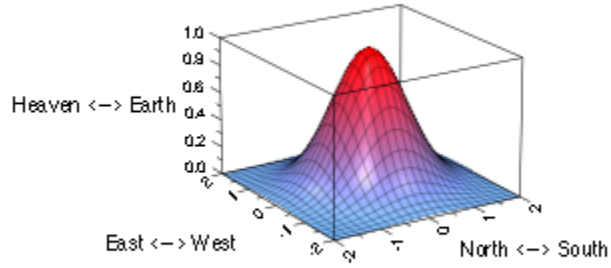
Example 3

In the following graphics, there is not enough space to squeeze in the requested high number of ticks in the *x* and *y* direction:

plot(plot::Function3d(exp(-x^2 - y^2), x = -2..2, y = -2..2, Submesh = [2, 2]), TicksNumber = High, AxesTitles = ["North <--> South", "East <--> West", "Heaven <--> Earth"]):



The tick labels fit with `Vertical` and `Diagonal` orientation: plot(plot::Function3d(exp(-x^2 - y^2), x = -2..2, y = -2..2, Submesh = [2, 2]), TicksNumber = High, XTicksLabelStyle = Vertical, YTicksLabelStyle = Diagonal, ZTicksLabelStyle = Horizontal, AxesTitles = ["North <--> South", "East <--> West", "Heaven <--> Earth"]):



See Also TicksAnchorTicksAtTicksBetweenTicksDistanceTicksLabelFontTicksLabelsVisibleTicksL

Purpose

TicksLength

Length of axes tick marks

Value Summary

Inherited	Positive output size

Graphics Primitives

Objects	TicksLength Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	2

Description

The tick marks along the coordinate axes consist of “major” tick marks bearing labels and of “minor” tick marks without labels.

`TicksLength` sets the length for the major tick marks on all coordinate axes. The length of minor tick marks (cf. TicksBetween) is half of `TicksLength` .

The value should be specified as an absolute physical length including a length unit such as `TicksLength = 2.5*unit::mm`. Numbers without a physical unit give the length in mm.

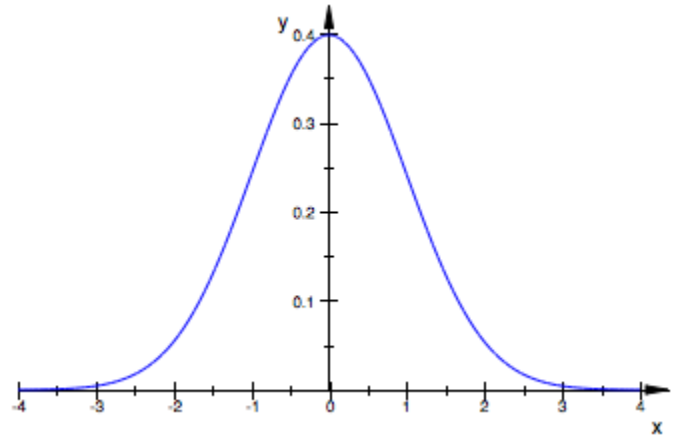
`TicksLength` sets the length of automatic tick marks (cf. TicksNumber) as well of special tick marks set via TicksAt.

It is not possible to change the length of tick marks on any single axis alone.

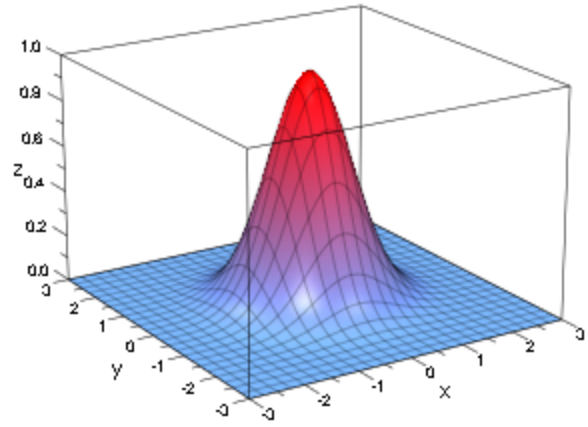
Examples

Example 1

We plot the density of the standard normal distribution. Compared to the default length of 2 mm, the ticks length is increased by 50%:
plot(plot::Function2d(stats::normalPDF(0, 1)(x), x = -4..4), TicksLength = 3*unit::mm):

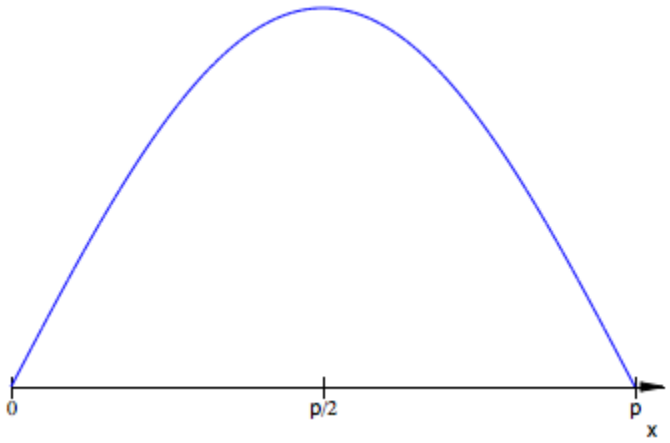


A corresponding plot in 3D:
plot(plot::Function3d(exp(-x^2 - y^2), x = -3..3, y = -3..3, Submesh = [2, 2]), TicksLength = 3*unit::mm)



Example 2

In the following plot of the sine function, we switch the automatic tick marks along the *x*-axis off via XTicksNumber = `None`. Some extra ticks are set via XTicksAt:
plot(plot::Function2d(sin(x), x = 0 .. PI), XTicksAt = [0 = "0", PI/2 = "p/2", PI = "p"], XTicksNumber = None, TicksLength = 4*unit::mm, TicksLabelFont = ["Symbol"], YAxisVisible = FALSE)



See Also TicksAnchorTicksAtTicksBetweenTicksDistanceTicksLabelFontTicksLabelStyleTicksLabelsV

Purpose

TicksNumberXTicksNumberYTicksNumberZTicksNumber
Number of axes tick marks

Value Summary

`TicksNumber`	Library wrapper for "{XTicksNumber, YTicksNumber}" (2D), "{XTicksNumber, YTicksNumber, ZTicksNumber}" (3D)	See below
`XTicksNumber`, `YTicksNumber`, `ZTicksNumber`	Inherited	`High`, `Low`, `None`, or Normal

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`TicksNumber`, `XTicksNumber`, `YTicksNumber`: `Normal`
plot::CoordinateSystem3d	`TicksNumber`, `XTicksNumber`, `YTicksNumber`, `ZTicksNumber`: `Normal`

Description

`TicksNumber` directs the internal routine that chooses tick marks along coordinate axes to produce no, few, or many ticks.

With `XTicksNumber` etc., the number of tick marks can be controlled separately for each single axis.

The tick marks along the coordinate axes consist of "major" tick marks bearing labels and of "minor" tick marks without labels.

The attributes `TicksNumber`, `XTicksNumber` etc. only refer to the labeled "major" tick marks. The "minor" tick marks are governed by the attribute TicksBetween.

Automatically generated equidistant tick marks are displayed along the coordinate axes, unless the user specifies the ticks explicitly via the attributes TicksAnchor and TicksDistance.

`TicksNumber` provides a hint for the automatic computation process, how many tick marks are to be displayed. The possible values are `None`, `Low`, `Normal`, and `Many`.

With `XTicksNumber` etc., ticks numbers may be controlled separately for each single axis.

If equidistant tick marks are set explicitly via TicksAnchor and TicksDistance, the attributes `TicksNumber`, `XTicksNumber` etc. are ignored.

There is no influence on special tick marks set via TicksAt, XTicksAt etc. either.

With `TicksNumber` = `None`, `XTicksNumber` = `None` etc., no automatically generated tick marks are displayed.

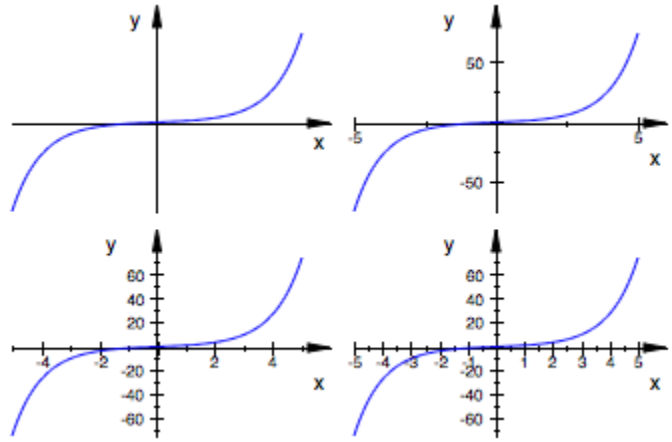
Tick marks may also be suppressed via TicksVisible = `FALSE`, XTicksVisible = `FALSE` etc. However, in contrast to `TicksNumber` = `None`, `XTicksNumber` = `None` etc., this also suppresses equidistant tick marks set explicitly via TicksAnchor, TicksDistance as well as special tick marks set via TicksAt, XTicksAt etc.

Examples

Example 1

We demonstrate the effect of various `TicksNumber` values:

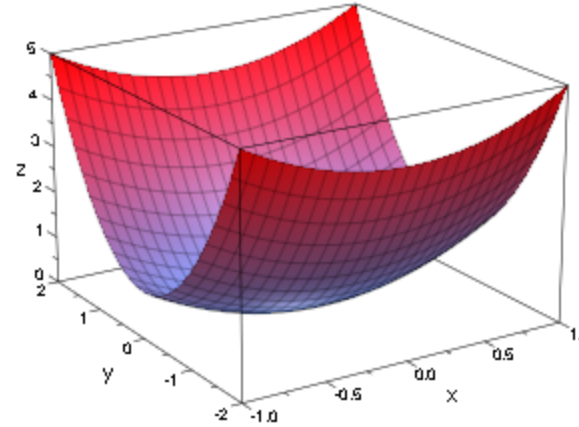
```
f := plot::Function2d(sinh(x), x = -5 .. 5): S1 := plot::Scene2d(f,
TicksNumber = None): S2 := plot::Scene2d(f, TicksNumber = Low):
S3 := plot::Scene2d(f, TicksNumber = Normal): S4 := plot::Scene2d(f,
TicksNumber = High): plot(S1, S2, S3, S4):
```



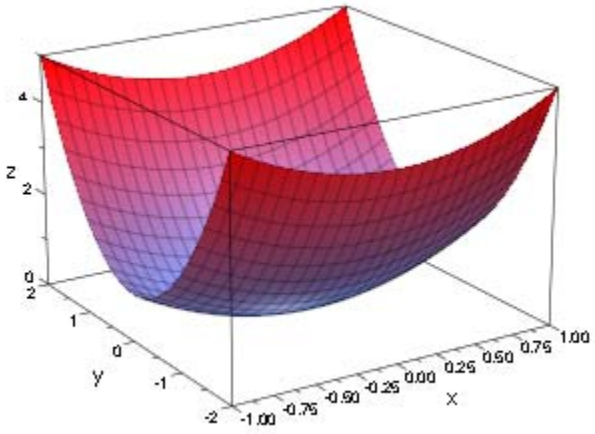
delete f, S1, S2, S3, S4:

Example 2

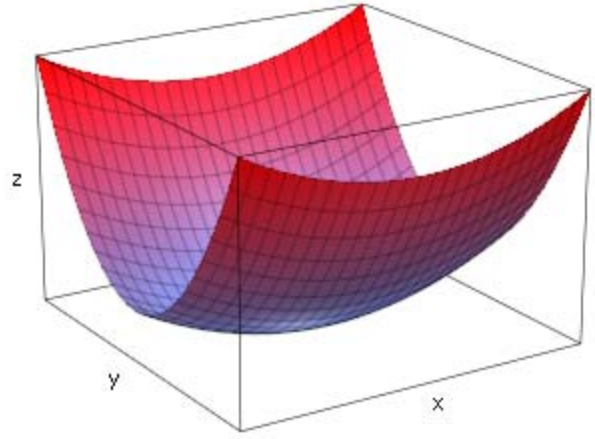
We demonstrate the effect of various `TicksNumber` values in a 3D plot:
s := plot::Function3d(x^2 + y^2, x = -1..1, y = -2..2): plot(s):



plot(s, XTicksNumber = High, YTicksNumber = Normal, ZTicksNumber = Low):



All tick marks are suppressed:
plot(s, TicksNumber = None)



delete s:

See Also TicksAnchorTicksAtTicksBetweenTicksDistanceTicksLabelFontTicksLabelStyleTicksLabelsV

Purpose

TicksVisibleXTicksVisibleYTicksVisibleZTicksVisible

Display axes tick marks?

Value Summary

`TicksVisible`	Library wrapper for "{XTicksVisible, YTicksVisible}" (2D), "{XTicksVisible, YTicksVisible, ZTicksVisible}" (3D)	`TRUE`, `FALSE`, or list of 2 or 3 of these, depending on the dimension
`XTicksVisible`, `YTicksVisible`, `ZTicksVisible`	Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`TicksVisible`, `XTicksVisible`, `YTicksVisible`: `TRUE`
plot::CoordinateSystem3d	`TicksVisible`, `XTicksVisible`, `YTicksVisible`, `ZTicksVisible`: `TRUE`

Description

`TicksVisible = TRUE` versus `TicksVisible = FALSE` switches tick marks along all coordinate axes on or off.

With `XTicksVisible = TRUE/FALSE` etc., the tick marks can be switched on or off separately for each single axis.

With `TicksVisible = FALSE`, the tick marks along all coordinate axes are switched off. The labels of the tick marks, however, remain visible.

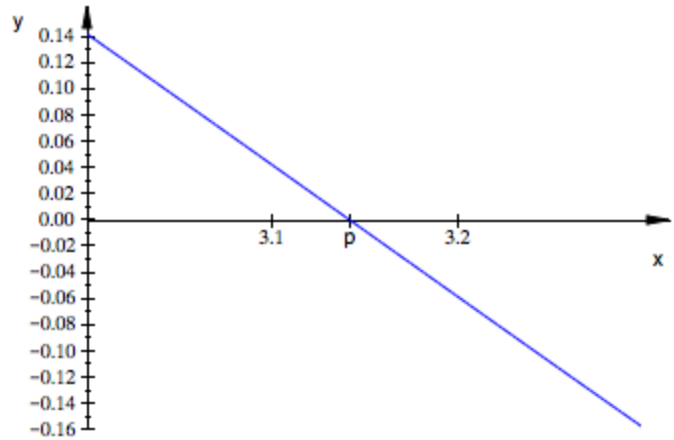
`TicksVisible` etc. refers to automatically generated tick marks (cf. TicksNumber), to equidistant tick marks that are requested explicitly via TicksAnchor, TicksDistance as well as to special tick marks set via TicksAt.

Ticks can also be suppressed via `TicksNumber = None`, `XTicksNumber = None` etc. In contrast to `TicksVisible = FALSE`, however, this affects only the automatically generated ticks and their labels. Ticks set by TicksAnchor, TicksDistance, TicksAt are not affected.

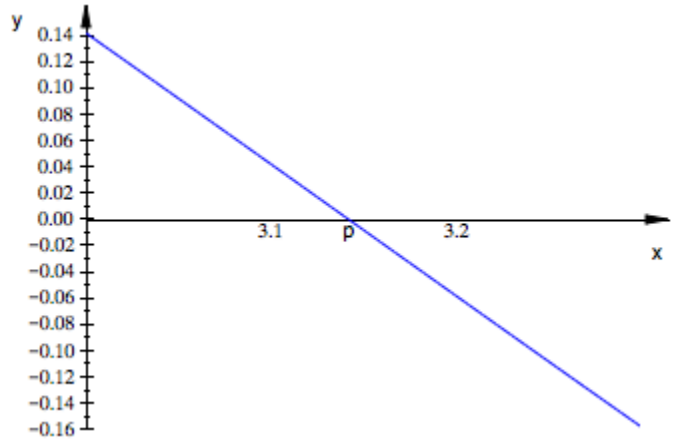
Examples

Example 1

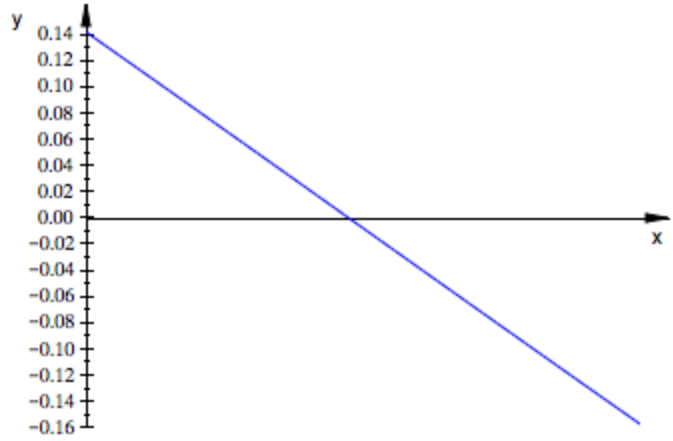
Visualizing that the sine function is nearly linear near its zeroes, we suppress the automatic tick marks along the `x`-axis via `XTicksNumber = None`. Three special ticks are set via XTicksAt:
f := plot::Function2d(sin(x), x = 3.0 .. 3.3): plot(f, XTicksNumber = None, XTicksAt = [3.1, PI = "p", 3.2], TicksLabelFont = ["Symbol"])



The tick marks along the *x*-axis are switched off:
plot(f, XTicksNumber = None, XTicksAt = [3.1, PI = "p", 3.2], TicksLabelFont = ["Symbol"], XTicksVisible = FALSE)



The labels of the ticks are switched off, too:
plot(f, XTicksNumber = None, XTicksAt = [3.1, PI = "p", 3.2], TicksLabelFont = ["Symbol"], XTicksVisible = FALSE, XTicksLabelsVisible = FALSE)



delete f:

Purpose

TicksLabelsVisibleXTicksLabelsVisibleYTicksLabelsVisibleZTicksLabelsVisible
Display axes tick labels?

Value Summary

`TicksLabelsVisible`	Library wrapper for "{XTicksLabelsVisible, YTicksLabelsVisible}" (2D), "{XTicksLabelsVisible, YTicksLabelsVisible, ZTicksLabelsVisible}" (3D)	See below
`XTicksLabelsVisible`, `YTicksLabelsVisible`, `ZTicksLabelsVisible`	Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`TicksLabelsVisible`, `XTicksLabelsVisible`, `YTicksLabelsVisible`: `TRUE`
plot::CoordinateSystem3d	`TicksLabelsVisible`, `XTicksLabelsVisible`, `YTicksLabelsVisible`, `ZTicksLabelsVisible`: `TRUE`

Description

`TicksLabelsVisible` = `TRUE` versus `TicksLabelsVisible` = `FALSE` switches the labeling of the tick marks along all coordinate axes on or off.

With `TicksLabelsVisible` = `FALSE`, the labeling of the tick marks along all coordinate axes is switched off. The tick marks themselves, however, remain visible. They are switched off via TicksVisible = `FALSE`.

With `XTicksLabelsVisible` = `TRUE/FALSE` etc., the tick labeling can be switched on or off separately for each single axis.

`TicksLabelsVisible`, `XTicksLabelsVisible` etc. refer to automatically generated tick marks (cf. TicksNumber), to equidistant tick marks that are requested explicitly via TicksAnchor, TicksDistance as well as to special tick marks set via TicksAt.

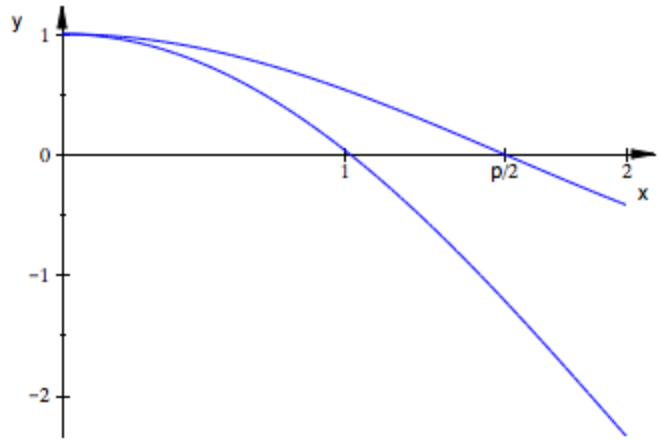
Ticks can also be suppressed via TicksNumber = `None`, XTicksNumber = `None` etc. In contrast to `TicksLabelsVisible` = `FALSE`, however, this affects only the automatically generated ticks and their labels. Ticks set by TicksAnchor, TicksDistance, TicksAt are not affected.

Examples

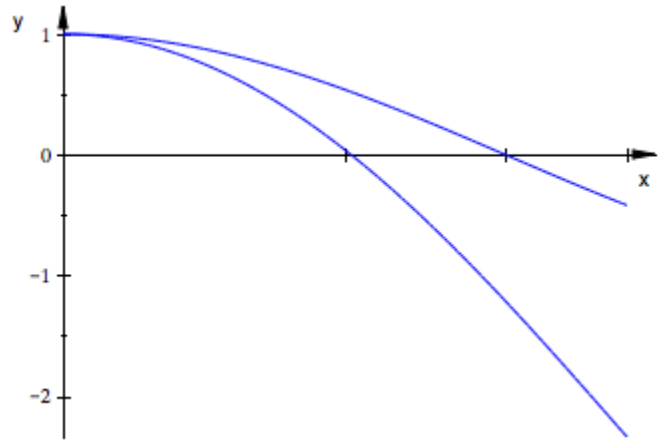
Example 1

We approximate the cosine function by a fourth order polynomial (a Taylor polynomial around the expansion point 0). The automatic tick marks along the *x*-axis are suppressed via XTicksNumber = `None`. Some special tick marks including the zero of the cosine function at x=PI/2 are inserted via XTicksAt:

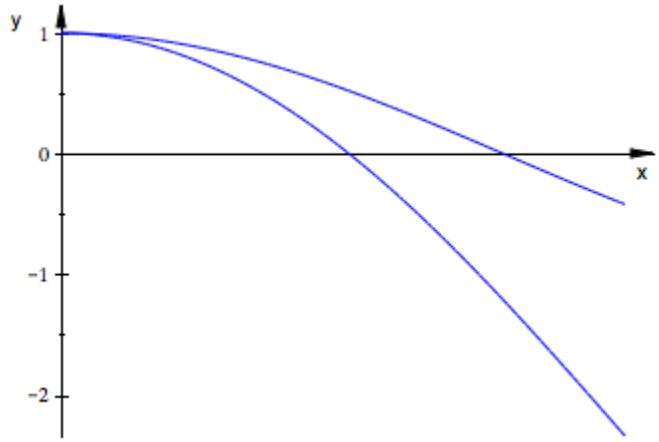
```
f1 := plot::Function2d(cos(x), x = 0..2): f2 := plot::Function2d(1 - x^2 +
x^4/4!, x = 0..2, LineColor = RGB::Blue): plot(f1, f2, XTicksNumber =
None, XTicksAt = [1, PI/2 = "p/2", 2], TicksLabelFont = ["Symbol"])
```



The labeling of the tick marks along the *x*-axis is switched off:
plot(f1, f2, XTicksNumber = None, XTicksAt = [1, PI/2 = "p/2", 2], TicksLabelFont = ["Symbol"], XTicksLabelsVisible = FALSE)



The ticks themselves are switched off, too:
plot(f1, f2, XTicksNumber = None, XTicksAt = [1, PI/2 = "p/2", 2], TicksLabelFont = ["Symbol"], XTicksLabelsVisible = FALSE, XTicksVisible = FALSE)



delete f1, f2:

GridInFront

Purpose

Coordinate grid in front of or behind graphical objects?

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	GridInFront Default Values
plot::CoordinateSystem2d	FALSE

Description

`GridInFront` = `TRUE` versus `GridInFront` = `FALSE` places 2D coordinate lines in front of or behind the graphical objects in the scene.

Setting GridVisible = `TRUE`, SubgridVisible = `TRUE`, one can display a coordinate grid extending the tick marks on the coordinate axes. See the help page of GridVisible for further information.

By default, the lines of the coordinate grid are plotted behind the graphical objects in a scene. Consequently, the objects may cover the coordinate grid. If only line objects and points are present in a 2D scene, this is desirable in most cases.

However, if there are filled areas such as filled polygons in the scene, the view to the coordinate grid may be totally blocked. In such a situation, you may want to draw the grid lines in front of the objects to guarantee visibility of the coordinate grid.

Although the default setting is `GridInFront` = `FALSE`, some objects which create filled areas send `GridInFront` = `TRUE` as a "hint" (see the section Primitives Requesting Special Scene Attributes: "Hints" of this documentation).

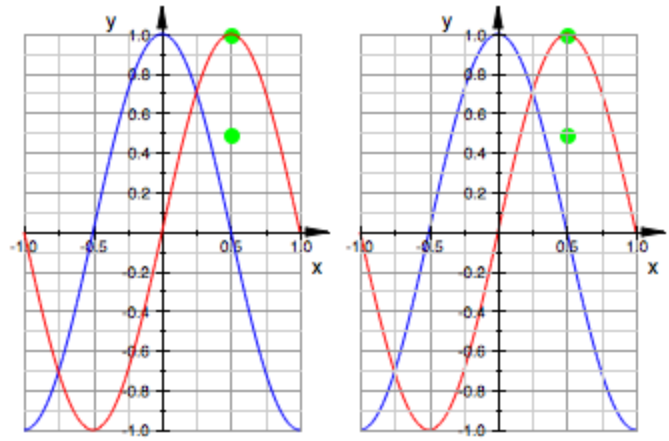
This attribute is available only in 2D.

Examples

Example 1

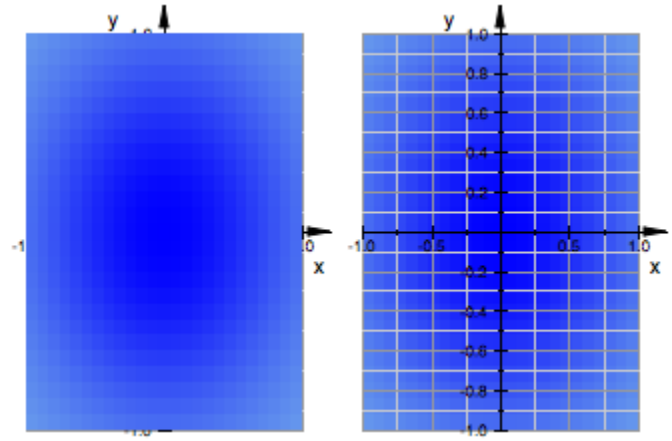
It is usually desirable to let line objects and points cover the coordinate grid:

```
p1 := plot::Point2d(0.5, 0.5, PointSize = 3*unit::mm, Color =
RGB::Green): p2 := plot::Point2d(0.5, 1.0, PointSize = 3*unit::mm,
Color = RGB::Green): f1 := plot::Function2d(cos(x*PI), x = -1 .. 1,
Color = RGB::Blue): f2 := plot::Function2d(sin(x*PI), x = -1 .. 1, Color
= RGB::Red): plot(plot::Scene2d(p1, p2, f1, f2, AxesInFront = FALSE,
GridInFront = FALSE), plot::Scene2d(p1, p2, f1, f2, AxesInFront =
TRUE, GridInFront = TRUE), GridVisible = TRUE, SubgridVisible =
TRUE):
```

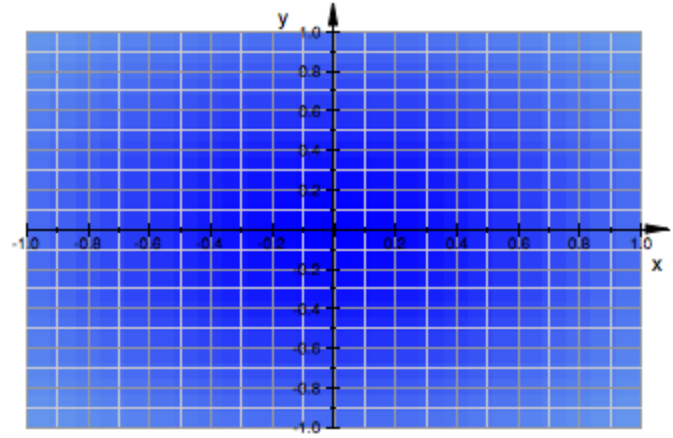


However, you probably want to have the coordinate grid visible in front of the following density plot:

```
d := plot::Density(exp(-x^2 - y^2), x = -1..1, y = -1 ..1, FillColor =
RGB::Blue): plot( plot::Scene2d(d, AxesInFront = FALSE, GridInFront =
FALSE), plot::Scene2d(d, AxesInFront = TRUE, GridInFront = TRUE),
GridVisible = TRUE, SubgridVisible = TRUE, Layout = Horizontal ):
```



Note that density objects of type plot::Density automatically send the "hint" `GridInFront = TRUE`, so there is no need to set this attribute explicitly:
plot(d, GridVisible = TRUE, SubgridVisible = TRUE):



delete p1, p2, f1, f2, d:

See Also GridLineColorGridLineStyleGridLineWidthGridVisible

GridLineColorSubgridLineColor

Purpose

Line color of the coordinate grid

Value Summary

`GridLineColor`, `SubgridLineColor`	Inherited	Color

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	`GridLineColor`: RGB::Grey60 `SubgridLineColor`: RGB::Grey80

Description

`GridLineColor`, SubgridLineColor govern the color of coordinate grid and subgrid lines extending the tick marks on coordinate axes.

Setting GridVisible = `TRUE`, SubgridVisible = `TRUE`, one can display a coordinate grid extending the tick marks on the coordinate axes. See the help page of GridVisible for further information.

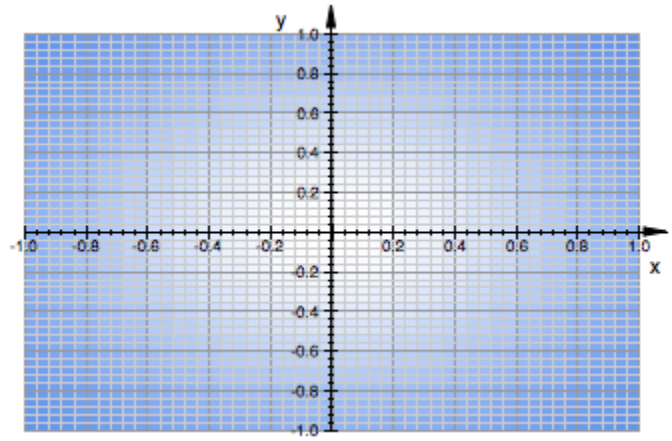
`GridLineColor`, SubgridLineColor set the RGB color for the coordinate grid and subgrid lines.

The color of the coordinate grid lines cannot be specified separately for the single coordinate directions.

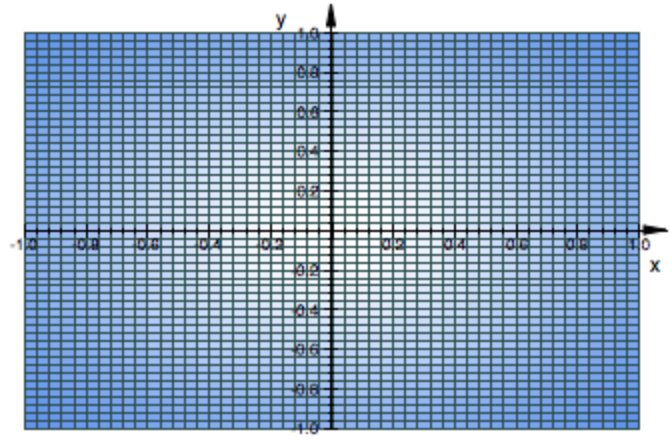
Examples

Example 1

The usual grey lines of the coordinate grid are not appropriate for the following density graphics:
d := plot::Density(exp(-x^2 - y^2), x = -1..1, y = -1 ..1, FillColor = RGB::White): plot(d, TicksNumber = Normal, TicksBetween = 4, GridVisible = TRUE, SubgridVisible = TRUE)



We change the grid color to a darker grey:
plot(d, TicksNumber = Normal, TicksBetween = 4, GridVisible = TRUE, SubgridVisible = TRUE, GridLineColor = RGB::SlateGreyDark, SubgridLineColor = RGB::SlateGreyDark, GridLineWidth = 0.5*unit::mm)



delete d:

See Also GridInFrontGridLineStyleGridLineWidthGridVisible

Purpose

GridLineStyleSubgridLineStyle
Line style of the coordinate grid

Value Summary

`GridLineStyle`, `SubgridLineStyle`	Inherited	`Dashed`, `Dotted`, or `Solid`

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	`GridLineStyle`, `SubgridLineStyle`: `Solid`

Description

`GridLineStyle`, SubgridLineStyle govern the style of the coordinate grid lines and subgrid lines extending the tick marks on coordinate axes.

Setting GridVisible = `TRUE`, SubgridVisible = `TRUE`, one can display a coordinate grid extending the tick marks on the coordinate axes. See the help page of GridVisible for further information.

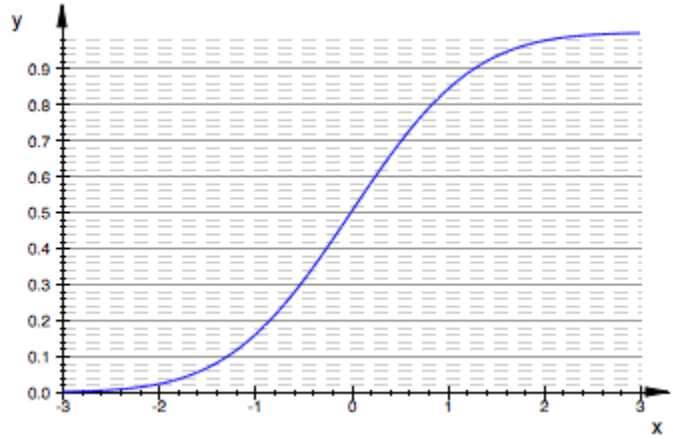
Styles for coordinate grid and subgrid lines can be either `Solid`, `Dashed`, or `Dotted`.

The line style of the coordinate grid cannot be specified separately for the single coordinate directions.

Examples

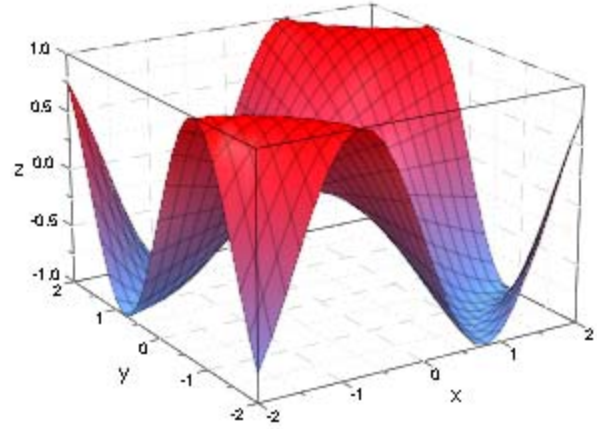
Example 1

We use horizontal coordinate lines to visualize quantiles for the normal distribution:
plot(plot::Function2d(stats::normalCDF(0, 1)(x), x = -3..3), Axes = Frame, TicksBetween = 4, YGridVisible = TRUE, YSubgridVisible = TRUE, GridLineStyle = Solid, SubgridLineStyle = Dashed):



Example 2

Here is an example of a function graph in 3D with different style settings for the coordinate grid and subgrid:
plot(plot::Function3d(sin(x*y), x = -2..2, y = -2..2), GridVisible = TRUE, SubgridVisible = TRUE, GridLineStyle = Dashed, SubgridLineStyle = Dotted):



See Also GridInFrontGridLineColorGridLineWidthGridVisible

GridLineWidthSubgridLineWidth

Purpose

Width of coordinate grid lines

Value Summary

`GridLineWidth`, `SubgridLineWidth`	Inherited	Positive output size

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	`GridLineWidth`, `SubgridLineWidth`: `0.1`

Description

`GridLineWidth`, SubgridLineWidth govern the width of coordinate grid lines and subgrid lines extending the tick marks on coordinate axes.

Setting GridVisible = `TRUE`, SubgridVisible = `TRUE`, one can display a coordinate grid extending the tick marks on the coordinate axes. See the help page of GridVisible for further information.

`GridLineWidth`, SubgridLineWidth set the linewidth for the coordinate grid and the subgrid, respectively. The values should be specified as absolute physical lengths including a length unit such as `GridLineWidth = 0.5*unit::mm`. Numbers without a physical unit give the size in mm.

`GridLinesWidth` and `SubgridLinesWidth` set a common line width for the grid lines in all coordinate directions.

`XGridLinesWidth` and `XSubgridLinesWidth` set the line width only for the grid lines extending the axes tick marks on the *x*-axis.

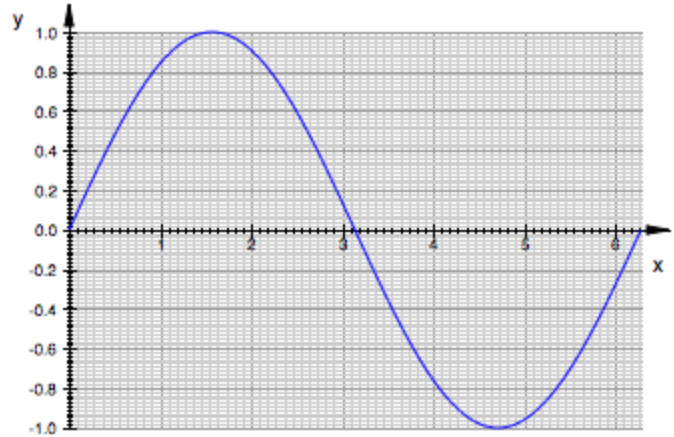
`YGridLinesWidth` etc. work correspondingly for the other coordinate directions.

Note that the graphics cannot always react to small changes of the line width because of the discretization into pixels.

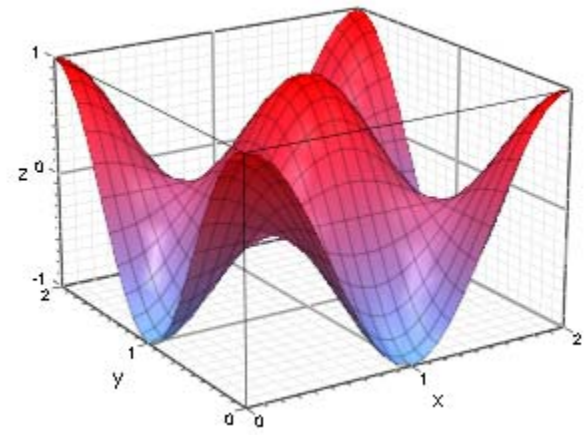
Examples

Example 1

We use the coordinate lines to plot the sine function on “lined paper”. Because of the rather high number of subgrid lines set by TicksBetween = 10, we use extra fine lines for the subgrid:
plot(plot::Function2d(sin(x), x = 0 .. 2*PI), TicksNumber = Normal, TicksBetween = 10, GridVisible = TRUE, SubgridVisible = TRUE, GridLineWidth = 0.5*unit::mm, SubgridLineWidth = 0.1*unit::mm)



Here is a corresponding plot in 3D:
plot(plot::Function3d(cos(x*PI)*cos(y*PI), x = 0 .. 2, y = 0 .. 2), TicksNumber = Low, TicksBetween = 9, GridVisible = TRUE, SubgridVisible = TRUE, GridLineWidth = 0.5*unit::mm, SubgridLineWidth = 0.1*unit::mm)



See Also GridInFrontGridLineColorGridLineStyleGridVisible

Purpose

GridVisibleSubgridVisibleXGridVisibleXSubgridVisibleYGridVisibleYSubgridVisibleZ
Display a coordinate grid?

Value Summary

`SubgridVisible`	Library wrapper for "{XSubgridVisible, YSubgridVisible}" (2D), "{XSubgridVisible, YSubgridVisible, ZSubgridVisible}" (3D)	See below
`XGridVisible`, `XSubgridVisible`, `YGridVisible`, `YSubgridVisible`, `ZGridVisible`, `ZSubgridVisible`	Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	`GridVisible`, `SubgridVisible`, `XGridVisible`, `XSubgridVisible`, `YGridVisible`, `YSubgridVisible`: `FALSE`
plot::CoordinateSystem3d	`GridVisible`, `SubgridVisible`, `XGridVisible`, `XSubgridVisible`, `YGridVisible`, `YSubgridVisible`, `ZGridVisible`, `ZSubgridVisible`: `FALSE`

Description

With `GridVisible` = `TRUE` versus `GridVisible` = `FALSE`, a coordinate grid extending the "major" axes tick marks is "switched on" or "off".

With `SubgridVisible`, additional grid lines extending the "minor" axes tick marks are switched on or off.

With `XGridVisible`, `XSubgridVisible` etc., the coordinate lines can be switched on or off separately for each single coordinate direction.

The regular equidistant tick marks along the coordinate axes consist of "minor" tick marks without labels (cf. TicksBetween) between "major" tick marks bearing labels (cf. TicksNumber, TicksAnchor, TicksDistance).

Extending the major tick marks, one obtains a grid of coordinate lines. Likewise, extending the minor tick marks yields a refined subgrid of coordinate lines.

With `GridVisible` = `TRUE`, the coordinate grid extending the major tick marks is displayed. With `SubgridVisible` = `TRUE`, the refined subgrid is displayed.

With `XGridVisible` = `TRUE`, `XSubgridVisible` = `TRUE`, only the coordinate lines passing through the ticks along the *x*-axis are

displayed. Likewise, `YGridVisible`, `YSubgridVisible`, `ZGridVisible`, `ZSubgridVisible` allow to display the coordinate lines passing through the ticks along the *y* and *z*-axis, respectively.

The coordinate grid is controlled by the ticks marks displayed along the coordinate axes.

Use TicksNumber to control the number of automatically generated major tick marks. Alternatively, use TicksAnchor, TicksDistance to specify the major tick marks explicitly.

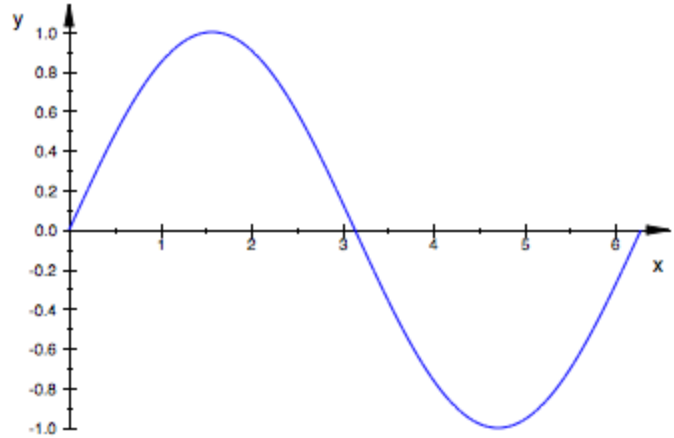
Use TicksBetween to control the number of minor tick marks.

Non-regular tick marks added via TicksAt do not generate additional grid lines.

Examples

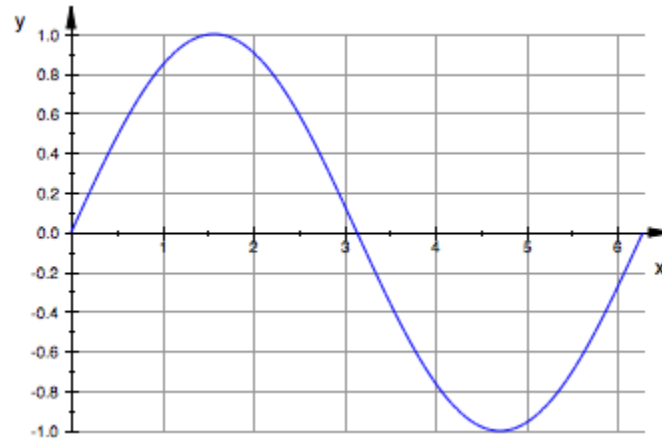
Example 1

We plot the graph of the sine function without grid lines:
plot(plot::Function2d(sin(x), x = 0..2*PI), XTicksNumber = Normal, YTicksNumber = High)

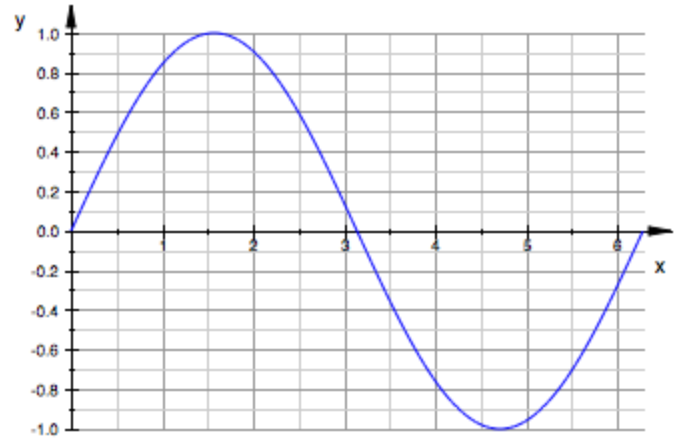


The grid lines are “switched on”:

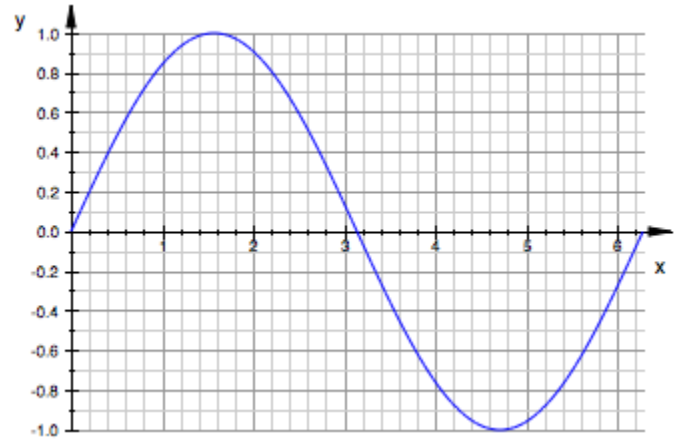
plot(plot::Function2d(sin(x), x = 0..2*PI), XTicksNumber = Normal, YTicksNumber = High, GridVisible = TRUE):



The subgrid lines are switched on as well:
plot(plot::Function2d(sin(x), x = 0..2*PI), XTicksNumber = Normal, YTicksNumber = High, GridVisible = TRUE, SubgridVisible = TRUE):

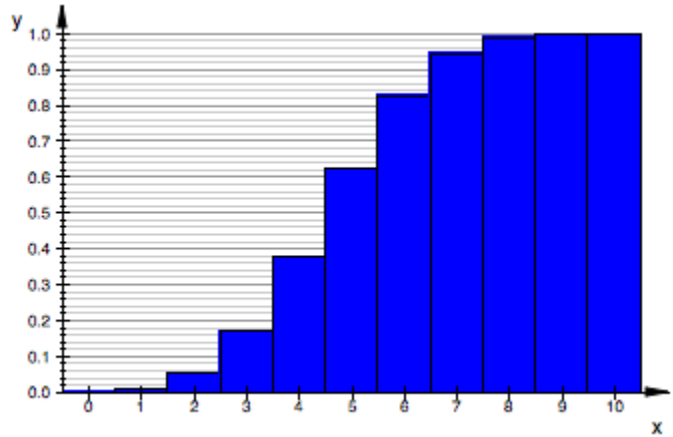


We refine the subgrid in the *x*-direction via XTicksBetween:
plot(plot::Function2d(sin(x), x = 0..2*PI), XTicksNumber = Normal, XTicksBetween = 4, YTicksNumber = High, GridVisible = TRUE, SubgridVisible = TRUE):



Example 2

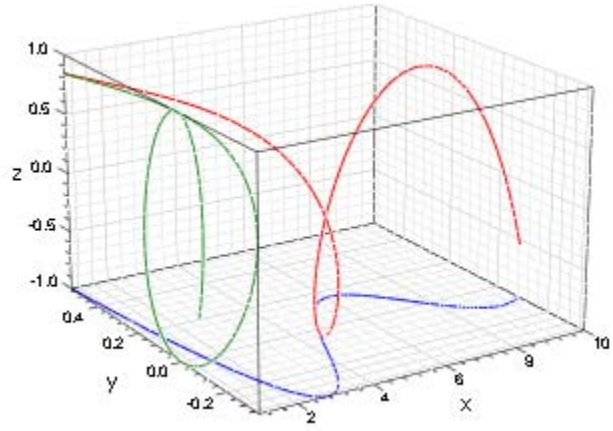
We consider the probabiliy of at least k successes when performing 10 independent experiments each with a 50% chance of success. Consider for this the cumulative density of the binomial distribution given by stats::binomialCDF. Quantiles are visualized by introducing horizontal grid lines:
f := stats::binomialCDF(10, 0.5): plot(plot::Bars2d([f(k) $ k = 0..10]), XTicksDistance = 1, XTicksBetween = 0, XAxisVisible, YTicksDistance = 0.1, YTicksBetween = 4, YGridVisible, YSubgridVisible)



delete f:

Example 3

Consider a curve in 3D with two of its projections to the coordinate planes. We render the coordinate grid visible:
c1 := plot::Curve3d([t, cos(t)/t, sin(t)], t = 1..10, LineColor = RGB::Red): c2 := plot::Curve3d([1, cos(t)/t, sin(t)], t = 1..10, LineColor = RGB::ForestGreen): c3 := plot::Curve3d([t, cos(t)/t, -1], t = 1..10, LineColor = RGB::Blue): plot(c1,c2, c3, TicksBetween = 4, GridVisible = TRUE, SubgridVisible = TRUE)

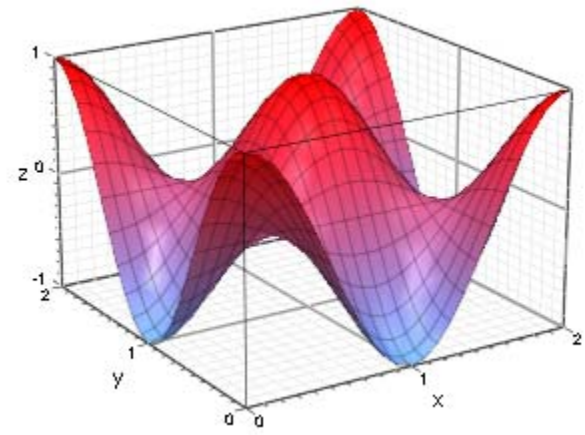


delete c1, c2, c3:

Example 4

Because of the rather large number of grid lines in the following plot, we use extra fine lines to render the subgrid:

```
plot(plot::Function3d(cos(x*PI)*cos(y*PI), x = 0 ..  2, y = 0
..  2), TicksNumber = Low, TicksBetween = 9, GridVisible =
TRUE, SubgridVisible = TRUE, GridLineWidth = 0.5*unit::mm,
SubgridLineWidth = 0.1*unit::mm)
```



See Also GridInFrontGridLineColorGridLineStyleGridLineWidth

AnimationStyle

Purpose

Behaviour of the animation toolbar

Value Summary

Inherited	`BackAndForth`, `Loop`, or `RunOnce`

Graphics Primitives

Objects	AnimationStyle Default Values
plot::Canvas	`RunOnce`

Description

`AnimationStyle` determines how an animation is played in VCam once it is activated.

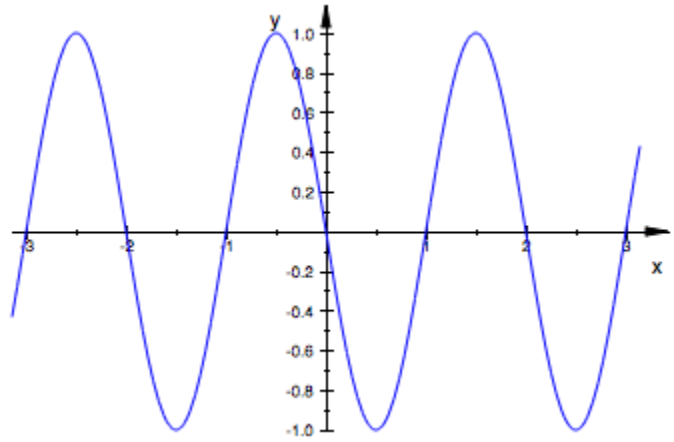
`AnimationStyle` determines what has to be done when an animation reaches the end of its playing time. With `RunOnce` the animation stops, with `BackAndForth` the animation reverts and runs through to the beginning and with `Loop` it jumps back to the beginning and runs on from there on.

`AnimationStyle` sets the initial value of the `Animation Style` menu in the animation toolbar according to its value.

Examples

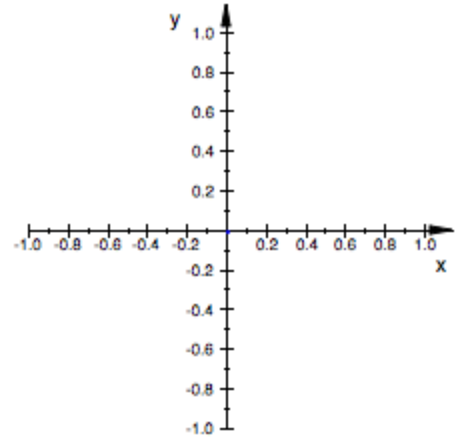
Example 1

This examples shows an animation which builds up a picture frame by frame and at the end of the animation time the complete picture is visible. For this kind of animation the value `RunOnce` is a good choice for `AnimationStyle`:
plot(plot::Line2d([a/36, 0], [sin(a/18*PI), cos(a/18*PI)], VisibleAfter = a/7.2, Color = [sin(a/18*PI), sin(a/18*PI), cos(a/18*PI)]) $ a = -36..36, AnimationStyle = RunOnce)



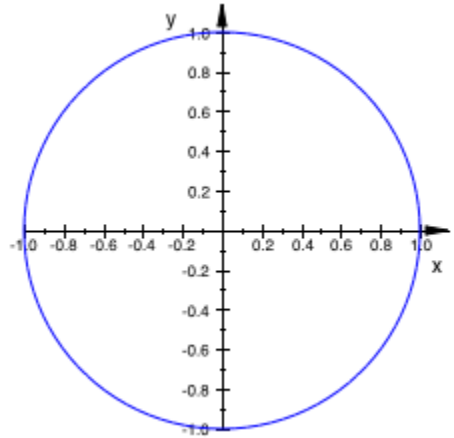
Example 2

This example plays in an endless loop and the value `Loop` is choosen because first frame is the natural successor of the last frame of the animation:
plot(plot::Function2d(sin(a*x), x = -PI..PI, a = -PI..PI), AnimationStyle = Loop)



Example 3

In this example the circle grows from radius 0 to radius 1. With `AnimationStyle = BackAndForth` the circle grows and shrinks in an endless loop:
plot(plot::Circle2d(a, a = 0..1), AnimationStyle = BackAndForth)



See Also InitialTime

Purpose

AutoPlay

Start animations automatically

Value Summary

Optional	FALSE, or TRUE

Graphics Primitives

Objects	AutoPlay Default Values
plot::Canvas	`TRUE`

Description

When plotting with `AutoPlay = TRUE`, animations will start automatically when the plot is activated. This is the default setting.

Animations created with `AutoPlay = FALSE` start when the corresponding button is pressed.

Frames

Purpose

Number of frames in an animation

Value Summary

Inherited	Positive integer

Description

`Frames` determines the number of frames in the animation of an object.

`Frames = n` with a positive integer `n` sets the number of frames for the animation of an object to `n`.

These frames are played during the real time period given by TimeBegin = t_0 and TimeEnd = t_1 (in seconds).

The resulting frame rate is $n/(t_1 - t_0)$ (frames per second).

Increasing the number of frames does not mean that the animation lasts longer, because the renderer does not work with a fixed number of frames per second.

Keeping the play period from TimeBegin = t_0 to TimeEnd = t_1 fixed, an increased number of frames just produces a higher frame rate leading to a smoother animation.

Note that the human eye cannot distinguish between different frames if they change with a rate of more than 25 frames per second. Thus, the number of frames *n* for an animation should satisfy $n < 25\ (t_1 - t_0)$.

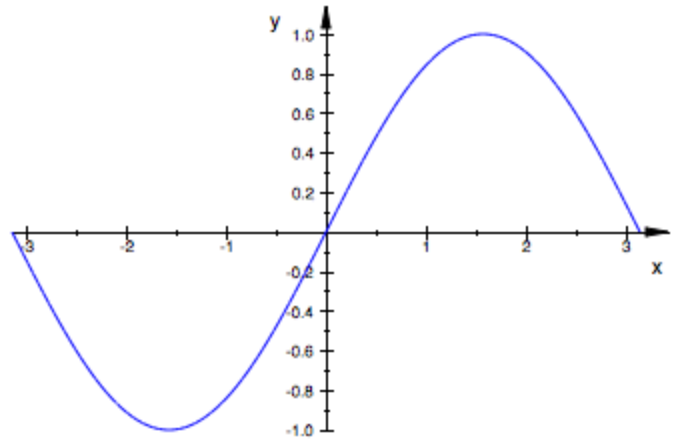
With the default time range TimeBegin = $t_0 = 0$, TimeEnd = $t_1 = 10$ (seconds), it does not make sense to specify `Frames = n` with `n > 250`. If a higher *n* is required to obtain a sufficient resolution of the animated object, one should increase the time for the animation by a sufficiently high value of TimeEnd.

Since the values of `Frames`, TimeBegin, TimeEnd may be set separately for different objects, it is possible to animate objects in a scene with different frame rates. Cf. “Example 2” on page 24-1427.

Examples

Example 1

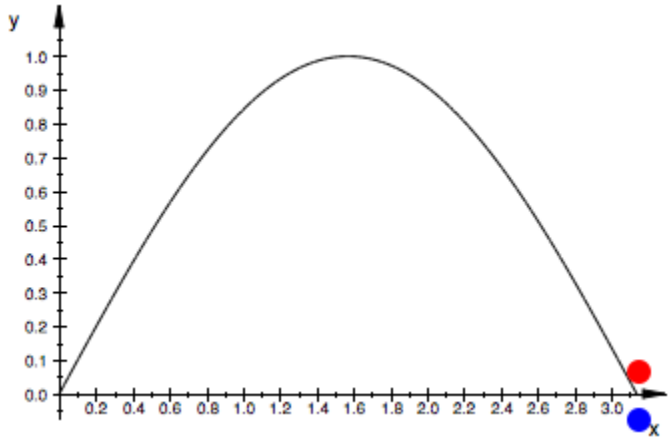
We set the number of frames for the following animation to 40. The default animation range of 10 seconds is used. This results in a frame rate of 4 frames per second:
plot(plot::Function2d(sin(a*x), x = -PI..PI, a = 1..2, Frames = 40)):



Example 2

Here is an example of different frame rates in one plot. The default animation range of 10 seconds is used.

The red point is sampled with 30 frames in 10 seconds, the blue one with 100 frames in 10 seconds. The animation of the blue point is much smoother:
plot(plot::Function2d(sin(x), x = 0..PI, Color = RGB::Black), plot::Point2d([a , sin(a) + 0.07], a = 0 .. PI, Color = RGB::Red, Frames = 30), plot::Point2d([a , sin(a) - 0.07], a = 0 .. PI, Color = RGB::Blue, Frames = 100), PointSize = 4*unit::mm):



See Also ParameterBeginParameterEndParameterNameParameterRangeTimeBeginTimeEndTimeRa

Concepts

- "The Number of Frames and the Time Range"

Purpose

TimeBeginTimeEndTimeRangeInitialTime
Time of the animation

Value Summary

`InitialTime`, `TimeBegin`, `TimeEnd`	Inherited	Real number
`TimeRange`	[`TimeBegin` .. TimeEnd]	Range of arithmetical expressions

Graphics Primitives

Objects	Default Values
plot::Canvas	

Description

`TimeBegin` = t_0 defines the starting time t_0 of the animation of an object.

`TimeEnd` = t_1 defines the time t_1 for the end of the animation.

`TimeRange` = `t_0 .. t_1` is a short cut for setting both `TimeBegin` = t_0 and `TimeEnd` = t_1.

`InitialTime` = t_2 defines the time t_2 for the initial position of the animation slider.

Animations are defined object by object. Each animated object is animated for a certain time span specified by `TimeBegin` and `TimeEnd` setting the real start and end time in seconds.

The total real time span of an animated plot is the physical real time given by the minimum of the `TimeBegin` values of all animated objects in the plot to the maximum of the `TimeEnd` values of all the animated objects:

- When a plot containing animated objects is created, the real time clock is set to the minimum of the `TimeBegin` values of all animated objects in the plot. The real time clock is started when pushing the 'play' button for animations in the graphical user interface.

- Before the real time reaches the `TimeBegin` value t_0 of an animated object, this object is static in the state corresponding to the begin of its animation. Depending on the attribute VisibleBeforeBegin, it may be visible or invisible before t_0.
- During the time from t_0 to t_1, the object changes from its original to its final state.
- After the real time reaches the `TimeEnd` value t_1, the object stays static in the state corresponding to the end of its animation. Depending on the attribute VisibleAfterEnd, it may stay visible or become invisible after t_1.
- The animation of the entire plot ends with the physical time given by the maximum of the `TimeEnd` values of all animated objects in the plot.

If all animated objects in a plot share the same values `TimeBegin` $= t_0$ and `TimeEnd` $= t_1$, the physical time span of the animation is $t_1 - t_0$ (in seconds). During this time, all animated objects change from their initial to their final state.

Separate settings for `TimeBegin` and `TimeEnd` in different animated objects allow to synchronize the animations.

With the optional attribute `InitialTime` the initial position of the animation slider can be set to any time value t_2 between t_0 and t_1. If `InitialTime` is not set, the slider will be placed at the beginning of the animation.

The attributes VisibleAfter, VisibleBefore, and VisibleFromTo allow special “visibility animations” in which objects are visible for a limited time only.

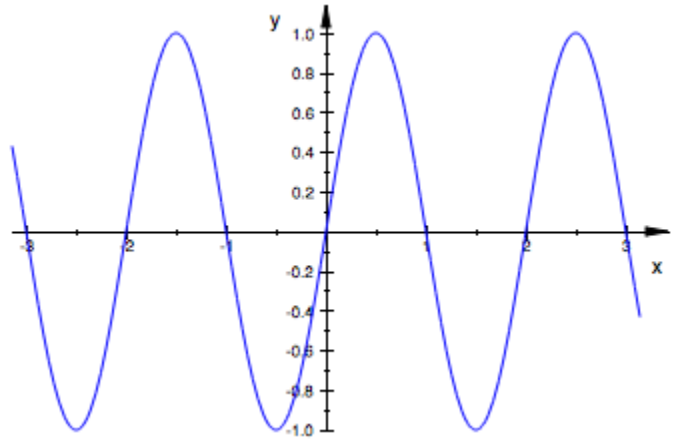
Note The attributes VisibleAfter, VisibleBefore, and VisibleFromTo implicitly set values for `TimeBegin` and `TimeEnd` (and, therefore, also for `TimeRange`). Consequently, these attributes should not be used simultaneously in the definition of an animated object.

Examples

Example 1

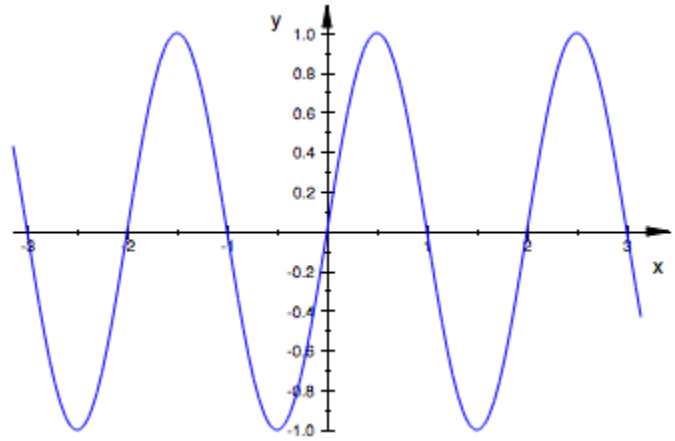
By default, an animation plays for 10 seconds. Keeping the default value `TimeBegin = 0`, this time can be reduced to 5 seconds by setting `TimeEnd = 5`:

```
plot(plot::Function2d(sin(a*x), x= - PI .. PI, a = -PI..PI, TimeEnd = 5)):
```



The total time of the animation is the difference between `TimeEnd` and `TimeBegin`. Hence, the following animation plays 5 seconds as well:

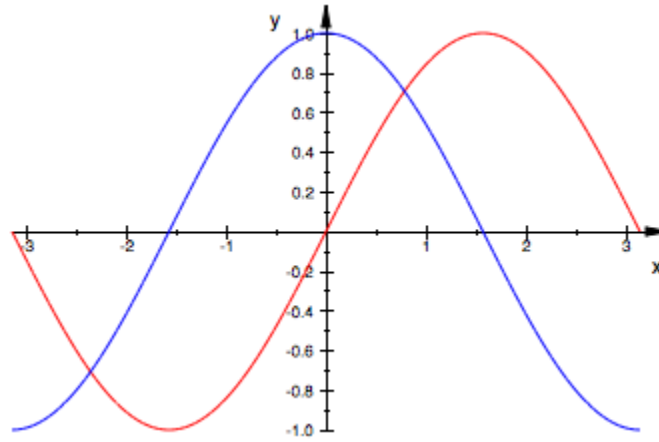
```
plot(plot::Function2d(sin(a*x), x = -PI..PI, a = -PI..PI, TimeRange =
5..10)):
```



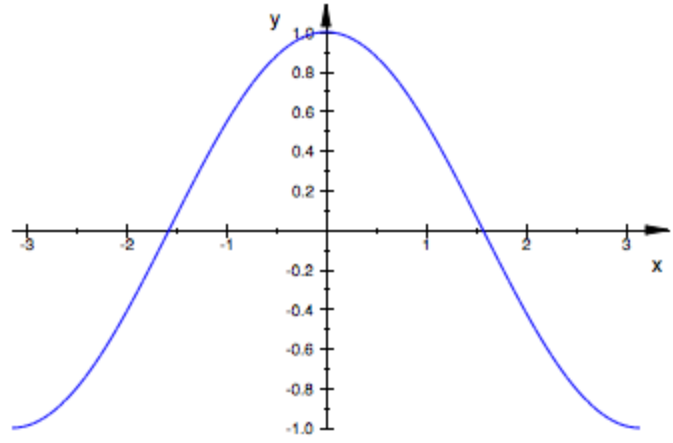
Example 2

Using different time ranges allows to synchronize the animations of different objects. Here we plot two functions. The first function is animated from 0 to 5 (seconds) and then stays static in its final state. The second function stays static in its initial state for 5 seconds and is then animated in the range from 5 to 10 (seconds):

```
f1 := plot::Function2d(a*sin(x), x = -PI..PI, a = -1..1, Color = RGB::Red,
TimeRange = 0..5): f2 := plot::Function2d(a*cos(x), x = -PI..PI, a = -1..1,
Color = RGB::Blue, TimeRange = 5..10): plot(f1 ,f2):
```



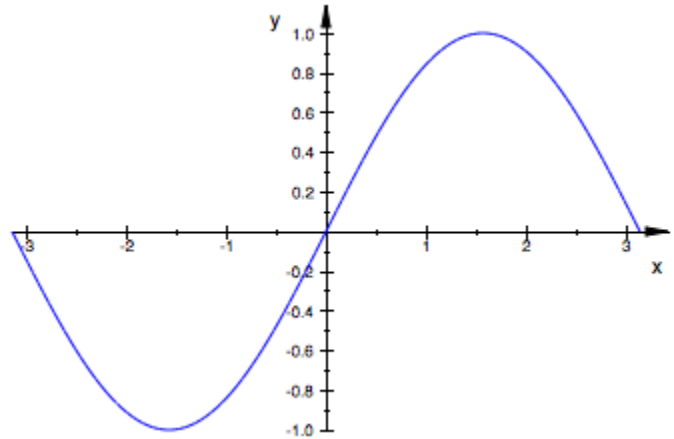
Both functions are visible outside the time range of their animations. We use the attributes VisibleAfterEnd and VisibleBeforeBegin to make them visible only during their animations:
f1::VisibleAfterEnd := FALSE: f2::VisibleBeforeBegin := FALSE: plot(f1, f2):



delete f1, f2:

Example 3

The following animation uses the implicitly given `TimeRange` from 0 to 10 seconds, but the first image shown is at the time 5:
plot(plot::Function2d(a*sin(x), x = -PI..PI, a = -1..1), InitialTime=5):



See Also AnimationStyleFramesParameterBeginParameterEndParameterNameParameterRangeVisib

Concepts

- "The Number of Frames and the Time Range"
- "Advanced Animations: The Synchronization Model"

VisibleAfterVisibleBeforeVisibleFromTo

Purpose

Object visible at time value

Value Summary

`VisibleAfter`, `VisibleBefore`, `VisibleFromTo`	Library wrapper for "TimeEnd, TimeBegin, VisibleAfterEnd, and VisibleBeforeBegin"	Non-negative real number

Description

`VisibleAfter` = t_0 renders an object invisible until the real time t_0 has elapsed in an animation. Then the object becomes visible.

`VisibleBefore` = t_1 renders an object visible until the time t_1. Then the object becomes invisible.

`VisibleFrom = t_0 .. t_1` renders an object invisible until the time t_0. Then the object becomes visible. After the time t_1 it becomes invisible again.

`VisibleAfter`, VisibleBefore, VisibleFromTo allow to implement animated visibility of objects. This also includes otherwise static objects, which become animated objects when one of these attributes is used.

The attributes VisibleBeforeBegin and VisibleAfterEnd control the visibility of objects outside the time range of their animation set by TimeBegin and TimeEnd. See TimeBegin, TimeEnd for details.

`VisibleAfter`, VisibleBefore, VisibleFromTo provide short cuts for suitable settings of the attributes TimeBegin, VisibleBeforeBegin, TimeEnd, VisibleAfterEnd that produce the desired visibility effects.

`VisibleAfter` = t_0 is a short cut for setting the following attribute values:

TimeBegin = t_0, VisibleBeforeBegin = `FALSE`,

TimeEnd = t_0, VisibleAfterEnd = `TRUE`.

The resulting effect is that the corresponding object is invisible at the beginning of the animation. It becomes visible at the time t_0, staying visible until the end of the animation.

The time t_0 has to be a real numerical value giving the real time in seconds.

`VisibleBefore` = t_1 is a short cut for setting the following attribute values:

TimeBegin = t_1, VisibleBeforeBegin = `TRUE`,

TimeEnd = t_1, VisibleAfterEnd = `FALSE`.

The resulting effect is that the corresponding object is visible at the beginning of the animation. At the time t_1 it becomes invisible, staying invisible until the end of the animation.

The time t_1 has to be a real numerical value giving the real time in seconds.

`VisibleFromTo = t_0 .. t_1` is a short cut for setting the following attribute values:

TimeBegin = t_0, VisibleBeforeBegin = `FALSE`,

TimeEnd = t_1, VisibleAfterEnd = `FALSE`.

The resulting effect is that the corresponding object is visible only from the time t_0 until the time t_1.

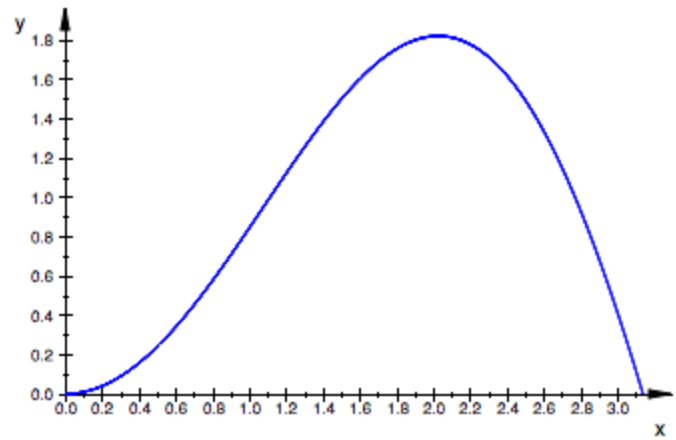
Note The attributes `VisibleAfter` = t_0 and `VisibleBefore` = t_1 should not be combined to create visibility for the time range between t_0 and t_1. (Conflicting values are set implicitly for VisibleBeforeBegin etc.) Use `VisibleFromTo = t_0 .. t_1` instead.

Note `VisibleAfter`, VisibleBefore, VisibleFromTo should not be combined with any of the the attributes TimeBegin, TimeEnd, VisibleBeforeBegin or VisibleAfterEnd, since implicit values for these attributes are set.

Examples

Example 1

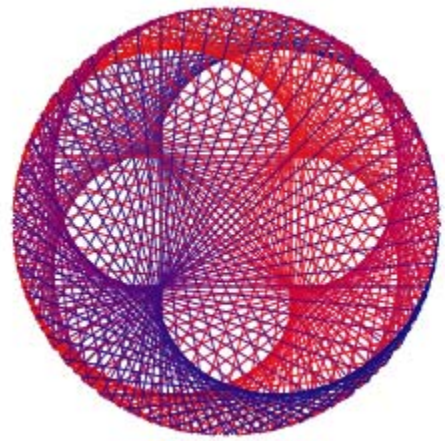
The following animation consists of 100 pieces of the graph of the function *xsin*(*x*). At the times *t* = 0.1, 0.2 etc., an additional piece of the function becomes visible until, finally, the whole graph is built up:
plot(plot::Function2d(x*sin(x), x = (i - 1)*PI/100 .. i*PI/100, VisibleAfter = i/10) $ i = 1..100)



Example 2

This example creates an animated “spider net”. It consists of several lines which appear one after the other at the times given by `VisibleAfter` until the full net is visible at the end of the animation:
SpiderNet := proc(move, move1, rc, gc, bc) local r, lines, x, y, x1, y1; begin r := 1.0: lines := [FAIL $ 361]: for i from 0 to 360 do thet := float(i*PI/180); x := r * cos(move * thet); y := r * sin(move

* thet); x1 := r * cos(move1 * thet); y1 := r * sin(move1 * thet); lines[i+1] := plot::Line2d([x, y] ,[x1, y1], Color = [abs(rc*sin(i*PI/360)), abs(gc*sin(i*PI/360 + PI/4)), abs(bc*sin(i*PI/360 + PI/2))], VisibleAfter = i/36); end_for: plot::Group2d(op(lines), Name = "SpiderNet", Axes = None, Scaling = Constrained) end_proc:plot(SpiderNet(3, 7, 0.9, 0.1, 0.5))



delete SpiderNet:

Example 3

This example creates an animated “Maurer rose”. Here the animation starts with the full object. During the animation the lines disappear at the times given by `VisibleBefore`:

MaurerRose := proc(n, b, rc, gc, bc) local lines, i, thet, r, x, y, x1, y1; begin r := 1.0; lines := [FAIL $ 361]: b := float(b*PI/180); for i from 0 to 360 do thet := float(i*PI/180); x := r * sin(n*thet) * cos(thet); y := r * sin(n*thet) * sin(thet); x1 := r * sin(n*(thet+b))* cos(thet+b); y1 := r * sin(n*(thet+b))* sin(thet+b); lines[i+1] := plot::Line2d([x, y], [x1, y1], Color = [abs(rc*sin(i*PI/360)), abs(gc*sin(i*PI/360 + PI/4)), abs(bc*sin(i*PI/360 + PI/2))], VisibleBefore = i/36); end_for: plot::Group2d(op(lines), Name = "MaurerRose", Axes = None, Scaling = Constrained): end_proc:plot(MaurerRose(4, 120, 0.1, 0.5, 0.9)):

delete MaurerRose:

Example 4

This example creates an animated “Lissajous net”. It is built up from lines that have a life span of only 2 seconds each, set by `VisibleFromTo`:

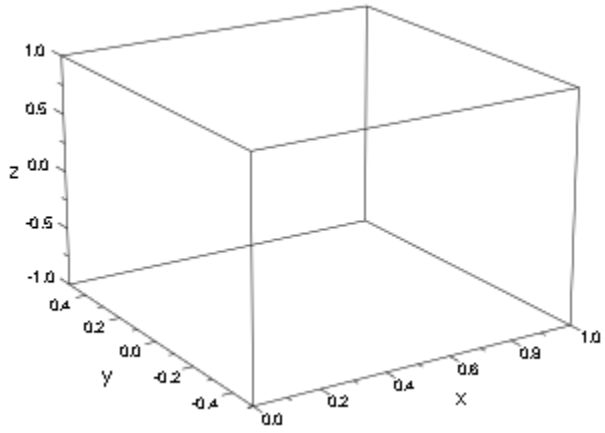
```
LissajousNet := proc(r, a, b, R, A, B, rc, gc, bc) local lines, i,
thet; begin lines := [FAIL $ 361]: for i from 0 to 360 do thet :=
float(i*PI/180); x := r * cos(a*thet); y := r * sin(b*thet); x1 := R *
cos(A*thet); y1 := R * sin(B*thet); lines[i+1] := plot::Line2d([x, y],
[x1, y1], Color = [abs(rc*sin(i*PI/360)), abs(gc*sin(i*PI/360 + PI/4)),
abs(bc*sin(i*PI/360 + PI/2))], VisibleFromTo = i/36 .. i/36 + 2 ); end_for:
plot::Group2d(op(lines), Name = "LissajousNet", Axes = None, Scaling =
Constrained): end_proc:plot(LissajousNet(2, 3, 4, 1, 6, 3, 0.7, 0.1, 0.99))
```

delete LissajousNet:

Example 5

Here is a 3D example of an animation. A “spider net” is built up with lines that have a life span of 4 seconds each:

```
SpiderNet3d := proc(a, b, c, rc, gc, bc) local r, lines, i, x, x1, y, y1,
thet, z1, z; begin r := 1.0: lines := [FAIL $ 361]: for i from 0 to
360 do thet := float(i*PI/180); x := r * cos(thet)*cos(thet); y := r *
sin(thet)*cos(thet); z := r * sin(thet): x1 := r * cos(a*thet)*cos(a*thet);
y1 := r * sin(b*thet)*cos(b*thet); z1 := r * sin(c*thet): lines[i+1]
:= plot::Line3d([x,y,z],[x1,y1,z1], Color = [abs(rc*sin(i*PI/360)),
abs(gc*sin(i*PI/360 + PI/4)), abs(bc*sin(i*PI/360 + PI/2))],
VisibleFromTo = i/36 .. i/36 + 4 ); end_for: plot::Group3d(op(lines),
Name = "SpiderNet3d"): end_proc:plot(SpiderNet3d(2, 1, 3, 0.99, 0.9,
0.1))
```



Algorithms

The last examples on this page are taken from the mathPAD Online Edition (`http://www.mupad.com/mathpad/recreations.html`) written by Prof. Mirek Majewski. See there for details about the mathematics behind the examples above.

- “Frame by Frame Animations”

VisibleBeforeBeginVisibleAfterEnd

Purpose

Object visible before or after its animation time starts?

Value Summary

`VisibleAfterEnd`, `VisibleBeforeBegin`	Inherited	FALSE, or TRUE

Description

`VisibleBeforeBegin`, VisibleAfterEnd determine the visibility of an object before the begin and after the end of its own animation time span, respectively.

Animations are defined object by object. Each animated object is animated for a certain time span specified by `TimeBegin` and `TimeEnd` setting the real start and end time in seconds.

The total real time span of an animated plot is the physical real time given by the minimum of the `TimeBegin` values of all animated objects in the plot to the maximum of the `TimeEnd` values of all the animated objects.

Thus, the time span of an animated plot may be larger than the time spans of the animations of individual objects.

With `VisibleBeforeBegin = TRUE`, an object is visible as a static object when the animation of the entire plot starts. Its state correponds to the start of its own animation. It begins to change, when the starting time of its own animation set by TimeBegin is reached.

With `VisibleBeforeBegin = FALSE`, an object is invisible when the animation of the entire plot starts. It becomes visible when the starting time of its own animation is reached.

With `VisibleAfterEnd = TRUE`, an object stays visible in the final state of its animation after the end of its own animation time span set by TimeEnd.

With `VisibleAfterEnd = FALSE`, an object becomes invisible at the end of its own animation.

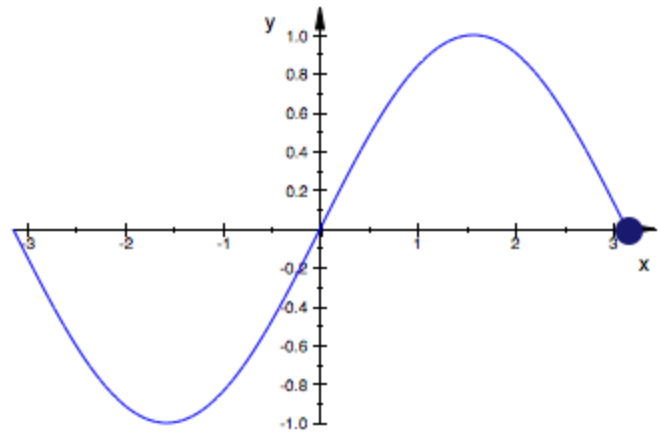
`VisibleBeforeBegin`, VisibleAfterEnd is useful only in plots consisting of several animated objects with different time spans of their animations.

Also consider the attributes VisibleAfter, VisibleBefore, and VisibleFromTo to animate the visibility of objects.

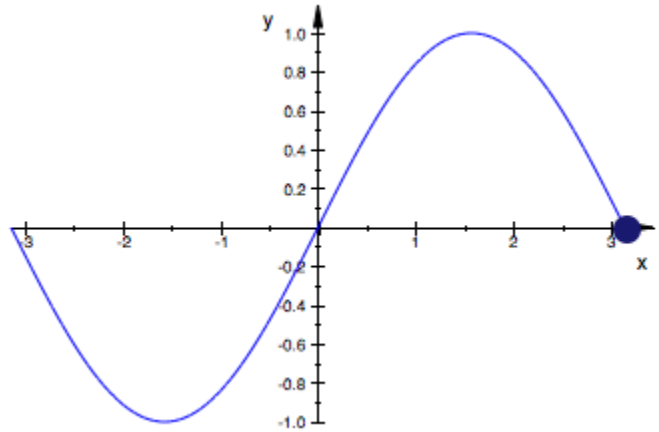
Examples

Example 1

In the first 5 seconds of the following animation, the sine function draws itself. Afterwards, a point wanders along the graph:
f := plot::Function2d(sin(x), x = -PI..a, a = -PI..PI, TimeRange = 0..5): p := plot::Point2d(a, sin(a), PointSize = 5*unit::mm, a = -PI..PI, TimeRange = 5..10): plot(f, p)



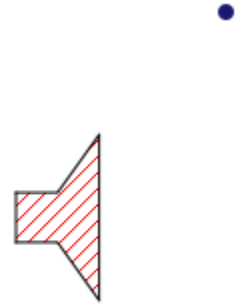
The point is visible for the first 5 seconds, too, because it used the default setting `VisibleBeforeBegin` = `TRUE`. With `VisibleBeforeBegin` = `FALSE`, the point is invisible at the start of the animation. It appears after 5 seconds, when its own animation begins:
p::VisibleBeforeBegin := FALSE: plot(f, p)



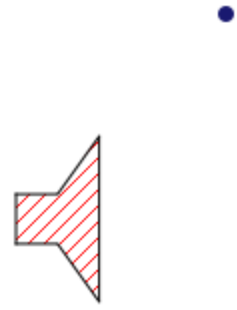
delete p, f:

Example 2

The plot::Polar object in the following animation is only visible in its TimeRange from the 3rd to the 7th second:
Speaker := plot::Polygon2d([[0.5, -1], [0.5, 1], [0, 0.3], [-0.5, 0.3], [-0.5, -0.3], [0, -0.3], [0.5, -1]], Color = RGB::Black, Filled): Point := plot::Point2d([2, a], a = -2.5..2.5, PointSize = 3*unit::mm):plot(plot::Polar([1 + 0.1*(2 + sin(20*a))*cos(20*phi), phi], phi = -1..1, a = 0..3, TimeRange = 3..7, VisibleBeforeBegin = FALSE, VisibleAfterEnd = FALSE), Speaker, Point, Axes = None)



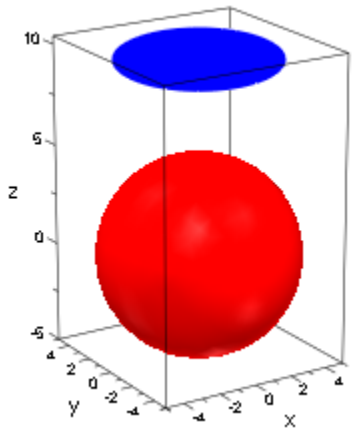
The previous command is equivalent to:
plot(plot::Polar([1 + 0.1*(2 + sin(20*a))*cos(20*phi), phi], phi = -1..1, a = 0..3, VisibleFromTo = 3..7), Speaker, Point, Axes = None)



delete Speaker, Point:

Example 3

A circle is tumbling around in 3D. After 3 seconds, a growing sphere becomes visible. From the 5th second through to the end of the animation, the sphere stays visible with the constant radius 5, while the circle moves further out:
plot(plot::Circle3d(4, [sin(a), cos(a), a], [sin(a), cos(a), a], a = 0..10, Frames = 100, TimeRange = 0..10, Filled = TRUE, FillColor = RGB::Blue), plot::Sphere(a, [0, 0, 0], Color=RGB::Red, a = 3..5, TimeRange = 3 .. 5, Frames = 20, VisibleBeforeBegin = FALSE)):



See Also FramesParameterBeginParameterEndParameterNameParameterRangeTimeBeginTimeEndT

FooterHeader

Purpose

Footer text

Value Summary

`Footer`, `Header`	Optional	Text string

Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	

Description

`Footer = " "` sets a text to be displayed at the bottom of a scene or canvas.

`Header = " "` sets a text to be displayed at the top of a scene or canvas.

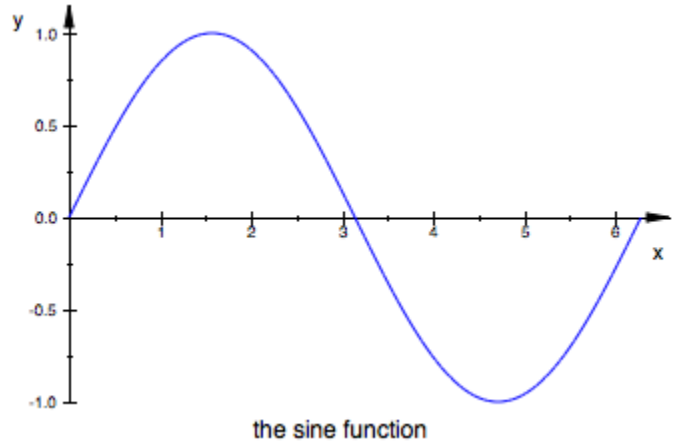
As described in the introduction, each plot consists of a canvas containing one or more scenes. Using `Header` and `Footer`, you can set captions for both levels of nesting, above and/or below the contents.

To change the appearance of the captions, please use the attributes FooterAlignment and HeaderAlignment for positioning and FooterFont and HeaderFont to control fonts and sizes.

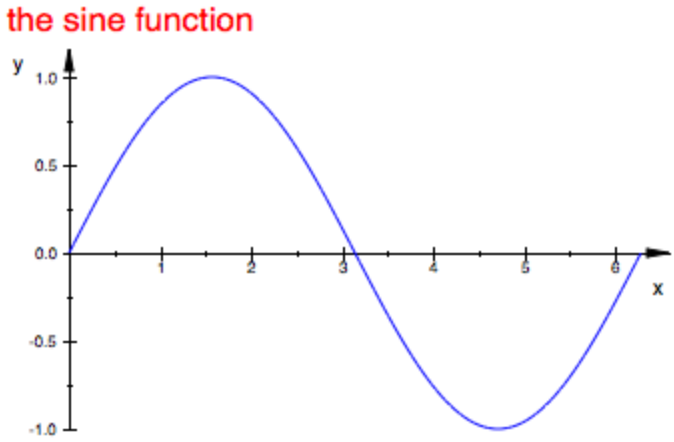
Examples

Example 1

The easiest way of setting a caption is to include a canvas-caption in a plot command:
plot(plot::Function2d(sin(x), x = 0..2*PI), Footer = "the sine function"):

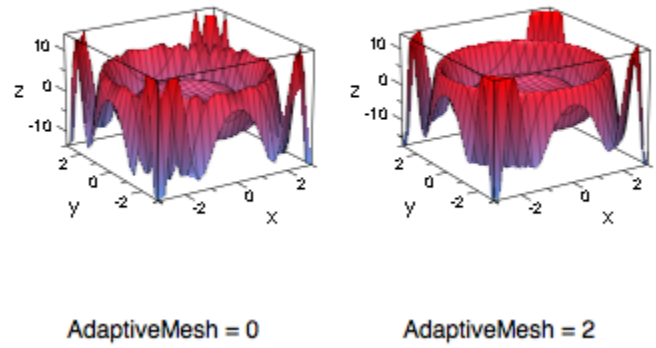


You can also set style controlling attributes in this context: plot(plot::Function2d(sin(x), x = 0..2*PI), Header = "the sine function", HeaderFont = ["Monotype Corsiva", 17, RGB::Red], HeaderAlignment = Left):



Example 2

Advanced users may want to plot several scenes together. These can be given individual captions:
f1 := plot::Function3d(sin(x^2 + y^2)*(x^2 + y^2), x = -3..3, y = -3 ..3, AdaptiveMesh = 0): f2 := plot::modify(f1, AdaptiveMesh = 2):s1 := plot::Scene3d(f1, Footer = "AdaptiveMesh = 0"): s2 := plot::Scene3d(f2, Footer = "AdaptiveMesh = 2"): plot(s1, s2, Layout = Horizontal)



See Also FooterAlignmentHeaderAlignmentFooterFontHeaderFontTitle

Purpose

FooterAlignmentHeaderAlignment
Alignment of footer of canvas and scenes

Value Summary

`FooterAlignment`, `HeaderAlignment`	Inherited	Center, Left, or `Right`

Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	`FooterAlignment`, `HeaderAlignment`: `Center`

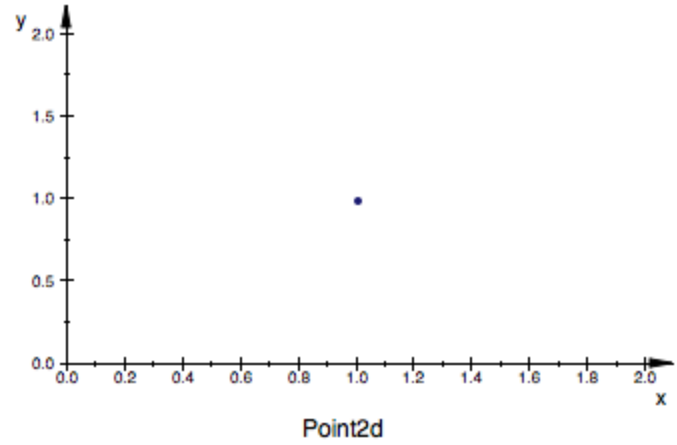
Description

Using the attributes Footer and Header, a canvas or scene can be given a caption. `FooterAlignment` and `HeaderAlignment` control the horizontal alignment of these captions.

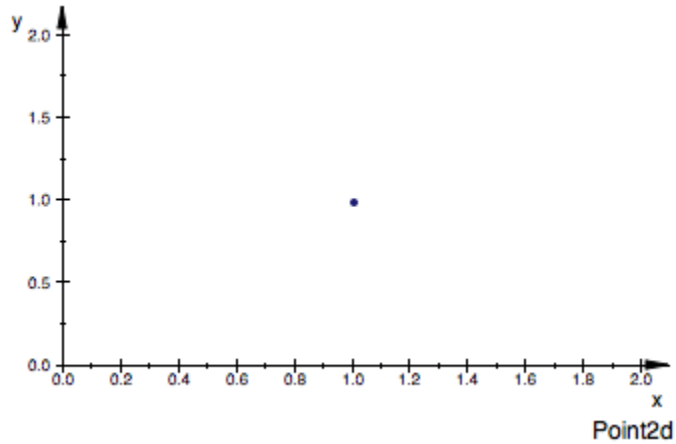
Examples

Example 1

Using the default placement, a footer is centered:
plot(plot::Point2d([1,1]), Footer="Point2d")



We may want to place the footer more to the right:
plot(plot::Point2d([1,1]), Footer="Point2d", FooterAlignment = Right)



See Also FooterFooterFontHeaderHeaderFontHorizontalAlignmentVerticalAlignmentLegendAlign

Purpose

HorizontalAlignmentTitleAlignmentVerticalAlignment
Horizontal alignment of text objects w.r.t. their coordinates

Value Summary

`HorizontalAlignment`, `TitleAlignment`	Inherited	Center, Left, or `Right`
`VerticalAlignment`	Inherited	`BaseLine`, Bottom, Center, or Top

Graphics Primitives

Objects	Default Values

plot::Text2d, plot::Text3d	`HorizontalAlignment`: `Left`
	`TitleAlignment`: `Center`
	`VerticalAlignment`: `BaseLine`

plot::Integral	`HorizontalAlignment`: `Left`
	`TitleAlignment`: `Center`
	`VerticalAlignment`: `Bottom`

Description

`TitleAlignment` controls the interpretation of the TitlePosition of the titles of graphical objects.

`HorizontalAlignment` and `VerticalAlignment` control the interpretation of the coordinates of text objects.

Titles of graphical objects are placed at the position defined by TitlePosition. `TitleAlignment` determines whether the beginning, the center, or the end of the title text is aligned at this position. See “Example 1” on page 24-1453.

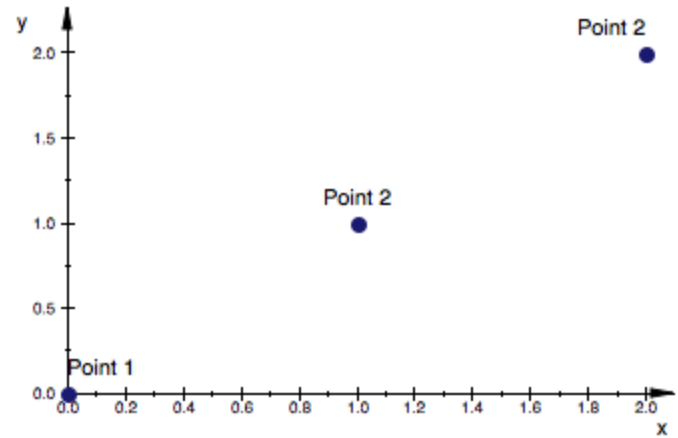
Text objects (i.e., objects of type plot::Text2d or plot::Text3d) carry, in their Position attribute, a position. `HorizontalAlignment` and `VerticalAlignment` together determine which point of the text this position refers to. For example, with `HorizontalAlignment = Left`

and `HorizontalAlignment = Bottom`, the given position is the lower left corner of the rendered text.

Examples

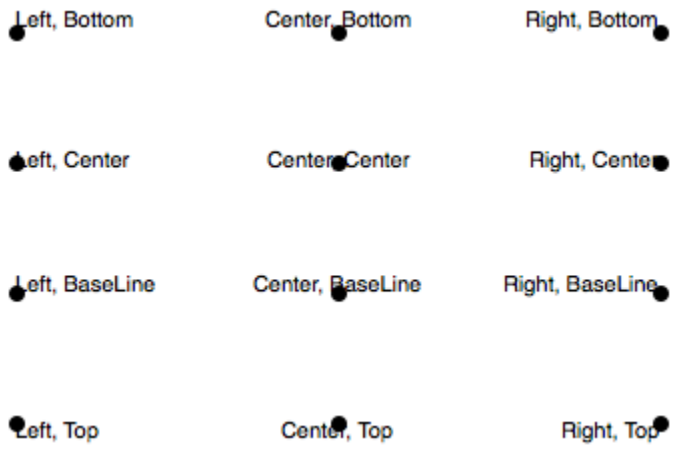
Example 1

We plot three points with title positions 0.1 above each point. The titles are aligned such that the beginning of the text (`Left`), the center of the text (`Center`), or the end of the text (`Right`) is at the TitlePosition:
plot(plot::Point2d(0, 0, Title = "Point 1", TitlePosition = [0, 0.1], TitleAlignment = Left), plot::Point2d(1, 1, Title = "Point 2", TitlePosition = [1, 1.1], TitleAlignment = Center), plot::Point2d(2, 2, Title = "Point 2", TitlePosition = [2, 2.1], TitleAlignment = Right), PointSize = 2.5*unit::mm)



Example 2

The following call generates a table showing all the combinations of `HorizontalAlignment` and `VerticalAlignment`:
Hor := [Left, Center, Right]: Vert := [Top, BaseLine, Center, Bottom]: plot((plot::Text2d(expr2text(Hor[i], Vert[j]), [i, j], HorizontalAlignment = Hor[i], VerticalAlignment = Vert[j]), plot::Point2d([i, j], Color = RGB::Black)) $ i = 1..3 $ j = 1..4, Axes = None, TitleFont = [13], PointSize = 2.5*unit::mm)



delete Hor, Vert:

See Also PositionTitleTitlePosition

Legend

Purpose

Makes a legend entry

Value Summary

Library wrapper for “LegendText, LegendEntry, and LegendVisible”	See below

Description

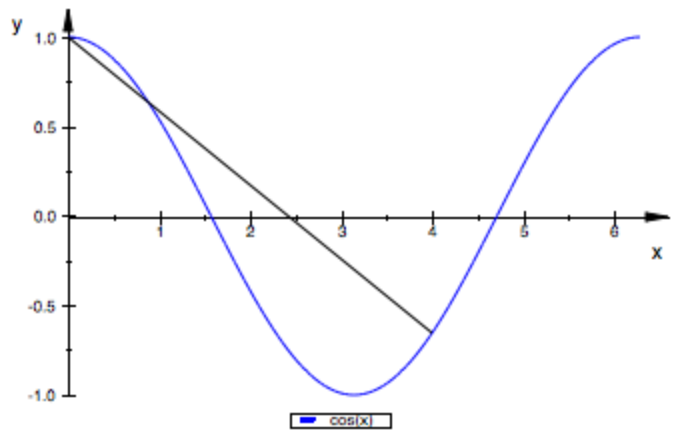
`Legend` makes a legend entry and activates the legend.

`Legend` is a library wrapper which sets a LegendText and simultaneously switches the legend on by setting LegendEntry and LegendVisible to TRUE.

Examples

Example 1

`Legend` is used to set a LegendText for the function and activate the legend. The line does not appear in the legend:
plot(plot::Function2d(cos(x), x = 0..2*PI, Legend = "cos(x)"), plot::Line2d([0, 1], [4, cos(4)], Color = RGB::Black))



See Also

LegendAlignmentLegendEntryLegendPlacementLegendTextLegendVisible

Ground

Concepts

- “Legends”

LegendEntry

Purpose

Add this object to the legend?

Value Summary

Inherited	FALSE, or TRUE

Description

`LegendEntry` turns legend entries of individual objects on and off, if `LegendVisible` is `TRUE`.

Note `LegendEntry` is a technical internal attribute. You will most likely want to use the library interface attribute Legend in order to set legend entries.

If legends are active (i.e., LegendVisible is set to `TRUE`), `LegendEntry` controls which objects have entries in the legend. Only objects with `LegendEntry = TRUE` show up there.

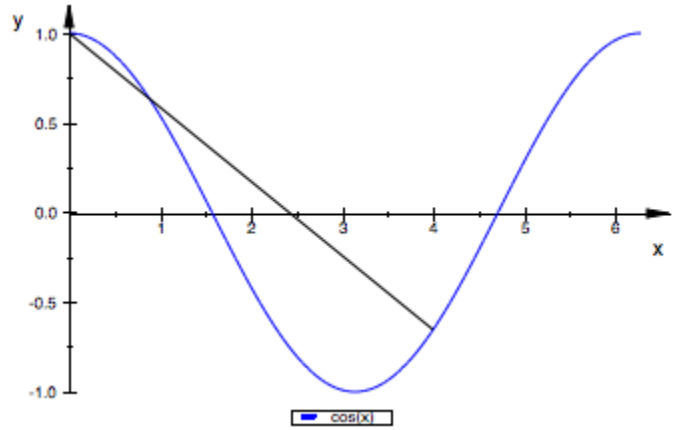
As long as `LegendVisible` has its default value of `FALSE`, `LegendEntry` has no effect whatsoever.

Examples

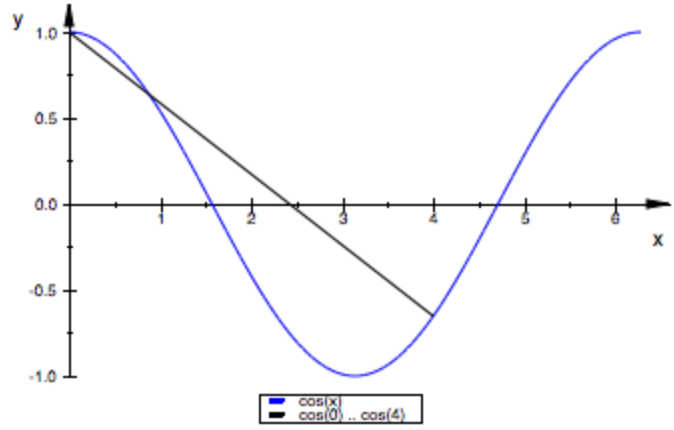
Example 1

By default, functions have `LegendEntry = TRUE`, while, e.g., lines do not:

```
plot(plot::Function2d(cos(x), x = 0..2*PI, Name = "cos(x)"),
plot::Line2d([0, 1], [4, cos(4)], Name = "cos(0) .. cos(4)", Color =
RGB::Black), LegendVisible)
```



Use `LegendEntry` to turn on the legend entry for the line:
plot(plot::Function2d(cos(x), x = 0..2*PI, Name = "cos(x)"), plot::Line2d([0, 1], [4, cos(4)], Name = "cos(0) .. cos(4)", Color = RGB::Black, LegendEntry = TRUE), LegendVisible)



See Also LegendLegendAlignmentLegendPlacementLegendTextLegendVisible

Concepts

- “Legends”

Ground

Purpose

LegendAlignmentLegendPlacementLegendVisible
Legend at left, center, or right

Value Summary

`LegendAlignment`	Inherited	Center, Left, or `Right`
`LegendPlacement`	Inherited	Bottom, or Top
`LegendVisible`	Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Default Values

plot::Scene2d, plot::Scene3d	`LegendAlignment`: `Center`
	`LegendPlacement`: `Bottom`
	`LegendVisible`: `FALSE`

Description

`LegendVisible` activates a legend identifying the individual objects in a plot.

`LegendAlignment` and `LegendPlacement` control the placement of this legend.

For complex plots with multiple objects, it is often helpful to include an explanation in form of a legend that states the connection from object color to object meaning.

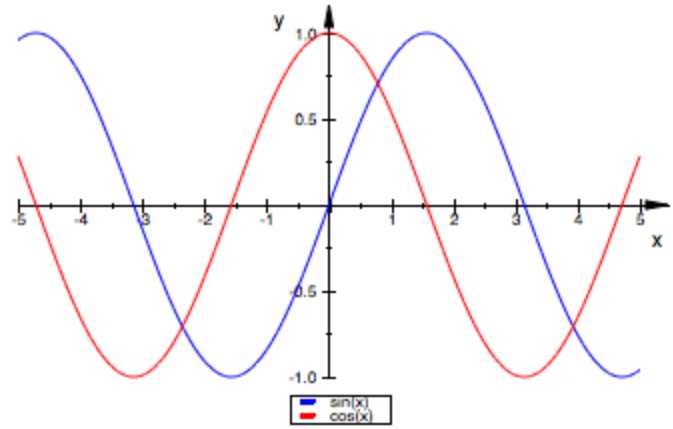
The entry for “object meaning” is usually not provided automatically but must be given using LegendText. As an exception, plotfunc2d and plotfunc3d set the function terms as “meaning”. Cf. “Example 1” on page 24-1461.

Using `LegendPlacement`, the legend can be moved from below the plot to above it. `LegendAlignment` controls whether the legend is displayed flush left, flush right, or centered (which is the default).

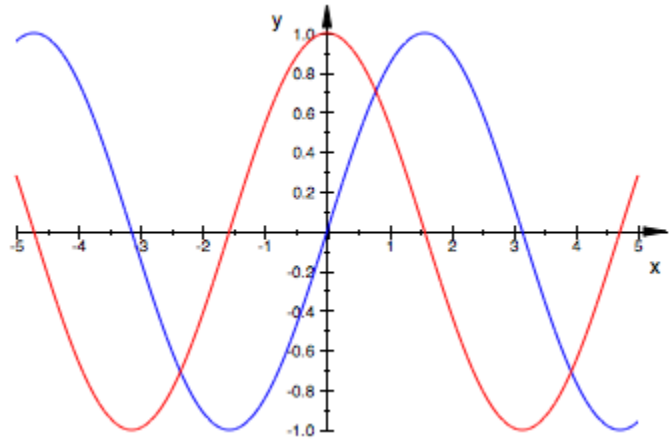
Examples

Example 1

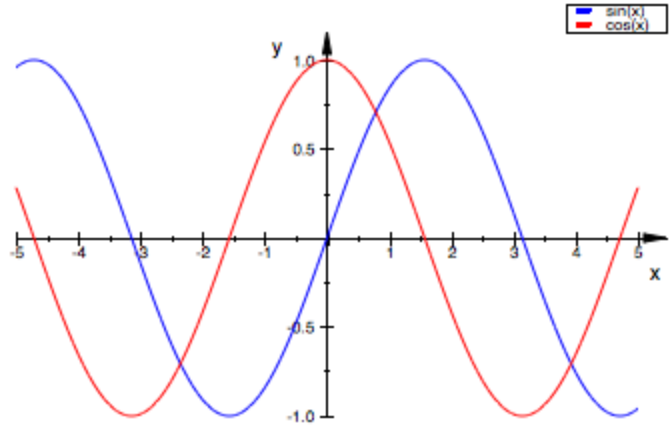
When plotting more than one object, plotfunc2d and plotfunc3d set `LegendVisible = TRUE`:
plotfunc2d(sin(x), cos(x))



It is possible to explicitly switch this automatic legend off:
plotfunc2d(sin(x), cos(x), LegendVisible = FALSE)

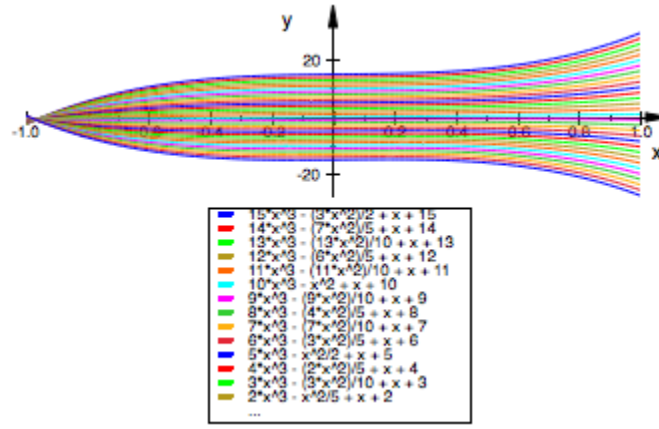


Using `LegendPlacement` and `LegendAlignment`, we place the legend in the upper right corner of the graphics:
plotfunc2d(sin(x), cos(x), LegendPlacement = Top, LegendAlignment = Right)

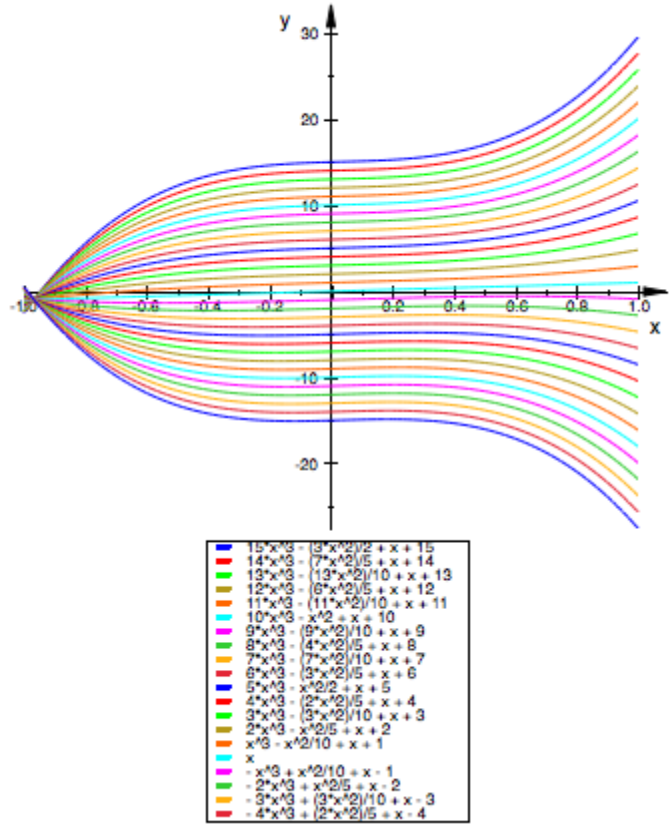


Example 2

When plotting many objects with active legend entries, the legend is abbreviated: It will never take up more than half of the scene height and it will not contain more than 20 entries:
plotfunc2d(-i*x^3+i/10*x^2+x-i $ i = -15..15, x=-1..1)



plotfunc2d(-i*x^3+i/10*x^2+x-i $ i = -15..15, x=-1..1, Height = 15*unit::cm)



See Also LegendLegendFontLegendText

Purpose

LegendText
Short explanatory text for legend

Value Summary

Optional		Text string

Description

`LegendText` sets the text for the legend entry of an object.

Note `LegendText` is a technical internal attribute. You will most likely want to use the library interface attribute Legend in order to set legend entries.

To have a legend entry, the object must have Legend set to `TRUE` and LegendVisible must be `TRUE` for the enclosing scene. Cf. “Example 1” on page 24-1465.

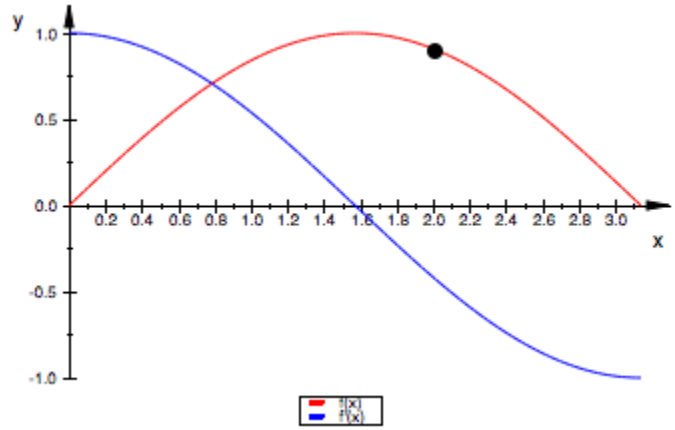
If `LegendText` is unset, but `Legend` and `LegendVisible` are `TRUE`, the legend entry is taken from the attribute Name. If that is unset, too, the name of the object type is displayed. Cf. “Example 2” on page 24-1467.

Examples

Example 1

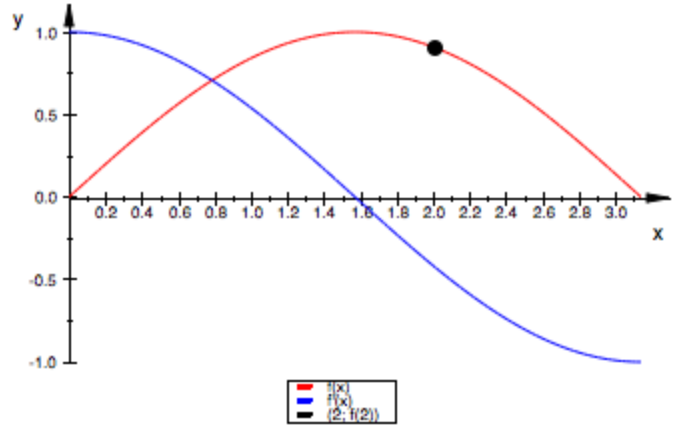
We create a few objects with values for `LegendText` set:
f := plot::Function2d(sin(x), x = 0..PI, LegendText = "f(x)", Color = RGB::Red): g := plot::Function2d(cos(x), x = 0..PI, LegendText = "f'(x)", Color = RGB::Blue): p := plot::Point2d([2, sin(2)], PointSize = 3*unit::mm, LegendText = "(2; f(2))", Color = RGB::Black):

Switching on the legend, we plot these objects:
plot(f, g, p, LegendVisible = TRUE)



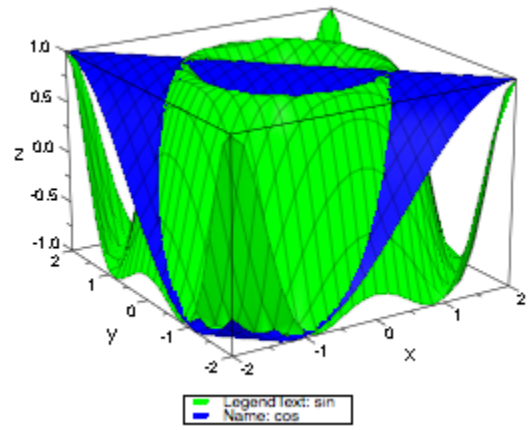
As we can see, only the function objects show up in the legend. If `p` is supposed to be shown there, too, we must explicitly set `LegendEntry` to `TRUE`:

```
p::LegendEntry := TRUE: plot(f, g, p, LegendVisible = TRUE)
```

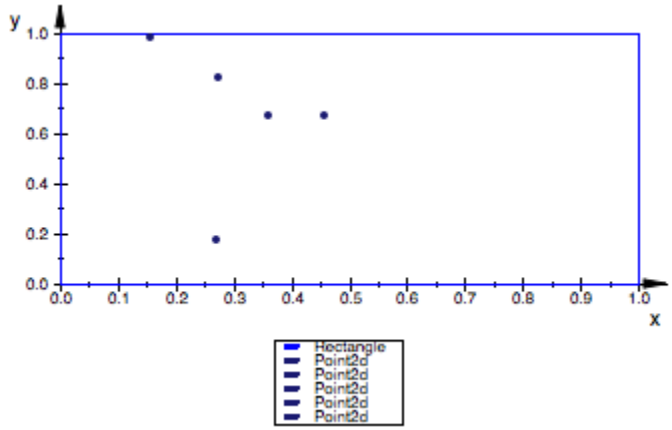


Example 2

If an object has a legend entry, but `LegendText` is not set, the first fall-back is the `Name` attribute of the object:
plot(plot::Function3d(sin(x^2 + y^2), x = -2..2, y = -2..2, Color = RGB::Green, FillColorType = Flat, LegendText = "LegendText: sin", Name = "Name: sin"), plot::Function3d(cos(x + y), x = -2..2, y = -2..2, Color = RGB::Blue, FillColorType = Flat, Name = "Name: cos"), LegendVisible)



As a last resort, the name of the type of object is used:
plot(plot::Rectangle(0..1, 0..1), plot::Point2d(frandom(), frandom()), plot::Point2d(frandom(), frandom()), plot::Point2d(frandom(), frandom()), plot::Point2d(frandom(), frandom()), plot::Point2d(frandom(), frandom()), LegendEntry = TRUE, LegendVisible = TRUE)



See Also LegendLegendVisibleName

Concepts

- “Legends”

ShowInfo

Purpose

Information about integral approximation

Value Summary

Optional	List of arithmetical expressions

Graphics Primitives

Objects	ShowInfo Default Values
plot::Integral	[2, `IntMethod`, `Integral`]

Description

`ShowInfo` defines the text information displayed by plot::Integral.

In plot::Integral, text information about the used approximation method, the values of the approximation and the exact integral, the number of subintervals and the error of the approximation can be displayed within the approximation object.

The attribute is specified by `ShowInfo = [entry`$_1$`, entry`$_2$`, ]` with a list of various entries. The user may specify the entries in arbitrary order.

If the list is empty, no text information is displayed.

Each entry in the list can be of one of the following types:

- an arbitrary string

  In the text, this entry is appended to the current line. No white space or line break is prepended or appended. The string itself, however, may contain white space or a line break (given by `\n`).

- "" (empty string)

  This inserts an empty line in the text.

- `IntMethod`

  In the text, this creates a new line

  `name: float_value`,

where `name` is the value of the attribute IntMethod and `float_value` is the numerical value of the integral approximation. This value is computed internally and inserted in the text, automatically.

- `IntMethod` = name

  In the text, this creates a new line

  `name:  float_value`,

  where `float_value` is the numerical value of the integral approximation.

  If `name` is one of the flags `RiemannLower` etc. listed on the help page of the attribute IntMethod, this flag is displayed in the text.

  Alternatively, `name` may be a string. When `name` is the empty string `""`, only the numerical approximation of the integral value is displayed.

- `Integral`

  In the text, this creates a new line

  `Integral:  float_value`,

  where `float_value` is a high precision float approximation of the exact integral value.

- `Integral` = string

  In the text, this creates a new line

  `string:  float_value`,

  where `string` is an arbitrary text string and `float_value` is a high precision float approximation of the exact integral value .

  When `string` is the empty string `""`, only the high precision approximation `float_value` is displayed.

- `Error`

  In the text, this creates a new line

  `Error:  float_value`,

where `float_value` is the absolute difference between the numerical value obtained by the chosen approximation method and a high precision float approximation of the exact integral value.

- `Error` = string

  In the text, this creates a new line

  `string:  float_value`,

  where `string` is an arbitrary text string and `float_value` is the absolute difference between the numerical value obtained by the chosen approximation method and a high precision float approximation of the exact integral value.

  When `string` is the empty string `""`, only the absolute quadrature error `float_value` is displayed.

- `Nodes`

  In the text, this creates a new line

  `Nodes:  n`,

  where the integer `n` is the number of intervals used for the integral approximation.

- `Nodes` = string

  In the text, this creates a new line

  `string:  n`,

  where `string` is an arbitrary text string and the integer `n` is the number of intervals used for the integral approximation.

  When `string` is the empty string `""`, only the integer `n` is displayed.

- `Position = [X, Y]`

  This entry determines the position of the text information. `X` and `Y` are the coordinates of the anchor point of the text. The alignment of the text with respect to the anchor point can be chosen by the attributes HorizontalAlignment and VerticalAlignment.

- a positive integer `digits`

  The integer `digits` determines the number of digits after the decimal point for all following float values.

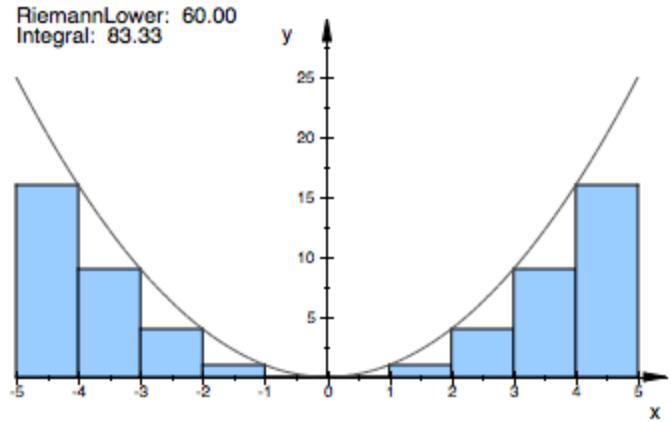
  Different float values can be displayed with a different number of digits by inserting several `digits` entries at appropriate positions in the list.

Without an explicit specification of `Position = [X, Y]`, the text is positioned automatically.

Examples

Example 1

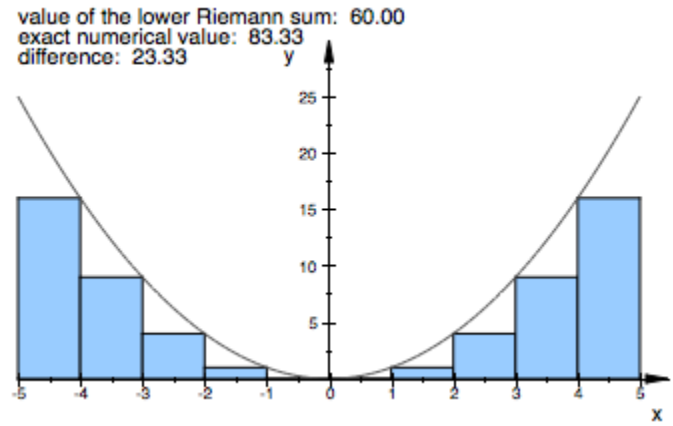
By default, the approximation method, the value of approximation and the integral is displayed with `2` digits after the decimal point:
f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannLower), f)



This call is equivalent to:
plot(plot::Integral(f, IntMethod = RiemannLower, ShowInfo = [2, IntMethod, Integral]), f):

The text can be changed:

plot(plot::Integral(f, IntMethod = RiemannLower, ShowInfo = [IntMethod = "value of the lower Riemann sum", Integral = "exact numerical value", Error = "difference"]), f)

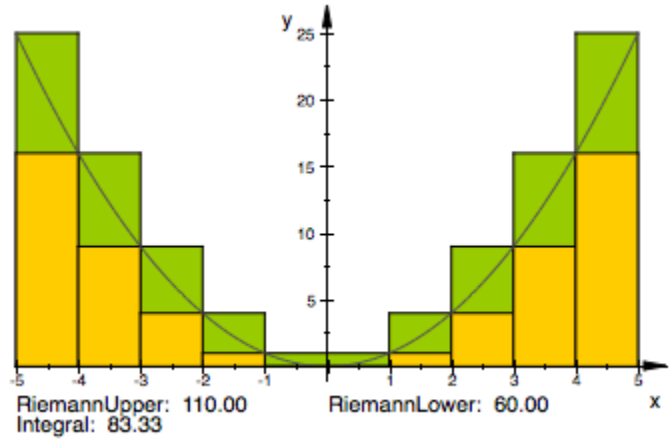


delete f:

Example 2

The position can be specified explicitely. In this case, the entries to be displayed must be specified explicitely, too. The text attribute VerticalAlignment aligns the text object:

f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannUpper, Color = RGB::Lime, ShowInfo = [IntMethod, Integral, Position = [-5, -1]], VerticalAlignment = Top), plot::Integral(f, IntMethod = RiemannLower, Color = RGB::Gold, ShowInfo = [IntMethod, Position = [0, -1]], VerticalAlignment = Top), f)

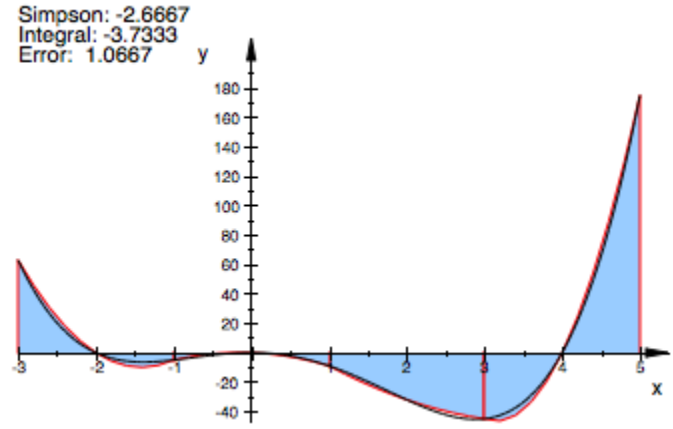


delete f:

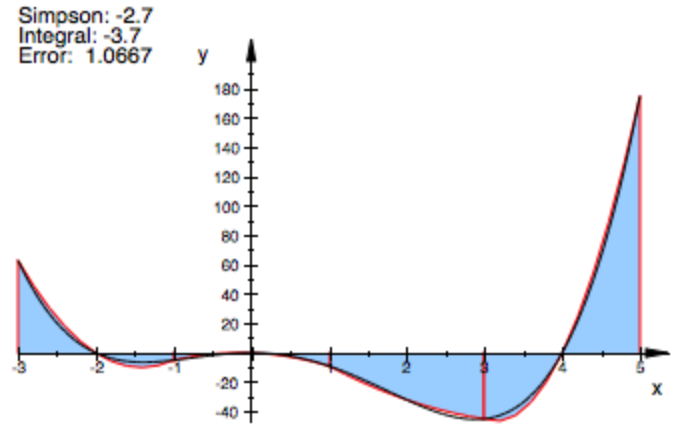
Example 3

The number of digits after the decimal point can be specified for each value. In the following example all values are displayed with four digits:

```
f := plot::Function2d(x^2*(x-4)*(x+2), x = -3..5, Color = RGB::Black):
plot(plot::Integral(f, 4, IntMethod = Simpson, LineColor = RGB::Red,
ShowInfo = [4, IntMethod, Integral, Error]), f)
```



Only the error shall be displayed with four digits after the decimal point. All other values are shown with only one digit:
plot(plot::Integral(f, 4, IntMethod = Simpson, LineColor = RGB::Red, ShowInfo = [1, IntMethod, Integral, 4, Error]), f)

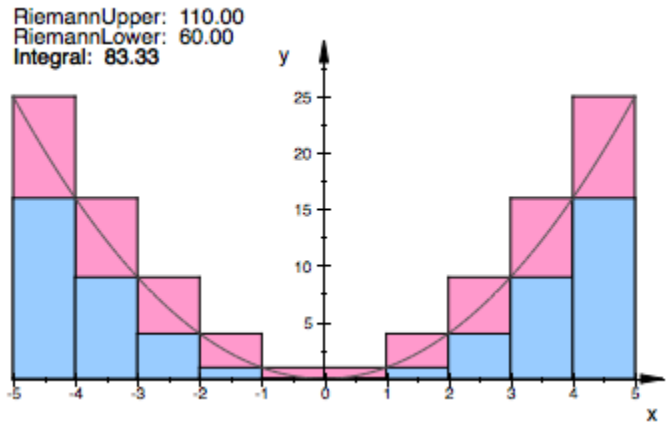


delete f:

Example 4

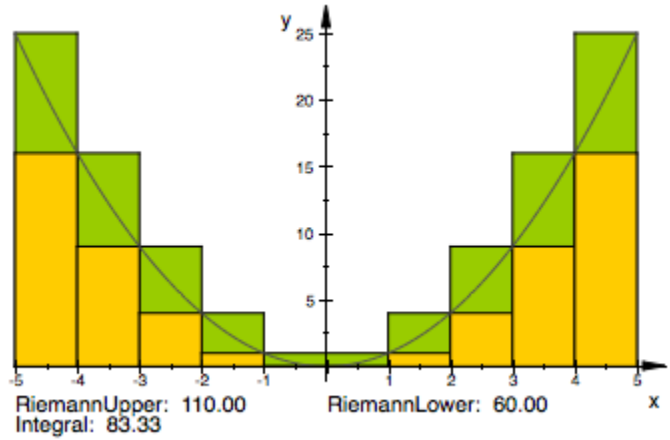
Two approximation objects shall be displayed in one plot. To prevent collision of the automatically positioned texts, we insert an empty line into the text of one of the objects to prevent collision of the automatically positioned texts:

```
f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannUpper, Color = RGB::Rose,
ShowInfo = [IntMethod, "", Integral]), plot::Integral(f, IntMethod =
RiemannLower, ShowInfo = [IntMethod, Integral]), f)
```



Alternatively, the position can be given explicitly:

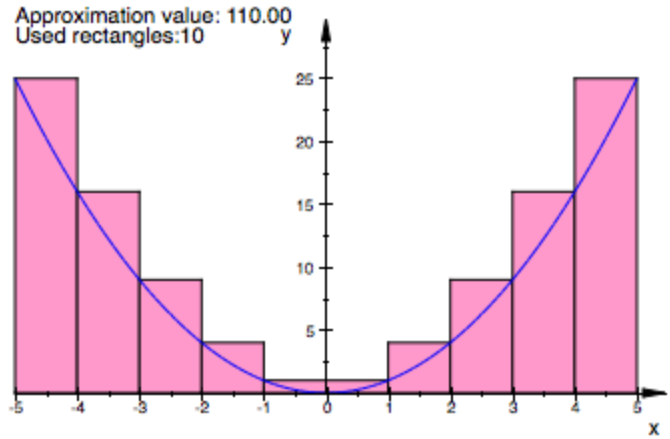
```
f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannUpper, Color = RGB::Lime,
ShowInfo = [IntMethod, Integral, Position = [-5, -1]], VerticalAlignment
= Top), plot::Integral(f, IntMethod = RiemannLower, Color = RGB::Gold,
ShowInfo = [IntMethod, Position = [0, -1]], VerticalAlignment = Top), f)
```



delete f:

Example 5

The text may contain additional messages:
f := plot::Function2d(x^2, x = -5..5): plot(plot::Integral(f, IntMethod = RiemannUpper, ShowInfo = ["Approximation value:", IntMethod = "", "\nUsed rectangles:", Nodes = ""], Color = RGB::Rose), f)



delete f:

Object title

Value Summary

`Title`, `Titles`	Optional	Text string

Graphics Primitives

Objects	Default Values
plot::Piechart2d, plot::Piechart3d	`Titles`: `[" "]`

Description

`Title` sets the title of an object to be displayed in the graphics.

`Titles` is a list of titles for parts of an object, e.g., the pieces of a pie chart.

Using `Title`, any graphical object can be given a title that will be displayed at the position given by the TitlePosition attribute.

The `Title` can additionally be horizontically aligned at the `TitlePosition` via TitleAlignment.

The object attribute Visible also affects the object's title: Invisible objects do not show their titles.

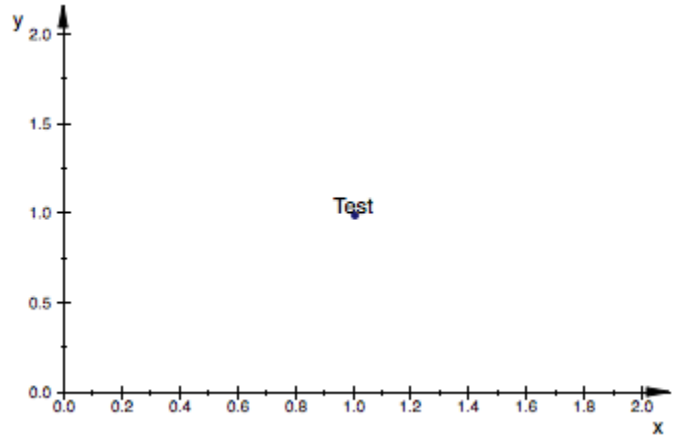
`Titles` is used to set a number of titles for sub-objects, such as the bars of a bar plot or the segments of a pie chart. These do not react to `TitlePosition`.

`Title` and `Titles` cannot be animated. But note that `TitlePosition` can.

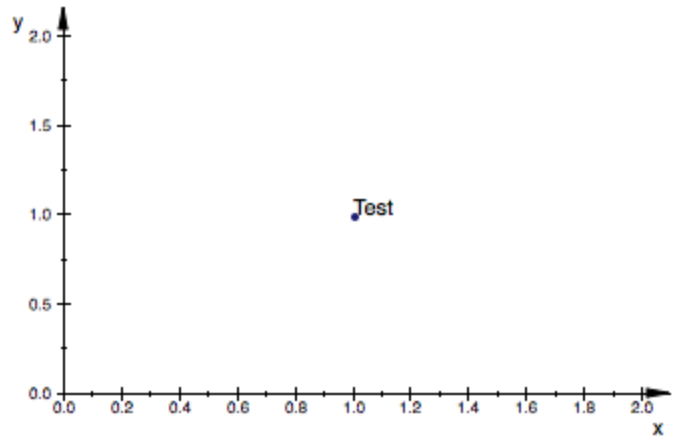
Examples

Example 1

The default positioning of a title relative to `TitlePosition` is to have the lower left corner of the title at this place:
plot(plot::Point2d(1, 1, Title = "Test", TitlePosition = [1, 1]))

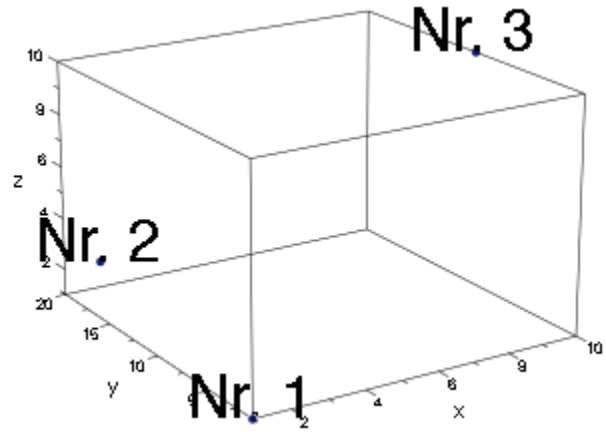


This position depends on the title alignment:
plot(plot::Point2d(1, 1, Title = "Test", TitlePosition = [1, 1], TitleAlignment = Left))



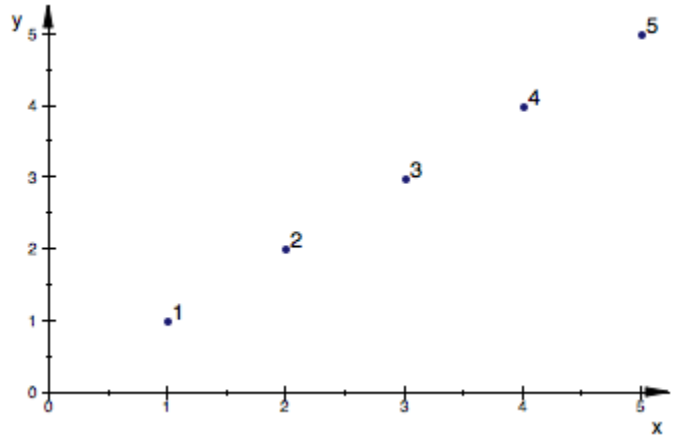
Example 2

In 3D, titles have so-called “bill-boarding”: Instead of having a fixed orientation, they are always drawn in a readable orientation and their sizes are not affected by zooming and perspective scaling:
plot(plot::Point3d(1, 1, 1, Title = "Nr. 1", TitlePosition = [1, 1, 1]), plot::Point3d(2, 20, 2, Title = "Nr. 2", TitlePosition = [2, 20, 2]), plot::Point3d(10, 10, 10, Title = "Nr. 3", TitlePosition = [10, 10, 10]), TitleFont = [30])



Example 3

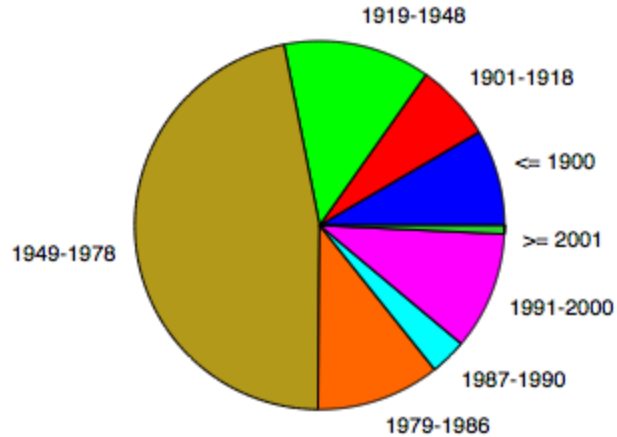
Titles of invisible objects are invisible themselves. This also applies to objects that are temporarily invisible:
plot(plot::Point2d(i, i, Title = expr2text(i), TitlePosition = [i+1/10, i], VisibleAfter = i) $ i = 1..5, TimeRange = 0..5, ViewingBox = [0..5, 0..5])



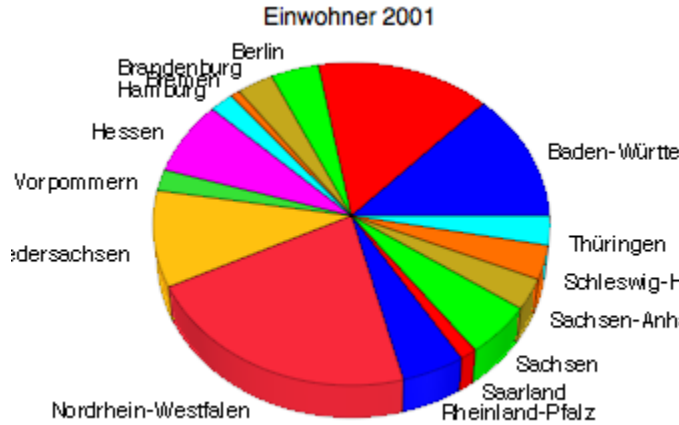
Example 4

Use `Titles` to label individual parts of statistical plots such as pie charts:

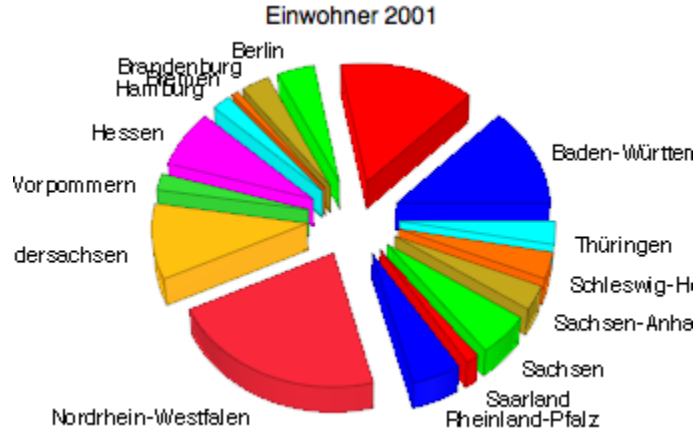
```
plot(plot::Piechart2d([3267, 2629, 4970, 18094, 4189, 1236, 4003, 297],
Titles = ["<= 1900", "1901-1918", "1919-1948", "1949-1978", "1979-1986",
"1987-1990", "1991-2000", ">= 2001"]))
```



Note that pie charts with many pies are in general tricky to label nicely:
p := plot::Piechart3d([10601, 12330, 3388, 2593, 660, 1726, 6078, 1760, 7956, 18052, 4049, 1066, 4384, 2581, 2804, 2411], Titles = ["Baden-Württemberg", "Bayern", "Berlin", "Brandenburg", "Bremen", "Hamburg", "Hessen", "Mecklenburg-Vorpommern", "Niedersachsen", "Nordrhein-Westfalen", "Rheinland-Pfalz", "Saarland", "Sachsen", "Sachsen-Anhalt", "Schleswig-Holstein", "Thüringen"]): plot(p, Header = "Einwohner 2001")



p::Moves := [0.3]: plot(p, Header = "Einwohner 2001")



See Also TitleAlignmentTitleFontTitlePosition

TitlePositionTitlePositionXTitlePositionYTitlePositionZ

Purpose

Position of object titles

Value Summary

`TitlePosition`	Library wrapper for "[TitlePositionX, TitlePositionY]" (2D), "[TitlePositionX, TitlePositionY, TitlePositionZ]" (3D)	See below
`TitlePositionX`, `TitlePositionY`, `TitlePositionZ`	Optional	MuPAD expression

Description

`TitlePosition` sets the position where the object title is displayed.

`TitlePositionX`, `TitlePositionY`, and `TitlePositionZ` refer to the individual components of `TitlePosition`.

An object can be given a title to be displayed in the graphic with the attribute Title. `TitlePosition`, TitlePositionX, TitlePositionY, TitlePositionZ determines the position of this title.

`TitlePosition`, TitlePositionX, TitlePositionY, TitlePositionZ determines the anchor point of the title, which is in 3D displayed in "bill-boarding mode," which means that the text will always face the observer and will always be displayed in the same size, regardless of zooming or perspective. The alignment of the text w.r.t. the anchor point is further determined by the setting of TitleAlignment, cf. "Example 1" on page 24-1486.

MuPAD does not have automatic positioning of titles; to have a title properly positioned, `TitlePosition` must be set.

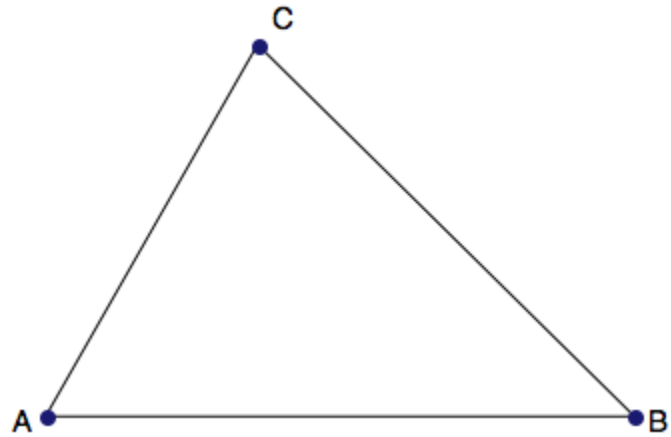
Examples

Example 1

We plot three points with titles attached to them, changing the alignment. For demonstration purposes, the title positions coincide with the points:
plot(plot::Point2d(0, 3, Title = "Left", TitlePosition = [0, 3], TitleAlignment = Left), plot::Point2d(0, 2, Title = "Center", TitlePosition = [0, 2], TitleAlignment = Center), plot::Point2d(0, 1, Title = "Right", TitlePosition = [0, 1], TitleAlignment = Right), Axes = None, PointSize = 2.0*unit::mm, ViewingBox = [-1..1, 0..4])

Example 2

A more realistic placement of titles is to separate them slightly from the points:
plot(plot::Polygon2d([[0, 0], [5, 0], [9/5, 12/5]], Closed), plot::Point2d([0, 0], Title = "A", TitlePosition = [-0.2, -0.1]), plot::Point2d([5, 0], Title = "B", TitlePosition = [5.2, -0.1]), plot::Point2d([9/5, 12/5], Title = "C", TitlePosition = [2.0, 2.5]), Axes = None, TitleFont = [15], LineColor = RGB::Black, LineWidth = 0.5*unit::mm, PointSize = 3*unit::mm)



See Also TitleTitleAlignmentTitleFont

Purpose

BottomLeft

Positioning of a scene in a canvas

Value Summary

`Bottom`, `Left`	Optional	See below

Graphics Primitives

Objects	Default Values
plot::Scene2d, plot::Scene3d	`Bottom`, `Left`: `0`

Description

With the canvas attribute Layout set to `Absolute` or `Relative`, scenes in the canvas can be scaled and positioned freely.

`Bottom = b` places the bottom side of a scene at a distance *b* above the bottom side of the canvas.

`Left = l` places the left hand side of a scene at a distance *l* to the right of the left hand side of the canvas.

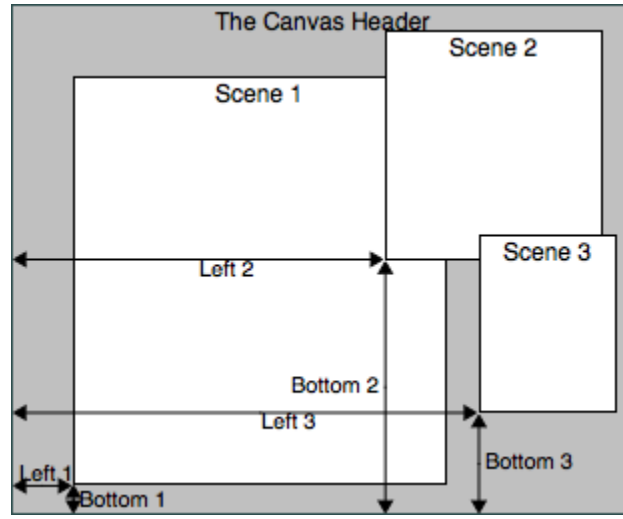
The automatic layout schemes Layout = `Horizontal`, Layout = `Vertical`, and Layout = `Tabular` are available for a canvas that contains several scenes.

The canvas settings Layout = `Absolute` and Layout = `Relative` switch the automatic layout mode off and allow to position each scene freely via the attributes `Bottom` and `Left`, respectively. These attributes set the distances of the lower left corner of the scene to the bottom, respectively left hand side of the canvas. These values can be set separately for each scene.

Note `Bottom` and `Left` are only respected for plots with Layout = `Absolute` or Layout = `Relative`.

The following pictures illustrates the positioning of scenes in a canvas via the scene attributes `Bottom` and `Left`:

```
read("layoutPictures.mu"): Scene6::Header := "Scene 1":
Scene7::Header := "Scene 2": Scene8::Header := "Scene 3":
plot(plot::Canvas(Height = 90*unit::mm, Width = 110*unit::mm,
Header = "The Canvas Header", HeaderFont = [fontsize], FooterFont
= [fontsize], Layout = Relative, BackgroundColor = RGB::Grey,
BorderWidth = 0.5*unit::mm, BorderColor = RGB::SlateGreyDark,
Scene6, Scene7, Scene8, SCENE3 ) ):
```



With Layout = `Absolute`, the distance of the lower left corner of the scene to the lower left corner of the canvas must be specified via physical lengths with a unit, e.g., `Bottom = 2*unit::mm`, `Left = 0.1*unit::inch`. Missing units are assumed to be mm.

With Layout = `Relative`, the distance of the bottom side of the scene to the bottom side of the canvas must be specified as a fraction of the canvas height, i.e., as a number between 0 and 1. The distance of the left hand side of the scene to the left hand side of the canvas must be specified as a fraction of the canvas width, i.e., as a number between 0 and 1.

The lower left corner of a scene may be placed outside the canvas. The parts of a scene outside the canvas are clipped.

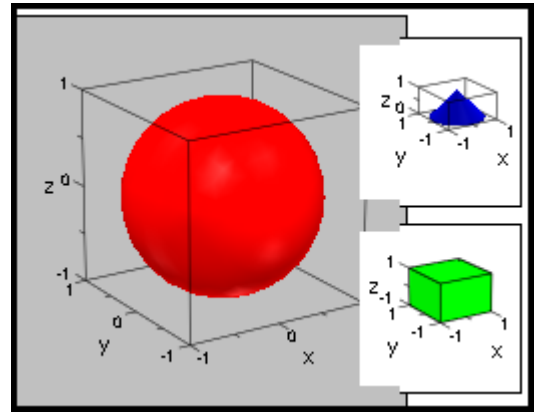
Overlapping scenes can be created. In such a situation it may be useful to create transparent scenes (without a background) via BackgroundTransparent = `TRUE`.

Examples

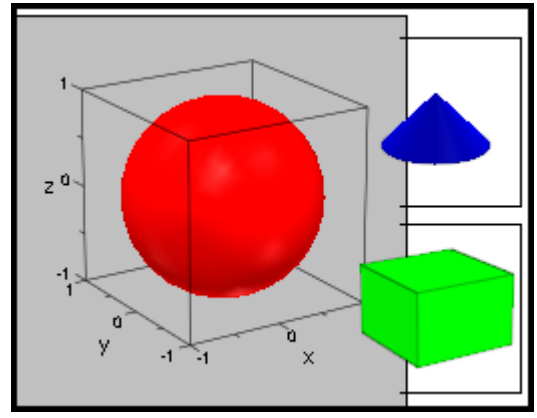
Example 1

We demonstrate the layout of the canvas with Layout = `Absolute`. The scene `S1` is positioned automatically in the canvas using the default values `Bottom = 0`, `Left = 0`. The smaller scenes `S2` and `S3` are positioned explicitly via `Bottom` and `Left`:

```
S1 := plot::Scene3d(plot::Sphere(1, [0, 0, 0], Color = RGB::Red),
Width = 70*unit::mm, Height = 70*unit::mm, BackgroundColor =
RGB::Grey): S2 := plot::Scene3d(plot::Box(-1..1, -1..1, -1..1, Color =
RGB::Green), Width = 30*unit::mm, Height = 30*unit::mm, Left =
60*unit::mm, Bottom = 3*unit::mm): S3 := plot::Scene3d(plot::Cone(1,
[0, 0, 0], [0, 0, 1], Color = RGB::Blue), Width = 30*unit::mm,
Height = 30*unit::mm, Left = 60*unit::mm, Bottom = 36*unit::mm):
plot(S1, S2, S3, Layout = Absolute, plot::Canvas::BorderWidth
= 1.0*unit::mm, plot::Canvas::BorderColor = RGB::Black,
plot::Canvas::Width = 92*unit::mm, plot::Canvas::Height =
72*unit::mm, plot::Scene3d::BorderWidth = 0.5*unit::mm,
plot::Scene3d::BorderColor = RGB::Black):
```



We make the background of the small scenes transparent and switch the axes off:
S2::BackgroundTransparent := TRUE: S2::Axes := None:
S3::BackgroundTransparent := TRUE: S3::Axes := None:
plot(S1, S2, S3, Layout = Absolute, plot::Canvas::BorderWidth = 1.0*unit::mm, plot::Canvas::BorderColor = RGB::Black, plot::Canvas::Width = 92*unit::mm, plot::Canvas::Height = 72*unit::mm, plot::Scene3d::BorderWidth = 0.5*unit::mm, plot::Scene3d::BorderColor = RGB::Black):

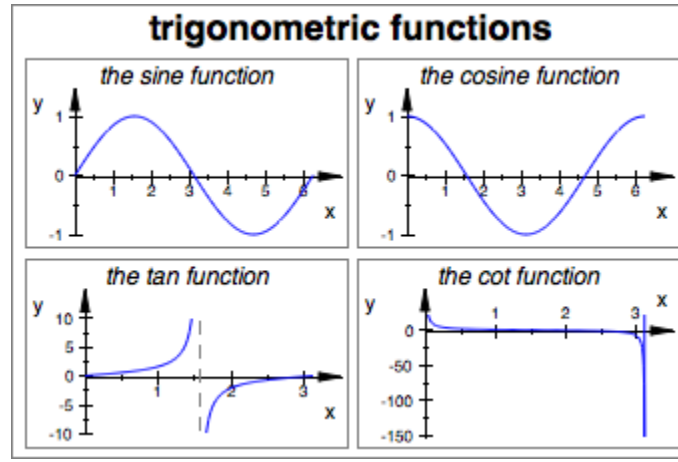


delete S1, S2, S3:

Example 2

We demonstrate the layout of the canvas with Layout = `Relative`. Apart from the scene headers and the positioning via `Bottom` and `Left`, all scene attributes are set in the `plot` call via specifications such as `plot::Scene2d::Width` etc. This distinguishes the scene attributes from the canvas attributes Width, BorderWidth etc.

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0..2*PI), Left
= 0.02, Bottom = 0.46, Header = "the sine function"): S2
:= plot::Scene2d(plot::Function2d(cos(x), x = 0..2*PI), Left
= 0.51, Bottom = 0.46, Header = "the cosine function"): S3
:= plot::Scene2d(plot::Function2d(tan(x), x = 0..PI), Left =
0.02, Bottom = 0.02, Header = "the tan function"): S4 :=
plot::Scene2d(plot::Function2d(cot(x), x = 0..PI), Left = 0.51,
Bottom = 0.02, Header = "the cot function"): plot(S1, S2, S3, S4,
Layout = Relative, Width = 120*unit::mm, Height = 80*unit::mm,
BorderWidth = 0.5*unit::mm, HeaderFont = ["Times New Roman",
18, Bold], Header = "trigonometric functions", plot::Scene2d::Width
= 0.475, plot::Scene2d::Height = 0.42, plot::Scene2d::BorderWidth =
0.2*unit::mm, plot::Scene2d::HeaderFont = ["Times New Roman", Italic,
12]):
```



delete S1, S2, S3, S4:

See Also

Layout

Ground

Purpose

HeightWidth

Heights and widths of canvases and scenes

Value Summary

`Height`, `Width`	Inherited	Positive output size

Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	`Height: 80` `Width: 120`

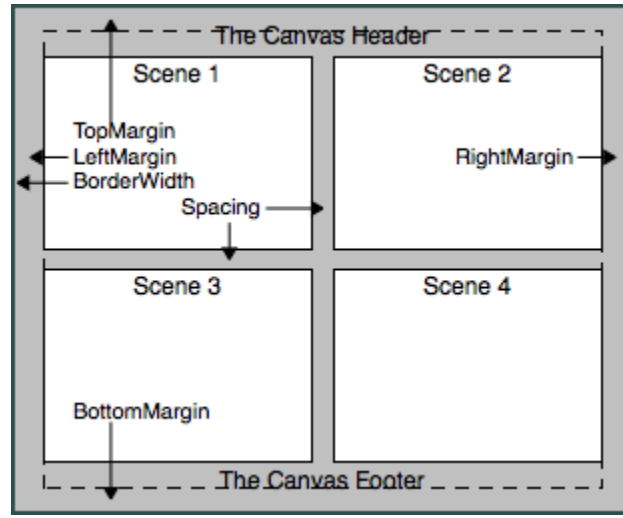
Description

`Height = h` and `Width = w` set the size of the canvas or scene to the height `h` and the width `w`.

For the canvas, the width and the height should be specified as physical lengths with a unit, e.g., `Width = 120*unit::mm`, `Height = 4.72*unit::inch`. Numbers without a physical unit give the size in mm.

These values specify the (approximate) physical size of the canvas, with which the graphics appears on the screen. A printout of the MuPAD graphics will have this physical size precisely.

The following picture illustrates the layout of the canvas:
read("layoutPictures.mu"): Scene1::Header := "Scene 1": Scene2::Header := "Scene 2": Scene3::Header := "Scene 3": Scene4::Header := "Scene 4": plot(plot::Canvas(Height = 90*unit::mm, Width = 110*unit::mm, Footer = "The Canvas Footer", Header = "The Canvas Header", HeaderFont = [12], FooterFont = [12], Spacing = 2.0*unit::mm, Margin = 3*unit::mm, BackgroundColor = RGB::Grey, BorderWidth = borderwidth*100*unit::mm, BorderColor = RGB::SlateGreyDark, Layout = Relative, Scene1, Scene2, Scene3, Scene4, SCENE1)):



The width and height of the canvas include the margin set by Margin and the border set by BorderWidth.

When only one scene is displayed in the canvas, this scene fills the canvas, i.e., the scene size coincides with the canvas size. When the canvas contains several scenes, there are various layout schemes, set by the canvas attribute Layout, to arrange the scenes in the canvas. Two schemes allow to set the size of the scenes indepently of the canvas size:

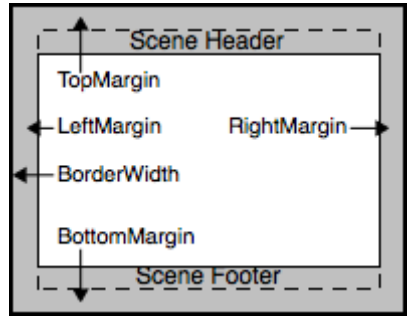
Note For scenes, the attributes `Width` and `Height` are only used when plotting with the canvas attribute Layout set to `Absolute` or `Relative`.

With `Layout = Absolute`, width and height of a scene must be specified as physical lengths with a unit, e.g., `Height = 40*unit::mm`, `Width = 2.4*unit::inch` (missing units are assumed to be mm).

With `Layout = Relative`, width and height of a scene must be specified as fractions of the canvas widht and height, i.e., as numbers between 0 and 1.

The lower left corner of a scene can be moved to any position via the attributes Bottom and Left.

The following picture illustrates the layout of a scene:
Scene5::Header := "Scene Header": Scene5::Footer := "Scene Footer": plot(Scene5, SCENE2, Layout = Relative, Height = canvasheight, Width = canvaswidth, Margin = 0, BorderWidth = 0):



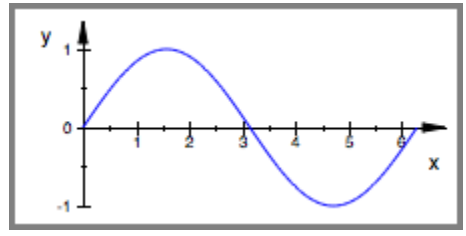
The width and height of the scene include the margin set by Margin and the border set by BorderWidth.

If a scene exceeds the canvas, the corresponding parts of the scene are clipped.

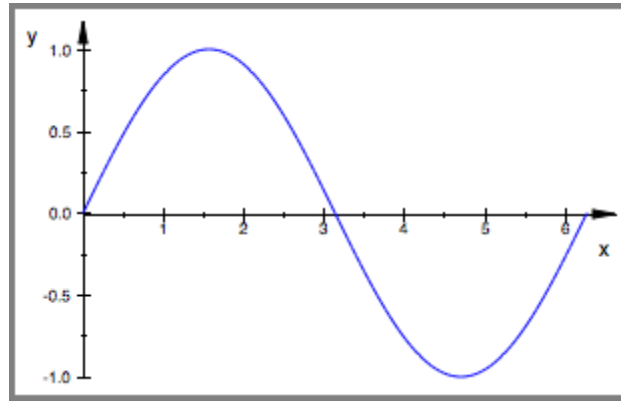
Examples

Example 1

The following calls produce plots of the physical sizes 8 4 cm and 11 7 cm, respectively.
f := plot::Function2d(sin(x), x = 0..2*PI): plot(f, Width = 80*unit::mm, Height = 4*unit::cm, BorderWidth = 1.0*unit::mm):



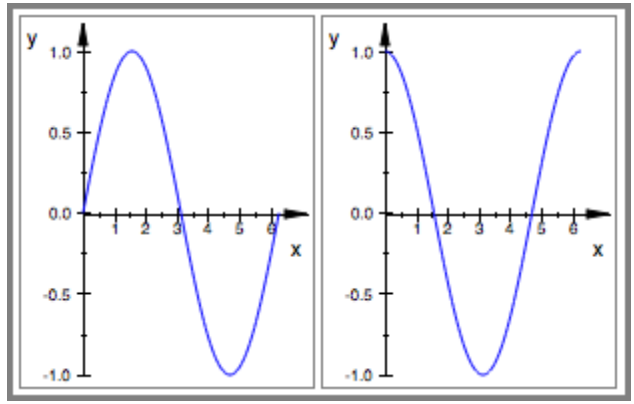
plot(f, Width = 110*unit::mm, Height = 7*unit::cm, BorderWidth = 1.0*unit::mm):



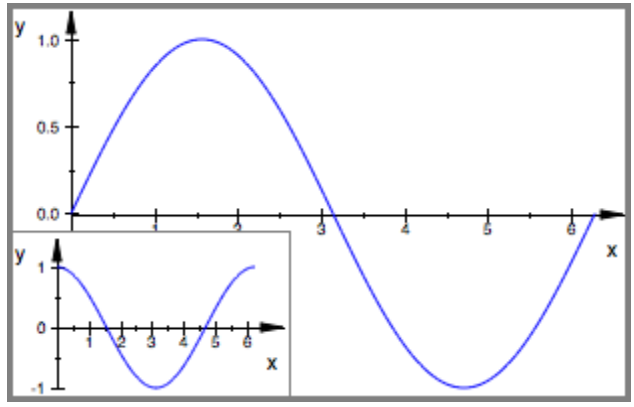
delete f:

Example 2

In the following graphics, we place two scenes in one canvas:
f1 := plot::Function2d(sin(x), x = 0..2*PI): f2 := plot::Function2d(cos(x), x = 0..2*PI): S1 := plot::Scene2d(f1, BorderWidth = 0.5*unit::mm, Height = 7*unit::cm, Width = 11*unit::cm): S2 := plot::Scene2d(f2, BorderWidth = 0.5*unit::mm, Height = 3*unit::cm, Width = 5*unit::cm): plot(S1, S2, Layout = Horizontal, BorderWidth = 1.0*unit::mm, Height = 7*unit::cm, Width = 11*unit::cm):

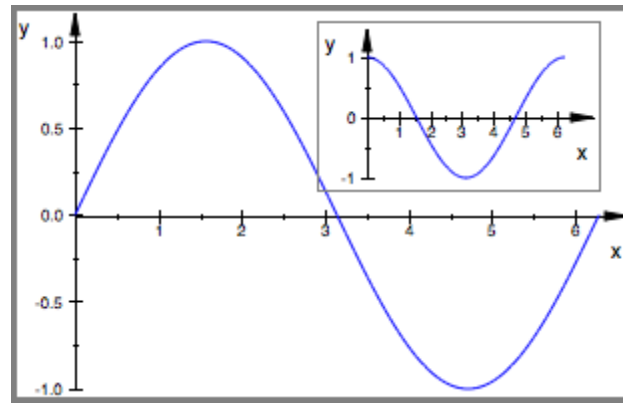


Note that with `Layout = Horizontal`, the size attributes of the scenes were ignored in the plot above. They affect the graphic when switching `Layout` to `Absolute`, either interactively in the inspector or directly in the plot call:
plot(S1, S2, Layout = Absolute, BorderWidth = 1.0*unit::mm, Height = 7*unit::cm, Width = 11*unit::cm):



Note that we did not set the attributes Bottom and Left of the scenes, so the bottom left corners of the scenes are placed in the bottom left corner of the canvas.

We make the background of the scene `S2` transparent via `BackgroundTransparent = TRUE` and shift this scene via suitable values of Bottom and Left:
S2::BackgroundTransparent := TRUE: S2::Bottom := 3.7*unit::cm: S2::Left := 5.4*unit::cm: plot(S1, S2, Layout = Absolute, BorderWidth = 1.0*unit::mm, Height = 7*unit::cm, Width = 11*unit::cm):



delete f1, f2, S1, S2:

BorderWidthBottomLayoutLeftMargin

Purpose

LayoutRowsColumns

Arrangement/layout of several scenes in a canvas

Value Summary

`Layout`	Optional	`Absolute`, `Horizontal`, `Relative`, `Tabular`, or `Vertical`
`Columns`, `Rows`	Optional	Positive integer

Graphics Primitives

Objects	Default Values
plot::Canvas	`Layout: Tabular` `Rows, Columns: 0`

Description

`Layout` determines the arrangement of several scenes in a canvas.

`Rows` determines the number of scene rows in a tabular arrangement of several scenes.

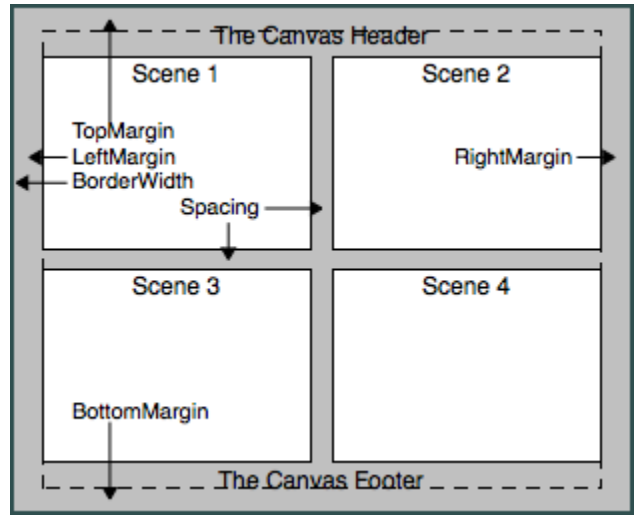
`Columns` determines the number of scene columns in a tabular arrangement of several scenes.

If a canvas contains more than one scene, the `Layout` attribute determines how the scenes are arranged in the canvas:

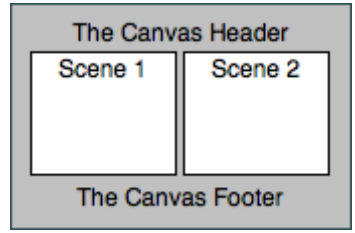
- With the default setting `Layout = Tabular`, a sequence of scenes in a canvas is arranged like a table with several columns and rows. The number of columns or rows may be chosen via the attributes `Columns` or `Rows`, respectively. If none of these attributes is given, the tabular layout scheme chooses some suitable values, automatically.

  The scenes are filled into the table according to standard western reading order, filling the upper row from left to right, then proceeding to the next row etc:

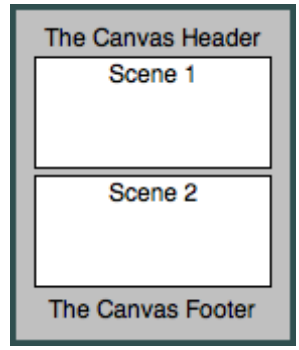
read("layoutPictures.mu"): Scene1::Header := "Scene 1": Scene2::Header := "Scene 2": Scene3::Header := "Scene 3": Scene4::Header := "Scene 4": plot(plot::Canvas(Height = 90*unit::mm, Width = 110*unit::mm, Footer = "The Canvas Footer", Header = "The Canvas Header", HeaderFont = [12], FooterFont = [12], Spacing = 2.0*unit::mm, Margin = 3*unit::mm, BackgroundColor = RGB::Grey, BorderWidth = borderwidth*100*unit::mm, BorderColor = RGB::SlateGreyDark, Layout = Relative, Scene1, Scene2, Scene3, Scene4, SCENE1)):



- `Layout` = `Horizontal` is a shortcut for `Layout` = `Tabular`, `Rows` = `1`. The scenes are placed side by side in a single row.
  plot(plot::Canvas(Height = 40*unit::mm, Width = 60*unit::mm, Footer = "The Canvas Footer", Header = "The Canvas Header", HeaderFont = [12], FooterFont = [12], Layout = Tabular, Rows = 1, BackgroundColor = RGB::Grey, BorderWidth = borderwidth*50*unit::mm, BorderColor = RGB::SlateGreyDark, Margin = 3*unit::mm, Scene1, Scene2)):



- `Layout` = `Vertical` is a shortcut for `Layout` = `Tabular`, `Columns` = `1`. The scenes a placed below each other in a single column.
  Scene3::Header := "Scene 2": plot(plot::Canvas(Height = 60*unit::mm, Width = 50*unit::mm, Footer = "The Canvas Footer", Header = "The Canvas Header", HeaderFont = [12], FooterFont = [12], Layout = Tabular, Columns = 1, Margin = 3*unit::mm, BackgroundColor = RGB::Grey, BorderWidth = 1*unit::mm, BorderColor = RGB::SlateGreyDark, Scene1, Scene3)):



The settings `Layout` = `Absolute` and `Layout` = `Relative` switch the automatic layout mode off and allow to position each scene via the scene attributes Left and Bottom. These attributes determine the position of the lower left corner of the scene and can be set separately for each scene.

- With `Layout` = `Absolute`, the values for the lower left corner of the scene as well as its width and height must be specified as

absolute physical lengths such as `Left = 3.0*unit::mm`, `Bottom = 4.5*unit::mm`, `Width = 10*unit::cm`, `Height = 4*unit::inch`.

- With `Layout = Relative`, these values must be specified as fractions of the canvas height and width. E.g.,

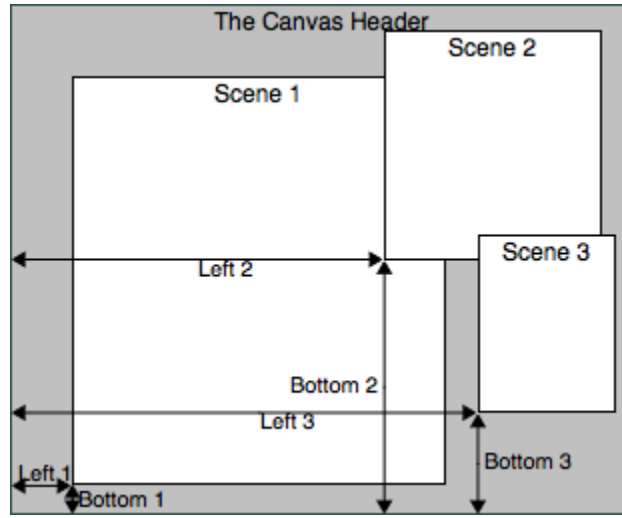
  ```
  Layout = Relative,
  Left = 0.3, Bottom = 0.2, Width = 0.5, Height = 0.5
  ```

  is equivalent to

  ```
  Layout = Absolut,
  Left = 0.3*canvaswidth, Bottom = 0.2*canvasheight,
  Width = 0.5*canvaswidth, Height = 0.5*canvasheight,
  ```

  where `canvaswidth` and `canvasheight` are the physical width and height of the canvas.

```
Scene6::Header := "Scene 1": Scene7::Header := "Scene 2":
Scene8::Header := "Scene 3": plot(plot::Canvas(Height = 90*unit::mm,
Width = 110*unit::mm, Header = "The Canvas Header", HeaderFont =
[fontsize], FooterFont = [fontsize], Layout = Relative, BackgroundColor
= RGB::Grey, BorderWidth = 0.5*unit::mm, BorderColor =
RGB::SlateGreyDark, Scene6, Scene7, Scene8, SCENE3 ) ):
```



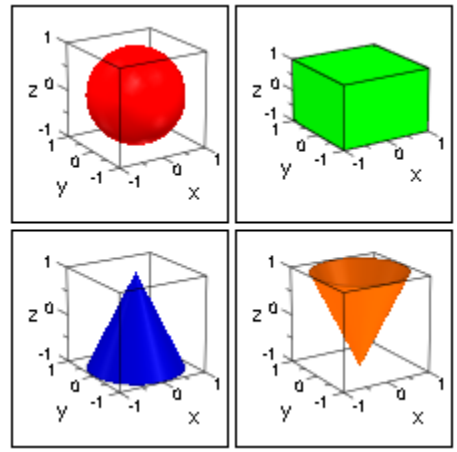
With `Layout` = `Absolute` and `Layout` = `Relative` overlapping scenes can be created. In such a situation it may be useful to create transparent scenes (without a background) via BackgroundTransparent = `TRUE`.

Examples

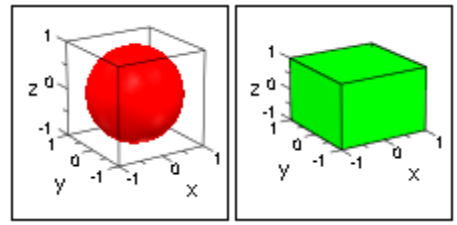
Example 1

We define four scenes:
S1 := plot::Scene3d(plot::Sphere(1, [0, 0, 0], Color = RGB::Red), BorderWidth = 0.2*unit::mm, BorderColor = RGB::Black): S2 := plot::Scene3d(plot::Box(-1..1, -1..1, -1..1, Color = RGB::Green), BorderWidth = 0.2*unit::mm, BorderColor = RGB::Black): S3 := plot::Scene3d(plot::Cone(1, [0, 0, -1], [0, 0, 1], Color = RGB::Blue), BorderWidth = 0.2*unit::mm, BorderColor = RGB::Black): S4 := plot::Scene3d(plot::Cone(1, [0, 0, 1], [0, 0, -1], Color = RGB::Orange), BorderWidth = 0.2*unit::mm, BorderColor = RGB::Black):

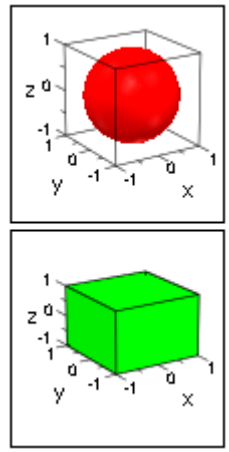
These scenes are positioned in the canvas in various ways:
plot(S1, S2, S3, S4, Layout = Tabular, Height = 80*unit::mm, Width = 80*unit::mm):



plot(S1, S2, Layout = Horizontal, Height = 40*unit::mm, Width = 80*unit::mm):

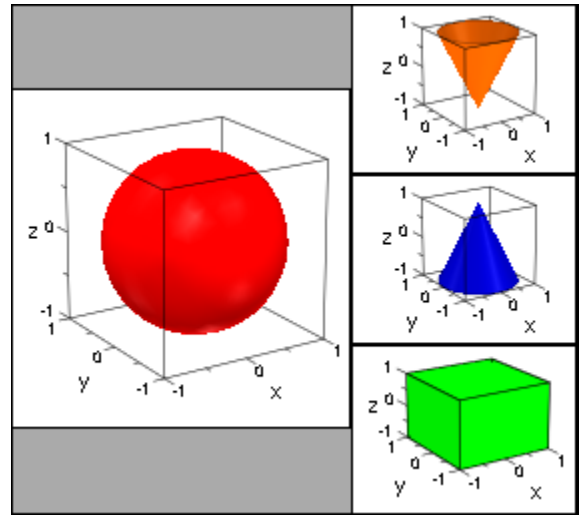


plot(S1, S2, Layout = Vertical, Height = 80*unit::mm, Width = 40*unit::mm):

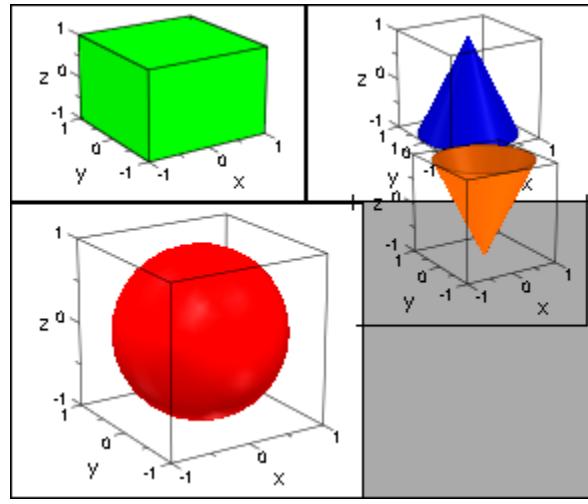


For explicit placement of the scenes, we set values for the Left, Bottom, Width, and Height attributes of the scenes:
S1::Left := 0: S1::Bottom := 15*unit::mm: S1::Width := 60*unit::mm: S1::Height:= 60*unit::mm: S2::Left := 60*unit::mm: S2::Bottom := 0*unit::mm: S2::Width := 40*unit::mm: S2::Height:= 30*unit::mm: S3::Left := 60*unit::mm: S3::Bottom := 30*unit::mm: S3::Width := 40*unit::mm: S3::Height:= 30*unit::mm: S4::Left := 60*unit::mm: S4::Bottom := 60*unit::mm: S4::Width := 40*unit::mm: S4::Height:= 30*unit::mm:

We use `Layout = Absolute`:
plot(S1, S2, S3, S4, Layout = Absolute, BorderWidth = 0.5*unit::mm, BorderColor = RGB::Black, BackgroundColor = RGB::LightGrey, Height = 90*unit::mm, Width = 100*unit::mm):



For `Layout = Relative`, the scene attributes Left, Width, Bottom, Height must be given as fractions of the canvas width and height, respectively:
S1::Left := 0: S1::Width := 0.6: S1::Bottom := 0: S1::Height := 0.6: S2::Left := 0: S2::Width := 0.5: S2::Bottom := 0.6: S2::Height := 0.4: S3::Left := 0.5: S3::Width := 0.5: S3::Bottom := 0.6: S3::Height := 0.4: S4::Left := 0.58: S4::Width := 0.4: S4::Bottom := 0.35: S4::Height := 0.4: S4::BackgroundTransparent := TRUE:plot(S1, S2, S3, S4, Layout = Relative, BorderWidth = 0.5*unit::mm, BorderColor = RGB::Black, BackgroundColor = RGB::LightGrey, Height = 87*unit::mm, Width = 104*unit::mm):



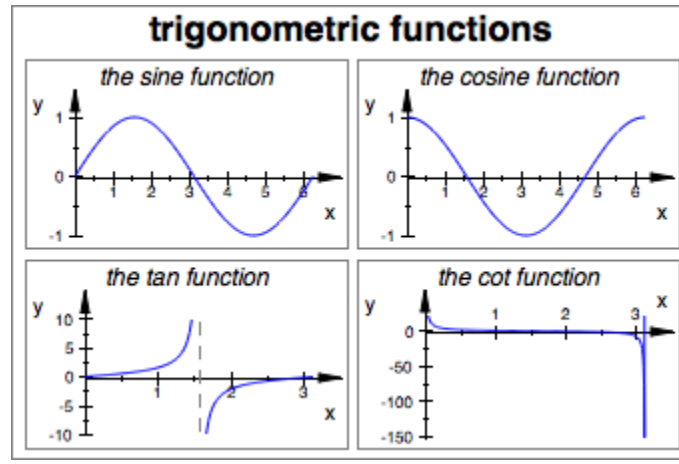
delete S1, S2, S3, S4:

Example 2

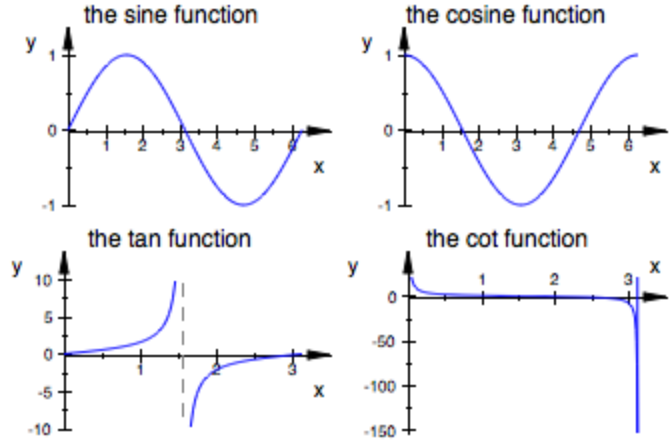
We demonstrate the layout of the canvas with `Layout = Relative`. Apart from the scene headers and the positioning via Bottom and Left, all scene attributes are set in the `plot` call via specifications such as `plot::Scene2d::Width` etc. This distinguishes the scene attributes from the canvas attributes Width, BorderWidth etc.

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0..2*PI), Left
= 0.02, Bottom = 0.46, Header = "the sine function"): S2
:= plot::Scene2d(plot::Function2d(cos(x), x = 0..2*PI), Left
= 0.51, Bottom = 0.46, Header = "the cosine function"): S3
:= plot::Scene2d(plot::Function2d(tan(x), x = 0..PI), Left =
0.02, Bottom = 0.02, Header = "the tan function"): S4 :=
plot::Scene2d(plot::Function2d(cot(x), x = 0..PI), Left = 0.51,
Bottom = 0.02, Header = "the cot function"): plot(S1, S2, S3, S4,
Layout = Relative, Width = 120*unit::mm, Height = 80*unit::mm,
BorderWidth = 0.5*unit::mm, HeaderFont = ["Times New Roman",
18, Bold], Header = "trigonometric functions", plot::Scene2d::Width
= 0.475, plot::Scene2d::Height = 0.42, plot::Scene2d::BorderWidth =
```

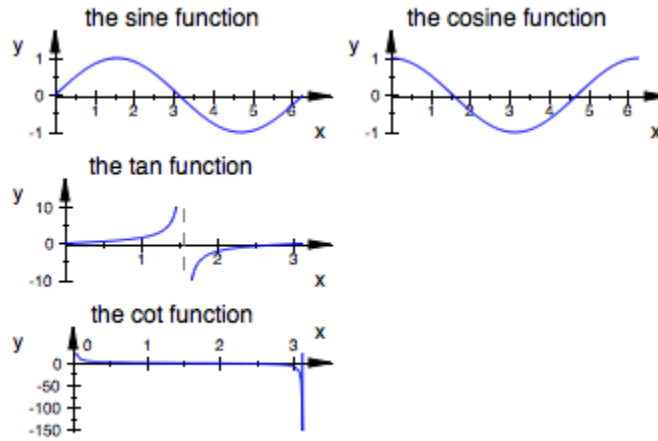
0.2*unit::mm, plot::Scene2d::HeaderFont = ["Times New Roman", Italic, 12]):



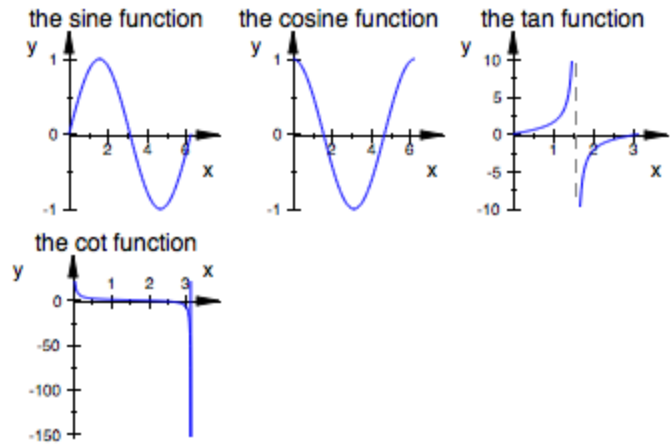
Finally, we demonstrate the attributes `Rows` and `Columns`. The automatic tabular layout ignores the explicit positioning of the scenes and chooses the following arrangement:
plot(S1, S2, S3, S4)



We explicitly request three rows:
plot(S1, S2, S3, S4, Rows = 3)



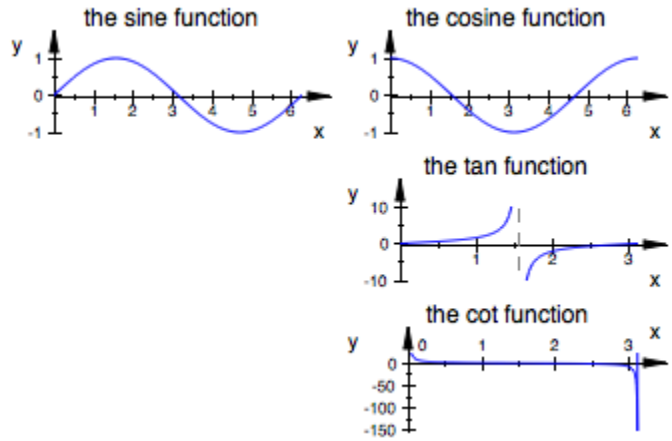
We explicitly request three columns:
plot(S1, S2, S3, S4, Columns = 3)



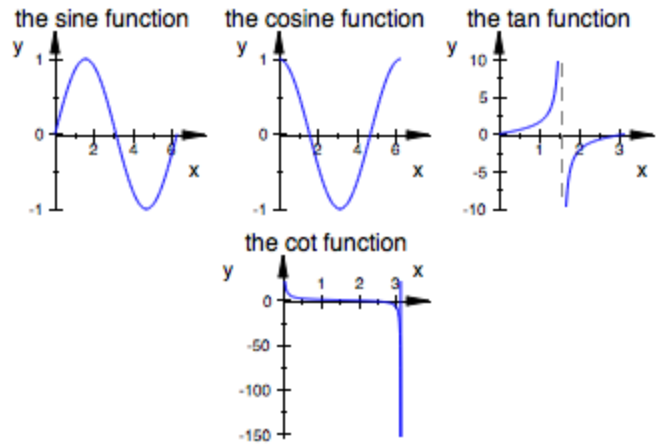
We generate an empty scene:

empty := plot::Scene2d(Axes = None):

The tabular layout is filled in with empty scenes:
plot(S1, S2, empty, S3, empty, S4, Rows = 3)



plot(S1, S2, S3, empty, S4, empty, Columns = 3)



delete S1, S2, S3, S4, empty:

See Also BorderWidthBorderColorBottomMarginLeftMarginMarginRightMarginTopMarginLeftBotton

Purpose

MarginBottomMarginTopMarginLeftMarginRightMargin

Margins around canvas and scenes

Value Summary

`Margin`	[{BottomMargin, LeftMargin, RightMargin, TopMargin}]	Non-negative output size
`BottomMargin`, `LeftMargin`, `RightMargin`, `TopMargin`	Inherited	Non-negative output size

Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	`Margin`, `BottomMargin`, `TopMargin`, `LeftMargin`, `RightMargin`: `1`

Description

`Margin = d` sets a margin of size `d` around a canvas or scene. The margins at the bottom, to the left etc. can also be specified separately via `BottomMargin = d`$_1$, `LeftMargin = d`$_2$ etc.

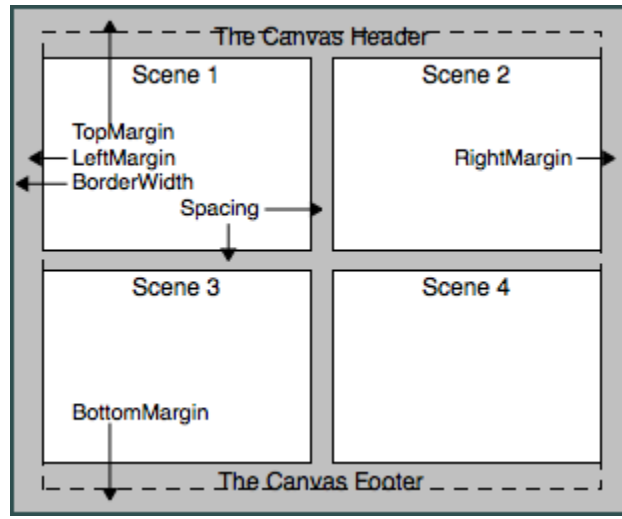
The canvas as well as the scenes have a margin that is not used for displaying graphical objects or captions. Its color coincides with the background color of the canvas or the scenes, respectively.

The size `d` of this margin is set by specifying `Margin = d` in a canvas or in a scene (of type plot::Scene2d or plot::Scene3d), respectively. Here, `d` is the physical width of the margin, e.g., `Margin = 0.5*unit::mm`.

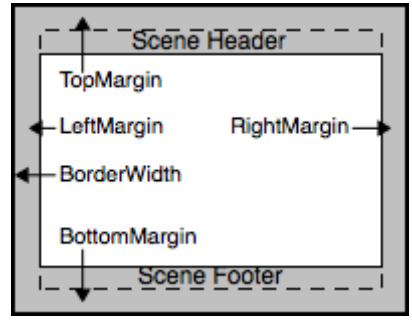
The margin sizes at the bottom, left, right, top of the canvas or the scenes can be specified separately via `BottomMargin = d`$_1$, `LeftMargin = d`$_2$, `RightMargin = d`$_3$, `TopMargin = d`$_4$.

The attribute `Margin = d` is a shortcut for `BottomMargin = d`, `LeftMargin = d`, `RightMargin = d`, `TopMargin = d`.

The following picture illustrates the layout of the canvas:
read("layoutPictures.mu"): Scene1::Header := "Scene 1":
Scene2::Header := "Scene 2": Scene3::Header := "Scene 3":
Scene4::Header := "Scene 4": plot(plot::Canvas(Height = 90*unit::mm,
Width = 110*unit::mm, Footer = "The Canvas Footer", Header
= "The Canvas Header", HeaderFont = [12], FooterFont = [12],
Spacing = 2.0*unit::mm, Margin = 3*unit::mm, BackgroundColor =
RGB::Grey, BorderWidth = borderwidth*100*unit::mm, BorderColor
= RGB::SlateGreyDark, Layout = Relative, Scene1, Scene2, Scene3,
Scene4, SCENE1)):



The following picture illustrates the layout of a scene:
Scene5::Header := "Scene Header": Scene5::Footer := "Scene Footer":
plot(Scene5, SCENE2, Layout = Relative, Height = canvasheight, Width
= canvaswidth, Margin = 0, BorderWidth = 0):



The size of a canvas, set by the attributes Width and Height, includes the width of the margin set by `Margin`. The same holds for the scenes.

With `BackgroundTransparent = TRUE`, transparent scenes (without a background) can be created. The margin becomes transparent as well.

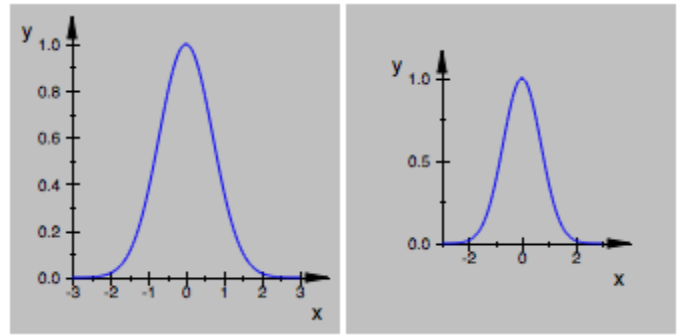
The margins do not react to `Layout = Relative`. One always has to specify the margin width as absolut physical lengths such as `0.5*unit::mm`.

Scenes do *not* inherit margin widths from the enclosing canvas. You can set margin widths for all scenes simultaneously by specifying them in plot::setDefault as `plot::Scene2d::Margin` or `plot::Scene3d::Margin`, respectively. Cf. “Example 2” on page 24-1516.

Examples

Example 1

The following two scenes display the same function graph using different margins:
f := plot::Function2d(exp(-x^2), x = -3..3): plot(plot::Scene2d(f, Margin = 2*unit::mm, BackgroundColor = RGB::Grey), plot::Scene2d(f, Margin = 8*unit::mm, BackgroundColor = RGB::Grey), Layout = Horizontal, Axes = Frame, Width = 120*unit::mm, Height = 60*unit::mm):



delete f:

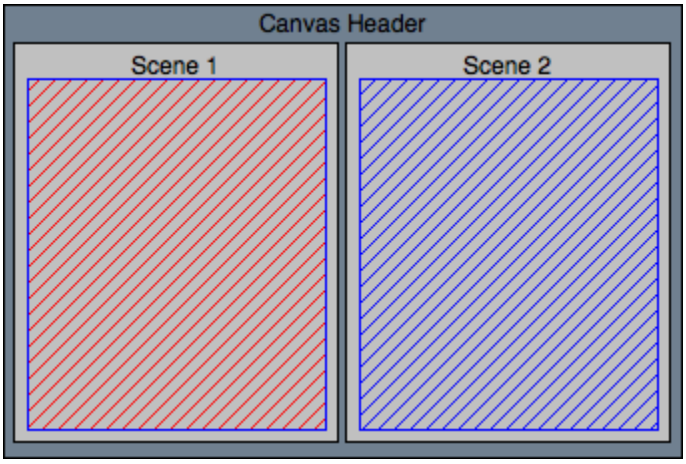
Example 2

We use plot::setDefault to define new default values for the layout and style parameters BorderWidth, BorderColor, `Margin`, and BackgroundColor:

```
plot::setDefault( plot::Canvas::BorderWidth = 0.5*unit::mm,
plot::Canvas::BorderColor = RGB::Black, plot::Canvas::Margin =
1.5*unit::mm, plot::Canvas::BackgroundColor = RGB::SlateGrey,
plot::Scene2d::BorderWidth = 0.5*unit::mm, plot::Scene2d::BorderColor
= RGB::Black, plot::Scene2d::Margin = 2*unit::mm,
plot::Scene2d::BackgroundColor = RGB::Grey ):
```

The following canvas contains two scenes. This plot uses the new defaults:

```
plot(plot::Scene2d(plot::Rectangle(-1..1, -1..1, Filled = TRUE, FillColor
= RGB::Red, Header = "Scene 1")), plot::Scene2d(plot::Rectangle(-1..1,
-1..1, Filled = TRUE, FillColor = RGB::Blue, Header = "Scene 2")),
Layout = Horizontal, Axes = None, Header = "Canvas Header"):
```



See Also BackgroundColorBackgroundColor2BackgroundTransparentBackgroundStyleBorderColo

Purpose

OutputUnits

Physical length unit used by the inspector

Value Summary

Optional	unit::cm, unit::dm, unit::inch, unit::km, unit::m, unit::mm, or unit::pt

Graphics Primitives

Objects	OutputUnits Default Values
plot::Canvas	`unit::mm`

Description

Various length parameters in the MuPAD graphics such as the width and the height of the canvas, the length of tick marks, the width of lines, the size of points etc. may be specified as physical lengths with a length unit. The inspector allows to display a physical length in the physical unit set by `OutputUnits`.

For example, when specifying the canvas size by the attributes `Width = 120*unit::mm`, `Height = 80*unit::mm`, the MuPAD graphics will appear on the screen in a canvas of 120 80 mm (approximately). A printout of the MuPAD graphics will have this physical size precisely.

One may also specify these lengths as pure numbers such as `Width = 120`, `Height = 80`. In this case, the physical length unit is given in mm.

In the “object inspector” of the MuPAD Graphics Tool (see the section Viewer, Browser, and Inspector: Interactive Manipulation of this document), lengths are displayed as numbers without unit. The actual physical length is given by these numbers times the physical length unit given by `OutputUnits`.

Note Note that the specification `Width = 10, OutputUnit = unit::inch` does not mean `Width = 10*unit::inch`, but `Width = 10*unit::mm`, displayed as `0.3937...` inches.

It is recommended to specify output sizes always as products of the numerical values times the unit.

Changing the value of `OutputUnits` does not change the physical lengths! When changing `OutputUnits = unit::mm` to `OutputUnits = unit::inch`, say, the numbers in the object inspector such as `Width = 120` (corresponding to a canvas size of 120 mm in the real world) change automatically to `Width = 4.7244...` (corresponding to the same canvas size 120 mm = 4.7244... inches).

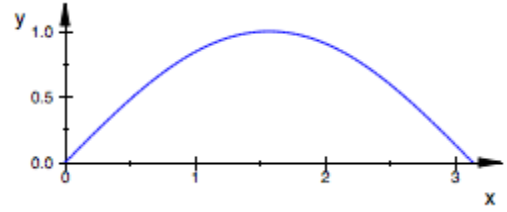
If you want to change the physical length, you need to change the number in the input region of `Width` in the object inspector.

Switching between different output units via `OutputUnits` is convenient if physical conditions such as the real world size of a printout have to be met. Depending on your nationality, you will have a preference for inches or millimeters.

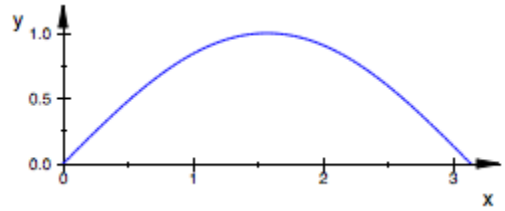
Examples

Example 1

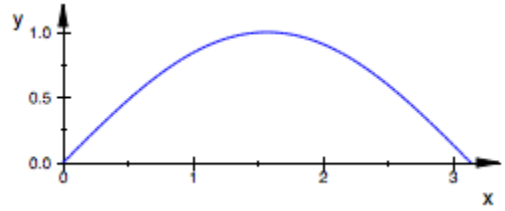
The following calls all produce graphical output of the same physical size:
f := plot::Function2d(sin(x), x = 0..PI): plot(f, Width = 90*unit::mm, Height = 40*unit::mm):



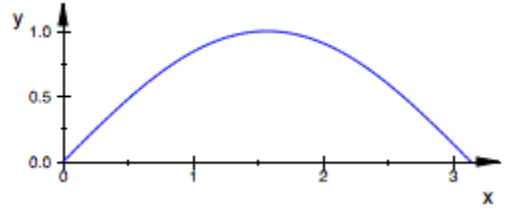
plot(f, Width = 90, Height = 40, OutputUnits = unit::mm):



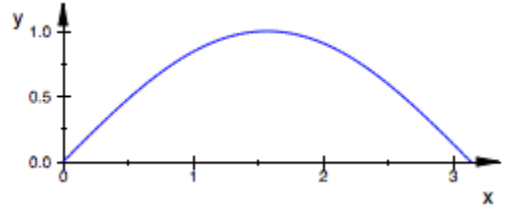
plot(f, Width = 90, Height = 40, OutputUnits = unit::inch):



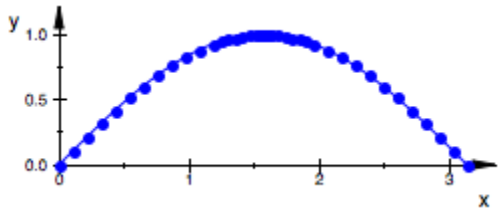
plot(f, Width = 3.544*unit::inch, Height = 40*unit::mm):



plot(f, Width = 3.544*unit::inch, Height = 1.575*unit::inch):



In the following plot command, the size of graphical points is specified in millimeters. The specification of `OutputUnits` = `unit::inch` does not change the physical point size of 2 mm = 0.07874... inch. It just means that the value of the point size is displayed as 0.07874 in the object inspector of the MuPAD Graphics Tool, not as 2:
plot(plot::Function2d(sin(x), x = 0..PI, Mesh = 30), PointsVisible = TRUE, PointSize = 2*unit::mm, Width = 90*unit::mm, Height = 40*unit::mm, OutputUnits = unit::inch):



delete f:

Example 2

The conversion between the output sizes can be computed via MuPAD:
120.0*unit::mm = unit::convert(120.0*unit::mm, unit::inch), 4.7244*unit::inch = unit::convert(4.7244*unit::inch, unit::pt)120.0*unit::mm = 4.724409449*unit::inch, 4.7244*unit::inch = 341.4323914*unit::pt

120.0 mm = 4.724409449 inch, 4.7244 inch = 341.4323914 pt

AxesLineWidthBottomBottomMarginGridLineWidthHeightLeftLeftMarginLineWidthPoi

Purpose

Spacing

Space between scenes

Value Summary

Optional	Non-negative output size

Graphics Primitives

Objects	Spacing Default Values
plot::Canvas	`1.0`

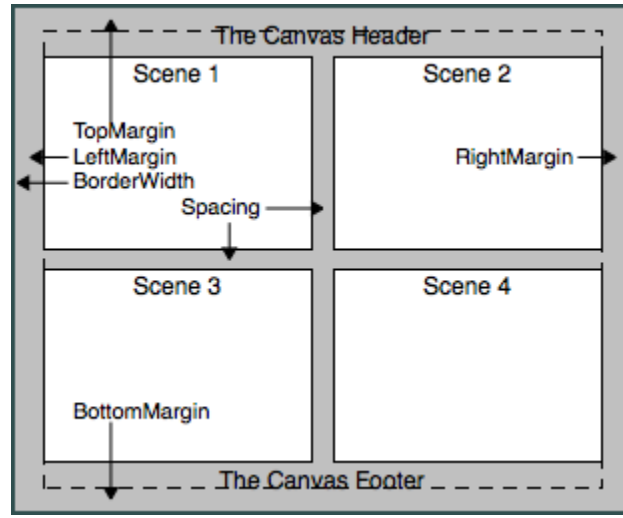
Description

`Spacing = d` sets a gap of size *d* between neighboring scenes in a canvas.

If a canvas contains several scenes, an automatic layout of the canvas may be requested by `Layout = Horizontal`, `Layout = Tabular`, or `Layout = Vertical`. In these modes, the scenes are separated by a gap that is set by `Spacing = d`. Here, `d` is the physical width of the gap, e.g., `Spacing = 0.5*unit::mm`.

The `Spacing` attribute has an effect only in conjunction with the automatic layout modes `Layout = Horizontal`, `Layout = Tabular`, or `Layout = Vertical`, respectively.

The following picture illustrates the layout of the canvas:
read("layoutPictures.mu"): Scene1::Header := "Scene 1": Scene2::Header := "Scene 2": Scene3::Header := "Scene 3": Scene4::Header := "Scene 4": plot(plot::Canvas(Height = 90*unit::mm, Width = 110*unit::mm, Footer = "The Canvas Footer", Header = "The Canvas Header", HeaderFont = [12], FooterFont = [12], Spacing = 2.0*unit::mm, Margin = 3*unit::mm, BackgroundColor = RGB::Grey, BorderWidth = borderwidth*100*unit::mm, BorderColor = RGB::SlateGreyDark, Layout = Relative, Scene1, Scene2, Scene3, Scene4, SCENE1)):

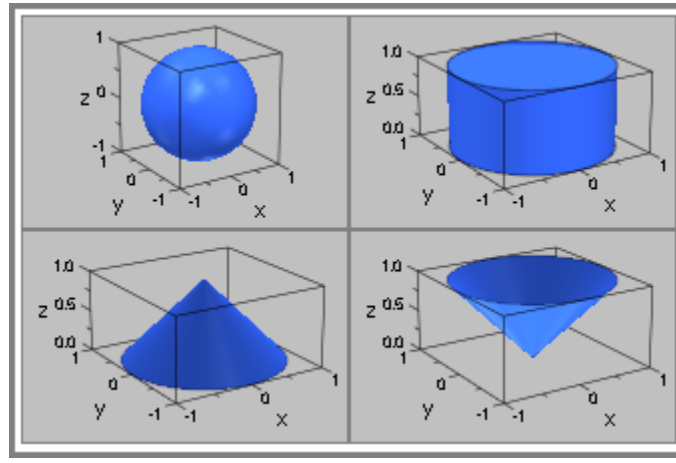


Examples

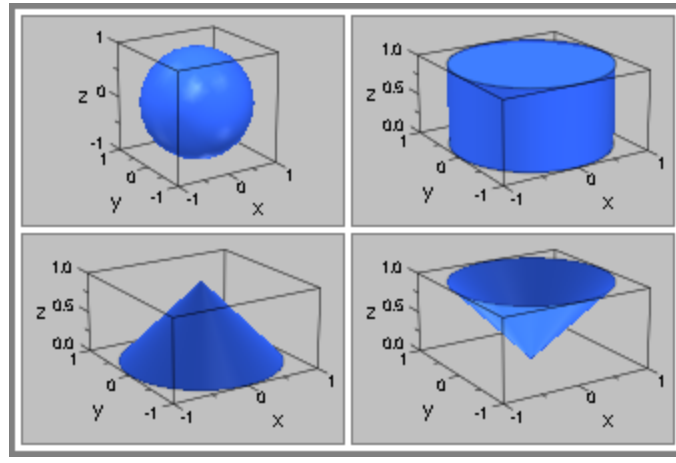
Example 1

We define four scenes:
S1 := plot::Scene3d(plot::Sphere(1, [0, 0, 0]), BackgroundColor = RGB::Grey, BorderWidth = 0.5*unit::mm): S2 := plot::Scene3d(plot::Cylinder(1, [0, 0, 0], [0, 0, 1]), BackgroundColor = RGB::Grey, BorderWidth = 0.5*unit::mm): S3 := plot::Scene3d(plot::Cone(1, [0, 0, 0], [0, 0, 1]), BackgroundColor = RGB::Grey, BorderWidth = 0.5*unit::mm): S4 := plot::Scene3d(plot::Cone(1, [0, 0, 1], [0, 0, 0]), BackgroundColor = RGB::Grey, BorderWidth = 0.5*unit::mm):

These scenes are positioned in the canvas with no gap between them (`Spacing = 0`). By default, the automatic layout mode Layout = `Tabular` is used:
plot(S1, S2, S3, S4, Spacing = 0, BorderWidth = 1.0*unit::mm):



We introduce a gap of 1 mm:
plot(S1, S2, S3, S4, Spacing = 1.0*unit::mm, BorderWidth = 1.0*unit::mm):



delete S1, S2, S3, S4:

See Also BottomMarginLeftMarginMarginRightMarginTopMarginLayoutLeftBottom

AbsoluteErrorRelativeError

Purpose

Maximal absolute discretization error

Value Summary

`AbsoluteError`, `RelativeError`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Ode2d, plot::Ode3d	
plot::Streamlines2d	`RelativeError`: `1/100000`

Description

`AbsoluteError = atol` sets the tolerance `atol` for the maximal absolute discretization error in the numerical solution of ODEs.

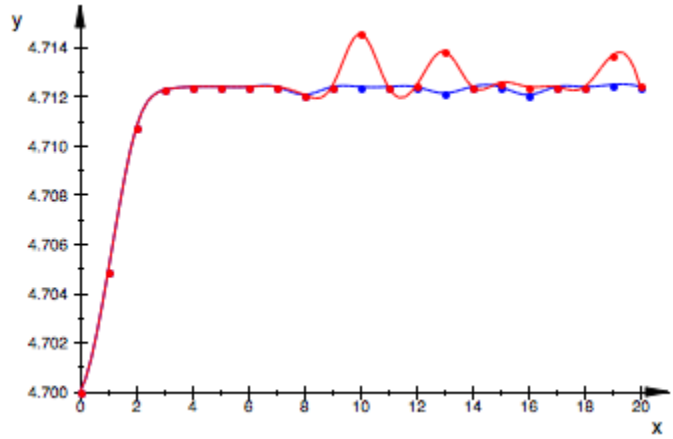
`RelativeError = rtol` sets the tolerance `rtol` for the maximal relative discretization error.

Internally, plot::Ode2d and plot::Ode3d call the routine numeric::odesolve for solving the given ODE numerically. The attributes `AbsoluteError`, RelativeError are forwarded to numeric::odesolve. See the corresponding help page for further details.

Examples

Example 1

We consider the initial value problem y'(t)=-t*cos(y(t)), y(0)=4.7$y'(t) = -t\cos(y(t)),\ y(0) = 4.7$. The ODE is solved numerically with different tolerances for the relative discretization error. The 'oscillating' behaviour of the red solution curve is a numerical artifact. The blue solution curve, computed with a smaller tolerance, is more precise:
f:= (t, Y) -> [-t*cos(Y[1])]: Y0 := [4.7]: plot(plot::Ode2d(f, [i $ i = 0..20], Y0, Color = RGB::Blue, RelativeError = 0.0001), plot::Ode2d(f, [i $ i = 0..20], Y0, Color = RGB::Red, RelativeError = 0.001))



delete f, Y0:

AdaptiveMesh

Purpose

Adaptive sampling

Value Summary

Inherited	Non-negative integer

Graphics Primitives

Objects	AdaptiveMesh Default Values
plot::Function2d	2
plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylindrical, plot::Function3d, plot::Implicit3d, plot::Polar, plot::Spherical, plot::Surface, plot::Sweep, plot::XRotate, plot::ZRotate	0
plot::Rootlocus	4

Description

`AdaptiveMesh = n` controls the adaptive sampling in the numerical evaluation of functions, curves and surfaces. With $n = 0$, adaptive sampling is disabled. With $n > 0$, adaptive sampling is enabled.

The "depth" n of the adaptive sampling should be a *small* integer such as 0, 1, 2, or 3.

Continuous graphical objects such as function graphs, parameterized curves and surfaces are approximated by a discrete mesh of numerical points.

This mesh may be controlled by the user via the attributes Mesh, Submesh, and `AdaptiveMesh`. (Depending on the object, the Mesh attribute splits into more specific versions such us UMesh and VMesh for curve and surface plots, or XMesh, YMesh, ZMesh for function and implicit plots.)

First, the object is evaluated numerically on an equidistant "initial mesh" set via the attribute Mesh (or the more specific versions mentioned above).

With `AdaptiveMesh = 0`, the numerical data over the initial mesh are used to render the object without any further adaptive refinement.

With `AdaptiveMesh = n`, $n > 0$, further numerical data are computed before the renderer is called. In particular, the data of neighboring points on the initial mesh are investigated. If a point is not reasonably represented by a straight line connecting the neighboring points, the corresponding intervals of the initial mesh are sub-divided recursively. The adaptive mechanism descends into the sub-intervals of the initial mesh if consecutive line segments of the discretized plot object deviate from a straight line by a "bend angle" of more than 10 degrees. The intervals involved in such a situation are split into halves, recursively.

The value of n should be a *small* integer that determines the recursive depth of the adaptive refinement. In each direction, up to $2^n - 1$ additional points are placed between the points of the initial mesh.

If the object looks smooth on the initial mesh set via the attribute Mesh or its more detailed variants, the adaptive mechanism does *not* descend into the intervals of the initial mesh. If there are fine structures hidden inside these intervals, specifying `AdaptiveMesh = n` with $n > 0$ will *not* help to improve the plot. In such a case, the initial mesh should be refined via the appropriate attribute for the initial mesh.

On the other hand, if the initial mesh is fine enough to indicate finer internal structures via the "max bend angle" criterion, it is often more efficient to use `AdaptiveMesh = n` than to refine the initial mesh, because the adaptive mechanism refines only those parts of the object that do need refinement. This effect can be seen in "Example 3" on page 24-1533.

Note Note that increasing the recursive depth n by 1 may increase the run time by a factor of 2 for line objects (2D function graphs and curves) and by a factor of 4 for surface objects (3D function graphs and surfaces). In most cases, a *small* value such as n {1, 2, 3} suffices to obtain a reasonably smooth plot object.

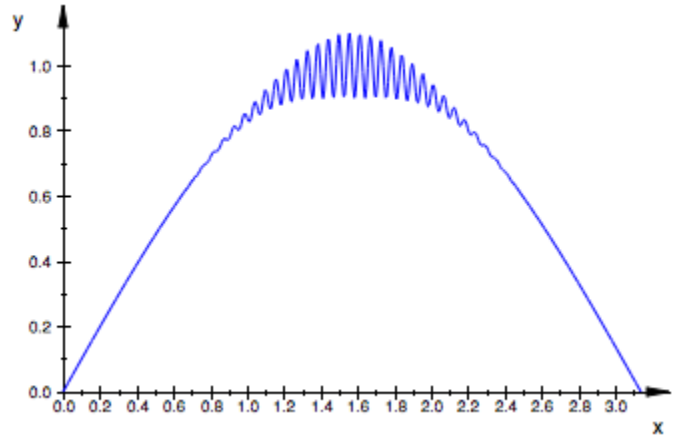
Note Note that the adaptive algorithm for surface objects in 3D is *very expensive!* As an alternative to values $n > 0$ in `AdaptiveMesh = n`, you may experiment with `AdaptiveMesh = 0`, `Submesh = [2^n- 1, 2^n- 1]` in 3D function graphs or surfaces. The granularity of the "initial mesh" generated with these attribute values is approximately of the same size as the adaptive mesh generated with `AdaptiveMesh = n`, `Submesh = [0, 0]`. The non-adaptive evaluation on the refined regular mesh may still be more efficient than the evaluation on the (irregular) non-adaptive mesh.

Examples

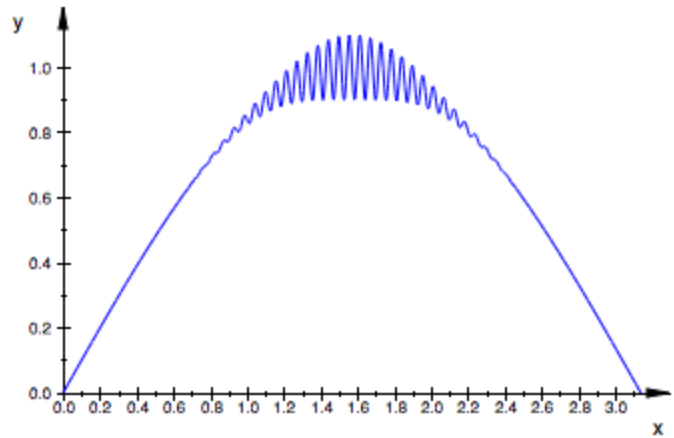
Example 1

The following function plot contains areas of high variation. Without a specification of `AdaptiveMesh`, the default mode `AdaptiveMesh = 0` is used and we clearly see artifacts caused by the evaluation on a discrete mesh:

```
plot(plot::Function2d( sin(x) + exp(-5*(x - PI/2)^2)*sin(110*x)/10, x = 0..PI)):
```

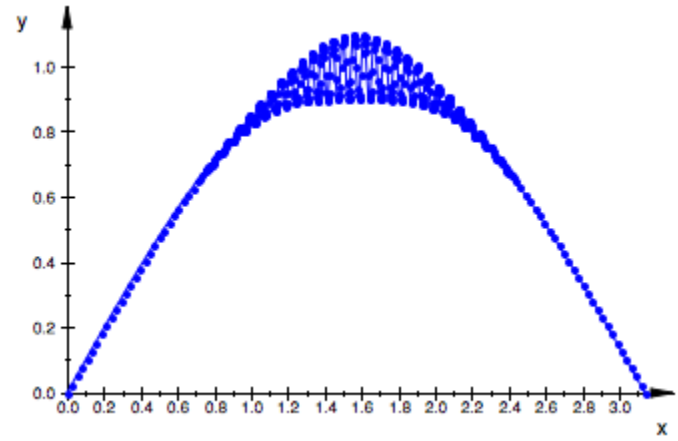


We activate the adaptive refinement with a high level of 3:
plot(plot::Function2d(sin(x) + exp(-5*(x - PI/2)^2)*sin(110*x)/10, x = 0..PI, AdaptiveMesh = 3)):



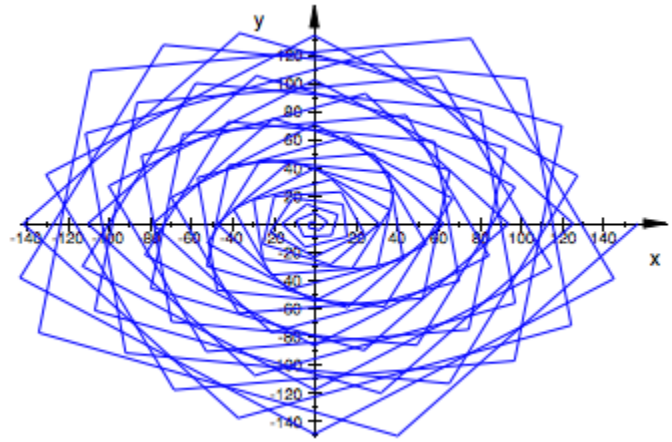
We set the attribute `PointsVisible = TRUE` so that the points of the adaptive mesh become visible:

plot(plot::Function2d(sin(x) + exp(-5*(x - PI/2)^2)*sin(110*x)/10, x = 0..PI, AdaptiveMesh = 3, PointsVisible = TRUE)):

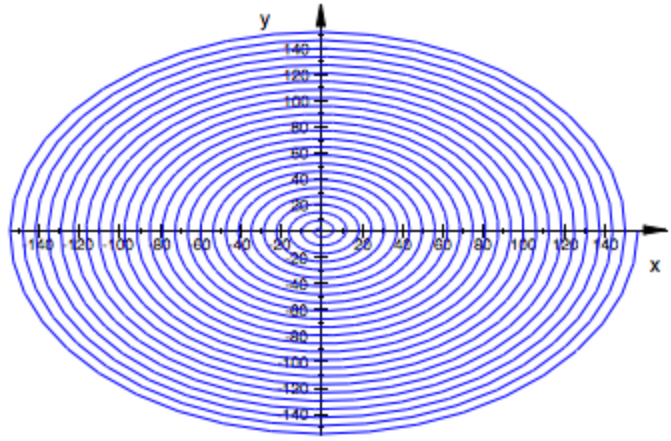


Example 2

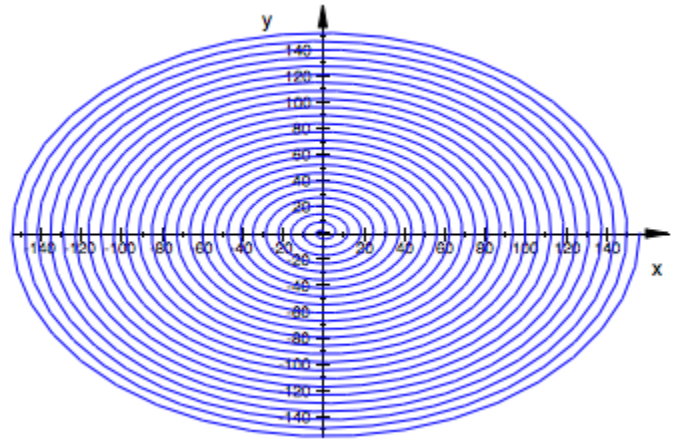
The default value of Mesh does not provide a sufficient resolution for the following spiral:
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI)):



Increasing the Mesh value improves the plot:
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI, Mesh = 1000)):



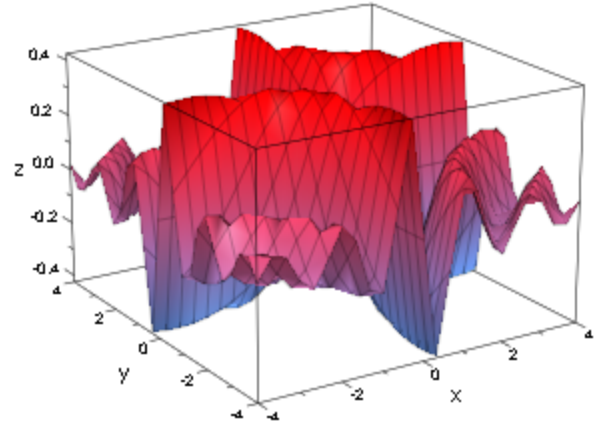
Alternatively, adaptive plotting can be used:
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI, AdaptiveMesh = 3)):



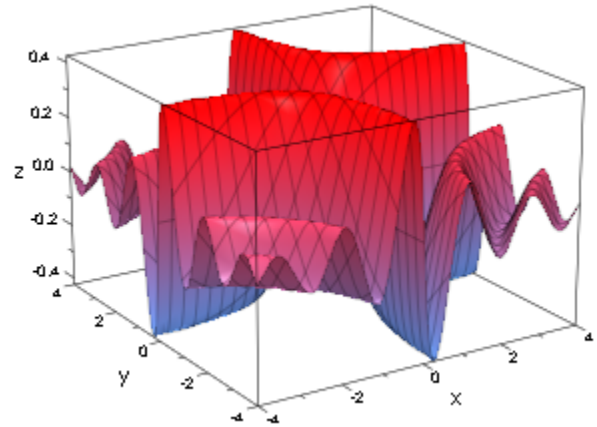
Example 3

In 3D the typical artifacts caused by the rectilinear initial mesh are “dents” on surface features that are not parallel to a parameter axis. Without a specification of `AdaptiveMesh`, the default mode `AdaptiveMesh = 0` is used:

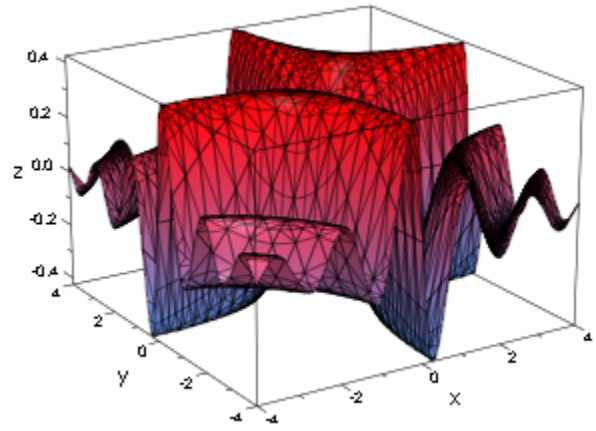
```
f := plot::Function3d(sin(x*y)/(abs(x*y) + 1), x = -4 .. 4, y = -4 .. 4): plot(f):
```



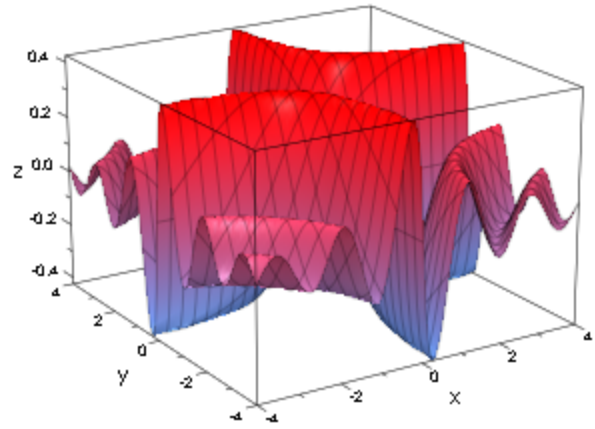
Activating the adaptive refinement, we get a much more accurate plot. However, the computation takes *much longer*:
plot(f, AdaptiveMesh = 2):



To see how local the refinement is, we set the attribute `MeshVisible = TRUE` so that the internal triangulation of the adaptive mesh becomes visible:
plot(f, AdaptiveMesh = 2, MeshVisible = TRUE):



We use a non-adaptive evaluation, but refine the regular mesh by setting Submesh values 2^n - 1 that correspond to the adaptive depth n = 2 used above. The result is of a similar quality as before:
plot(plot::Function3d(sin(x*y)/(abs(x*y) + 1), x = -4 .. 4, y = -4 .. 4, Submesh = [3, 3])):



delete f:

See Also MeshMeshVisibleSubmeshUMeshUSubmeshVMeshVSubmeshXMeshXSubmeshYMeshYSubr

DiscontinuitySearch

Purpose

Semi-symbolic search for discontinuities

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	DiscontinuitySearch Default Values
plot::Curve2d, plot::Curve3d, plot::Function2d, plot::Polar, plot::Sweep	`TRUE`

Description

`DiscontinuitySearch` = `TRUE` versus `DiscontinuitySearch` = `FALSE` determines whether a graphical object is checked (semi-)symbolically for discontinuities and singularities.

Certain graphical objects such as function graphs or parametrized curves may have singularities. This may create graphical artifacts such as spurious lines between numerical sample points that enclose a singularity. With `DiscontinuitySearch` = `TRUE`, the object is pre-processed to find potential singularities. If singular points are found, the object is split into several disjoint sub-objects (“branches”), each of which is smooth.

Note `DiscontinuitySearch` is only available for line objects (2D function graphs and parametrized curves in 2D and 3D). It is not available for surface objects such as 3D function graphs and parametrized surfaces!

Discontinuities will only be detected if they are caused by system functions that are implemented as a function environment with an appropriate `"realDiscont"` or `"numericDiscont"` slot.

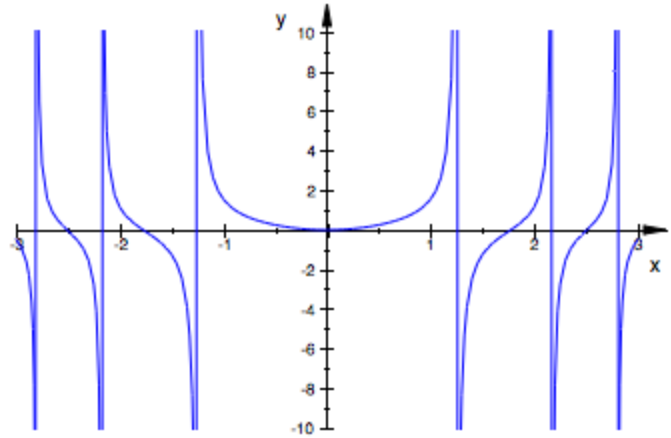
The search for discontinuities uses interval arithmetic. If special functions are involved that do not support this kind of arithmetic, the search will not succeed.

For efficiency reasons, it is recommended to disable the search for discontinuities with `DiscontinuitySearch = FALSE` when it is known that the graphical object is continuous.

Examples

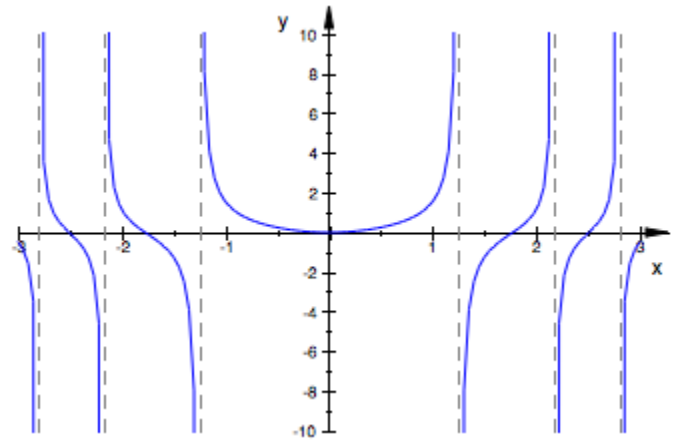
Example 1

The following plot contains first order poles. When the discontinuity search is disabled, spurious vertical lines occur connecting sample points to the left of a pole with neighbouring sample points to the right of the pole. Further, the neighbourhood of the poles is poorly sampled:
plot(plot::Function2d(tan(x^2), x=-3..3, ViewingBoxYRange = -10..10, DiscontinuitySearch = FALSE)):



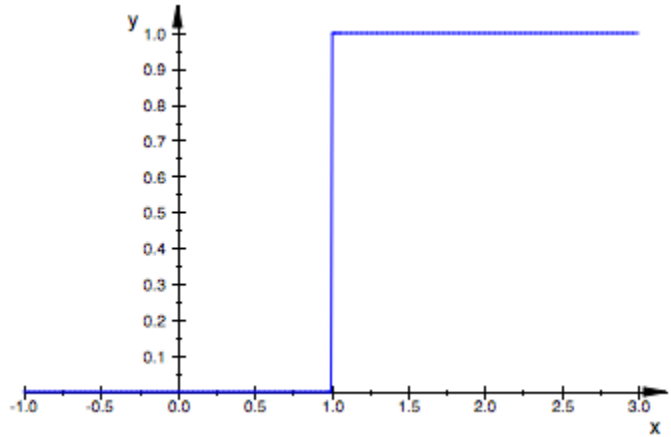
Without specification of `DiscontinuitySearch`, the default setting `DiscontinuitySearch = TRUE` is used. The spurious lines disappear. With the default `VerticalAsymptotesVisible = TRUE`, they are replaced by dashed vertical asymptotes indicating the poles. Also note that the numerical sampling near the poles is better, because the

existence of the singularities and their positions is known before the numerical evaluation of the function graph starts:
plot(plot::Function2d(tan(x^2), x=-3..3, ViewingBoxYRange = -10..10)):



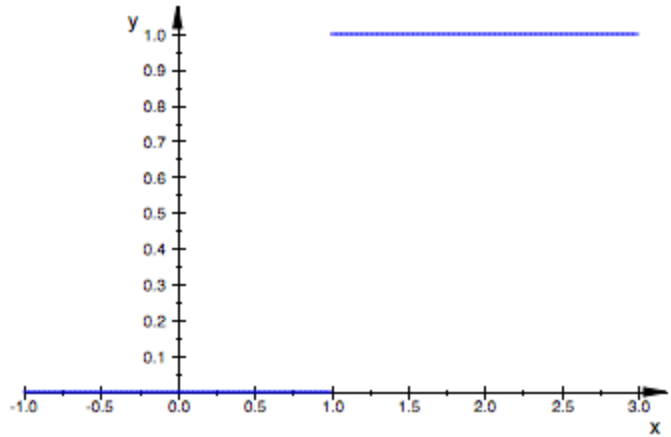
Example 2

The Heaviside function has a jump discontinuity. Without a discontinuity search, a spurious line connecting the left and the right limit points of the jump appears:
plot(plot::Function2d(heaviside(x-1), x = -1..3, DiscontinuitySearch = FALSE)):



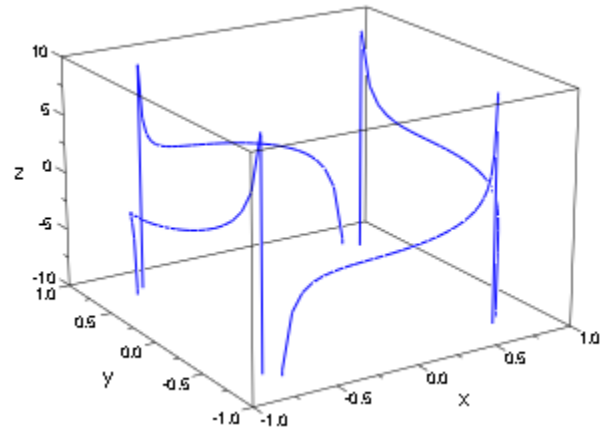
This spurious line disappears with the default setting `DiscontinuitySearch = TRUE`:

```
plot(plot::Function2d(heaviside(x-1), x = -1..3),
VerticalAsymptotesVisible = FALSE):
```



Example 3

Without a discontinuity search, the poles of the following singular 3D curve are poorly presented graphically:
plot(plot::Curve3d([cos(u), sin(u), tan(2*u)], u = 0..2*PI, ViewingBox = [-1..1, -1..1, -10..10], DiscontinuitySearch = FALSE)):



The default setting `DiscontinuitySearch = TRUE` produces a better graphical presentation:
plot(plot::Curve3d([cos(u), sin(u), tan(2*u)], u = 0..2*PI, ViewingBox = [-1..1, -1..1, -10..10])):

plot::Matrixplot	`Submesh: [2, 2]`
plot::Ode2d, plot::Ode3d	`Submesh: 4`
plot::Listplot	`Submesh: 6`

Description

The attributes `Mesh` and `Submesh` determine the number of sample points used for the numerical approximation of plot objects.

Many plot objects have to be evaluated numerically on a discrete mesh. Depending on the object type, there are type specific attributes such as XMesh (for 2D function graphs), UMesh, VMesh (for parametrized surfaces), XMesh, YMesh, ZMesh (for implicit plots in 3D) etc. setting the number of sample points of the numerical mesh.

The `Mesh` attribute unifies these more specific attributes and can be set for all objects that use a discrete numerical mesh. Depending on the object, the values for `Mesh` must be integer numbers or lists of such numbers. The more specific attributes are set automatically when `Mesh` values are specified.

E.g., in a 2D function plot of type plot::Function2d, `Mesh = 200` is equivalent to `XMesh = 200`. In a 3D surface plot of type plot::Surface, `Mesh = [40, 50]` is equivalent to `UMesh = 40`, `VMesh = 50`.

In the “object inspector” of the interactive graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation in this document), only the type specific attributes are visible, not the `Mesh` attribute.

Roughly speaking, high `Mesh` values yield smooth plots but cost run time.

With the attribute `Submesh = m`, additional *m* equidistant sample points are inserted between each pair of adjacent sample points set by the `Mesh` attribute. This smoothens the object.

Like `Mesh`, the attribute `Submesh` unifies type specific attributes such as XSubmesh, USubmesh etc. Depending on the object, the values of `Submesh` have to be integers or lists of integers.

There is a semantical difference between the "major" mesh points set by `Mesh` and the "minor" mesh points inserted by `Submesh`. There are coordinate lines associated with the (regular) numerical mesh. See XLinesVisible, ULinesVisible etc. The coordinates lines are available only for the mesh given by the "major" mesh points, whereas `Submesh` does not influence the number of coordinate lines. Thus, increased `Mesh` values yield a smoother plot with more coordinate lines, whereas `Submesh` can be used to smoothen the plot without adding further coordinate lines.

Apart from this effect, the pair `Mesh = n`, `Submesh = m` corresponds to the combination `Mesh = (n - 1) (m + 1) + 1`, `Submesh = 0`.

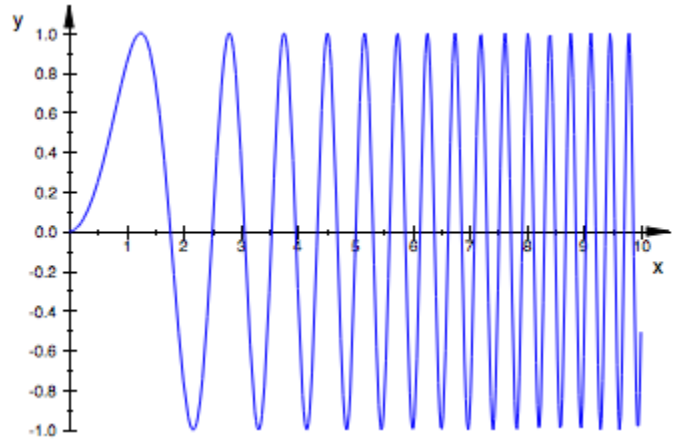
If adaptive sampling is enabled, further non-equidistant sample points are chosen automatically between the equidistant points of the 'initial mesh' set via the `Mesh` and `Submesh` attributes.

Examples

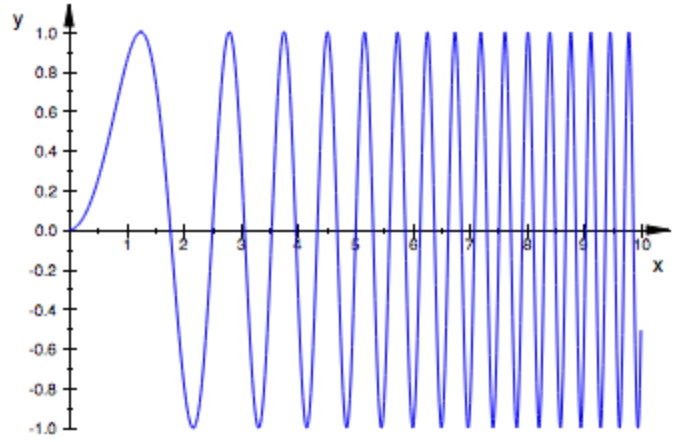
Example 1

In the following plot, the default value of `Mesh` does not suffice to produce a sufficiently exact picture:

```
plot(plot::Function2d(sin(x^2), x = 0..10)):
```

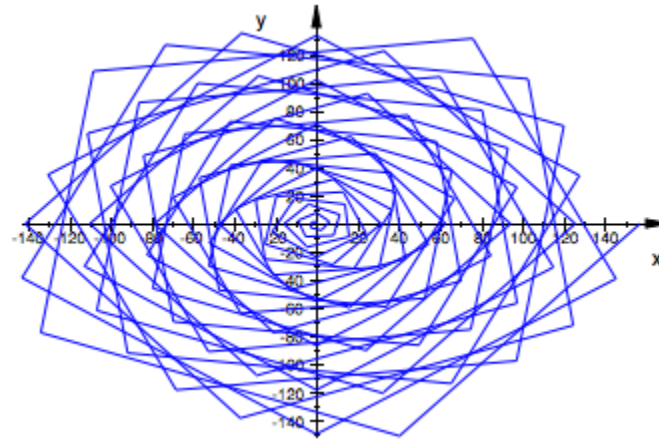


A mesh with more sample points yields a higher resolution graphics:
plot(plot::Function2d(sin(x^2), x = 0..10, Mesh = 500)):



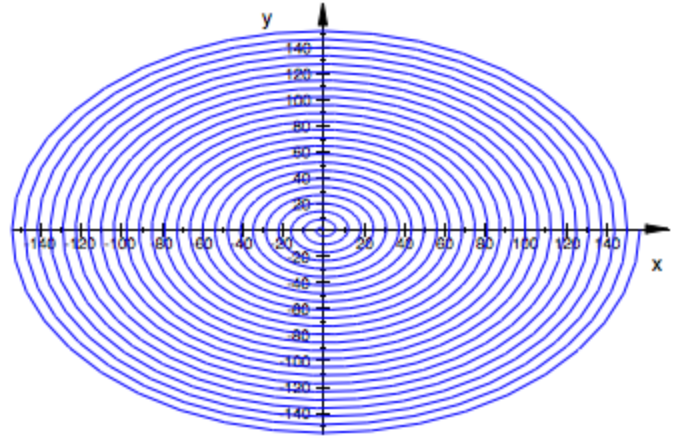
Example 2

The default value of `Mesh` does not provide a sufficient resolution for the following spiral:
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI)):



The spiral winds around the origin 25 times. We wish to have approximately 40 sample points per revolution, so we need to use a total of 1000 sample points:

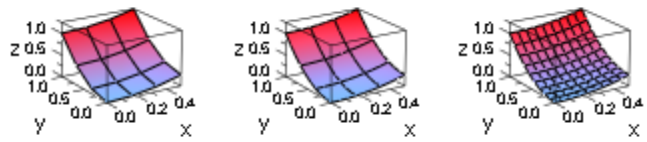
```
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI, Mesh = 1000)):
```



Example 3

Note the difference between increased `Mesh` values and additional sample points inserted via `Submesh`. `Submesh` does not introduce additional coordinate lines:

```
S1 := plot::Scene3d(plot::Function3d( x^2 + y^2, x = 0..1/2, y = 0..1, Mesh = [4, 4])): S2 := plot::Scene3d(plot::Function3d( x^2 + y^2, x = 0..1/2, y = 0..1, Mesh = [4, 4], Submesh = [2, 2])): S3 := plot::Scene3d(plot::Function3d( x^2 + y^2, x = 0..1/2, y = 0..1, Mesh = [10, 10])): plot(S1, S2, S3, Layout = Horizontal, Height = 5*unit::cm, Width = 12*unit::cm, LineColor = RGB::Black):
```



delete S1, S2, S3:

See Also AdaptiveMeshUMeshUSubmeshVMeshVSubmeshXMeshYMeshZMesh

MinimumDistance

Purpose

Space between stream lines

Value Summary

Optional	MuPAD expression

Graphics Primitives

Objects	MinimumDistance Default Values
plot::Streamlines2d	

Description

`MinimumDistance` determines how closely spaced the stream lines generated by a plot::Streamlines2d object are.

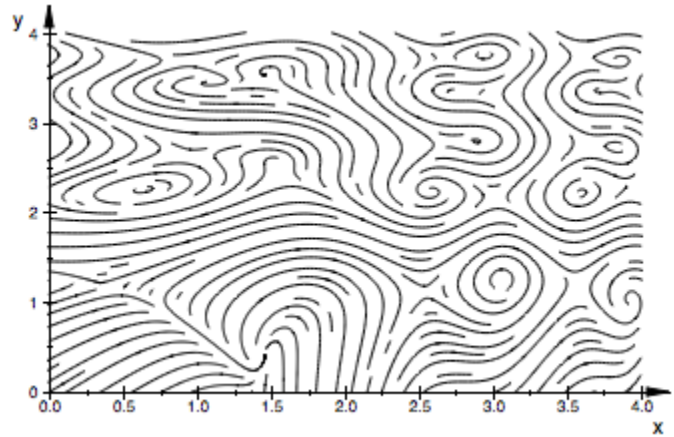
plot::Streamlines2d displays orbits (stream lines) of ODEs which are at least m and at most $2m$ units apart from one another, if `MinimumDistance` has been set to m.

The distance of stream lines is taken as the Euclidean distance, measured in coordinate units. If `MinimumDistance` is not set, it defaults to 0.02 times the maximum extent in either direction.

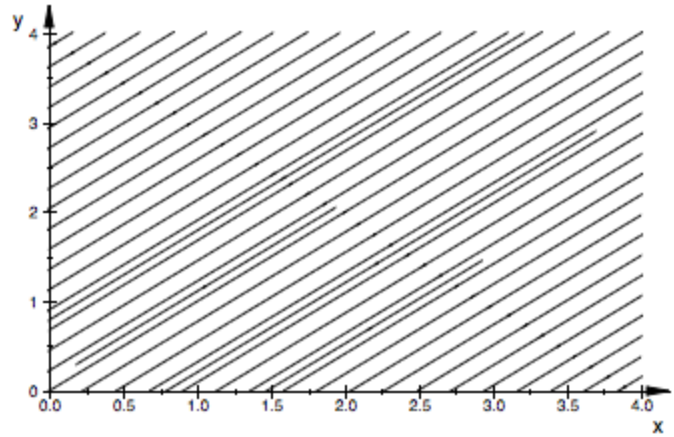
Examples

Example 1

The default setting is adequate for many stream lines plots:
plot(plot::Streamlines2d([sin(x)^2-cos(y^2), sin(x^2)-cos(y)^2], x=0..4, y=0..4))



To display simple ODEs, you may wish to reduce the number of stream lines:
plot(plot::Streamlines2d([1, 1], x=0..4, y=0..4))



plot(plot::Streamlines2d([1, 1], x=0..4, y=0..4, MinimumDistance=0.25))

Purpose

ODEMethodStepsize

Numerical scheme used for solving the ODE

Value Summary

`ODEMethod`, `Stepsize`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Ode2d, plot::Ode3d	`ODEMethod: DOPRI78`
plot::Streamlines2d	`ODEMethod: ABM4`

Description

`ODEMethod = method` determines the numerical scheme for solving the ODE. The parameter `method` is a name such as `EULER1`, `RK4`, `RKF78` etc.

`Stepsize = h` sets a constant step size h that is used to compute the numerical solution.

Internally, plot::Ode2d, plot::Ode3d, and plot::Streamlines2d call the routine numeric::odesolve for solving the given ODE numerically. The method set by the attribute `ODEMethod = method` and/or the step size set by `Stepsize = h` are forwarded to numeric::odesolve. See the corresponding help page for a complete list of all methods available and for further details on the step size.

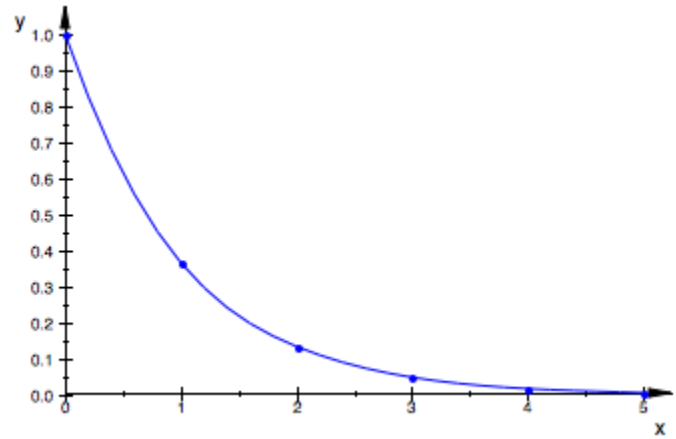
The setting `ODEMethod = ABM4` is an exception to the above: It is only available with plot::Streamlines2d and makes the plot use a fast Adams-Bashforth-Moulton predictor corrector integrator of fourth order with fixed step size. It ignores the settings of RelativeError and AbsoluteError.

Examples

Example 1

We solve the initial value problem y'(t)=-y(t), y(0)=1 $y'(t) = -y(t),\ y(0) = 1$ numerically by the classical 4th order Runge-Kutta scheme `RK4` using a constant step size 0.1:

```
f := (t, Y) -> [-Y[1]]:  Y0 := [1]:  timemesh:= [0, 1, 2, 3, 4, 5]:
plot(plot::Ode2d(f, timemesh, Y0, ODEMethod = RK4, Stepsize = 0.1))
```

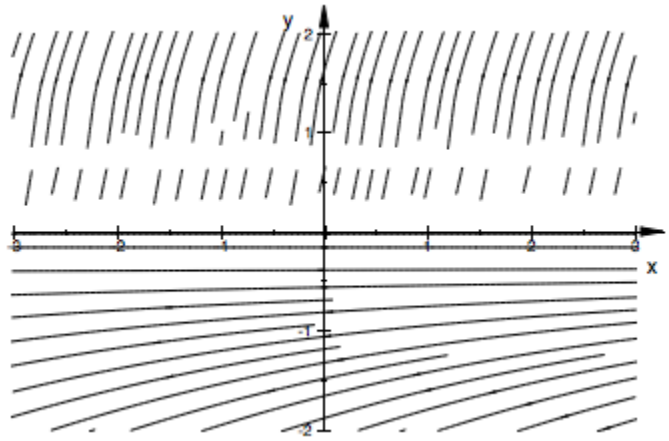


```
delete f, Y0, timemesh:
```

Example 2

With the default settings, plot::Streamlines2d is not able to plot the vector field [1, 3^(2/y)] $\left[1,\ 3^{2/y}\right]$ (which is not Lipschitz continous) in a satisfying way:

```
plot(plot::Streamlines2d([1, surd(3,y)^2], x=-3..3, y=-2..2))
```



By using a different numerical integrator, the problems can be overcome (at the cost of longer computation):
plot(plot::Streamlines2d([1, surd(3,y)^2], x=-3..3, y=-2..2, ODEMethod=RKF43, RelativeError=1e-3))

plot::Ode2d, plot::Ode3d	`USubmesh: 4`

Description

The attributes `UMesh` etc. determine the number of sample points used for the numerical approximation of parameterized plot objects such as curves and surfaces.

Many plot objects have to be evaluated numerically on a discrete mesh. The attributes described on this help page serve for setting the number of sample points of the numerical mesh.

For curves in 2D and 3D given by a parametrization $x(u)$, $y(u)$ and, possibly, $z(u)$ with the curve parameter u, the attribute `UMesh = n` creates a numerical mesh of n equidistant u values. The attribute `USubmesh = m` inserts additional m mesh points between each pair of adjacent points set by `UMesh`.

The combinations `UMesh = n`, `USubmesh = m` and `UMesh = (m + 1) (n - 1) + 1`, `USubmesh = 0` are equivalent.

Specifying Mesh, Submesh has the same effekt as specifying `UMesh`, `USubmesh`.

The sample points of a curve can be made visible by setting `PointsVisible = TRUE`.

Surface objects in 3D are parameterized by coordinate functions $x(u, v)$, $y(u, v)$, $z(u, v)$ of two surface parameters u, v.

The attribute `UMesh = n`$_u$ sets the number n_u of sample points for the first surface parameter. The attribute `VMesh = n`$_v$ sets the number nv of sample points for the second surface parameter. The parametrization is evaluated on a regular mesh of n_u n_v values of the surface parameters u, v.

With the `USubmesh`, `VSubmesh` attributes, additional equidistant sample points can be inserted between each pair of adjacent sample points set by the `UMesh`, `VMesh` attributes.

With `ULinesVisible = TRUE` and `VLinesVisible = TRUE`, respectively, the parameter lines of the regular mesh set by the attributes `UMesh`, `VMesh` are displayed on the surface. Additonal points inserted via `USubmesh`, `VSubmesh` do *not* create additional parameter lines.

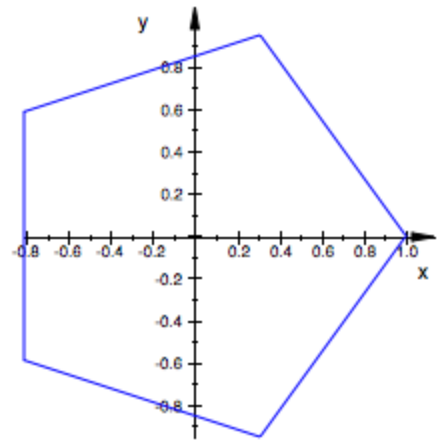
You can also specify `UMesh = n`$_u$, `VMesh = n`$_v$, `USubmesh = m`$_u$, `VSubmesh = m`$_v$ in the shorter form Mesh = `[n`$_u$`, n`$_v$`]`, Submesh = `[m`$_u$`, m`$_v$`]`.

If adaptive sampling is enabled, further non-equidistant sample points are chosen automatically between the equidistant points of the 'initial mesh' set via the `UMesh, USubmesh, VMesh, VSubmesh` attributes.

Examples

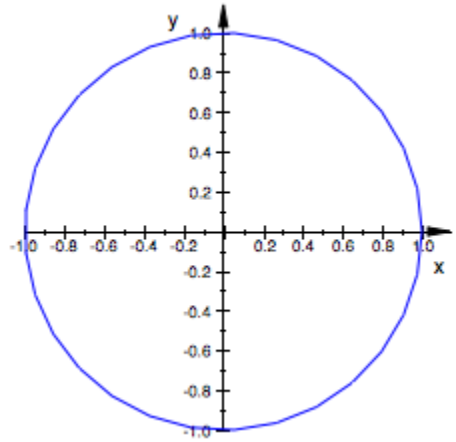
Example 1

It is possible to use low settings of mesh parameters to achieve special effects. As an example, we draw a parametrization of a circle with just six evaluation points:
plot(plot::Curve2d([cos(t), sin(t)], t = 0..2*PI, UMesh = 6, Scaling = Constrained))



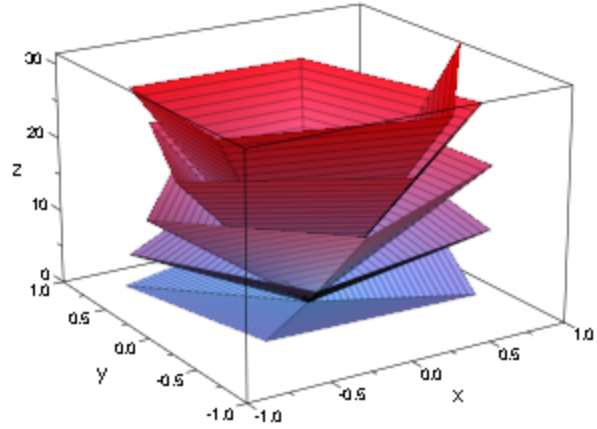
The reason we get a pentagon here and not a hexagon is that the first and the last evaluation points coincide: six points in a line means five line segments.

With `UMesh = 30`, the circle looks like a circle:
plot(plot::Curve2d([cos(t), sin(t)], t = 0..2*PI, UMesh = 30, Scaling = Constrained))

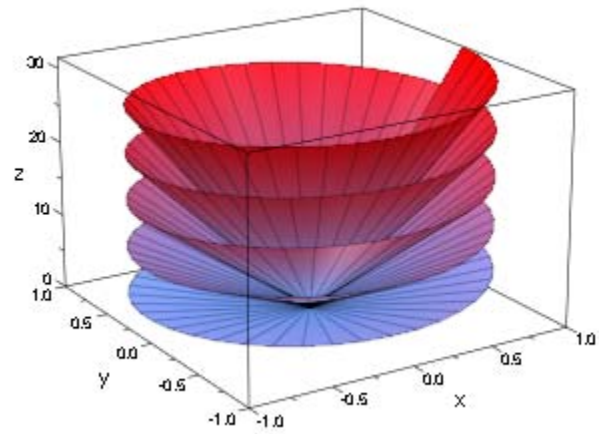


Example 2

The default values of `UMesh`, `VMesh` do not provide a sufficient resolution for the following graphics:
plot(plot::Surface([r*cos(phi), r*sin(phi), r*phi], r = 0.. 1, phi = 0..10*PI)):



The spiral winds around the *z*-axis 5 times. We wish to have approximately 40 sample points per revolution, so we need to use a total of 200 sample points with respect to the angle parameter `phi`. The coordinate lines related to the radial parameter `r` are straight lines, so a very low resolution in this direction suffices:
plot(plot::Surface([r*cos(phi), r*sin(phi), r*phi], r = 0.. 1, phi = 0..10*PI, UMesh = 2, VMesh = 200)):



When refining the mesh via `VSubmesh`, no additional parameter lines are created:
plot(plot::Surface([r*cos(phi), r*sin(phi), r*phi], r = 0.. 1, phi = 0..10*PI, UMesh = 2, VMesh = 25, VSubmesh = 8)):

Description

The attributes `XMesh` etc. determine the number of sample points used for the numerical approximation of plot objects such as function graphs, implicit plots etc.

Various object types use numerical function evaluations on a discrete equidistant mesh. `XMesh`, `YMesh`, and for plot::Implicit3d also `ZMesh` set the number of points of this mesh. An exception of this are parameterized curves and surfaces, which use the attributes UMesh, USubmesh, VMesh, and VSubmesh.

For most of the object types listed above, the interpretation of the integers set by these attributes is as follows: In each of XRange, YRange, ZRange, the corresponding number of points is spread out equidistantly. For `XMesh = 2` and `XRange = 0..1`, for example, evaluation takes place for $x = 0$ and $x = 1$. For `XMesh = 3`, a further mesh point at x=1/2$_{x = \frac{1}{2}}$ is used.

The exception to this rule is plot::Implicit2d: Here, the values of `XMesh` and `YMesh` determine the density of the grid *usd for finding components* and increasing their values helps exactly in those cases where components (i.e., lines) are missing from the plot. Decreasing `XMesh` and `YMesh` in a 2D implicit plot will not make the curves appear rougher; it may result in curves missing.

For types reacting to AdaptiveMesh and for plot::Implicit3d, this mesh is used to find *initial* values that can be refined further. See the documentation of the specific types and of AdaptiveMesh for details.

In general, a finer mesh (higher values) leads to a longer computation, while a coarser mesh may cause details being missed.

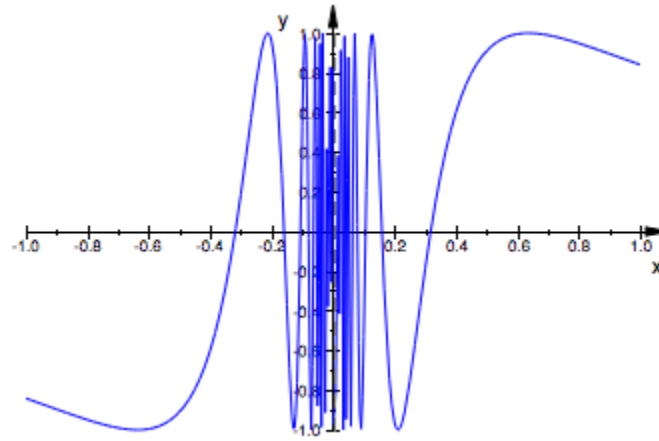
One may specify `XMesh` = n_x, `YMesh` = n_y, `XSubmesh` = m_x, `YSubmesh` = m_v also in the shorter Form `Mesh` = `[`n_x`, `n_y`]`, `Submesh` = `[`m_x`, `m_y`]`.

Examples

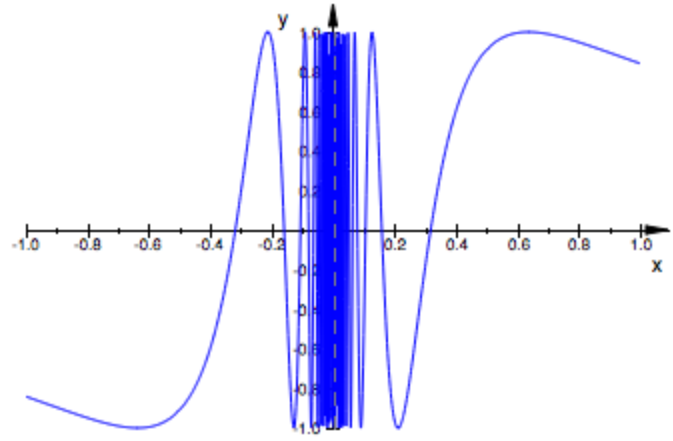
Example 1

The notorious function sin(1/x)$_{\sin(\frac{1}{x})}$ oscillates wildly near the origin. The standard mesh values do not suffice to resolve the behavior of the function near the critical point:

```
plot(plot::Function2d(sin(1/x), x = -1 .. 1))
```



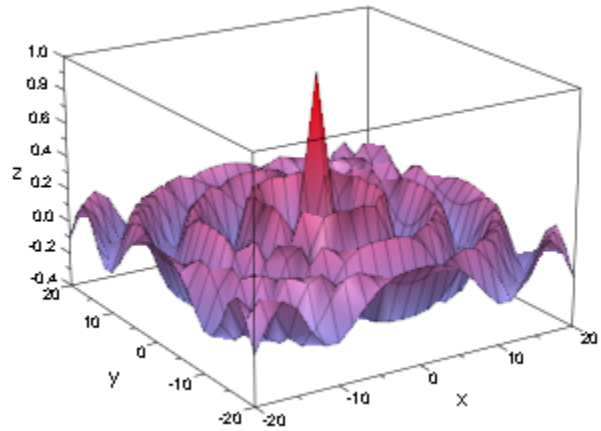
We get a better result with an increased value of `XMesh`:
plot(plot::Function2d(sin(1/x), x = -1 .. 1), XMesh = 1000)



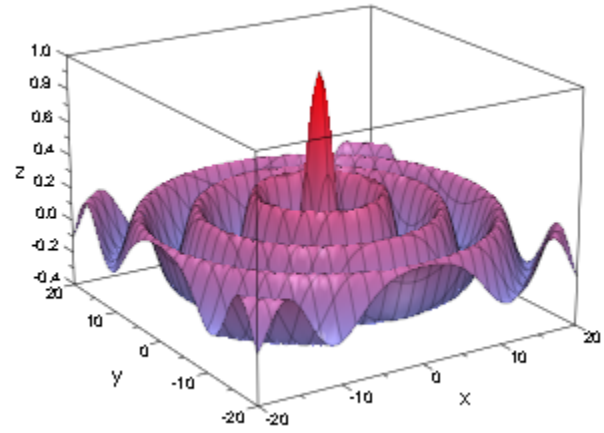
Example 2

In the following plot, the default values of `XMesh`, `YMesh` do not suffice to produce a sufficiently smooth function graph:

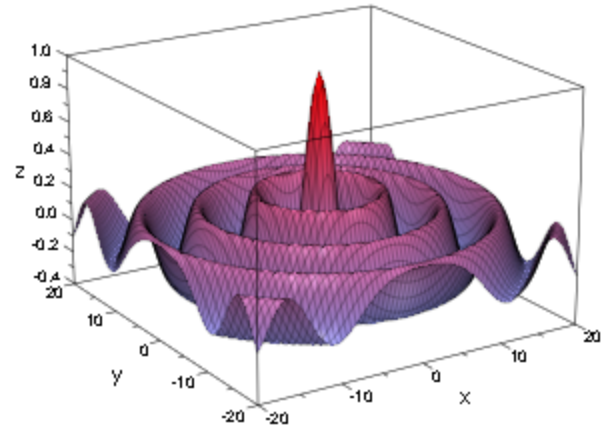
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)), x = -20 .. 20, y = -20 .. 20)):



Increasing the default values `XSubmesh = 0`, `YSubmesh = 0` yields a higher resolution plot. Note that this does not influence the number of mesh lines that are displayed:
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)), x = -20 .. 20, y = -20 .. 20, XSubmesh = 2, YSubmesh = 2)):

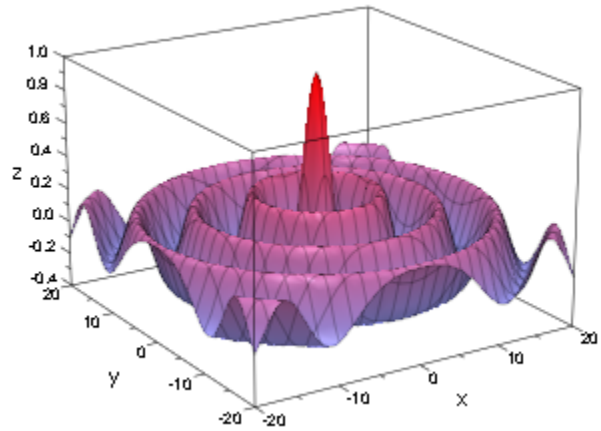


Alternatively, we increase the values of `XMesh`, `YMesh` and use the default values `XSubmesh = 0`, `YSubmesh = 0`. This, however, increases the number of mesh lines that are displayed:
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)), x = -20 .. 20, y = -20 .. 20, XMesh = 73, YMesh = 73)):



Yet another possibility is to use the default values of `XMesh`, `YMesh`, `XSubmesh`, `YSubmesh` and activate the adaptive mechanism to smoothen the critical regions of the plot. However, this plot consists almost completely of critical regions and the adaptive mechanism will therefore be slower than a direct calculation with a finer mesh that leads to almost the same result:

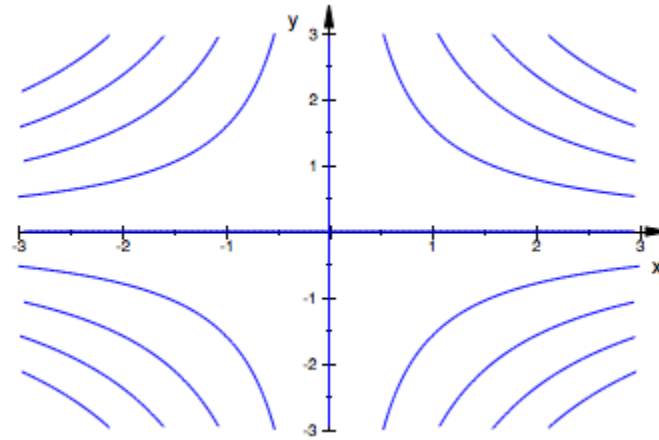
```
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)), x = -20 .. 20, y = -20 .. 20, AdaptiveMesh = 2)):
```



Example 3

For two-dimensional implicit plots, `XMesh` and `YMesh` determine the mesh of "seed points" that are used to find components (see the documentation of plot::Implicit2d for more details). In effect, this means that if some components are missing from a plot, the values of these attributes should be increased:

```
plot(plot::Implicit2d(sin(2*x*y), x = -3..3, y = -3..3))
```



plot(plot::Implicit2d(sin(2*x*y), x = -3..3, y = -3..3, XMesh = 20, YMesh = 20))

Purpose

CameraCoordinates

Position of light sources relative to the camera?

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	CameraCoordinates Default Values
plot::DistantLight, plot::PointLight, plot::SpotLight	`FALSE`

Description

With `CameraCoordinates = FALSE`, the coordinates defining the position of a light are interpreted as model coordinates in 3 space. Thus, the lights are positioned relative to the objects in the scene. They do not move when the camera moves.

With `CameraCoordinates = TRUE`, these coordinates are interpreted as "camera coordinates". Thus, the lights are attached to the camera and move automatically with the camera when it is moved.

A vector (x, y, z) in "camera coordinates" has to be interpreted as follows:

The x-coordinate refers to the horizontal axis of the picture that you see in the finder of the camera. Positive x values are to your right hand side, negative x values to your left hand side.

The y-coordinate refers to the vertical axis of the picture that you see in the finder. Positive y values are above you, negative y values below you.

The z-coordinate refers to the position along the optical axis of the camera. Positive z values refer to points in front of you, negative z values to points behind you.

In camera coordinates, the camera position is (0, 0, 0).

For example, a point light positioned at the point (0, 1, 0) in camera coordinates is a "head lamp" fixed at a distance of 1 above the camera.

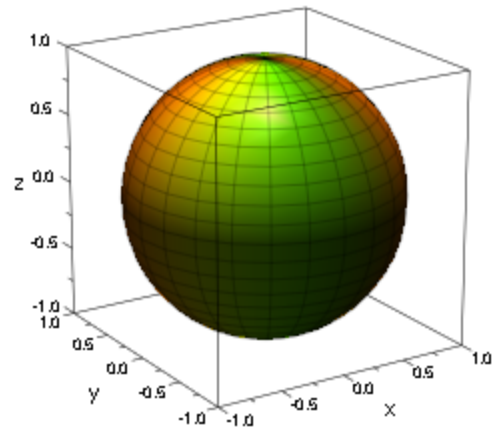
A 3D plot may contain several cameras. Changing the state of `CameraCoordinates` for a light affects its relation to *all* cameras of a scene. With `CameraCoordinates = TRUE`, the position of the light in 3 space changes, when a new camera is chosen interactively.

Examples

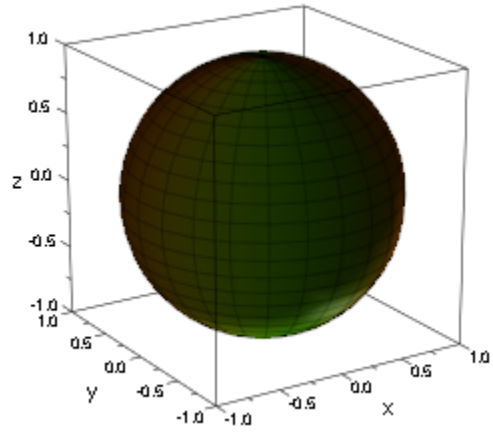
Example 1

We define a sphere:
sphere := plot::Spherical([1, u, v], u = 0..2*PI, v = 0..PI, FillColorType = Functional, FillColorFunction = proc(u, v) begin [(2 + cos(2*u))/3, (2 + sin(2*u))/3, 0] end_proc):

We define sunlight shining from above:
sunlight := plot::DistantLight([0, 0, 1], [0, 0, 0]): plot(sphere, sunlight):



Next, the sunlight is defined relative to the camera. In camera coordinates, “above the camera” is given by the `Position[0, 1, 0]`. Because the camera points downwards, we set the direction of the sunlight “behind” the camera as well by choosing the direction `[0, 1, -1.5]` w.r.t. the camera:
sunlight := plot::DistantLight([0, 1, -1.5], [0, 0, 0], CameraCoordinates = TRUE): plot(sphere, sunlight):

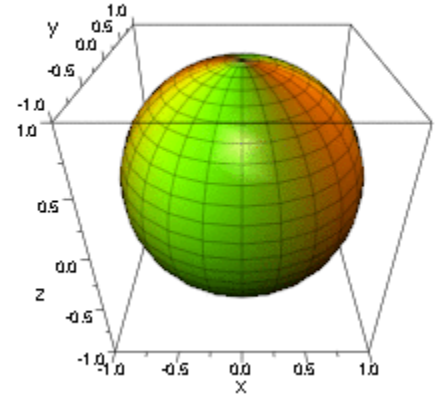


delete sphere, sunlight, pointlight:

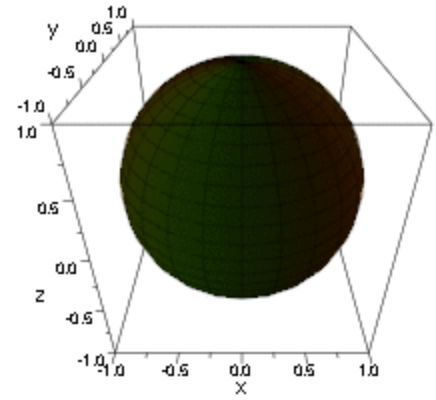
Example 2

We define the same sphere as in the previous example:
sphere := plot::Spherical([1, u, v], u = 0..2*PI, v = 0..PI, FillColorType = Functional, FillColorFunction = proc(u, v) begin [(2 + cos(2*u))/3, (2 + sin(2*u))/3, 0] end_proc):

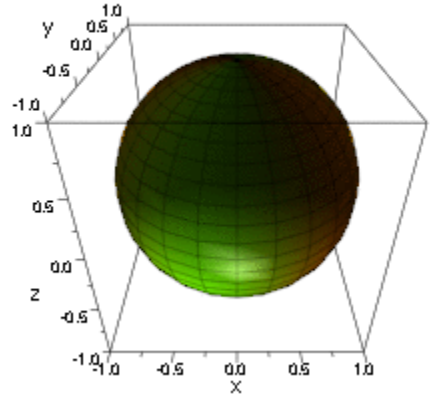
We define an animated camera. First, we use sunlight fixed in space:
camera := plot::Camera([-3*sin(a), -3*cos(a), 2], [0, 0, 0], 0.3*PI, a = 0..2*PI): sunlight:= plot::DistantLight([0, -2, 3], [0, 0, 0]): plot(sphere, camera, sunlight):



Next, we use sunlight moving with the camera:
sunlight:= plot::DistantLight([0, 3, -2], [0, 0, 0], CameraCoordinates = TRUE): plot(sphere, camera, sunlight):



We define a point light that is fixed to some point above the camera:
pointlight := plot::PointLight([0, 1, 0], CameraCoordinates = TRUE):
plot(sphere, camera, pointlight):

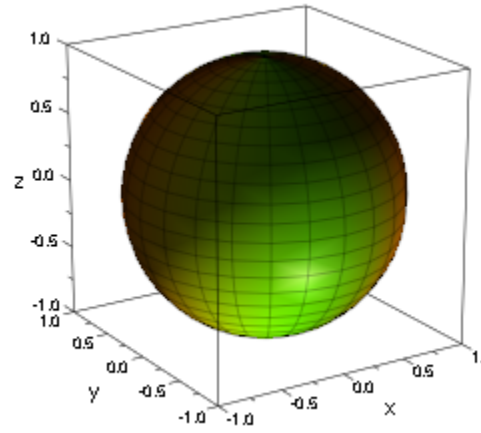


delete sphere, camera, sunlight, pointlight:

Example 3

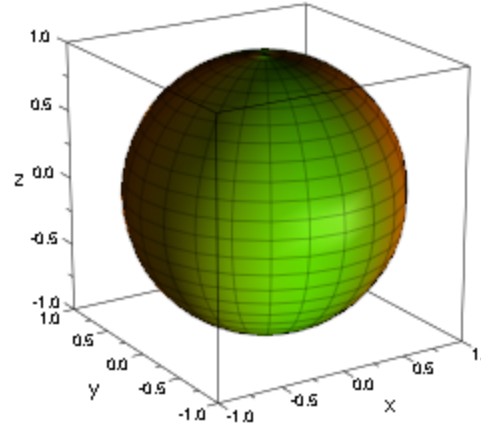
We define the same sphere as in the previous examples:
sphere := plot::Spherical([1, u, v], u = 0..2*PI, v = 0..PI, FillColorType = Functional, FillColorFunction = proc(u, v) begin [(2 + cos(2*u))/3, (2 + sin(2*u))/3, 0] end_proc):

We define an animated point light that is positioned below the camera initially. It moves to some point above the camera during the animation:
pointlight := plot::PointLight([0, 10*a, 0], a = -1..1, CameraCoordinates = TRUE): plot(sphere, pointlight):



We define an animated point light that is positioned to the left of the camera initially. It moves to the right of the camera:

```
pointlight := plot::PointLight([10*a, 0, 0], a = -1 .. 1, CameraCoordinates = TRUE): plot(sphere, pointlight):
```



delete sphere, pointlight:

See Also LightColorLightIntensityPositionSpotAngleTarget

Purpose

CameraDirectionCameraDirectionXCameraDirectionYCameraDirectionZ
Direction of the automatic camera

Value Summary

`CameraDirection`	Library wrapper for "[CameraDirectionX, CameraDirectionY, CameraDirectionZ]" (3D)	See below
`CameraDirectionX`, `CameraDirectionY`, `CameraDirectionZ`		See below

Graphics Primitives

Objects	Default Values
plot::Scene3d	

Description

`CameraDirection` controls the direction where the automatically set camera is positioned.

`CameraDirectionX` etc. refer to the single coordinates of this direction.

When creating a 3D scene, an "automatic camera" is used. It is placed somewhere along the ray starting at the center of the scene (or the center of an explicitly requested ViewingBox, respectively) with the direction given by `CameraDirection`.

The distance to the scene is chosen automatically such that the graphical scene or ViewingBox fills the drawing area optimally.

The `CameraDirection` value is a list or vector of numbers.

Note This vector represents a direction, where the camera is found when starting at the center of the scene or viewing box. It is not the position of the camera!

The length of the `CameraDirection` does not matter, only its direction. The length should not be zero, though.

`CameraDirection = [0, 0, 1]` (looking straight down onto the *x*-*y* plane along the *z*-axis) does not yield a well defined camera view. This direction is automatically replaced by a direction that is close to, but not exactly equal to the *z* direction and orients the scene similiar to a 2D plot.

The `CameraDirection` attributes cannot be animated.

The automatic camera is designed to produce a picture of the entire scene or viewing box, filling the drawing area optimally. `CameraDirection` is the only means to control it.

If only parts of a scene shall be visible, or if the camera is not to aim at the center of the scene, or if large perspective distortions are desired, or if the camera position is to be animated, one has to define one's own camera of type plot::Camera. It can be placed at an arbitrary Position with an arbitrary FocalPoint and can have an arbitrary ViewingAngle. Further, it can be animated (allowing to realize a flight through a 3D scene).

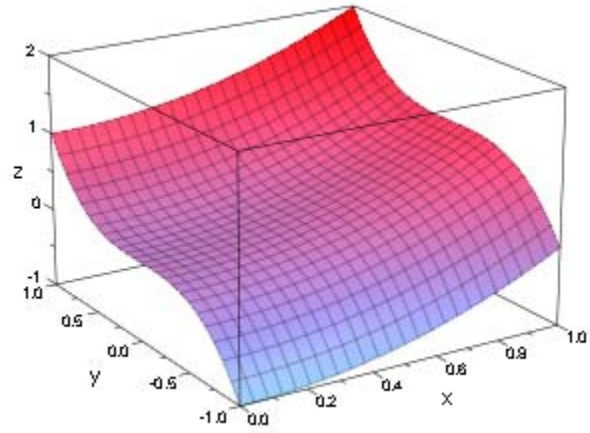
When such a camera object is inserted in a graphical scene, the automatic camera is switched off and the user defined camera takes over, automatically. It uses its own perspective parameters and ignores the attribute `CameraDirection`.

Examples

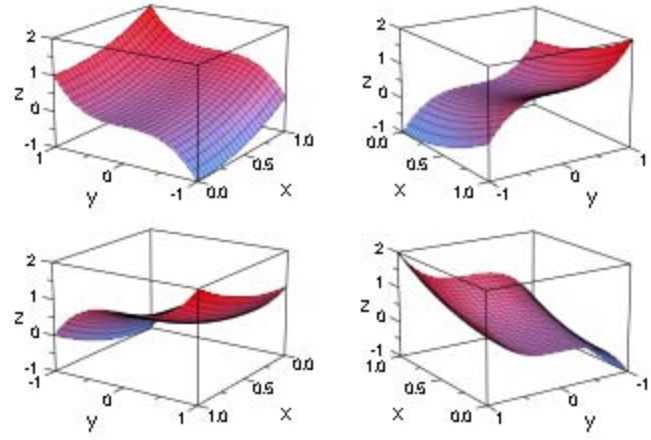
Example 1

We look at a function with the default direction of the automatic camera:

```
f := plot::Function3d(x^2 + y^3, x = 0..1, y = -1 ..1): plot(f):
```

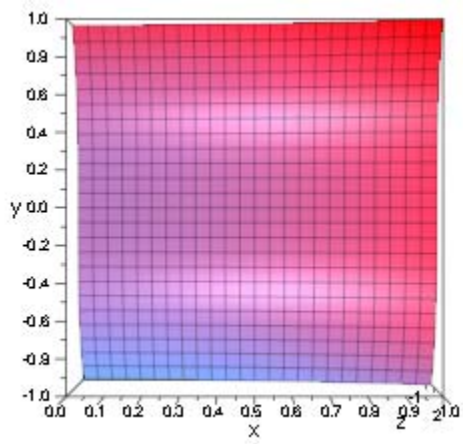


We look from different directions:
S1 := plot::Scene3d(f, CameraDirection = [-3,-4, 5]): S2 := plot::Scene3d(f, CameraDirection = [3,-4, 5]): S3 := plot::Scene3d(f, CameraDirection = [3, 4, 5]): S4 := plot::Scene3d(f, CameraDirection = [-3, 4, 5]): plot(S1, S2, S3, S4)



We look straight down onto the *x*-*y* plane along the *z*-axis:

plot(f, CameraDirection = [0, 0, 1])



delete f, S1, S2, S3:

See Also FocalPointOrthogonalProjectionPositionViewingAngle

FocalPointFocalPointXFocalPointYFocalPointZ

Purpose

Focal point of a camera

Value Summary

`FocalPoint`	Library wrapper for "[FocalPointX, FocalPointY, FocalPointZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`FocalPointX`, `FocalPointY`, `FocalPointZ`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Camera	

Description

The attribute `FocalPoint` refers to the point a camera taking pictures of a 3D scene is aimed at. Its value is a list or vector of coordinates (numerical values or symbolic expressions of an animation parameter).

`FocalPointX` etc. refer to the single coordinates `x` etc.

The optical axis of the camera is given by the vector from the camera Position to its `FocalPoint`.

When creating a camera by

```
camera := plot::Camera(camera_position, focal_point, opening_angle),
```

the focal point is the second argument. Internally, this point is stored as the attribute `FocalPoint` and can be accessed and changed as `camera::FocalPoint`.

The focal point attributes can be animated.

Of course, the focal point should be set such that the camera points into the direction of the objects that are to be rendered. Typically, for a

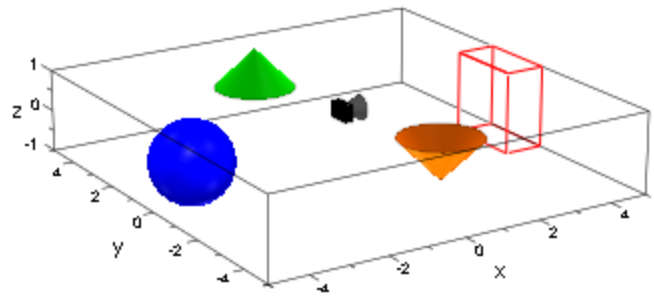
camera positioned outside the graphical scene, a good focal point is the center of the scene.

Examples

Example 1

We define a scene consisting of 4 geometric objects:
b := plot::Box(4..5, -1..1, -1..1, Filled = FALSE, LineColor = RGB::Red): c1 := plot::Cone(1, [0, 4, 0], [0, 4, 1], Color = RGB::Green): s := plot::Sphere(1, [-4, 0, 0], Color = RGB::Blue): c2 := plot::Cone(1, [0, -4, 1], [0, -4, 0], Color = RGB::Orange):

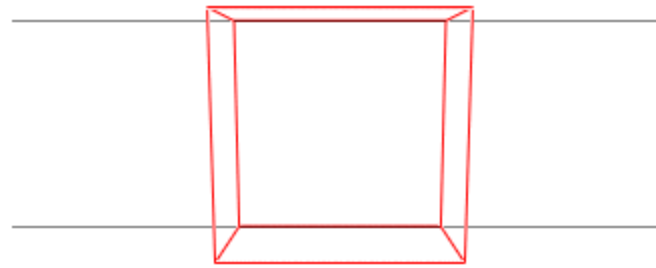
We use a small black object to mark the point (0, 0, 0.5), where we wish to place an animated camera:
cameraposition := plot::Group3d(plot::Box(-0.1..0.1, -0.3..0.3, 0.3..0.7, Color = RGB::Black), plot::Cone(0.1, [0, 0, 0.5], 0.3, [0.5, 0, 0.5], Color = RGB::DarkGrey)): plot(b, c1, s, c2, cameraposition)



When defining the camera, the second argument is the `FocalPoint`. In this case, it is animated: The camera is to turn around the *z*-axis.
camera := plot::Camera([0, 0, 0.5], [4*cos(a), 4*sin(a), 0], PI/4, a = 0..2*PI): camera::FocalPoint[4*cos(a), 4*sin(a), 0]

[4 cos(a), 4 sin(a), 0]

We insert the animated camera:
plot(b, c1, s, c2, camera)

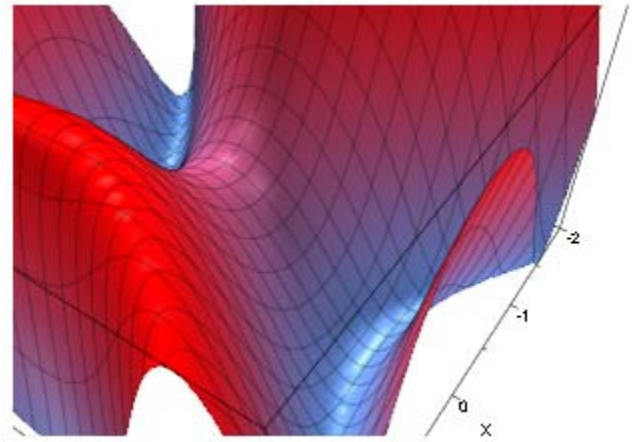


delete b, c1, s, c2, cameraposition, camera:

Example 2

We define a function and a camera with an animated focal point:

```
f := plot::Function3d(sin(x^2-y^2), x = -2..2, y = -2..2, Submesh = [2, 2]):
camera := plot::Camera([3, 3, 3], [sin(a), cos(a), 0], PI/6, a = 0..2*PI):
plot(f, camera)
```



delete f, camera:

See Also CameraDirectionOrthogonalProjectionPositionViewingAngle

LightColor

Purpose

Color of light

Value Summary

Inherited	Color

Description

`LightColor` sets the color of user-defined light sources such as plot::AmbientLight, plot::DistantLight etc.

The value of `LightColor` must be an RGB or RGBa color, i.e., a list of three or four numerical values between 0 and 1. (The fourth value is the opacity entry of an RGBa color. It is accepted but does not have any effect on the light color.)

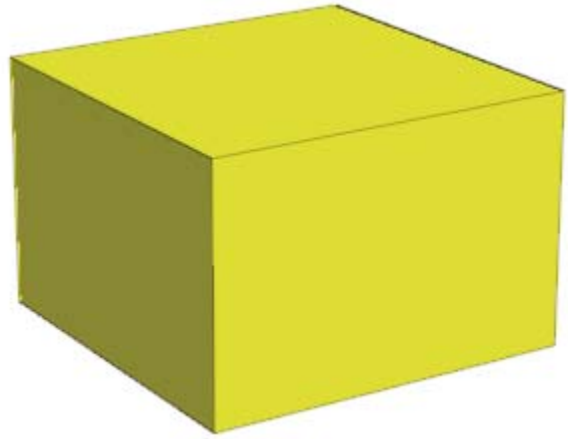
The RGB library provides many predefined colors such as `RGB::Blue` etc. See Section of this document for more information on colors.

`LightColor` cannot be animated.

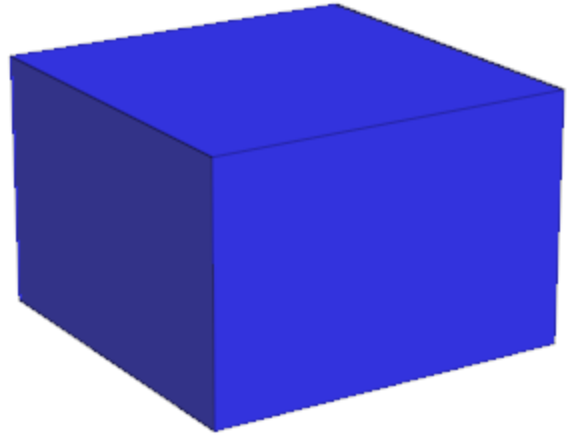
Examples

Example 1

We define a white box and illuminate it by a yellow distant light:
b := plot::Box(-1..1, -1..1, -1..1, Color = RGB::White): light := plot::DistantLight([-1, -2, 3], [0, 0, 0], Color = RGB::Yellow): plot(b, light, Axes = None)



We change the color of the light source:
light::LightColor := RGB::Blue: plot(b, light, Axes = None)



delete b, light:

See Also CameraCoordinatesLightIntensityPositionSpotAngleTarget

Lighting

Purpose

Light schemes for 3D graphics

Value Summary

Inherited	`Automatic`, `Explicit`, or `None`

Graphics Primitives

Objects	Lighting Default Values
plot::Scene3d	`Automatic`

Description

`Lighting` determines the light scheme used to illuminate a 3D scene.

With the default `Lighting = Automatic`, several light sources are set automatically to illuminate a 3D scene. Firstly, there is ambient white light of type plot::AmbientLight:

- Light 0: `LightIntensity = 0.25, LightColor = RGB::White`

In addition, there are 6 directed lights of type plot::DistantLight with LightColor = `RGB::White`. Their directions is given as follows: Think of the graphical scene as being scaled to a standard box extending from -1 to 1 in each coordinate direction. In these scaled coordinates, the directed lights shine into the directions given by the following Target attributes:

- Light 1: Target = `[-5, -6, -8]`, LightIntensity = `0.50`,
- Light 2: Target = `[ 5,  6,  8]`, LightIntensity = `0.60`,
- Light 3: Target = `[ 5, -6, -8]`, LightIntensity = `0.20`,
- Light 4: Target = `[-5,  6,  8]`, LightIntensity = `0.25`,
- Light 5: Target = `[-5,  6, -8]`, LightIntensity = `0.20`,
- Light 6: Target = `[ 5, -6,  8]`, LightIntensity = `0.25`.

User-defined lights in the scene are ignored with `Lighting = Automatic`.

With `Lighting = Explicit`, the light sources set via `Lighting = Automatic` are switched off and user-defined light sources are switched on.

A plot command searches for light objects set by the user. If `Lighting` is not specified and any kind of user-defined light object is found in the scene, `Lighting = Explicit` is set automatically.

Switching between `Lighting = Automatic` and `Lighting = Explicit` in the inspector, one can easily compare the effect of the automatic lights with the effect of ones own lights.

With `Lighting = None`, the 3D shading algorithm based on reflections of light emitted from light sources in the graphical scene is switched off. This does not mean that the graphical scene turns black: all objects are painted in the color they are defined with. However, the scene will appear flat, because the depth of a 3D scene is created via the shading caused by different reflections of light at different points of the scene.

The maximal number of lights that can be used to illuminate a 3D scene depends on the OpenGL driver installed on the computer.

Note Some OpenGL drivers do not allow more than 6 light sources. If there are more light sources in the scene, the surplus lights are ignored. Lights that are switched off via `Visible = FALSE` are not counted.

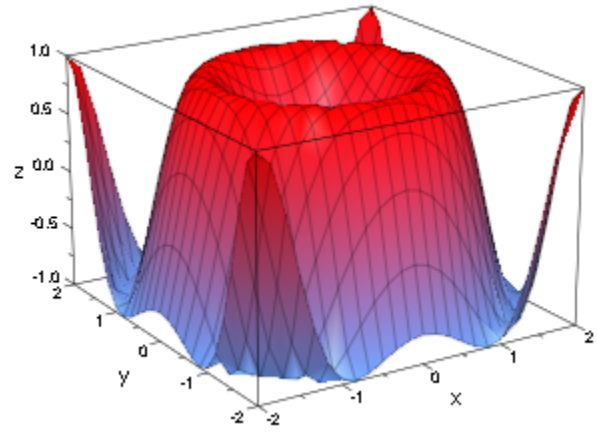
After activating a 3D plot (by clicking it), the "Help" menu contains an item "OpenGL Info" that provides information about the maximal number of lights.

Examples

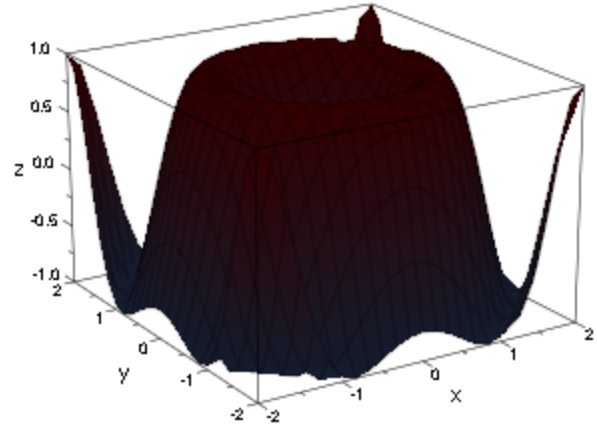
Example 1

In our first scene, no lights are specified. The default setting `Lighting = Automatic` is used:

```
f := plot::Function3d(sin(x^2 + y^2), x = -2..2, y = -2..2): plot(f):
```

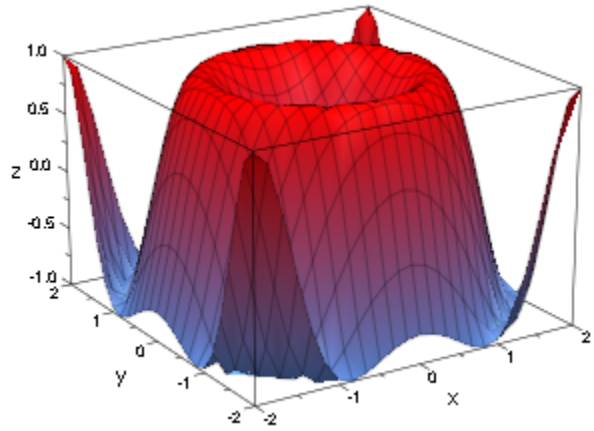


When specifying `Lighting = Explicit`, the lights set by the user are used. Since the scene does not contain any lights, the scene turns dark: plot(f, Lighting = Explicit):

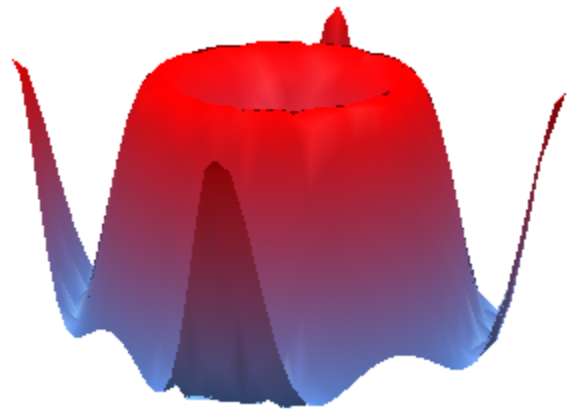


Lights are specified in the next scene. The setting `Lighting = Explicit` is used automatically:

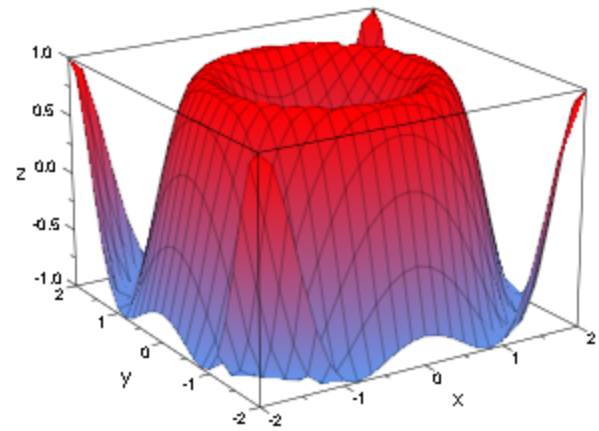
Light0 := plot::AmbientLight(0.25): Light1 := plot::DistantLight([1, 0, 1], [0, 0, 0], 0.3): Light2 := plot::DistantLight([-1, 0, 1], [0, 0, 0], 0.3): Light3 := plot::DistantLight([0, 1, 1], [0, 0, 0], 0.3): Light4 := plot::DistantLight([0, -1, 1], [0, 0, 0], 0.3): plot(f, Light0, Light1, Light2, Light3, Light4):



We switch off the parameter lines:
plot(f, Light0, Light1, Light2, Light3, Light4, XLinesVisible = FALSE, YLinesVisible = FALSE, Axes = None):



In the next scene, the 3D shading model is switched off via `Lighting = None`:
plot(f, Lighting = None):



In the previous picture, the axes box and the mesh lines are switched on and create a certain 3D effect. After switching the box and the mesh lines off, the scene appears flat when rendered without shading:

plot(f, Lighting = None, Axes = None, XLinesVisible = FALSE, YLinesVisible = FALSE):

delete f, Light0, Light1, Light2, Light3, Light4:

See Also

LightColorLightIntensitySpotAngleplot::AmbientLightplot::DistantLightplot::PointLigl

LightIntensity

Purpose

Intensity of light

Value Summary

Optional	Arithmetical expression between 0 and 1

Description

`LightIntensity` governs the intensity of user defined light sources such as plot::AmbientLight, plot::DistantLight etc.

The intensity of all user defined light source can be set by `Intensity = intensity`. The value `intensity` must be a number between 0 and 1. Values smaller than 0 or larger than 1 are accepted and handled like 0 or 1, respectively.

This attribute can be animated.

Undirected ambient light of intensity 1 dominates all other light sources.

Examples

Example 1

When generating a light source of type plot::DistantLight, the third argument is the light intensity. Internally, this value is stored as the attribute `LightIntensity` and can be accessed and changed as the corresponding slot of the light object:
light := plot::DistantLight([2, -1, 3], [0, 0, 0], 0.5): light::LightIntensity0.5

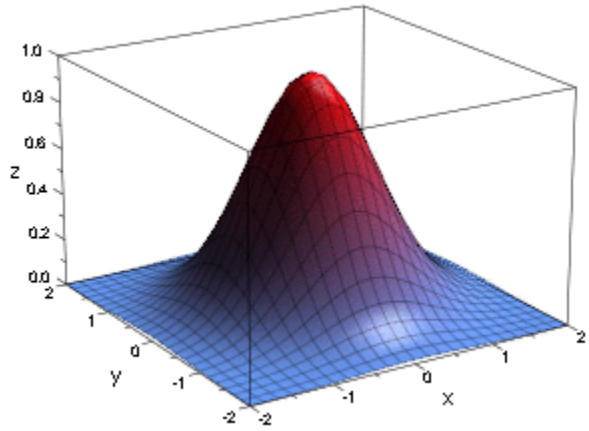
0.5

light::LightIntensity:= 0.4: light::LightIntensity0.4

0.4

We illuminate a function plot by two distant lights with animated intensities:

```
plot(plot::Function3d(exp(-x^2 - y^2), x = -2..2, y = -2..2),
plot::DistantLight([5, -1, 3], [0, 0, 0], 1 - a, a = 0..1),
plot::DistantLight([-3, 5, 2], [0, 0, 0], a, a = 0..1)):
```



delete light:

OrthogonalProjection

Purpose

Parallel projection without perspective distortion

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	OrthogonalProjection Default Values
plot::Camera	FALSE

Description

Setting `OrthogonalProjection = TRUE`, a camera uses parallel projection without perspective distortion.

By default, a camera uses `OrthogonalProjection = FALSE`. Depending on the distance of the camera to the graphical scene (set by the attribute Position), the scene is subject to some natural perspective distortion. The distortion is large when the camera is near the scene. It is small when the camera is far away.

In principle, using parallel projection is equivalent to placing a camera at a very large distance from the scene, looking through a very powerful tele lense.

For technical reasons, however, you should *not* suppress perspective distortion by placing the camera yourself somewhere far away via the attribute Position and turning the camera's lens into a tele lense by setting a small value for its opening angle (cf. ViewingAngle). This may lead to problems with the hidden line algorithm used by the 3D renderer. Further, a suitable opening angle has to be found experimentally such that the scene fills a reasonable portion of the drawing area.

Use `OrthogonalProjection = TRUE` instead. The scaling of the scene is done automatically to fill the drawing area optimally.

With `OrthogonalProjection` = `TRUE`, the view is only determined by the direction of the vector from the FocalPoint of the camera to its Position. (The camera is moved to infinity along the ray given by this "optical axis", using an infinitesimal opening angle.)

The absolute camera position in 3-space as well as its opening angle are ignored.

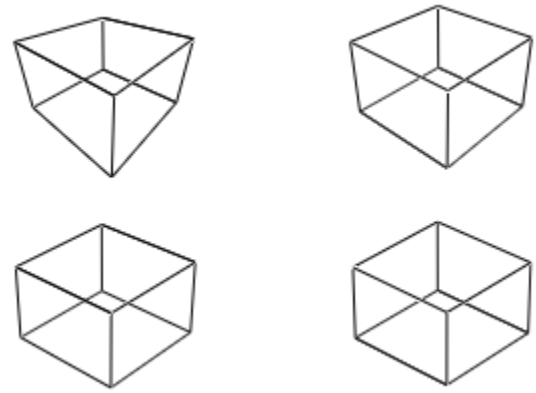
Examples

Example 1

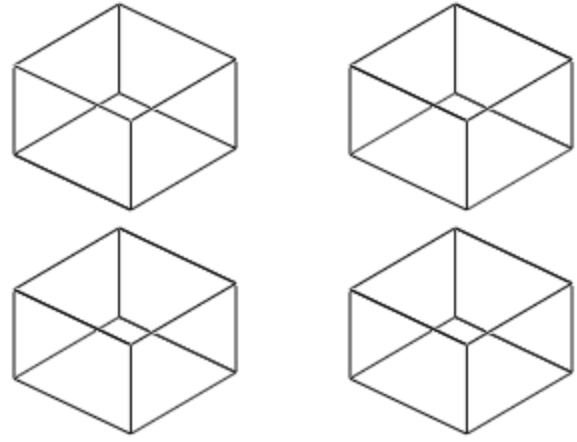
We look at a box with side length 2 using cameras at different positions. We double the distance between the camera and the center of the box from one scene to the next. At the same time, we use more and more powerful tele lenses by decreasing the camera's opening angle by a factor of $1/2_{\frac{1}{2}}$, so that the box has approximately the same size.

- In `S1`, the camera is close to the box. The box is distorted heavily.
- In `S2`, the camera is farther away. The perspective distortions are smaller.
- In `S3`, the distance of the camera to the box center is about 5 times the diameter of the box. Only minor perspective distortions are visible.
- In `S4`, the distance of the camera is about 10 times the diameter of the box. The perspective distortions are almost gone:

```
b := plot::Box(-1..1, -1..1, -1..1, Filled = FALSE, LineColor = RGB::Black):
S1:= plot::Scene3d(b, plot::Camera([ 2, 1.8, 2.5], [0, 0, 0], PI/3)): S2:=
plot::Scene3d(b, plot::Camera([ 4, 3.6, 5.0], [0, 0, 0], PI/6)): S3:=
plot::Scene3d(b, plot::Camera([ 8, 7.2, 10.0], [0, 0, 0], PI/12)): S4:=
plot::Scene3d(b, plot::Camera([16, 14.4, 20.0], [0, 0, 0], PI/24)): plot(S1,
S2, S3, S4, Axes = None)
```



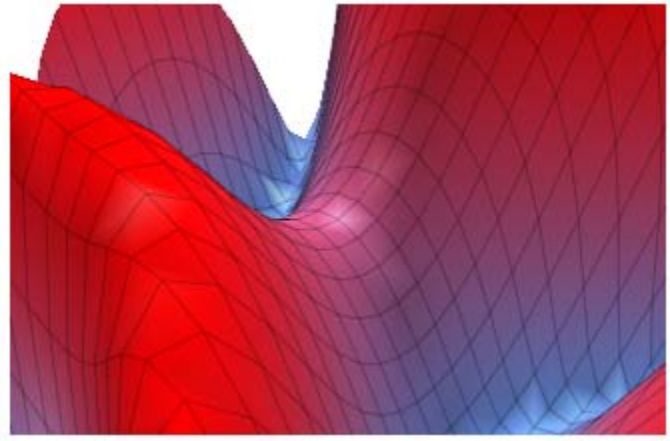
We suppress the distortions completely by setting `OrthogonalProjection = TRUE`. Note the automatic scaling of the scene:
plot(S1, S2, S3, S4, Axes = None, OrthogonalProjection = TRUE)



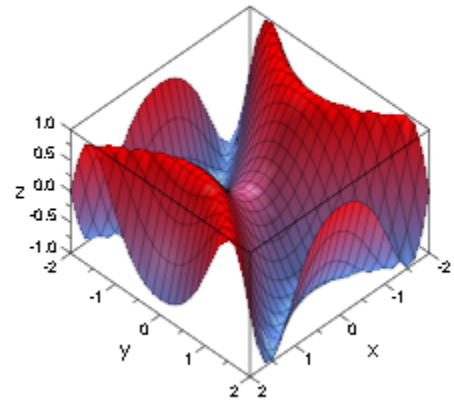
delete b, S1, S2, S3, S4:

Example 2

The following camera is too close to the scene to make all parts of the function graph visible:
f := plot::Function3d(sin(x^2 - y^2), x = -2..2, y = -2..2): camera := plot::Camera([2, 2, 2], [0, 0, 0], PI/5): plot(f, camera)



With `OrthogonalProjection` = `TRUE`, the specified position and opening angle are ignored. The effect of `OrthogonalProjection` is the same as placing the camera far away and choosing a tiny opening angle such that the scene fills the drawing area optimally:
camera::OrthogonalProjection := TRUE: plot(f,camera)



delete f, camera:

See Also CameraDirectionFocalPointPositionViewingAngle

SpotAngle

Purpose

Opening angle of the light cone of a spot light

Value Summary

Mandatory	Real-valued expression (interpreted in radians)

Graphics Primitives

Objects	SpotAngle Default Values
plot::SpotLight	

Description

`SpotAngle` sets the opening angle of the light cone of a spot light in radians, and defines the opening angle of the light cone emitted by spot lights of type plot::SpotLight.

The values for `SpotAngle` have to be given in radians. Reasonable value lie between 0 and π.

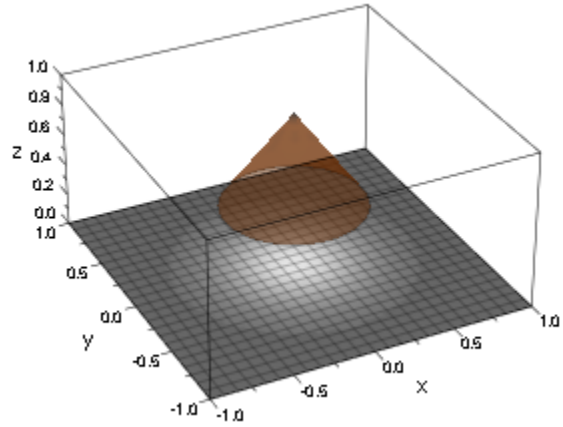
`SpotAngle` can be animated.

Examples

Example 1

When creating a spot light, the third argument is the `SpotAngle`: spotlight := plot::SpotLight([0, 0, 1], [0, 0, 0], a*PI, 1, a = 0..0.4, LightColor = RGB::White): spotlight::SpotAnglePI*a

We illuminate the *x*-*y* plane by the animated spot light and some ambient light. The spot light is visualized by a cone: ambientlight := plot::AmbientLight(0.2): s := plot::Surface([x, y, 0], x = -1..1, y = -1..1, Submesh = [2, 2], Color = RGB::White, FillColorType = Flat): c := plot::Cone(0, [0, 0, 1], 0.6*tan(a*PI/2), [0, 0, 1 - 0.6], a = 0..0.4, Color = RGB::Orange.[0.5]): plot(s, c, spotlight, ambientlight, CameraDirection = [-9, -18, 12])



delete spotlight, ambientlight, s, c:

See Also CameraCoordinatesLightColorLightIntensityPositionTarget

Purpose

TargetTargetXTargetYTargetZ

Target point of a light

Value Summary

`Target`	Library wrapper for "[TargetX, TargetY, TargetZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`TargetX`, `TargetY`, `TargetZ`	Mandatory	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::DistantLight, plot::SpotLight	

Description

The `Target` attribute refers to the point a spot light is aimed at. It also controls the direction of a distant light which is given by the vector `Target` - Position.

`Target` sets the position of the point lights of type plot::DistantLight and plot::SpotLight are aimed at. `TargetX` etc. refer to the single coordinates of this point.

The value of `Target` is a list or vector of coordinates. `TargetX = x` etc. refer to the single coordinates of this list.

These attributes can be animated.

By default, the positions and the targets of light objects are given in model coordinates that have nothing to do with the camera that is used to view the scene.

When using the attribute `CameraCoordinates` = `TRUE`, the light source is fixed to the camera. It moves automatically, when the camera is moved.

Examples

Example 1

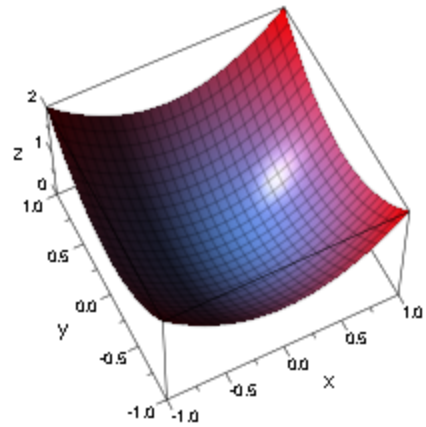
When generating lights of type plot::DistantLight and plot::SpotLight, the second argument ist the `Target`. In the following expample, it is animated:

```
sunlight := plot::DistantLight([0, 0, 2], [cos(a), sin(a), 1], a = 0..2*PI):
spotlight := plot::SpotLight([0, 0, 1], [cos(a), sin(a), 1/2], PI/5, a = 0..2*PI): sunlight::Target, spotlight::Target[cos(a), sin(a), 1], [cos(a), sin(a), 1/2]
```

$$[\cos(a), \sin(a), 1],\ \left[\cos(a), \sin(a), \frac{1}{2}\right]$$

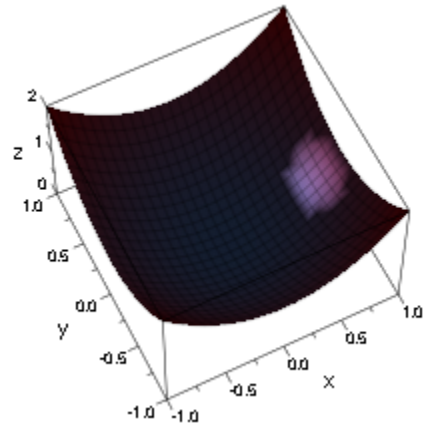
We illuminate a paraboloid with sunlight. Its direction is animated by the `Target` attribute:

```
f := plot::Function3d(x^2 + y^2, x = -1..1, y = -1..1): plot(f, sunlight, CameraDirection = [-1, -2, 6])
```



We use the animated spot light:

```
plot(f, spotlight, CameraDirection = [-1, -2, 6])
```



delete sunlight, spotlight, f:

See Also CameraCoordinatesSpotAnglePositionLightIntensity

UpVectorUpVectorXUpVectorYUpVectorZKeepUpVector

Purpose

Up direction of a camera

Value Summary

`UpVector`	Library wrapper for "[UpVectorX, UpVectorY, UpVectorZ]" (3D)	List of 2 or 3 expressions, depending on the dimension
`UpVectorX`, `UpVectorY`, `UpVectorZ`	Optional	MuPAD expression
`KeepUpVector`	Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Default Values
plot::Camera	`UpVector`: [`0.0`, `0.0`, `1.0`]
	`UpVectorX`, `UpVectorY`: `0.0`
	`UpVectorZ`: `1.0`
	`KeepUpVector`: `TRUE`

Description

`UpVector = [x, y, z]` sets the 3D vector that corresponds to the vertical direction of the 2D picture taken by the camera.

`UpVectorX` etc. denote the coordinates of the `UpVector`.

`KeepUpVector = TRUE` keeps the `UpVector` constant when the camera is moved. With `KeepUpVector = FALSE`, the `UpVector` is kept orthogonal to the optical axis when the camera is moved.

The picture taken by a camera is defined by the attributes Position (the 3D position of the camera) and FocalPoint (the 3D point the camera is pointed at). The vector from the position to the focal point is the optical axis of the camera.

As an additional degree of freedom, the camera may be rotated around the optical axis. This rotation is defined by specifying a 3D vector `UpVector`. In the final 2D picture taken by the camera, this vector is parallel to the vertical axis, pointing upwards.

With the default value `UpVector = [0, 0, 1]` the `z`-axis in 3D points upwards in the 2D picture.

The `UpVector` of a camera must not be zero and must not be parallel to the optical axis.

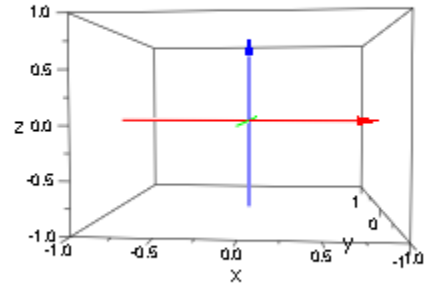
The default values are `UpVector = [0, 0, 1]` and `KeepUpVector = TRUE`.

The restriction that the `UpVector` must not be parallel to the optical axis leads to discontinuities when the camera moves in such a way that this restriction is violated. In such a case, `KeepUpVector = FALSE` should be used. Cf. “Example 2” on page 24-1606.

Examples

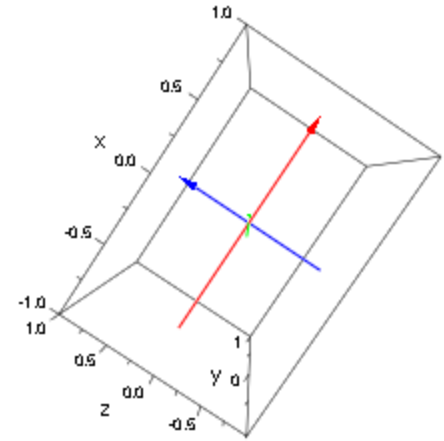
Example 1

We view a cross of three arrows by a camera with the usual `UpVector` pointing into `z`-direction:
camera := plot::Camera([0.3, -4.0, 0.2], [0, 0, 0], PI/4, UpVector = [0, 0, 1]): plot(plot::Arrow3d([-1, 0, 0], [1, 0, 0], Color = RGB::Red), plot::Arrow3d([0, -1, 0], [0, 1, 0], Color = RGB::Green), plot::Arrow3d([0, 0, -1], [0, 0, 1], Color = RGB::Blue), camera)



We redefine the `UpVector` of the camera to point into the direction `[1, 0, 1]`. Now, this 3D direction becomes the vertical direction of the 2D picture:

```
camera::UpVector := [1, 0, 1]: plot(plot::Arrow3d([-1, 0, 0], [1, 0, 0], Color = RGB::Red), plot::Arrow3d([0, -1, 0], [0, 1, 0], Color = RGB::Green), plot::Arrow3d([0, 0, -1], [0, 0, 1], Color = RGB::Blue), camera)
```

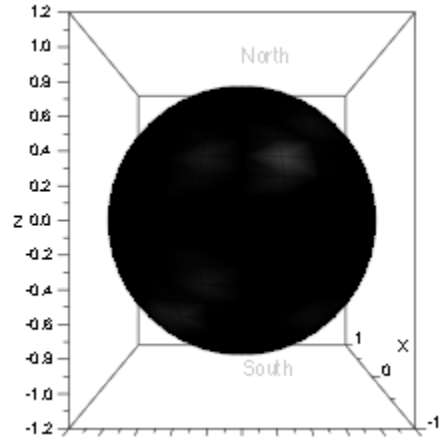


delete camera:

Example 2

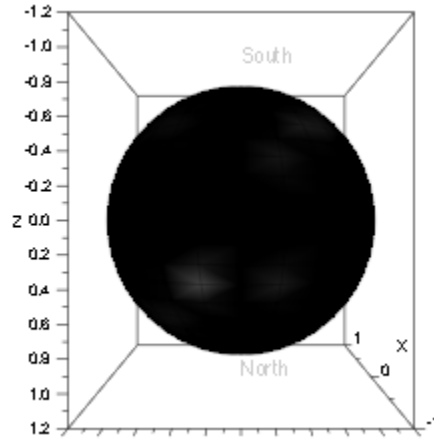
We use an animated camera to fly over the north pole of a planet using the default `UpVector = [0, 0, 1]`. With `KeepUpVector = TRUE`, we encounter a discontinuity when the camera is positioned exactly over the north poly pointing straight down. The `UpVector` is parallel to the optical axis at this point:

```
camera := plot::Camera([4*cos(a), 0, 4*sin(a)], [0, 0, 0], PI/4, a = 0..PI,
Frames = 300, UpVector = [0, 0, 1], KeepUpVector = TRUE): planet :=
plot::Surface([cos(u)*sin(v), sin(u)*sin(v), cos(v)], u = 0..2*PI, v = 0..PI,
FillColorFunction = proc(u, v) begin [cos(u)*cos(v)^2, cos(u)*cos(v)^2,
cos(u)] end_proc): font := ["sans-serif", 10, RGB::Grey80]: text1
:= plot::Text3d("North", [0, 0, 1.2], TextFont = font): text2 :=
plot::Text3d("South", [0, 0, -1.2], TextFont = font): plot(camera, planet,
text1, text2, Scaling = Constrained);
```



With `KeepUpVector = FALSE`, no such discontinuity is encountered. However, when reaching the equator on the dark side of the planet, the `UpVector` has turned around: the upper side of the picture now is south, the lower side is north:

```
camera::KeepUpVector := FALSE: plot(camera, planet, text1, text2,
Scaling = Constrained);
```



delete camera, planet, font, text1, text2:

See Also FocalPointPosition

Purpose

ViewingAngle

Opening angle of the camera lense

Value Summary

Mandatory	MuPAD expression

Graphics Primitives

Objects	ViewingAngle Default Values
plot::Camera	

Description

`ViewingAngle` defines the viewing angle of a camera. It is also known as the "opening angle" of the camera's lense and is determined by its focal length.

Small viewing angles correspond to a tele lense, large opening angles to a wide angle lense. Angles close to π correspond to an (extreme) fish eye lense.

The values for `ViewingAngle` have to be given in radians. The angles should be larger than 1/100 $\frac{1}{100}$ and smaller than π. Other values are replaced by some small positive angle or by an angle slightly less than π, respectively.

Note that when using a wide angle lense, the scene may fill only a part of the drawing area. With a tele lense, only parts of the scene may be visible.

When using a camera object with a given Position, you have to find out experimentally what viewing angle is suitable to make the scene fill a reasonable portion of the drawing area.

`ViewingAngle` does not have any effect when the attribute OrthogonalProjection = `TRUE` is set for the camera.

Note In fact, when a parallel projection without perspective distortion is desired, one should *not* position the camera far away from the scene and use an extreme tele lense (i.e, very small `ViewingAngle` values). This may lead to problems with the hidden line algorithm of the 3D renderer. Use OrthogonalProjection = `TRUE` instead.

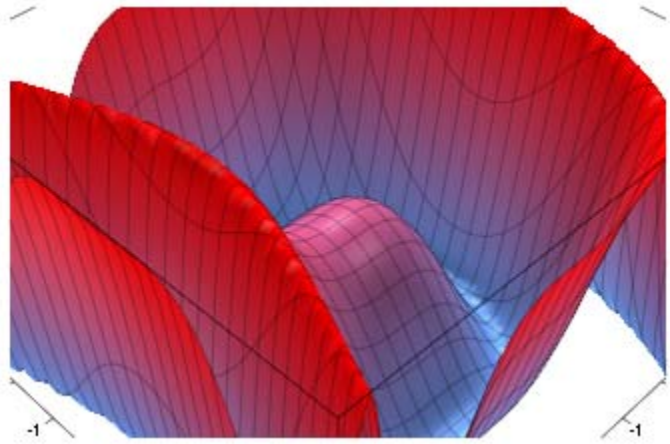
`ViewingAngle` can be animated. Increasing or decreasing values of `ViewingAngle` correspond to "zooming out" or "zooming in", respectively.

Examples

Example 1

When creating a camera object, the third argument is the `ViewingAngle`:
camera:= plot::Camera([5, 5, 5], [0, 0, 0], PI/4):
camera::ViewingAnglePI/4

We animate `ViewingAngle`. With the initial value of PI/3, the scene is fully visible (but rather small). Zooming in by decreasing the viewing angle, only parts of the scene are visible:
f := plot::Function3d(sin(x^3 - y^2), x = -2..2, y = -2..2, Submesh = [2, 2]): camera:= plot::Camera([5, 5, 5], [0, 0, 0], (1 - a)*PI/3 + a*PI/10, a = 0..1, Frames = 200): plot(f, camera)



delete f, camera:

See Also CameraDirectionFocalPointOrthogonalProjectionPosition

AntiAliased

Purpose

Antialiased lines and points?

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	AntiAliased Default Values
plot::Arc2d, plot::Arrow2d, plot::Circle2d, plot::Conformal, plot::Curve2d, plot::Ellipse2d, plot::Function2d, plot::Hatch, plot::Histogram2d, plot::Implicit2d, plot::Integral, plot::Line2d, plot::Listplot, plot::Ode2d, plot::Parallelogram2d, plot::Piechart2d, plot::Point2d, plot::PointList2d, plot::Polar, plot::Polygon2d, plot::QQplot, plot::Rootlocus, plot::Scatterplot, plot::Sequence, plot::SparseMatrixplot, plot::Streamlines2d, plot::Turtle, plot::VectorField2d	TRUE
plot::Bars2d, plot::Boxplot, plot::Density, plot::Inequality, plot::Iteration, plot::Lsys, plot::Raster, plot::Rectangle, plot::Sum	FALSE

Description

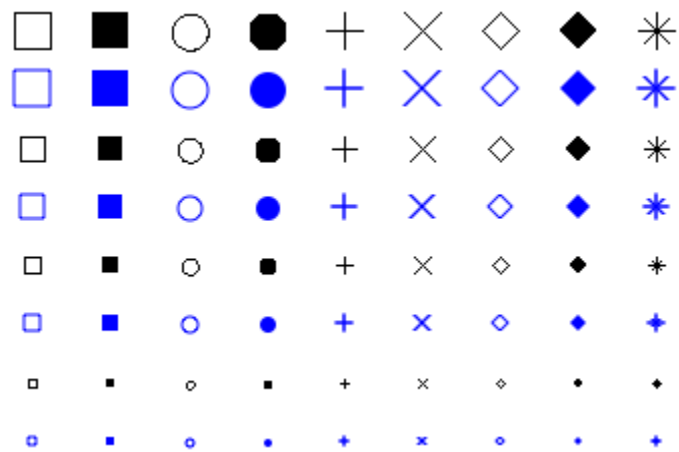
`AntiAliased` controls whether lines and points are drawn antialiased or not. With `AntiAliased` enabled graphics usually look smoother.

Examples

Example 1

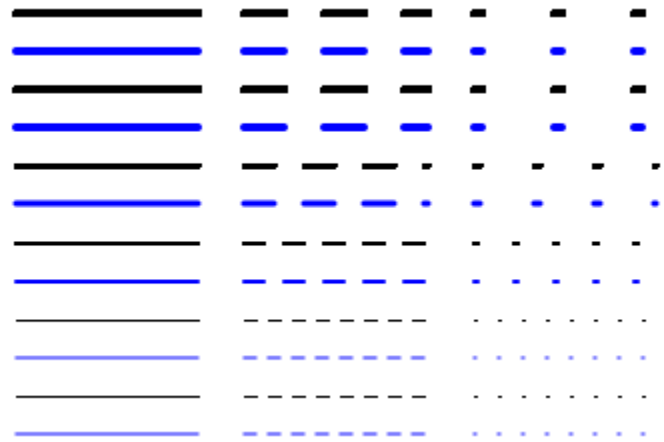
We draw a points in different sizes and point styles. The black points are drawn with `AntiAliased = FALSE`, the blue points are drawn with `AntiAliased = TRUE`:

```
pointStyles := [Squares, FilledSquares, Circles, FilledCircles, Crosses,
XCrosses, Diamonds, FilledDiamonds, Stars]: pointSizes := [1.5, 3,
4.5, 6]: plot(Axes = None, (plot::Point2d(i, 2*j, AntiAliased=TRUE,
PointStyle=pointStyles[i], PointSize=pointSizes[j], Color=RGB::Blue),
plot::Point2d(i, 2*j+1, AntiAliased=FALSE, PointStyle=pointStyles[i],
PointSize=pointSizes[j], Color=RGB::Black)) $ i = 1 .. nops(pointStyles)
$ j = 1..nops(pointSizes))
```



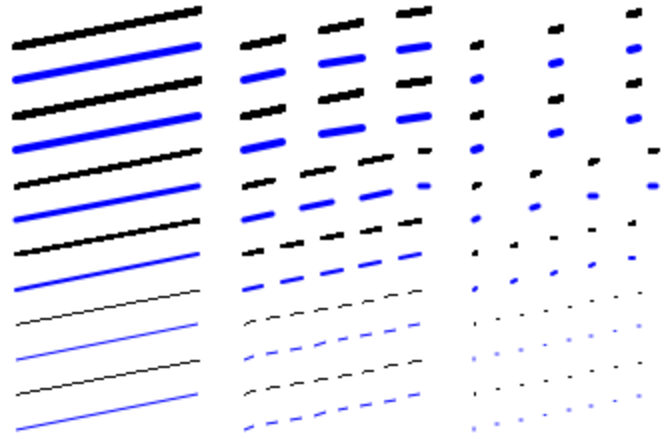
With horizontal lines we see not much difference between `AntiAliased = FALSE` (black lines) and `AntiAliased = TRUE` (blue lines):

```
lineStyles := [Solid, Dashed, Dotted]: lineWidth := [.25, .5, .75,
1, 1.25, 1.5]: plot(Axes = None, (plot::Line2d([i, 2*j], [i+.8, 2*j],
AntiAliased=TRUE, LineStyle=lineStyles[i], LineWidth=lineWidth[j],
Color=RGB::Blue), plot::Line2d([i, 2*j+1], [i+.8, 2*j+1],
AntiAliased=FALSE, LineStyle=lineStyles[i], LineWidth=lineWidth[j],
Color=RGB::Black)) $ i = 1 .. nops(lineStyles) $ j = 1..nops(lineWidth))
```

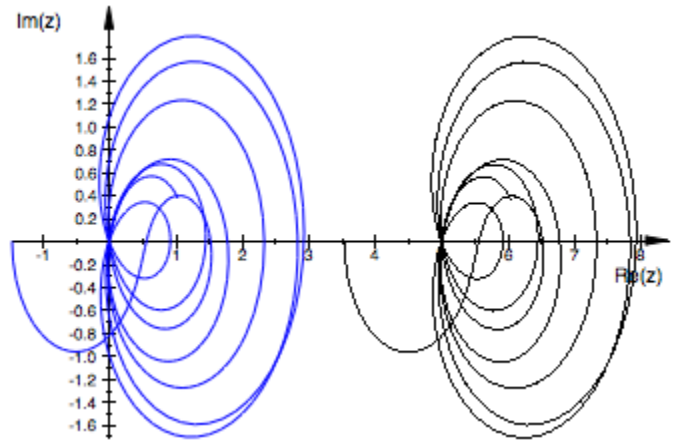


Diagonal lines are much smoother with `AntiAliased = TRUE`:

```
lineStyles := [Solid, Dashed, Dotted]: lineWidth := [.25, .5, .75, 1,
1.25, 1.5]: plot(Axes = None, (plot::Line2d([i, 2*j], [i+.8, 2*j+1],
AntiAliased=TRUE, LineStyle=lineStyles[i], LineWidth=lineWidth[j],
Color=RGB::Blue), plot::Line2d([i, 2*j+1], [i+.8, 2*j+2],
AntiAliased=FALSE, LineStyle=lineStyles[i], LineWidth=lineWidth[j],
Color=RGB::Black)) $ i = 1 .. nops(lineStyles) $ j = 1..nops(lineWidth))
```



By default curves are plotted with `AntiAliased = TRUE` (blue curve) which is much nicer:
f := plot::Curve2d([Re, Im](zeta(I*y+1/2)), y=0..42, AdaptiveMesh=3):
f1 := plot::modify(f, AntiAliased=FALSE, Color=RGB::Black): plot(f, plot::Translate2d([5, 0], f1), XAxisTitle = "Re(z)", YAxisTitle = "Im(z)")



See Also LineStylePointStyle

Purpose

ArrowLength

Scaling of arrows in a vector field

Value Summary

Inherited	`Fixed`, `Logarithmic`, or `Proportional`

Graphics Primitives

Objects	ArrowLength Default Values
plot::VectorField2d, plot::VectorField3d	`Proportional`

Description

`ArrowLength` determines how the lengths of the arrows in a vector field plot depend on the norms of the field at the evaluated points.

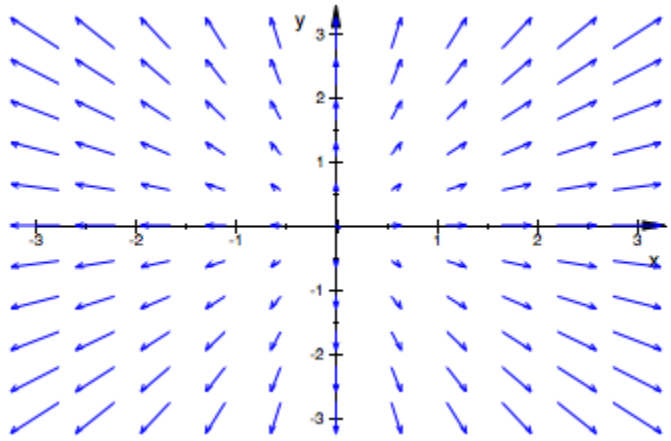
plot::VectorField2d plots a vector field by placing arrows at regular intervals, pointing in the directions of the field at these points. `ArrowLength` determines whether the lengths of those arrows are constant (`ArrowLength =Fixed`), proportional to the norms of the field (`ArrowLength =Proportional`, the default), or proportional to the logarithm of these values increased by 1 (`ArrowLength =Logarithmic`).

Examples

Example 1

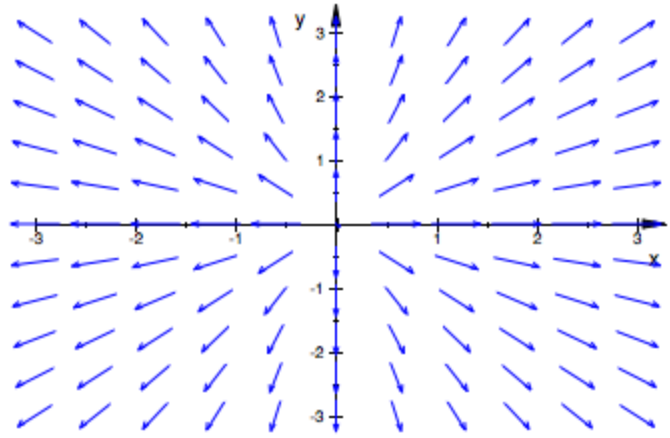
The vector field defined by $f(x, y) = (x, y)^t$ takes on different absolute values at different points. By default, plot::VectorField2d plots arrows whose lengths are proportional to the norms of the field:

```
v := plot::VectorField2d(x, y, x=-3..3, y=-3..3): plot(v)
```



If you only want to display the direction of the field, not its “strength”, use `ArrowLength =Fixed`:

```
v::ArrowLength := Fixed: plot(v)
```



Purpose

AxesTitleFontFooterFontHeaderFontLegendFontTextFontTicksLabelFontTitleFon
Font of axes titles

Value Summary

`AxesTitleFont`, `FooterFont`, `HeaderFont`, `LegendFont`, `TextFont`, `TicksLabelFont`, `TitleFont`	Inherited	Font definition

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	`AxesTitleFont`: [" sans-serif ", 10] `TicksLabelFont`: [" sans-serif ", 8]
plot::Canvas	`FooterFont`, `HeaderFont`: [" sans-serif ", 12]
plot::Scene2d, plot::Scene3d	`FooterFont`, `HeaderFont`: [" sans-serif ", 12] `LegendFont`: [" sans-serif ", 8]
plot::Integral, plot::Piechart2d, plot::Piechart3d, plot::Text2d, plot::Text3d	`TextFont`, `TitleFont`: [" sans-serif ", 11]

Description

`AxesTitleFont` etc. determine the fonts to be used for axes titles etc.

A font is specified as follows:

```
XXXFont              =                  [< family >, <
                                        size >, <<Bold>>,
                                        <<Italic>, < color
                                        >>, < alignment
                                        >].
```

The meaning of the parameters is:

`family` – the font family name: a string.

The available font families depend on the fonts that are installed on your machine. For example, typical font families available on Windows systems are `"Times New Roman"` (of type “serif”), `"Arial"` (of type “sans-serif”), or `"Courier New"` (of type “monospace”).

To find out which fonts are available on your machine, open the menu “Format”, submenu “Font” in your MuPAD notebook. The first column in the font dialog provides the names of the font families that you may specify. You may also specify one the three generic family names `"serif"`, `"sans-serif"`, or `"monospace"`, and the system will automatically choose one of the available font families of the specified type for you.

`size` – the size of the font in integral points: a positive integer.

`Bold` – if specified, the font is bold.

`Italic` – if specified, the font is italic.

`color` – an RGB color value: a list of 3 numerical values between 0 and 1

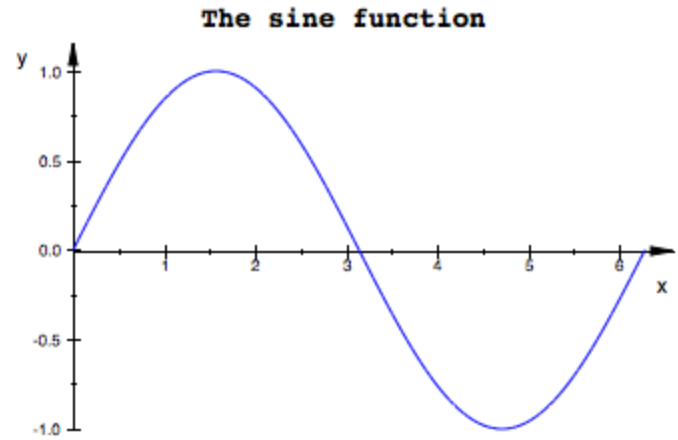
`alignment` text alignment in case of new-lines: one of the flags `Left`, `Center`, or `Right`.

All font parameters are optional; some default values are chosen for entries that are not specified. For example, if you do not care about the footer font family for your plot, but you insist on a specific font size, you may specify an 18 pt font for the canvas footer by `FooterFont = [18]`.

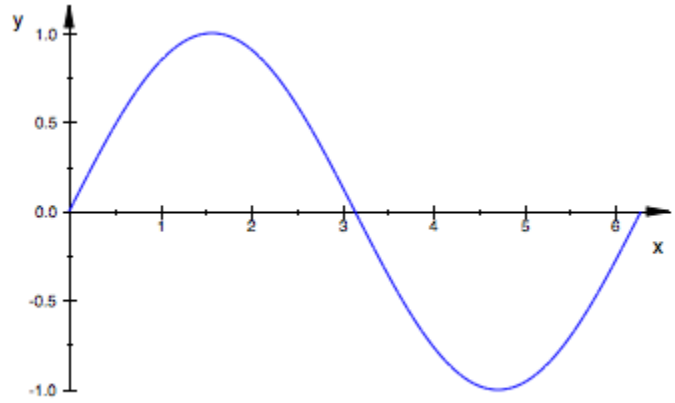
Examples

Example 1

We specify the font for the canvas header:
plot(plot::Function2d(sin(x), x = 0 .. 2*PI), Header = "The sine function", HeaderFont = ["monospace", 14, Bold])



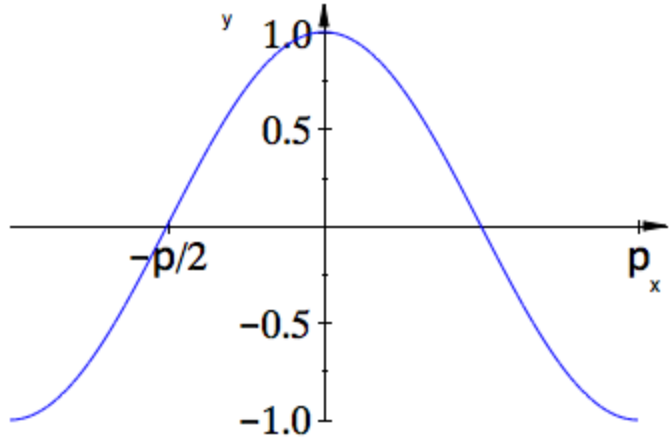
We specify a font size of 18 pt for the canvas footer:
plot(plot::Function2d(sin(x), x = 0 .. 2*PI), Footer = "The sine function", FooterFont = [18])



The sine function

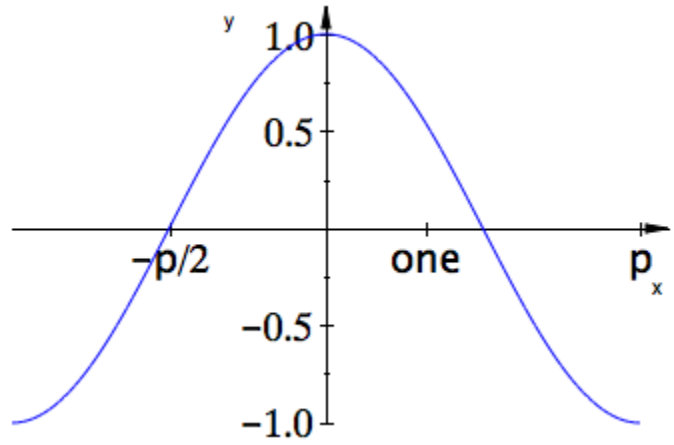
Example 2

With the “Symbol” font, it is possible to display Greek characters. The symbol π is referred to as the letter *p*:
plot(plot::Function2d(cos(x), x = -PI..PI), XTicksNumber = None, XTicksAt = [-PI/2 = "-p/2", PI = "p"], TicksLabelFont = ["Symbol", 20])



Note, however, that this font is used for *all* tick labels:

```
plot(plot::Function2d(cos(x), x = -PI..PI), XTicksNumber = None,
XTicksAt = [-PI/2 = "-p/2", PI = "p", 1.0 = "one"], TicksLabelFont =
["Symbol", 20])
```



See Also AxesTitlesFooterHeaderLegendTextLegendVisibleTicksAtTicksLabelsVisibleTitle

Concepts

- “Fonts”

Purpose

BackgroundColorBackgroundColor2

Background color

Value Summary

`BackgroundColor`, `BackgroundColor2`	Inherited	Color

Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d	`BackgroundColor`: RGB::White
plot::Scene3d	`BackgroundColor`: RGB::White `BackgroundColor2`: RGB::Grey75

Description

These attributes set background colors for scenes, scene margins, and the remaining space in a canvas.

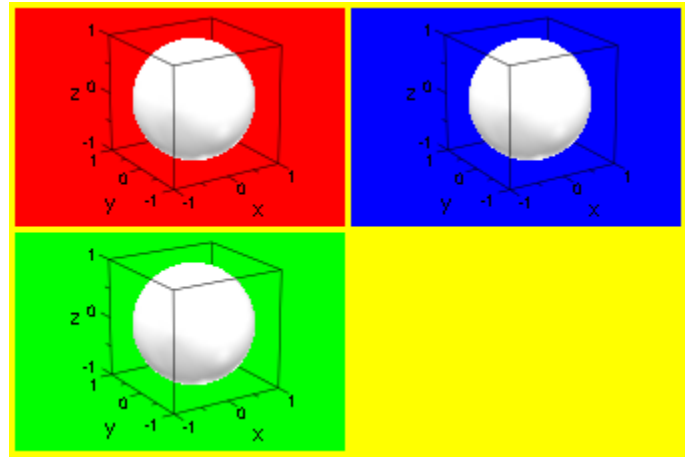
`BackgroundColor` sets the background color of a scene or canvas, where "background" refers to any area not occupied by graphical elements, including the margin.

For a 3D-scene, if BackgroundStyle is not `Flat`, the actual scene background (not including the margin) is a blend from `BackgroundColor` to `BackgroundColor2`. See BackgroundStyle for details.

Examples

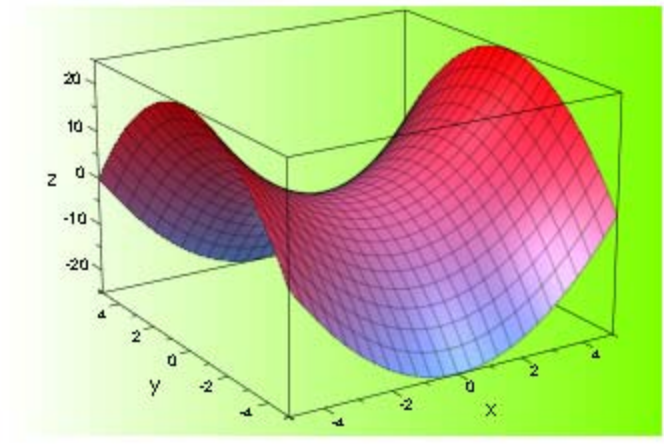
Example 1

In the following plot, we combine three scenes with backgrounds in red, blue, and green and set the background color of the canvas to yellow:
s1 := plot::Scene3d(plot::Sphere(1, Color = RGB::White), BackgroundColor = RGB::Red): s2 := plot::modify(s1, BackgroundColor = RGB::Blue): s3 := plot::modify(s1, BackgroundColor = RGB::Green): plot(s1, s2, s3, BackgroundColor = RGB::Yellow):



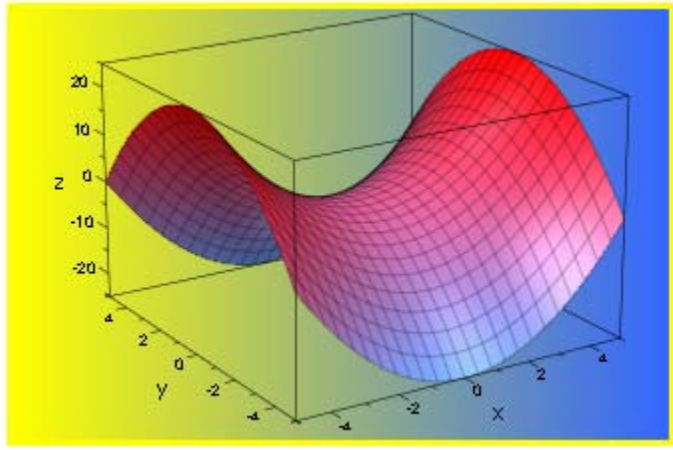
Example 2

Using `BackgroundColor2` and BackgroundStyle, you can set the background of 3D-scenes to use a color blend:
plotfunc3d(x^2-y^2, BackgroundStyle = LeftRight, BackgroundColor2 = RGB::Chartreuse)



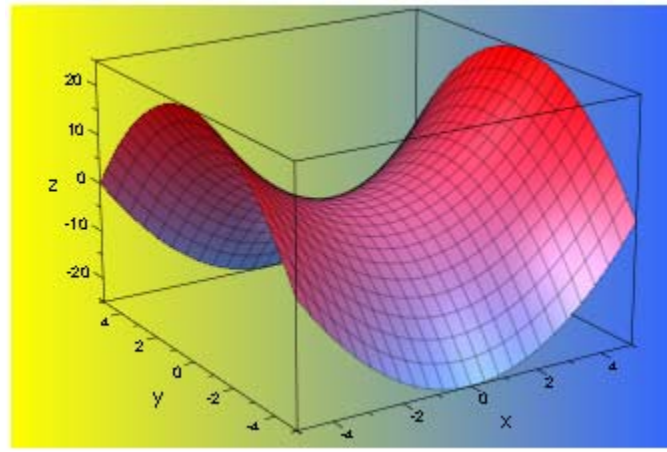
But note that the margin of the scene is still painted in its `BackgroundColor`:

```
plotfunc3d(x^2-y^2, plot::Scene3d::BackgroundColor =
RGB::Yellow, plot::Scene3d::BackgroundStyle = LeftRight,
plot::Scene3d::BackgroundColor2 = RGB::LightBlue)
```



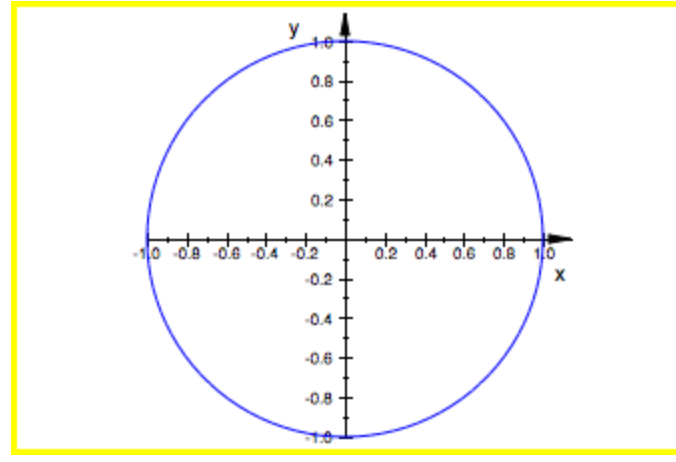
To avoid this margin, we set its width to zero:

```
plotfunc3d(x^2-y^2, plot::Scene3d::BackgroundColor =
RGB::Yellow, plot::Scene3d::BackgroundStyle = LeftRight,
plot::Scene3d::BackgroundColor2 = RGB::LightBlue,
plot::Scene3d::Margin = 0)
```

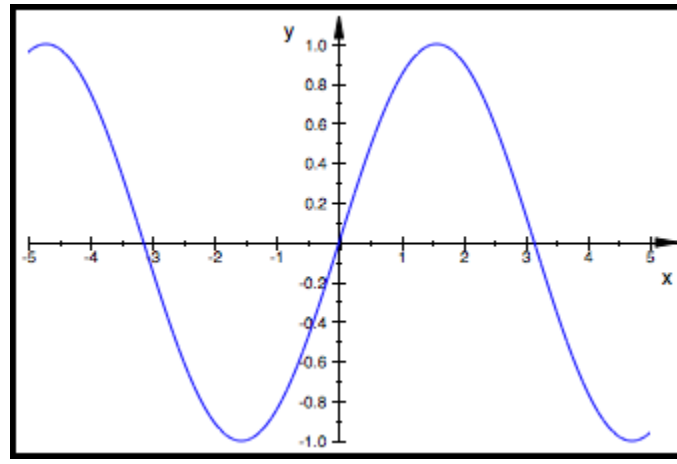


Example 3

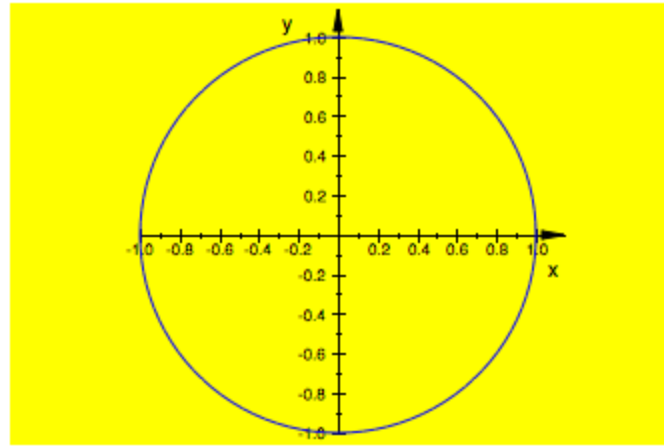
The fact that `BackgroundColor` is an attribute of both canvas and scenes has the effect that giving it directly in a plot command will only affect the canvas, not the implicitly generated scenes of a plot:
plot(plot::Circle2d(1), BackgroundColor = RGB::Yellow)



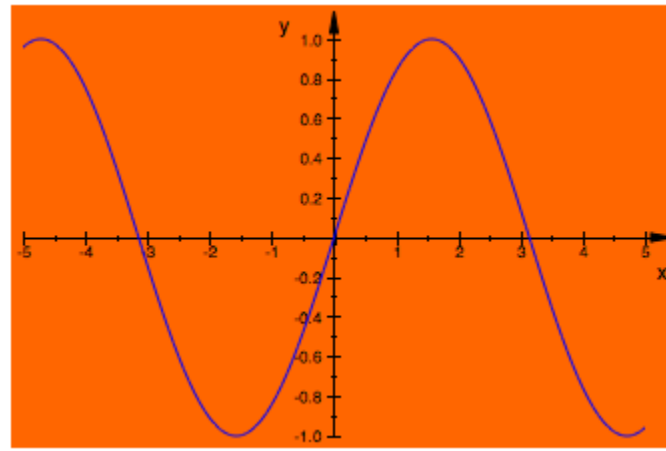
plotfunc2d(sin(x), BackgroundColor = RGB::Black)



To set the background color of a scene, use one of the styles illustrated above: Either create a scene explicitly:
plot(plot::Scene2d(plot::Circle2d(1), BackgroundColor = RGB::Yellow))



Or, set the attribute explicitly for scenes:
plotfunc2d(sin(x), plot::Scene2d::BackgroundColor = RGB::Orange)



There is also a third option, not used in the examples above: You can set `BackgroundColor` as a hint in an object to be shown (but this does not work for plotfunc2d and plotfunc3d):
plot(plot::Text2d("Sample", [0, 0], TextFont = [RGB::White, 60], HorizontalAlignment = Center, BackgroundColor = RGB::Black))

See Also BackgroundStyleBackgroundTransparentMargin

Purpose

BackgroundStyle

Color blends in the background

Value Summary

Inherited	`Flat`, `LeftRight`, `Pyramid`, or `TopBottom`

Graphics Primitives

Objects	BackgroundStyle Default Values
plot::Scene3d	`Flat`

Description

`BackgroundStyle` gives a color blend in the background of a 3D scene.

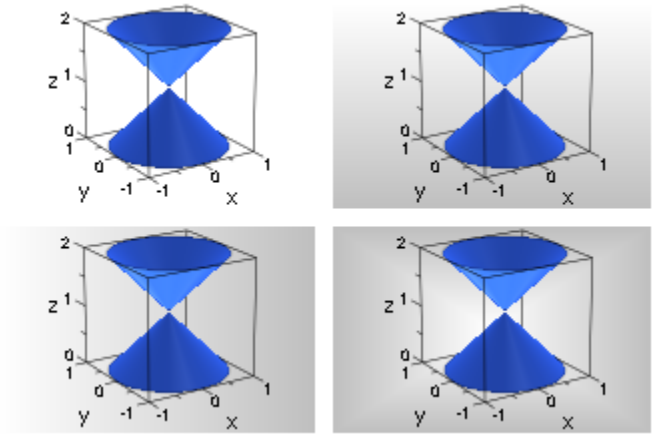
The background of a 3D scene may be set to a single color (`BackgroundStyle = Flat`, using BackgroundColor) or to a blend from BackgroundColor to BackgroundColor2, in one of three possible directions: `LeftRight` and `TopBottom` are linear blends from left to right or from top to bottom, respectively, while `Pyramid` sets a linear blend from the center to the borders.

Examples

Example 1

We demonstrate all possible styles, using a simple plot and the default values for BackgroundColor and BackgroundColor2:

```
c1 := plot::Cone(1, [0, 0, 0], [0, 0, 1]): c2 := plot::Cone(1, [0, 0, 2], [0, 0, 1]):
plot(plot::Scene3d(c1, c2, BackgroundStyle = Flat), plot::Scene3d(c1, c2,
BackgroundStyle = TopBottom), plot::Scene3d(c1, c2, BackgroundStyle
= LeftRight), plot::Scene3d(c1, c2, BackgroundStyle = Pyramid), Layout
= Tabular)
```



delete c1, c2:

See Also BackgroundColorBackgroundColor2

BackgroundTransparent

Purpose

Plot a scene on a transparent background

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	BackgroundTransparent Default Values
plot::Scene2d, plot::Scene3d	FALSE

Description

Using `BackgroundTransparent`, you can have a scene "without a background."

By default, each scene has an opaque background. In the case of overlapping scenes (which you can achieve by setting `Layout = Absolute` or `Layout = Relative` in the canvas and providing suitable values for Bottom and Left for the scenes), this may be undesirable. Using `BackgroundTransparent`, you can make the background of a scene transparent, so the canvas background and scenes behind it are visible.

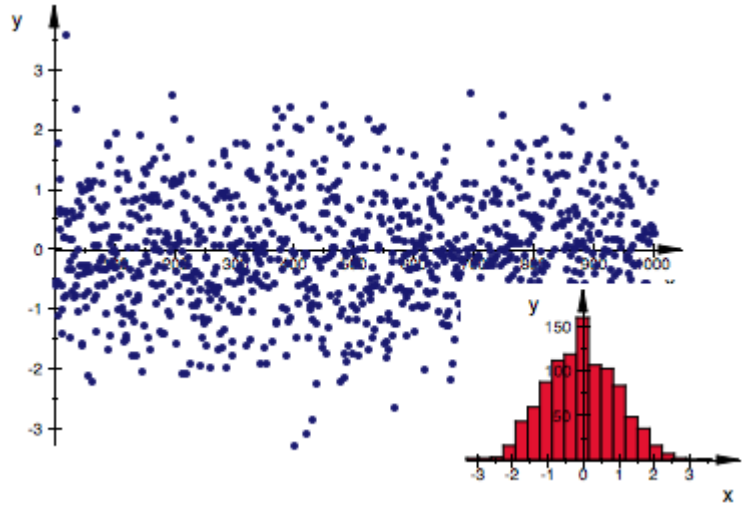
With `BackgroundTransparent = TRUE`, other background settings (BackgroundColor, BackgroundStyle, BackgroundColor2) are ignored.

Examples

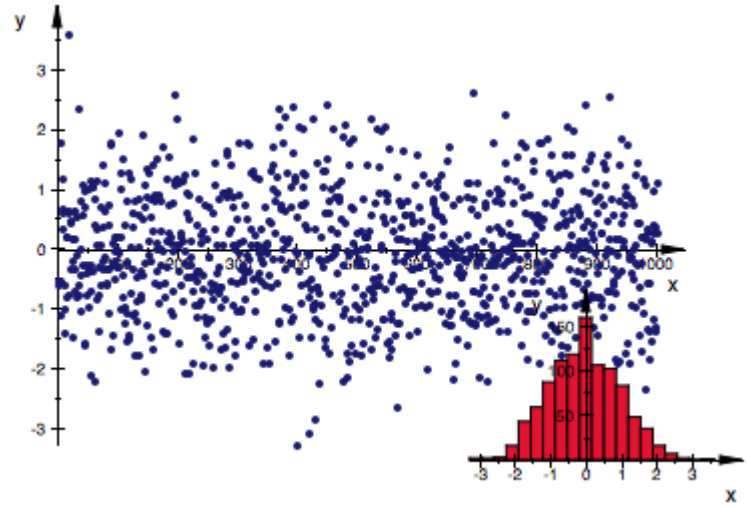
Example 1

We create a number of random points and two statistical plots of this sample:

```
gen := stats::normalRandom(0, 1): data := [gen() $ i = 1..1000]:
s1 := plot::Scene2d(plot::PointList2d([[i, data[i]] $ i = 1..1000]),
Left = 0, Bottom = 10, Width = 120, Height = 80): s2 :=
plot::Scene2d(plot::Histogram2d(data, Cells=[20]), Left = 80, Bottom
= 0, Width = 50, Height = 40): plot(s1, s2, Layout = Absolute, Width
= 130, Height = 90)
```



The histogram plot obscures parts of the point list in a rectangle much larger than the bars of the histogram plot. Using `BackgroundTransparent`, we an set this rectangle to transparent: s2::BackgroundTransparent := TRUE: plot(s1, s2, Layout = Absolute, Width = 130, Height = 90)



See Also BackgroundColorBackgroundColor2BottomLayoutLeft

Billboarding

Purpose

Text orientation in space or towards observer

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Billboarding Default Values
plot::Piechart3d, plot::Text3d	TRUE

Description

With `Billboarding = TRUE`, text objects are always facing the observer. With `Billboarding = FALSE`, text objects retain their orientation relative to other objects.

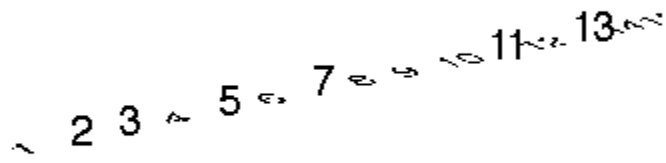
Often, text objects in 3D are used to label certain places in a graphic (note that objects can contain a title, so text objects are usually only necessary for additional descriptions). In this case, it is desirable that they always face the observer to be readable and not rotate along with the rest of the scene. This is the default behavior. To get text objects that are actually part of the scene in the sense that rotating the scene also rotates the texts, set `Billboarding = FALSE`.
plot::getDefault(plot::Text3d::Billboarding)TRUE

TRUE

Examples

Example 1

In the following image, the prime numbers use `Billboarding = TRUE`, while other numbers do not:
plot(plot::Text3d(expr2text(i), [3*i, 0, 0], TextOrientation = [1, 0, 0, 0, 1, 0], Billboarding = isprime(i)) $ i = 1..15, TextFont = [20], Scaling = Constrained, Axes = None)



Note that text objects with `Billboarding = TRUE` ignore TextOrientation.

See Also Title

BorderColorBorderWidth

Purpose

Color of frame/border around canvas and scenes

Value Summary

`BorderColor`, `BorderWidth`	Inherited	Color

Graphics Primitives

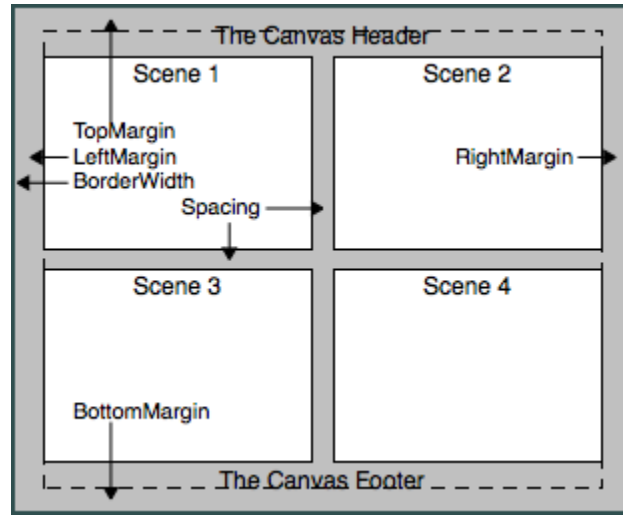
Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	`BorderColor`: RGB::Grey50 `BorderWidth`: `0`

Description

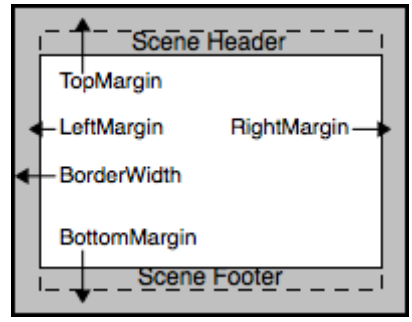
The canvas as well as the scenes in a canvas can be framed by a rectangular border. The width of the border is set by `BorderWidth`, its color is set by `BorderColor`.

With the attributes `BorderWidth` and `BorderColor`, a canvas or individual scenes can be given a border, similar to an image frame. The border is "switched off" with the default value `BorderWidth = 0`. Set the border width to some positive value such as `BorderWidth = 0.5*unit::mm` to make the border visible.

The following picture illustrates the layout of the canvas:
read("layoutPictures.mu"): Scene1::Header := "Scene 1": Scene2::Header := "Scene 2": Scene3::Header := "Scene 3": Scene4::Header := "Scene 4": plot(plot::Canvas(Height = 90*unit::mm, Width = 110*unit::mm, Footer = "The Canvas Footer", Header = "The Canvas Header", HeaderFont = [12], FooterFont = [12], Spacing = 2.0*unit::mm, Margin = 3*unit::mm, BackgroundColor = RGB::Grey, BorderWidth = borderwidth*100*unit::mm, BorderColor = RGB::SlateGreyDark, Layout = Relative, Scene1, Scene2, Scene3, Scene4, SCENE1)):



The following picture illustrates the layout of a scene:
Scene5::Header := "Scene Header": Scene5::Footer := "Scene Footer":
plot(Scene5, SCENE2, Layout = Relative, Height = canvasheight, Width = canvaswidth, Margin = 0, BorderWidth = 0):



The size of a canvas, set by the attributes Width and Height, includes the width of the border set by `BorderWidth`. The same holds for the scenes.

With `BackgroundTransparent = TRUE`, transparent scenes (without a background) can be created. The borders do *not* become transparent!

The scene borders do not react to `Layout = Relative`. One always has to specify the border width as absolut physical lengths such as `BorderWidth = 0.5*unit::mm`.

Scenes do *not* inherit borders from the enclosing canvas. You can set the borders for all scenes simultaneously by specifying them in plot::setDefault as

`plot::Scene2d::BorderWidth`, `plot::Scene2d::BorderColor`

or

`plot::Scene3d::BorderWidth`, `plot::Scene3d::BorderColor`,

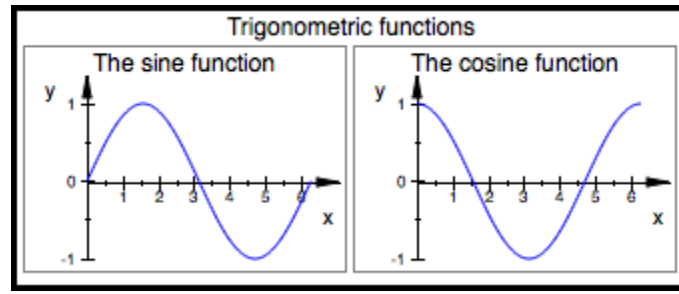
respectively. Cf. “Example 2” on page 24-1639.

Examples

Example 1

Two scenes are displayed side by side. The borders of the canvas and the two scenes are “switched on” by specifying positive values for `BorderWidth`:

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0 .. 2*PI), Header
= "The sine function", BorderWidth = 0.5*unit::mm): S2 :=
plot::Scene2d(plot::Function2d(cos(x), x = 0 .. 2*PI), Header = "The
cosine function", BorderWidth = 0.5*unit::mm): plot(S1, S2, Header
= "Trigonometric functions", Width = 120*unit::mm, Height =
50*unit::mm, BorderWidth = 1.0*unit::mm, BorderColor = RGB::Black,
Layout = Horizontal):
```



delete S1, S2:

Example 2

We use plot::setDefault to define new default values for the layout and style parameters BorderWidth, `BorderColor`, `Margin`, and BackgroundColor:
plot::setDefault(plot::Canvas::BorderWidth = 0.5*unit::mm, plot::Canvas::BorderColor = RGB::Black, plot::Canvas::Margin = 1.5*unit::mm, plot::Canvas::BackgroundColor = RGB::SlateGrey, plot::Scene2d::BorderWidth = 0.5*unit::mm, plot::Scene2d::BorderColor = RGB::Black, plot::Scene2d::Margin = 2*unit::mm, plot::Scene2d::BackgroundColor = RGB::Grey):

The following canvas contains two scenes. This plot uses the new defaults:
plot(plot::Scene2d(plot::Rectangle(-1..1, -1..1, Filled = TRUE, FillColor = RGB::Red, Header = "Scene 1")), plot::Scene2d(plot::Rectangle(-1..1, -1..1, Filled = TRUE, FillColor = RGB::Blue, Header = "Scene 2")), Layout = Horizontal, Axes = None, Header = "Canvas Header"):

Ground

BoxCentersBoxWidths

Purpose

Position of boxes in a box plot

Value Summary

`BoxCenters`, `BoxWidths`	Optional	List of arithmetical expressions

Graphics Primitives

Objects	Default Values
plot::Boxplot	`BoxCenters`: [1] `BoxWidths`: [0.8]

Description

`BoxCenters` and `BoxWidths` govern horizontal center positions and widths of boxes in statistical box plots of Type plot::Boxplot.

A plot of type plot::Boxplot serves for visualizing and comparing statistical data samples.

A data sample defines the vertical coordinates of the corresponding box. The position along the horizontal axis as well as the horizontal width, however, is arbitrary and may be manipulated by the attributes `BoxCenters` and `BoxWidths`.

By default, the box of the i-th data sample is positioned at the horizontal value $x = i$. With the default width of 0.8, the i-th box extends from $x = i - 0.4$ to $x = i + 0.4$.

The value of the attribute `BoxCenters` must be a list of x-values for the horizontal centers of the boxes.

If the length of this list is smaller than the number of data samples in the box plot, the center values are incremented by 1 for each surplus box.

If the length of the `BoxCenters` list is larger than the number of data samples, the surplus center values are ignored.

Setting BoxCenters = [x_1], the first box is centered at $x = x_1$, while the standard distance between the boxes is kept. Thus, BoxCenters = [x_1] allows to shift the entire box plot along the horizontal axis.

The value of the attribute BoxWidths must be a list of positive real values.

If the length of this list is smaller than the number of data samples in the box plot, the default width 0.8 is used for the surplus boxes.

If the length of the BoxWidth list is larger than the number of data samples, the surplus width values are ignored.

If the attribute DrawMode = Horizontal is set in the plot::Boxplot object, the boxes are drawn from left to right instead from bottom to top.

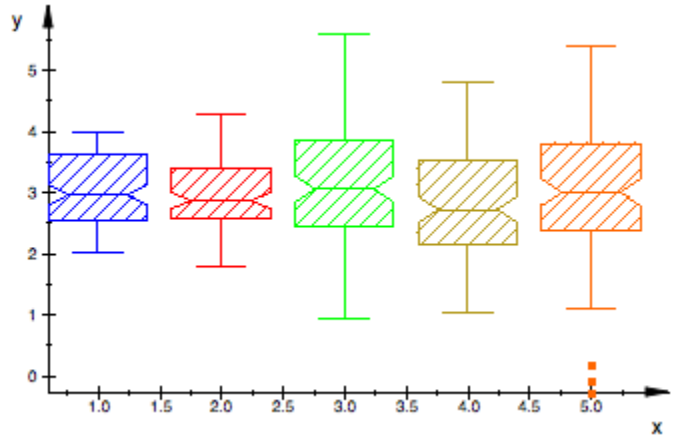
In this case, the attributes BoxCenters and BoxWidths refer to the vertical coordinates of the boxes.

Examples

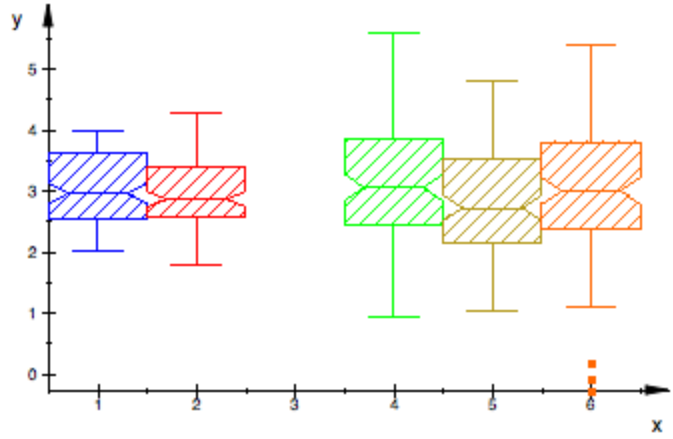
Example 1

We create a box plot visualizing 5 data samples:

```
data1 := [stats::uniformRandom(2, 4)() $ k = 1..100]: data2
:= [stats::normalRandom(3, 0.3)() $ k = 1..100]: data3
:= [stats::normalRandom(3, 1)() $ k = 1..100]: data4
:= [stats::normalRandom(3, 1)() $ k = 1..100]: data5 :=
[stats::normalRandom(3, 1)() $ k = 1..100]: plot(plot::Boxplot(data1,
data2, data3, data4, data5, Notched = TRUE)):
```

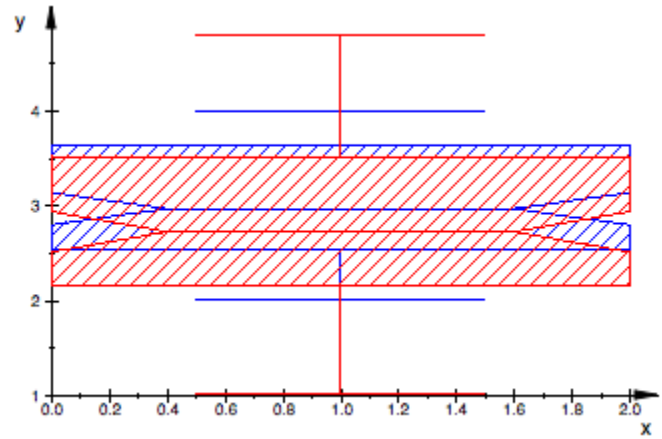


We specify the horizontal centers and the widths of the boxes such that the first two and the last three boxes touch each other:
plot(plot::Boxplot(data1, data2, data3, data4, data5, Notched = TRUE, BoxCenters = [1, 2, 4, 5, 6], BoxWidths = [1, 1, 1, 1, 1])):



We place two of the data boxes on top of each other for direct comparison:

plot(plot::Boxplot(data1, data4, Notched = TRUE, BoxCenters = [1, 1], BoxWidths = [2, 2]))



delete data1, data2, data3, data4, data5:

See Also DrawModeNotchedNotchWidth

Purpose

DrawMode

Orientation of boxes and bars

Value Summary

Optional	`Horizontal` or `Vertical`

Graphics Primitives

Objects	DrawMode Default Values
plot::Bars2d, plot::Boxplot, plot::Histogram2d	`Vertical`

Description

`DrawMode` = `Vertical` versus `DrawMode` = `Horizontal` determines the orientation of boxes in a box plot and bars in bar plots and histogram plots.

A plot of type plot::Boxplot serves for visualizing and comparing statistical data samples. The plot reduces the data to few simple descriptive parameters.

One coordinate direction provides information on the statistical data (25% quantile, median, 75% quantile etc.). The other coordinate direction just serves for placing several boxes associated with different data samples side by side for comparison.

With `DrawMode` = `Vertical`, the vertical direction provides the information on the statistical data.

With `DrawMode` = `Horizontal`, the boxes are turned by 90 degrees. Now, the horizontal direction provides the information on the statistical data.

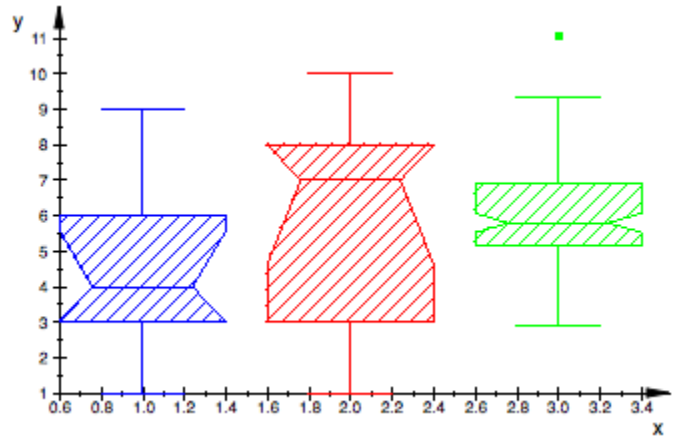
Corresponding statements hold for the bars in a 2D bar plot of type plot::Bars2d and 2D histograms of type plot::Histogram2d.

Examples

Example 1

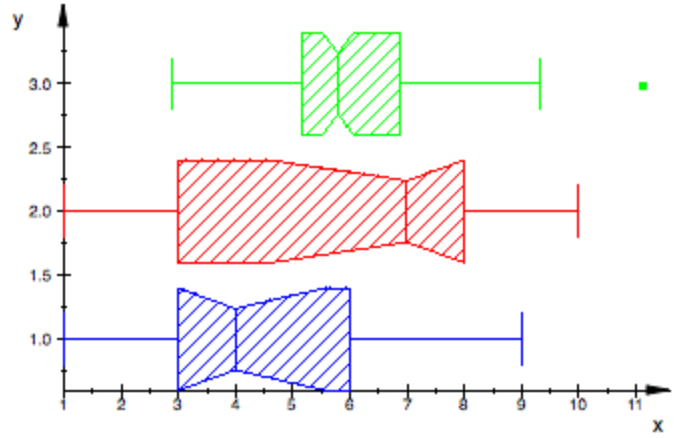
We create a box plot:

```
data1 := [2, 6, 4, 3, 1, 7, 9, 5, 3]: data2 := [2, 4, 8, 8, 7, 6, 8, 7,
3, 1, 10]: data3 := [stats::normalRandom(6, 2)() $ k = 1 .. 100]:
plot(plot::Boxplot(data1, data2, data3, Notched = TRUE)):
```



The boxes are rendered horizontally:

```
plot(plot::Boxplot(data1, data2, data3, Notched = TRUE, DrawMode
= Horizontal)):
```



```
delete data1, data2, data3:
```

See Also BoxCentersBoxWidthsNotchedNotchWidth

Purpose

GapXGapYGap

Gaps between the bars of a bar chart

Value Summary

`Gap`	[[XGap, YGap]]	See below
`XGap`, `YGap`	Optional	MuPAD expression

Graphics Primitives

Objects	Default Values
plot::Bars3d	`Gap`: `[0, 0]` `XGap`, `YGap`: `0`

Description

`Gap`, XGap, YGap sets gaps between the bars of a bar chart.

In plot::Bars3d, the attribute `Gap = [`g_x`, `g_y`]` or, equivalently, `XGap` = g_x, `YGap` = g_y allows to introduce gaps between adjacent bars. The values g_x, g_y may be real numerical values between 0 and 1 or expressions of the animation parameter. These values set the fraction of the space reserved for a bar that is not filled by the bar.

With g_x = `0`, g_y = `0`, there are no gaps. With g_x = `0.5`, g_y = `0.5`, the gaps between adjacent bars are of the same size as the bars. With g_x = `1`, g_y = `1`, there bars become lines.

Values of g_x, g_y larger than 1 are treated like 1, negative values like 0.

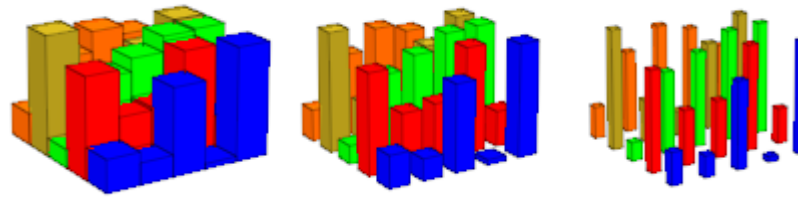
The `Gap` attribute has an effect only for `BarStyle` = `Boxes`.

Examples

Example 1

We display the same data with different `Gap` values:

```
A := matrix::random(5, 5, frandom) : plot(plot::Scene3d(plot::Bars3d(A, Gap = [0, 0])), plot::Scene3d(plot::Bars3d(A, Gap = [0.4, 0.4])), plot::Scene3d(plot::Bars3d(A, Gap = [0.7, 0.7])), Width = 150*unit::mm, Height = 50*unit::mm, Layout = Horizontal):
```



delete A:

NotchedNotchWidth

Purpose

Notched boxes in box plots

Value Summary

`Notched`, `NotchWidth` Optional `TRUE` or `FALSE`

Graphics Primitives

Objects	Default Values
plot::Boxplot	`Notched`: `FALSE` `NotchWidth`: `0.2`

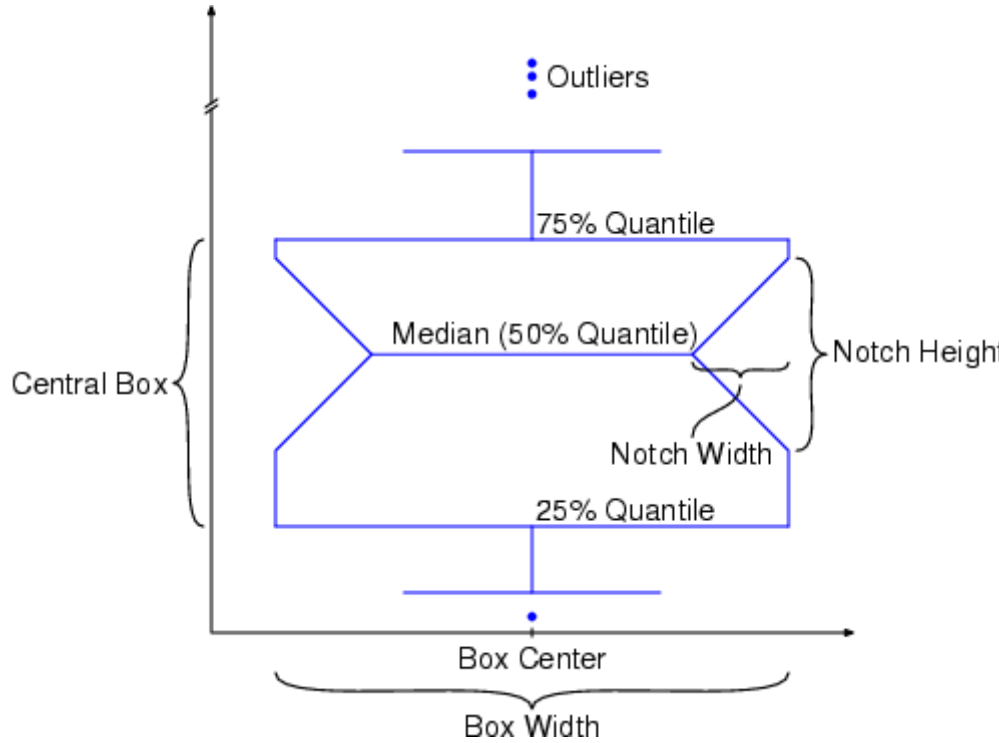
Description

With `Notched = TRUE`, the boxes in a statistical box plot of type plot::Boxplot are notched. The notches provide further information on the statistical data.

The attribute `NotchWidth` determines the horizontal width of the notches.

A plot of type plot::Boxplot serves for visualizing and comparing statistical data samples. The plot reduces the data to few simple descriptive parameters.

One graphical parameter is the height of notches that are displayed in the sides of the boxes when using `Notched = TRUE`. A typical notched box looks like this:



The height of the notches is 3.14 times the height of the central box divided by the square root of the number of data elements in the corresponding data sample.

Notched box plots are useful for determining whether two random samples were drawn from the same population. Similar notches of boxes indicate that the data visualized by the boxes have the same distribution.

This, however, is not a *rigorous* criterion that the data samples are indeed identically distributed.

The horizontal width of the notches bears no statistical significance and is just a layout parameter. Setting `NotchWidth` = *r*, the absolute

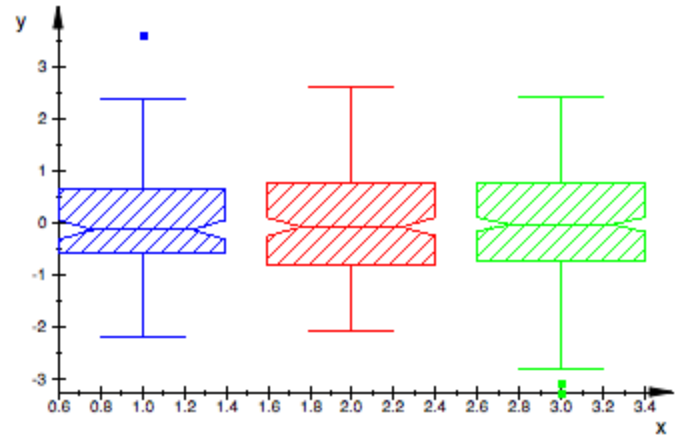
horizontal notch width of a box is *r* times the width of the box. Reasonable values for *r* lie between 0 and 1/2$\frac{1}{2}$.

The widths of the boxes can be set via the attribute BoxWidths.

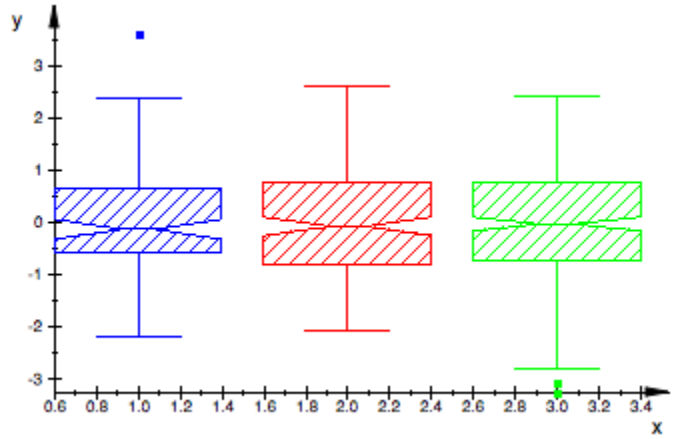
Examples

Example 1

We create a notched box plot of several random samples:
r := stats::normalRandom(0, 1): data1 := [r() $ k = 1..100]: data2 := [r() $ k = 1..200]: data3 := [r() $ k = 1..300]: plot(plot::Boxplot(data1, data2, data3, Notched = TRUE)):



We change the `NotchWidth`:
plot(plot::Boxplot(data1, data2, data3, Notched = TRUE, NotchWidth = 0.4)):



delete r, data1, data2, data3:

See Also BoxCentersBoxWidthsDrawMode

Projectors

Purpose

Project an ODE solution to graphical points

Value Summary

Mandatory		List of arithmetical expressions

Graphics Primitives

Objects	Projectors Default Values
plot::Ode2d, plot::Ode3d	

Description

`Projectors` defines "generators of plot data" that project solution points $(t, Y(t))$ of an ODE to graphical points $[x, y]$ in 2D or $[x, y, z]$ in 3D, respectively.

Internally, plot::Ode2d and plot::Ode3d generate a sequence of numerical solution points $(t_0, Y(t_0))$, $(t_1, Y(t_1))$ etc. of an ODE. Each of these solution points is mapped to a graphical point via the "projectors" defined by `Projectors`.

Each projector G_i in `Projectors = [[G`$_1$`], [G`$_2$`], ]` is a list

$[G_i]$=`[(t, Y) -> [x(t,Y), y(t,Y), <z(t, Y)>], <Style = style>, <Color = color>]` .

The procedures `(t, Y) -> [x(t, Y), y(t, Y), <z(t, Y)>]` map the solution points (t_i, Y_i) of the ODE to points $[x(t_i, Y_i), y(t_i, Y_i)]$ in 2D (for plot::Ode2d) or $[x(t_i, Y_i), y(t_i, Y_i), z(t_i, Y_i)]$ in 3D (for plot::Ode3d). These points are drawn in the picture, interpolated by linear or cubic spline interpolation according to the attribute `Style= style` in the color set by the attribute `Color = color`.

The style parameter may be one of the flags `Points` (only the points are displayed), `Lines` (only interpolating line segments are displayed), `Splines` (only the interpolating cubic spline curve is displayed), `[Lines, Points]` (interpolating line segments together with the interpolation points are displayed) , or `[Splines, Points]` (the interpolating cubic spline curve together with the interpolation points are displayed).

The default style is `Style= [Splines, Points]`.

Each of the projectors G_1, G_2 etc. (denoted by G in the following) is a mapping funcDecl(G, fenced(t, Y), [x(t,Y), y(t,Y)])$G: (t, Y) \to [x(t, Y), y(t, Y)]$ in 2D or funcDecl(G, fenced(t, Y), [x(t,Y), y(t,Y), z(t,Y)])$G: (t, Y) \to [x(t, Y), y(t, Y), z(t, Y)]$ in 3D. It must accept a numerical argument t and a vector Y (a list or a one-dimensional array) and must return a list of numerical coordinate values `[x, y]` (in plot::Ode2d) or `[x, y, z]` (in plot::Ode3d), respectively. Defining appropriate projectors, any information on the solution curve of the ODE can be displayed graphically.

Here are some examples:

`G := (t, Y) -> [t, Y[1]]` creates a 2D plot of the first component of the solution vector along the y-axis, plotted against the time variable `t` along the x-axis

`G := (t, Y) -> [Y[1], Y[2]]` creates a 2D phase plot, plotting the first component of the solution along the x-axis and the second component along the y-axis. The result is a solution curve in phase space (parametrized by the time `t`).

`G := (t, Y) -> [Y[1], Y[2], Y[3]]` creates a 3D phase plot of the first three components of the solution curve.

If no projectors are specified in a call to plot::Ode2d, the default projectors `Generators = [[G1], [G2], ]` are used, where

`[G_i] = [(t, Y) -> [t, Y[i]], Style = [Splines, Points]]`.

This plots the i-th component of the solution vector along the y-axis against the "time" t plotted along the x-axis.

In plot::Ode3d, the default projectors are

`[G_i] = [(t, Y) -> [t, Y[2*i - 1], Y[2*i]], Style = [Splines,Points]]`.

This plots two of the components of the solution vector along the y- and z-axis against the "time" t plotted along the x-axis.

Examples

Example 1

We consider the 2nd order ODE y”=-y+sin(3*y), y(0)=1, y’(0)=0$y'' = -y + \sin(3\,y),\ y(0) = 1,\ y'(0) = 0$. As a dynamical system for Y=fenced(Y[1], Y[2])=fenced(y, y’)$Y = (Y_1,\ Y_2) = (y,\ y')$, the ODE to be solved is

(d)/(dt) * Y=(d)/(dt) * matrix([[Y[1]], [Y[2]]])=matrix([[Y[2]], [-Y[1]+sin(3*Y[1])]])

$$\frac{d}{dt}\,Y = \frac{d}{dt}\begin{pmatrix} Y_1 \\ Y_2 \end{pmatrix} = \begin{pmatrix} Y_2 \\ -Y_1 + \sin(3\,Y_1) \end{pmatrix}$$

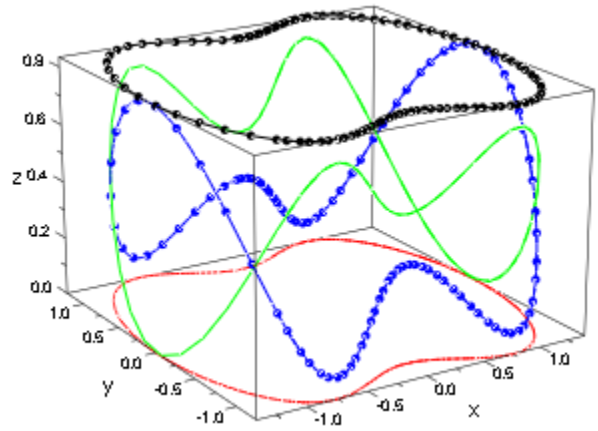
The first projector G_1 plots the solution in red as a phase curve in the (x, y)-plane.

The second projector G_2 plots the kinectic energy

Y[2]^2/2=(y’)^2/2$\frac{Y_2^2}{2} = \frac{y'^2}{2}$ in green along the z-axis.

The third projector G_3 plots the potential energy Y[1]^2+cos(3 * Y[1])/3=y^2/2+cos(3 * y)/3$Y_1^2 + \frac{\cos(3\,Y_1)}{3} = \frac{y^2}{2} + \frac{\cos(3\,y)}{3}$ in blue along the z-axis.

The fourth projector G_4 plots the total energy in black along the z-axis: f := (t, Y) -> [Y[2], - Y[1] + sin(3*Y[1])]: Y0 := [0, 1]: G1 := (t, Y) -> [Y[1], Y[2], 0]: G2 := (t, Y) -> [Y[1], Y[2], Y[2]^2/2]: G3 := (t, Y) -> [Y[1], Y[2], Y[1]^2/2 + cos(3*Y[1])/3]: G4 := (t, Y) -> [Y[1], Y[2], Y[1]^2/2 + cos(3*Y[1])/3 + Y[2]^2/2]: plot(plot::Ode3d(f, [i/10 $ i = 0..100], Y0, [G1, Style = Splines, Color = RGB::Red], [G2, Style = Lines, Color = RGB::Green], [G3, Color = RGB::Blue], [G4, Style = [Lines, Points], Color = RGB::Black]))



delete f, Y0, G1, G2, G3, G4:

Purpose

ScalingYXRatioZXRatio
Scaling ratios

Value Summary

`Scaling`	Inherited	`Automatic`, `Constrained`, or `Unconstrained`
`YXRatio`, `ZXRatio`	Inherited	Positive real numberReal number

Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	`Scaling: Unconstrained`
plot::Scene3d	`YXRatio: 1` `ZXRatio: 2/3`

Description

With `Scaling = Constrained`, the graphics output is scaled like the model coordinates, i.e., circle appear as circles, spheres as spheres.

With `Scaling = Unconstrained`, the graphics output is scaled independently in each coordinate direction such that the graphics fits optimally into the viewing area. Circles may appear as ellipses, spheres as ellipsoids.

For `Scaling = Unconstrained`, the scaling ratios of the different coordinate directions in a 3D plot can be set via the attributes `YXRatio` and `ZXRatio`.

If the graphics consists of geometrical objects such as circles, pie charts, spheres etc., the setting `Scaling = Constrained` is appropriate. This prevents circles from being deformed to ellipses in the graphical output.

For the visualization of non-geometrical data (usually, in function plots etc.), a scaling constrained to model coordinates is usually not appropriate. Think of the graph of $y = e^x$ for x in Interval([0,

10])$x \in [0, 10]$, where the *y* values extend over the range y in Interval([e^0, e^10])$y \in [e^0, e^{10}]$, which is roughly Interval([1, 22026])$[1, 22026]$. With `Scaling = Constrained`, the graphical output would consist of a narrow vertical strip with the side ratio `y : x = 22025 : 10`. Here, `Scaling = Unconstrained` is appropriate.

The default value is `Scaling = Unconstrained`. However, many "geometrical" objects in the MuPAD `plot` library override this default setting via the "hint mechanism" (see section Primitives Requesting Special Scene Attributes: "Hints" in this document). Whenever such an object is plotted in a scene, the whole scene uses `Scaling = Constrained`. A complete list of these "geometrical objects" such as circles, spheres, cones etc. is given further up on this help page.

With `Scaling = Automatic`, the graphics uses `Scaling = Constrained` for plots in which the coordinate ranges to be displayed have a ratio close to `1 : 1` in 2D or `1 : 1 : 1` in 3D. Otherwise, `Scaling = Unconstrained` is used.

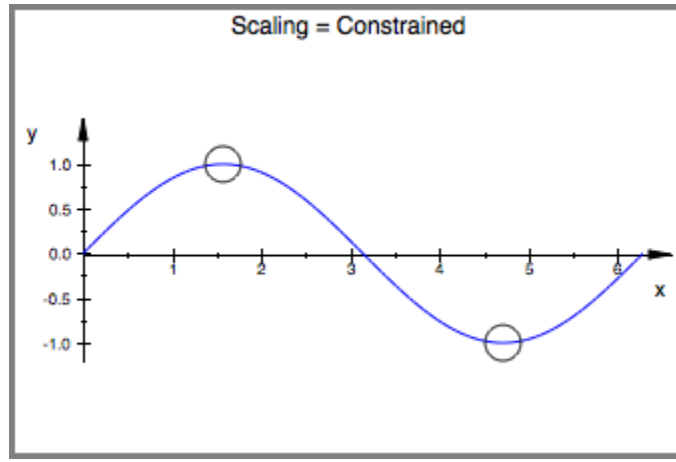
The attributes `YXRatio =` r_1 and `ZXRatio =` r_2 only have an effect in 3D with `Scaling = Unconstrained`. The graphical scene is scaled to a box with side ratios `z : y : x =` r_2`:` r_1`: 1`. On the screen, the bounding box of the scene looks like a box with these side ratios.

Examples

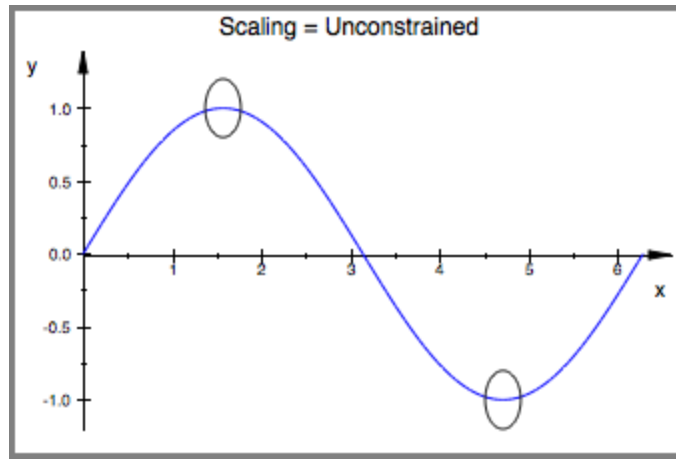
Example 1

We plot a scene containing a function graph and some circles highlighting the extrema. Because the circle sends the "hint"`Scaling = Constrained`, this scaling is used for the whole scene. Consequently, the circles appear as circles:

```
plot(plot::Function2d(sin(x), x = 0 .. 2*PI), plot::Circle2d(0.2, [PI/2, 1], Color = RGB::Black), plot::Circle2d(0.2, [3*PI/2, -1], Color = RGB::Black), BorderWidth = 1.0*unit::mm, Header = "Scaling = Constrained")
```

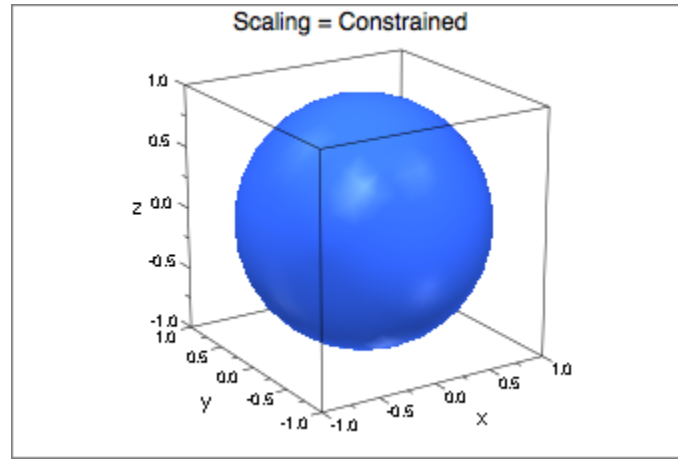


With `Scaling = UnConstrained`, we get a better fit of the plot in the canvas. However, the circles are deformed to ellipses:
plot(plot::Function2d(sin(x), x = 0 .. 2*PI), plot::Circle2d(0.2, [PI/2, 1], Color = RGB::Black), plot::Circle2d(0.2, [3*PI/2, -1], Color = RGB::Black), Scaling = Unconstrained, BorderWidth = 1.0*unit::mm, Header = "Scaling = Unconstrained")

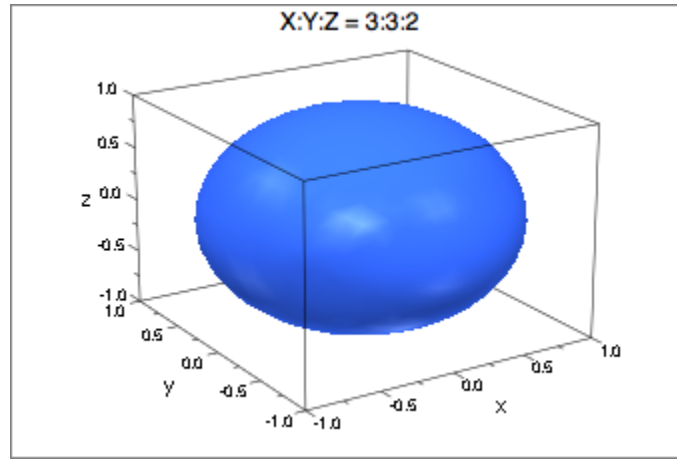


Example 2

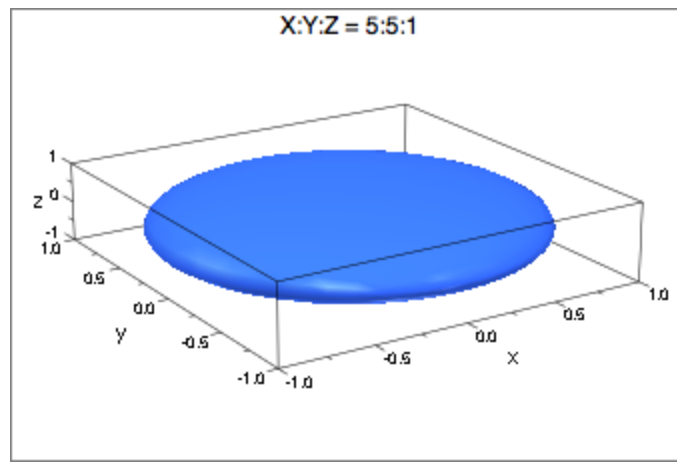
A sphere of type plot::Sphere sends the "hint" `Scaling = Constrained`. With this scaling, `YXRatio`, `ZXRatio` have no effect:
s := plot::Sphere(1, [0, 0, 0]): plot(s, BorderWidth = 0.5*unit::mm, Header = "Scaling = Constrained", YXRatio = 3, ZXRatio = 10)



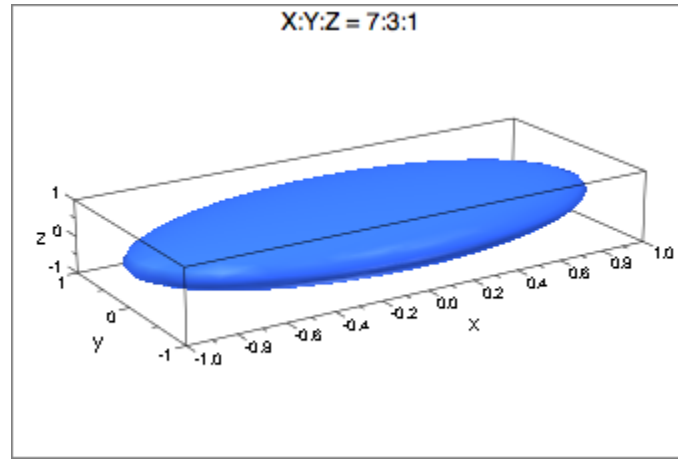
We use `Scaling = Unconstrained`. With the default values `YXRatio = 1`, `ZXRatio = 2/3`, the objects in a 3D scene are displayed like a box with side ratios `X : Y : Z = 3 : 3 : 2`:
plot(s, BorderWidth = 0.5*unit::mm, Scaling = Unconstrained, Header = "X:Y:Z = 3:3:2")



We request different scaling ratios:
plot(s, BorderWidth = 0.5*unit::mm, Header = "X:Y:Z = 5:5:1", Scaling = Unconstrained, YXRatio = 1, ZXRatio = 1/5, BorderWidth = 0.5*unit::mm)



plot(s, BorderWidth = 0.5*unit::mm, Header = "X:Y:Z = 7:3:1", Scaling = Unconstrained, YXRatio = 3/7, ZXRatio = 1/7, BorderWidth = 0.5*unit::mm)



delete s:

Purpose

VerticalAsymptotesVisibleVerticalAsymptotesStyleVerticalAsymptotesColorVerticalAs
Vertical asymptotes indicating poles

Value Summary

`VerticalAsymptotesVisible`	Inherited	FALSE, or TRUE
`VerticalAsymptotesStyle`	Inherited	`Dashed`, `Dotted`, or `Solid`
`VerticalAsymptotesColor`	Inherited	Color
`VerticalAsymptotesWidth`		

Graphics Primitives

Objects	Default Values

plot::Function2d	`VerticalAsymptotesVisible`: `TRUE`
	`VerticalAsymptotesStyle`: `Dashed`
	`VerticalAsymptotesColor`: RGB::Grey50
	`VerticalAsymptotesWidth`: `0.2`

Description

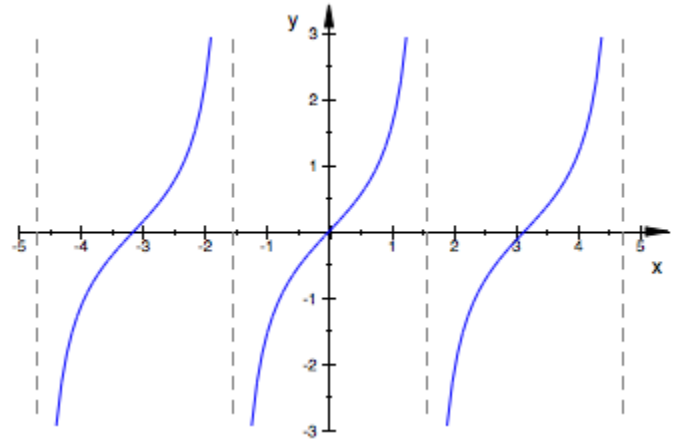
These options control the appearance of vertical asymptotes in 2D function plots.

plot::Function2d and plotfunc2d are able to indicate poles by drawing vertical asymptotes. These asymptotes can be switched off with `VerticalAsymptotesVisible = FALSE`. Other than that, the attributes `VerticalAsymptotesStyle`, `VerticalAsymptotesColor`, and `VerticalAsymptotesWidth` influence their appearance, in the same way LineStyle, LineColor, and LineWidth do for other lines.

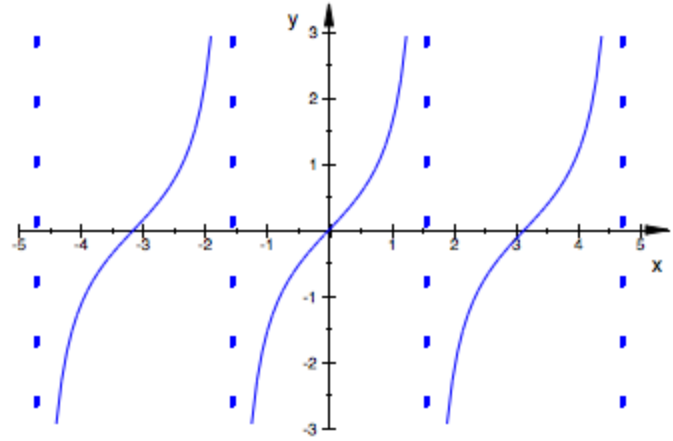
Examples

Example 1

By default, vertical asymptotes are drawn as dashed, gray lines:
plotfunc2d(tan(x))

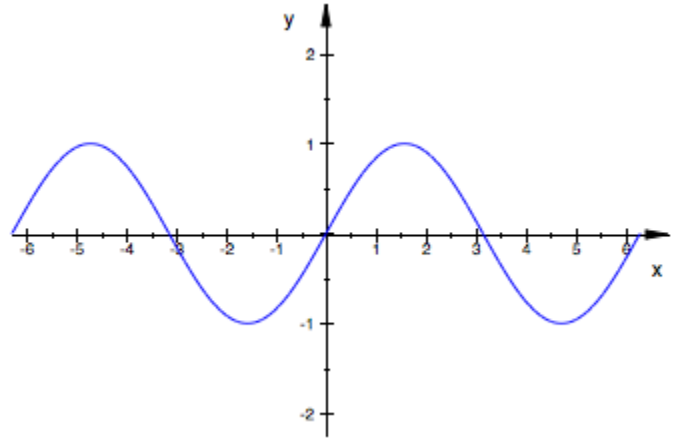


The attributes mentioned above can be used to change these settings: plotfunc2d(tan(x), VerticalAsymptotesColor = RGB::Blue, VerticalAsymptotesWidth = 1.0*unit::mm, VerticalAsymptotesStyle = Dotted)



Example 2

Note that vertical asymptotes obey the setting of Visible of their function object: No asymptotes are drawn for an invisible object.
t := plot::Function2d(tan(x), x = -2*PI..2*PI, Visible = FALSE): s := plot::Function2d(sin(x), x = -2*PI..2*PI): plot(s, t)



To have `t` show its asymptotes, we must set `Visible` to `TRUE`. If we only want to see the asymptotes, we can set LinesVisible to `FALSE`:
t::Visible := TRUE: t::LinesVisible := FALSE: plot(s, t)

Description

`LineColor` sets the color of line objects such as 2D function graphs, curves in 2D and 3D, parameter lines on surfaces etc.

`LineColor2` is a secondary color used for color blends.

`LineColor` determines the RGB color of line objects. The RGB library provides many pre-defined colors such as `RGB::Red` etc. See the section Colors of this document for more information on colors.

For pure line objects such as lines, curves, arrows, 2D function graphs etc., the line color can also be set by the attribute Color.

For surface objects such as 3D function graphs, surfaces etc., however, the attribute Color sets the FillColor. If you wish to change the color of the parameter lines on a surface, you have to use `LineColor`.

The RGB color set by `LineColor` cannot be animated. However, setting `LineColorType = Functional`, you can define a LineColorFunction that overrides the color set by `LineColor`. The line color function accepts an animation parameter, thus allowing to implement animated coloring of lines. See the help page of LineColorFunction for further details.

When the attribute LineColorType is set to one of the values `Dichromatic` or `Rainbow`, many line objects react to a secondary color set by the attribute `LineColor2`.

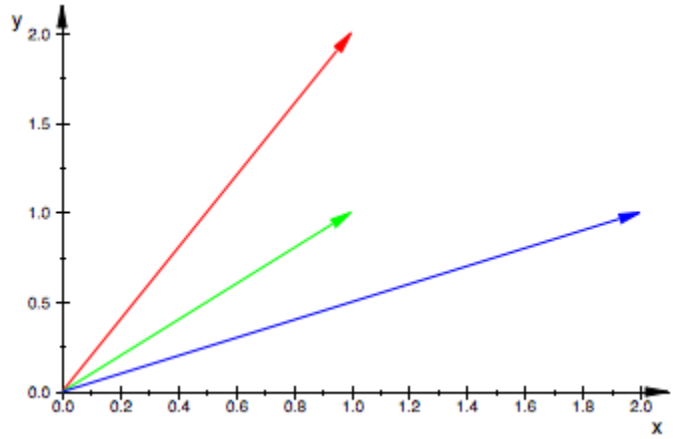
A gradient between the colors defined by `LineColor` and `LineColor2` is created.

The color of the coordinate axes is set by the attribute AxesLineColor.

Examples

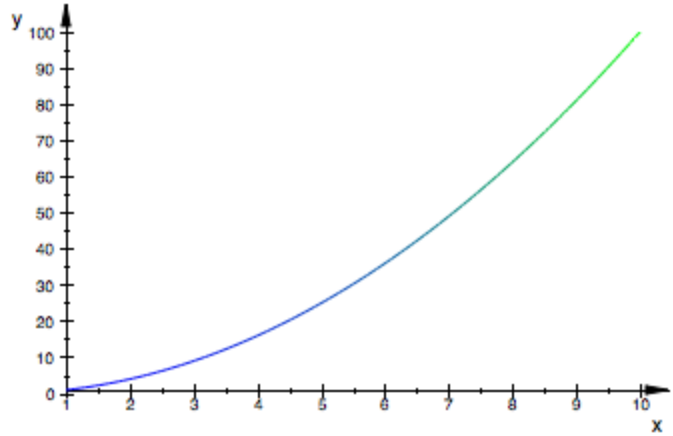
Example 1

We draw arrows of different colors:
plot(plot::Arrow2d([0, 0], [1, 2], LineColor = RGB::Red), plot::Arrow2d([0, 0], [1, 1], LineColor = RGB::Green), plot::Arrow2d([0, 0], [2, 1], LineColor = RGB::Blue)):



Example 2

We draw a parabola with a gradient between green and blue:
plot(plot::Function2d(x^2, x = 1..10, LineColorType = Dichromatic, LineColor = RGB::Green, LineColor2 = RGB::Blue)):



Example 3

As with any attribute, the line color can be read and changed using the ::-notation:
p := plot::Line2d([1, 2], [4, 5]): p::LineColor := RGB::Blue[0.0, 0.0, 1.0]

[0.0, 0.0, 1.0]
p::LineColor[0.0, 0.0, 1.0]

[0.0, 0.0, 1.0]
delete p:

Example 4

For surface objects such as 3D function graphs, `LineColor` sets the color of the parameter lines on the surface. Here, a semi-transparent RGBa color is chosen that gives only a faint indication of these lines:
plot(plot::Function3d(x^2 + y^2, x = -1..1, y = -1 ..1, LineColor = RGB::Green.[0.25])):

	`LineColorDirectionY`, `LineColorDirectionZ`: `1`

Description

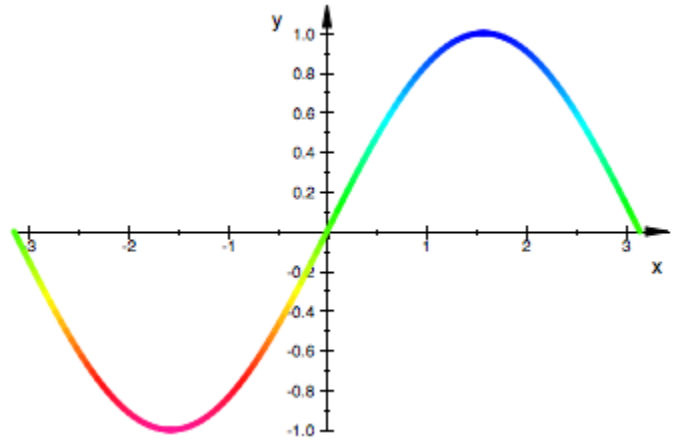
`LineColorDirection` determines the direction in which the color transitions for `LineColorType = Dichromatic` etc. take place.

When setting LineColorType to some other value than `Flat` or `Functional`, MuPAD produces a “height-coloring.” By default, this color method actually uses the height of a point. Using `LineColorDirection`, the axis along which the color method should be applied can be changed.

Examples

Example 1

By default, MuPAD uses height coloring along the *y* axis for 2D objects: f := plot::Function2d(sin(x), x=-PI..PI, LineWidth = 1, LineColorType = Rainbow): plot(f)



By changing `LineColorDirection`, this direction can be set to any angle. Note that `LineColorDirection` is an inherited attribute and may therefore be set at "top level" in the plot call:
plot(f, LineColorDirection = [1, 1])

Line coloring types

Value Summary

Inherited	`Dichromatic`, `Flat`, `Functional`, `Monochrome`, or `Rainbow`

Graphics Primitives

Objects	LineColorType Default Values
plot::Arc3d, plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylindrical, plot::Dodecahedron, plot::Ellipse3d, plot::Function2d, plot::Function3d, plot::Hexahedron, plot::Icosahedron, plot::Implicit2d, plot::Implicit3d, plot::Integral, plot::Listplot, plot::Matrixplot, plot::Octahedron, plot::Polar, plot::Polygon2d, plot::Polygon3d, plot::Prism, plot::Pyramid, plot::Rootlocus, plot::Sequence, plot::Spherical, plot::Streamlines2d, plot::Sum, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::VectorField2d, plot::VectorField3d, plot::Waterman, plot::XRotate, plot::ZRotate	`Flat`

Description

`LineColorType` controls the type of line coloring used. With the exception of `Flat` and `Functional`, the coloring schemes depend on the height, i.e., the *z* or *y* value (in 2D or 3D, respectively) of points on the line, relative to the extension of the viewing box.

By default, lines are drawn in the color set by the attribute LineColor. This is caused by the setting `LineColorType = Flat`. The other possible values for `LineColorType` mean:

- `Dichromatic`

  The color of a point on a line depends on its height, with the lowest point using `LineColor2`, the highest one using `LineColor`, and all other points using a linear interpolation in RGB color space.

- `Flat`

  The line is drawn with `LineColor`. No blend is used.

- `Monochrome`

  The line is drawn with a blend from `LineColor` to a dimmed version of `LineColor`.

- `Rainbow`

  This setting is technically similar to `Dichromatic`, but the effect is vastly different, since interpolation takes place in HSV color space. This creates a “rainbow effect”, which mostly conforms with a physical rainbow for suitable choices of colors.

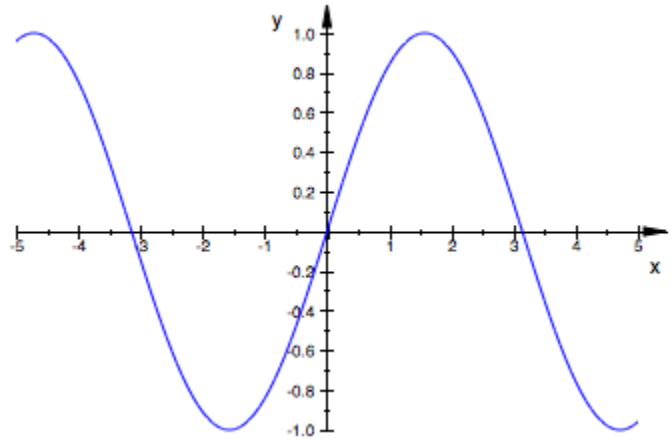
- `Functional`

  Both `LineColor` and `LineColor2` are ignored; the color scheme is derived from `LineColorFunction`. See `?`LineColorFunction for details (which depend on the object type). If no color function is given, the object will be rendered with `LineColorType = Flat`.

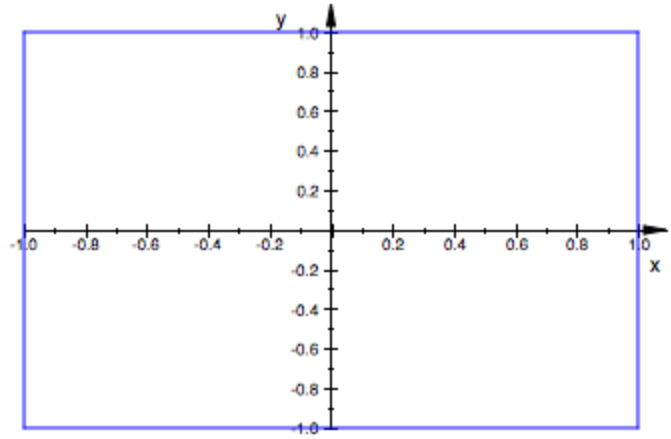
Examples

Example 1

By default, lines are drawn in one flat color:
plotfunc2d(sin(x))

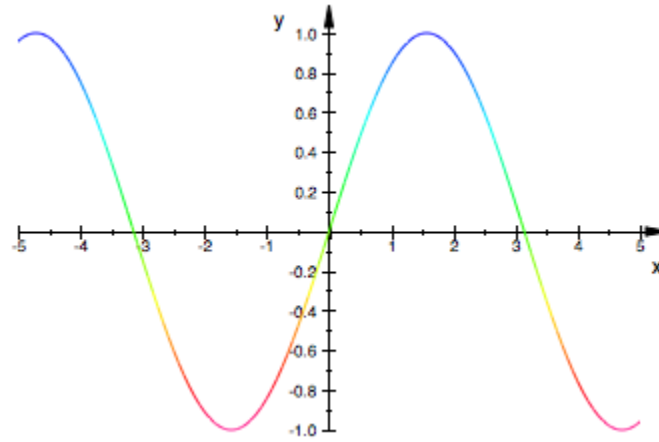


plot(plot::Polygon2d([[-1,-1], [1,-1], [1,1], [-1,1]], Closed = TRUE, Filled = FALSE))



Example 2

Using `LineColorType = Dichromatic`, `Monochrome`, or `Rainbow` causes a height-dependent color effect:
plotfunc2d(sin(x), LineColorType = Rainbow)



Note that height coloring depends on the height of the whole scene, not only on that of individual objects:
plot(plot::Function2d(sin(x) + 0.2, LineColorType = Dichromatic), plot::Function2d(sin(x) + 0.0, LineColorType = Monochrome), plot::Function2d(sin(x) - 0.2, LineColorType = Rainbow), LineColor = RGB::Red, LineColor2 = RGB::Blue)

Description

`LineStyle` sets the style of line objects such as 2D function graphs, curves in 2D and 3D, arrows, parameter lines on surfaces etc.

The available line styles are `Solid`, `Dashed`, or `Dotted`.

This attribute may be useful to distinguish different curves.

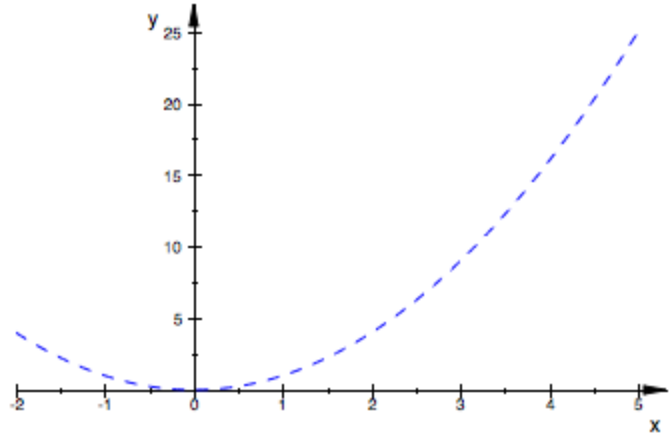
`LineStyle` does not have an effect on the line style of axes and coordinate grid lines. Axes are always displayed as solid lines. The style of the coordinate grid can be set by the attribute GridLineStyle.

Examples

Example 1

We draw a dashed parabola:

```
plot(plot::Function2d(x^2, x = -2..5, LineStyle = Dashed))
```



We draw a paraboloid with dashed coordinate lines:

```
plot(plot::Function3d(x^2 + y^2, x = -2..5, y = -2..5, Mesh = [8, 8],
Submesh = [3, 3], LineStyle = Dashed))
```

plot::Function3d	`LinesVisible`, `XLinesVisible`, `YLinesVisible`: `TRUE`
plot::Cylindrical, plot::Matrixplot, plot::Spherical, plot::Surface, plot::Sweep, plot::Tube, plot::XRotate, plot::ZRotate	`ULinesVisible`, `VLinesVisible`, `XLinesVisible`, `YLinesVisible`: `TRUE`

Description

`LinesVisible` = `TRUE` versus `LinesVisible` = `FALSE` governs the visibility of line objects.

`ULinesVisible`, `VLinesVisible` governs the visibility of coordinate lines on parametrized surfaces in 3D.

`XLinesVisible`, `YLinesVisible` governs the visibility of coordinate lines on 3D function graphs and matrix plots.

For most object types, `LinesVisible` determines whether lines are drawn. This includes the lines making up 2D function plots, curves, polygons, etc. as well as the circumference of (filled) circles, the edges of 2D rectangles and 3D boxes etc.

The exception are surface objects that exhibit parameter lines in two directions, such as 3D function plots, parameterized surfaces, tube plots etc. Depending on whether they react to XMesh, YMesh or to UMesh, VMesh, the parameter lines on the surfaces can be made visible or invisible with the attributes `XLinesVisible`, `YLinesVisible` or `ULinesVisible`, `VLinesVisible`, respectively.

Note that setting `LinesVisible` = `FALSE` for a 2D function plot without setting PointsVisible = `TRUE` will render the function invisible. (In

case of singular functions, the vertical asymptotes may remain visible, though).

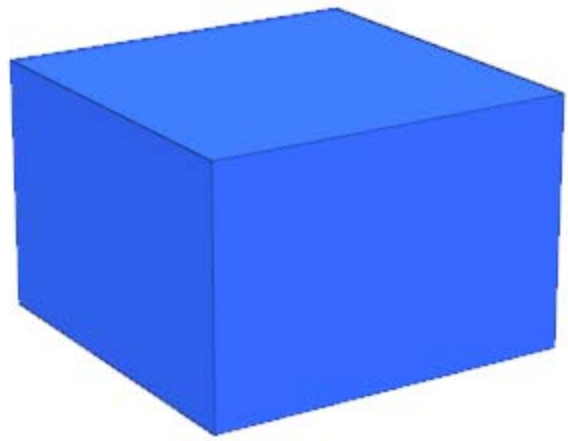
The same holds true for plots involving filled areas: switching off the lines and the filling makes such objects invisible.

`LinesVisible` etc. do not have an effect on coordinate axes and coordinate grid lines. Use the attributes AxesVisible and GridVisible to control the visibility of axes and coordinate grid.

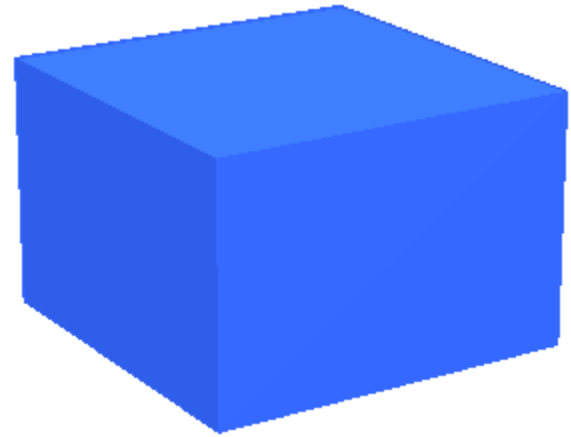
Examples

Example 1

By default, the lines of a box are visible:
plot(plot::Box(1..4, 2..5, 3..6), Axes = None)

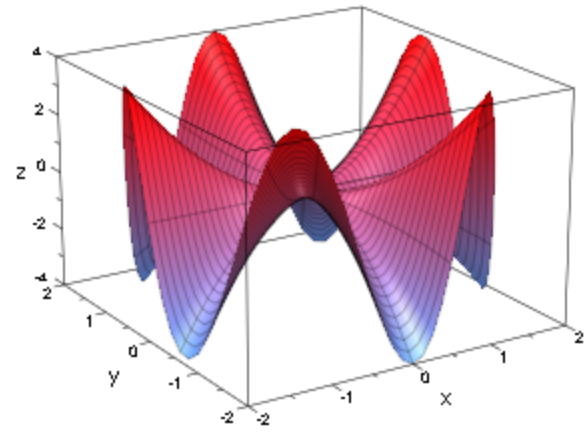


We set `LinesVisible` = `FALSE` to switch them off:
plot(plot::Box(1..4, 2..5, 3..6, LinesVisible = FALSE), Axes = None)



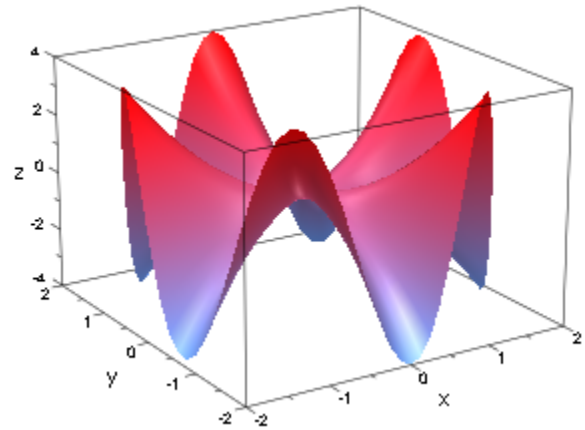
Example 2

By default, parameter lines are drawn on a parametrized surface:
plot(plot::Surface([u*cos(v), u*sin(v), u^2*sin(5*v)], u = 0..2, v = 0..2*PI, VSubmesh = 3)):

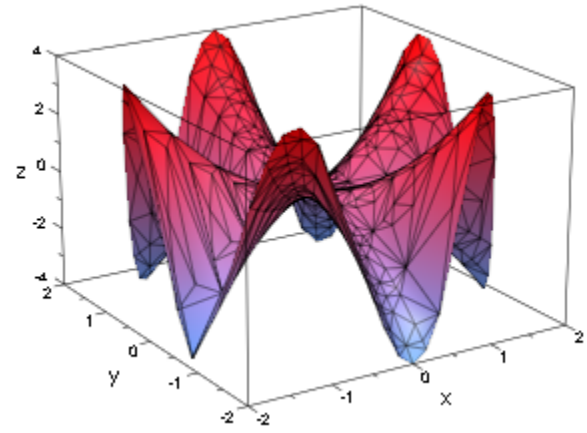


You can switch these lines off interactively, or, as we do here, by setting `ULinesVisible` and `VLinesVisible` to `FALSE` in the plot command:

plot(plot::Surface([u*cos(v), u*sin(v), u^2*sin(5*v)], u = 0..2, v = 0..2*PI, VSubmesh = 3, ULinesVisible = FALSE, VLinesVisible = FALSE)):

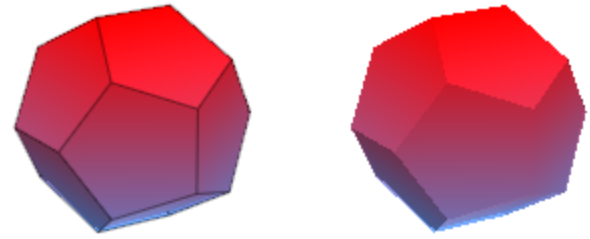


When the surface is created with an adaptive mesh, we can make the irregular adaptive mesh visible by setting MeshVisible = `TRUE`:
plot(plot::Surface([u*cos(v), u*sin(v), u^2*sin(5*v)], u = 0..2, v = 0..2*PI, UMesh = 5, VMesh = 10, ULinesVisible = FALSE, VLinesVisible = FALSE, AdaptiveMesh = 3, MeshVisible = TRUE)):



Example 3

We plot a dodecahedron with and without the border lines of its faces:
plot(plot::Scene3d(plot::Dodecahedron(LinesVisible = TRUE)),
plot::Scene3d(plot::Dodecahedron(LinesVisible = FALSE)), Layout =
Horizontal, Axes = None):



See Also AxesVisibleGridVisibleLineColorLineColorTypeLineStyleLineWidth

Purpose

LineWidth
Width of lines

Value Summary

Graphics Primitives

Objects	LineWidth Default Values
plot::Arc2d, plot::Arc3d, plot::Arrow2d, plot::Arrow3d, plot::Bars2d, plot::Bars3d, plot::Box, plot::Boxplot, plot::Circle2d, plot::Circle3d, plot::Cone, plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylinder, plot::Cylindrical, plot::Density, plot::Dodecahedron, plot::Ellipse2d, plot::Ellipse3d, plot::Function2d, plot::Function3d, plot::Hexahedron, plot::Histogram2d, plot::Icosahedron, plot::Implicit2d, plot::Implicit3d, plot::Inequality, plot::Integral, plot::Iteration, plot::Line2d, plot::Line3d, plot::Listplot, plot::Lsys, plot::Matrixplot, plot::Octahedron, plot::Ode2d, plot::Ode3d, plot::Parallelogram2d, plot::Parallelogram3d, plot::Piechart2d, plot::Piechart3d, plot::Polar,	`0.35`

Objects	LineWidth Default Values
plot::Polygon2d, plot::Polygon3d, plot::Prism, plot::Pyramid, plot::QQplot, plot::Raster, plot::Rectangle, plot::Rootlocus, plot::Scatterplot, plot::Sequence, plot::Spherical, plot::Sum, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::Turtle, plot::VectorField2d, plot::XRotate, plot::ZRotate	
plot::VectorField3d	`0.1`
plot::Waterman	`0.25`
plot::Streamlines2d	`0.35*unit::mm`

Description

`LineWidth` sets the width of line objects such as 2D function graphs, curves in 2D and 3D, arrows, parameter lines on surfaces etc.

The value should be specified as an absolute physical length including a length unit such as `LineWidth = 1.5*unit::mm`. Numbers without a physical unit give the size in mm.

Note that the graphics cannot always react to small changes of the line width because of the discretization into pixels.

One cannot make lines invisible by setting their width to 0. Use LinesVisible = `FALSE` instead.

`LineWidth` does not have an effect on the line width of axes and coordinate grid lines. Use the attributes AxesLineWidth and GridLineWidth to manipulate axes and coordinate grid, respectively.

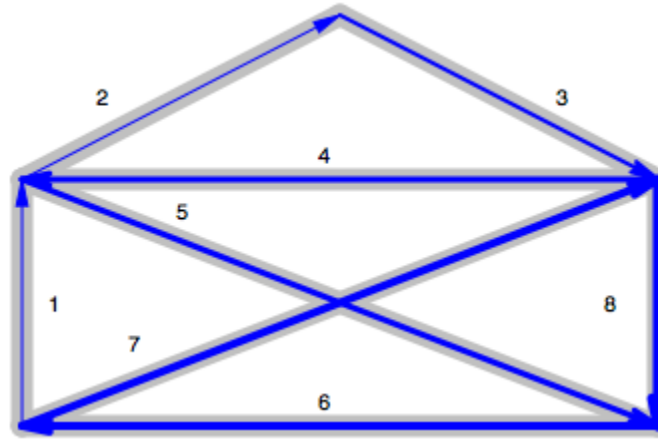
Examples

Example 1

We draw a house with thick walls:

plot(plot::Polygon2d([[0, 0], [0, 3], [2, 5], [4, 3], [0, 3], [4, 0], [0, 0], [4, 3], [4, 0]], LineWidth = 4*unit::mm, Color = RGB::Grey), Axes = None):

The building instructions are added by arrows. The drawing order is indicated by the titles of the arrows and their increasing line width: plot(plot::Polygon2d([[0, 0], [0, 3], [2, 5], [4, 3], [0, 3], [4, 0], [0, 0], [4, 3], [4, 0]], LineWidth = 4*unit::mm, Color = RGB::Grey), plot::Arrow2d([0, 0], [0, 3], LineWidth = 0.3*unit::mm, Title = "1", TitlePosition = [0.2, 1.4]), plot::Arrow2d([0, 3], [2, 5], LineWidth = 0.5*unit::mm, Title = "2", TitlePosition = [0.5, 3.9]), plot::Arrow2d([2, 5], [4, 3], LineWidth = 0.7*unit::mm, Title = "3", TitlePosition = [3.4, 3.9]), plot::Arrow2d([4, 3], [0, 3], LineWidth = 0.9*unit::mm, Title = "4", TitlePosition = [1.9, 3.2]), plot::Arrow2d([0, 3], [4, 0], LineWidth = 1.1*unit::mm, Title = "5", TitlePosition = [1.0, 2.5]), plot::Arrow2d([4, 0], [0, 0], LineWidth = 1.3*unit::mm, Title = "6", TitlePosition = [1.9, 0.2]), plot::Arrow2d([0, 0], [4, 3], LineWidth = 1.5*unit::mm, Title = "7", TitlePosition = [0.7, 0.9]), plot::Arrow2d([4, 3], [4, 0], LineWidth = 1.7*unit::mm, Title = "8", TitlePosition = [3.7, 1.4]), Axes = None, TipLength = 5*unit::mm):



See Also AxesLineWidthGridLineWidthLineColorLineColorTypeLineStyleLinesVisible

MeshVisible

Purpose

Visibility of irregular mesh lines in 3D

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	MeshVisible Default Values
plot::Cylindrical, plot::Function3d, plot::Implicit3d, plot::Spherical, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::XRotate, plot::ZRotate	`FALSE`

Description

`MeshVisible` = `TRUE` versus `MeshVisible` = `FALSE` controls the visibility of the irregular mesh defining surfaces that are either computed by an adaptive algorithm or are given explicitly by a triangulation.

3D function plots and parametrized surfaces are usually defined over a regular mesh. When setting AdaptiveMesh = `n` with `n > 0`, an irregular adaptive mesh is created that refines the graphical object automatically in critical regions.

While visibility of the regular mesh is controlled by the attributes XLinesVisible, YLinesVisible or ULinesVisible, VLinesVisible, respectively, the visibility of the adaptively refined mesh is set `MeshVisible`.

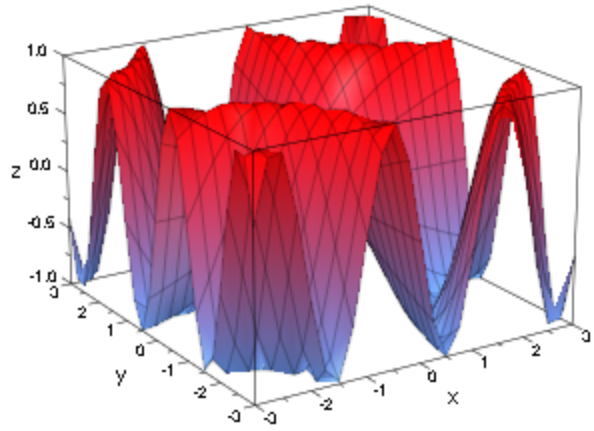
Also special surfaces created from a given triangulation such as plot::SurfaceSet and plot::SurfaceSTL allow to make the triangulation visible by setting `MeshVisible` = `TRUE`.

The irregular mesh lines switched on by `MeshVisible` = `TRUE` react to the attributes LineColor, LineStyle, and LineWidth.

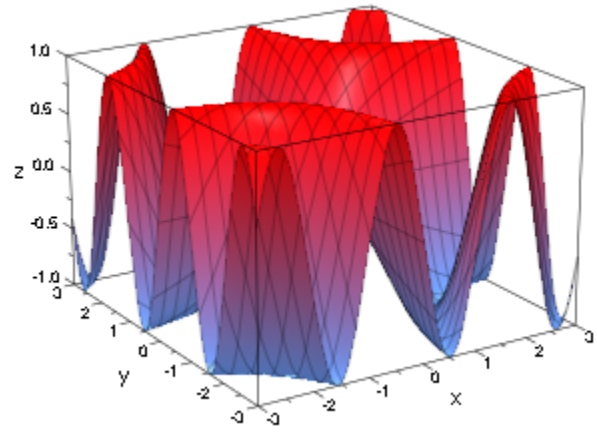
Examples

Example 1

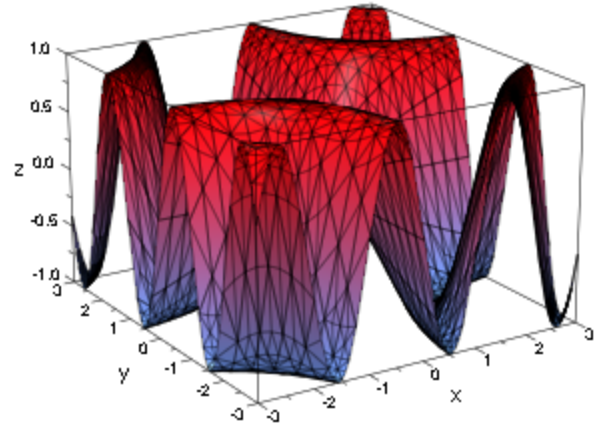
We create a 3D function plot:
plot(plot::Function3d(sin(x*y), x = -3..3, y = -3..3))



By default, only the regular mesh is visible, even if adaptive evaluation is used:
plot(plot::Function3d(sin(x*y), x = -3..3, y = -3..3, AdaptiveMesh = 2))

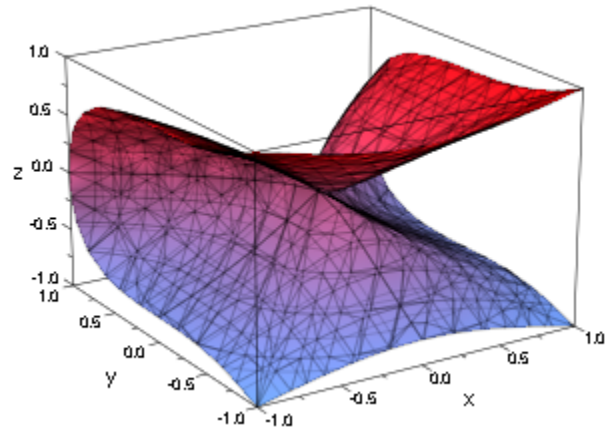


The irregular mesh is made visible when using `MeshVisible = TRUE`: plot(plot::Function3d(sin(x*y), x = -3..3, y = -3..3, AdaptiveMesh = 2, MeshVisible = TRUE))

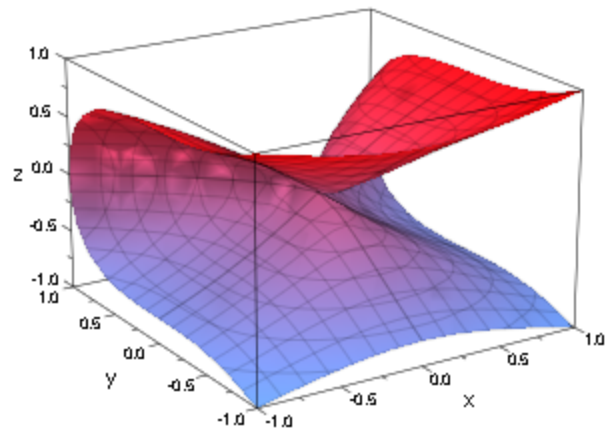


A 3D plot of an implicit surface does not have regular mesh lines. We plot such a surface with and without the irregular mesh:

plot(plot::Implicit3d(z^4 + z^2 - x^2 + y^3, x = -1..1, y = -1..1, z = -1..1, MeshVisible = TRUE))



plot(plot::Implicit3d(z^4 + z^2 - x^2 + y^3, x = -1..1, y = -1..1, z = -1..1, MeshVisible = FALSE))



See Also AdaptiveMeshLineColorLineStyleLineWidth

XContoursYContoursZContours

Purpose

Contour lines at constant x values

Value Summary

`XContours`, `YContours`, `ZContours`	Optional	List of arithmetical expressions

Graphics Primitives

Objects	Default Values
plot::Implicit3d	`XContours`, `YContours`, `ZContours`: [`Automatic`, 15]
plot::Cylindrical, plot::Function3d, plot::Spherical, plot::Surface, plot::XRotate, plot::ZRotate	`XContours`, `YContours`, `ZContours`: []

Description

`XContours`, `YContours`, and `ZContours` cause contour lines on surface objects at constant *x*, *y*, or *z*-values, respectively.

By setting these attributes, many surface objects (such as implicit surfaces, function objects etc.) can be instructed to display contour lines.

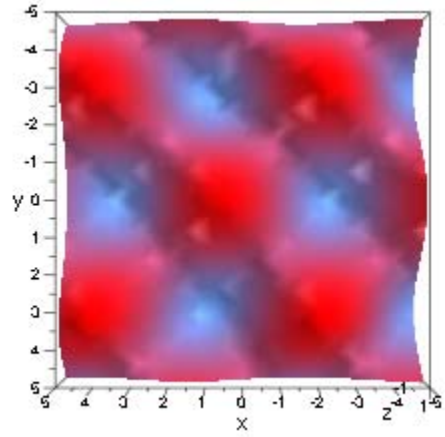
By setting `ZContours = [`z_1`, `z_2`, ]`, contour lines can be requested at specific places. This is demonstrated in “Example 1” on page 24-1699.

`ZContours = [Automatic, n]` causes *n* contour lines to be evenly spaced along the range of *z* values of the object. Cf. “Example 2” on page 24-1701.

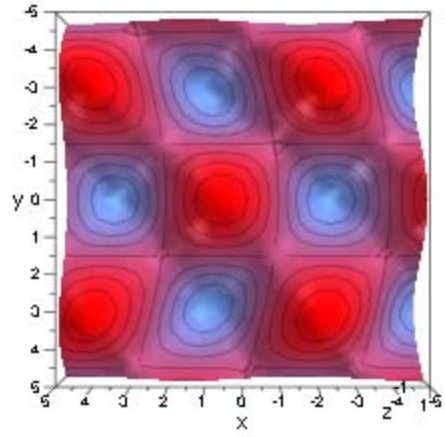
Examples

Example 1

A function plot by default uses height coloring and mesh lines to improve the visual display. With mesh lines disabled, height coloring is often still sufficient:
plotfunc3d(sin(x+cos(0.3*y))*cos(y), XLinesVisible=FALSE, YLinesVisible=FALSE, CameraDirection=[0,0.01,1])



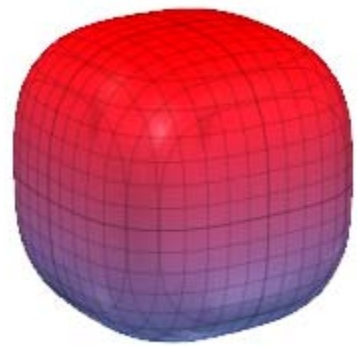
To get a better depth impression, it would help in this example to add contour lines:
plotfunc3d(sin(x+cos(0.3*y))*cos(y), ZContours=[$ -1..1 step 0.25], XLinesVisible=FALSE, YLinesVisible=FALSE, CameraDirection=[0,0.01,1])



Example 2

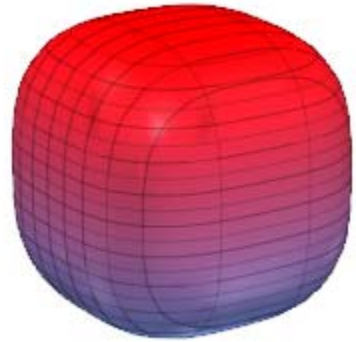
In the previous example, we set *z* values for the contour lines explicitly. There is an easier way of specifying equidistant lines, though, by giving the special value `Automatic`, followed by the number of lines to use. For example, implicit surfaces by default use 15 lines in each direction of space:

```
plot(plot::Implicit3d(abs(x)^3+abs(y)^3+abs(z)^3 - 1, x = -1..1, y=-1..1,
z=-1..1), Axes = None, Scaling = Constrained)
```



To change the number of lines, we use the syntax outlined above:

```
plot(plot::Implicit3d(abs(x)^3+abs(y)^3+abs(z)^3 - 1, x = -1..1, y=-1..1,
z=-1..1, XContours = [Automatic, 4], YContours = [Automatic, 11],
ZContours = [Automatic, 21]), Axes = None, Scaling = Constrained)
```

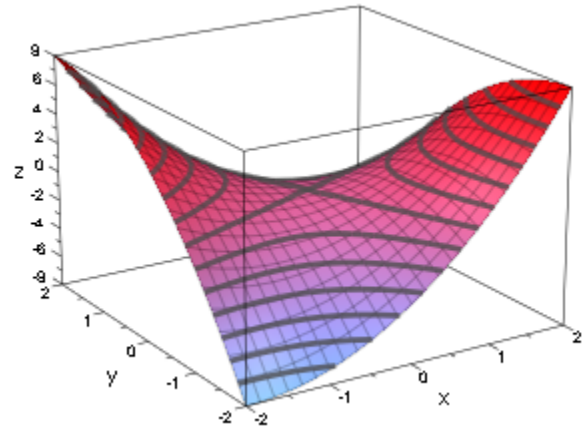


Note that two of the lines are at the extremal values and therefore usually not visible.

Example 3

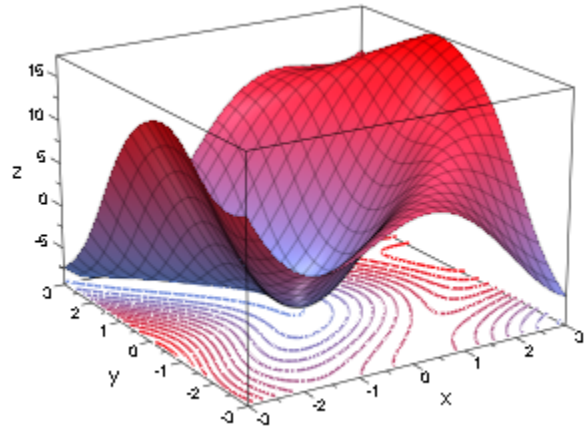
Contour lines are drawn using the same settings for LineWidth and LineColor as parameter lines are. In the following example, we use a modified copy of a function object that *only* displays contour lines, but with settings different from the function object proper.

```
f := plot::Function3d(x^2 - 2*x*y - y^2, x = -2..2, y = -2..2): plot(f,
plot::modify(f, ZContours = [Automatic, 15], LineWidth = 1, LineColor =
RGB::Gray30.[0.8], XLinesVisible = FALSE, YLinesVisible = FALSE,
Filled = FALSE))
```



By using a transformation that maps space into a plane, we can use this technique (by setting some more options) to display height-colored contour lines below a function plot:
f := plot::Function3d(8*sin(x-cos(y))+(x^2+x*y), x = -3..3, y = -3..3, Submesh=[2,2]): plot(f, plot::Transform3d([0, 0, -9], [1, 0, 0, 0, 1, 0, 0, 0, 0], plot::modify(f, ZContours = [Automatic, 15], LineWidth = 0.5, LineColorType = Dichromatic, LineColor = RGB::Red, LineColor2 = RGB::CornflowerBlue, XLinesVisible = FALSE, YLinesVisible = FALSE, Filled = FALSE)))

Ground



See Also LineColorLinesVisibleLineWidth

PointColor

Purpose

Color of points

Value Summary

Inherited	Color

Graphics Primitives

Objects	PointColor Default Values
plot::Matrixplot, plot::Point2d, plot::Point3d, plot::PointList2d, plot::PointList3d, plot::SparseMatrixplot, plot::Sum	RGB::MidnightBlue
plot::Listplot, plot::QQplot, plot::Scatterplot	RGB::Black

Description

`PointColor` determines the color of points. The RGB library provides many pre-defined colors such as `RGB::Red` etc. See section Colors of this document for more information on colors.

Many graphical objects such as curves, surfaces etc. are approximated by a numerical mesh. With PointsVisible = `TRUE`, the points of this mesh become visible. These points do *not* react to `PointColor`.

`PointColor` cannot be animated.

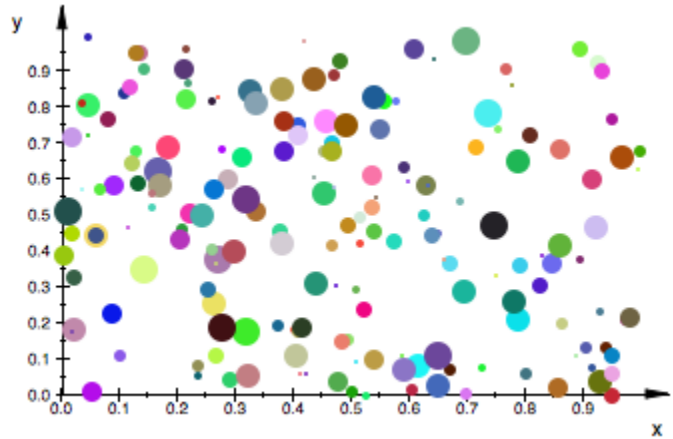
For points of type plot::Point2d and plot::Point3d, the point color can also be set by the attribute Color.

Examples

Example 1

We plot a cluster of random points with random sizes and random colors:

```
r := frandom: plot(plot::Point2d([r(),r()], PointSize = 5*r()*unit::mm,
PointColor = [r(), r(), r()]) $ i = 1 .. 200):
```



delete r:

Example 2

We can access the `PointColor` attribute from a point and change it:
p := plot::Point2d(1, 2): p::PointColor := RGB::Black: p::PointColor[0.0, 0.0, 0.0]

[0.0, 0.0, 0.0]

delete p:

PointColor2PointColorTypePointSizePointStylePointsVisible

PointColor2

Purpose

Secondary point color for color blends

Value Summary

Optional	Color

Graphics Primitives

Objects	PointColor2 Default Values
plot::SparseMatrixplot	RGB::Red

Description

`PointColor2` sets the secondary point color in objects of type plot::SparseMatrixplot.

Objects of type plot::SparseMatrixplot color their points according to the attribute PointColorType = `Flat` or PointColorType = `Dichromatic`, respectively.

With PointColorType = `Flat`, all points in a plot::SparseMatrixplot object are displayed in the color given by PointColor.

With PointColorType = `Dichromatic`, the points are colored differently using a color blend from the color PointColor to the color `PointColor2`. The actual color of a point indicates the size of the matrix entry visualized by plot::SparseMatrixplot.

PointColor corresponds to small matrix entries, `PointColor2` corresponds to large matrix entries.

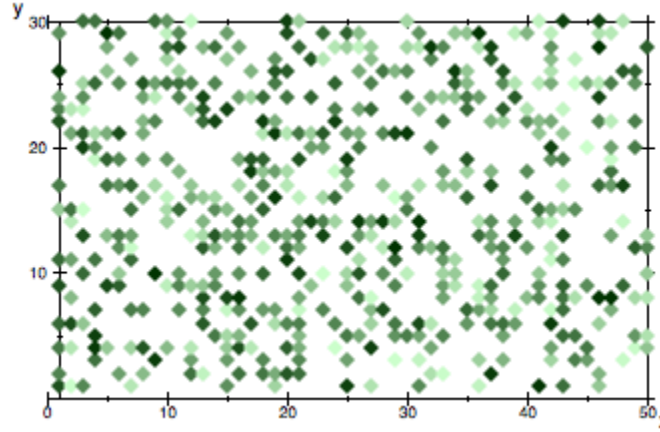
Examples

Example 1

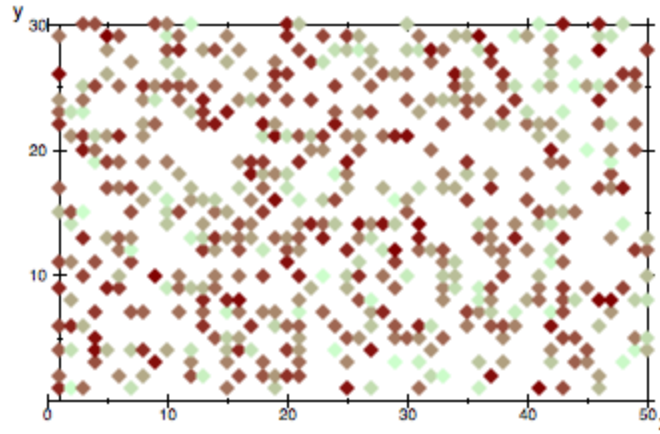
We create a 30 50 matrix with 500 random entries.
smp := plot::SparseMatrixplot(matrix::random(30, 50, 500, frandom)):

We use the color type `Dichromatic` and request a dark green for large matrix entries and a light green for small matrix entries:
smp::PointColorType := Dichromatic: smp::PointColor := RGB::LightGreen: smp::PointColor2 := RGB::DarkGreen:

smp::PointStyle := FilledDiamonds: smp::PointSize := 2.5*unit::mm:
plot(smp):



The secondary color is changed to a dark red:
smp::PointColor2 := RGB::DarkRed: plot(smp):



delete smp:

See Also PointColorPointColorTypePointSizePointStyle

Purpose

PointColorType

Point coloring types

Value Summary

Optional	`Dichromatic`, or `Flat`

Graphics Primitives

Objects	PointColorType Default Values
plot::SparseMatrixplot	`Flat`

Description

`PointColorType` controls the type of point coloring used in objects of type plot::SparseMatrixplot.

With `PointColorType` = `Flat`, all points in a plot::SparseMatrixplot object are displayed in the color given by PointColor.

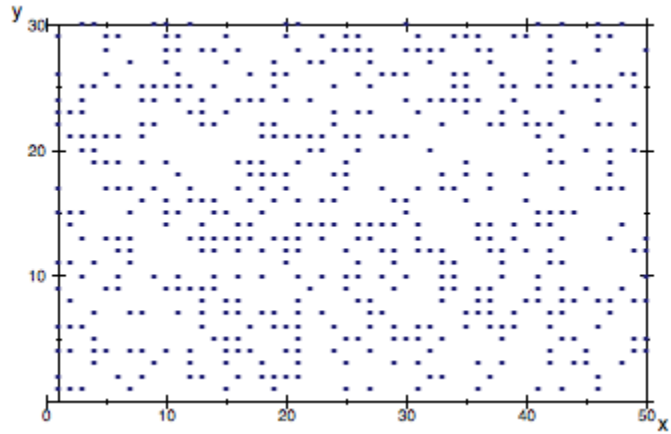
With `PointColorType` = `Dichromatic`, the points are colored differently using a color blend from the color PointColor to the color PointColor2. The actual color of a point indicates the size of the matrix entry visualized by plot::SparseMatrixplot.

Examples

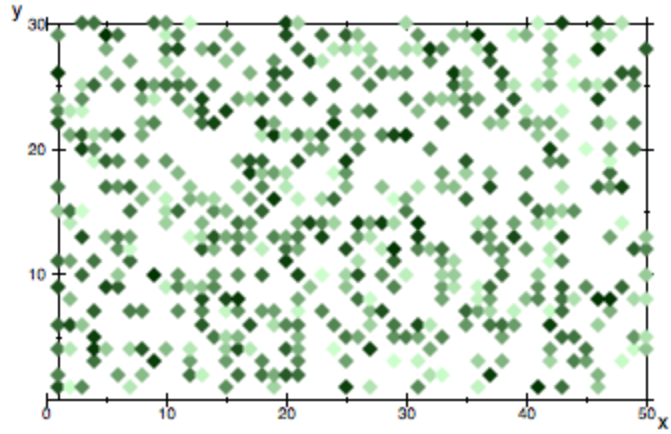
Example 1

We create a 30 50 matrix with 500 random entries. With the default setting of `PointColorType` = `Flat`, all nonzero entries are displayed in the color given by PointColor:

```
smp := plot::SparseMatrixplot( matrix::random(30, 50, 500, frandom)):
plot(smp):
```



We change the color type to `Dichromatic` and request a dark green for large matrix entries and a light green for small matrix entries:
smp::PointColorType := Dichromatic: smp::PointColor := RGB::LightGreen: smp::PointColor2 := RGB::DarkGreen: smp::PointStyle := FilledDiamonds: smp::PointSize := 2.5*unit::mm: plot(smp):



delete smp:

Description

Objects	PointSize Default Values
plot::Waterman, plot::XRotate, plot::ZRotate	
plot::Rootlocus, plot::SparseMatrixplot	1.0
plot::Sequence	2

`PointSize` determines the physical size of points. The value should be specified as an absolute physical length including a length unit such as `PointSize = 1.5*unit::mm`. Numbers without a physical unit give the size in mm.

Typical points have a size of only a few pixels on the screen. Hence, the renderers cannot always react to small changes of the `PointSize`, because the actual size of the graphical points can attain only discrete values.

Depending on your hardware, there is a maximal size of the graphical points that can be rendered in 3D. If the `PointSize` is too large, the 3D renderer uses the maximal size that is supported.

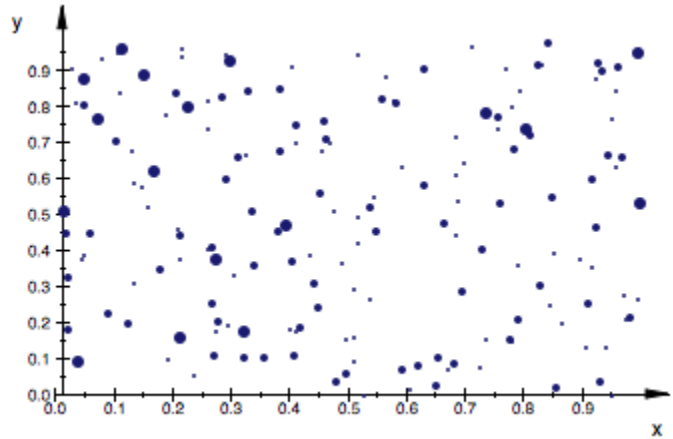
Many graphical objects such as curves, surfaces etc. are approximated by a numerical mesh. With PointsVisible = `TRUE`, the points of this mesh become visible. These points react to `PointSize`.

`PointSize` cannot be animated.

Examples

Example 1

We plot a cluster of points with random sizes within the unit square: r := frandom: plot(plot::Point2d(r(),r(), PointSize = 2*r()*unit::mm) $ i = 1 .. 200)

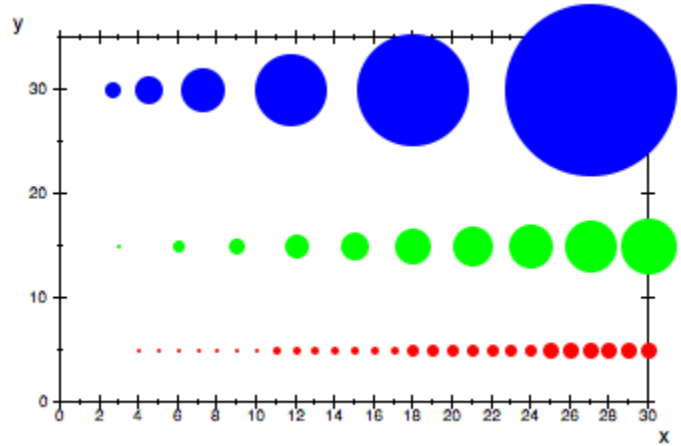


delete r:

Example 2

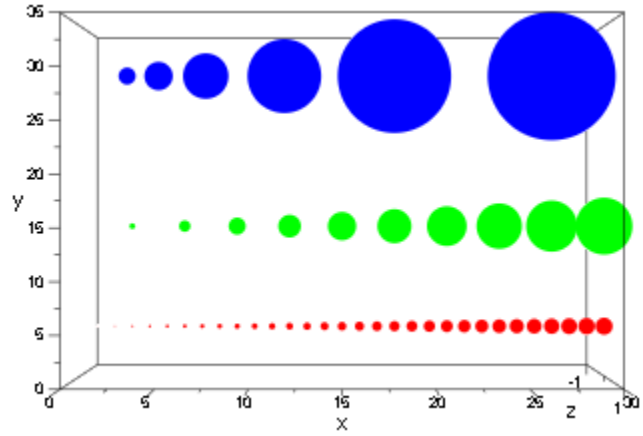
Due to pixelation, there is only a discrete number of `PointSize` values that the renderers can display faithfully. Further, note that the large points may protrude over the edges of the viewing box without being clipped:

```
plot(plot::Point2d([i, 5], PointSize = i*0.1*unit::mm, Color = RGB::Red) $ i = 1 .. 30, plot::Point2d([3*i, 15], PointSize = i*unit::mm, Color = RGB::Green) $ i = 1 .. 10, plot::Point2d([9*i , 30], PointSize = i*unit::cm, Color = RGB::Blue) $ i in [0.3, 0.5, 0.8, 1.3, 2, 3], ViewingBox = [0 .. 30, 0 .. 35], Axes = Boxed)
```



Here are the same points in 3D. Note the threshold for `PointSize` beyond which the graphical points do not grow:

```
plot(plot::Point3d([i, 5, 0], PointSize = i*0.1*unit::mm, Color =
RGB::Red) $ i = 1 .. 30, plot::Point3d([3*i, 15, 0], PointSize = i*unit::mm,
Color = RGB::Green) $ i = 1 .. 10, plot::Point3d([9*i , 30, 0], PointSize =
i*unit::cm, Color = RGB::Blue) $ i in [0.3, 0.5, 0.8, 1.3, 2, 3], ViewingBox
= [0 .. 30, 0 .. 35, -1 .. 1], Axes = Boxed, CameraDirection = [0, -10,
1000], YXRatio = 2/3)
```



Example 3

We can access the `PointSize` attribute from a point and change it:

```
p := plot::Point2d(1, 2): p::PointSize := 4*unit::inch:
p::PointSize(508/5)*unit::mm
```

508 mm
5

```
delete p:
```

Description

Objects	PointStyle Default Values
plot::Tetrahedron, plot::Turtle, plot::Waterman, plot::XRotate, plot::YRotate, plot::ZRotate	Diamonds

`PointStyle` determines the presentation style of points. The various styles are demonstrated in "Example 1" on page 24-1719.

In 3D, only two styles `FilledCircles` and `FilledSquares` are supported by the renderer.

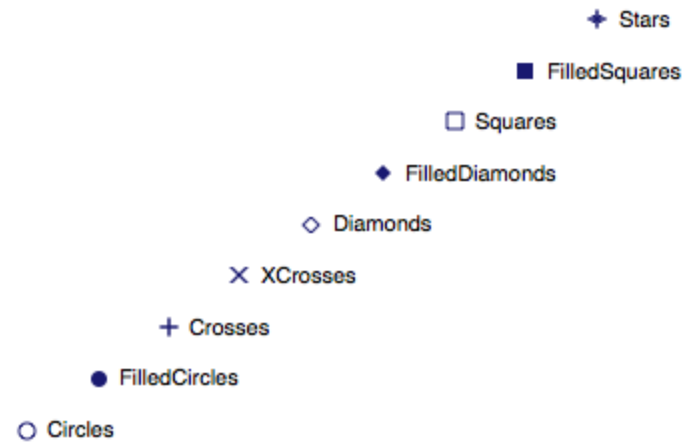
Many graphical objects such as curves, surfaces etc. are approximated by a numerical mesh. With PointsVisible = `TRUE`, the points of this mesh become visible. These points react to `PointStyle`.

`PointStyle` cannot be animated.

Examples

Example 1

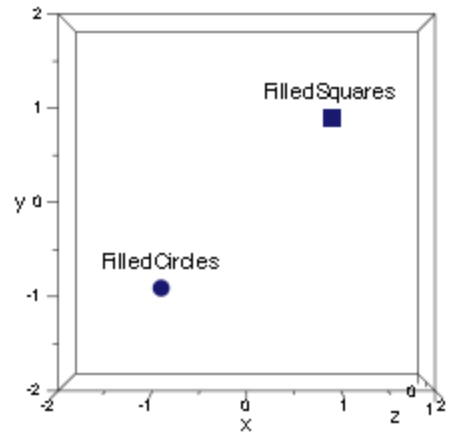
We plot 2D points in all available styles:
styles := [Circles, FilledCircles, Crosses, XCrosses, Diamonds, FilledDiamonds, Squares, FilledSquares, Stars]: points := null(): for i from 1 to nops(styles) do points := points, plot::Point2d([i, i], PointStyle = styles[i], Title = expr2text(styles[i]), TitlePosition = [i + 0.3, i - 0.15]): end_for: plot(points, PointSize = 3*unit::mm, Axes = None, TitleAlignment = Left):



delete styles, points, i:

Example 2

In 3D, the renderer only supports the point styles `FilledCircles` and `FilledSquares`:
plot(plot::Point3d([-1, -1, 0], PointStyle = FilledCircles, Title = "FilledCircles", TitlePosition = [-1, -0.8, 0]), plot::Point3d([1, 1, 0], PointStyle = FilledSquares, Title = "FilledSquares", TitlePosition = [1, 1.2, 0]), PointSize = 3*unit::mm, ViewingBox = [-2..2, -2..2, 0..1], CameraDirection = [0, -1, 1000]):



Example 3

We can access the `PointStyle` attribute from a point and change it:
p := plot::Point2d(1, 2): p::PointStyle := Diamonds:
p::PointStyleDiamonds

Diamonds
delete p:

See Also PointColorPointSizePointsVisible

PointsVisible

Purpose

Visibility of mesh points

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	PointsVisible Default Values
plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylindrical, plot::Dodecahedron, plot::Function2d, plot::Function3d, plot::Hexahedron, plot::Icosahedron, plot::Implicit3d, plot::Integral, plot::Octahedron, plot::Polar, plot::Polygon2d, plot::Polygon3d, plot::Prism, plot::Pyramid, plot::Rootlocus, plot::Spherical, plot::Sum, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::Turtle, plot::Waterman, plot::XRotate, plot::ZRotate	FALSE
plot::Listplot, plot::Matrixplot, plot::Ode2d, plot::Ode3d, plot::QQplot, plot::Scatterplot, plot::Sequence, plot::SparseMatrixplot, plot::VectorField3d	TRUE

Description

`PointsVisible = TRUE/FALSE` enables/disables the plotting of mesh and submesh points.

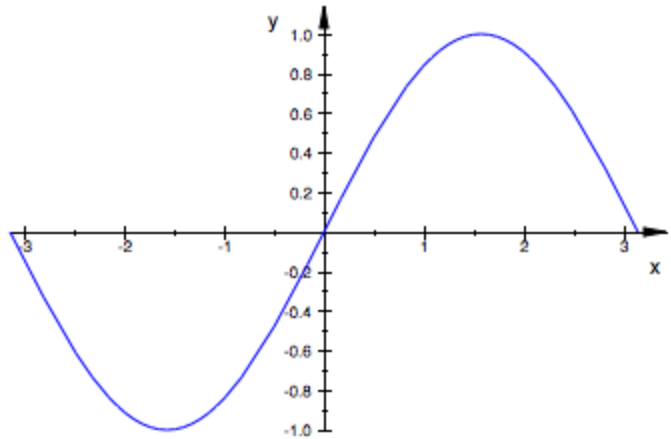
The mesh points react to the attributes PointSize and PointStyle. However, they do *not* react to the attribute PointColor. Typically, mesh points are painted in the same color used for the line objects defined by the mesh points.

`PointsVisible` cannot be animated.

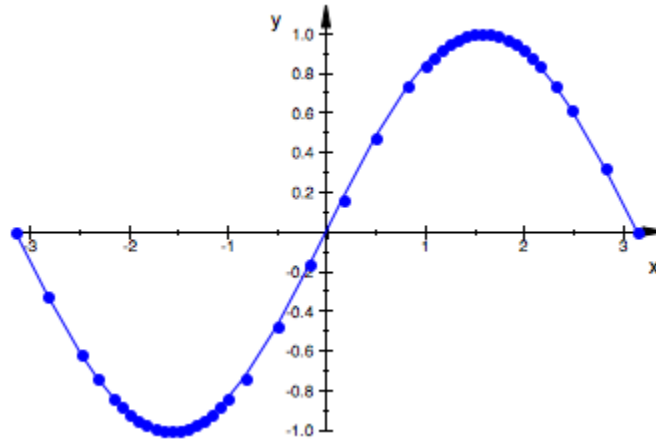
Examples

Example 1

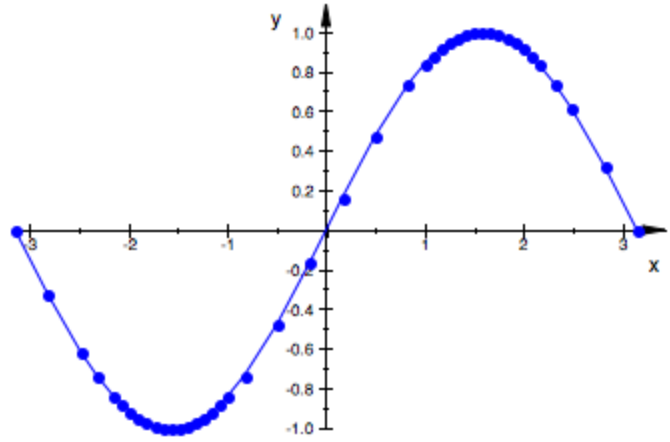
We plot the sine function on a rather coarse mesh using the `PointsVisible` default value `FALSE`:
f := plot::Function2d(sin(x), x = -PI .. PI, Mesh = 20): plot(f):



We use `PointsVisible` = `TRUE` to make the mesh points visible:
f::PointsVisible := TRUE: plot(f, PointSize = 2*unit::mm)



We enable adaptive plotting:
f::AdaptiveMesh := 2: plot(f, PointSize = 2*unit::mm)



delete f:

See Also PointSizePointStyle

Purpose

BarCentersBarWidths
Position of bars

Value Summary

`BarCenters`, `BarWidths`	Optional	List of arithmetical expressions

Graphics Primitives

Objects	Default Values
plot::Bars2d	`BarWidths`: [[`1.0`]]

Description

`BarCenters` and `BarWidths` govern horizontal center positions and widths of the bars in 2D bar plots of Type plot::Bars2d.

A plot of type plot::Bars2d serves for visualizing and comparing discrete data samples by a 2D bar plot.

The data values define the vertical coordinates of the bars. The position along the horizontal axis and the horizontal width of the bars are controlled by the attributes `BarCenters` and `BarWidths`.

The value of the attribute `BarCenters` may be a list [x_1, x_2, ...] of numerical values or expressions of the animation parameter. These values define the horizontal coordinates of the bar centers.

If several data samples are to be displayed simultaneously, the value of `BarCenters` may be a list of lists [[x_{11}, x_{12}, ...], [x_{21}, x_{22}, ...], ...], where x_{ij} is the center position of the bar indicating the j-th data point in the i-th sample.

If the length of a list in the `BarCenters` attribute is smaller than the number of data in the corresponding sample, the center values are chosen automatically for the surplus data items.

If the length of the `BarCenters` list is larger than the number of corresponding data items, the surplus center values are ignored.

Setting `BarCenters = [x1]`, the first bar is centered at $x = x_1$, while the standard distance between the bars is kept. Thus, `BarCenters = [x1]` allows to shift the entire bar plot along the horizontal axis.

The value of the attribute `BarWidths` may be a numerical value or an expression of the animation parameter. This sets the horizontal width of *all* bars.

Alternatively, it may be a list of values $[w_1, w_2, \ldots]$ allowing to define differents widths of the bars. If several data samples are specified, each data sample uses the same list of `BarWidths` values.

Alternatively, the value of `BarWidths` may be a list of lists $[[w_{11}, w_{12}, \ldots], [w_{21}, w_{22}, \ldots], \ldots]$, where w_{ij} is the horizontal width of the bar indicating the j-th data point in the i-th sample.

If the length of a list in the `BarWidths` attribute is smaller than the number of data in the corresponding sample, the width values are chosen automatically for the surplus data items.

If the length of the `BarWidths` list is larger than the number of corresponding data items, the surplus width values are ignored.

The `BarWidths` attribute only has an effect in conjunction with the (default) BarStyle = `Boxes`.

If the attribute DrawMode = `Horizontal` is set in the plot::Bars2d object, the bars are drawn from left to right instead from bottom to top.

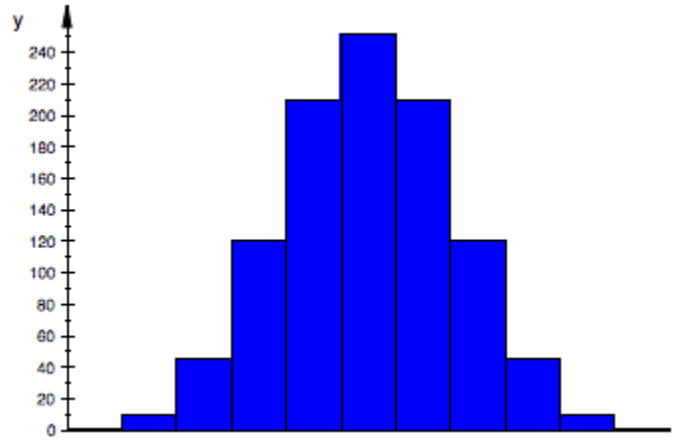
In this case, the attributes `BarCenters` and `BarWidths` refer to the vertical coordinates of the bars.

Examples

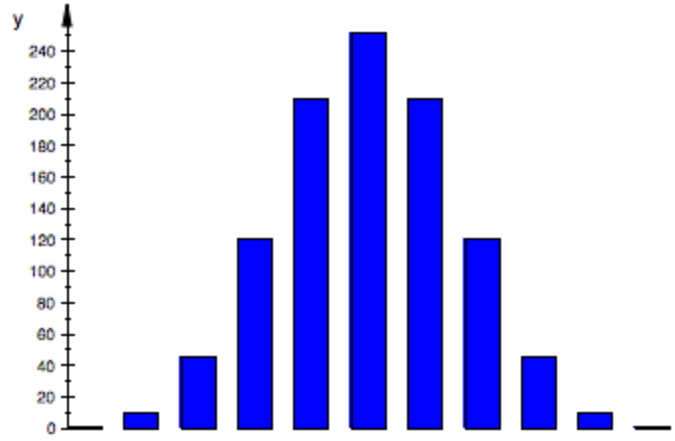
Example 1

We display some discrete values as a bar plot:

```
data := [binomial(10, j) $ j = 0..10]: plot(plot::Bars2d(data, BarCenters =
[j $ j = 0..10])):
```



We reduce the widths of the bars:
plot(plot::Bars2d(data, BarCenters = [j $ j = 0..10], BarWidths = 0.6)):



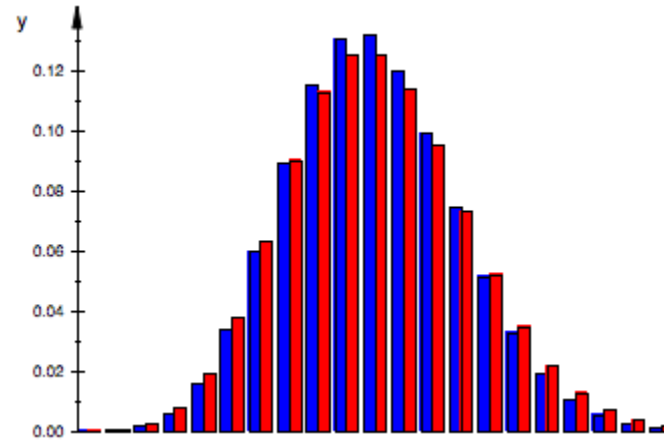
delete data:

Example 2

For large values of n and small values of p, the binomial distribution `stats::binomialPF(n, p)` is approximated by the Poisson distribution

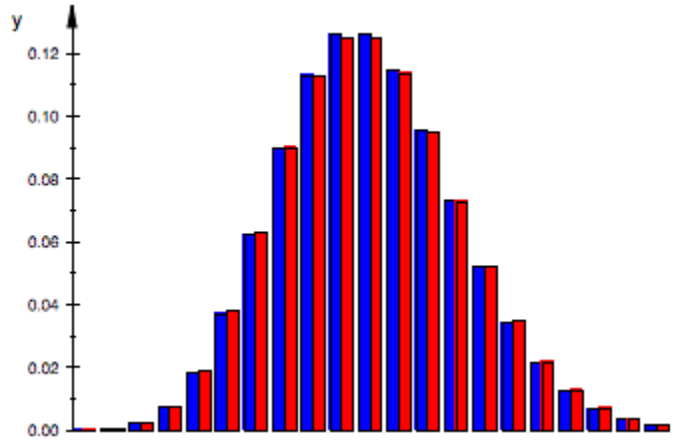
`stats::poissonPF(n*p)`. We demonstrate this fact by plotting the probability values of these distributions in one bar plot:

```
n := 100: p:= 0.1: data1 := [stats::binomialPF(n, p)(j) $ j = 0..20]: data2
:= [stats::poissonPF(n*p)(j) $ j = 0..20]: plot(plot::Bars2d([data1, data2],
BarCenters = [[j $ j = 0..20], [j + 0.4 $ j = 0..20]], BarWidths = 0.4)):
```



The approximation is better for larger values of n. We reduce p accordingly to have the same value of np as in the previous plot:

```
n := 500: p:= 0.02: data1 := [stats::binomialPF(n, p)(j) $ j = 0..20]: data2
:= [stats::poissonPF(n*p)(j) $ j = 0..20]: plot(plot::Bars2d([data1, data2],
BarCenters = [[j $ j = 0..20], [j + 0.4 $ j = 0..20]], BarWidths = 0.4)):
```



delete n, p, data1, data2:

See Also DrawModeBarStyle

BarStyleShadows

Purpose

Display style of bar plots

Value Summary

`BarStyle`	Optional	`Boxes`, `Lines`, `LinesPoints`, or `Points`
`Shadows`	Optional	`TRUE` or `FALSE`

Graphics Primitives

Objects	Default Values
plot::Bars3d	`BarStyle`: `Boxes`
plot::Bars2d	`BarStyle`: `Boxes` `Shadows`: `FALSE`

Description

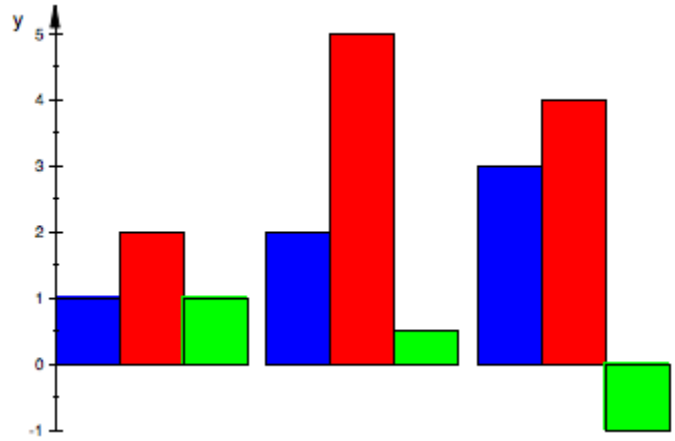
`BarStyle` selects between bars drawn as boxes, as lines, just points, or lines with points. For box diagrams, `Shadows` can be used to have simple “shadows” drawn.

Bar plots can use different types of bars. The options are shown in the examples.

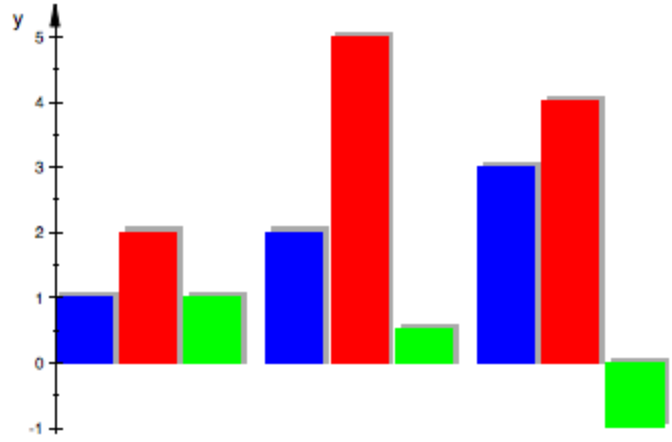
Examples

Example 1

With only few data, the option `Boxes` is often the most useful one:
plot(plot::Bars2d([[1,2,3],[2,5,4],[1,0.5,-1]], BarStyle = Boxes))

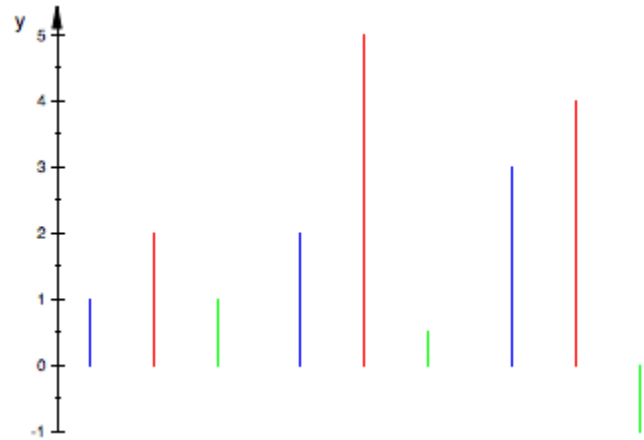


It can be combined with `Shadows = TRUE` and possibly `LinesVisible = FALSE` for a more pleasant display:
plot(plot::Bars2d([[1,2,3],[2,5,4],[1,0.5,-1]], BarStyle = Boxes, Shadows = TRUE, LinesVisible = FALSE))



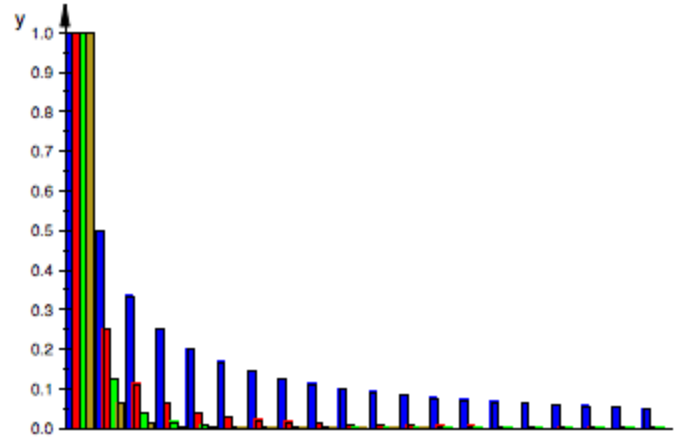
Shadows are not displayed for the other bar styles:

plot(plot::Bars2d([[1,2,3],[2,5,4],[1,0.5,-1]], BarStyle = Lines, Shadows = TRUE))

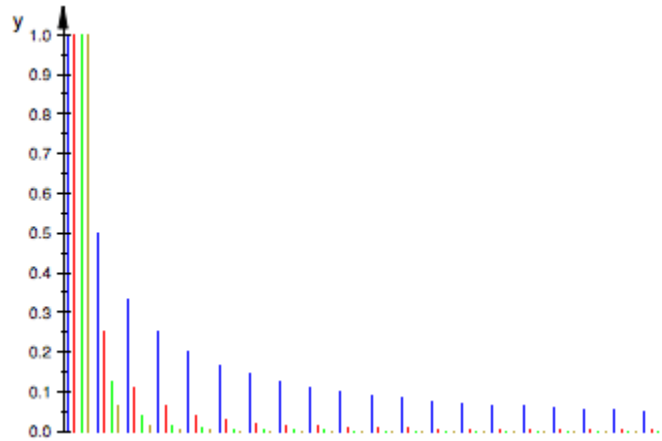


Example 2

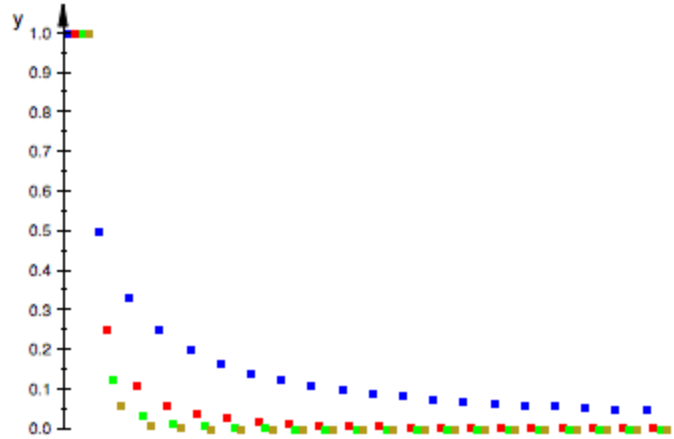
When more data is to be displayed, a bar plot may be less adequate:
b := plot::Bars2d([[1/i^k$i=1..20] $ k = 1..4]): plot(b)



We demonstrate the alternatives without any further comment:
b::BarStyle := Lines: plot(b)



b::BarStyle := Points: plot(b)



b::BarStyle := LinesPoints: plot(b)

plot::Iteration	RGB::Grey50
plot::Bars2d, plot::Bars3d, plot::Boxplot, plot::Piechart2d, plot::Piechart3d	
plot::Waterman	RGB::SafetyOrange
plot::Integral	RGB::PaleBlue

Description

`Color` refers to the "main color" of an object.

Depending on the object type, `Color` refers to the line color (e.g., plot::Function2d), the fill color (plot::Surface), the point color (plot::Point2d), the light color (plot::PointLight), or the one-and-only entry in Colors (plot::Histogram2d).

In general, the main color of an object is the first one available in the list

1 The first entry of Colors, if Colors contains exactly one entry.

2 FillColor

3 LineColor

4 PointColor

5 LightColor

The following object types deviate from this general rule and choose the line color as main color: plot::Arc2d, plot::Arc3d, plot::Circle2d, plot::Circle3d, plot::Ellipse2d, plot::Ellipse3d, plot::Ode2d, plot::Ode3d, plot::Parallelogram2d, plot::Polygon2d, plot::Polygon3d, and plot::Rectangle. plot::Sequence uses PointColor as the main color. prog::init(plot): map(select(plot::allGraphPrim, x->slot(slot(plot, x), "primaryColor") <> FAIL), x -> x = slot(slot(plot, x), "primaryColor")){"SparseMatrixplot" = PointColor, "Arc2d" = LineColor, "Arc3d" = LineColor, "Circle2d" = LineColor, "Circle3d" = LineColor, "Ellipse2d" = LineColor, "Ellipse3d" = LineColor, "Parallelogram2d" = LineColor, "Polygon2d" = LineColor, "Polygon3d" = LineColor, "Rectangle" = LineColor, "Rootlocus" = LineColor, "Sequence" = LineColor, "Sum" = LineColor, "Sweep" = LineColor}

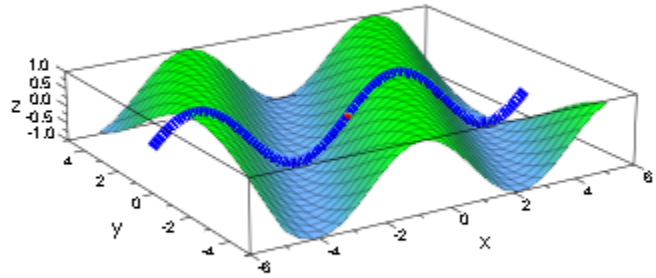
Note Color is a *library attribute* and does not appear in the inspector.

Examples

Example 1

`Color` is useful for unified input of different object types:

```
plot(plot::Function3d(sin(x-y/2), Color = RGB::Green), plot::Point3d([0,
0, 0], Color = RGB::Red), plot::Curve3d([x, 0, sin(x)], x = -6..6, LineWidth
= 2*unit::mm, Color = RGB::Blue), Scaling = Constrained)
```



See Also ColorsFillColorLineColorPointColor

Ground

Purpose

Colors

List of colors to use

Value Summary

Optional	List of colors

Graphics Primitives

Objects	Colors Default Values
plot::Bars2d, plot::Bars3d, plot::Ode2d, plot::Ode3d	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson, RGB::Aqua, RGB::Lavender, RGB::SeaGreen, RGB::AureolineYellow, RGB::Banana, RGB::Beige, RGB::YellowGreen, RGB::Wheat, RGB::IndianRed, RGB::Black]
plot::MuPADCube	[RGB::Green, RGB::Blue, RGB::Red, RGB::Yellow, RGB::Antique]
plot::Boxplot, plot::Piechart2d, plot::Piechart3d	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson]

Description

`Colors` sets a list of colors to use for object parts.

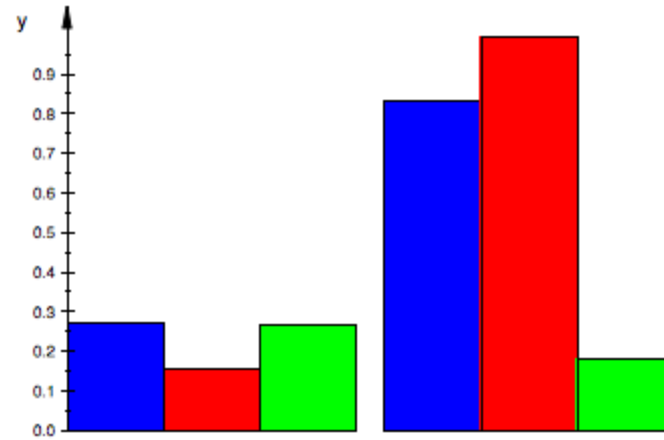
Plot objects like plot::Piechart3d or plot::MuPADCube that use more than one color use `Colors` to have a configurable list of colors to use.

The length of the list in `Colors` need not be fixed, it just must not be empty. If the list contains more colors than needed, the remaining colors are simply not used; if the list contains fewer colors than needed, it will be used cyclically, i.e., as if it were repeated as often as necessary. Cf. “Example 2” on page 24-1740.

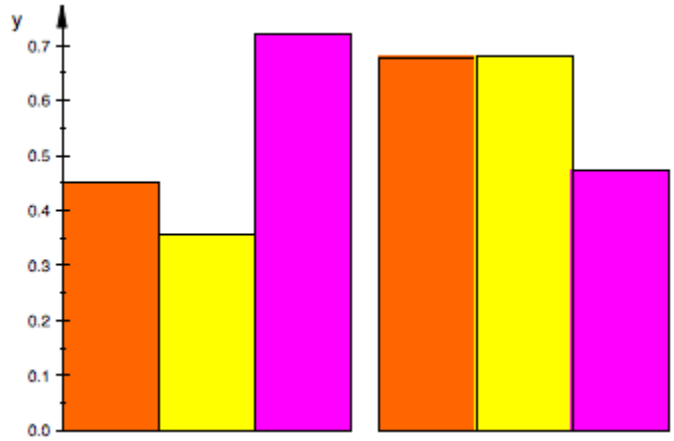
Examples

Example 1

Most of the statistical plots use `Colors` for the colors of their groups:
plot(plot::Bars2d([[frandom() $i=1..2] $ i = 1..3]))

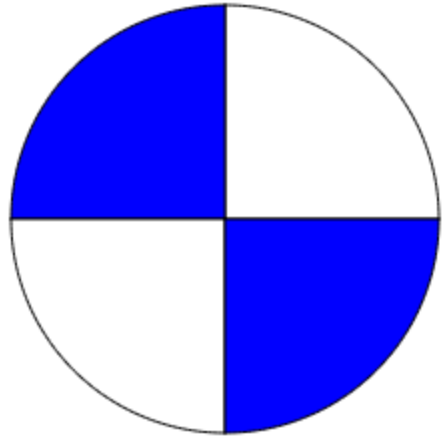


plot(plot::Bars2d([[frandom() $i=1..2] $ i = 1..3], Colors = [RGB::Orange, RGB::Yellow, RGB::Magenta]))



Example 2

If more colors are required than given in `Colors`, the given list is used cyclically:
plot(plot::Piechart2d([1, 1, 1, 1], Colors = [RGB::White, RGB::Blue]))



See Also ColorFillColorLineColorPointColor

Purpose

FillColorFillColor2

Color of areas and surfaces

Value Summary

`FillColor`, `FillColor2`	Inherited	Color

Graphics Primitives

Objects	Default Values
plot::Histogram2d	`FillColor`: RGB::GeraniumLake
plot::Cylindrical, plot::Density, plot::Dodecahedron, plot::Function3d, plot::Hexahedron, plot::Icosahedron, plot::Implicit3d, plot::Matrixplot, plot::Octahedron, plot::Prism, plot::Pyramid, plot::Spherical, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::XRotate, plot::ZRotate	`FillColor`: RGB::Red `FillColor2`: RGB::CornflowerBlue
plot::Box, plot::Circle3d, plot::Cone, plot::Cylinder, plot::Ellipsoid, plot::Plane, plot::Polygon3d, plot::Sphere	`FillColor`: RGB::LightBlue
plot::Arc2d, plot::Circle2d, plot::Ellipse2d, plot::Hatch, plot::Parallelogram2d, plot::Polygon2d, plot::Rectangle, plot::Sum	`FillColor`: RGB::Red

Objects	Default Values
plot::Arc3d, plot::Ellipse3d, plot::Parallelogram3d	`FillColor`: RGB::LightBlue `FillColor2`: RGB::CornflowerBlue
plot::Waterman	`FillColor`: RGB::SafetyOrange `FillColor2`: RGB::CornflowerBlue
plot::Integral	`FillColor`: RGB::PaleBlue

Description

`FillColor` determines the color used to fill all types of areas and surfaces. `FillColor2` is used for color blends. `FillColors` is used for objects that need more than one color.

2D objects that have a notion of "area" and 3D objects that have a surface support `FillColor` to determine the primary color to show objects in. If FillColorType is set to `Dichromatic`, `FillColor2` sets the second color to blend to.

Functions and primitives displaying more than one object, such as plot::Bars2d, use `FillColors` for a list of colors used cyclically.

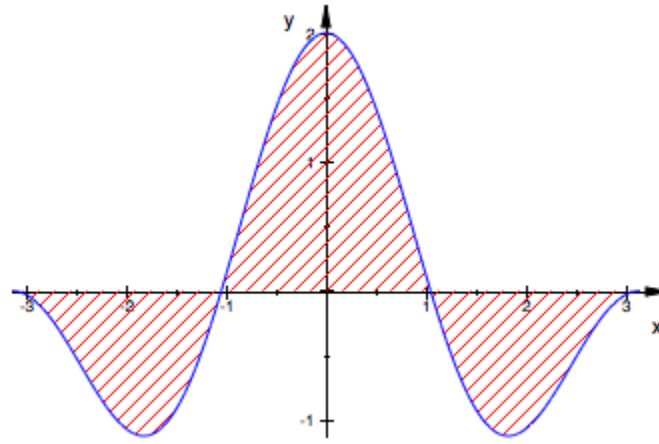
Examples

Example 1

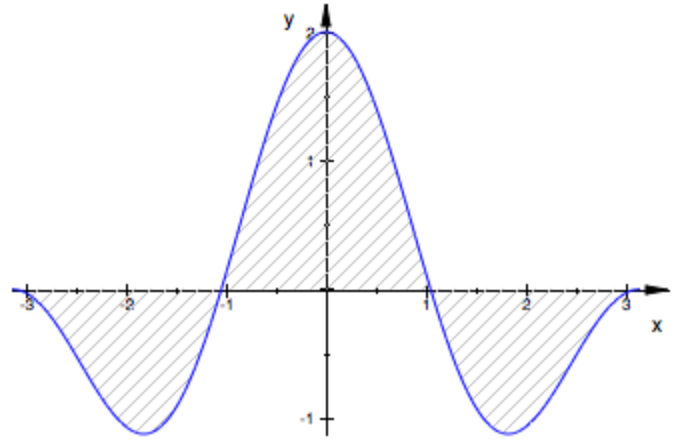
By default, plot::Hatch objects are hatched in `RGB ::Red`, the same color used by default for plot::Function2d:
plot::getDefault(plot::Hatch::FillColor),
plot::getDefault(plot::Function2d::LineColor)[1.0, 0.0, 0.0], [0.0, 0.0, 1.0]

[1.0, 0.0, 0.0], [0.0, 0.0, 1.0]

```
f := plot::Function2d(cos(2*x)+cos(x), x=-PI..PI): h := plot::Hatch(f):
plot(h, f)
```



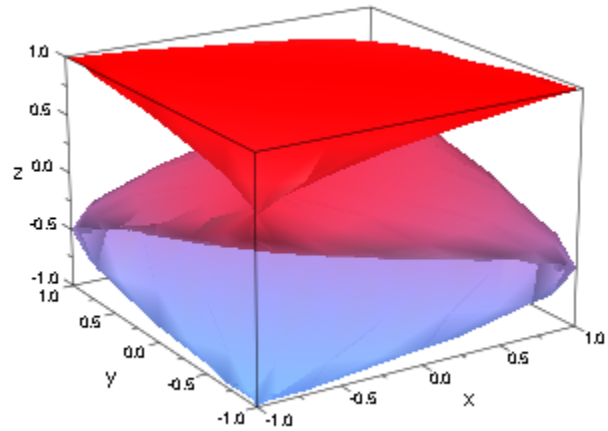
To change the color of the hatch, simply set the `"FillColor"`-slot to some other value:
h::FillColor := RGB::Grey: plot(h, f)



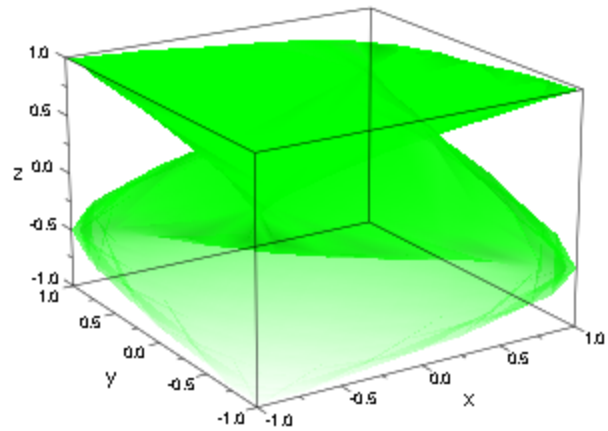
Example 2

The default setting for a surface is to have a height-dependent coloring with a linear blend from `FillColor` to `FillColor2`:

s := plot::Surface([cos(2*u+v), sin(u+2*v), sin(u+v)], u = 0..2*PI, v = 0..2*PI, ULinesVisible = FALSE, VLinesVisible = FALSE): plot(s)



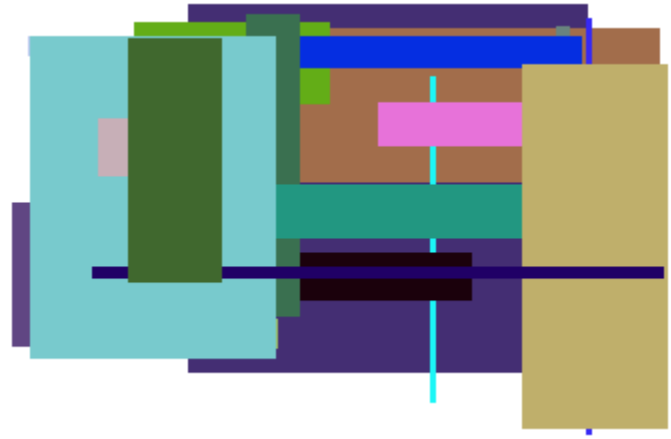
These colors can be manipulated in the usual way. As an example, we set the transition to a monochrome transition from opaque to transparent:
s::FillColor := RGB::Green: s::FillColor2 := s::FillColor . [0.0]: plot(s)



Example 3

Using a utility function `randrange` that returns random ranges in [0, 1], we can plot random rectangles with random colors:

```
randrange := () -> _range(op(sort([frandom(), frandom()]))):
plot(plot::Rectangle(randrange(), randrange(), LinesVisible = FALSE,
Filled = TRUE, FillPattern = Solid, FillColor = [frandom(), frandom(),
frandom()]) $k=1..20, AxesVisible = FALSE)
```



See Also FillColorTypeFilledFillPatternLineColorShading

Purpose

FillColorDirectionFillColorDirectionXFillColorDirectionYFillColorDirectionZ
Direction of color transitions on surfaces

Value Summary

`FillColorDirection`	Library wrapper for "[FillColorDirectionX, FillColorDirectionY]" (2D), "[FillColorDirectionX, FillColorDirectionY, FillColorDirectionZ]" (3D)	See below
`FillColorDirectionX`, `FillColorDirectionY`, `FillColorDirectionZ`	Inherited	Real number

Graphics Primitives

Objects	Default Values
plot::Arc3d, plot::Cylindrical, plot::Dodecahedron, plot::Ellipse3d, plot::Function3d, plot::Hexahedron, plot::Icosahedron, plot::Implicit3d, plot::Matrixplot, plot::Octahedron, plot::Parallelogram3d, plot::Prism, plot::Pyramid, plot::Spherical, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::Waterman, plot::XRotate, plot::ZRotate	`FillColorDirection`: [0, 0, 1] `FillColorDirectionX`, `FillColorDirectionY`: 0 `FillColorDirectionZ`: 1
plot::Listplot	`FillColorDirection`: [0, 0]

Description

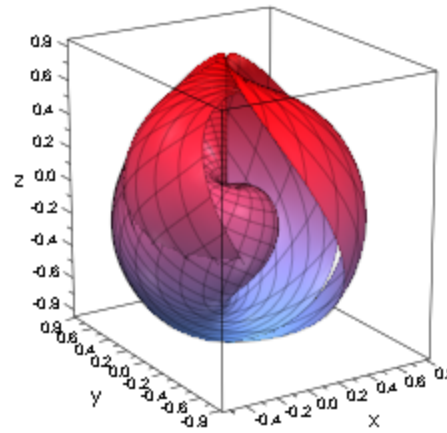
`FillColorDirection` determines the direction in which the color transitions for `FillColorType = Dichromatic` etc. take place.

When setting FillColorType to some other value than `Flat` or `Functional`, MuPAD produces a “height-coloring.” By default, this color method actually uses the height of a point. Using `FillColorDirection`, the axis along which the color method should be applied can be changed.

Examples

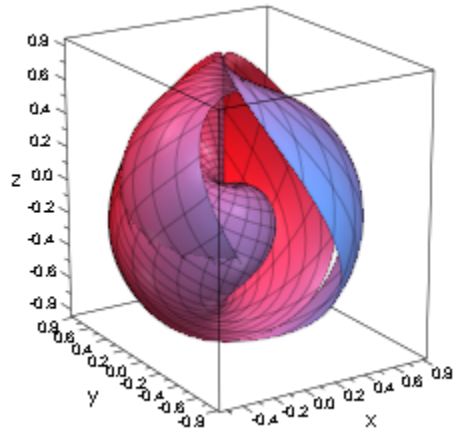
Example 1

By default, MuPAD uses height coloring along the *z* axis for 3D objects:
s := plot::Spherical([sin(r),thet/(r+1)+1, thet*r], r=0..1, thet=0..3*PI, Submesh=[2,2]): plot(s)



By changing `FillColorDirection`, the color can be rotated on the object:
plot(s, FillColorDirection = [0, 1, 0])

Ground



See Also FillColorFillColor2FillColorTypeLineColorDirection

FillColorTrueFillColorFalseFillColorUnknown

Purpose

Color for “true” areas (inequality plot)

Value Summary

`FillColorFalse`, `FillColorTrue`, `FillColorUnknown`	Optional	Color

Graphics Primitives

Objects	Default Values
plot::Inequality	`FillColorTrue`: RGB::Green `FillColorFalse`: RGB::Red `FillColorUnknown`: RGB::Black

Description

`FillColorTrue`, `FillColorFalse`, and `FillColorUnknown` define the three colors use by plot::Inequality for the areas where the inequalities are fulfilled (true), violated (false) or the granularity is too small to decide (unknown).

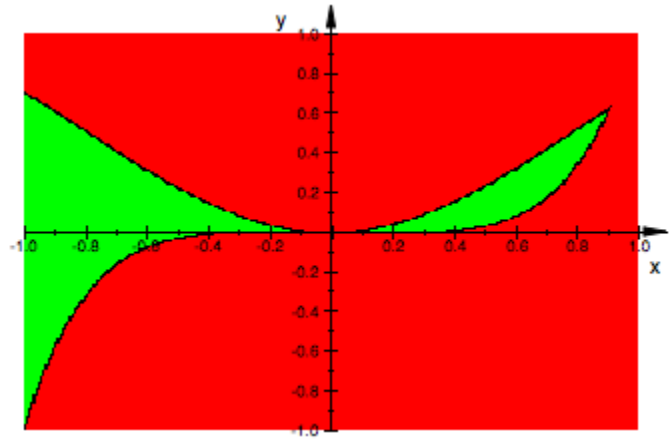
plot::Inequality divides the plot area into rectangles that are colored according to these three attributes. Rectangles over which the inequalities are true get the color set by `FillColorTrue`; rectangles over which at least one inequality is violated (i.e., false over the whole rectangle) use `FillColorFalse`. If neither of these two apply and the rectangle is already too small for subdivision (the settings for XMesh and YMesh control this), it will be painted in `FillColorUnknown`.

Examples

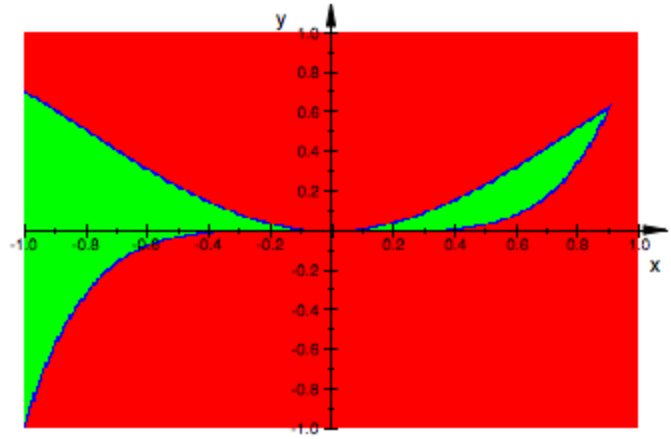
Example 1

We show the same inequality plot with different settings of these three attributes:

```
ineq := plot::Inequality([sin(x)^2>y, y>x^5], x=-1..1, y=-1..1): plot(ineq)
```



```
ineq::FillColorTrue := RGB::Green: ineq::FillColorFalse := RGB::Red:
ineq::FillColorUnknown := RGB::Blue: plot(ineq)
```



Purpose

FillColorType

Surface filling types

Value Summary

Inherited	`Dichromatic`, `Flat`, `Functional`, `Monochrome`, or `Rainbow`

Graphics Primitives

Objects	FillColorType Default Values
plot::Cylindrical, plot::Density, plot::Dodecahedron, plot::Function3d, plot::Hexahedron, plot::Icosahedron, plot::Implicit3d, plot::Matrixplot, plot::Octahedron, plot::Prism, plot::Pyramid, plot::Spherical, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::XRotate, plot::ZRotate	`Dichromatic`
plot::Arc3d, plot::Ellipse3d, plot::Parallelogram3d, plot::Waterman	`Flat`

Description

`FillColorType` selects the type of surface fill color used.

With the exception of `Flat` and `Functional`, the coloring schemes depend on the height, i.e., the *z* value of points on the surface, in relation to the height of the whole coordinate system. (Everything on this page relating to surfaces holds for objects of type plot::Density, too, with the values plotted replacing height information.)

By default, surfaces are drawn with a linear blend from FillColor to FillColor2. This behavior may be changed with `FillColorType`, using one of the following options:

- `Dichromatic`

  The default just described.

- `Flat`

  The surface is filled with `FillColor`. No blend is used.

- `Monochrome`

  The surface is filled with a blend from `FillColor` to a dimmed version of `FillColor`.

- `Rainbow`

  This setting is technically similar to `Dichromatic`, but the effect is vastly different, since interpolation takes place in HSV color space. This creates a rainbow effect, similar to a physical rainbow for suitable choices of colors.

- `Functional`

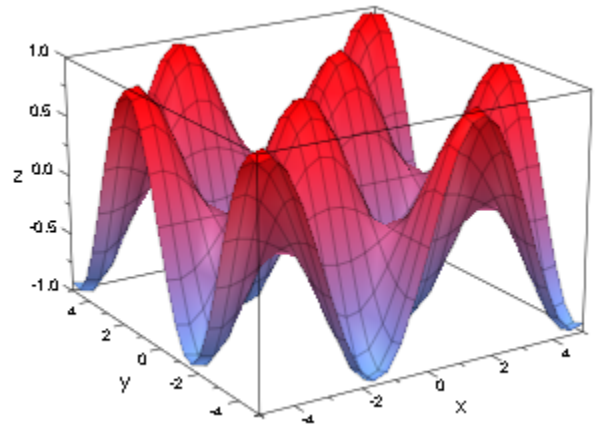
  Both `FillColor` and `FillColor2` are ignored; the color scheme is derived from `FillColorFunction`. See FillColorFunction for details (which depend on the object type). If no color function is given, the object will be rendered with `FillColorType` = `Flat`.

In this context, "a blend from *A* to *B*" means that color *A* is used at the top of the coordinate system (the part with the lowest *z* coordinate), color *B* is used at the bottom and in between each or the red, green, blues, and alpha channel are interpolated linearly.

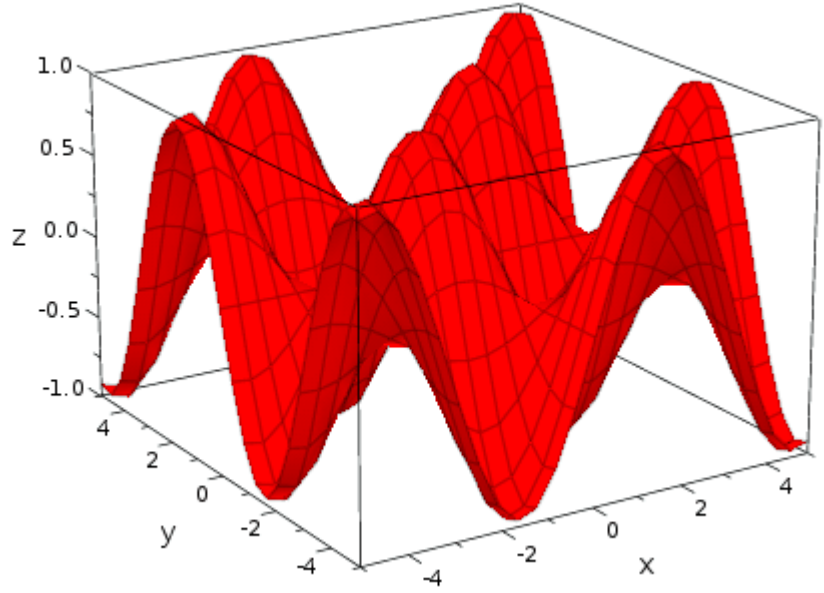
Examples

Example 1

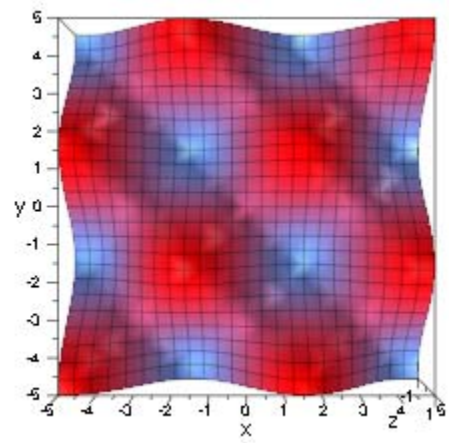
By default, function plots use `FillColorType = Dichromatic` with a color range from blue to red (as in a temperature scale):
plotfunc3d(sin(x)*sin(y))



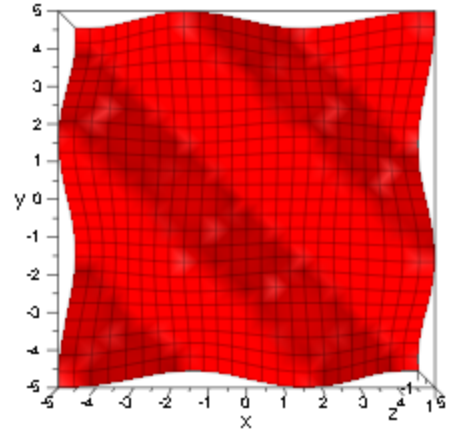
Using `FillColorType`, we color the graph completely in red:
plotfunc3d(sin(x)*sin(y), FillColorType = Flat)



Note, however, that the coloring is a visual aid, e.g., when looking from above:
plotfunc3d(sin(x)*sin(y), CameraDirection = [0, 0, 1])



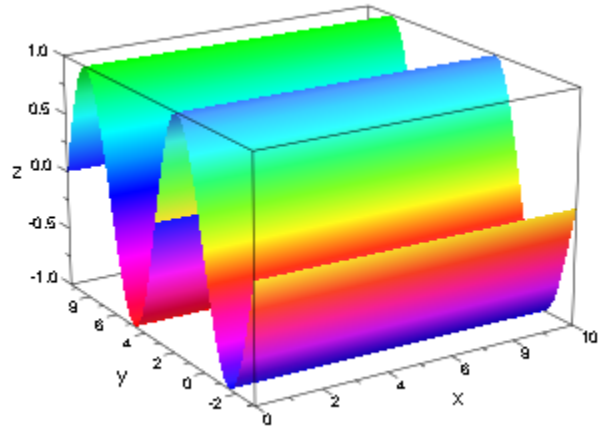
plotfunc3d(sin(x)*sin(y), FillColorType = Flat, CameraDirection = [0, 0, 1])



Example 2

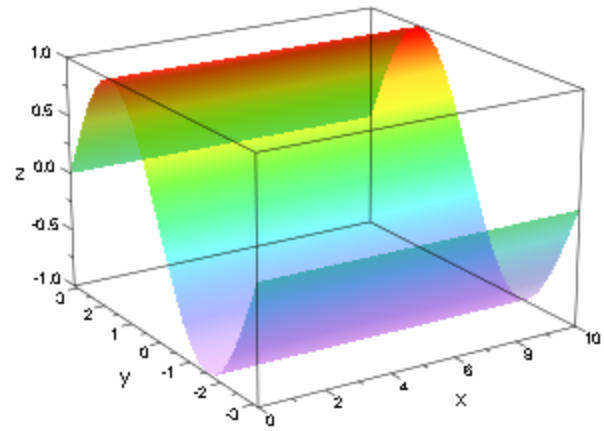
In MuPAD, rainbow coloring does react to `FillColor` and `FillColor2`. The following plot uses different color settings to show this effect:

plot(plot::Function3d(sin(y), x = 0..10, y = -PI..PI, FillColor = RGB::BlueLight, FillColor2 = RGB::Blue), plot::Function3d(sin(y), x = 0..10, y = PI..3*PI, FillColor = RGB::Green, FillColor2 = RGB::Red), FillColorType = Rainbow, XLinesVisible = FALSE, YLinesVisible = FALSE)



What is happening here technically is that MuPAD performs a linear interpolation in HSV color space, i.e., the *longest* path round the following color circle is followed, with saturation and value (roughly speaking, whiteness and blackness) interpolated linearly:
plot(plot::Curve2d([sin(x), cos(x)], x=0..2*PI, LineWidth = (22-i)/2, Mesh = 500, LineColorFunction = (x -> RGB::fromHSV([180/PI*x, 1, 1]))) $ i = 1..20, Scaling = Constrained, Axes = None)

The opacity of colors is treated the same way in both the `Rainbow` and `Dichromatic` settings of `FillColorType`, by linear interpolation:
plot((f:=plot::Function3d(sin(y), x = 0..10, y = -PI..PI, FillColorType = Rainbow, FillColor2 = RGB::VioletDark.[0.2], XLinesVisible = FALSE, YLinesVisible = FALSE)))



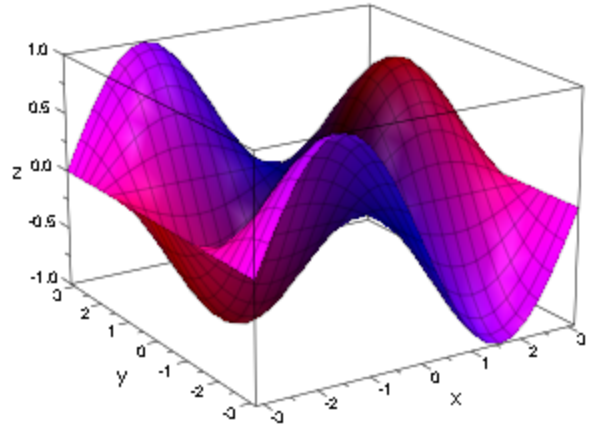
Example 3

Setting a FillColorFunction for an object automatically sets `FillColorType` to `Functional`:

```
colorfunc := (x, y) -> [abs(x)/PI, 0, abs(y)/PI]: f := plot::Function3d(sin(x)*cos(y), x = -PI..PI, y = -PI..PI, FillColorFunction = colorfunc): f::FillColorTypeFunctional
```

```
Functional
```

```
plot(f)
```



```
delete colorfunc, f:
```

See Also FillColorFillColor2FilledFillPatternLineColorTypeShading

Filled

Purpose

Filled or transparent areas and surfaces

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Filled Default Values
plot::Bars2d, plot::Bars3d, plot::Box, plot::Boxplot, plot::Cone, plot::Cylinder, plot::Cylindrical, plot::Dodecahedron, plot::Function3d, plot::Hexahedron, plot::Histogram2d, plot::Icosahedron, plot::Implicit3d, plot::Integral, plot::Matrixplot, plot::Octahedron, plot::Parallelogram3d, plot::Piechart2d, plot::Piechart3d, plot::Plane, plot::Prism, plot::Pyramid, plot::Spherical, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::Waterman, plot::XRotate, plot::ZRotate	TRUE
plot::Arc2d, plot::Arc3d, plot::Circle2d, plot::Circle3d, plot::Ellipse2d, plot::Ellipse3d, plot::Parallelogram2d, plot::Polygon2d, plot::Polygon3d, plot::Rectangle, plot::Sum	FALSE

Description

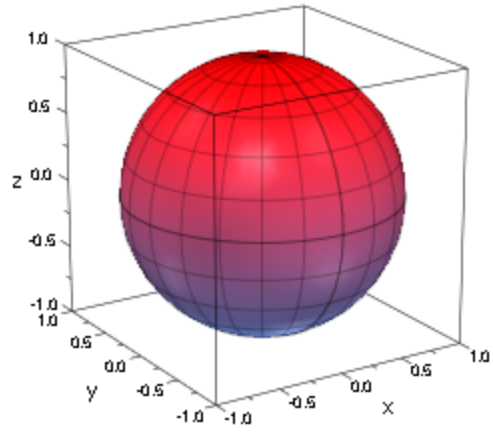
`Filled` controls whether areas and surfaces are filled or transparent.

With `Filled = FALSE`, areas and surfaces are not filled. This means that, e.g., a surface plot is reduced to a wire frame model.

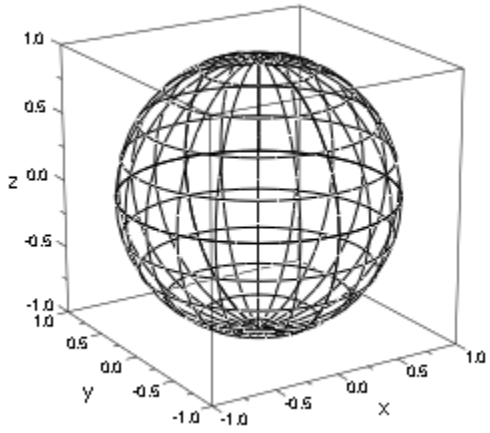
Examples

Example 1

The following parametrization of a sphere uses a mesh similar to the graticule (longitudes and latitudes) of geography:
globe := plot::Surface([sin(u)*cos(v), cos(u)*cos(v), sin(v)], u = 0..2*PI, v = 0..2*PI, Mesh = [12, 12], Submesh = [3, 3]): plot(globe, Scaling = Constrained)



To get a wire frame model, we set `Filled = FALSE`:
plot(globe, Filled = FALSE, LineColor = RGB::Black, Scaling = Constrained)



See Also ColorsFillColorFillColor2FillColorTypeFillPatternFillStyleLinesVisibleULinesVisibleVLi

Purpose

FillPatternFillPatterns
Type of area filling

Value Summary

`FillPattern`	Inherited	`CrossedLines`, `DiagonalLines`, `FDiagonalLines`, `HorizontalLines`, `Solid`, `VerticalLines`, or `XCrossedLines`
`FillPatterns`	Optional	`Solid`, `HorizontalLines`, `VerticalLines`, `DiagonalLines`, `FDiagonalLines`, `CrossedLines`, or `XCrossedLines`

Graphics Primitives

Objects	Default Values
plot::Arc2d, plot::Boxplot, plot::Circle2d, plot::Ellipse2d, plot::Hatch, plot::Parallelogram2d, plot::Polygon2d, plot::Rectangle	`FillPattern`: `DiagonalLines`
plot::Bars2d, plot::Histogram2d, plot::Inequality, plot::Integral, plot::Piechart2d, plot::Sum	`FillPattern`, `FillPatterns`: `Solid`

Description

`FillPattern` determines the style of area filling used: lines, grids, or a solid fill.

`FillPatterns` is used for objects with more than one type of area to fill.

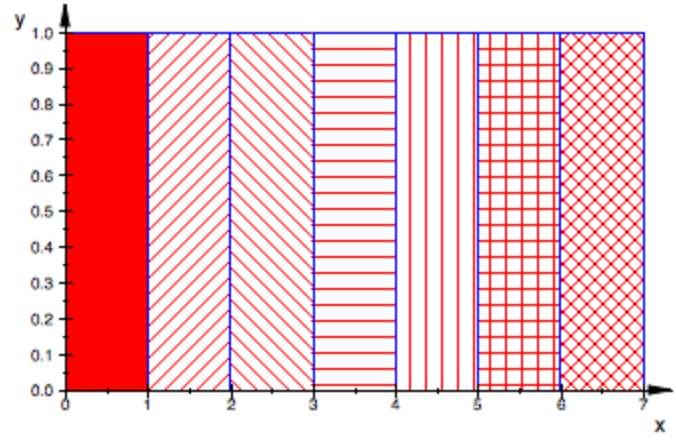
Areas can be filled in various ways. You can have horizontal, vertical, or diagonal lines (`HorizontalLines`, `VerticalLines`, `DiagonalLines`, `FDiagonalLines`), a horizontal/vertical grid (`CrossedLines`), a diagonal grid (`XCrossedLines`), or a solid fill (`Solid`).

For types like plot::Bars2d, `FillPatterns` is a list of fill patterns used cyclically, in this case for the groups of data plotted.

Examples

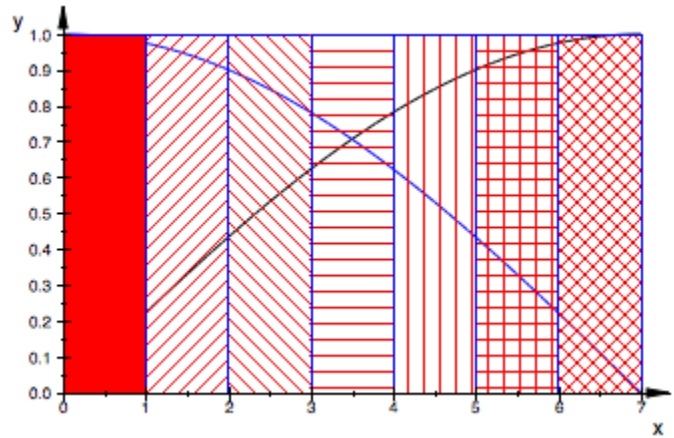
Example 1

The fill patterns look like this:
plot(plot::Rectangle(0..1, 0..1, FillPattern = Solid), plot::Rectangle(1..2, 0..1, FillPattern = DiagonalLines), plot::Rectangle(2..3, 0..1, FillPattern = FDiagonalLines), plot::Rectangle(3..4, 0..1, FillPattern = HorizontalLines), plot::Rectangle(4..5, 0..1, FillPattern = VerticalLines), plot::Rectangle(5..6, 0..1, FillPattern = CrossedLines), plot::Rectangle(6..7, 0..1, FillPattern = XCrossedLines), Filled = TRUE, AxesInFront = TRUE)



Except for `Solid`, the fill patterns let objects below be seen:
plot(plot::Function2d(sin(x*PI/14), x = 0..7, Color = RGB::Black), plot::Function2d(cos(x*PI/14), x = 0..7, Color = RGB::Blue), plot::Rectangle(0..1, 0..1, FillPattern = Solid), plot::Rectangle(1..2,

0..1, FillPattern = DiagonalLines), plot::Rectangle(2..3, 0..1, FillPattern = FDiagonalLines), plot::Rectangle(3..4, 0..1, FillPattern = HorizontalLines), plot::Rectangle(4..5, 0..1, FillPattern = VerticalLines), plot::Rectangle(5..6, 0..1, FillPattern = CrossedLines), plot::Rectangle(6..7, 0..1, FillPattern = XCrossedLines), Filled = TRUE, AxesInFront = TRUE)



See Also ColorColorsFillColorFillColorTypeFilled

Purpose

FillStyle

Definition of inside/outside

Value Summary

Inherited	`EvenOdd`, or `Winding`

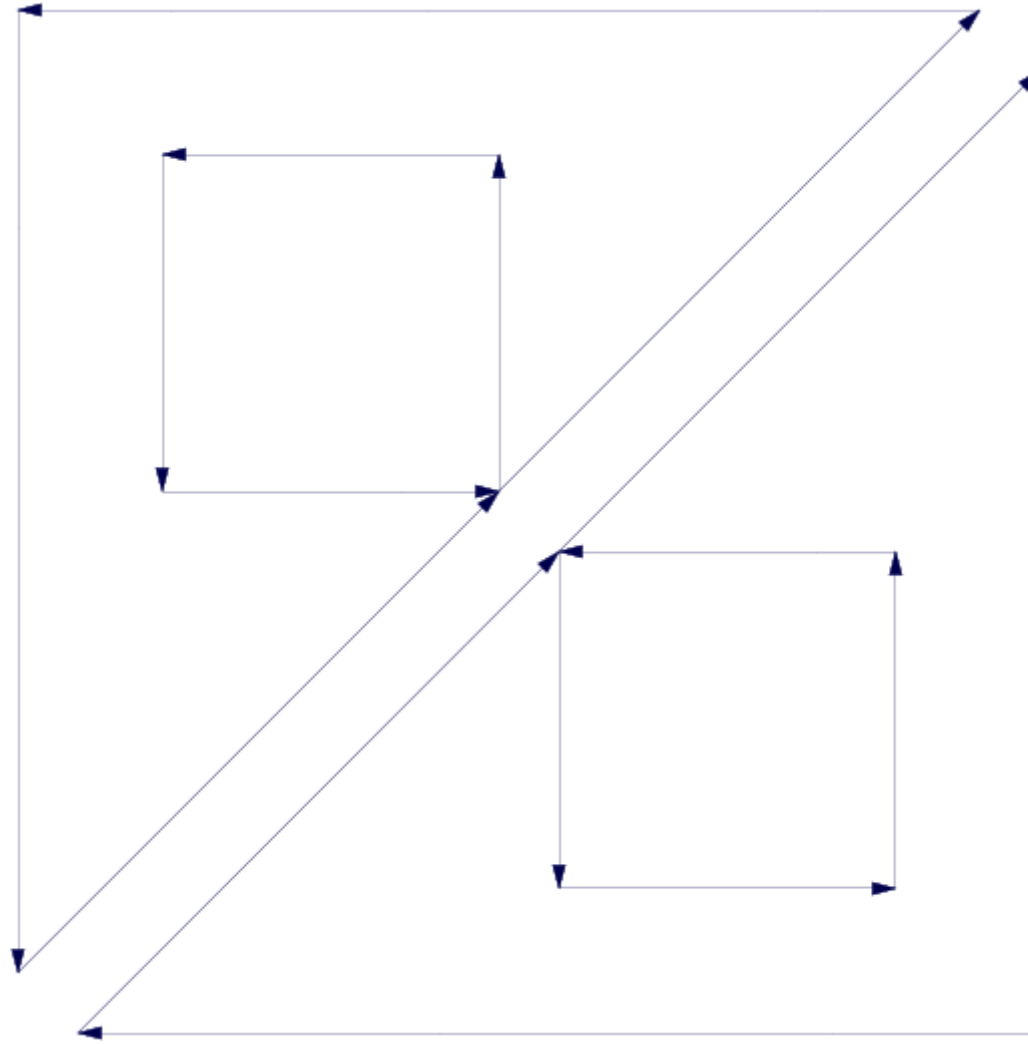
Graphics Primitives

Objects	FillStyle Default Values
plot::Polygon2d	`EvenOdd`

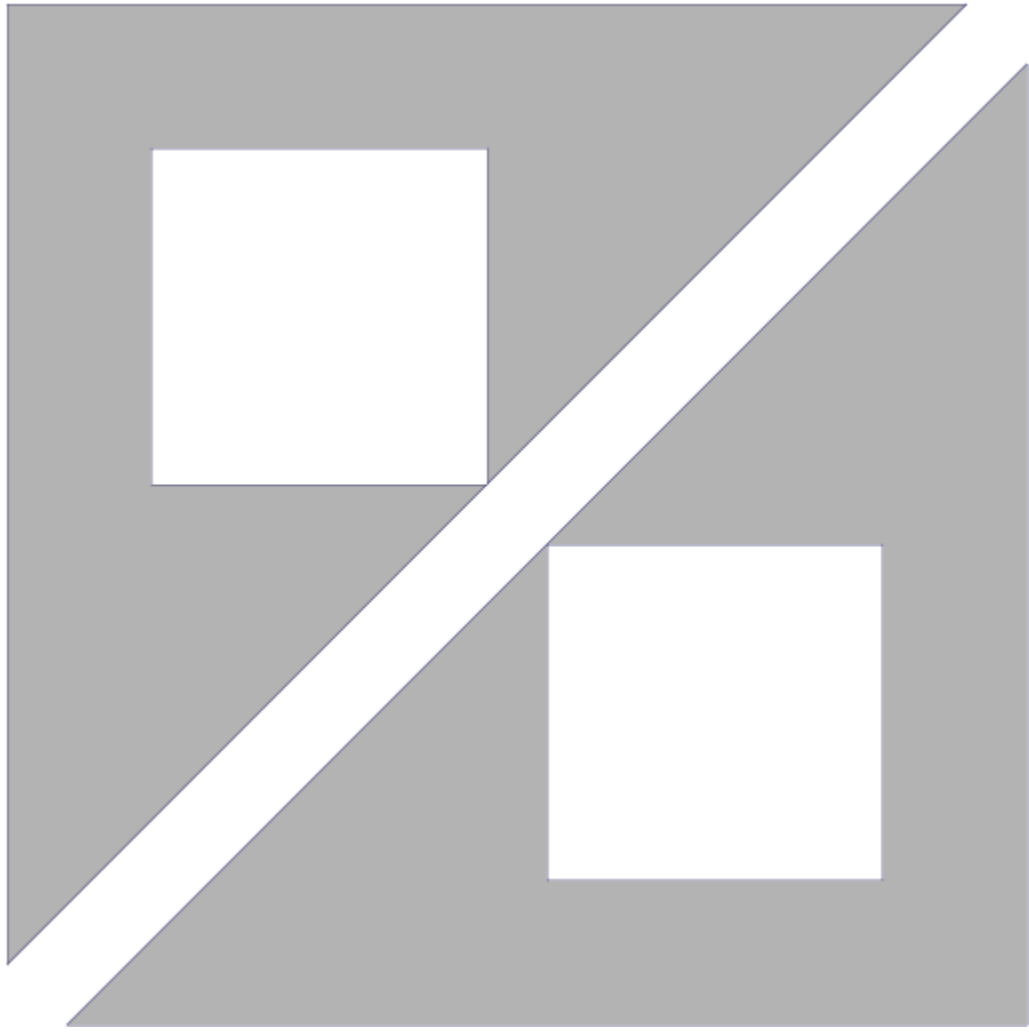
Description

For self-intersecting closed curves, `FillStyle` determines how holes are detected/defined.

Closed curves have an inside and an outside. With self-intersecting curves, the inside may have holes which are considered outside and not filled. To explain the difference between `EvenOdd` and `Winding`, we use the following two polygons which differ only in the order the inner points are visited:

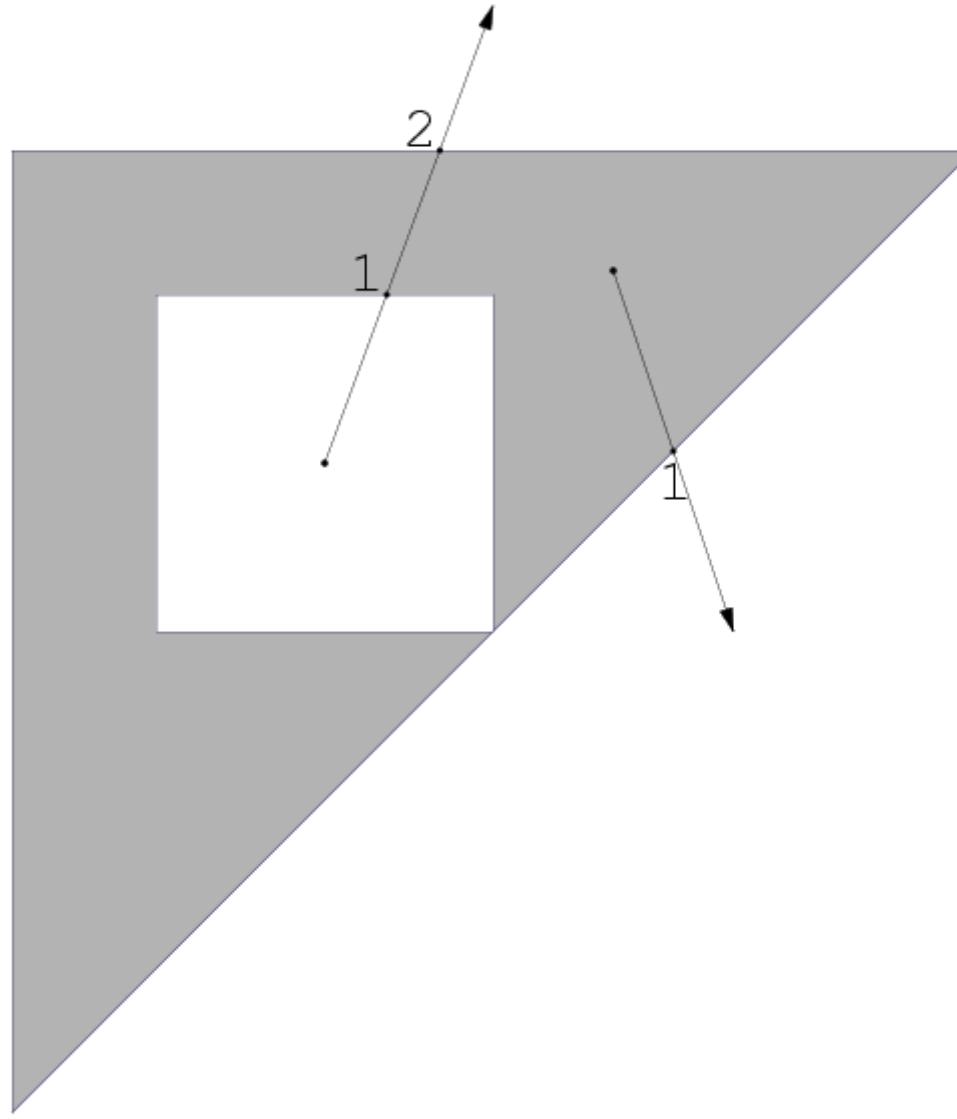


If plotted with `FillStyle = EvenOdd`, there is no difference between the two:

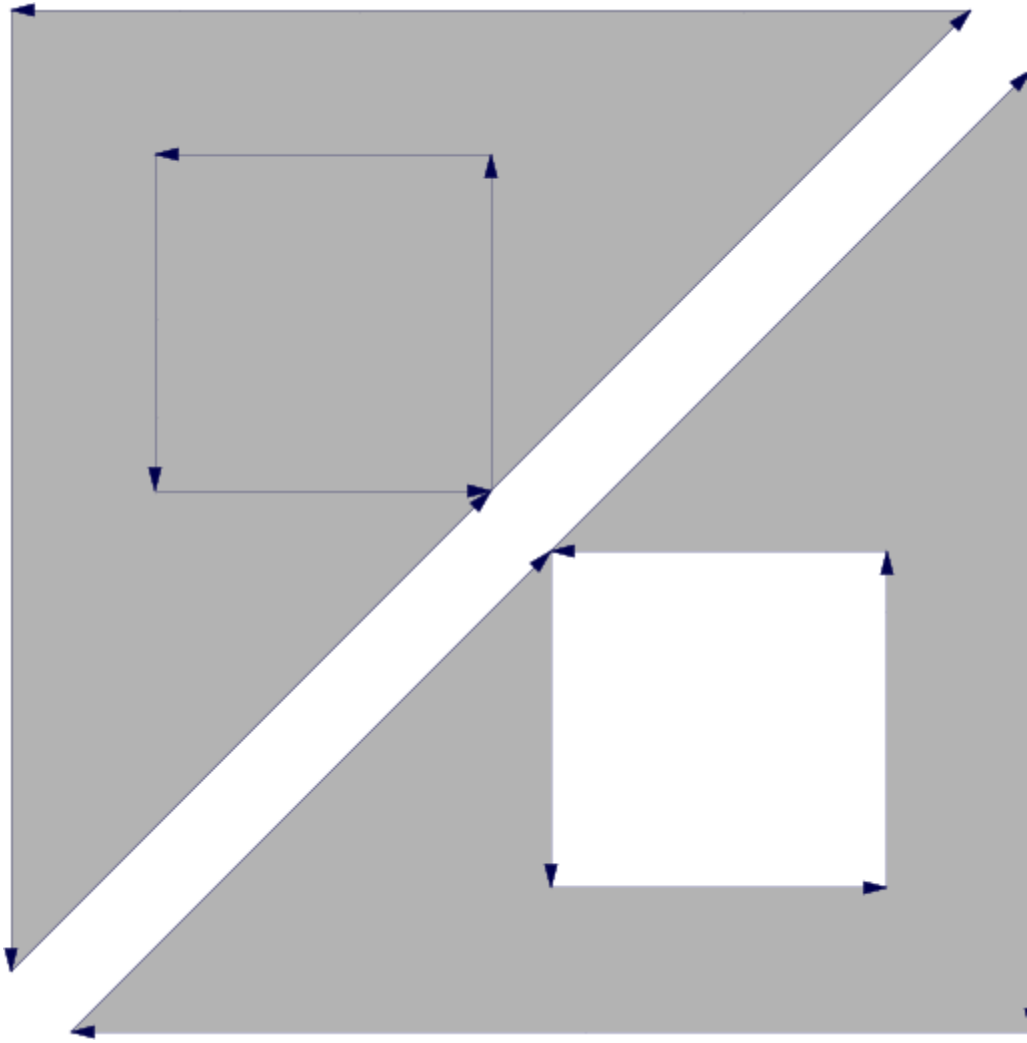


This is because for `FillStyle = EvenOdd`, a point is considered "inside" if a ray starting from the point and extending to infinity has an *odd* number of intersections with the polygon:

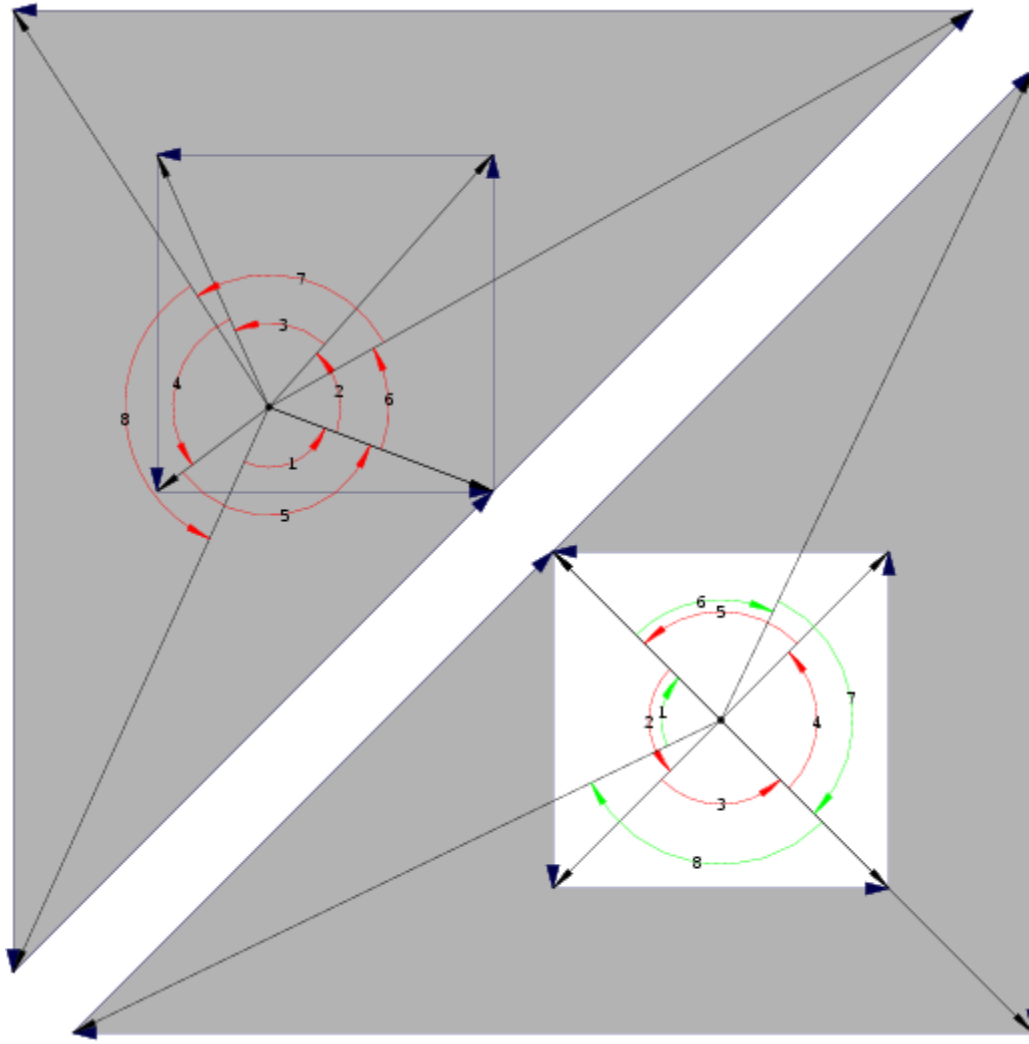
Ground



With `FillStyle = Winding`, however, the triangles look different from one another:

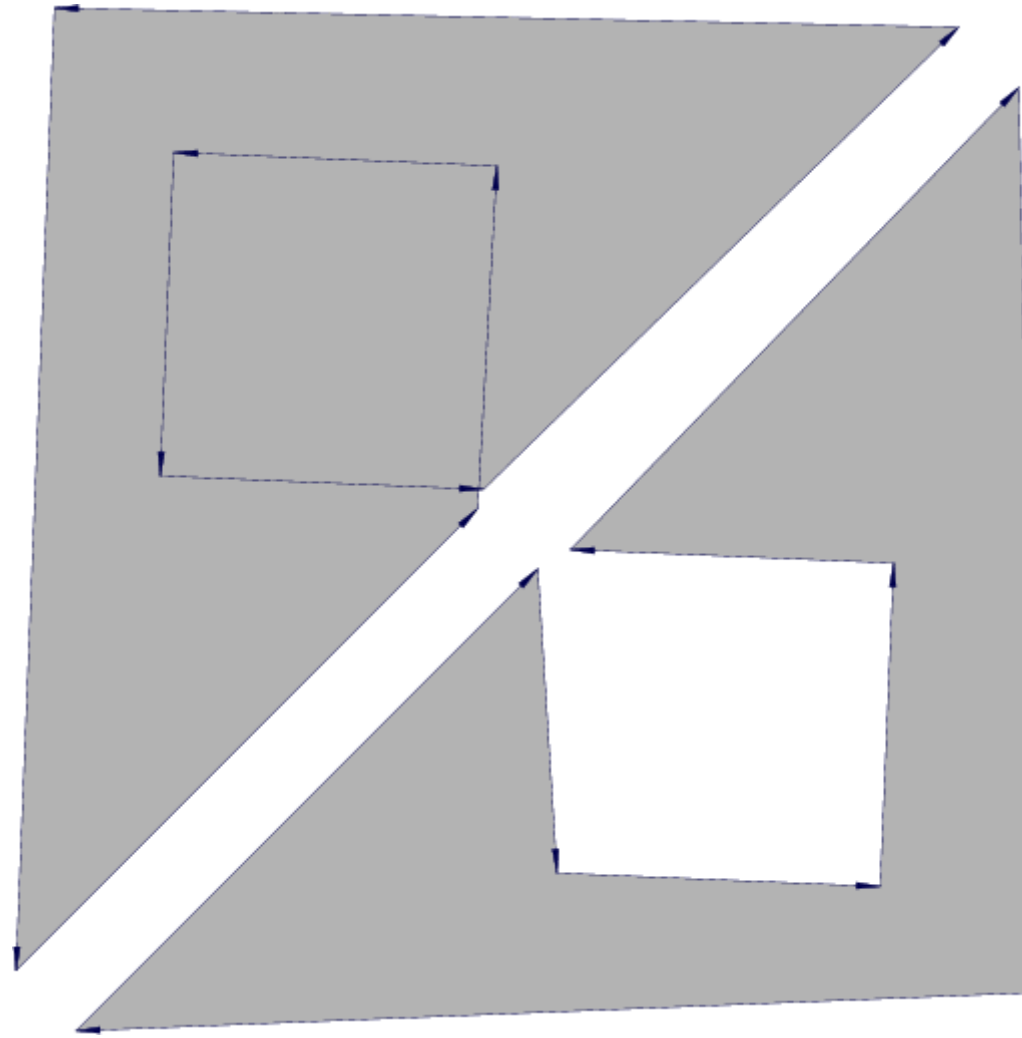


For `FillStyle = Winding`, the *winding number* of a point must be nonzero for this point to be “inside”. The winding number is the number of times the polygon line actually “runs around” the point. It can be determined by sequentially looking at all the edges, summing up the angles under which neighboring edges are seen (take care of the sign of he angle!) and dividing by 2π. In our example, a point in the square in the upper triangle has a winding number of 2, while one in the square in the lower triangle has a winding number of 0:



`FillStyle = Winding` is similar to a complete filling of the polygon area, but it is stable under small displacements of the polygon points:

Ground



See Also Filled

GroupStyle

Purpose

Grouping options in 2D bar plots

Value Summary

Optional	`MultipleBars`, or `SingleBars`

Graphics Primitives

Objects	GroupStyle Default Values
plot::Bars2d	`MultipleBars`

Description

`GroupStyle` determines whether a bar plot visualizes the data of different groups by separate bars or by single bars that are split into colored regions.

2D bar plots can group the bars in various ways. With the default setting `GroupStyle` = `MultipleBars`, data that are split into several groups are displayed by separate bars for each value in each group. With `GroupStyle` = `SingleBars`, corresponding data items in different groups are stacked up to one single bar. It is split into differently colored parts that correspond to the different groups.

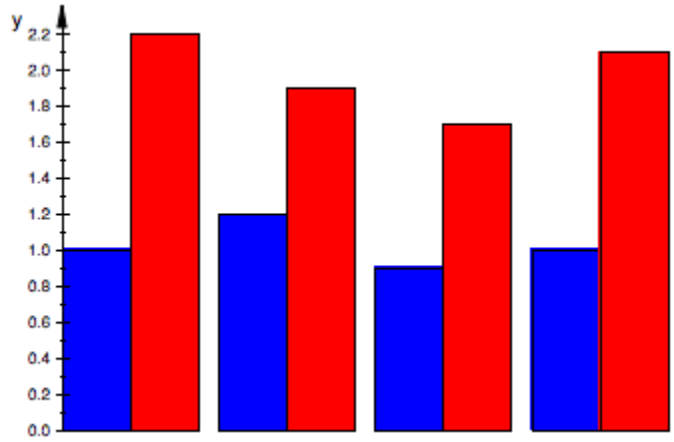
With `SingleBars`, all data must be nonnegative.

`SingleBars` has no effect if the data of only one group are given. If you wish to visualize the data in a single bar, you have to turn each data item into a separate group. Cf. “Example 2” on page 24-1776.

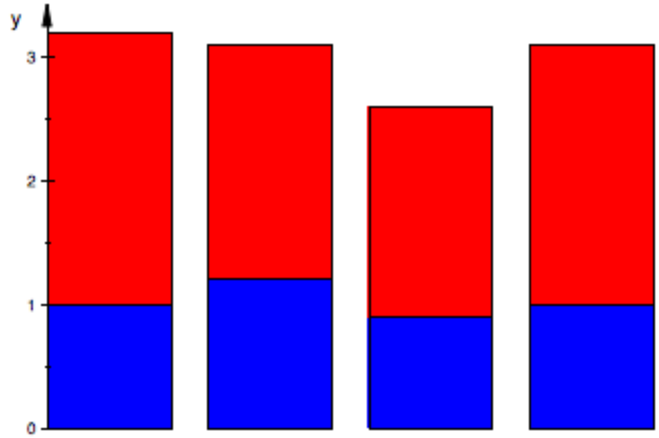
Examples

Example 1

The attribute `GroupStyle` can have the values `MultipleBars` or `SingleBars`:
group1 := [1.0, 1.2, 0.9, 1.0]: group2 := [2.2, 1.9, 1.7, 2.1]: data:= [group1, group2]: plot(plot::Bars2d(data, GroupStyle = MultipleBars))



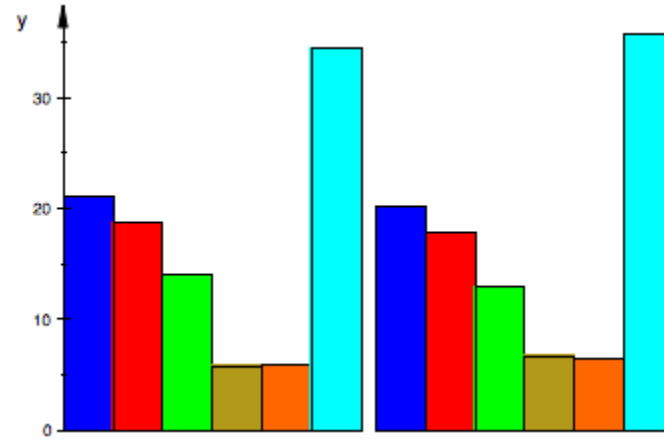
With `SingleBars`, corresponding data items in the different groups are collected in a single bar:
plot(plot::Bars2d(data, GroupStyle = SingleBars))



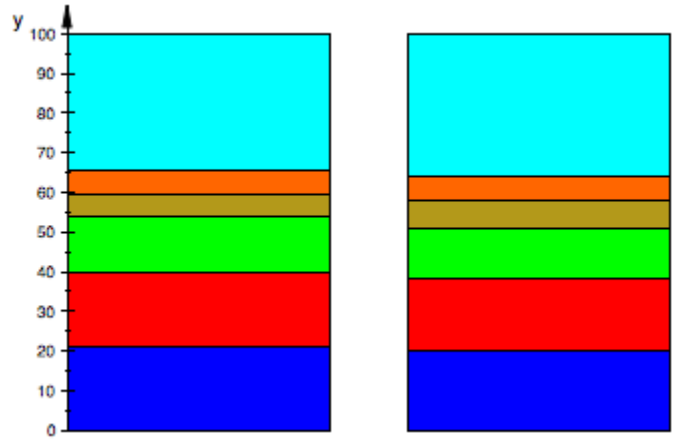
The following data are the australian market shares (in percent) of major car producers in the years 2004 and 2005:

// 2004 2005 Toyota:= [21.1, 20.2]: Holden_GM:= [18.7, 17.9]: Ford:= [14.0, 13.0]: Mazda:= [5.8, 6.7]: Mitsubishi:= [5.9, 6.4]: Others:= [34.5, 35.8]: data:= [Toyota, Holden_GM, Ford, Mazda, Mitsubishi, Others]:

We visualize the change of the market shares by bar plots using different group styles:
plot(plot::Bars2d(data, GroupStyle = MultipleBars))



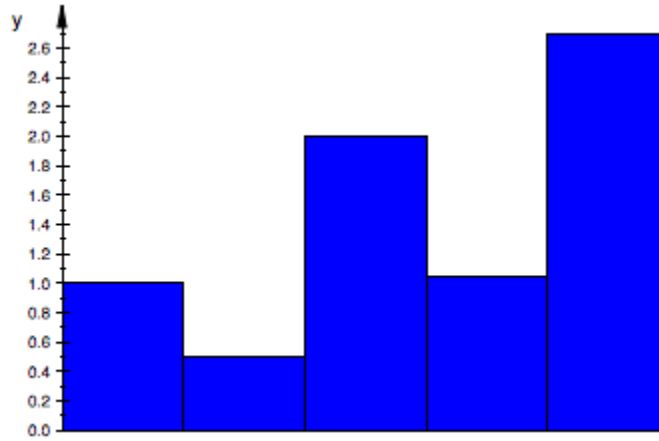
plot(plot::Bars2d(data, GroupStyle = SingleBars))



delete group1, group2, data, Toyota, Holden_GM, Ford, Mazda, Mitsubishi, Others:

Example 2

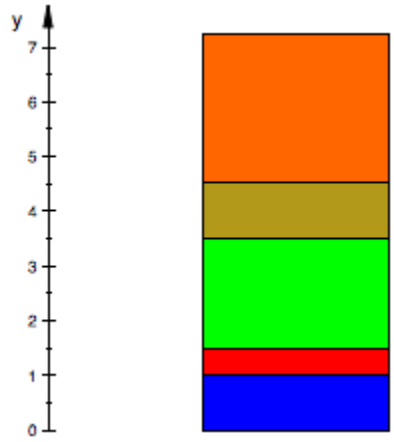
The option `SingleBars` has no effect when the data of only one group are given:
group:= [1, 0.5, 2, PI/3, 2.7]: plot(plot::Bars2d(group, GroupStyle = SingleBars))



Each value is turned into a separate group:
groups:= [[x] $ x in group][[1], [0.5], [2], [PI/3], [2.7]]

$$\left[[1], [0.5], [2], \left[\frac{\pi}{3}\right], [2.7]\right]$$

Now, `SingleBars` has an effect:
plot(plot::Bars2d(groups, GroupStyle = SingleBars, BarCenters = [0.4], BarWidths = [0.3]), ViewingBox = [0..1, Automatic])



delete group, groups:

See Also BarStyleColorsFillPatterns

InterpolationStyle

Purpose

Interpolation via linear or cubic splines

Value Summary

Optional	`Cubic`, or `Linear`

Graphics Primitives

Objects	InterpolationStyle Default Values
plot::Listplot, plot::Matrixplot	`Linear`

Description

`InterpolationStyle` determines whether discrete data are interpolated linearly or via cubic splines.

With the default setting `InterpolationStyle = Linear`, the curve connecting the data points in a plot of type plot::Listplot consists of line segments. Similarly, the surface generated from the matrix data in plot::Matrixplot consists of linear segments (triangles).

These plot objects do not react to the attribute Submesh when using linear interpolation.

With `InterpolationStyle = Cubic`, the curve connecting the data points in a plot of type plot::Listplot is the graph of the cubic spline function interpolating the data points. Similarly, the surface generated by plot::Matrixplot is the graph of the cubic spline function interpolating the matrix data.

The spline functions can be rendered smoothly by setting appropriate values for the attribute Submesh.

For large amounts of data, rendering with cubic spline interpolation may be much more costly than linear interpolation.

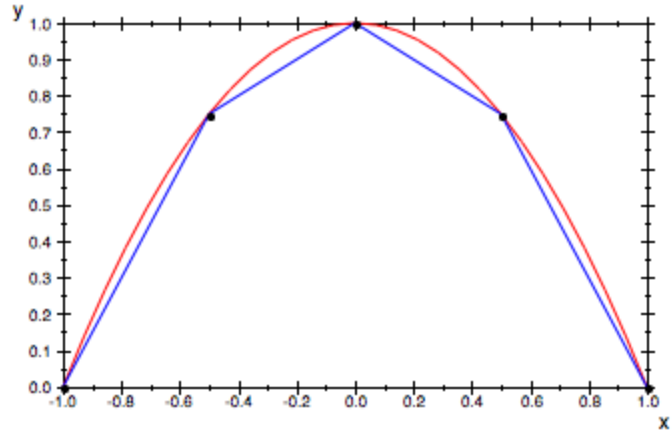
Examples

Example 1

We sample the function f(x)=1/fenced(1+x^2) at various points and store the data in a list. The data are displayed via plot::Listplot with different interpolation styles:

$$f(x) = \frac{1}{(1+x^2)}$$

```
L := [1 - (i/2)^2 $ i = -2..2]:  plot(plot::Listplot(L, x = -1..1,
InterpolationStyle = Cubic, Color = RGB::Red), plot::Listplot(L, x =
-1..1, InterpolationStyle = Linear, Color = RGB::Blue)):
```

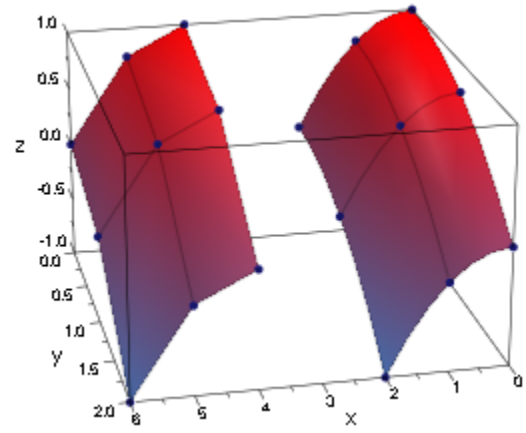


delete L:

Example 2

We sample the function $f(x, y) = 1 - x^2 - y^2$ at various points and store the data in a matrix. The matrix data are displayed as a matrix plot with different interpolation styles:

```
A := matrix([[1 - (i/2)^2 - (j/2)^2 $ j = 0..2] $ i = 0..2]):
plot(plot::Matrixplot(A, x = 0..2, y = 0..2, InterpolationStyle = Cubic),
plot::Matrixplot(A, x = 4..6, y = 0..2, InterpolationStyle = Linear),
CameraDirection = [10, 15, 9]):
```



delete A:

See Also Submesh

Shading

Purpose

Smooth color blend of surfaces

Value Summary

Inherited	`Flat`, or `Smooth`

Graphics Primitives

Objects	Shading Default Values
plot::Cone, plot::Dodecahedron, plot::Ellipsoid, plot::Function3d, plot::Hexahedron, plot::Icosahedron, plot::Implicit3d, plot::Matrixplot, plot::Octahedron, plot::Prism, plot::Pyramid, plot::Sphere, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Tetrahedron, plot::Tube, plot::Waterman, plot::XRotate, plot::ZRotate	`Smooth`

Description

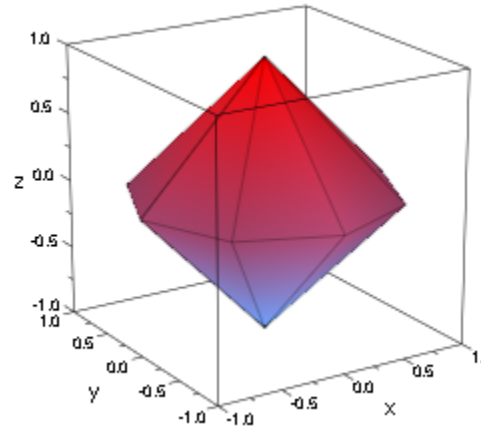
Using `Shading`, a smooth color blend of triangulated surfaces can be (de-)activated.

Most surfaces in 3D are triangulated for display. The triangles are then drawn using Gouraud-shading to achieve a smooth visual effect. Using `Shading = Flat`, you can instruct the viewer to display the plain triangles.

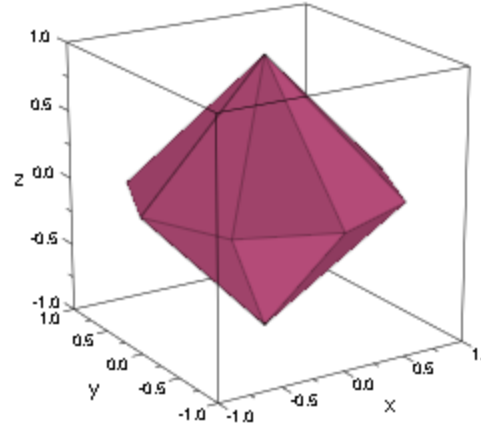
Examples

Example 1

Reducing the mesh density of a surface usually has more effect on its outer rim than on the display of the middle:
plot(plot::Spherical([1, u, v], u=0..PI, v=0..2*PI, UMesh=5, VMesh=5))



Setting `Shading = Flat`, you can see the triangles from which the sphere is constructed:
plot(plot::Spherical([1, u, v], u=0..PI, v=0..2*PI, UMesh=5, VMesh=5), Shading = Flat)



See Also LightingUMeshVMeshUSubmeshVSubmesh

UseNormals

Purpose

Use predefined normals?

Value Summary

Optional	`TRUE` or `FALSE`

Graphics Primitives

Objects	UseNormals Default Values
plot::SurfaceSet, plot::SurfaceSTL	`TRUE`

Description

`UseNormals` controls whether predefined normals of triangulation data are used when plotting a surface.

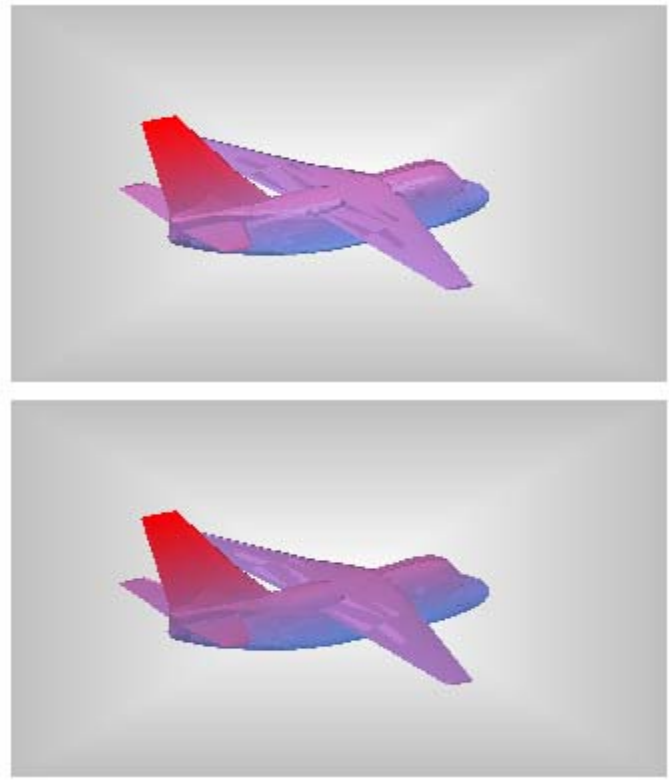
With `UseNormals = FALSE`, the predefined normals given in the triangulation data (MeshList) of a plot::SurfaceSet or in an STL file imported by a plot::SurfaceSTL are ignored when plotting this surface. This may reduce the data volume of the graphical object and the computing time as well. However, it usually leads to a somewhat less brilliant image.

Examples

Example 1

By default, the normals defined in STL files are used when plotting the corresponding MuPAD object. For comparison, an STL graphics is plotted with and without using the normals provided by the STL file:

```
READPATH:= READPATH,
"DATA":plot(plot::Scene3d(plot::SurfaceSTL("skin.stl")),
plot::Scene3d(plot::SurfaceSTL("skin.stl", UseNormals = FALSE)),
Width = 120*unit::mm, Height = 140*unit::mm, Layout = Vertical,
BackgroundStyle = Pyramid, Axes = None):
```



See Also MeshListMeshListNormalsFilled

Purpose

TipAngle

Opening angle of arrow heads

Value Summary

Inherited	Positive real number

Graphics Primitives

Objects	TipAngle Default Values
plot::Arrow2d, plot::Arrow3d, plot::Streamlines2d	`(2*PI)/15`
plot::VectorField2d	`0.6283185307`

Description

`TipAngle` determines the opening angle of arrow heads in radians.

`TipAngle` determines the opening angle of the tips of arrows of type plot::Arrow2d and plot::Arrow3d. Also the arrow tips in a vector field of type plot::VectorField2d are controlled by `TipAngle`. The opening angle must be specified in radians. Values for `TipAngle` between 0 and π are reasonable.

The tip angle is the geometric angle of the arrow heads as visible in the graphical output. It is invariant under scaling and zooming.

The values of `TipAngle` cannot be animated.

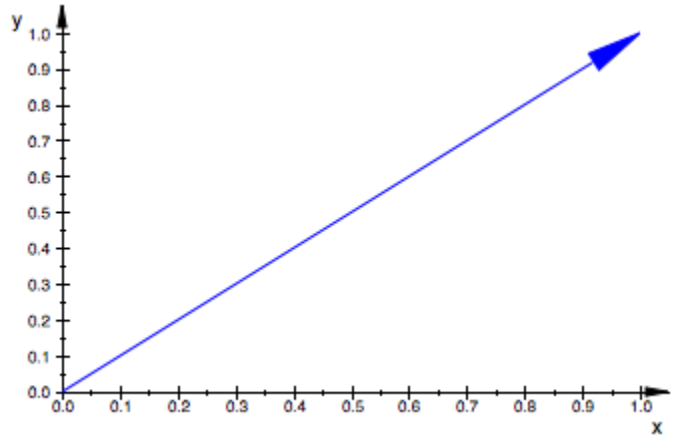
The attribute TipStyle sets the presentation style of arrow tips. TipLength sets the physical tip length.

Examples

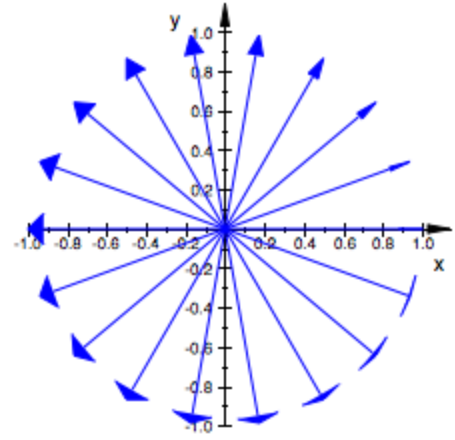
Example 1

We create an arrow whose arrow tip has an angle of 20 degrees. This corresponds to PI/9 radians:

```
plot(plot::Arrow2d([0, 0], [1, 1], TipAngle = PI/9, TipLength =
10*unit::mm)):
```

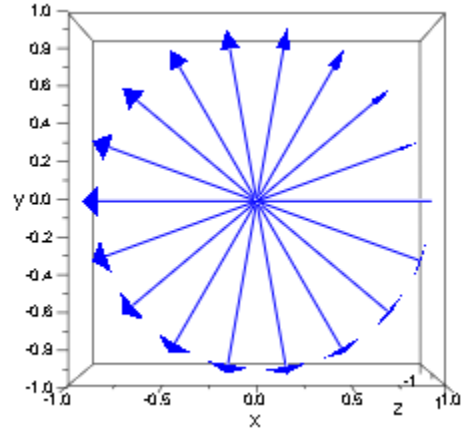


We create several arrows with different tip angles. The angle is increased by 10 degrees from one arrow to the next:
plot(plot::Arrow2d([0, 0], [cos(a*2*PI/18), sin(a*2*PI/18)], TipAngle = a*PI/18) $ a = 0 .. 17, Scaling = Constrained):

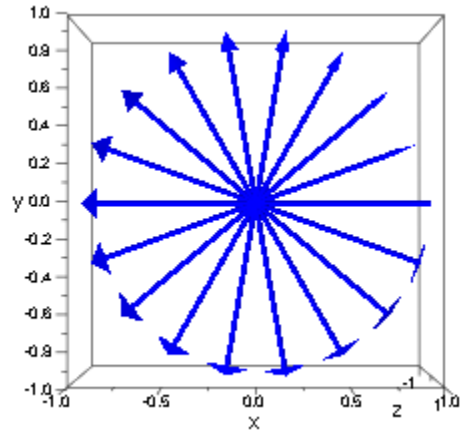


Here are corresponding arrows in 3D:

plot(plot::Arrow3d([0, 0, 0], [cos(a*2*PI/18), sin(a*2*PI/18), 0], TipAngle = a*PI/18) $ a = 0 .. 17, Scaling = Constrained, CameraDirection = [0, -10, 1000]):



We use Tubular = TRUE:
plot(plot::Arrow3d([0, 0, 0], [cos(a*2*PI/18), sin(a*2*PI/18), 0], TipAngle = a*PI/18) $ a = 0 .. 17, Tubular = TRUE, Scaling = Constrained, CameraDirection = [0, -10, 1000]):



See Also TipLengthTipStyleTubeDiameterTubular

Purpose

TipLength

Length of arrow heads

Value Summary

Inherited	Non-negative output size

Graphics Primitives

Objects	TipLength Default Values
plot::Arrow2d, plot::Arrow3d	4
plot::VectorField2d	1.5
plot::Streamlines2d	0

Description

`TipLength` determines the physical length of arrow heads

`TipLength` determines the length of the tips of arrows of type plot::Arrow2d and plot::Arrow3d. Also the arrow tips in a vector field of type plot::VectorField2d are controlled by `TipLength`. The value should be specified as an absolute physical length including a length unit such as `TipLength = 2.5*unit::mm`. Numbers without a physical unit give the size in mm.

The tip length is the physical length of the arrow heads as visible in the graphical output. It is invariant under scaling and zooming.

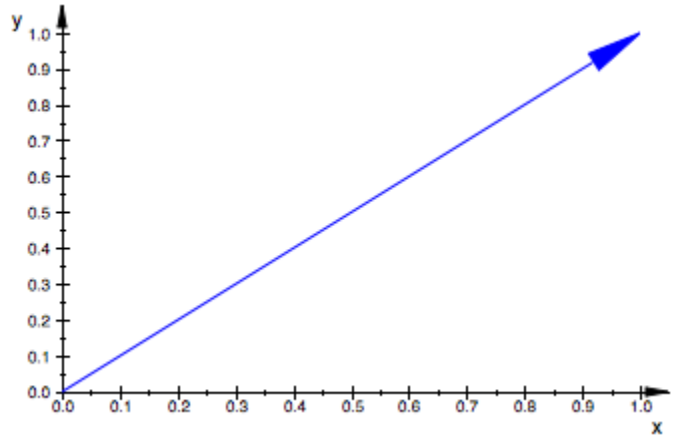
The values of `TipLength` cannot be animated.

The attribute TipStyle sets the presentation style of arrow tips. TipAngle sets the opening angle of the tips.

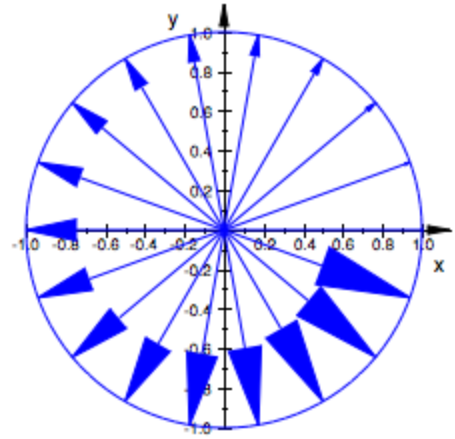
Examples

Example 1

We create an arrow whose tip has physical length of 10 mm:
plot(plot::Arrow2d([0, 0], [1, 1], TipAngle = PI/9, TipLength = 10*unit::mm)):

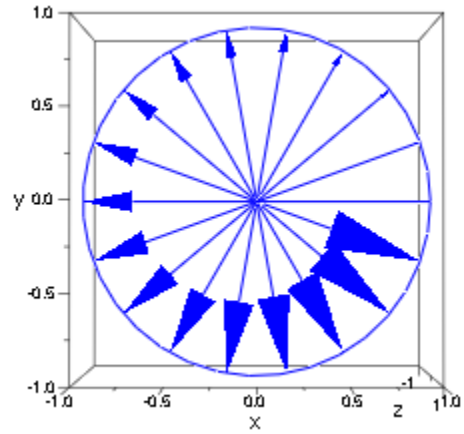


We create several arrows with different tip lengths. The length is increased by 0.7 mm from one arrow to the next:
plot(plot::Arrow2d([0, 0], [cos(a*2*PI/18), sin(a*2*PI/18)], TipLength = a*unit::mm) $ a = 0 .. 17, plot::Circle2d(1, [0, 0]), Scaling = Constrained):



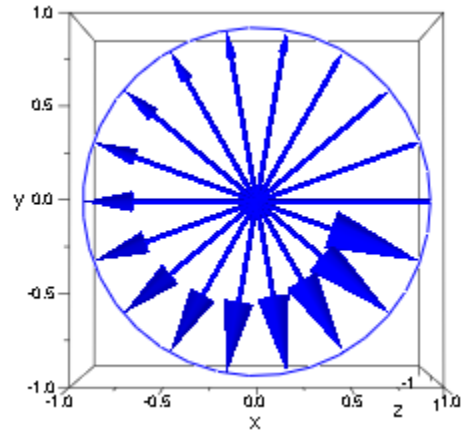
Here are corresponding arrows in 3D:

```
plot(plot::Arrow3d([0, 0, 0], [cos(a*2*PI/18), sin(a*2*PI/18), 0],
TipLength = a*unit::mm) $ a = 0 .. 17, plot::Circle3d(1, [0, 0, 0], [0, 0,
1]), Scaling = Constrained, CameraDirection = [0, -10, 1000]):
```



We use Tubular = TRUE:

```
plot(plot::Arrow3d([0, 0, 0], [cos(a*2*PI/18), sin(a*2*PI/18), 0],
TipLength = a*unit::mm) $ a = 0 .. 17, plot::Circle3d(1, [0, 0, 0], [0,
0, 1]), Tubular = TRUE, Scaling = Constrained, CameraDirection =
[0, -10, 1000]):
```



See Also TipAngleTipStyleTubeDiameterTubular

Purpose

TipStyle

Presentation style of arrow heads

Value Summary

Inherited	Closed, Filled, or `Open`

Graphics Primitives

Objects	TipStyle Default Values
plot::Arrow2d, plot::Arrow3d, plot::Streamlines2d	`Filled`
plot::VectorField2d	`Open`

Description

`TipStyle` governs the appearance of arrow heads.

`TipStyle` determines how the tips of arrows of type plot::Arrow2d and plot::Arrow3d look. Also the arrow tips in a vector field of type plot::VectorField2d are controlled by `TipStyle`.

With `TipStyle` = `Open`, the tips are given by two lines.

With `TipStyle` = `Closed`, the tips are given by a triangle.

With `TipStyle` = `Filled`, the tips are given by a filled triangle.

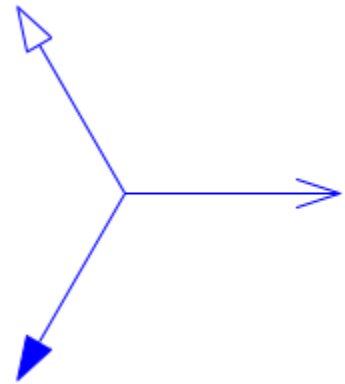
`TipStyle` cannot be animated.

The opening angle and the physical length of the arrow tips are set by the attributes TipAngle and TipLength, respectively.

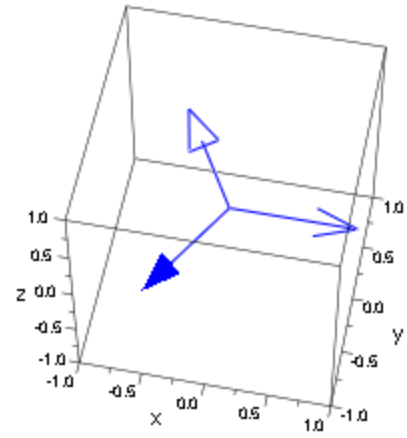
Examples

Example 1

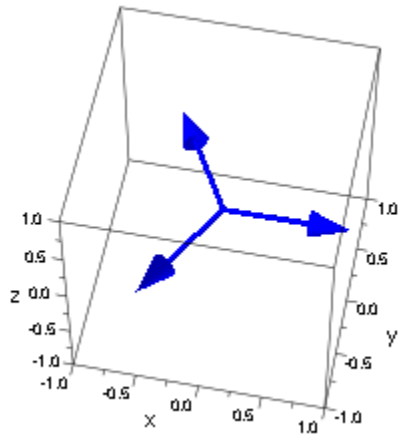
We draw arrows with different tip styles:
plot(plot::Arrow2d([0, 0], [1, 0], TipStyle = Open), plot::Arrow2d([0, 0], [cos(2*PI/3), sin(2*PI/3)], TipStyle = Closed), plot::Arrow2d([0, 0], [cos(4*PI/3), sin(4*PI/3)], TipStyle = Filled), Axes = None, ViewingBox = [-1..1, -1..1], TipLength = 8*unit::mm, TipAngle = PI/5, Scaling = Constrained):



Here are corresponding arrows in 3D:
plot(plot::Arrow3d([0, 0, 0], [1, 0, 0], TipStyle = Open), plot::Arrow3d([0, 0, 0], [cos(2*PI/3), sin(2*PI/3), 0], TipStyle = Closed), plot::Arrow3d([0, 0, 0], [cos(4*PI/3), sin(4*PI/3), 0], TipStyle = Filled), ViewingBox = [-1..1, -1..1, -1..1], TipLength = 8*unit::mm, TipAngle = PI/5, Scaling = Constrained, CameraDirection = [2, -10, 15]):



We use Tubular = TRUE:
plot(plot::Arrow3d([0, 0, 0], [1, 0, 0], TipStyle = Open), plot::Arrow3d([0, 0, 0], [cos(2*PI/3), sin(2*PI/3), 0], TipStyle = Closed), plot::Arrow3d([0, 0, 0], [cos(4*PI/3), sin(4*PI/3), 0], TipStyle = Filled), TipLength = 8*unit::mm, TipAngle = PI/5, Tubular = TRUE, ViewingBox = [-1..1, -1..1, -1..1], Scaling = Constrained, CameraDirection = [2, -10, 15]):



See Also TipAngleTipLengthTubeDiameterTubular

TubeDiameter

Purpose

Diameter of tubular arrows and lines. , and coordinate axes

Value Summary

Inherited	Positive output size

Graphics Primitives

Objects	TubeDiameter Default Values
plot::Arrow3d, plot::Line3d	`1.0`

Description

`TubeDiameter` governs the size of tubular arrows and lines in 3D.

Arrows of type plot::Arrow3d as well as lines of type plot::Line3d can be rendered as 3D tubes by setting the attribute Tubular = `TRUE`.

The attribute `TubeDiameter` determines the diameter of tubular arrows and lines. Its value should be specified as an absolute physical length including a length unit such as `TubeDiameter = 2.5*unit::mm`. Numbers without a physical unit give the size in mm.

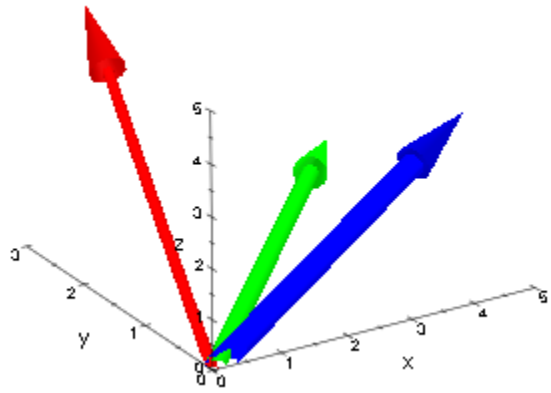
Tubular arrows have a tip that is rendered as a little cone. The size of these cones is adjusted when the diameter of the arrow shaft changes.

The attribute `TubeDiameter` is not available in 2D.

Examples

Example 1

We draw some tubular arrows with different tube diameters:
plot(plot::Arrow3d([0, 0, 0], [1, 3, 5], Color = RGB::Red, TubeDiameter = 2.0*unit::mm), plot::Arrow3d([0, 0, 0], [5, 3, 1], Color = RGB::Green, TubeDiameter = 3.0*unit::mm), plot::Arrow3d([0, 0, 0], [5, 1, 3], Color = RGB::Blue, TubeDiameter = 4.0*unit::mm), Tubular = TRUE, TipLength = 18*unit::mm, Axes = Origin):



See Also TipAngleTipLength

Tubular

Purpose

Display 3D arrows and lines as tubes?

Value Summary

Inherited	FALSE, or TRUE

Graphics Primitives

Objects	Tubular Default Values
plot::Arrow3d, plot::Line3d	FALSE

Description

With `Tubular = TRUE`, arrows of type plot::Arrow3d and lines of type plot::Line3d are rendered as tubes (cylinders). The diameter is set by the attribute TubeDiameter.

Tubular arrows have a tip that is rendered as a little cone. The tip is determined by the attributes TipLength and TipAngle.

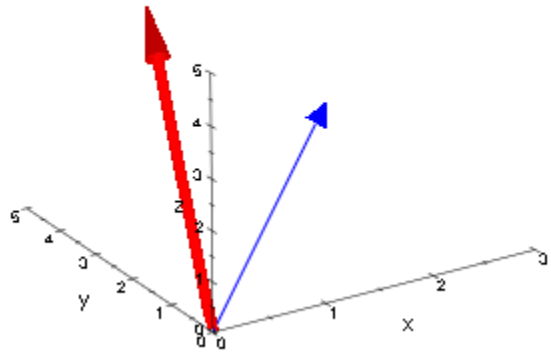
With `Tubular = FALSE`, arrows and lines are displayed as simple lines.

The attribute `Tubular` is not available in 2D.

Examples

Example 1

We draw a tubular arrow together with an arrow displayed as a line:
plot(plot::Arrow3d([0, 0, 0], [1/2, 3, 5], Tubular = TRUE, TubeDiameter = 2*unit::mm, Color = RGB::Red), plot::Arrow3d([0, 0, 0], [3, 5, 1], Tubular = FALSE, Color = RGB::Blue), TipLength = 12*unit::mm, Axes = Origin):



See Also TubeDiameterTipAngleTipLength

polylib – Manipulating Polynomials

==REFNAME==

polylib::coeffRing

Purpose

Coefficient ring of a polynomial

Syntax

```
polylib::coeffRing(P)
polylib::coeffRing(p)
```

Description

`polylib::coeffRing(p)` returns the coefficient ring of `p`.

`polylib::coeffRing`(p) allows to query in a uniform way the coefficient ring of the polynomial `p` or the polynomial domain `P`.

`P` can be any polynomial domain (Dom::UnivariatePolynomialx, Dom::DistributedPolynomial[x,y], ...).

`P` can also be of the form `polylib::Poly([x,y],K)`. If `K` is Expr or `IntMod(n)`, then the corresponding domains `Dom::ExpressionField()` or `Dom::IntegerMod(p)` is returned. See poly for the details about Expr and `IntMod(n)`.

`p` can be a kernel polynomial (DOM_POLY), or an element of one of the above domains

Examples

Example 1

We define a polynomial ring over the ring of integers modulo 4, and query for its coefficient ring:
P := Dom::UnivariatePolynomial(x, Dom::IntegerMod(4)):
polylib::coeffRing(P)Dom::IntegerMod(4)

Dom::IntegerMod(4)

The coefficient ring of the elements of this domain can be queried the same way:
polylib::coeffRing(P(x))Dom::IntegerMod(4)

Dom::IntegerMod(4)

polylib::coeffRing(Dom::Matrix(Dom::IntegerMod(3)))Dom::IntegerMod(3)

Dom::IntegerMod(3)

Example 2

When no coefficient ring is specified, poly currently constructs kernel polynomials over the fake domain Expr instead of the mathematically equivalent field `Dom::ExpressionField()` of arbitrary expression (this happens to be more efficient with the current kernels):
extop(poly(x))x, [x], Expr

x, [*x*], Expr
polylib::coeffRing(poly(x))Dom::ExpressionField()

Dom::ExpressionField()

This makes it possible to plug the result right away as coefficient ring of some other domain:
Dom::UnivariatePolynomial(x,
polylib::coeffRing(poly(x)))Dom::UnivariatePolynomial(x,
Dom::ExpressionField(), LexOrder)

Dom::UnivariatePolynomial(*x*, Dom::ExpressionField(), LexOrder)

Parameters

P

A polynomial domain

P

A polynomial

Return Values

Domain

polylib::cyclotomic

Purpose

Cyclotomic polynomials

Syntax

```
polylib::cyclotomic(n, x)
```

Description

`polylib::cyclotomic(n, x)` computes the n-th cyclotomic polynomial, expressed in the indeterminate x.

The n-th cyclotomic polynomial is defined to be the minimal polynomial of any n-th primitive root of unity over the field of rational numbers.

Examples

Example 1

We compute the 20th cyclotomic polynomial.

```
polylib::cyclotomic(20, z);poly(z^8 - z^6 + z^4 - z^2 + 1, [z])
```

$$\mathrm{poly}\left(z^8 - z^6 + z^4 - z^2 + 1, [z]\right)$$

Parameters

n

Positive integer

x

Identifier

Return Values

Polynomial over `Expr` in the indeterminate `x`.

See Also

numlib::phi

polylib::decompose

Purpose

Functional decomposition of a polynomial

Syntax

```
polylib::decompose(p)
polylib::decompose(p, x)
```

Description

`polylib::decompose(p,x)` returns a sequence of polynomials q_1, ..., q_n such that $p(x) = q_1(...q_n(x)...)$.

The second argument may be left out if the polynomial is univariate, as in "Example 1" on page 25-5.

If a polynomial has several decompositions, it is not specified which of them is returned.

Examples

Example 1

In the simplest case, an univariate polynomial is decomposed with respect to its only variable:
polylib::decompose(x^4+x^2+1)x^2 + x + 1, x^2

$$x^2 + x + 1,\ x^2$$

Example 2

If there are several variables, a main variable must be specified:
polylib::decompose(y*x^4+y,y);y*x^4 + y

$$y\,x^4 + y$$

Parameters

p

Polynomial or polynomial expression

x

One of the indeterminates of the polynomial `p`

Return Values If a decomposition is possible, `polylib::decompose` returns it as an expression sequence, each element being of the same type as the input. If no decomposition is possible, the input is returned.

Overloaded By p

References A description of the algorithm behind `polylib::decompose` can be found in *Barton and Zippel*, Polynomial decomposition algorithms, Journal of Symbolic Computation, 1 (1985), pp. 159–168.

See Also factor

polylib::discrim

Purpose

Discriminant of a polynomial

Syntax

```
polylib::discrim(p, x)
```

Description

`polylib::discrim(p, x)` returns the discriminant of the polynomial `p` with respect to the variable `x`.

The function normal is applied to the discriminant before returning it.

Examples

Example 1

We compute the discriminant of the general quadratic equation:
polylib::discrim(a*x^2 + b*x + c, x);b^2 - 4*a*c

$$b^2 - 4\,a\,c$$

Parameters

x

Indeterminante

p

Polynomial or polynomial expression

Return Values

`polylib::discrim` returns an element of the coefficient ring of `p`. If the coefficient ring is `Expr` or `IntMod(n)`, an expression is returned.

Overloaded By

`p`

Algorithms

The discriminant of `p` with respect to the variable `x` is defined as:

fenced(-1)^(d * fenced(d-1)/2) * res[x](p,p')/c

$$\frac{(-1)^{\frac{d(d-1)}{2}} \operatorname{res}_x(p, p')}{c}$$

where d is the degree and c is the leading coefficient of p.

See Also polylib::resultant

polylib::divisors

Purpose

Divisors of a polynomial, polynomial expression, or Factored element

Syntax

```
polylib::divisors(p)
polylib::divisors(f)
polylib::divisors(e)
```

Description

`polylib::divisors(p)` computes the set of all monic divisors of the polynomial or polynomial expression `p`.

`polylib::divisors(f)` returns all monic divisors of a pre-factored polynomial. Cf. “Example 3” on page 25-9.

`polylib::divisors` works on polynomials of category Cat::Polynomial as well. Cf. “Example 4” on page 25-10.

Examples

Example 1

If the argument is a polynomial, a set of polynomials is returned:
polylib::divisors(poly(x^2 - 2*x + 1)){poly(1, [x]), poly(x - 1, [x]), poly(x^2 - 2*x + 1, [x])}

$$\{\mathrm{poly}(1, [x]),\ \mathrm{poly}(x - 1, [x]),\ \mathrm{poly}(x^2 - 2\,x + 1, [x])\}$$

Example 2

If the argument is a polynomial expression, a set of polynomial expressions is returned:
polylib::divisors(x^2 - 1){1, x^2 - 1, x - 1, x + 1}

$$\{1,\ x^2 - 1,\ x - 1,\ x + 1\}$$

Example 3

If the argument is of type Factored (a factor return value) a set of polynomials is returned:
p := factor(poly(x^2 - 1)); polylib::divisors(p)poly(x - 1, [x])*poly(x + 1, [x])

$\text{poly}(x-1,[x])\ \text{poly}(x+1,[x])$

{poly(1, [x]), poly(x - 1, [x]), poly(x + 1, [x]), poly(x^2 - 1, [x])}

$\{\text{poly}(1,[x]),\ \text{poly}(x-1,[x]),\ \text{poly}(x+1,[x]),\ \text{poly}(x^2-1,[x])\}$

The polynomials in the resulting set have the same type as the polynomials in the Factored element:
p := factor(x^2 - 1); polylib::divisors(p)(x - 1)*(x + 1)

$(x-1)\ (x+1)$

{1, x^2 - 1, x - 1, x + 1}

$\{1,\ x^2-1,\ x-1,\ x+1\}$

Example 4

`polylib::divisors` works on polynomials from category Cat::Polynomial as well:
P := Dom::Polynomial(Dom::IntegerMod(7)): polylib::divisors(P(x^3 + 2*x^2 + 1))

{1 mod 7, (1 mod 7)*x^3 + (2 mod 7)*x^2 + (1 mod 7)}

$\{1 \bmod 7,\ (1 \bmod 7)\,x^3 + (2 \bmod 7)\,x^2 + (1 \bmod 7)\}$

Parameters

p

A polynomial or polynomial expression

f

Factored (return value of factor)

e

Element of a domain of category Cat::Polynomial

Return Values

`polylib::divisors` returns a set of polynomials. The polynomials are from the same type as the polynomials in the argument.

See Also

Cat::PolynomialDOM_POLYDom::PolynomialDom::MultivariatePolynomialDom::U

polylib::Dpoly

Purpose

Differential operator for polynomials

Syntax

```
polylib::Dpoly(f)
polylib::Dpoly(indexlist, f)
```

Description

If `f` is a polynomial in the indeterminates `x1` through xn, `polylib::Dpoly([i1,..,ik], f)` computes the *k*-th partial derivative

diff(f, x[i1], dots, x[ik]) $\frac{\partial}{\partial x_{ik}} \frac{\partial}{\partial \ldots} \frac{\partial}{\partial x_{i1}} f$.

`polylib::Dpoly(f)` returns the derivative of `f` with respect to its only variable for an univariate polynomial `f`.

If some element of `indexlist` is greater than the number of indeterminates of `f`, the zero polynomial is returned.

`polylib::Dpoly([], p)` returns `p`.

If the coefficients of the polynomial are elements of a domain `d`, then this domain must have the method `"intmult"` (`d::intmult(e,i)`) that must calculate the integer multiple of a domain element `e` and a positive integer `i`.

Examples

Example 1

We differentiate a univariate polynomial with respect to its only indeterminate. In this case, we may leave out the first argument.
polylib::Dpoly(poly(2*x^2 + x + 1));poly(4*x + 1, [x])

poly(4 *x* + 1, [*x*])

Example 2

Now we differentiate a bivariate polynomial, and must specify the indeterminate in this case.
polylib::Dpoly([1], poly(x^2*y + 3*x + y, [x, y]));poly(2*x*y + 3, [x, y])

poly(2 *x* *y* + 3, [*x*, *y*])

Example 3

It is also possible to compute second or higher partial derivatives.
polylib::Dpoly([1, 2], poly(x^2*y + 3*x + y, [x, y]));poly(2*x, [x, y])

Parameters

f

Polynomial

indexlist

List of positive integers

Return Values

`polylib::Dpoly` returns a polynomial in the same indeterminates and over the same coefficient ring as the input.

Overloaded By

`f`

See Also

Ddiff

polylib::elemSym

Purpose

Elementary symmetric polynomials

Syntax

```
polylib::elemSym(l, k)
```

Description

`polylib::elemSym([x1,...,xn], k)` returns the `k`-th elementary symmetric polynomial in the given variables `x1` through `xn`.

A given list `l` is a valid first argument only if its elements can be used as indeterminates of a polynomial .

Examples

Example 1

The first elementary symmetric polynomial is just the sum of its variables:
polylib::elemSym([x,y,z], 1);poly(x + y + z, [x, y, z])

$$\mathrm{poly}(x + y + z, [x, y, z])$$

Example 2

Indeterminates may also be e.g. trigonometric functions:
polylib::elemSym([sin(u),cos(u), exp(u)], 2);poly(sin(u)*cos(u) + sin(u)*exp(u) + cos(u)*exp(u), [sin(u), cos(u), exp(u)])

$$\mathrm{poly}(\sin(u)\cos(u) + \sin(u)\,e^{u} + \cos(u)\,e^{u}, [\sin(u), \cos(u), e^{u}])$$

Parameters

l

List of indeterminatess

k

Positive integer

Return Values

Result is a polynomial over the coefficient ring Expr. If `k` is greater than the number of operands of `l`, undefined is returned.

References

For more information about elementary symmetric polynomials, see v.d. Waerden, Algebra, vol. 1.

See Also

polylib::representByElemSym

polylib::makerat

Purpose

Convert expression into rational function over a suitable field

Syntax

```
polylib::makerat(a, <maxd>)
polylib::makerat(l, <maxd>)
```

Description

`polylib::makerat(a)` returns two polynomials f and g over the rationals and a list of substitutions such that applying the substitutions to the rational function (f)/(g) $\frac{f}{g}$ gives `a`.

`polylib::makerat(l)` does the same for every element of the list `l` and returns lists of resulting f's and g's.

`polylib::makerat(a, maxd)` replaces d-th roots of integers by elements of some algebraic extension field over the rationals if $d \leq maxd$, and returns polynomials f and g over that extension field.

`polylib::makerat(a)` replaces all irrational subexpressions (except identifiers) in `a` by newly created identifiers, thereby producing a rational function over the rationals. It returns the numerator and denominator of that rational function as polynomials over `Expr`, and the substitutions to be made to get back the numerator and denominator of the original input `a`.

`polylib::makerat(l)` replaces all irrational subexpressions in all elements of `l` by newly created identifiers.

Every subexpression is replaced by the same identifier every time it occurs.

All indeterminates of the input and all of the new identifiers become indeterminates of the result, unless a second argument `maxd` is given.

The imaginary unit I is handled in a special way: it is replaced by the element `` `#I` `` of the algebraic extension field with minimal polynomial `` `\#I`^2 + 1 ``. If I occurs in the input, the result consists of polynomials over that extension field.

If a second argument `maxd` is given, d-th roots of rationals are replaced by elements of a suitable field extension of the rationals if $d \leq maxd$.

In the same way, nested fractional powers of rationals are replaced unless the denominator of some exponent exceeds `maxd`. In this case, the returned result consists of polynomials over a tower of extension fields over the rationals.

Examples

Example 1

In the simplest case (integer polynomial), the numerator equals the input, the denominator equals 1, and no substitutions are necessary:
polylib::makerat(x^2+3)poly(x^2 + 3, [x]), poly(1, [x]), []

$$\mathrm{poly}\left(x^2 + 3, [x]\right), \mathrm{poly}(1, [x]), []$$

Example 2

Transcendental expressions are replaced by new identifiers. The result indicates on which variables the generated identifiers depend:
polylib::makerat(sin(u)/x)poly(X5, [X5, x]), poly(x, [X5, x]), [X5 = sin(u)]

$$\mathrm{poly}(X5, [X5, x]), \mathrm{poly}(x, [X5, x]), [X5 = \sin(u)]$$

Example 3

Floating point numbers are considered transcendental:
polylib::makerat(0.27*x)poly(X9*x, [X9, x]), poly(1, [X9, x]), [X9 = 0.27]

$$\mathrm{poly}(X9\ x, [X9, x]), \mathrm{poly}(1, [X9, x]), [X9 = 0.27]$$

Example 4

By default, radicals are treated like transcendental subexpressions:
polylib::makerat(sqrt(2)/x)poly(X12, [X12, x]), poly(x, [X12, x]), [X12 = sqrt(2)]

$$\mathrm{poly}(X12, [X12, x]), \mathrm{poly}(x, [X12, x]), [X12 = \sqrt{2}]$$

Example 5

If a sufficiently large second argument is given, radicals are replaced by elements of algebraic extensions:
polylib::makerat(sqrt(2)/x, 2)poly(X16, [x], Dom::AlgebraicExtension(Dom::Rational, X16^2 - 2 = 0, X16)), poly(x, [x], Dom::AlgebraicExtension(Dom::Rational, X16^2 - 2 = 0, X16)), [X16 = sqrt(2)]

Parameters

$$\text{poly}\left(X16, [x], \text{Dom::AlgebraicExtension}\left(\text{Dom::Rational}, X16^2 - 2 = 0, X16\right)\right),$$

$$\text{poly}\left(x, [x], \text{Dom::AlgebraicExtension}\left(\text{Dom::Rational}, X16^2 - 2 = 0, X16\right)\right), [X16 = \sqrt{2}]$$

a

Polynomial over `Expr` or arithmetical expression

l

List or set of polynomials over `Expr` or arithmetical expressions

maxd

Positive integer

Return Values

`polylib::makerat` returns an expression sequence consisting of three operands:

- The first operand represents the numerator (or the list/set of numerators, respectively). It is a single polynomial if the call was `polylib::makerat(a)`, otherwise it is a set or list of polynomials (the same type as the input). The polynomial(s) may have more indeterminates than the input. The coefficient ring is either `Expr` or a Dom::AlgebraicExtension.
- The second operand represents the denominator (or the list/set of denominators, respectively). It is of the same type as the first operand.
- The third operand is a list of equations.

See Also rationalize

polylib::minpoly

Purpose

Approximate minimal polynomial

Syntax

```
polylib::minpoly(a, n, x)
```

Description

`polylib::minpoly(a, n, x)` computes a univariate polynomial `f` in the variable `x` of degree `n` with integer coefficients such that `a` equals a root of `f` up to the precision given by `DIGITS`, and such that the sum of squares of its coefficients is minimal among all polynomials with this property.

Environment Interactions

`polylib::minpoly` is sensitive to the environment variable `DIGITS`.

Examples

Example 1

We compute a polynomial of degree 4 that has a root close to PI (up to 6 decimal digits) and small integer coefficients:
DIGITS:=6: polylib::minpoly(PI, 4, x); delete DIGITS:poly(x^4 - 5*x^3 + 5*x^2 + 9*x - 20, [x])

$$\mathrm{poly}\left(x^4 - 5\,x^3 + 5\,x^2 + 9\,x - 20, [x]\right)$$

If the root has to be even closer to PI, bigger coefficients are needed:
DIGITS:=20: polylib::minpoly(PI, 4, x); delete DIGITSpoly(- 108*x^4 - 1717*x^3 + 6952*x^2 - 258*x - 4045, [x])

$$\mathrm{poly}\left(-108\,x^4 - 1717\,x^3 + 6952\,x^2 - 258\,x - 4045, [x]\right)$$

Parameters

a

Arithmetical expression that can be converted to a floating point number

n

Positive integer

x

Identifier

Return Values

`polylib::minpoly` returns a polynomial in `x`. Its coefficient ring is `Expr`, all of its coefficients are integers.

Algorithms

The problem reduces to finding a shortest integer vector in the lattice ImageSet(e[i]+a^i*e[(n+1)], 0 <= i <= n)$\{e_i + a^i e_{n+1} \mid 0 \le i \le n\}$, where e_i denotes the vector with $e_i[j] = \delta_{i,j}$ (Kronecker symbol). This problem is solved using the algorithm of Lenstra/Lenstra/Lovasz.

Lenstra/Lenstra/Lovasz, Factoring polynomials with rational coefficients, Math. Ann. 261(1982), pp. 515–534.

See Also

interpolatelllintstats::linReg

polylib::Poly

Purpose

Domain of polynomials

Syntax

Domain Creation

```
polylib::Poly([x1,  ], <R>)
```

Description

`polylib::Poly([x1,...,xn], R)` creates the ring of polynomials in the unknowns `x1` through `xn` over the coefficient ring `R`. If the argument `R` is missing, `Expr` is used.

`polylib::Poly` is a facade domain; it has no domain elements. It serves only as a coefficient ring for polynomials.

The attempt to create an element of `polylib::Poly` results in a DOM_POLY.

The arithmetical operations of the domain are realized by the corresponding kernel methods.

Examples

Example 1

`polylib::Poly` can be used for defining polynomials in `x` whose coefficients are polynomials in `y`. Such polynomials must not be confused with bivariate polynomials in `x` and `y`.

```
delete x,y:  e:= x*(y^2*2 + y) + 3*y:  poly(e, [x, y]); poly(e, [x],
polylib::Poly([y]))poly(2*x*y^2 + x*y + 3*y, [x, y])
```

$$\mathrm{poly}(2\,x\,y^2 + x\,y + 3\,y,\ [x,\ y])$$

```
poly((y + 2*y^2)*x + 3*y, [x], polylib::Poly([y], Expr))
```

$$\mathrm{poly}((y + 2\,y^2)\,x + 3\,y,\ [x],\ \mathrm{polylib::Poly}([y],\ \mathrm{Expr}))$$

Parameters

x_1

Unknown

R

Admissible coefficient ring for polynomials. See poly.

Entries

"zero"	the zero polynomial
"one"	the constant polynomial one
"indets"	list of unknowns
"coeffRing"	the coefficient ring `R`

See Also

Dom::DistributedPolynomial

polylib::primitiveElement

Purpose

Primitive element for tower of field extensions

Syntax

```
polylib::primitiveElement(F, G)
```

Description

For given field extensions $F = K(\alpha)$ and $G = F(\beta)$, `polylib::primitiveElement(F, G)` returns a list consisting of a simple algebraic extension of K that is K-isomorphic to G, a symbol for a primitive element of that extension, and the images of α and β under some fixed K-isomorphism.

It is presumed that the extension is separable. Otherwise, it may happen that the algorithm does not terminate.

Examples

Example 1

Since the rational numbers are perfect, extensions of them can always be handled:

```
F := Dom::AlgebraicExtension(Dom::Rational, sqrt2^2 - 2): G := Dom::AlgebraicExtension(F, sqrt3^2 - 3):
```

Now G=Q(sqrt(2), sqrt(3))$G = Q(\sqrt{2}, \sqrt{3})$, and we use `polylib::primitiveElement` to find a primitive element for `G`:

```
polylib::primitiveElement(F, G)[Dom::AlgebraicExtension(Dom::Rational, X1^4 - 10*X1^2 + 1 = 0, X1), X1, X1^3/2 - (9*X1)/2, (11*X1)/2 - X1^3/2]
```

$$\left[\text{Dom::AlgebraicExtension}\left(\text{Dom::Rational}, -10\,X1^2 + X1^4 + 1 = 0, X1\right), X1, \frac{X1^3}{2} - \frac{9\,X1}{2}, \frac{11\,X1}{2} - \frac{X1^3}{2}\right]$$

This means that a primitive element X_1 of the extension is determined by its minimal polynomial ${X_1}^4 - 10{X_1}^2 + 1$. The last two operands of the list are field elements whose squares are 2 and 3, respectively.

Example 2

The function works also for subdomains of Dom::AlgebraicExtension, e.g., Galois fields.

```
F := Dom::GaloisField(7, 2): G :=
Dom::GaloisField(F, 2): polylib::primitiveElement(F,
G)[Dom::AlgebraicExtension(Dom::IntegerMod(7), X5^4 + 2*X5^3 -
X5^2 + 3*X5 - 1 = 0, X5), X5, - 3*X5^3 + 3*X5^2 - 3*X5 - 2, X5]
```

$$[\text{Dom::AlgebraicExtension}(\text{Dom::IntegerMod}(7),\ 3\,X5 - X5^2 + 2\,X5^3 + X5^4 - 1 = 0,\ X5),\ X5,\ -3\,X5^3 + \ldots$$

Parameters

F

A field created by Dom::AlgebraicExtension

G

A field created by Dom::AlgebraicExtension with ground field `F`

Return Values

List consisting of four operands:

- a field `H` of type Dom::AlgebraicExtension over the same ground field as `F`;
- an identifier that equals the entry `H::variable`;
- an object of type `H` that satisfies the minimal polynomial for α;
- an object of type `H` that satisfies the minimal polynomial for β.

Algorithms

The chosen primitive element is $\alpha + s\beta$, where s is a positive integer.

See Also

Dom::AlgebraicExtensionpolylib::splitfield

polylib::primpart

Purpose

Primitive part of a polynomial

Syntax

```
polylib::primpart(f)
polylib::primpart(q)
polylib::primpart({xpr}, <{inds}>)
```

Description

`polylib::primpart(f)` returns the primitive part of the polynomial `f`.

If the input is a polynomial, the greatest common divisor of its coefficients is removed. The function gcd must be able to calculate this gcd.

If the first argument is an expression, it is converted into a polynomial in the indeterminates specified by the second argument, or in all of its indeterminates if no second argument is given. `polylib::primpart` returns FAIL if the expression cannot be converted into a polynomial.

For a rational number, its sign is returned.

Examples

Example 1

In the following example, a bivariate polynomial is given. Its coefficients are the integers 3, 6, and 9; the primitive part is obtained by dividing the polynomial by their gcd.

```
polylib::primpart(poly(6*x^3*y + 3*x*y + 9*y, [x, y]));poly(2*x^3*y
+ x*y + 3*y, [x, y])
```

$$\mathrm{poly}(2\,x^3\,y + x\,y + 3\,y, [x, y])$$

However, consider the same polynomial viewed as a univariate polynomial in `x`. Its coefficients are polynomials in `y` in this case, and their gcd `3*y` is divided off.

```
polylib::primpart(poly(6*x^3*y + 3*x*y + 9*y, [x]));poly(2*x^3 + x + 3,
[x])
```

$$\mathrm{poly}(2\,x^3 + x + 3, [x])$$

Example 2

`polylib::primpart` divides the coefficients by their gcd, but does not normalize the result. This must be done explicitly:

```
polylib::primpart(4*x*y + 6*x^3 + 6*x*y^2 + 9*x^3*y, [x])(x^3*(9*y + 6))/(3*y + 2) + (x*(6*y^2 + 4*y))/(3*y + 2)
```

$$\frac{x^3\,(9\,y+6)}{3\,y+2}+\frac{x\,(6\,y^2+4\,y)}{3\,y+2}$$

```
normal(polylib::primpart(4*x*y + 6*x^3 + 6*x*y^2 + 9*x^3*y, [x]))3*x^3 + 2*y*x
```

$$3\,x^3+2\,y\,x$$

Parameters

f

Polynomial

q

Rational number

xpr

Expression

inds

List of identifiers

Return Values

`polylib::primpart` returns an object of the same type as the input, or FAIL.

Overloaded By

`f`

Algorithms

The primitive part of a polynomial f is a polynomial g whose coefficients are relatively prime such that $f = rg$ for some element r of the coefficient ring.

contentfactorgcdicontentirreducible

polylib::randpoly

Purpose

Create a random polynomial

Syntax

```
polylib::randpoly()
polylib::randpoly(<list>, <ring>, <Degree = n>, <Terms
= k>, <Coeffs = f>, <Monic>)
```

Description

`polylib::randpoly()` returns a univariate random polynomial with integer coefficients; the global identifier `x` is used as the indeterminate.

`polylib::randpoly(list)` returns a random polynomial in all indeterminates given in `list`.

`polylib::randpoly(list, ring)` returns a random polynomial in the indeterminates given in `list` over the coefficient ring `ring`.

See poly for a detailed description of possible indeterminates and coefficient rings.

The polynomial is created by randomly choosing as many exponents as specified through the option `Terms` and then choosing random coefficients. It may of course happen that for some coefficient 0 is chosen, therefore the actual number of terms in the result can be smaller than the value of the option `Terms`.

If the option `Coeffs=f` is given, the random coefficients are generated by calling `f()`. Otherwise, if `ring` is `Expr`, the coefficients will be random integers in the range - 999, ..., 999. If `ring` is a user-defined domain, it must have a method `"random"` to create the coefficients if no function is given.

If the option `Monic` is given, the resulting polynomial has exactly the specified degree and the leading coefficient is 1.

If the requested number of terms exceeds the maximal possible number of terms for the specified degree and number of variables, a warning is emitted and a dense polynomial is created.

Environment Interactions

Unless a generator is specified through the option `Coeffs`, `polylib::randpoly` uses random to create the exponents and coefficients. Therefore it is sensitive to the environment variable `SEED`.

Examples

Example 1

We generate a univariate random polynomial in the indeterminate `z`, and use the default values for the other options. Therefore the polynomial has integer coefficients, is of degree 5, and has 6 terms.
polylib::randpoly([z])poly(- 535*z^5 + 916*z^4 + 663*z^3 - 764*z^2 - 741*z - 65, [z])

$$\mathrm{poly}(-535\,z^5+916\,z^4+663\,z^3-764\,z^2-741\,z-65,\,[z])$$

Example 2

We create a bivariate random polynomial over the finite field with 7 elements. This works because Dom::IntegerMod has a `"random"` slot that generates random elements:
polylib::randpoly([x,y],Dom::IntegerMod(7),Degree=3,Terms=4);poly(2*x^3*y^3 + x^3*y + 4*x*y, [x, y], Dom::IntegerMod(7))

$$\mathrm{poly}(2\,x^3\,y^3+x^3\,y+4\,x\,y,\,[x,\,y],\,\mathrm{Dom::IntegerMod}(7))$$

Parameters

list

List of indeterminates

ring

Coefficient ring

Options

Degree

Option, specified as `Degree = k`

The maximum degree the result can have in each variable. `k` must be a nonnegative integer. Default is 6.

Terms

Option, specified as `Terms = t`

Makes `polylib::randpoly` generate the sum of `t` random terms. `t` must be a positive integer or infinity. If `t` equals infinity, `polylib::randpoly` returns a dense polynomial. Default is 5.

Coeffs

Option, specified as `Coeffs = f`

Create the coefficients of the result by calling `f()`.

Monic

The created polynomial is monic, i.e., the leading coefficient is 1.

Return Values

Polynomial in the given indeterminates over the given ring. If no list of indeterminates is given, `[x]` is used. If no ring is given, `Expr` is used.

See Also

polyrandom

polylib::realroots

Purpose

Isolate all real roots of a real univariate polynomial

Syntax

```
polylib::realroots(p)
polylib::realroots(p, eps)
```

Description

`polylib::realroots(p)` returns intervals isolating the real roots of the real univariate polynomial `p`.

`polylib::realroots(p, eps)` returns refined intervals approximating the real roots of `p` to the relative precision given by `eps`.

All coefficients of `p` must be real and numerical, i.e., either integers, rationals or floating-point numbers. Numerical symbolic objects such as `sqrt(2)`, `exp(10*PI)` etc. are accepted, if they can be converted to real floating-point numbers via float. The same holds for the precision goal `eps`.

The isolating intervals are ordered such that their centers are increasing, i.e., $a_i + b_i < a_{i+1} + b_{i+1}$.

The number `nops(realroots(p))` of intervals is the number of real roots of `p`. Multiple roots are counted only once. Cf. “Example 3” on page 25-35.

Isolating intervals may be quite large. The optional argument `eps` may be used to refine the intervals such that they approximate the real roots to a relative precision `eps`. With this argument the returned intervals satisfy b[i]-a[i]<= eps * abs(a_i+b_i)/2$b_i - a_i \le \frac{\text{eps}\,\left|a_i+b_i\right|}{2}$, i.e., each center fenced(a[i]+b[i])/2$\frac{(a_i+b_i)}{2}$ approximates a root with a relative precision `eps/2`.

Note Some care should be taken when trying to obtain highly accurate approximations of the roots via small values of `eps`. Internally, bisectioning with exact rational arithmetic is used to locate the roots to the precision `eps`. This process may take much more time than determining the isolating intervals without using the second argument `eps` in `polylib::realroots`. It may be faster to use moderate values of `eps` to obtain first approximations of the roots via `polylib::realroots`. These approximations may then be improved by a fast numerical solver such as numeric::fsolve with an appropriately high value of DIGITS. Cf. "Example 6" on page 25-36. However, note that `polylib::realroots` will always succeed in locating the roots to the desired precision eventually. Numerical solvers may fail or return a root not belonging to the interval which was used for the initial approximation.

Note Unexpected results may be obtained when the polynomial contains irrational coefficients. Internally, any such coefficient *c* is converted to a floating-point number. This float is then replaced by an approximating rational number *r* satisfying abs(r-c)<=10^(-(DIGITS)) * abs(c) $|r-c| \le \frac{1}{10^{DIGITS}} |c|$. Finally, `polylib::realroots` returns rigorous bounds for the real roots of the rationalized polynomial. Despite the fact that all coefficients are approximated correctly to `DIGITS` decimal places this may change the roots drastically. In particular, multiple roots or clusters of poorly separated simple roots are very sensitive to small perturbations in the coefficients of the polynomial. See "Example 4" on page 25-35 and "Example 5" on page 25-36.

Environment Interactions

The function is sensitive to the environment variable DIGITS, if there are non-integer or non-rational coefficients in the polynomial. Any such coefficient is replaced by a rational number approximating the coefficient to DIGITS significant decimal places.

Examples

Example 1

We use a polynomial expression as input to `polylib::realroots`:
p := (x - 1/3)*(x - 1)*(x - 4/3)*(x - 2)*(x - 17):polylib::realroots(p)[[0, 1], [1, 1], [1, 2], [2, 2], [16, 32]]

[[0, 1], [1, 1], [1, 2], [2, 2], [16, 32]]

The roots 1 and 2 are found exactly: the corresponding intervals have length 0. The other isolating intervals are quite large. We refine the intervals such that they approximate the roots to 12 decimal places. Note that this is independent of the current value of DIGITS, because no floating-point arithmetic is used:
polylib::realroots(p, 10^(-12))[[1466015503701/4398046511104, 733007751851/2199023255552], [1, 1], [1466015503701/1099511627776, 733007751851/549755813888], [2, 2], [17, 17]]

$$\left[\left[\frac{1466015503701}{4398046511104}, \frac{733007751851}{2199023255552}\right], [1, 1], \left[\frac{1466015503701}{1099511627776}, \frac{733007751851}{549755813888}\right], [2, 2], [17, 17]\right]$$

We convert these exact bounds for the real roots to floating point approximations. Note that with the default value of `DIGITS=10` we ignore 2 of the 12 correct digits the rational bounds could potentially give:
map(%, map, float)[[0.3333333333, 0.3333333333], [1.0, 1.0], [1.333333333, 1.333333333], [2.0, 2.0], [17.0, 17.0]]

[[0.3333333333, 0.3333333333], [1.0, 1.0], [1.333333333, 1.333333333], [2.0, 2.0], [17.0, 17.0]]

delete p:

Example 2

Orthogonal polynomials of degree n have n simple real roots. We consider the Legendre polynomial of degree 5, available in the library `orthpoly` for orthogonal polynomials:
polylib::realroots(orthpoly::legendre(5, x), 10^(-DIGITS)):map(%, float@op, 1)[-0.906179846, -0.5384693101, 0.0, 0.5384693101, 0.9061798459]

[-0.906179846, -0.5384693101, 0.0, 0.5384693101, 0.9061798459]

Example 3

We consider a polynomial with a multiple root:
p := poly((x - 1/3)^3*(x - 1), [x])poly(x^4 - 2*x^3 + (4*x^2)/3 - (10*x)/27 + 1/27, [x])

$$\text{poly}\left(x^4 - 2\,x^3 + \frac{4\,x^2}{3} - \frac{10\,x}{27} + \frac{1}{27}, [x]\right)$$

Note that only one isolating interval `[0, 1]` is returned for the triple root $1/3$:
polylib::realroots(p)[[0, 1], [1, 1]]

[[0, 1], [1, 1]]

delete p:

Example 4

We consider a polynomial with non-rational roots:
p := (x - 3)^2*(x - PI)^2:

Converting the result of `polylib::realroots` to floating-point numbers one sees that the exact roots `3, 3, PI, PI` are approximated only to 3 decimal places:
map(polylib::realroots(p, 10^(-10)), map, float)[[2.998807805, 2.998807805], [3.001213582, 3.001213582], [3.140323518, 3.140323519], [3.142840401, 3.142840401]]

[[2.998807805, 2.998807805], [3.001213582, 3.001213582], [3.140323518, 3.140323519], [3.1

This is caused by the internal rationalization of the coefficients of `p`. Information on the rationalized polynomial may be optained by a builtin userinfo command:
setuserinfo(polylib::realroots, 1):polylib::realroots(p, 10^(-10))Info: polynomial rationalized to poly(x^4 - 12283185307/1000..) ...

The intervals returned by `polylib::realroots(p, 10^(-10))` correctly locate the 4 exact roots of this rationalized polynomial to a precision of 10 digits. However, because all 4 roots are close, the small perturbations of the coefficients introduced by rationalization have a drastic effect on the location of the roots. In particular, rationalization splits the two original double roots into 4 simple roots.
setuserinfo(polylib::realroots, 0): delete p:

Example 5

We consider a further example involving non-exact coefficients. First we approximate the roots of a polynomial with exact coefficients:
p1 := (x - 1/3)^3*(x - 4/3):map(polylib::realroots(p1, 10^(-10)), map, float)[[0.3333333333, 0.3333333333], [1.333333333, 1.333333333]]

```
[[0.3333333333, 0.3333333333], [1.333333333, 1.333333333]]
```

Now we introduce roundoff errors by replacing one entry by a floating-point approximation:
p2 := (x - 1.0/3)^3*(x - 4/3):map(polylib::realroots(p2, 10^(-10)),map,float)[[0.3332481323, 0.3332481323], [1.333333333, 1.333333333]]

```
[[0.3332481323, 0.3332481323], [1.333333333, 1.333333333]]
```

In this example rationalization caused the triple root `1/3` to split into one real root and two complex conjugate roots.
delete p1, p2:

Example 6

We want to approximate roots to a precision of 1000 digits:
p := x^5 - 129/20*x^4 + 69/5*x^3 - 14*x^2 + 12*x - 8:

We recommend not to obtain the result directly by `polylib::realroots(p,10^(-1000))`, because the internal bisectioning process for refining crude isolating intervals converges only linearly. Instead, we compute first approximations of the roots to a precision of 10 digits:

approx := map(polylib::realroots(p, 10^(-10)), float@op, 1)[1.489177599, 1.752191733, 3.255184556]

[1.489177599, 1.752191733, 3.255184556]

These values are used as starting points for a numerical root finder. The internal Newton search in numeric::fsolve converges quadratically and yields the high precision results much faster than `polylib::realroots`: DIGITS := 1000:roots := map(approx, x0 -> numeric::fsolve([p = 0], [x = x0]))[[x = 1.489177598846870281338916114673844643894...], [x = 1.752191733304413195335101727880090131407...], [x = 3.255184555797733438479691333705558491124...]][[x = 1.489177598846870281338916114673844643894669835092536119855751693956795
[x =

approx, DIGITS, roots, x0:

Parameters

p

A univariate polynomial: either an expression or a polyomial of domain type DOM_POLY.

eps

A (small) positive real number determining the size of the returned intervals.

Return Values

List of lists $[[a_1, b_1], [a_2, b_2], \ldots]$ with rational numbers $a_i \le b_i$ is returned. Lists with $a_i = b_i$ represent exact rational roots. Lists with $a_i < b_i$ represent open intervals containing exactly one real root. If the polynomial has no real roots, then the empty list `[ ]` is returned.

numeric::fsolvenumeric::polyrootsnumeric::realrootnumeric::realroots

polylib::representByElemSym

Purpose

Represent symmetric by elementary symmetric polynomials

Syntax

```
polylib::representByElemSym(f, l)
```

Description

`polylib::representByElemSym(f, [x1,...,xn])` returns a polynomial `g` in the identifiers x_1 through x_n such that replacing each `xi` by the `i`-th elementary symmetric polynomial gives `f`.

The list `l` must have as many operands as `f` has indeterminates.

The result is FAIL if the input is not symmetric.

Examples

Example 1

The symmetric polynomial $x^2 + y^2$ can be written as $(x + y)^2 - 2(xy)$: polylib::representByElemSym(poly(x^2+y^2), [u,v]);poly(u^2 - 2*v, [u, v])

$$\mathrm{poly}(u^2 - 2\,v, [u, v])$$

Example 2

`polylib::representByElemSym` works over domains also: f:=poly(x^2+y^2, Dom::IntegerMod(7)): polylib::representByElemSym(f, [u,v])poly(u^2 + 5*v, [u, v], Dom::IntegerMod(7))

$$\mathrm{poly}(u^2 + 5\,v, [u, v], \mathrm{Dom::IntegerMod}(7))$$

Parameters

f

Symmetric polynomial

l

List of indeterminates

Return Values Result is a polynomial having the same coefficient ring as `f`.

Algorithms It is a well-known theorem that every symmetric polynomial can be written in this way.

See Also polylib::elemSym

polylib::resultant

Purpose

Resultant of two polynomials

Syntax

```
polylib::resultant(f, g, <x>)
polylib::resultant(fexpr, gexpr, <inds>, <x>)
```

Description

`polylib::resultant(f, g)` returns the resultant of `f` and `g` with respect to their first variable.

`polylib::resultant(f, g, x)` returns the resultant of `f` and `g` with respect to the variable `x`.

`polylib::resultant(fexpr, gexpr, inds, x)` returns the resultant of `fexpr` and `gexpr` with respect to the variable `x`; `fexpr` and `gexpr` are viewed as polynomials in the indeterminates `inds`.

Both input polynomials must have exactly the same second and third operand, i.e. their variables and coefficient rings must be identical.

If the arguments are expressions then these are converted into polynomials using poly. `polylib::resultant` returns `FAIL` if the expressions cannot be converted.

If the argument `inds` is missing, the input expressions are converted into polynomials in all indeterminates occurring in at least one of them. They are *not* independently converted, hence the conversion cannot result in two polynomials with different variables causing an error. See “Example 1” on page 25-41.

If the coefficient ring is a domain, it must have a `"_divide"` method.

If the coefficient ring is `Expr`, `polylib::resultant` returns an expression if called with two univariate polynomials. See “Example 2” on page 25-41.

For polynomials over `IntMod(n)`, the computation may stop with an error if `n` is not prime.

Examples

Example 1

If the input consists of expressions, the sets of indeterminates occurring in the expressions need not coincide:
polylib::resultant(a*x + c, c*x + d, x);a*d - c^2

$$a\,d - c^2$$

Example 2

If the coefficient ring of two univariate input polynomials is `Expr`, the result is an expression:
polylib::resultant(poly(x^2 -1), poly(x + 1));0

$$0$$

Parameters

f

g

Polynomials

fexpr

gexpr

Expressions

x

Indeterminate

inds

List of indeterminates

Return Values

If the input consists of polynomials in at least two variables, `polylib::resultant` returns a polynomial in one variable less than the input.

Overloaded By p, q

Algorithms The resultant of two polynomials is defined to be the determinant of their Sylvester matrix. A call to `polylib::resultant` is more efficient than consecutive calls to linalg::sylvester and linalg::det.

See Also polylib::discrimlinalg::detlinalg::sylvester

polylib::sortMonomials

Purpose

Sorting monomials with respect to a term ordering

Syntax

```
polylib::sortMonomials(f)
polylib::sortMonomials(f, vars)
polylib::sortMonomials(f, ord)
polylib::sortMonomials(f, vars, ord)
```

Description

`polylib::sortMonomials(f, ord)` returns a list of all monomials constituting the polynomial `f`, sorted in descending order with respect to `ord`.

A monomial ordering may be: one of the identifiers `LexOrder`, `DegreeOrder`, `DegInvLexOrder`; or an object of type `Dom::MonomOrdering` or convertible to that type; or any object returning a number when called as `ord(m1,m2)` for two degree vectors `m1` and `m2`. A degree vector is a list of integers, as returned by degreevec.

If no order is given, the lexikographical order is used.

If no list of variables is given, all indeterminates of `f` are used.

Given two degree vectors, `m1` is considered to be greater than `m2` if and only if `ord(m1,m2)` is positive.

Examples

Example 1

The monomials of the polynomial below are compared using a monomial ordering from `Dom::MonomOrdering` .

```
polylib::sortMonomials(poly(x^2+x*y^3+2,  [x,y]),
DegRevLex(2))[poly(x*y^3, [x, y]), poly(x^2, [x, y]), poly(2, [x, y])]
```

$$[\mathrm{poly}(x\,y^3, [x, y]), \mathrm{poly}(x^2, [x, y]), \mathrm{poly}(2, [x, y])]$$

Parameters

f

Polynomial or polynomial expression

vars

Nonempty list of identifiers

ord

Monomial ordering

Return Values

List of polynomials or expressions of the same type as `f`.

Overloaded By

`f`

See Also

Dom::MonomOrderinglmonomialnthmonomial

polylib::splitfield

Purpose

Splitting field of a polynomial

Syntax

```
polylib::splitfield(p)
```

Description

Given a polynomial p over a field K in one indeterminate X, `polylib::splitfield(p)` returns a simple field extension F of K and some elements a_1, ..., a_n of F, such that product(X-Symbol::alpha[i], i=1..n)$\prod_{i=1}^{n}(X-\alpha_i)$ is an associate of p, and such that F is the smallest extension of K containing all of the a_i.

If the input is a polynomial expression, as in "Example 1" on page 25-45, it is treated as a polynomial over the rationals.

The polynomial `p` need not be irreducible.

The name for the primitive element of the field extension is generated using genident and is therefore different in every call of `polylib::splitfield`, even if the same polynomial is passed.

MuPAD must be able to factor polynomials over the coefficient field of `p`.

The coefficient field must be perfect. Otherwise, it may happen that `polylib::splitfield` does not terminate.

Examples

Example 1

We adjoin sqrt(-1)$\sqrt{-1}$ to the rationals:
polylib::splitfield(x^2+1)[Dom::AlgebraicExtension(Dom::Rational, X1^2 + 1 = 0, X1), [X1, 1, -X1, 1]]

```
[Dom::AlgebraicExtension(Dom::Rational, X1^2 + 1 = 0, X1), [X1, 1, -X1, 1]]
```

Example 2

A call to `polylib::splitfield` becomes more interesting for polynomials for of degree at least 3:
polylib::splitfield(x^3-2)[Dom::AlgebraicExtension(Dom::Rational, X3^6 + 108 = 0, X3), [X3/2 - X3^4/36, 1, X3^4/18, 1, - X3^4/36 - X3/2, 1]]

$$\left[\text{Dom::AlgebraicExtension}\left(\text{Dom::Rational}, X3^6 + 108 = 0, X3\right), \left[\frac{X3}{2} - \frac{X3^4}{36}, 1, \frac{X3^4}{18}, 1, -\frac{X3^4}{36} - \frac{X3}{2}, 1\right]\right]$$

Example 3

In this example, we work over the field of univariate rational functions (the quotient field of the univariate polynomials) over the rationals:

```
R:=Dom::DistributedPolynomial([x],  Dom::Rational):
F:=Dom::Fraction(R):  f:=poly(y^3-x,[y],F):
polylib::splitfield(f)[Dom::AlgebraicExtension(Dom::Fraction(Dom::DistributedPolynom
Dom::Rational, LexOrder)), X5^6 + 27*x^2 = 0, X5), [X5/2 - X5^4/(18*x),
1, X5^4/(9*x), 1, - X5/2 - X5^4/(18*x), 1]]
```

Parameters

p

$$\left[\text{Dom::AlgebraicExtension}\left(\text{Dom::Fraction}\left(\text{Dom::DistributedPolynomial}\left([x], \text{Dom::Rational}, \text{LexOrder}\right)\right), X5\right.\right.$$

$$\left.\left.\left[\frac{X5}{2} - \frac{X5^4}{18\,x}, 1, \frac{X5^4}{9\,x}, 1, -\frac{X5}{2} - \frac{X5^4}{18\,x}, 1\right]\right]\right]$$

Univariate polynomial over a field or univariate polynomial expression

Return Values

`polylib::splitfield` returns a list of two operands: the first one is the splitting field of the polynomial, i.e. a Dom::AlgebraicExtension of the coefficient ring; the second one is a list of all roots of the polynomial in the splitting field, each root followed by its multiplicity.

See Also

factorevalp

polylib::sqrfree

Purpose

Square-free factorization of polynomials

Syntax

```
polylib::sqrfree(f, <recollect>)
```

Description

`polylib::sqrfree(f)` returns the square-free factorization of `f`, that is, a factorization of f in the form $f = up_1^{e_1} \ldots p_r^{e_r}$ with primitive and pairwise different square-free divisors p_i.

`polylib::sqrfree(f)` returns the square-free factorization of the polynomial f, that is, a factorization of f in the form $f = uf_1^{e_1} \ldots f_r^{e_r}$ with primitive and pairwise different square-free divisors f_i (i.e., $gcd(f_i, f_j) = 1$ for $i \neq j$).

u is a unit of the coefficient ring of f, and e_i are positive integers.

The result of `polylib::sqrfree` is an object of the domain type Factored. Let `g:= polylib::sqrfree(f)` be such an object. It is represented internally as the list `[u, f1, e1, ..., fr, er]` of odd length $2r + 1$.

You may extract the unit u and the terms $f_i^{e_i}$ by the ordinary index operator `[ ]`, i.e., `g[1] = u, g[2] = f1^e1, g[2] = f2^e2, ....`

The calls `Factored::factors(g)` and `Factored::exponents(g)` return a list of the factors f_i and the exponents e_i ($1 \leq i \leq r$), respectively. The call `convert(g, DOM_LIST)` gives the internal representation of a factored object, i.e., the list `[u, f1, e1, ..., fr, er]`.

Note that the result of `polylib::sqrfree` is printed as an expression and behaves like that. As an example, the result of `polylib::sqrfree(x^2+2*x+1)` is the object printed as `(x+1)^2` which is of type `"_power"`.

Please read the help page of Factored for details.

The call `polylib::sqrfree(f, FALSE)` returns a square-free factorization of `f`, where the exponents e_i need not be pairwise different.

`polylib::sqrfree` can handle univariate and multivariate polynomials over `Expr`, residue class rings `IntMod(p)` with prime modulus `p`,

domains representing a unique factorization domain of characteristic zero, and finite fields.

If the argument of `polylib::sqrfree` is an expression, its numerator and denominator are converted into polynomials in all occurring indeterminates.

These polynomials are regarded as polynomials over some extension of the rational numbers (i.e., over `Expr`, see poly). The choice of that extension follows the same rules as in the case of the function factor.

Factors of the denominator of an expression are indicated by negative multiplicities.

Examples

Example 1

The factors in a squarefree factorization are pairwise relatively prime, but they need not be irreducible:
polylib::sqrfree(2 - 2*x - 6*x^4 + 6*x^5 + 6*x^8 - 6*x^9 -2*x^12 + 2*x^13)2*(x^3 + x^2 + x + 1)^3*(x - 1)^4

$$2\,(x^3+x^2+x+1)^3\,(x-1)^4$$

Example 2

Even if a factorization into irreducibles has been found, irreducible factors with the same multiplicity are collected again:
polylib::sqrfree(x^6 + x^4*y*6 + x^2*y^2*9)(x*(x^2 + 3*y))^2

$$(x\,(x^2+3\,y))^2$$

You can avoid this by giving a second argument:
polylib::sqrfree(x^6 + x^4*y*6 + x^2*y^2*9, FALSE)x^2*(x^2 + 3*y)^2

$$x^2\,(x^2+3\,y)^2$$

Example 3

`polylib::sqrfree` works also for polynomials:

```
polylib::sqrfree(poly(2 + 5*x + 4*x^2 + x^3))poly(x + 2, [x])*poly(x +
1, [x])^2
```

$$\mathrm{poly}(x+2,[x])\,\mathrm{poly}(x+1,[x])^2$$

Parameters

f

A polynomial or an arithmetical expression

recollect

`TRUE` or `FALSE`

Return Values

Factored object, i.e., an object of the domain type Factored.

See Also

contentfactorFactoredirreduciblepolylib::primpart

polylib::subresultant

Purpose

Subresultants of two polynomials

Syntax

```
polylib::subresultant(f, g, <x>, <i>)
polylib::subresultant(fexpr, gexpr, <x>, <i>)
```

Description

`polylib::subresultant(f, g)` returns the table of subresultants of polynomials `f` and `g` with respect to their first variable.

`polylib::subresultant(f, g, i)` returns the `i`th subresultant of polynomials `f` and `g` with respect to their first variable.

`polylib::subresultant(f, g, x)` returns the table of subresultants of polynomials `f` and `g` with respect to the variable `x`.

`polylib::subresultant(f, g, x, i)` returns the `i`th subresultant of polynomials `f` and `g` with respect to the variable `x`.

`polylib::subresultant(fexpr, gexpr, x)` returns the table of subresultants of polynomial expressions `fexpr` and `gexpr` with respect to the variable `x`.

`polylib::subresultant(fexpr, gexpr, x, i)` returns the `i`th subresultant of polynomial expressions `fexpr` and `gexpr` with respect to the variable `x`.

`polylib::subresultant` returns a particular subresultant or a table of all subresultants.

The variables and coefficient rings of both input polynomials must be identical.

The 0th subresultant is the resultant of two polynomials. See “Example 1” on page 25-51

If you do not specify the variable when computing the subresultants of two polynomials, `polylib::subresultant` returns subresultants of the polynomials with respect to their first variable. See “Example 2” on page 25-52.

If you call `polylib::subresultant` for polynomial expressions, you must specify the variable with respect to which you want to compute subresultants. MuPAD uses the poly function to convert polynomial expressions to polynomials with the specified variable. The system also converts computed subresultants back to polynomial expressions.

If poly cannot convert expressions to polynomials, `polylib::subresultant` returns FAIL.

If the degree of the polynomial `f` is less than the degree of the polynomial `g`, the `polylib::subresultant` function interchanges `f` and `g`.

If the coefficient ring is a domain, it must have a `_divide` method.

Examples

Example 1

If you do not specify which subresultant to return, `polylib::subresultant` returns the table of all subresultants:

```
f := poly(3*x^4 + 3*x^3 + 4): g := poly(x^4 + x^3 + x^2 + x + 1):
polylib::subresultant(f, g)table(4 = poly(3*x^4 + 3*x^3 + 4, [x]), 3 =
poly(3*x^2 + 3*x - 1, [x]), 2 = poly(9*x^2 + 9*x - 3, [x]), 1 = poly(9*x -
39, [x]), 0 = poly(205, [x]))
```

0	$\mathrm{poly}(205, [x])$
1	$\mathrm{poly}(9x - 39, [x])$
2	$\mathrm{poly}(9x^2 + 9x - 3, [x])$
3	$\mathrm{poly}(3x^2 + 3x - 1, [x])$
4	$\mathrm{poly}(3x^4 + 3x^3 + 4, [x])$

You can specify the number of the subresultant that you want to compute. For example, compute the 0th subresultant of the polynomials f and g:

```
polylib::subresultant(f, g, 0)poly(205, [x])
```

$\mathrm{poly}(205, [x])$

The 0th subresultant is also the resultant of the polynomials:
polylib::resultant(f, g)205

205

Example 2

`polylib::subresultant` handles multivariate polynomials and polynomial expressions. When you compute subresultants of multivariate polynomials or polynomial expressions, you can specify the variable with respect to which you want to compute subresultants:
f := poly(3*x^4*y + 4*z^2): g := poly(x^4 + x^3*y^3*z^3):
polylib::subresultant(f, g, z)table(3 = poly(x^4 + z^3*x^3*y^3, [x, y]), 2 = poly(3*x^4*y + 4*z^2, [x, y]), 1 = poly((-12*z)*x^7*y^4 + 16*x^4, [x, y]), 0 = poly(27*x^18*y^9 + 64*x^8, [x, y]))

0	$\mathrm{poly}(27\,x^{18}\,y^{9} + 64\,x^{8}, [x, y])$
1	$\mathrm{poly}(16\,x^{4} - 12\,x^{7}\,y^{4}\,z, [x, y])$
2	$\mathrm{poly}(3\,x^{4}\,y + 4\,z^{2}, [x, y])$
3	$\mathrm{poly}(x^{4} + x^{3}\,y^{3}\,z^{3}, [x, y])$

For multivariate polynomials, specifying the variable is not necessary. If you do not specify the variable when computing the subresultants of two polynomials, `polylib::subresultant` returns subresultants of the polynomials with respect to their first variable:
f := poly(3*x^4*y + 4*z^2): g := poly(x^4 + x^3*y^3*z^3):
polylib::subresultant(f, g)table(4 = poly((3*x^4)*y + 4*z^2, [y, z]), 3 = poly((3*x^3)*y^4*z^3 - 4*z^2, [y, z]), 2 = poly(12*y^7*z^8 + (12*x)*y^4*z^5, [y, z]), 1 = poly(48*y^7*z^10 + (48*x)*y^4*z^7, [y, z]), 0 = poly(192*y^13*z^18 + 256*z^8, [y, z]))

0	$\mathrm{poly}(192\,y^{13}\,z^{18} + 256\,z^{8}, [y, z])$
1	$\mathrm{poly}(48\,y^{7}\,z^{10} + 48\,x\,y^{4}\,z^{7}, [y, z])$
2	$\mathrm{poly}(12\,y^{7}\,z^{8} + 12\,x\,y^{4}\,z^{5}, [y, z])$
3	$\mathrm{poly}(4\,z^{2} + 3\,x^{3}\,y^{4}\,z^{3}, [y, z])$
4	$\mathrm{poly}(3\,x^{4}\,y + 4\,z^{2}, [y, z])$

If you call `polylib::subresultant` for polynomial expressions, you must specify the variable with respect to which you want to compute subresultants:

```
f := 3*x^4*y + 4*z^2: g := x^4 + x^3*y^3*z^3: polylib::subresultant(f, g)
Error: A variable is missing. [polylib::subresultant]
polylib::subresultant(f, g, x)table(4 = 3*y*x^4 + 4*z^2, 3 = 3*x^3*y^4*z^3 - 4*z^2, 2 = 12*y^7*z^8 + 12*x*y^4*z^5, 1 = 48*y^7*z^10 + 48*x*y^4*z^7, 0 = 192*y^13*z^18 + 256*z^8)
```

0	$192\,y^{13}\,z^{18} + 256\,z^{8}$
1	$48\,y^{7}\,z^{10} + 48\,x\,y^{4}\,z^{7}$
2	$12\,y^{7}\,z^{8} + 12\,x\,y^{4}\,z^{5}$
3	$4\,z^{2} + 3\,x^{3}\,y^{4}\,z^{3}$
4	$3\,x^{4}\,y + 4\,z^{2}$

Parameters

f

Polynomials over `Expr` (the ring of arbitrary MuPAD expressions)

fexpr

gexpr

Polynomial expressions

x

An indeterminate

i

A nonnegative integer

Return Values Subresultant of two polynomials (or polynomial expressions) or a table of subresultants.

Overloaded By p, q

See Also polylib::resultantpolylib::discrimlinalg::detlinalg::sylvester

polylib::support

Purpose

Support of a polynomial

Syntax

```
polylib::support(p)
```

Description

`polylib::support(p)` returns the support of `p`, that is, the list of indices with non zero coefficient in `p`.

Examples

Example 1

The support of a multivariate polynomial is the list of the degree vectors of its terms:

```
polylib::support(poly(x*y*z + x + 1, [x, y, z]))
```

```
[[1, 1, 1], [1, 0, 0], [0, 0, 0]]
```

For a univariate polynomial, the support is the list of the degrees of its terms. In the following polynomial `x` appears with degrees `3`, `1`, and `0`:

```
polylib::support(Dom::UnivariatePolynomial(x)(x^3*y*z + x + 1))
```

```
[3, 1, 0]
```

Parameters

`p`

A polynomial.

Return Values

List of elements of the support.

Ground

Pref – User Preferences

==REFNAME==

Pref::abbreviateOutput

Purpose

Controls the use of abbreviations in outputs

Syntax

```
Pref::abbreviateOutput(TRUE)
Pref::abbreviateOutput(FALSE)
Pref::abbreviateOutput(NIL)
Pref::abbreviateOutput()
```

Description

When displaying results, MuPAD by default finds common subexpressions and replaces them with abbreviations. See “Example 1” on page 26-2.

If you want to see the results without abbreviations, use the `Pref::abbreviateOutput(FALSE)` command. See “Example 2” on page 26-3.

The `Pref::abbreviateOutput()` command shows whether abbreviations are enabled or disabled. See “Example 3” on page 26-4.

To restore the default setting, use the `Pref::abbreviateOutput(NIL)` command. See “Example 4” on page 26-4.

The output of the `Pref::abbreviateOutput` command itself displays the previous setting. You can save this previous setting and switch to a new setting in a single call of `Pref::abbreviateOutput`. See “Example 5” on page 26-4.

Examples

Example 1

By default, you can see the abbreviations in long outputs:

```
solve(a*x^3 + b*x + c, x, MaxDegree = 3,
IgnoreSpecialCases){(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) -
c/(2*a))^(1/3) - b/(3*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) -
c/(2*a))^(1/3)), b/(6*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) -
c/(2*a))^(1/3)) - (sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)/2
- (sqrt(3)*((sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3) +
b/(3*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)))*I)/2,
b/(6*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3))
- (sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)/2 +
```

(sqrt(3)*((sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3) +
b/(3*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)))*I)/2}

Example 2

Setting `Pref::abbreviateOutput(FALSE)`, you can disable the abbreviations in outputs:

Pref::abbreviateOutput(FALSE): solve(a*x^3 + b*x + c, x, MaxDegree = 3, IgnoreSpecialCases){(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3) - b/(3*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)), b/(6*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)) - (sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)/2 - (sqrt(3)*((sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3) + b/(3*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)))*I)/2, b/(6*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)) - (sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)/2 + (sqrt(3)*((sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3) + b/(3*a*(sqrt(b^3/(27*a^3) + c^2/(4*a^2)) - c/(2*a))^(1/3)))*I)/2}

Example 3

You can check the current setting:

```
Pref::abbreviateOutput()
```

```
FALSE
```

Example 4

You can restore the default setting:

```
Pref::abbreviateOutput(NIL): Pref::abbreviateOutput()
```

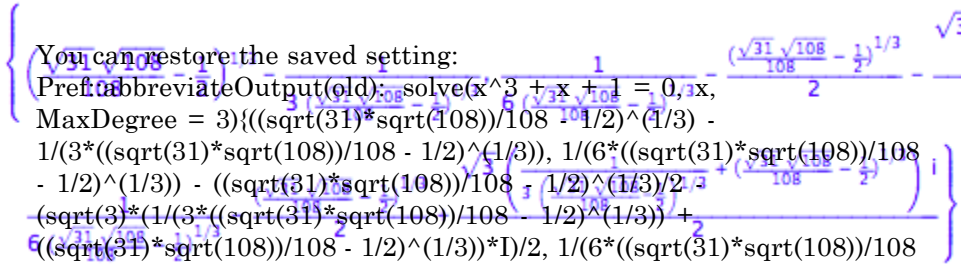
```
TRUE
```

Example 5

You can save the current setting and switch it to a new one in one function call:

```
old := Pref::abbreviateOutput(FALSE): solve(x^3 + x
+ 1 = 0, x, MaxDegree = 3)
```

1/2)^(1/3) - 1/(3*((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)),
1/(6*((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)) - ((sqrt(31)*sqrt(108))/108
- 1/2)^(1/3)/2 - (sqrt(3)*(1/(3*((sqrt(31)*sqrt(108))/108 -
1/2)^(1/3)) + ((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3))*I)/2,
1/(6*((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)) - ((sqrt(31)*sqrt(108))/108
- 1/2)^(1/3)/2 + (sqrt(3)*(1/(3*((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)) +
((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3))*I)/2}



You can restore the saved setting:
Pref:abbreviateOutput(old): solve(x^3 + x + 1 = 0,x,
MaxDegree = 3){((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3) -
1/(3*((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)), 1/(6*((sqrt(31)*sqrt(108))/108
- 1/2)^(1/3)) - ((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)/2 -
(sqrt(3)*(1/(3*((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)) +
((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3))*I)/2, 1/(6*((sqrt(31)*sqrt(108))/108
- 1/2)^(1/3)) - ((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)/2 +
(sqrt(3)*(1/(3*((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3)) +
((sqrt(31)*sqrt(108))/108 - 1/2)^(1/3))*I)/2}

Return Values

Previously set value TRUE or FALSE

See Also

output::subexproutput::asciiAbbreviate

Pref::alias

Purpose

Controls the output of aliased expressions

Syntax

```
Pref::alias(TRUE)
Pref::alias(FALSE)
Pref::alias(NIL)
Pref::alias()
```

Description

An alias is an abbrevation for a MuPAD expression. If `Pref::alias` is enabled, the `alias` abbrevations will be used for output.

`Pref::alias()` returns the current value.

`Pref::alias(TRUE)` switches the usage of alias abbrevations in outputs on. This is the default setting.

`Pref::alias(FALSE)` switches the usage of aliases in outputs off.

`Pref::alias(NIL)` restores the default value which is TRUE.

`Pref::alias` has no effect on print and fprint.

Environment Interactions

`Pref::alias` changes the output of aliased expressions.

Examples

Example 1

If an aliased expression occurs in output, it is replaced by the alias abbrevation:
alias(X = a + b): X, a + bX, X

```
X, X
```

This only works if the syntactical structure of expression matches the aliased expression:
2*X2*a + 2*b

```
2 a + 2 b
```

prog::exprtree shows that `2*X` does not contain `a + b` any more:
prog::exprtree(X): prog::exprtree(2*X): _plus | +-- a | '-- b _plus | +-- _mult | | | +-- a | | | '-- 2 | '-- _mult | +-- b | '-- 2

The same holds for `X+c`:
X + c; prog::exprtree(X + c):a + b + c

$a + b + c$

_plus | +-- a | +-- b | '-- c

With `Pref::alias(FALSE)` the back translation of aliases in the output is disabled:
Pref::alias(FALSE): Xa + b

$a + b$

`Pref::alias` has no effect on print and fprint outputs:
Pref::alias(TRUE): print(X):a + b

$a + b$

Return Values

Previously set value

See Also

aliasexpr2textfprintprint

Pref::autoExpansionLimit

Purpose

Set a limit for automatic expansions

Syntax

```
Pref::autoExpansionLimit(n)
Pref::autoExpansionLimit(NIL)
Pref::autoExpansionLimit()
```

Description

`Pref::autoExpansionLimit(n)` sets a limit for the size of the arguments up to which the functions bernoulli, Ei, euler, fact, fact2, gamma, harmonic, igamma, psi, and zeta produce explicit results. Cf. “Example 1” on page 26-9.

It also sets a limit for the exponent up to which real and imaginary parts of powers are computed explicitly. Cf. “Example 2” on page 26-10.

Use expand for larger arguments if explicit results are desired. Cf. “Example 1” on page 26-9.

The call `Pref::autoExpansionLimit()` returns the current value of the limit without changing it.

The call `Pref::autoExpansionLimit(NIL)` resets the limit to its default value 1000.

Examples

Example 1

The functions bernoulli, euler, gamma, zeta etc. automatically produce explicit results if the arguments are not too large:
bernoulli(22), euler(24), gamma(26), zeta(28)854513/138, 15514534163557086905, 15511210043330985984000000, (6785560294*PI^28)/56465366017007627367 1875

$$\frac{854513}{138},\ 15514534163557086905,\ 15511210043330985984000000,\ \frac{6785560294\,\pi^{28}}{56465366017007627367}$$

These functions return symbolic answers when the argument is larger than the limit set by `Pref::autoExpansionLimit`:
Pref::autoExpansionLimit()1000

1000

bernoulli(1002), euler(2002), gamma(3001), zeta(4001)bernoulli(1002), euler(2002), gamma(3001), zeta(4001)

bernoulli(1002), euler(2002), Γ(3001), ζ(4001)

We reduce this limit:
Pref::autoExpansionLimit(20):bernoulli(22), euler(24), gamma(26), zeta(28)bernoulli(22), euler(24), gamma(26), zeta(28)

bernoulli(22), euler(24), Γ(26), ζ(28)

We can use expand to obtain explicit results:
expand(bernoulli(22)), expand(euler(24)), expand(gamma(26)), expand(zeta(28))854513/138, 1551453416355708690 5, 1551121004333098598400000 0, (6785560294*PI^28)/5646536601700762736718 75

$\frac{854513}{138}$, 1551453416355708690 5, 1551121004333098598400000 0, $\frac{6785560294\,\pi^{28}}{5646536601700762736718 75}$

We restore the default value:
Pref::autoExpansionLimit(NIL):

Example 2

If binomial expansion is needed, the closed formula for the real part of an expression can become quite large:
Re((a+sqrt(2)*I)^6) assuming a in R_sqrt(2)*(sqrt(2)*(sqrt(2)*(2*sqrt(2)*a^2 + sqrt(2)*(a^2 - 2)) + a*(4*a - a*(a^2 - 2))) - a*(a*(2*sqrt(2)*a^2 + sqrt(2)*(a^2 - 2)) - sqrt(2)*(4*a - a*(a^2 - 2)))) - a*(sqrt(2)*(a*(2*sqrt(2)*a^2 + sqrt(2)*(a^2 - 2)) - sqrt(2)*(4*a - a*(a^2 - 2))) + a*(sqrt(2)*(2*sqrt(2)*a^2 + sqrt(2)*(a^2 - 2)) + a*(4*a - a*(a^2 - 2))))

$$\sqrt{2}\,(\sqrt{2}\,(\sqrt{2}\,(2\sqrt{2}\,a^2+\sqrt{2}\,(a^2-2))+a\,(4\,a-a\,(a^2-2)))-a\,(a\,(2\sqrt{2}\,a^2+\sqrt{2}\,(a^2-2))-\sqrt{2}\,(4\,a$$

$$-a\,(\sqrt{2}\,(a\,(2\sqrt{2}\,a^2+\sqrt{2}\,(a^2-2))-\sqrt{2}\,(4\,a-a\,(a^2-2)))+a\,(\sqrt{2}\,(2\sqrt{2}\,a^2+\sqrt{2}\,(a^2-2))+a\,(4$$

Thus, for exponents beyond `Pref::autoExpansionLimit()`, no expansion is carried out:

Re((a+sqrt(2)*I)^123456) assuming a in R_Re((a + sqrt(2)*I)^123456)

$$\Re\left((a+\sqrt{2}\,i)^{123456}\right)$$

Parameters

n

The limit: a positive numerical real value

Return Values

Previously defined limit.

Pref::autoPlot

Purpose

Automatically plot graphical objects

Syntax

```
Pref::autoPlot(TRUE)
Pref::autoPlot(FALSE)
Pref::autoPlot(NIL)
Pref::autoPlot()
```

Description

`Pref::autoPlot(TRUE)` makes graphical objects be plotted instead of typeset.

By default, graphical objects such as plot::Function3d are output just like any other MuPAD object, i.e., as a rendered representation of the input. After setting `Pref::autoPlot(TRUE)`, graphical objects and sequences of such objects are automatically rendered instead, as if the user had written `plot(...)`.

This setting only works when typesetting is enabled.

Return Values

Previously set value

See Also

plot

Pref::callBack

Purpose

Informations during evaluation

Syntax

```
Pref::callBack(<func>)
```

Description

The function `func` defined by `Pref::callBack(func)` will be called permanently, when the MuPAD kernel works. Therewith informations can be displayed to inform the user.

A call of `Pref::callBack` without arguments returns the current value. The argument `NIL` resets the default value, which is `NIL`.

Examples

Example 1

The following combination of Pref::postInput (initialization) and time count with `Pref::callBack` shows the seconds during evaluating. Pref::postInput(proc() begin START:= time(); TIME:= START end_proc): Pref::callBack(proc() begin if time() - TIME > 1000 then // 1 sec TIME:= TIME+1000; print(floor((time() - START)/1000)) end_if end_proc): NOW:= time(): while time() - NOW <= 10000 do 1 end_while:1

Parameters **func**

Function to display informations

Return Values Previously defined function

See Also Pref::reportPref::postInputPref::postOutput

Pref::callOnExit

Purpose

Defines an exit handler

Syntax

```
Pref::callOnExit(f)
Pref::callOnExit(list)
Pref::callOnExit(NIL)
Pref::callOnExit()
```

Description

`Pref::callOnExit(f)` defines a function `f` which is called on exit or reset of MuPAD.

`Pref::callOnExit(list)` defines a list of functions which are executed in the order of their occurence in `list` on exit of MuPAD.

`Pref::callOnExit(NIL)` sets the default value, which is NIL.

`Pref::callOnExit()` returns the current value.

Parameters

f

A function

list

A list of functions

Return Values

`Pref::callOnExit` returns the previously defined function, list of functions, or NIL.

Algorithms

`Pref::callOnExit` can be used to send communication modules a disconnect message or to remove temporary user-defined files when leaving MuPAD.

See Also

quitPref::postOutputreset

Pref::dbgAutoDisplay

Purpose

Enables the autodisplay mode of the debugger

Syntax

```
Pref::dbgAutoDisplay(TRUE)
Pref::dbgAutoDisplay(FALSE)
Pref::dbgAutoDisplay(NIL)
Pref::dbgAutoDisplay()
```

Description

`Pref::dbgAutoDisplay(TRUE)` switches on the autodisplay mode of the debugger.

`Pref::dbgAutoDisplay()` returns the current value.

`Pref::dbgAutoDisplay(NIL)` or `Pref::dbgAutoDisplay(TRUE)` switch on the autodisplay mode. After every halt of the terminal debugger or up/down movements in the stack the expressions `args()`, `last(1)` (`%`) and the formal parameters and local variables of the currently visible procedure are added to the list of display variables.

`Pref::dbgAutoDisplay(FALSE)` switches the autodisplay mode off.

In the MuPAD debugger the automatically inserted expressions and variables are visible in the Watch window.

Environment Interactions

Changes the behaviour of the debugger.

Examples

Example 1

If the autodisplay feature is disabled, the terminal debugger only prints short messages:

```
>> Pref::dbgAutoDisplay(FALSE):
>> debug(int(f(x), x))
#0 in int($1=x, $2=x) at lib/STDLIB/int.mu:26
29 in lib/STDLIB/int.mu
mdx>
```

If the autodisplay feature is activated, we see the values of `args()`, `%`, the formal parameters `f` and `x` and the value of the local variable `integral`:

```
>> Pref::dbgAutoDisplay(TRUE):
>> debug(int(f(x), x))
#1 in int($1=f(x), $2=x)
29 in lib/STDLIB/int.mu
args() = f(x), x
% =
f = f(x)

debugPref::dbgAutoList

Pref::dbgAutoList

Purpose

Enables the autolist mode of the terminal debugger

Syntax

```
Pref::dbgAutoList(TRUE)
Pref::dbgAutoList(FALSE)
Pref::dbgAutoList(NIL)
Pref::dbgAutoList()
```

Description

`Pref::dbgAutoList()` returns the current value.

`Pref::dbgAutoList(TRUE)` switches on the autolist mode. After every halt of the terminal debugger or up/down movements in the stack a short listing will be printed.

`Pref::dbgAutoList(NIL)` or `Pref::dbgAutoList(FALSE)` will reset the default value, which is `FALSE`.

In the terminal debugger the autolist mode can be toggled with the debugger command 't'.

Environment Interactions

Changes the behaviour of the terminal debugger.

Examples

Example 1

If the autolist feature is disabled, the terminal debugger only prints short messages:

```
>> debug(int(x, x))
#0 in int($1=x, $2=x) at lib/STDLIB/int.mu:26
26 in lib/STDLIB/int.mu
mdx>
```

If the autolist feature is activated, a short excerpt of the debugged function is printed whenever the debugger halts:

```
>> Pref::dbgAutoList(TRUE):
#0 in int($1=x, $2=x) at lib/STDLIB/int.mu:26
26 in lib/STDLIB/int.mu

  21    ++*/
  22
  23    int:= funcenv(
  24    proc(f, x=null())
  25    begin
  26 ->   if args(0)=0 then error("No argument given") end_if;
  27
  28      if testargs() and has([args()],FAIL) then
  29         error("illegal argument(s)")
  30      end_if;
  31

mdx>
>> Pref::dbgAutoList(FALSE):
```

Return Values

Previously set value

See Also

debugPref::dbgAutoDisplay

Pref::floatFormat

Purpose

Representation of floating-point numbers

Syntax

```
Pref::floatFormat(mode)
Pref::floatFormat(NIL)
Pref::floatFormat()
```

Description

`Pref::floatFormat` controls the output format of floating-point numbers.

The representation mode can be one of the characters `"e"`, `"f"`, `"g"`, `"h"`, or `"x"`. These are the standard `C`-command `printf` switches. Their meaning is:

- "e":

  exponential representation (floating-point representation, “scientific format”).

- "f":

  decimal representation without exponents.

- "g":

  a mix between `"e"` and `"f"`. Numbers x satisfying

  10^(-DIGITS)<=abs(x)<=10^DIGITS $\frac{1}{10^{DIGITS}} \le |x| \le 10^{DIGITS}$ are displayed without exponents. All other numbers are displayed in floating-point representation.

- "h" or "x":

  hexadecimal representation, except for expr2text and typesetting, which fall back to `"g"`.

The default value is `"g"`.

`Pref::floatFormat()` returns the current mode without changing it. The call `Pref::floatFormat(NIL)` resets to the default value `"g"`.

Examples

Example 1

The exponential representation of a floating-point number consists of its sign, its mantissa and its exponent:
Pref::floatFormat("e"): 12345.67890, -0.000123451.23456789e4, -1.2345e-4

12345.6789, -0.00012345

Without exponents, the size of a number is indicated by trailing or leading zeroes:
Pref::floatFormat("f"): 7.0*10^21, 7.0/10^21700000000000000000000.0, 0.00000000000000000007

$7.0\ 10^{21}$, $7.0\ 10^{-21}$

The mixed representation:
Pref::floatFormat("g"): 1e-10, 9.99e-110.0000000001, 9.99e-11

0.0000000001, $9.99\ 10^{-11}$

2.0^36, 2.0^3768719476744.0, 1.374389535e11

68719476744.0, $1.374389535\ 10^{11}$

Hexadecimal display is ignored in typeset output and expr2text:
Pref::floatFormat("h"): 12345.67890, 0.00012345;
expr2text(12345.67890, 0.00012345)12345.6789, 0.00012345

12345.6789, 0.00012345

"12345.6789, 0.00012345"

"12345.6789, 0.00012345"

Hexadecimal display is used in the ASCII print output:

print(Plain, 12345.67890, 0.00012345) 3.039adcc63f141208@3, 8.1725b672ee34260@-4

The representation is reset to the default mode: Pref::floatFormat(NIL):

Parameters

mode

One of the character strings `"e"`, `"f"`, `"g"`, `"h"`, or `"x"`

Return Values

Previously defined representation mode

See Also

DIGITSPref::trailingZeroesPref::outputDigitsprint

Pref::fourierParameters

Purpose

Specify parameters for Fourier and inverse Fourier transforms

Syntax

```
Pref::fourierParameters(c, s)
Pref::fourierParameters([c, s])
Pref::fourierParameters(NIL)
Pref::fourierParameters()
```

Description

`Pref::fourierParameters(c, s)`, or the equivalent call `Pref::fourierParameters([c, s])`, specifies parameters used by the fourier and ifourier functions when computing Fourier and inverse Fourier transforms. See “Example 1” on page 26-24.

The Fourier transform of the expression `f = f(t)` with respect to the variable `t` at the point `w` is defined as follows:
F(w) = c*int(f(t)*exp(I*s*w*t), t=(-infinity)..(infinity))

$$F(w) = c \int_{-\infty}^{\infty} f(t)\, e^{i\,s\,w\,t}\, d\,t$$

The inverse Fourier transform of the expression `F = F(w)` with respect to the variable `w` at the point `t` is defined as follows:
f(t) = abs(s)/(2*PI*c)*int(F(w)*exp(‘{-i s w t}‘), w = -infinity..infinity)

$$f(t) = \frac{|s|}{2\,\pi\,c} \int_{-\infty}^{\infty} F(w)\, e^{-i\,s\,w\,t}\, d\,w$$

`c` and `s` are the parameters of the Fourier transform controlled by `Pref::fourierParameters`.

By default, `c = 1` and `s = -1`. Other common choices for the parameter `c` are 1/(2*PI) $\frac{1}{2\,\pi}$ or 1/sqrt(2*PI) $\frac{1}{\sqrt{2\,\pi}}$. Other common choices for the parameter `s` are 1, - 2π, or 2π.

`Pref::fourierParameters()` returns the current values of the Fourier parameters without changing them.

`Pref::fourierParameters(NIL)` restores the default settings `c = 1`, `s = -1`.

`Pref::fourierParameters` also controls the parameters used by the fourier::addpattern and ifourier::addpattern functions. See “Example 2” on page 26-25.

Environment Interactions

Changing Fourier parameters using `Pref::fourierParameters` can affect results returned by fourier and ifourier in the current MuPAD session.

Examples

Example 1

Compute the Fourier transform of this expression using the default values `c = 1`, `s = -1` of the Fourier parameters:
assume(Re(a) > 0): fourier(t*exp(-a*t^2), t, w)-(sqrt(PI)*w*exp(-w^2/(4*a))*I)/(2*a^(3/2))

$$-\frac{\sqrt{\pi}\, w\, e^{-\frac{w^2}{4a}}\, i}{2\, a^{3/2}}$$

Use `Pref::fourierParameters` to change the values of the Fourier parameters to `c = 1`, `s = 1`. Then compute the Fourier transform of the same expression again:
Pref::fourierParameters(1, 1): fourier(t*exp(-a*t^2), t, w)(sqrt(PI)*w*exp(-w^2/(4*a))*I)/(2*a^(3/2))

$$\frac{\sqrt{\pi}\, w\, e^{-\frac{w^2}{4a}}\, i}{2\, a^{3/2}}$$

Change the values of the Fourier parameters to 1/(2*PI) $\frac{1}{2\pi}$ and 1. Compute the Fourier transform using these values:
Pref::fourierParameters(1/(2*PI), 1): fourier(t*exp(-a*t^2), t, w)(w*exp(-w^2/(4*a))*I)/(4*sqrt(PI)*a^(3/2))

$$\frac{w\, e^{-\frac{w^2}{4a}}\, i}{4\sqrt{\pi}\, a^{3/2}}$$

For further computations, restore the default values of the Fourier transform parameters:
Pref::fourierParameters(NIL):

Example 2

Use the default values of the Fourier transform parameters:
Pref::fourierParameters()[1, -1]

$$[1, -1]$$

Add this new Fourier transform pattern for the function `foo`:
fourier::addpattern(foo(t), t, w, bar(w)): fourier(foo(t), t, w)bar(w)

$$\mathrm{bar}(w)$$

The Fourier pair `(foo, bar)` is assumed to be valid for the current values of the Fourier parameters. When changing these parameters, you change the definition of the Fourier transform. Therefore, after changing Fourier parameters, the transform of `foo(t)` is not `bar(w)` anymore. The fourier function computes the result which is valid for the new parameters:
Pref::fourierParameters(c, s): fourier(foo(t), t, w)c*bar(-s*w)

$$c\,\mathrm{bar}(-s\,w)$$

Now restore the Fourier transform parameters to their default values 1 and -1:
Pref::fourierParameters(NIL):

Parameters

c

Arithmetical expression

s

Arithmetical expression

Return Values List containing the previously set values of `c` and `s`

See Also fourierifourierfourier::addpatternifourier::addpattern

Pref::ignoreNoDebug

Purpose

Controls debugging of procedures

Syntax

```
Pref::ignoreNoDebug(TRUE)
Pref::ignoreNoDebug(FALSE)
Pref::ignoreNoDebug(NIL)
Pref::ignoreNoDebug()
```

Description

`Pref::ignoreNoDebug(TRUE)` allows debugging of procedures even if they have the option `noDebug` set.

`Pref::ignoreNoDebug()` returns the current value.

`Pref::ignoreNoDebug(NIL)` resets the default value, which is `FALSE`.

`Pref::ignoreNoDebug(FALSE)` resets the default value, which is `FALSE`.

Return Values

Previously set value

See Also

DOM_PROCdebug

Pref::keepOrder

Purpose

Order of terms in sum outputs

Syntax

```
Pref::keepOrder(<Always>)
Pref::keepOrder(<DomainsOnly>)
Pref::keepOrder(<System>)
Pref::keepOrder(NIL)
Pref::keepOrder()
```

Description

`Pref::keepOrder` influences the output order of terms in sums.

Usually, the output system uses its own ordering of the terms in a sum to optimize the appearance of the output. This order may be different from the internal ordering of the sum. The output system prefers to re-order the terms such that the first term is positive.

Sometimes it is desirable to see the terms of a sum in the internal order. This can be achieved with `Pref::keepOrder(Always)`.

By default, the term order of polynomials and domain elements is left unchanged.

`Pref::keepOrder(NIL)` restores the default state, which is `DomainsOnly`.

`Pref::keepOrder()` returns the currently set value.

Examples

Example 1

Here we create a domain element `e`, an expression `f`, and a polynomial `p` containing sums. With the default setting `DomainsOnly`, only the output of the expression `f` is not in the internal order:
d := newDomain("d"): d::print := x -> extop(x): e := new(d, b - a): f := b - a: p := poly(1 - x): e, f, p- a + b, b - a, poly(- x + 1, [x])

$$-a+b,\ b-a,\ \mathrm{poly}(-x+1,\ [x])$$

With the setting `Always`, `e`, `f`, and `p` are all printed in the internal order:
Pref::keepOrder(Always): e, f, p- a + b, - a + b, poly(- x + 1, [x])

$-a+b,\ -a+b,\ \mathrm{poly}(-x+1,\ [x])$

With the setting `System`, the output order differs from the internal ordering for `e`, `f`, and `p`:
Pref::keepOrder(System): e, f, pb - a, b - a, poly(1 - x, [x])

$b-a,\ b-a,\ \mathrm{poly}(1-x,\ [x])$

`Pref::keepOrder(NIL)` restores the default state; `Pref::keepOrder()` returns the current setting:
Pref::keepOrder(NIL): Pref::keepOrder()DomainsOnly

DomainsOnly

Options

Always

The output always corresponds to the internal order.

DomainsOnly

In polynomials and domain elements, the ordering of terms corresponds to the internal order. Other sums may be re-ordered by the output system.

This is the default setting of `Pref::keepOrder`.

System

The output order of terms in sums is determined by the output system and does not necessarily correspond to the internal order.

Return Values

Previously defined value: `Always`, `DomainsOnly`, or `System`.

DOM_POLYDom::MultivariatePolynomialDom::PolynomialDom::UnivariatePolyno

Pref::kernel

Purpose

Version number of the presently used kernel

Syntax

```
Pref::kernel()
Pref::kernel(<BitsInLong>)
Pref::kernel(<BuildNr>)
```

Description

The version numbers of the kernel and the library may differ. `Pref::kernel` refers to the kernel, whereas the call `version()` returns the version number of the installed MuPAD library.

Examples

Example 1

Here the version numbers of kernel and library differ:
Pref::kernel() = version()[5, 9, 0] = [5, 9, 0]

Example 2

A 32-bit architecture:
Pref::kernel(BitsInLong)32

```
32
```

Example 3

At the time of this writing, kernels build number was 42703:
Pref::kernel(BuildNr)42703

```
42703
```

Options

BitsInLong

`Pref::kernel(BitsInLong)` returns the number of bits of a long integer number. On a 64-bit architecture it returns 64, otherwise 32.

BuildNr

The kernel has an additional build number which enables the developers to identify the exact sources for this kernel.

Return Values

Version number: a list of three nonnegative integers or a number.

See Also

buildnumberversion

Pref::maxMem

Purpose

Set a memory limit for the session

Syntax

```
Pref::maxMem(kbytes)
Pref::maxMem(NIL)
Pref::maxMem()
```

Description

`Pref::maxMem(kbytes)` with `kbytes` greater than 0 sets a limit for the physically allocated memory of the current MuPAD session. A computation exceeding this memory limit raises an error.

The physically allocated memory is the second of the values returned by `bytes()`.

Note The memory limit is "soft" because the memory is checked only occasionally. Usually, more memory is actually used before the excess is detected. Cf. "Example 1" on page 26-32.

The call `Pref::maxMem()` returns the current value of the memory limit without changing it.

The call `Pref::maxMem(NIL)` switches off the memory watch dog.

Examples

Example 1

No computation should increase the memory usage of the current MuPAD session to more than a total of 10 megabytes:
Pref::maxMem(10 * unit::MByte):

The following loop creates larger and larger matrices until the memory limit is exceeded. Note that the current physical memory allocation returned by `bytes()[2]` is measured in bytes:
for n from 100 to 150 step 5 do A := linalg::vandermonde([x.j $ j=1..n]); print(n, ceil(bytes()[2]/1024)*unit::kByte); end_for:100, 7311*unit::kByte

100, 7311 kByte
105, 9311*unit::kByte

105, 9311 kByte
110, 9648*unit::kByte

110, 9648 kByte
115, 10113*unit::kByte

115, 10113 kByte
Error: Out of memory [watchdog-memory]; Evaluating: linalg::vandermonde for n from 100 to 150 step 5 do A := linalg::vandermonde([x.j $ j=1..n]); end_for: Error: Out of memory. [watchdog-memory] Evaluating: linalg::vandermonde

Note that the memory limit was exceeded when computing the 115 115 Vandermonde matrix. However, because the memory consumption is measured only occasionally, this matrix was generated successfully without an error. Only in the next step, the memory watchdog recognizes excessive memory usage and aborts the computation of the 120 120 Vandermonde matrix.
Pref::maxMem(NIL): delete A:

Parameters

kbytes

The memory limit in kBytes: a nonnegative integer or an expression using unit::Byte, unit::kByte, unit::MByte, or unit::GByte.

Return Values

Previously defined memory limit: 0 or an expression involving unit::MByte.

See Also

bytesMAXDEPTHPref::maxTime

Pref::maxTime

Purpose

Time limit for computations

Syntax

```
Pref::maxTime(seconds)
Pref::maxTime(NIL)
Pref::maxTime()
```

Description

`Pref::maxTime(seconds)` with `seconds` greater than 0 sets a time limit for all following MuPAD instructions. Each computation not finished within the given time raises an error.

The call `Pref::maxTime()` returns the current value of the time limit without changing it.

The call `Pref::maxTime(NIL)` switches off the timer watch dog.

Examples

Example 1

No computation should take more than 10 seconds:
Pref::maxTime(10 * unit::sec):

Note that time returns the CPU time in milliseconds. The following while loop is designed to run longer than 10 seconds:
TIME:= time(): while time() - TIME < 20000 do null() end_while Error: Execution time is exceeded. [watchdog-time] Pref::maxTime(NIL): delete TIME:

Parameters

seconds

The time limit in seconds: a nonnegative integer or an expression involving time units.

Return Values

Previously defined time limit: 0 or an expression involving unit::sec.

See Also

Pref::maxMemrtimetimetraperror

Pref::output

Purpose

Modify the screen output of objects

Syntax

```
Pref::output(f)
Pref::output(NIL)
```

Description

`Pref::output` allows to modify the screen output of objects returned by the MuPAD kernel.

When the MuPAD kernel returns a result `x`, say, of a computation, the function `f` is called before the result is printed to the screen. Instead of `x`, the return value `f(x)` is used as screen output of the computation.

Make sure that a user-defined output function `f` processes *arbitrary MuPAD objects*.

The call `Pref::output(NIL)` resets the output function to the identity map: the screen output coincides with the object returned by the computation. NIL is the default value of the output function.

Examples

Example 1

All numbers of type Type::Numeric shall be displayed as floating point numbers. Since the kernel may return sequences of objects, the output function may be called with an unknown numbers of parameters. It uses map to apply its functionality to all of its arguments. Whenever a numerical object of type Type::Numeric is encountered, it is replaced by a floating-point approximation:
f := proc(x) begin if args(0) > 1 then return(map(args(), f)) end_if; if testtype(x, Type::Numeric) then return(float(x)) else return(x) end_if; end_proc: Pref::output(f):4/9; sin(3); 4/9, sin(3), 1/2 + 17*I0.4444444444

```
0.4444444444
```

sin(3)

```
sin(3)
```

0.4444444444, sin(3), 0.5 + 17.0*I

```
0.4444444444, sin(3), 0.5 + 17.0 i
```

We restore the standard mode:
Pref::output(NIL): delete f:

Example 2

The procedure generate::TeX is applied to the result of a computation. The corresponding TeX code (a string) is displayed:
Pref::output(generate::TeX): sqrt(x^2 - 1/x)"\\sqrt{x^2 - \\frac{1}{x}}"

```
"\sqrt{x^2 - \frac{1}{x}}"
```

We restore the standard mode:
Pref::output(NIL):

Parameters

f

The “output function”: a procedure

Return Values

Previously defined “output function”, or NIL.

See Also

Pref::postOutputPref::postInputPref::keepOrder

Pref::outputDigits

Purpose

Set the number of digits in floating-point outputs

Syntax

```
Pref::outputDigits(n)
Pref::outputDigits(<UseDigits>)
Pref::outputDigits(<InternalPrecision>)
Pref::outputDigits()
```

Description

`Pref::outputDigits(n)` sets the number of digits in outputs of floating-point numbers to an integer `n`. This command does not set the precision for calculations. See "Example 1" on page 26-37.

`Pref::outputDigits(InternalPrecision)` sets the number of digits in floating-point outputs to settings MuPAD used when creating these floating-point numbers. If you use `Pref::outputDigits(InternalPrecision)`, the lengths of floating-point numbers in the same output region can differ because the numbers were created with different precision. See "Example 2" on page 26-38.

`Pref::outputDigits(UseDigits)` restores the setting to the number of digits previously set by DIGITS. The default value for DIGITS is 10. Suppose, you use internal precision for displaying numbers or explicitly specify a number of digits in outputs. If you want to switch back to the number of digits specified by DIGITS, use `Pref::outputDigits(UseDigits)`. See "Example 3" on page 26-39.

`Pref::outputDigits()` returns the current setting for the number of digits in outputs of floating-point numbers. This command does not change the setting.

Examples

Example 1

Display the floating-point approximation of $1/3$ using 40 digits without changing the precision for calculations. The default number of digits that MuPAD uses for calculations with floating-point numbers is 10. MuPAD can increase the precision of calculations by several digits

(guard digits). Round-off errors cause the last digits in the following result to be incorrect:
Pref::outputDigits(40):
float(1/3)0.333333333333333333044212754003865484 2647

0.33333333333333333304421275400386548426 47

Note Always explicitly set the precision you need. Do not rely on having guard digits.

To set the precision for calculations with floating-point numbers, use DIGITS. Display the floating-point approximation of 1/3 using 40 and 15 digits:
DIGITS := 40: float(1/3); Pref::outputDigits(15):
float(1/3)0.333333333333333333333333333333333333 3333

0.333333333333333333333333333333333333 3333
0.333333333333333

0.333333333333333

Example 2

Approximate the ratio 1/6 with different precisions:
DIGITS := 15: x := float(1/6): DIGITS := 3: y := float(1/6): DIGITS := 40: z := float(1/6):

Display the floating-point approximation of 1/6 using the number of digits that MuPAD uses internally. The lengths of floating-point numbers in the same output region can differ because the numbers were created with different precision:
Pref::outputDigits(InternalPrecision): x; y; z0.166666666666667

0.166666666666667

0.167

```
0.167
```

0.16666666666666666666666666666666666666666667

```
0.16666666666666666666666666666666666666666667
```

Example 3

To switch back to the number of digits set previously by DIGITS, use `Pref::outputDigits(UseDigits)`:

```
Pref::outputDigits(UseDigits):   x;  y;
```

z0.16666666666666666666666677695741500707036

```
0.16666666666666666666666677695741500707036
```

0.16666666666787932626903057098388671875

```
0.16666666666787932626903057098388671875
```

0.16666666666666666666666666666666666666666667

```
0.16666666666666666666666666666666666666666667
```

Parameters

n

An integer

Return Values

Previously set value

See Also

DIGITSfloatPref::floatFormat

Pref::postInput

Purpose

Actions after input

Syntax

```
Pref::postInput(f)
Pref::postInput(NIL)
Pref::postInput()
```

Description

`Pref::postInput` allows to set user actions directly after input.

After entering any MuPAD command `x`, say, and sending this command to the kernel, `f(x)` is called before the kernel starts to process the input. This happens for any input until the post-input is switched off via the call `Pref::postInput(NIL)`.

The function `f` implicitly uses the option hold, i.e., `f` sees the input command as entered and parsed without any evaluation.

`f` cannot change the input command that is sent to the kernel for evaluation. However, `f` can store the input in some global variable for later processing, or some other actions can be performed.

`Pref::postInput()` returns the current value of the post-input function or NIL, respectively.

`Pref::postInput`, possibly in conjunction with Pref::postOutput, is useful for initializing variables to compute status information such as the execution time for the command that is to be executed. See “Example 2” on page 26-41.

Examples

Example 1

The post-input function sees the input as entered, i.e., before evaluation by the kernel:

```
Pref::postInput(proc() begin print(Unquoted, "input" = args()) end):1
+ 2 input = 1 + 2 3
```

```
3
```

```
1 + 2, x = sin(0.1) input = (1 + 2, x = sin(0.1)) 3, x = 0.09983341665
```

3, $x = 0.09983341665$
x := 1234; y := 5678 input = (x := 1234) 1234

1234
input = (y := 5678) 5678

5678

Post-input is switched off. This command calls the post-input function for the very last time:
Pref::postInput(NIL): input = Pref::postInput(NIL) delete x, y:

Example 2

For any command, the run time is to be computed and displayed. The function declared in `Pref::postInput` sets a global timer value `TIME` after each input. After the output of the result, the function declared in Pref::postOutput compares the current time and the starting time `TIME`.
Pref::postInput(() -> (TIME:= time())): Pref::postOutput(() -> "Time: ".expr2text((time() - TIME)*msec)):int(cos(x)*exp(sin(x)), x)exp(sin(x))

$e^{\sin(x)}$
Time: 40 msec Pref::postInput(() -> (TIME:= time())): Pref::postOutput(() -> "Time: "."40 msec"):int(cos(x)*exp(sin(x)), x)exp(sin(x))

$e^{\sin(x)}$
Time: 40 msec Pref::postInput(NIL): Pref::postOutput(NIL): delete TIME:

Example 3

As another example of using `Pref::postInput` for storing information to influence the output, we combine it with Pref::output to include (a rendered version of) the input and the result:

```
Pref::postInput(() -> (LASTINPUT := args())):  Pref::output(() ->
val(LASTINPUT) = args()):
```

This makes MuPAD write “input = result” to the screen, while leaving the history (accessible by %) intact:

```
int(x, x); sum((-1)^i/(2*i+1), i=0..infinity); sin(%)int(x, x) = x^2/2
```

$$\int x \, dx = \frac{x^2}{2}$$

```
sum((-1)^i/(2*i + 1), i = 0..infinity) = PI/4
```

$$\sum_{i=0}^{\infty} \frac{(-1)^i}{2\,i+1} = \frac{\pi}{4}$$

```
sin(“%“) = sqrt(2)/2
```

$$\sin(\%) = \frac{\sqrt{2}}{2}$$

Parameters

f

The function to be executed after input: a procedure. The default value of this function is NIL (no post-input).

Return Values

Previously set post-input function.

See Also

Pref::postOutput

Pref::postOutput

Purpose

Actions after output

Syntax

```
Pref::postOutput(f)
Pref::postOutput(NIL)
Pref::postOutput()
```

Description

After the result `x`, say, of a MuPAD command is printed on the screen, `f(x)` is called and executed before the next prompt for user input appears. This happens for any output until the post-output is switched off via `Pref::postOutput(NIL)`.

After the usual output of the result `x` of a MuPAD command, the return value of `f(x)` is printed on the screen with PRETTYPRINT = FALSE. However, `f(x)` does not return any value to the MuPAD session. It cannot be accessed via last.

`Pref::postOutput()` returns the current value of the post-output function or NIL, respectively.

`Pref::postOutput`, possibly in conjunction with Pref::postInput, can be used to produce status information after each output. One may think of timer informations, memory usage, result types etc.

Examples

Example 1

Here, `Pref::postOutput` is used to enumerate the output line and display the type of the result. It uses the global variable `LineNumber` which must be initialized before any output is produced. The definition of the post-output operation as well as the initialization of the global variable can be done in the file "`userinit.mu`" which is read automatically during start-up.

```
Pref::postOutput( proc() begin LineNumber:= LineNumber + 1; "Out["
. expr2text(LineNumber). "]: ". "type = ".expr2text(op(map([args()],
domtype))); end_proc): LineNumber:= 0:int(x^5*exp(-x), x)-exp(-x)*(x^5
+ 5*x^4 + 20*x^3 + 60*x^2 + 120*x + 120)
```

$$-e^{-x}\left(x^5+5\,x^4+20\,x^3+60\,x^2+120\,x+120\right)$$

Out[1]: type = DOM_EXPR int(x^5*exp(-x), x = 0..infinity), numeric::int(x^5*exp(-x), x = 0..infinity)120, 120.0

120, 120.0

Out[2]: type = DOM_INT, DOM_FLOAT

The following print command returns the void object `null()` to the MuPAD session. The output of `null()` is suppressed:
print("print returns the void object")"print returns the void object"

"print returns the void object"

The following command is terminated by a semicolon to suppress the output. Consequently, no post-output is created, either.
x := sin(2):

Post-output is switched off:
Pref::postOutput(NIL): delete LineNumber, x:

Example 2

For any command, the run time is to be computed and displayed. The function declared in Pref::postInput sets a global timer value `TIME` after each input. After the output of the result, the function declared in Pref::postInput compares the current time and the starting time `TIME`. The current TEXTWIDTH is used to prepend some suitable whitespace via stringlib::format to flush right the timer information:
Pref::postInput(() -> (TIME:= time())): Pref::postOutput(proc()
begin stringlib::format("Time: ".expr2text(time() - TIME)." msec",
TEXTWIDTH-1, Right) end_proc):int(x^10*exp(-x), x)-exp(-x)*(x^10 +
10*x^9 + 90*x^8 + 720*x^7 + 5040*x^6 + 30240*x^5 + 151200*x^4 +
604800*x^3 + 1814400*x^2 + 3628800*x + 3628800)

$$-e^{-x}\left(x^{10}+10\,x^9+90\,x^8+720\,x^7+5040\,x^6+30240\,x^5+151200\,x^4+604800\,x^3+1814400\,x^2+3628\right.$$

Time: 84.005 msec Pref::postInput(NIL): Pref::postOutput(NIL): delete T, TIME:

Example 3

The following post-output lists all identifiers with properties in the result of the last MuPAD command. It extracts the indeterminates via indets and uses property::hasprop to query whether they have properties:

```
Pref::postOutput( proc() begin select(indets({args()}), property::hasprop);
"identifiers with properties: " . expr2text(op(%)) end_proc):assume(0 <
a < b): a + b + ca + b + c
```

$$a + b + c$$

identifiers with properties: a, b Pref::postOutput(NIL): delete a, b:

Parameters

f

The function to be executed after output: a procedure. The default value of this function is NIL (no post-output).

Return Values

Previously set post-output function.

See Also

Pref::postInput

Pref::report

Purpose

Informations during evaluation

Syntax

```
Pref::report(level)
```

Description

`Pref::report` controls the frequency of report messages of the MuPAD kernel during evaluation.

A kernel function displays frequently the three informations *memory used*, *memory reserved* and *evaluation time in seconds*.

The level `0` disables printing information. If `level` is `1`, about every hour a message will be printed. With `9` as argument the most reports will be printed. The frequency depends on the machine's speed.

A call of `Pref::report` without arguments returns the current value. The argument `NIL` resets the default value `0`.

Examples

Example 1

Frequently information:
Pref::report(9): limit((1+1/n)^n,n=infinity)[used=1612k, reserved=1738k, seconds=1] [used=2716k, reserved=2856k, seconds=2] exp(1)

Reset to no information:
Pref::report(0):

Parameters

level

An integer between `0` and `9`, or NIL

Return Values

Last defined level

See Also

Pref::callBack

Pref::trailingZeroes

Purpose

Trailing zeroes when printing floating-point numbers

Syntax

```
Pref::trailingZeroes(value)
Pref::trailingZeroes()
```

Description

`Pref::trailingZeroes` determines, whether trailing zeroes will be appended, when floating-point numbers are printed.

If enabled (with argument TRUE), after the significant numbers of a floating-point number (behind the point) zeroes will be appended until the number of digits reaches the value of DIGITS.

A call of `Pref::trailingZeroes` without arguments will return the current value. The argument NIL will reset the default value, which is FALSE.

Examples

Example 1

By default, trailing zeroes will not be displayed:
DIGITS:= 10: 1.41.4

```
1.4
```

Display of trailing zeroes will be enabled:
Pref::trailingZeroes(TRUE): 1.41.400000000

```
1.4
```

1.400000000

The default mode is restored:
Pref::trailingZeroes(NIL):

Parameters

value

`TRUE`, `FALSE` or NIL

Return Values Last defined value.

See Also DIGITSPref::floatFormatprint

Pref::typeCheck

Purpose

Type checking of formal parameters

Syntax

```
Pref::typeCheck(Always | Interactive | None)
Pref::typeCheck(NIL)
Pref::typeCheck()
```

Description

`Pref::typeCheck` determines the kind of type checking of procedure parameters.

The definition of a MuPAD procedure may contain formal parameters. There is a syntax to attach a type specification to these parameters. If and when type checking is enabled, the types of actual parameters are checked against the type specifications and an error is raised if a parameter does not meet the specification.

Type specifications are used as the second parameter of testtype. The most important ones are “Domain Types” and objects of the domain Type. With Type, user defined types can be easily added to the system to extend the type checking mechanism.

The arguments of `Pref::typeCheck` can be:

- `None`

  No parameters are checked.

- `Interactive`

  Parameters entered interactively are checked. This is the default.

- `Always`

  All formal parameters are checked.

The default value `Interactive` means: When the user is calling a procedure `f`, its parameters will be checked, but none of the procedures called by the user called procedure `f` performs type checking.

A call of `Pref::typeCheck` without arguments returns the current value. The argument `NIL` resets the default value, which is `Interactive`.

Examples

Example 1

We define a procedure `f` expecting an identifier and an integer:
f:= proc(a : DOM_IDENT, b : DOM_INT) begin evalassign(a, b, 1) end_proc: f(a, 2)2

```
2
```

Now `a` has the value `2`, but an identifier is expected:
f(a, 2) Error: The type of argument number 1 must be 'DOM_IDENT'. The object '2' is incorrect. Evaluating: f delete a:

Options

Always

Parameter types are checked for every call.

Interactive

Parameter types are checked for interactive calls, not for "inner" calls during the computation.

None

No parameter type checks are performed by the MuPAD kernel. Explicit checks inside procedures still use the usual testargs mechanism.

Return Values

Previously defined value

Algorithms

The syntax to test parameters directly (without a test in the procedure body) is the formal parameter followed by a colon and then the type object: `proc(a : DOM_IDENT, b : Type::Integer)`. This means: `a` must be of the type `DOM_IDENT` and `b` must be of the type `Type::Integer`.

Note that you cannot use automatic type checking for arguments that are used for overloading inside the procedure.

The objects of the Type library are usually more general than the MuPAD kernel types.

See Also

DOM_PROCargsdomtypehastypeproctestargstesttypetype

Purpose

Pref::unloadableModules

Allow unload of dynamic modules

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
Pref::unloadableModules(<value>)
```

Description

`Pref::unloadableModules(TRUE)` allows unloading dynamic modules.

Unloading modules can be useful during the development on dynamic modules. It allows to unload and reload a recompiled module during a running MuPAD session. Modules are unloaded particularly by reset when allowed.

`Pref::unloadableModules` was introduced because of a compiler bug. When it is enabled MuPAD may become unstable and crash.

A call of `Pref::unloadableModules` without arguments will return the current value. The argument `NIL` will reset the default value, which is `FALSE`.

Parameters

value

`TRUE`, `FALSE`, or NIL

Return Values

Previously defined value

Pref::userOptions

Purpose

Additional options when starting MuPAD

Syntax

```
Pref::userOptions()
```

Description

`Pref::userOptions()` returns additional options, given by the user when calling MuPAD.

When starting the MuPAD kernel with the flag `"-U"` the user can define options that can be used in the MuPAD session.

Examples

Example 1

If you start MuPAD with the command `mupad -U "Hello World"`, `Pref::userOptions` returns the string `"Hello World"`:
Pref::userOptions()"Hello World"

Example 2

To define several user options one can use a separator between the strings. MuPAD is called with `mupad -U "myhome,/home/user/myhome,2"`:
Pref::userOptions()"myhome,/home/user/myhome,2"

The following call splits the string into the three parts (to demonstrate, the string is written explicitely):
s := "myhome,/home/user/myhome,2": opts := []: ind := 0: while (ind := stringlib::contains(s, ",", Index)) <> FALSE do opts := opts . [s[1 .. ind-1]]; s := s[ind+1 .. length(s)]: end_while: opts := opts . [s]["myhome", "/home/user/myhome", "2"]

```
["myhome", "/home/user/myhome", "2"]
```

delete s, opts, ind:

Return Values

User defined options as strings

Pref::verboseRead

Purpose

Shows reading of files

Syntax

```
Pref::verboseRead(value)
Pref::verboseRead()
```

Description

With `Pref::verboseRead` the reading of library packages and files can be shown.

The arguments of `Pref::verboseRead` represent:

- `0:`

  no messages when reading files (default).

- `1:`

  message if a library packages will be read.

- `2:`

  messages if a package or any library function will be read.

- `NIL:`

  restore the default value `0`.

A call of `Pref::verboseRead` without arguments returns the current value.

Examples

Example 1

Show the reading of library packages:
reset(): Pref::verboseRead(1): sin(x)loading package 'Type' [mupad/share/lib/lib.tar#lib/] 0.8414709848

Show reading of all library files:
reset(): Pref::verboseRead(2): sin(1.0)reading file mupad/share/lib/lib.tar#lib/SPECFUNC/sin.mu reading file mupad/share/lib/lib.tar#lib/SPECFUNC/sinh.mu reading file mupad/share/lib/lib.tar#lib/STDLIB/infinity.mu loading

package 'Type' [mupad/share/lib/lib.tar#lib/] reading file mupad/share/lib/lib.tar#lib/TYPE/Arith.mu 0.8414709848

The default mode is restored:
Pref::verboseRead(NIL):

Parameters

value

0, 1, 2, or NIL

Return Values

Last defined value

See Also

readfreadprog::traceloadproc

Pref::warnDeadProcEnv

Purpose

Warnings about wrong usage of lexical scope

Syntax

```
Pref::warnDeadProcEnv(TRUE)
Pref::warnDeadProcEnv(FALSE)
Pref::warnDeadProcEnv(NIL)
Pref::warnDeadProcEnv()
```

Description

`Pref::warnDeadProcEnv()` returns the current setting.

`Pref::warnDeadProcEnv(TRUE)` switches on warnings about unreachable procedure environments.

`Pref::warnDeadProcEnv(FALSE)` switches warning messages off.

`Pref::warnDeadProcEnv(NIL)` will reset the default value, which is `FALSE`.

If a procedure is executed a *procedure environment* is created for this procedure. It contains the current values of formal parameters and local variables. On exit of the procedure this procedure environment is normally not needed any more and destroyed.

If a procedure returns a local procedure as its result, this local *procedure escapes its scope*. Usually this is no problem. Only if the escaping procedure contains references to formal parameters or local variables of the outer procedure these *variables escape their scope*. These variables can not be dereferenced since they reference values of a procedure environment of the outer procedure which does not exist any more.

Use option *escape* in the outer procedure in order to keep its procedure environment untouched.

Environment Interactions

Allows or suppresses warning messages.

Examples

Example 1

Here we write procedure `p` which returns a local procedure. The returned procedure adds the value of its argument `y` to the value of the argument `x` of the first procedure. The following naive implementation produces a strange output and, when the resulting procedure is called, a warning message and an error:
Pref::warnDeadProcEnv(FALSE): p := proc(x) begin y -> x + y end: f := p(1); f(2)y -> DOM_VAR(1, 2) + y

$$y \to \text{DOM\_VAR}(1, 2) + y$$

Warning: Uninitialized variable 'unknown' used. Evaluating: f Error: Illegal operand. [_plus] Evaluating: f

If `Pref::warnDeadProcEnv` is set to TRUE MuPAD will print a warning message when the local procedure escapes its scope:
Pref::warnDeadProcEnv(TRUE): p := proc(x) begin y -> x + y end: f := p(1) Warning: Found dead closure of procedure 'p'. y -> DOM_VAR(1, 2) + y

$$y \to \text{DOM\_VAR}(1, 2) + y$$

Use option *escape* in the outer procedure to prevent this warning. The returned procedure `f` will then work as expected:
p := proc(x) option escape; begin y -> x + y end: f := p(1); f(2)y -> x + y

$$y \to x + y$$

3

$$3$$

Return Values

Previously set value

proc

prog – Programmer's Toolbox

==REFNAME==

prog::calledFrom

Purpose

Name of the calling procedure

> **Note** `prog::calledFrom` will be removed in a future release. Use `context(hold(procname))` instead.

Syntax

```
prog::calledFrom()
prog::calledFrom(Name)
```

Description

`prog::calledFrom` returns inside a procedure information about the calling procedure as string `"'f' is called from 'g'"`, where `f` is the name of the procedure that calls `prog::calledFrom`, and `g` is the name of the procedure, that calls `f`.

Options

Name

With this option, only the name `g` of the calling procedure is returned as string (see above).

Return Values

String

See Also

prog::getnameprocname

prog::calltree

Purpose

Visualize the call structure of nested function calls

Note `prog::calltree` will be removed in a future release. Use `prog::trace` instead.

Syntax

```
prog::calltree(statement, options)
```

Description

`prog::calltree(statement)` visualizes the call structure of nested function calls while evaluating `statement`.

`statement` can be any MuPAD statement. If a function is called, `prog::calltree` prints all functions called while executing `statement` in a tree structure.

Using this output, dependencies between functions can be observed and analyzed.

Parameters

statement

A MuPAD statement to examine

Options

Args

The arguments of every function call are printed.

Exclude

Option, specified as `Exclude = set`

`set` is a set that contains the names of MuPAD functions. If `set` contains a function, any call of this function is removed from screen, and all other functions called inside this excluded function are not displayed, too.

MaxDepth

Option, specified as `MaxDepth = num`

`num` must be a positive integer. With this number, the displayed tree is displayed only with this depth, all subtrees and nodes below are truncated.

Tree

The call of `prog::calltree` returns an object of type adt::Tree without showing the tree.

No output is printed on screen. The return object contains all call structure information that would be printed on screen without this option (see adt::Tree).

Return Values

`prog::calltree` returns the result of the execution of `statement`. Additionally, information on the flow of control is printed.

See Also

prog::tracedebugprog::profileprog::tcov

prog::check

Purpose

Checking objects

Syntax

```
prog::check(object, <infolevel>, options)
```

Description

The call `prog::check(object)` checks the MuPAD object `object`. `object` may be a procedure, a function environment, or a domain. One may also give a list of such objects.

If `All` is given as first parameter, all defined procedures, function environments and domains are checked (see anames).

`infolevel` determines the amount of information given while checking. The following values are useful:

- 1

  summarizing number of warnings per checked object, if at least one warning occurs (default)

- 2

  as 1, but a short message is printed even if no warning was produced

- 3

  summary of warnings per checked object

- 5

  displays each checked object, followed by individual warnings, followed by a summary and the number of warnings, if any.

- 10 ... 15

  additional outputs (for debugging/information)

`options` can be any of the described options.

With option `All`, all are checked. Without options, the set `{Domain, Global, Interface, Level, Local, Protect, Save}` is used.

Note The arguments of hold expressions are not checked.

Examples

Example 1

The following function contains a number of mistakes, some of which were actually legal in previous versions of MuPAD.

Lines 1 and 2 contains declarations of local variables. In line 4 an undeclared (global) variable g is used. Line 7 applies level to a local variable (the call simply returns the value of X in MuPAD 2.0). Line 10 contains an assignment to a formal parameter. This parameter will be overwritten and its old value lost:
f:= proc(X, Y) // 1 Local local a, b; // 2 Local begin // 3 g:= proc(X) // 4 Global option hold; // 5 begin // 6 a:= level(X, 2); // 7 Level a:= a + X // 8 end_proc; // 9 Y:= g(Y); // 10 Assign, Global end_proc: prog::check(f, 3)Critical usage of 'level' on local variable ' [f] Function 'level' applied to variables: {X} in [f, proc in 'f'] Global idents: {g} in [f] Unused local variables: {b} in [f] Warnings: 3 [f]

Only search for global variables, but give more messages:
prog::check(f, 5, Global)Checking f (DOM_PROC) Global variable 'g' in [f] Global variable 'g' in [f] Global idents: {g} in [f] Warnings: 1 [f]

Now check everything:
prog::check(f, 5, All)Checking f (DOM_PROC) Global variable 'g' in [f] Critical usage of 'level' on local variable ' [f] Function 'level' applied to variables: {X} in [f, proc in 'f'] Procedure environment of [f] used by [f, proc in 'f'] Assignment to formal parameter 'Y' in [f]. Global variable 'g' in [f] Global idents: {g} in [f] Unused local variables: {b} in [f] Unused formal parameters: {X} in [f] Assignments to formal parameters: {Y} in [f] Warnings: 8 [f]

Global variables declared with the option "save" are allowed:
f:= proc(X) // 1 Local save g; // 2 Save begin // 3 g:= X end_proc: prog::check(f, 2, Global, Save)Warnings: 0 [f]

Parameters

object

Procedure, function environment or domain to check, the identifier `All`, or a list of objects

infolevel

Positive integer that determines the completeness of messages

Options

All

Enables all known options

Global

Report unknown global identifiers

Local

Report unused local variables

These are variables that were declared by `local`, but never used in the procedure.

Localf

Report unused local variables *and* unused formal parameters

The same as `Local`, but the same check is additionally performed for formal parameters of a procedure. Those are the argument names as given in the definition of the procedure.

Assign

Report assignments to formal parameters of procedures

Because a formal parameter will be overwritten, those assignments *could* indicate a programming error (however, not imperative).

Level

The application of level to local variables is reported. Starting with MuPAD 2.0, local variables are simply replaced by their values on evaluation and calling `level` on them does not have any effect.

Domain

Report undefined entries of domains (uses the slot `"undefinedEntries"`)

Interface

Information about undefined entries of a domain interface are printed, i.e., entries in the domain interface, that are not defined as entries of the domain.

Environment

Information about assignments to environment variables of MuPAD are printed. These assignments could change the global behavior of MuPAD if the change is not undone (preferably using save, to catch error conditions).

Protect

Information about assignments to protected variables of MuPAD are printed.

Save

A message about a global identifier is suppressed, when the checked object is a procedure and the identifier is saved with option “save”.

Special

Information about some special cases are printed. Currently, the only implemented special case is assignments to HISTORY.

Escape

`prog::check` prints warnings about procedures which may require the option escape.

Return Values

`prog::check` returns the void object `null()`. Output messages are printed on the screen.

See Also

debugprog::initprog::isGlobalprog::traceprog::getname

prog::exprlist

Purpose

Convert an expression into a nested list

Syntax

```
prog::exprlist(ex)
```

Description

`prog::exprlist` returns a list that contains all operands of the expression `ex`. Each operand of type DOM_EXPR is converted into a list, too.

The return value of `prog::exprlist` can be used directly as argument for adt::Tree resp. output::tree.

Examples

Example 1

The example shows the nested list for the expression `a + b*2 - d*(a + c)`:
prog::exprlist(a + b*2 - d*(a + c))[_plus, a, [_mult, b, 2], [_mult, d, [_plus, a, c], -1]]

[_plus, *a*, [_mult, *b*, 2], [_mult, *d*, [_plus, *a*, *c*], −1]]

The return value can be used to create and display a tree:
expose(adt::Tree(prog::exprlist(a + b*2 - d*(a + c)))) _plus | +-- a | +-- _mult | | | +-- b | | | '-- 2 | '-- _mult | +-- d | +-- _plus | | | +-- a | | | '-- c | '-- -1

Parameters

ex

Expression to convert

Return Values

List

See Also

prog::exprtreeadt::Treeoutput::tree

prog::exprtree

Purpose

Visualize an expression as tree

Syntax

```
prog::exprtree(ex, <Quiet>)
```

Description

`prog::exprtree(ex)` visualizes any MuPAD expression `ex` as tree.

Every expression in MuPAD is internally a tree. The operations are the nodes, and the operands are the leafs.

Examples

Example 1

The example shows the structure of the expression `a + b*2 - d*(a + c)`:

```
prog::exprtree(a + b*2 - d*(a + c)) _plus | +-- a | +-- _mult | | | +-- b | | | `-- 2 | `-- _mult | +-- d | +-- _plus | | | +-- a | | | `-- c | `-- -1 Tree1
```

```
Tree1
```

`Tree1` is the return value of type adt::Tree. This object can be exposed or taken for other operations.

The option `Quiet` suppresses the output, only the tree is returned:

```
prog::exprtree(a + b*2 - d*(a + c), Quiet)Tree2
```

```
Tree2
```

Parameters

ex

Expression to visualize

Options

Quiet

With this option no output will be printed on screen. The return value of type adt::Tree represents the tree structure of `ex`.

Return Values Object of type adt::Tree

See Also adt::Tree

prog::error

Purpose

Error message and internal error number

> **Note** `prog::error` will be removed in a future release. Use `getlasterror` instead.

Syntax

```
prog::error(number)
prog::error(message)
```

Description

`prog::error` converts an internal error number into the corresponding message and vice versa.

Parameters

number

An integer internal error number

message

An error message as string

Return Values

String with the error message or an integer internal error number

See Also

getlasterrorerrorwarningtraperrorlasterror

prog::find

Purpose

Find operands of objects

Syntax

```
prog::find(obj, piece, <Depth = d>, <Type>)
```

Description

`prog::find(obj, piece)` returns the position of the object `piece` in the MuPAD object `obj` as list. The list represents a "path" to the given object. With this list and the functions op and subsop, the object can directly be accessed.

A path to an object `piece` is a list that contains integers `i1, ..., in`.

The meaning is that `piece` is the `in`-th operand of the `(in - 1)`-st operand etc. of the `i1`-st operand of the given object `obj`.

Stated differently, `op(ex, [i1, ..., in]) = opr`.

If the searched object is containing several times, a sequence of lists is returned.

An empty list `[ ]` as path determines the object `obj` itself.

Examples

Example 1

The identifier `a` is the first operand of the expression:
prog::find(a + b + c, a)[1]

```
[1]
```

The number `1` occurs several times:
prog::find(f(1, 1, 1), 1)[1], [2], [3]

```
[1], [2], [3]
```

Example 2

The identifier `a` is the first operand of the second operand of the first operand of the expression:
prog::find(b*(a - 1) + b*(x - 1), a)[1, 2, 1]

[1, 2, 1]

The result of `prog::find` can be used to access the element with op or replace it with subsop:
op(b*(a - 1) + b*(x - 1), [1, 2, 1]); subsop(b*(a - 1) + b*(x - 1), [1, 2, 1] = A)a

a

b*(A - 1) + b*(x - 1)

$b\,(A-1)+b\,(x-1)$

Example 3

How many calls of return does sin contain?
nops([prog::find(sin, return)])48

48

sin contains many `return` calls! However, sin is a function environment and the slots are examined, too. To examine only the main procedure, take the first operand of the function environment:
nops(prog::find(op(sin, 1), return))21

21

Example 4

`prog::find` can also find all objects of a given type:
nops(prog::find(sin, DOM_PROC, Type))60

60

To find only the top level procedures, option `Depth` can be used:
nops(prog::find(sin, DOM_PROC, Type, Depth = 1))14

14

Example 5

`prog::find` works with tables and other containes, too:
T := table(1 = sin(x), 2 = cos(x), 3 = tan(x), 4 = tan(y), 5 = sin(y), 6 = cos(y)): prog::find(T, sin)[1, 2, 0], [5, 2, 0]

```
[1, 2, 0], [5, 2, 0]
```

prog::find(T, "cos", Type)[2, 2], [6, 2]

```
[2, 2], [6, 2]
```

Example 6

In this example we show how to manipulate an existing function by substitution. We use subsop for the substitution and `prog::find` to get the path for the substitution. Here we replace the ^-function by the function `mypower` which additionally counts the number of its calls:
f := x -> `+`(x^j $ j = 1 .. random(10)()): mypower := (b, e) -> (count := count + 1; b^e): map([prog::find(f, `^`)], X -> (f := subsop(f, X = mypower))):

After calling the function `f` ten times in a loop, we see the resulting number of calls of ^ in `count`:
count := 0: for i from 1 to 10 do f(i); end: count48

```
48
```

Parameters

obj

Any MuPAD object

piece

Any MuPAD object

Options

Depth

Option, specified as `Depth = d`

This option allows examining operands of the given object, that are domains, procedures and function environments, only with recursion depth `d`.

Option `Depth` can be used to find procedures, but not locally defined procedures inside the procedures that were found in the first step.

Type

When the option `Type` is given, `prog::find` does not search positions `p` in `obj` such that `op(obj, p) = piece`, but rather those with `testtype(op(obj, p), piece) = TRUE`. Cf. "Example 4" on page 27-14.

Return Values

List of numbers that determine the position of the given object inside of the given expression, or a sequence of lists, if the expression contains the object several times

Algorithms

`prog::find` can be used to examine and manipulate complex MuPAD objects with subsop.

See Also

opsubsophasprog::exprtree

prog::getname

Purpose

Name of an object

Syntax

```
prog::getname(object)
```

Description

`prog::getname(object)` returns the name of the MuPAD object `object`.

The return value is a string, irrespective of the type of the input.

Names can be extracted from procedures, identifiers, function environments, domains and their methods (and strings, of course). If no name can be extracted from an object, the string `"(noname)"` is returned.

For all other MuPAD objects the result of `expr2text(object)` is returned as name.

Examples

Example 1

My own name:
prog::getname(prog::getname)"prog::getname"

"prog::getname"

The name of a Domain:
prog::getname(Dom::ExpressionField())"Dom::ExpressionField()"

"Dom::ExpressionField()"

The “name” of an arbitrary MuPAD object:
prog::getname(1)"1"

"1"

prog::getname(a + 2*b)"a + 2*b"

```
"a + 2*b"
```

Parameters

object

Any MuPAD object

Return Values

Name as string

See Also

opprintexpr2texttext2exprinfo

prog::getOptions

Purpose

Get and verify options within a procedure

Syntax

```
prog::getOptions(n, arguments, allOptions,
<ErrorOnUnexpected>, <optionTypes>)
```

Description

`prog::getOptions` called within a procedure collects and verifies all options from the list of arguments of the calling procedure.

When you write your own procedure, `prog::getOptions` lets you embed the collection and verification of all options of the procedure. When a user calls your procedure, `prog::getOptions` scans all the arguments and provides a data structure that contains all option values. See "Example 1" on page 27-20.

The `prog::getOptions` function returns a list that contains a table of all valid options along with their values and a list of unexpected arguments. For expected options, `prog::getOptions` returns the following values:

If an option can have only TRUE or FALSE values, a user of your procedure can provide the option name, instead of providing an option-value pair. If a user provides an option without specifying its value, `prog::getOptions` returns the Boolean value TRUE for that option. See "Example 2" on page 27-21.

`prog::getOptions` returns a list with two components: a table of expected options and a list of unexpected arguments. You can access the components of that list separately by using the index operator (see _index). See "Example 3" on page 27-22.

By default, the `prog::getOptions` function does not error when it finds an unexpected argument. To switch to issuing errors on unexpected arguments, use the parameter `ErrorOnUnexpected`. See "Example 4" on page 27-22.

The procedure that includes `prog::getOptions` must accept the arguments in the following order: first nonoptional parameters, and then all options. The `prog::getOptions` function lets you specify the

number `n` of the argument from which the function starts verifying options. The `prog::getOptions` function assumes that the first `n - 1` arguments are parameters and, therefore, does not verify them. See "Example 5" on page 27-22.

The parameter `optionTypes` lets you specify acceptable types for the option values. You can specify acceptable types for some or all of the expected options provided in the `allOptions` table. See "Example 6" on page 27-23.

The first three parameters of `prog::getOptions` (`n`, `arguments`, and `allOptions`) are required. `ErrorOnUnexpected` and `optionTypes` are optional. You must provide the parameters of `prog::getOptions` using the order shown in the Calls section of this page. Therefore, if you want to use the fifth parameter `optionTypes`, you also must explicitly use the fourth parameter `ErrorOnUnexpected`.

The second parameter of the `prog::getOptions` function, `arguments`, is a list of all arguments of your procedure. `prog::getOptions` scans the arguments provided in that list. Although `prog::getOptions` accepts any list as a second argument, the calling procedure always must provide a list of all its arguments (both parameters and options) to avoid potential errors. The syntax `[ args()]` provides a list of all arguments of the calling procedure. See "Example 7" on page 27-24.

Examples

Example 1

To embed the option collection and verification step into your procedure, call `prog::getOptions` function within that procedure. To test the behaviour of `prog::getOptions`, create a function `f` that calls `prog::getOptions` to scan and verify the arguments of `f`. For example, create the function `f` that accepts only one option `All`:

```
f := () -> prog::getOptions(1, [args()], table(All = TRUE)):
```

`prog::getOptions` returns a list. The first entry of the list is a table containing all expected options and their values. The second entry is a list of unexpected arguments. For example the function call `f()` does not contain any unexpected arguments:

```
f();[table(All = TRUE), []]
```

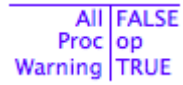
The function call `f(Unexpected)` contains the unexpected argument `Unexpected`:
f(Unexpected);[table(All = TRUE), [Unexpected]]

Example 2

When users call the procedure that includes `prog::getOptions`, they can specify new values for any of the valid options of that procedure. In this case, `prog::getOptions` returns the new values. If a user uses the option without specifying its value, `prog::getOptions` returns the Boolean value TRUE for that option. If a user does not explicitly use an expected option, `prog::getOptions` returns the default value of that option provided in the `allOptions` table. For example, in the function call `f(Proc = op, Warning)`, the `prog::getOptions` function returns the following values:

- If a user provides a value for the option, `prog::getOptions` returns that value.
- If a user does not use the option in a procedure call, `prog::getOptions` returns the default value for that option.

f := () -> prog::getOptions(1, [args()], table(All = FALSE, Proc = id, Warning = FALSE))[1]: f(Proc = op, Warning)table(Warning = TRUE, Proc = op, All = FALSE)



Example 3

To access the table of expected options and the list of unexpected arguments separately, use the index operator (see _index):
f := () -> prog::getOptions(1, [args()], table(All = TRUE))[1]: g := () -> prog::getOptions(1, [args()], table(All = TRUE))[2]: ExpectedOptions = f(Unexpected); UnexpectedOptions = g(Unexpected)ExpectedOptions = table(All = TRUE)

ExpectedOptions = All | TRUE
UnexpectedOptions = [Unexpected]

UnexpectedOptions = [Unexpected]

Example 4

When a user supplies unexpected arguments to your procedure, `prog::getOptions` can collect these arguments and return them as a list. Also, `prog::getOptions` can stop and issue an error when it finds the first unexpected argument. To issue an error instead of listing unexpected arguments, use TRUE as the fourth parameter of `prog::getOptions`:
f := () -> prog::getOptions(1, [args()], table(All = TRUE), TRUE): f(Unexpected) Error: The argument number 1 is invalid. Evaluating: f

Example 5

The `prog::getOptions` function does not distinguish parameters from options automatically. If some arguments of a procedure are parameters, exclude them from option verification. Otherwise, the `prog::getOptions` function lists those parameters as unexpected arguments. For example, `prog::getOptions` lists 1 and 2 as unexpected arguments of the function call `f(1, 2, All)`:
f := () -> prog::getOptions(1, [args()], table(All = TRUE))[2]: UnexpectedOptions = f(1, 2, All);UnexpectedOptions = [1, 2]

UnexpectedOptions = [1, 2]

If you set the `prog::getOptions` function to error on unexpected arguments, it will error on the parameters too:
f := () -> prog::getOptions(1, [args()], table(All = TRUE), TRUE): f(1, 2, All); Error: The argument number 1 is invalid. Evaluating: f

To exclude first `n` parameters of a function from option verification, provide the number `n + 1` as a first argument of `prog::getOptions`. In a function call, specify all `n` parameters before you specify options. For example, to avoid checking the first two arguments in the function call `f(1, 2, All)`, use the following syntax:
f := () -> prog::getOptions(3, [args()], table(All = TRUE))[2]: UnexpectedOptions = f(1, 2, All);UnexpectedOptions = []

UnexpectedOptions = []

When you use `prog::getOptions`, you must provide all nonoptional parameters first, and then provide the options. The following syntax does not work because `prog::getOptions` assumes that the first two arguments in the function call `f(1, All, 2)` are parameters, and the number 2 is an option:
f := () -> prog::getOptions(3, [args()], table(All = TRUE), TRUE): f(1, All, 2); Error: The argument number 3 is invalid. Evaluating: f

Example 6

To specify acceptable types of the option values, use a table that contains acceptable options as indices and their expected types as entries. For example, specify that the `All` option must be of the type DOM_BOOL, and the `Proc` option must be of the type Type::Function:
f:= () -> prog::getOptions(1, [args()], table(All = TRUE, Proc = id), TRUE, table(All = DOM_BOOL, Proc = Type::Function))[1]:

Now, options can have only values of the correct types:
f(All = FALSE, Proc = id)table(Proc = id, All = FALSE)

All	FALSE
Proc	id

If you try to use a value of the wrong type, the function issues an error:

f(All = FALSE, Proc = 0) Error: The type of argument number 2 is incorrect. Evaluating: f

Also, you can define and use a procedure for performing the type check. For arguments of the valid type, the procedure must return TRUE or an expression that can be evaluated to TRUE by the bool function:
f:= () -> prog::getOptions(2, [args()], table(File=""), TRUE, table(File = (X -> contains({DOM_STRING, DOM_INT}, type(X)))))[1]: f(FALSE, File = 0), f(TRUE, File = "test.log")table(File = 0), table(File = "test.log")

Example 7

Using `arguments` to separate options from parameters is not recommended because it can lead to errors. Always use the first parameter of `prog::getOptions` to specify how many parameters you have. Although prog::getOptions accepts any list as a second argument, the best practice is to use only `args()`. The following example demostrates that using `arguments` to separate options from parameters can result in the wrong error message. Although this error message correctly indicates that one of the options has a value of the wrong type, the index of the argument is wrong:
f := () -> prog::getOptions(1, [args(2..args(0))], table(Option1 = TRUE), TRUE, table(Option1 = DOM_BOOL)): f(x, Option1 = 1, Option2) Error: The type of argument number 1 is incorrect. Evaluating: f

To get the correct error message for this example, use the first parameter of `prog::getOptions` to exclude `x` from option verification:
f := () -> prog::getOptions(2, [args()], table(Option1 = TRUE), TRUE, table(Option1 = DOM_BOOL)): f(x, Option1 = 1, Option2) Error: The type of argument number 2 is incorrect. Evaluating: f

Parameters

n

A positive integer that specifies the number of the first option in the list of arguments. When calling the procedure, a user must provide all nonoptional paramaters before the options.

arguments

A list of all arguments of the procedure. Use `args()` to access all arguments.

allOptions

A table that contains all acceptable options as indices and their default values as entries: `table(Option = defaultValue)`

ErrorOnUnexpected

A Boolean constant TRUE or FALSE. If the value is TRUE, `prog::getOptions` issues an error when it finds an unexpected argument. If the value is FALSE, `prog::getOptions` collects all unexpected arguments and returns them as a list. By default, `ErrorOnUnexpected` = FALSE.

optionTypes

A table that contains acceptable options as indices and their expected types as entries: `table(Option = optionType)`. Here `optionType` must be a valid second argument of the testtype function or a procedure that returns TRUE (or an expression that can be evaluated to TRUE by the bool function) for arguments of the valid type. If you want to specify `optionTypes`, you also must explicitly specify `ErrorOnUnexpected`.

Return Values

List that contains a table and a list. The table contains all valid options of the calling procedure and their values. For expected options that are not specified in the procedure, the values are their default values. The list contains all unexpected arguments in the procedure.

testtype

prog::init

Purpose

Loading objects

Syntax

```
prog::init(object)
```

Description

`prog::init(object)` initializes the MuPAD object `object`.

Almost all MuPAD objects (domains, procedures etc.) are loaded into memory at their first use. This mechanism saves a lot of memory and time while starting MuPAD. Most of the MuPAD objects are not needed in a given session and would only fill up the system.

This strategy is transparent with respect to the usage of MuPAD objects. On slower computers, you may notice a delay on the first use of a function or domain.

Using Pref::verboseRead, you can make MuPAD print information on files loaded automatically.

Examples

Example 1

Initializing all objects from any additional MuPAD library increases the memory requirements. For example, you can initialize the object from the linalg library:
bytes() 522304, 815604, 2147483647 prog::init(linalg):

Check the memory usage again:
bytes() 15990660, 16507016, 2147483647

Example 2

Using Pref::verboseRead, we obtain information on what is loaded by the system:
reset(): Pref::verboseRead(2): prog::init(prog::trace)loading package 'prog' [lib/] reading file lib/PROG/checkini.mu reading file lib/PROG/trace.mu

Parameters

object

MuPAD object to initialize or option `All`

Options

All

Initializing all MuPAD objects

With this option (instead of some MuPAD object), all MuPAD objects will be initialized.

Return Values

`prog::init` returns the void object `null()`.

See Also

loadprocPref::verboseReadprog::check

prog::isGlobal

Purpose

Information about reserved identifiers

Syntax

```
prog::isGlobal(ident)
```

Description

`prog::isGlobal(ident)` checks whether the identifier `ident` is "used by the system". Here, "used by the system" means that `ident` is an environment variable (e.g., PRETTYPRINT), a system-wide constant (e.g., `PI` or undefined), an option (for some function call, e.g., `All`), or a system function (such as sin).

The most of those identifiers are protected (see protect).

Examples

Example 1

Assume you would like to use some identifiers as options for a new function you wrote. In this example, we will check the elements of the list `[All, Beta, Circle, D, eval, First]` for suitability. (Note that `eval` would not be a good choice, even if it was not a system function, because options should start with a capital letter.)

We define a test function which is mapped to the list and returns FAIL, if the tested object is not an identifier, TRUE, if the identifier is used by the system and FALSE otherwise:
LIST:= [All, Beta, Circle, D, eval, First]: map(LIST, X -> if domtype(X) <> DOM_IDENT then X = FAIL else X = prog::isGlobal(X) end_if)[All = TRUE, Beta = FALSE, Circle = FALSE, D = FAIL, eval = FAIL, First = TRUE]

```
[All = TRUE, Beta = FALSE, Circle = FALSE, D = FAIL, eval = FAIL, First = TRUE]
```

The identifiers `All` and `First` can be used as options because they have already been protected by the system (actually, they are already used as options, which makes them a good choice), the identifiers `Beta` and `Circle` are free and one must only take care that they have no value if they will be used as options—they should be protected first. `D` and `eval` have values and cannot be used as options.

Parameters

ident

Identifier to check

Return Values

`prog::isGlobal` return `TRUE`, if the given identifier is used by the system, otherwise `FALSE`.

See Also

prog::checkanamestypedomtype

prog::memuse

Purpose

Memory usage of a computation

> **Note** `prog::memuse` will be removed in a future release. Use `prog::trace(Mem)` or `bytes()` instead.

Syntax

```
prog::memuse(stmt)
```

Description

`prog::memuse(stmt)` shows the memory usage for computation and loading library functions while evaluating `stmt`.

If any function or library is loaded, `prog::memuse` prints the increment of memory usage.

In the end, a summary is printed showing the memory usage in two parts: `loadproc` means the memory used by loaded functions and libraries, `executing` means the memory allocated while computing.

The result of `prog::memuse` is the result of the evaluation of `stmt`.

`prog::memuse` works only on machines like UNIX. It uses the temporary file `/tmp/mem.tmp`.

Parameters

stmt

A MuPAD statement

Return Values

Result of `stmt`

Algorithms

MuPAD does not load all its library functions on startup or after a `reset()`. This saves a lot of time and memory. The library functions are loaded on their first use, which may in some cases cause a noticeable delay on the first invocation.

See Also

Pref::verboseReadprog::traceprog::profile

prog::ntime

Purpose

Hardware independent time unit

Syntax

```
prog::ntime()
```

Description

`prog::ntime()` returns a time unit that represents roughly the speed of the current machine *for typical library programs*.

`prog::ntime` can be used to perform timing tests of typical MuPAD library programs on different machines.

`prog::ntime` uses a mix of different operations to calculate the time factor.

One call to `prog::ntime` takes about 1.5 seconds.

A real timing value must be divided by the value of `prog::ntime`, to get a machine independent timing value.

Examples

Example 1

On this machine, a timing must be divided by the value of `prog::ntime`, then the timing is comparable with the timing of the same code on another machine, also divided by the value of `prog::ntime` on the other machine:
prog::ntime() 0.7052155095

Return Values

Floating point number

See Also

timeprog::testinit

prog::profile

Purpose

Display timing data of nested function calls

Syntax

```
prog::profile(stmt)
```

Description

`prog::profile(stmt)` evaluates the MuPAD statement `stmt` and displays timing data of all nested function calls, additionally a graph with the calling structure.

`prog::profile` measures and displays the time usage of *library functions*. Kernel functions are not measured. For every function called during the evaluation of `stmt`, `prog::profile` prints the time spent in this function and the number of calls.

`prog::profile` can be helpful in finding time critical functions and unnecessary nested function calls.

`stmt` could be reading a whole test file, too.

A trick to observe also kernel functions is to call prog::trace with the kernel function as argument. prog::trace takes a library wrapper procedure around the kernel function, that has the same name and can be found in the output of `prog::profile`, when the kernel function is used during the evaluation of `stmt`. The time use of the wrapper function is nearly zero.

The first part of the output is a table with the timing values for each procedure, the second part is a graph, that presents information about the dependences between all measured functions, when `stmt` is evaluated.

The table contains several columns that are described below.

Each row shows all data of one function (called “the function”), that was measured by `prog::profile`. There is one special entry: The first entry is called `procedure entry point`. It shows the sum of all functions and reperesents the evaluation of `stmt`.

- `"percent usage of all"`

the time spent in the function with respect to the whole time used for the evaluation of `stmt` (in percent)

- `"time self per single call"`

  the value `"time self"` divided by the sum of all calls of the function (in milli seconds)

- `"time self"`

  the whole time spent *in the body* of the function, i.e., the sum of all calls, without the time, used by all other measured functions called by the function (in milli seconds)

- `"time children per single call"`

  the value `"time children"` divided by the sum of all calls of the function (in milli seconds)

- `"time children"`

  the sum of *all time* (`self` and `children`) spent in all functions that are called by the function directly

- `"calls/normal exit"`

  number of all calls of the function that leave the function without errors

- `"calls/remember exit"`

  number of all calls of the function that return a remembered value by the kernel remember mechanism (and does not call the function body)

- `"calls/errors"`

  number of all calls of the function that leave the function with an error

- `["[index] function name"]`

  the index of the function (assigned by `prog::profile`) and the name of the function

An index is assigned to each function, in descending order of time usage, to identify and find the function in the call graph that is described now.

The second part of the output of `prog::profile` is a dependence graph. It shows each function, their parents (functions that call the function directly), and their children (functions that are called from the function directly), together with timing information and the number of calls.

Each part of the graph that is separated by horizontal lines of minus chars, belongs to one function. It contains several columns:

- `"index"`

  the index, assigned unique to the function

- `"%time"`

  the percentage of the function on the whole run time

- `"self"`

  the sum of all times used by the function (in milli seconds)

- `"children"`

  the sum of all times used by the children of the function (in milli seconds)

- `"called"`

  the number of all calls of the function

- `["[index] name"]`

  the index and the name of the function

  There are two kinds of entries: the function that belongs to the part has its index in the first column of the part, and in this column, only their name is printed.

  All other functions (parents and children of the function) are only printed in this column with their index and name together, with small indentation for highlighting the function that belongs to the part.

The parents are located above the function itself, all children are written below the line with the function, the part belongs to.

For a more detailed explanation of the lines in a graph part see the first example.

Examples

Example 1

We define three functions `f`, `g` and `h`. `prog::profile` displays the time spent in each function and the number of calls to it:

```
f := proc() local t; begin t := time(); while time() < 10 + t do nothing
end_while end_proc: g := proc() local t; begin f(); t := time(); while
time() < 10 + t do nothing end_while; f() end_proc: h := proc() begin
g(), f(), g() end_proc:prog::profile(h()): percent usage of all | time self
per single call | | time self | | | time children per single call | | | |
time children | | | | | calls/normal exit | | | | | | calls/remember
exit | | | | | | | calls/errors | | | | | | | | [index] funct. name
---------------------------------------------------------------- 100.0 70.0 70.0 . . 1
. . [0] proc. entry pt. ----------------------------------------------------------------
71.4 10.0 50.0 . . 5 . . [1] f 28.6 10.0 20.0 20.0 40.0 2 . . [2] g . . .
70.0 70.0 1 . . [3] h ----------------------------------------------------------------
index %time self children called [index] name
----------------------------------------------------------------
[0] 100.0 70 0 1 proc. entry point 0 70 1 [3] h
---------------------------------------------------------------- 40 0 4 [2] g 10 0 1
[3] h [1] 71.4 50 0 5 f ----------------------------------------------------------------
20 40 2 [3] h [2] 28.6 20 40 2 g 40 0 4 [1] f
---------------------------------------------------------------- [3] 0.0 0 70 1 h 10
0 1 [1] f 20 40 2 [2] g ----------------------------------------------------------------
Time sum: 70 ms
```

(The output is shortened slightly, because the page is too small.)

The lines of the table above are described following:

```
percent usage of all | time self per single call | | time self
| | | time children per single call | | | | time children |
| | | | calls/normal exit | | | | | | calls/remember exit |
| | | | | | calls/errors | | | | | | | | [index] funct. name
```

---------- 100.0 70.0 70.0 . . 1 . . [0] proc. entry pt. ----------

The whole function call takes `100` percent of the time (certainly), `70.0` milli seconds and is called once (the evaluation of `stmt`), without an error.
71.4 10.0 50.0 . . 5 . . [1] f

Function `f` takes `71.4` percent of all evaluation time in its body. It uses `10.0` milli seconds per call on the average (in this case exactly), their children (if existing) uses no time measurable (because it has no children), and it is called `5` times and returns without errors. `f` has the index `1`.
28.6 10.0 20.0 20.0 40.0 2 . . [2] g

Function `g` takes `28.6` percent of the whole time that are `20.0` milli seconds, and `10.0` milli seconds on the average per call. Their children uses `20.0` milli seconds pre call on the average and `40.0` total, and `g` is called twice and returns without errors. `g` gets the index `2`.
. . . 70.0 70.0 1 . . [3] h

Function `h` uses nearly no evaluation time, their children uses `70.0` milli seconds on the average and `70.0` total, and `h` is called once and finished without errors. `h` gets the index `3`.

The parts of the graph above are described following:
index %time self children called [index] name
---------- [0] 100.0 70 0 1 proc entry point 0 70 1 [3] h ----------

The whole function call takes `100` percent of the evaluation time (by definition), that are `70.0` milli seconds, and it is called once.

It calls once the function `h` with index `[3]` (as argument of `prog::profile`), and `h` uses `70.0` milli seconds of the time that are spent in the children of `h`, not in the body.
index %time self children called [index] name
---------- 40 0 4 [2] g 10 0 1 [3] h [1] 71.4 50 0 5 f ----------

Function f spends 71.4 percent of the whole evaluation time. It uses 50.0 milli seconds, their children uses no time measurable, and it is called 5 times.

f has two parents and no children.

f is called by its parent g4 times and by h once.

f spends 40 milli seconds by itself (in its body), when it is called from g (the first line in the part of f), and f spends 10 milli seconds in its body, when it is called from h (the second line).
index %time self children called [index] name
---------- 20 40 2 [3] h [2] 28.6 20 40 2 g 40 0 4 [1] f ----------

Function g takes 28.6 percent of the whole time, 20 milli seconds in its body, and their children take 40 milli seconds. g is called twice.

g is called from h twice, and spends 20 ms in its body and 40 ms in its children.

g calls the function f four times, and f spend 40 ms in its body, when it is called from g.
index %time self children called [index] name
---------- [3] 0.0 0 70 1 h 10 0 1 [1] f 20 40 2 [2] g ----------

Function h takes nearly no evaluation time, their children spends 70.0 milli seconds, and h is called once.

h calls the functions f and g directly, f once and g twice.

f uses 10 ms in its body, when it is called from h, and g uses 20 ms in its body and 40 ms in its children.

Parameters

stmt

A MuPAD statement

Return Values

Result of stmt

Algorithms

The timings displayed by `prog::profile` are generated by the kernel.

The evaluation of `stmt` inside `prog::profile` takes partly substantially longer than evaluating `stmt` directly. This extra time does not influence the validity of the timings, i.e., if `prog::profile` reports `f` taking three times as long as `g`, then this is also the case when evaluating `stmt` directly.

See Also

prog::tracetime

prog::remember

Purpose

Extended remember mechanism for procedures

Syntax

```
prog::remember(f, <depends>, <PreventRecursion, <predef>>)
```

Description

`prog::remember(f)` returns a modified copy of the procedure `f` that stores previously computed results and additional information in a remember table. When you call `f` with arguments that you already used in previous calls, `f` finds the results in its remember table and returns them immediately.

If you assign `f` to an identifier or a domain slot, you also must assign the copy returned by `prog::remember` to the same identifier or slot, for example, `f := prog::remember(f)`.

`f :=prog::remember(f)` remembers results without context information, such as properties or the value of DIGITS. The first time you call `f` with any new combination of input parameters, the remember table of `f` stores `` `input`->`f(input)` ``. After that, when you call `f` with the same input parameters, it takes the result `f(input)` from the remember table instead of recomputing it. See “Example 1” on page 27-41.

`f := prog::remember(f, depends)` remembers results and additional context information. The dependency function `depends` lets you specify the context information to store along with computed results in the remember table and verify in each function call. See “Example 2” on page 27-41.

Typically, it is useful to store and verify properties of the input and the values of DIGITS and ORDER. To access properties of the input, use property::depends. This dependency function verifies all three values:

```
() -> [property::depends(args()), DIGITS, ORDER]
```

Another common problem is that an overloading function does not register when its overloading slot changes in some other function or

domain. This dependency function that uses slotAssignCounter lets you avoid this problem:

```
() -> [property::depends, slotAssignCounter("foo")]
```

To combine all three tasks, use this dependency function:

```
() -> [property::depends(args()), DIGITS, ORDER, slotAssignCounter("foo")
```

The first time you call `f` with any new combination of input parameters, the remember table of `f` stores `` `[input, depends(input)]`->`f(input)` ``. After that, when you call `f` with the same input paramters, it checks whether `depends(input)` returns the same value as before. If it does, then `f` takes the result `f(input)` from the remember table. Otherwise, it computes `f(input)` and adds the new values `` `[input, depends(input)]`->`f(input)` `` to the remember table. The only exception to this rule is results computed with different values of MAXEFFORT. If in previous calls `f(input)` was computed with lower MAXEFFORT, then the new call with higher MAXEFFORT is evaluated and remembered results are replaced with the new ones.

If the dependency function is constant or returns the value that does not depend on the input, then the remember mechanism disregards context information.

You can call the modified procedure with the `Remember` option as the first argument, and one of these special options as the second argument:

- `Clear` clears the remember table of the procedure.
- `ClearPrevent` clears the remember table that prevents infinite recursions inside the procedure. For details about preventing infinite recursions, see the description of the `PreventRecursion` option.
- `Print` returns the remember table of the procedure.

For example, the call `f(Remember, Clear)` clears the remember table of `f`. Also see “Example 3” on page 27-43.

Examples

Example 1

Create this function:
f := X -> if X > 1 then f(X - 1)*f(X - 2) - f(X - 2) else 1 end_if:

Calling this function is time-consuming because the function calls itself recursively and evaluates every call:
f(20), time(f(20))0, 3260.204

```
0, 3260.204
```

Using the remember mechanism eliminates these reevaluations. To enable the remember mechanism, use `prog::remember`:
f := prog::remember(f):f(200), time(f(200))f(200), float(round(time(f(200))))0, 0.0

```
0, 0.0
```

Example 2

Create the procedure `pos` that checks if its parameter is positive:
pos := proc(x) begin is(x > 0) end_proc:

Enable the remember mechanism for `pos`:
pos := prog::remember(pos):

`pos` returns UNKNOWN for variable `a`:
pos(a)UNKNOWN

```
UNKNOWN
```

Now use assume to specify that variable `a` is positive:
assume(a > 0):

When you call `pos` for variable `a`, it finds the value of `pos(a)` in the remember table. In this case, the remember table does not store

the context information, and therefore does not check for the new assumptions on variable `a`. It returns the remembered result, which is incorrect because of the new assumption:
pos(a)UNKNOWN

```
UNKNOWN
```

Calling `pos` for `a^3` returns the correct result because `pos(a^3)` is not in the remember table yet:
pos(a^3)TRUE

```
TRUE
```

Assume that `a` is negative:
assume(a < 0):

Now both calls return incorrect values because the results are taken from the remember tables:
pos(a), pos(a^3)UNKNOWN, TRUE

```
UNKNOWN, TRUE
```

To make the remember mechanism aware of the changes in assumptions, use `prog::remember` with the second argument property::depends as the dependency function:
unassume(a): pos := proc(x) begin is(x > 0) end_proc: pos := prog::remember(pos, property::depends): pos(a)UNKNOWN

```
UNKNOWN
```

Now `pos` reacts properly to the new assumption:
assume(a > 0): pos(a)TRUE

```
TRUE
```

`pos` also returns the correct result after you clear the assumption:

unassume(a): pos(a)UNKNOWN

UNKNOWN

Example 3

Create the procedure `pos` and enable the remember mechanism for it:
pos := proc(x) begin is(x > 0) end_proc: pos := prog::remember(pos, getprop):

Call `pos` for these parameters:
pos(a): assume(b > a, _and): pos(b):

After you call the procedure at least once, it creates the remember table. To see the remember table of a procedure, use the special option `Print`. The value 10^6 in the second column is the value of MAXEFFORT used during computations.
pos(Remember, Print)table([pos(a), [C_, 0]] = [UNKNOWN, 1000000.0], [pos(b), [Dom::Interval(a, infinity), 0]] = [UNKNOWN, 1000000.0])

[pos(*a*), [ℂ, 0]]	[UNKNOWN, 1000000.0]
[pos(*b*), [(*a*, ∞), 0]]	[UNKNOWN, 1000000.0]

To clear the remember table of a procedure and thus force the function to reevaluate all results, use the special option `Clear`:
pos(Remember, Clear): pos(b)UNKNOWN

UNKNOWN

Example 4

Create the procedure `deps` that collects all operands of the properties of a given expression, including the identifiers of assumed properties:
deps := proc(x) begin if domtype(x) <> DOM_IDENT then op(map(indets(x), deps)) else x, deps(getprop(x)) end_if end_proc:

Set the following assumption. Note that now `deps` contains potentially infinite recursions because the property of `x` refers to `y`, and the property of `y` refers back to `x`:
assume(x > y):deps(x)Error: Recursive definition [See ?MAXDEPTH]

To prevent infinite recursions, use `prog::remember` with the `PreventRecursion` option:
deps := prog::remember(deps, PreventRecursion): deps(x)x, y, x

x, y, x

To simplify the return value of `deps`, rewrite the function so that it returns a set of all identifiers:
deps := proc(x) begin if domtype(x) <> DOM_IDENT then _union(op(map(indets(x), deps))) else {x} union deps(getprop(x)) end_if end_proc: deps := prog::remember(deps, PreventRecursion):deps(x){x, y} union x

$\{x, y\} \cup x$

Now `deps` expects the return value to be a set. By default, when recursion is detected, the procedure returns the value of its input (which is not a set in this example). When preventing recursion in a procedure where the type of the input differs from the type of the return value, specify the value `predef` that the procedure returns when recursion is detected:
deps := proc(x) begin if domtype(x) <> DOM_IDENT then _union(op(map(indets(x), deps))) else {x} union deps(getprop(x)) end_if end_proc: deps := prog::remember(deps, PreventRecursion, () -> {args()}):

Here `predef` returns a set with the input as an operand:
deps(x){x, y}

$\{x, y\}$

Parameters

f

A procedure or function environment

depends

A procedure or expression

predef

A procedure or expression

Options

PreventRecursion

With this option, the procedure returned by `prog::remember` uses remembered information to prevent infinite recursion inside the procedure.

`f := prog::remember(f, PreventRecursion, predef )` stores the input parameters only during the function call. This approach lets you avoid reevaluating the same function call when the function calls itself recursively. Instead, it returns the input (by default) or the result of the call `predef(input)` (if you specify `predef`). If returning the input is not an appropriate result for the function call (for example, if the return value of `f` and the input are of different types), then you must specify the value `predef`. See "Example 4" on page 27-43.

At the end of the function call, all remembered values are discarded. If you call the function with the same input parameters again, the function call is evaluated with the same costs as before.

You can prevent recursion inside the function call and simultaneously use the remember mechanism outside the function call by using this syntax: `f := prog::remember(f, depends, PreventRecursion, predef )`. If you want to use the remember mechanism with the context information, specify the dependency function `depends` as usual. If you want to use the remember mechanism without the context information and prevent recursions inside a procedure, specify `depends` as a constant (or any function whose return value does not depend on

the input). Note that if you omit the `depends` function and just use the syntax `f := prog::remember(f, PreventRecursion, predef )`, then the remember mechanism does not work outside the function call. In this case, you only prevent recursions.

Return Values

Modified procedure or function environment

- "Remember Mechanism"

prog::sort

Purpose

Sort objects by an index function

Syntax

```
prog::sort(list, func, <Reverse>, <p1, p2,  >)
```

Description

`prog::sort(list, func)` applies the function `func` to any object of the list `list` and returns a list with the given objects sorted by the order of the indices calculated by `func`.

`func` is applied only once to any object in `list`.

If optional arguments are present, then the indices are computed from the objects `x` of `list` by `f(x, p1, p2, ...)`.

An alternative call to `prog::sort` is the call `sort(list, (X, Y) -> func(X) <= func(Y))`.

Examples

Example 1

Sort a list of expressions by their length:
prog::sort([2*x, x - 4, sin(x), x + y + z], length)[sin(x), 2*x, x + y + z, x - 4]

$$[\sin(x),\ 2\,x,\ x+y+z,\ x-4]$$

Sort a list of lists by the number of operands, with descending order:
prog::sort([[1,2,3],[4,2],[0 $ 10],[]], nops, Reverse)[[0, 0, 0, 0, 0, 0, 0, 0, 0, 0], [1, 2, 3], [4, 2], []]

$$[[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],\ [1, 2, 3],\ [4, 2],\ []]$$

Parameters

list

A list of MuPAD objects

func

A function that must return a numerical value, when applied to any object of the list

Reverse

An option

p1, p2, ...

Any MuPAD objects accepted by `func` as additional parameters

Options

Reverse

`prog::sort` compares the calculated indices in reverse order.

Return Values

List with the same objects as the given list

sortsysorderstringlib::order

prog::tcov

Purpose

Report on test coverage (passed program lines)

Syntax

```
prog::tcov(Reset)
prog::tcov(<stmt>, Write = fname)
prog::tcov(Append = fname)
prog::tcov(<stmt>, Info, <Summary>, <Lines>,
<Hidden>, <Unused>, <All>)
prog::tcov(<stmt>, Annotate, <Path = pname>,
<Comment = comment>)
prog::tcov(<stmt>, Export = fname, <Annotate>, <Path =
pname>, <Comment = comment>, <Graphical>)
```

Description

`prog::tcov` inspects the data on the statements executed in library code. MuPAD collects these data if you start the MuPAD engine with the option -t. To set different options for starting the MuPAD engine, use the **Arguments** field in the Engine dialog.

You can use `prog::tcov` in two different modes:

- With a given first argument `stmt`, `prog::tcov` resets all tcov information, evaluates the statement, and shows all debug node passes for this statement during the evaluation. `prog::tcov(stmt)` clears all information about the debug node passes of current session.
- Without the first argument `stmt`, `prog::tcov` shows the debug node pass information collected by the MuPAD engine during the whole session.

You can display the logged debug node passes on the screen or export the data to an HTML file. You also can save the data about the debug node passes to a file, which enables you to read or recover a whole session state later.

`prog::tcov` can produce annotated source files containing the information collected by `prog::tcov` and the MuPAD source code.

Environment Interactions

`prog::tcov` can produce screen outputs.

If you use the `Annotate` option, `prog::tcov` creates new files. For some operating systems creating new files might require special permissions.

Examples

Example 1

To use `prog::tcov`, start the kernel in tcov mode with option -t.

The outputs in the following examples are cropped in this documentation.

The following example shows a short procedure created and called inside `prog::tcov`. The line numbers correspond to the ones in the Debugger: f:= // 1 proc(a, b) // 2 begin // 3 if a > b then // 4 return(a) // 5 else // 6 return(f(b, a)) // 7 end_if // 8 end_proc: // 9

`prog::tcov` returns all the lines passed during the evaluation of `f`: prog::tcov(f(2, 1), Info, Lines) File: /tmp/debug0.5932 Use index: 50% Nodes: 2/4 (0 hidden) Passes: 2 Line 4,0: 1 pass Line 5,0: 1 pass prog::tcov(f(1, 2), Info, Lines) File: /tmp/debug0.5932 Use index: 75% Nodes: 3/4 (0 hidden) Passes: 4 Line 4,0: 2 passes Line 5,0: 1 pass Line 7,0: 1 pass

Example 2

The following example shows the logging of passes during a session. Before running this example, define the function `f` from “Example 1” on page 27-50.

If you start the kernel with the option -v, the expose command shows the debug nodes with pass information.

`prog::tcov(Reset)` resets all tcov information: prog::tcov(Reset): prog::tcov(Info)SUMMARY Files : 1 in 1 libraries Nodes : 0/4 (0 hidden) Use index : 0% Passes : 0 (~ 0.00 passes per all nodes)

If you call the function `f` twice, the number of passes doubles: f(1, 2): f(1, 4): prog::tcov(Info) File: /tmp/debug0.5932 Use index: 75% Nodes: 3/4 (0 hidden) Passes: 8 Line 4,0: 4 passes Line 5,0: 2 passes Line 7,0: 2 passes

To see the passes, expose the function `f`:
expose(f) proc(a, b) name f; begin // /tmp/debug0.5932:4,0 [4 passes]; if b < a then // /tmp/debug0.5932:5,0 [2 passes]; return(a) else // /tmp/debug0.5932:7,0 [2 passes]; return(f(b, a)) end_if; // /tmp/debug0.5932:9,0 [0 passes] end_proc

You can write the tcov data to a data file:
prog::tcov(Write = "tcov_example.dat"):

To delete the information about the previous passes, use the `Reset` option:
prog::tcov(Reset): prog::tcov(Info)SUMMARY Files : 1 in 1 libraries Nodes : 0/4 (0 hidden) Use index : 0% Passes : 0 (~ 0.00 passes per all nodes)

To retrieve the former state, use the `Append` option:
prog::tcov(Append = "tcov_example.dat"): prog::tcov(Info, Summary)SUMMARY Files : 1 in 1 libraries Nodes : 3/4 (0 hidden) Use index : 75% Passes : 8 (~ 2.00 passes per all nodes)

Also, you can use the `Append` option to add the passes:
prog::tcov(Append = "tcov_example.dat"): prog::tcov(Info, Summary)SUMMARY Files : 1 in 1 libraries Nodes : 3/4 (0 hidden) Use index : 75% Passes : 16 (~ 4.00 passes per all nodes)

Example 3

The following example presents incomplete pieces of code. Note that you cannot execute this example without additional code lines.

Suppose, you have a source file with the following function:

```
1:  f := proc(a, b)
2:       begin
3:         if a > b then
4:           return(a)
5:         elif a = b then return(0)
6:         else
7:           f(b, a)
8:         end_if
```

```
 9:       end_proc:
```

Before executing this source file, read the commands. After reading commands, all the objects defined in the source file are available in the notebook. Calling the function `f` several times and creating the annotated source file, you get:
f(2, 1): // passing the lines 3 and 4 f(1, 1): // passing the lines 3 and 5 twice, because line 5 has two debug nodes f(1, 2): // passing the lines 3, 5 and 7 and the recursively 3 and 4, leave via line 9 // because the statement in line 7 has no return prog::tcov(Annotate)

The annotated source file uses the same path as the source file and looks like this:

```
// Generated by prog::tcov session

 1:  f := proc(a, b)
 2:       begin
 3:4         if a > b then
 4:2           return(a)
 5:2         elif a = b then return(
 5:1                                0)
 6:          else
 7:1           f(b, a)
 8:          end_if
 9:1       end_proc:
```

Note that the line 5 contains two debug nodes and appears in two lines. The line splits where the second debug node starts.

For better readability of the annotated source files, use the HTML export.

Parameters

stmt

Any MuPAD statement or MuPAD expression

fname

A file name given as a string

pname

A directory name given as a string

comment

Any string

Options

Reset

Reset the number of passes at each debug node to 0.

Write

Option, specified as `Write = fname`

This option allows you to write the information about all debug node passes of the current session to the file `fname`. You can use this file for external analysis (see the Algorithms section) or to recover or merge the information collected by `prog::tcov` (see the `Append` option).

Append

Option, specified as `Append = fname`

Append all information about debug node passes from the file `fname` to the current session.

This option allows you to merge the data generated during several sessions.

Info

Display the information about debug node passes.

Summary

Display only a short summary.

Lines

Display each pass through a debug node.

Unused

Display all code lines with debug nodes, including unpassed ones.

Hidden

This option allows you to display the hidden debug nodes. A hidden debug node is a node in a procedure with the noDebug option.

All

Display unpassed and hidden debug nodes.

Export

Option, specified as `Export = fname`

This option allows you to display the debug node passes information in summary for all read source files and for all individual source files.

The information is ordered according to the names of the directories containing the source files. Directory names can be folded.

You can see the list of all the files of a library below each library name.

Each file name presents a link that points to the annotated source file.

You can select graphical indices. Each point leads to the related line in the annotated source file.

Annotate

This option allows you to rewrite each executed MuPAD source file `filename.mu` as `filename.tcov` with an annotation at the beginning of each line. The annotation contains the line number of a debug node and the number of passes of this line, followed by the source code.

In text mode the line containing several debug nodes splits so that each line contains one debug node (see “Example 3” on page 27-51).

The new files have the extension '.tcov' instead of '.mu'. See also option `Path`.

If this option is used together with `Export`, `prog::tcov` creates the annotated source files as `HTML` files with the extension `.tcov.html`. The line colors depend on the passes.

Path

Option, specified as `Path = pname`

This option allows you to specify a path `pname` to the annotated source files and the exported status file. If you do not specify the path, `prog::tcov` creates the files in the same directory where the source files are.

Comment

Option, specified as `Comment = comment`

This option allows you to write the string `comment` on the first line of each annotated source file (see the option `Annotate`) or in the header of an exported HTML file (see the option `Export`).

Graphical

Show a graphical index for each source file in an HTML export file.

Return Values

`prog::tcov` returns the void object `null()` of type DOM_NULL.

Algorithms

To be able to use the `prog::tcov` function, start the MuPAD engine with option -t. Use the *Arguments* field in the Engine dialog to set this option.

If you start the kernel using both options `-v` and `-t`, the function expose shows information about the debug node and passes (see “Example 2” on page 27-50).

The functionality of `prog::tcov` depends on the internal debugger. For details, see the help page for the debug command.

Some special considerations:

- If the MuPAD library is read from a tar archive (file `lib.tar`), `prog::tcov` excludes from inspection all the files from this archive. The output of `prog::tcov` also includes the call of `prog::tcov` itself and some other MuPAD utility function passes.
- `prog::tcov` counts only the lines containing a “debug node”.

When called with the option `Write` or the option `Append`, `prog::tcov` creates a data file using the following format: `"filename":fileindex:`. For each read MuPAD source file, "filename" is the name of the source file and fileindex is a numerical index. For temporary files, the index is negative:

- `-1:-1:`

The colon separates the first and the second parts:

- `fileindex:line:column:hidden:passes:unused:`

For each debug node, fileindex corresponds to the first part, line and column determine the start of the debug node in the source file, hidden is 1 for hidden nodes, otherwise 0, passes is the number of passes, unused is an empty and currently unused string.

prog::test

Purpose

Automatic comparing of calculation results

Syntax

```
prog::test(stmt, res | TrapError = errnr, <Timeout
= sec>, <message>, options)
prog::test(stmt)
```

Description

`prog::test` works in two different modes: interactive and inside of test files.

In interactive mode a single call of `prog::test` can be used to compare two MuPAD statements.

The call `prog::test(stmt, res)` evaluates both arguments `stmt` and `res`. When the evaluation leads to exactly the same MuPAD object and no `Enhancement` was requested, nothing is printed and `prog::test` returns the void object `null()`.

If the results are different, the test fails and a message is printed.

The additional arguments are described in the following part for using `prog::test` in test files.

Another mode is using `prog::test` inside of test files. A test file must start with `prog::testinit` . This function initializes the test file. Then you can write several tests using `prog::test`. The last statement in a test file must be `prog::testexit()`. You also can specify the name of the tested procedure by using `print(Unquoted, "testname")` after `prog::testinit`. This name does not affect the tested procedure itself. It only appears in the test reports generated by your test script.

The tests can be arbitrary MuPAD statements and `prog::test` statements. However, most of the functionality should be executed as argument of `prog::test`. Only initialization of variables should be performed outside of `prog::test` statements in a test file, because `prog::test` traps every error (with the function traperror) and prints a specific error message.

Note If an error occurs outside of `prog::test`, reading of the test file is interrupted.

If no error occurs (as should be the default case), the results are compared and a message is printed, if they are different.

Timing information can be collected and compared that consider only the evaluation time of the first argument `stmt` of `prog::test` (see prog::testinit).

If a test fails, for example, the two first arguments of `prog::test` lead to different MuPAD objects, or if an enhancement request was given, `prog::test` prints a message. This message lists the following pieces of information:

1. The first line starts with the `Error in test` string and contains the name and a sequence number of the individual test.
2. The next three lines contain the input, the expected result, and the result actually observed.
3. For each of the options `Priority`, `Enhancement`, `Message`, `Developers`, and `BugId`, if the option has been set, a corresponding line will be printed. Note that `Message` can be set by simply providing a message string.

This information is followed by an empty blank line.

If only one argument is given, the argument is evaluated and compared with TRUE, i.e., `prog::test(ex)` is equivalent to `prog::test(ex, TRUE)`.

After the statement `setuserinfo(prog::test, 2)`, additional information for every test is printed on screen.

When a test is initialized with prog::testinit and ended by prog::testexit, a short message is printed with the following format:

```
Info:  20 test, 1 error, runtime factor 1.7 (expected 2.0)
```

The message contains the number of all tests performed (20), the number of errors (1), and two time factors: The first time factor is the based on the actual time of the test and the second time factor is the expected value given by prog::testinit.

Examples

Example 1

`prog::test` can be called interactively:
prog::test(1 + 1, 2): prog::test(is(2 > 1)): prog::test(sin(PI), 0, "check sin"):

These tests checked all right. In the next tests wrong results are tested against, to demonstrate the messages given by `prog::test`:
prog::test(1 + 2, 2):Error in test interactive 4Input: 1 + 2Expected: 2Got: 3prog::test(is(x > 1)):Error in test interactive 5Input: is(1 < x)Expected: TRUEGot: UNKNOWNprog::test(sin(PI), PI, "check sin"):Error in test interactive 6Input: sin(PI)Expected: PIGot: 0Message: check sin

Example 2

A test file must contain calls to prog::testinit and prog::testexit. In the following file, we test a function defined in the same file, which is rather uncommon, obviously.

```
// test file "test.tst"
test:= (a, b) -> a^2 + 2*b^2 - a*b:
prog::testinit("test", 0.1):
print(Unquoted, "testname"):
prog::test(test(1, 4), 29, Message = "my first example"):
prog::test(test(3, -2), 24, "the second example"):
prog::test(error("test"), TrapError = 1028):
prog::testexit():
```

The first statement is only a comment. The second line contains an initialization of a test procedure called `test`. Then the test is initialized with prog::testinit.

After that three tests are performed: The first test is right, the second expected result is wrong, and the third test produces an error, but the expected result is this error, the error number returned by traperror is `1028` (user call of error).

The whole test takes nearly no time:
read("test.tst")test:= (a, b) -> a^2 + 2*b^2 - a*b: prog::testinit("test", 0.1): prog::test(test(1, 4), 29, Message = "my first example"): prog::test(test(3, -2), 24, "the second example"): prog::test(error("test"), TrapError = 1028): prog::testexit():Error in test testname 2Input: test(3, -2)Expected: 24Got: 23Message: the second exampleNear line: 5Info: time used outside of 'prog::test' takes 100%Info: expected test time is very short; only changes above 2070% are reportedInfo: 3 tests, 1 error, runtime factor 0.0 (expected 0.1)Info: All tests 3 [prog::testexit]Info: Memory allocation 6516280 bytes [prog::testexit]

After calling setuserinfo with level `2` a message is printed additionally for each test:
setuserinfo(prog::test, 2): read("test.tst")setuserinfo(prog::test, 2): test:= (a, b) -> a^2 + 2*b^2 - a*b: prog::testinit("test", 0.1): prog::test(test(1, 4), 29, Message = "my first example"): prog::test(test(3, -2), 24, "the second example"): prog::test(error("test"), TrapError = 1028): prog::testexit():Info: testing 'testname' 1 Info: for test(1, 4) = 29 Info: testing 'testname' 2 Info: for test(3, -2) = 24 Error in test testname 2Input: test(3, -2)Expected: 24Got: 23Message: the second exampleInfo: testing 'testname' 3 Info: for error("test") = Error No. 1028 Info: time used outside of 'prog::test' takes 100%Info: expected test time is very short; only changes above 2080% are reportedInfo: 3 tests, 1 error, runtime factor 0.0 (expected 0.1)Info: All tests 3 [prog::testexit]Info: Memory allocation 6516280 bytes [prog::testexit]setuserinfo(prog::test, 0):

Example 3

Most of the options accepted by `prog::test` are more or less directly placed in the output:
prog::test(1+1, 1, Baseline, Message(2)="well ...", Priority=Low, BugId="123-456")Baseline Error in test interactive 7Input: 1 + 1Expected: 1Got: 2Priority: LowMessage: well ...BugId: 123-456

Example 4

To test that a certain call does not take longer than a specified number of seconds, use the option `Timeout`:
prog::testnum(1): prog::test(prog::wait(5.0), null(), Timeout = 10): prog::test(prog::wait(8.0), null(), Timeout = 4):[used=4609k, reserved=6057k, seconds=1] [used=4609k, reserved=6057k, seconds=2] Error in test interactive 2Input: prog::wait(8.0)Expected: null()Got: TrapError = 1320

Example 5

In most cases, the actual and the expected result are simply compared for equality. Sometimes, however, this is not desirable, especially for floating-point results:
prog::testnum(1): prog::test(float(PI), 3.1415926535897932385) Warning: This function will be removed in a future release. Directly access 'prog::TestCount' instead. [prog::testnum] Error in test interactive 1Input: float(PI)Expected: 3.141592654Got: 3.141592654

The problem here is that there are many floating-point values which are not identical, yet are displayed as such (unless you increase DIGITS far enough to see the difference). Using the option `Method`, you can provide a function to compare the values:
prog::test(float(PI), 3.1415926535897932385, Method = '~=')

Example 6

When implementing symbolic algorithms, there are often multiple correct and acceptable answers. In some cases, getting any of a certain set of solutions is fine. In these cases, using `Method = _in` is a reasonable way of writing tests (_in is the functional form of the in operator):
prog::test(int(ln(ln(a*x)^(1/2)), x), { x*ln(ln(a*x)^(1/2)) - Li(a*x)/(2*a), x*ln(ln(a*x))/2 - Li(a*x)/(2*a) }, Method = _in, Timeout = 20)

Sometimes, however, while multiple results are acceptable, you are actually targeting for one particular output. For these cases, you can use `Enhancement` to set the golden goal:

prog::test((x^2+2*x+1)/(x+1), (x^2+2*x+1)/(x+1), Enhancement = x+1)Enhancement request: interactive 4Input: (x^2 + 2*x + 1)/(x + 1)Got: (x^2 + 2*x + 1)/(x + 1)Requested: x + 1

If the enhancement request ever is fulfilled, the output changes:
prog::test(normal((x^2+2*x+1)/(x+1)), (x^2+2*x+1)/(x+1), Enhancement = x+1)Enhancement done: interactive 5Input: normal((x^2 + 2*x + 1)/(x + 1))Got: x + 1Requested: x + 1

Note that a test with an enhancement request is, first and foremost, still an ordinary test and behaves as such:
prog::test((x^2+x+1)/(x+1), (x^2+2*x+1)/(x+1), Enhancement = x+1)Error in test interactive 6Input: (x^2 + x + 1)/(x + 1)Expected: (x^2 + 2*x + 1)/(x + 1)Got: (x^2 + x + 1)/(x + 1)

Example 7

Certain calls are expected to give warnings to the user:
numeric::quadrature(sin(1/x), x=0..1) Warning: Precision goal is not achieved after 10000 function calls. Increase 'MaxCalls' and try again for a more accurate result. [numeric::quadrature] 0.5040669411

```
0.5040669411
```

Placing such calls into an unadorned call to `prog::test` causes the test to fail, because by default, `prog::test` expects the calls not to emit any warnings:
sysassign(prog::ntime, 0.65): timeOrig := time: sysassign(time, () -> 615):prog::test(bool(numeric::quadrature(sin(1/x), x=0..1) < 1), TRUE)Error in test interactive 7Input: bool(numeric::quadrature(sin(1/x), x = 0..1) < 1)Expected: TRUEGot: TRUEExpected warnings: []Got warnings: [message("symbolic:numeric:PrecisionGoalNotReached", 10000)]Used Time: 0.615 (0.946*prog::ntime())

To check for this warning, add `ExpectedWarnings` with the list shown above:
sysassign(time, timeOrig): delete timeOrig:prog::test(bool(numeric::quadrature(sin(1/x), x=0..1) < 1), TRUE,

ExpectedWarnings = ["Precision goal is not achieved after 10000" . " function calls. Increase 'MaxCalls' and try again for a more accurate result."])

It is possible to abbreviate the excepted warnings (and make tests robust against changes in places where they are expected) by using regular expression matching for the expected warnings (see strmatch for details on pattern matching):
prog::test(bool(numeric::quadrature(sin(1/x), x=0..1) < 1), TRUE, ExpectedWarnings = ["Precision goal is not achieved .* for a more accurate result."])

Parameters

stmt

A MuPAD statement to test

res

A MuPAD expression or statement that determines the expected result.

message

A message (a string) that is displayed if the test fails – see option `Message` below

Options

TrapError

Option, specified as `TrapError = errnr`

Expect the test to throw an error. `errnr` must be the integer expected from the call `traperror(stmt)` or a list of an integer and a string, as returned by `getlasterror()`.

Method

Option, specified as `Method = comp`

A method used to compare the actual and the expected result. Will be called with both expressions and must return TRUE or FALSE.

Timeout

Option, specified as `Timeout = sec`

A timeout for the evaluation of the tests. Both the actual and the expected result are evaluated with this time limit. If the computation takes too long, `prog::test` behaves as if the command had resulted in a timeout error (error number 1320).

Message

Option, specified as `Message = message` or `Message(res1) = message`

Append a message (a string) to the output of `prog::test`. If res_1 is given, the message is given if the result of evaluating `stmt` is res_1.

Baseline

Mark this test as failing in some sort of "baseline," to differentiate new bugs (stemming from new code developments, regression failures) from bugs already present in some specific earlier version. This affects the output of `prog::test`.

Enhancement

Option, specified as `Enhancement = res1`

Request some other output than the one currently tested for. Semantically, a call of the form `prog::test(inp, out, Enhancement = out2)` means "check that the call `inp` results in the same thing as the call `out`, but note that we'd actually prefer to see `out2`."

ExpectedWarnings

Option, specified as `ExpectedWarnings = list`

Gives a list of warnings the call should emit, as strings. Not emitting these warnings, or additional ones, is considered an error.

High

Low

Medium

Priority

Option, specified as `Priority = Low | Medium | High`

Denote the importance of this test. This will usually be a very subjective question and affects the output of `prog::test` only, to allow tools parsing the output displaying the problems of higher priority more prominently.

Developers

Option, specified as `Developers = devnames`

A string included in the output of `prog::test`, denoting the developers deemed responsible for the code tested. This is intended for post-processing tools.

BugId

Option, specified as `BugId = bugid`

Again, for the output of `prog::test`, include a reference to some bug tracking system. `bugid` can be any MuPAD object.

Return Values

`prog::test` returns the void object `null()`.

See Also

prog::testexitprog::testinittraperror

prog::testexit

Purpose

Closing tests

Syntax

```
prog::testexit()
```

Description

`prog::testexit` closes automatic tests from test files and prints a short statistic about the test (see prog::test).

`prog::testexit` closes the last opened protocol file.

Note `prog::testexit` must be called before beginning of a new test with prog::testinit.

Return Values

`prog::testexit` returns the void object `null()` and closes the last opened protocol file.

See Also

prog::testprog::testinit

prog::testfunc

Purpose

Name of the currently tested function

Note `prog::testfunc` will be removed in a future release. Use `print(Unquoted, "...")` instead.

Syntax

```
prog::testfunc(func)
```

Description

`prog::testfunc(func)` sets the name of `func` as name of the currently tested function and resets the current test number to `1`.

The name is used for printed messages (see prog::test).

The function `prog::testfunc` must be called at least once after prog::testinit to initialize automatic tests.

Between prog::testinit and prog::testexit several calls of `prog::testfunc` can be performed. Always the name is set and the test number is set to `1`. All messages about failed tests are collected in the same protocol file opened by prog::testinit until it is closed by prog::testexit.

Parameters

func

Any MuPAD function, an identifier or a string

Return Values

`prog::testfunc` returns the void object `null()`.

See Also

prog::testprog::testinitprog::testexit

prog::testinit

Purpose

Initialize tests

Syntax

```
prog::testinit()
prog::testinit(string)
prog::testinit(expected_time, <All>)
prog::testinit(string, expected_time, <All>)
prog::testinit(arch = expected_time,  , <All>)
prog::testinit(string, arch = expected_time,  , <All>)
```

Description

The function `prog::testinit` initializes automatic tests (see prog::test).

The second argument `expected_time` determines the time, that the test should need.

Note This time is not the real time, but a time factor that is given by prog::testexit at the end of a complete test.

This time factor is computed to be independent of the real speed of the used machine.

In general (without option `All`) the base for the time factor is the sum of all times for the evaluation of the first arguments of each call of prog::test.

The time factor can be useful to detect differences of the run time of tests, e.g., when the system or programs where changed.

For tests which run time depends on the architecture of the computer, the expected test time factor can be given apart for each test system as equation `arch = time_factor`.

The string `arch` must be one of the results returned by the function sysname. `time_factor` is the time factor given by prog::testexit at the end of the complete test on the reference system.

Examples

Example 1

Initialize a test that should need a run time factor of `2.0`:
prog::testinit("test1", 2.0):

Initialize a test that should need a run time factor of `2.8`, where the time is measured between `prog::testinit` and prog::testexit:
prog::testinit("test2", 2.8, All):

Initialize a test that should need a run time factor of `12.0` on Linux and `15.5` on Windows:
prog::testinit("test3", "glnxa64" = 12.0, "win32" = 15.5):

Parameters

string

String: a test name

expected_time

Expected test time factor (see below) in seconds as floating point number

arch

The computer architecture name as string (see sysname)

Options

All

The base for the time factor is the whole time between the command `prog::testinit` and prog::testexit.

Return Values

`prog::testinit` returns the void object `null()`.

See Also

prog::testprog::testexit

prog::testmethod

Purpose

Method for comparing in test results with Prog::test

> **Note** `prog::testmethod` will be removed in a future release. Use `prog::test(..., Method = myTestMethod)` instead.

Syntax

```
prog::testmethod(func)
```

Description

`prog::testmethod(func)` sets the procedure `func` for comparing of the arguments of the test function prog::test.

Without determining a procedure with `prog::testmethod`, the arguments of prog::test are compared with bool and _equal.

See prog::test and option `Method`.

Parameters

func

A procedure that expects two arguments and returns TRUE, when the test succeeds, FALSE otherwise.

Return Values

Given argument

See Also

prog::testbooltesteq

prog::testnum

Purpose

Current test number

Note `prog::testnum` will be removed in a future release.

Syntax

```
prog::testnum()
prog::testnum(num)
```

Description

`prog::testnum()` returns the current test number while reading a test file (see prog::test). The number can be used to display messages about the current test.

`prog::testnum(num)` sets the number for the next test to `num`. This can be used for better identifying a test inside of loops, e.g., the first test of each loop pass gets a multiple of `10` or `100` as number.

Parameters

num

The test number for the next test: a positive integer

Return Values

Current test number as positive integer or the void object

See Also

prog::testprog::testexitprog::testinit

prog::trace

Purpose

Observe functions

Syntax

```
prog::trace(obj, <Recursive = FALSE>)
prog::trace({obj_1, obj_2,  }, <Recursive = FALSE>)
prog::trace(options)
```

Description

`prog::trace(obj)` manipulates the MuPAD object `obj` to observe entering and exiting this object.

Note `prog::trace` has a new syntax and a new set of options. The old syntax has been removed.

`prog::trace` lets you observe functions, domains, domain methods, and function environments. Use the `prog::trace` function for debugging. See "Example 1" on page 24-58.

`prog::trace` lets you specify a set of functions, domains, methods, or function environments that you want to observe. See "Example 2" on page 27-73.

`prog::trace` lets you observe the relations between calls to the traced objects.

To trace the object `obj`, use the function call `prog::trace(obj)`. After that call, every time the function call enters or exits the object `obj`, MuPAD prints a message and returns the arguments and the return value of that call. See "Example 3" on page 27-74.

`prog::trace` lets you observe a domain or a function environment. When you call the `prog::trace` function for a domain, the function observes all methods of the domain. When you call `prog::trace` for a function environment, it observes all slots of the function environment. To trace only particular methods (slots), provide a set of these methods (slots). See the slot help page for more details. See "Example 8" on page 27-77.

To prevent tracing of all slots of a function environment, set the value of the `Recursive` option to FALSE. See “Example 7” on page 27-76.

The function `prog::untrace(obj)` terminates tracing of an object `obj`. Here `obj` is a function, a set of functions, a domain, a domain method, or a function environment. The function prog::traced detects whether the system currently traces a particular object.

Examples

Example 1

Define a function `f`, and observe this function:
f := x -> if x > 0 then x else -f(-x) end: prog::trace(f): f(-2)enter f(-2) enter f(2) computed 2 computed -2 -2

```
-2
```

Change the function, and reassign the new function to `f`. Although you use the same function name (`f`), MuPAD does not trace the new function:
f := x -> if x > 0 then x else f(-x) end: f(-2)2

```
2
```

To trace the new function, call `prog::trace` again. Now, the trace mechanism observes the updated function:
prog::trace(f): f(-2)enter f(-2) enter f(2) computed 2 computed 2 2

```
2
```

For further computations, stop observation of the function:
prog::untrace(f)

Example 2

If you want to trace more than one function, use a set to specify these functions in one function call:
prog::trace({sin, cos, exp}): sin(5*PI/2); cos(5*PI); exp(5)enter sin((5*PI)/2) enter sin(PI/2) remembered 1 computed 1 1

1

enter cos(5*PI) enter cos(PI) remembered -1 computed -1 -1

-1

enter exp(5) computed exp(5) exp(5)

e^5

To stop observation of all functions, use prog::untrace without arguments:
prog::untrace()

Example 3

Define a short function that calls itself recursively, and observe the calls:
fib:= proc(n) begin if n < 2 then n else fib(n - 1) + fib(n - 2) end_if end_proc: prog::trace(fib): fib(3)enter fib(3) enter fib(2) enter fib(1) computed 1 enter fib(0) computed 0 computed 1 enter fib(1) computed 1 computed 2 2

2

To limit the number of the nested function calls displayed by `prog::trace`, use the `Depth` option. To specify the value of `Depth`, use a separate `prog::trace` function call:
prog::trace(fib): prog::trace(Depth = 2); fib(12)enter fib(12) enter fib(11) computed 89 enter fib(10) computed 55 computed 144 144

144

The `Depth` option is independent of the `fib` procedure. Now, if you use `prog::trace` to trace any other procedure, `prog::trace` displays the nested calls to that procedure using `Depth = 2`. Remove this global option for further computations:
prog::untrace(fib): prog::trace(Depth = 0)

Example 4

To display memory usage, use the `Mem` option:
prog::trace(Mem): prog::trace(sin): sin(3/2*PI)enter remember::sin((3*PI)/2) [mem: 3267052] enter remember::sin(PI/2) [mem: 4033596] remembered 1 [mem: 4033436] computed -1 [mem: 4033072] -1

The `Mem` option is independent of the traced procedure. Now, if you use `prog::trace` to trace any other procedure, `prog::trace` displays memory usage in every step of that procedure. Remove this global option for further computations::
prog::untrace(sin): prog::trace(Mem = FALSE)

Example 5

The `NoArgs` option suppresses the output of arguments of traced objects:
prog::trace(linalg): prog::trace(NoArgs); linalg::eigenvalues(matrix([[1, 0, 0], [0, -1, 2], [0, 1, 1]]))enter linalg::eigenvalues enter linalg::checkForFloats return enter linalg::charpoly enter linalg::charpolyBerkowitz return return return {1, sqrt(3), -sqrt(3)}

$$\{1, \sqrt{3}, -\sqrt{3}\}$$

The `NoArgs` option is independent of the traced procedure. Now, if you use `prog::trace` to trace any other procedure, `prog::trace` hides arguments in every step of that procedure. Remove this global option for further computations:
prog::untrace(linalg): prog::trace(NoArgs = FALSE)

Example 6

If you use the `Parent` option, `prog::trace` shows the name of the procedure that calls the traced object:
prog::trace(cos): prog::trace(Parent): f := x -> cos(2*x): g := (x, y) -> f(x) + f(y): g(3/2*PI, -3/2*PI)enter cos(3*PI) (called from f) enter cos(PI) (called from cos) remembered -1 computed -1 enter cos(-3*PI) (called from f) enter cos(3*PI) (called from cos) remembered -1 computed -1 -2

```
-2
```

prog::trace(f): prog::trace(g): g(-PI, PI)enter g(-PI, PI) enter f(-PI) (called from g) enter cos(-2*PI) (called from f) enter cos(2*PI) (called from cos) enter cos(0) (called from cos) remembered 1 computed 1 computed 1 computed 1 enter f(PI) (called from g) enter cos(2*PI) (called from f) remembered 1 computed 1 computed 2 2

```
2
```

The `Parent` option is independent of the traced procedures. Now, if you use `prog::trace` to trace any other object, `prog::trace` shows relations between calls to the traced objects. Remove this global option for further computations:
prog::untrace(cos): prog::trace(Parent = FALSE)

Example 7

By default, the `prog::trace` function traces all slots of a function environment. For example, trace the besselJ function and observe the following function call:
prog::trace(besselJ); besselJ(1, 2.3)enter besselJ(1, 2.3) enter besselJ::float(1, 2.3) computed 0.5398725326 computed 0.5398725326 0.5398725326

```
0.5398725326
```

To omit tracing of all slots, set the value of the `Recursive` option to FALSE:
prog::untrace(besselJ); prog::trace(besselJ, Recursive=FALSE); besselJ(1, 4.5)enter besselJ(1, 4.5) computed -0.2310604319 -0.2310604319

```
-0.2310604319
```

For further computations, stop observation of the besselJ function:
prog::untrace(besselJ)

Example 8

You can trace domains and domain methods. For example, create the following small domain:
T := newDomain("T"): T::new := proc(h, m = 0) name T; begin new(T, h*60 + m) end: T::intern := x -> [op(x) div 60, op(x) mod 60]: T::print := x -> expr2text(T::intern(x)[1]).":". substring(expr2text(100 + T::intern(x)[2]), 2, 2): T::_plus := () -> new(T, _plus(map(args(), op))): T::expr := op: T::_mult := () -> new(T, _mult(map(args(), expr))): prog::trace(T): T(1, 30) + T(0, 45)*T(1, 05)enter T(1, 30) computed 1:30 enter T(0, 45) computed 0:45 enter T(1, 5) computed 1:05 enter T::_mult(0:45, 1:05) computed 48:45 enter T::_plus(1:30, 48:45) computed 50:15 ‘50:15‘

```
50:15
```

MuPAD does not trace the process of displaying traced outputs. Therefore, the `T::intern` and `T::print` methods do not appear in the traced outputs.

Now, trace the arithmetic methods only. When specifying the methods to trace, use their slot names, such as `slot(T, "_plus")` or `T::_plus`: prog::untrace(): prog::trace({T::_plus, T::_mult}): T(1, 30) + T(0, 45)*T(1, 05)enter T::_mult(0:45, 1:05) computed 48:45 enter T::_plus(1:30, 48:45) computed 50:15 ‘50:15‘

```
50:15
```

prog::untrace():

Parameters

obj

A MuPAD function, a domain, a method, or a function environment to observe. Specify methods by their slot names (strings).

{obj_1, obj_2, ...}

A set of MuPAD functions, domains, methods, or function environments to observe.

Options

Depth

Option, specified as `Depth = level`

Display nested function calls only up to the recursion depth `level`. Here `level` is a positive integer. After you set this option, all new and regenerated outputs for traced objects show the nested function calls only up to the specified recursion depth. See "Example 3" on page 27-74.

Mem

Show the current memory usage. After you set this option, all new and regenerated outputs for traced objects show the information about the current memory usage. See "Example 4" on page 27-75.

NoArgs

Do not show the arguments of calls to traced objects and the returned values. Without this option, all outputs for traced objects show the arguments and returned values for each call of a traced object. See "Example 5" on page 27-75.

Parent

Show the name of the procedure that calls the traced object. After you set this option, all new and regenerated outputs for traced objects show the names of the procedures that call the traced objects. See "Example 6" on page 27-75.

Recursive

Option, specified as `Recursive = FALSE`

Do not trace all slots of a function environment or domain. By default, `Recursive = TRUE`. See "Example 7" on page 27-76.

Return Values

`prog::trace` returns the void object `null()`.

See Also prog::untraceprog::tracedsetuserinfodebugprog::profile

prog::traced

Purpose

Find traced functions

Syntax

```
prog::traced(<obj>)
```

Description

`prog::traced()` lists all traced functions.

`prog::traced(obj)` detects, whether the function `obj` is traced. If `obj` is a library or a function environment, then all methods will be checked. If no argument is given, all traced functions will be displayed.

`prog::traced` determines whether a copy exists and whether the function has been manipulated the way prog::trace does.

Examples

Example 1

The sin function is traced:
prog::trace(sin): prog::traced(sin)TRUE

```
TRUE
```

The cos function is not traced:
prog::traced(cos)FALSE

```
FALSE
```

Parameters

obj

A MuPAD function, a function environment or a library

Return Values

`prog::traced` returns the void object `null()`.

See Also

prog::traceprog::untrace

prog::untrace

Purpose

Terminates observation of functions

Syntax

```
prog::untrace(obj)
prog::untrace()
```

Description

`prog::untrace(obj)` terminates the observation of the MuPAD function `obj` performed by prog::trace.

`obj` can be a domain or a function environment, too. Then all methods of the domain or function environment will be restored.

If no argument is given, all observed objects will be restored from observation.

Examples

Example 1

The observation of a function will be terminated:
prog::trace(sin): sin(2)enter sin(2) computed sin(2) sin(2)

```
sin(2)
```

prog::untrace(sin): sin(2)sin(2)

```
sin(2)
```

Parameters

obj

The MuPAD function that is observed, or a domain or a function environment

Return Values

`prog::untrace` returns the void object `null()`.

See Also

prog::tracesetuserinfodebugprog::profile

prog::wait

Purpose

Wait for a while

Syntax

```
prog::wait(m)
prog::wait(s)
```

Description

`prog::wait(m)` waits for `m` milli seconds.

`prog::wait(s)` waits for `s` seconds.

`prog::wait` uses the function rtime for time measurement.

Examples

Example 1

Wait for `3` seconds:
prog::wait(3000)

Wait for `3` seconds again:
prog::wait(3.0)

The next example shows the difference between the system time and the CPU time used by MuPAD:
time(prog::wait(2.5))2040

```
2040
```

In `2.5` seconds realtime the MuPAD process runs nearly two seconds.

Example 2

Use traperror to limit the evaluation time:
traperror(prog::wait(100.0), 5): lasterror() Error: Execution time is exceeded. Evaluating: prog::wait

Parameters

m

Milli seconds to wait as positive integer

s

Seconds to wait as positive floating-point number

Return Values

`prog::wait` returns the empty object `null()`.

rtimetimetraperror

Ground

property – Properties and Assumptions

==REFNAME==

property::depends

Purpose

Dependence table with all properties of an expression

Syntax

```
property::depends(ex,  )
```

Description

`property::depends(...)` returns a table which contains all information about the properties of the whole input. This table can be used to determine any change of the properties of an expression.

The returned table is mainly used inside the MuPAD library, to ensure the validity of remembered results of the remember mechanism.

A MuPAD expression can have different properties at different times, without changing its value.

Note The kernel remember mechanism cannot determine the change of the properties and returns wrong results, when the result depends on the properties of the input.

In this case the extended remember mechanism provided by prog::remember should be used together with `property::depends`.

Examples

Example 1

A compare of the dependence table at different times detects changes of the properties of an expression.

The first call to the defined function `has_changed` initializes the table `DEPENDS` that keeps the dependence information:
DEPENDS := table(): has_changed := proc(ex) begin if not contains(DEPENDS, ex) or property::depends(ex) <> DEPENDS[ex] then DEPENDS[ex] := property::depends(ex); TRUE else FALSE end_if end_proc: has_changed(sin(x*PI)):

The properties has not changed:
has_changed(sin(x*PI))FALSE

FALSE

Every change is detected:
assume(x, Type::Integer): has_changed(sin(x*PI))TRUE

TRUE
assume(x, Type::PosInt): has_changed(sin(x*PI))TRUE

TRUE
assume(x >= 0): has_changed(sin(x*PI))TRUE

TRUE
unassume(x): has_changed(sin(x*PI))TRUE

TRUE
delete DEPENDS, has_changed:

Example 2

The next example shows the problems with the kernel remember mechanism:
pos := proc(x) option remember; begin is(x > 0) end: pos(x)UNKNOWN

UNKNOWN

The result `UNKNOWN` was stored for the input `x` and is returned, although the properties of `x` are changed:
assume(x > 0): pos(x); assume(x < 0): pos(x)UNKNOWN

UNKNOWN
UNKNOWN

UNKNOWN

This problem can only be solved by the extended remember mechanism together with `property::depends` (`x` still is less than zero):
pos := proc(x) begin is(x > 0) end: pos := prog::remember(pos, property::depends): pos(x)FALSE

```
FALSE
```

After changing the properties of the input, the defined function recomputes the result:
assume(x > 0): pos(x); unassume(x): pos(x)TRUE

```
TRUE
```

UNKNOWN

```
UNKNOWN
```

Parameters

ex

Any MuPAD expression

Return Values

Table that can be compared with another dependence table

See Also

assumegetpropisprog::remember

property::hasprop

Purpose

Does an object have properties?

Syntax

```
property::hasprop(object)
property::hasprop()
```

Description

`property::hasprop(object)` tests, whether the object has properties and returns TRUE if the object or any subexpression has a property, otherwise FALSE.

Compared with getprop, `property::hasprop` is a fast function and can be used to determine, whether an object has properties without using the slower functions getprop or is.

Note In some cases, the function is can derive some aspects without any defined property (see “Example 2” on page 28-6)!

Examples

Example 1

Does the expression `2*(x+1)` have any properties?
property::hasprop(2*(x + 1))FALSE

FALSE

assume(x > 0): property::hasprop(2*(x + 1))TRUE

TRUE

getprop(2*(x + 1))Dom::Interval(2, infinity)

(2, ∞)

delete x:

Example 2

`property::hasprop` returns FALSE, but is can determine an answer unequal to UNKNOWN:
property::hasprop(0 < x/(x + y) + y/(x + y))FALSE

FALSE
is(exp(x) = 0)FALSE

FALSE

Parameters

object

Any MuPAD object

Return Values

TRUE or FALSE

See Also

assumegetpropisindetsunassume

property::showprops

Purpose

What assumptions are made?

Syntax

```
property::showprops(object)
```

Description

`property::showprops(object)` shows all assumptions set for identifiers in `object`. If no assumptions were set, the empty list ist returned.

Examples

Example 1

assume(x > 0); property::showprops(x);[0 < x]

$$[0 < x]$$

assumeAlso(x < 1): property::showprops(x);[x < 1, 0 < x]

$$[x < 1,\ 0 < x]$$

delete x:

Parameters

object

Any MuPAD object

Return Values

List containing all assumptions.

solvelib – Datatypes and Utilities for the Solver

==REFNAME==

solvelib::BasicSet

Purpose

Basic infinite sets

Syntax

Domain Creation

```
solvelib::BasicSet(Dom::Integer)
solvelib::BasicSet(Dom::Rational)
solvelib::BasicSet(Dom::Real)
solvelib::BasicSet(Dom::Complex)
```

Description

The domain `solvelib::BasicSet` comprises the four sets of integers, reals, rationals, and complex numbers, respectively.

The four basic sets are assigned to the identifiers `Z_`, `Q_`, `R_`, and `C_` during system initialization.

The set of positive integers, too, is assigned to the identifier `N_` during system initialization. It is not represented by a basic set but by the intersection of `Z_` and the interval `Dom::Interval([1], infinity)`.

Superdomain

Dom::BaseDomain

Axioms

Ax::canonicalRep

Categories

Cat::Set

Examples

Example 1

The domain of basic sets know about the basic arithmetical and set-theoretic functions:
J:=Dom::Interval(3/2, 21/4): Z_ intersect J{2, 3, 4, 5}

```
{2, 3, 4, 5}
```

solvelib::cartesianPower

Purpose

Cartesian power of a set

Syntax

Domain Creation

```
solvelib::cartesianPower()
solvelib::cartesianPower(S, n)
```

Description

`solvelib::cartesianPower` is the domain of all cartesian powers of subsets of the complex numbers.

`solvelib::cartesianPower(S, n)` returns the set of all n-tuples of elements of `S`.

`solvelib::cartesianPower(S, n)` returns the `n`-fold cartesian product of `S` with itself, that is, the set of all vectors of length `n` whose components are elements of `S`.

`S` must represent a subset of the complex numbers; see solve for an overview of the different kinds of sets in MuPAD.

The set of one-tuples of elements of `S` consists of vectors and therefore differs from the set `S` in the same way as matrices of type matrix with one row and one column are different from numbers.

Superdomain

Dom::BaseDomain

Categories

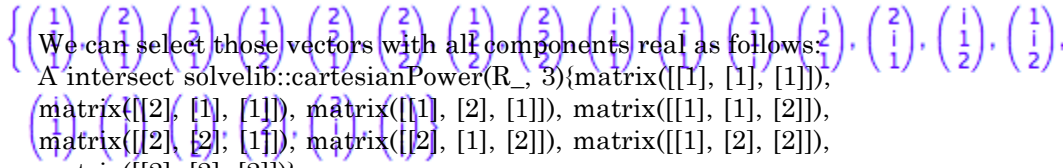
Cat::Set

Examples

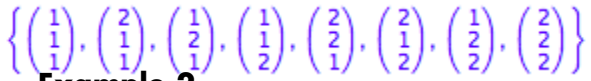
Example 1

A cartesian power of a finite set of numbers is a finite set of vectors:
A:= solvelib::cartesianPower({1, 2, I}, 3){matrix([[1], [1], [1]]), matrix([[2], [1], [1]]), matrix([[1], [2], [1]]), matrix([[1], [1], [2]]), matrix([[2], [2], [1]]), matrix([[2], [1], [2]]), matrix([[1], [2], [2]]), matrix([[2], [2], [2]]), matrix([[I], [1], [1]]), matrix([[1], [I], [1]]), matrix([[1], [1], [I]]), matrix([[I], [2], [1]]), matrix([[2], [I], [1]]), matrix([[I], [1], [2]]), matrix([[1], [I], [2]]), matrix([[2], [1], [I]]), matrix([[1], [2], [I]]), matrix([[I], [2], [2]]), matrix([[2], [I], [2]]),

matrix([[2], [2], [I]]), matrix([[I], [I], [1]]), matrix([[I], [1], [I]]), matrix([[1], [I], [I]]), matrix([[I], [I], [2]]), matrix([[I], [2], [I]]), matrix([[2], [I], [I]]), matrix([[I], [I], [I]])}



We can select those vectors with all components real as follows:
A intersect solvelib::cartesianPower(R_, 3){matrix([[1], [1], [1]]), matrix([[2], [1], [1]]), matrix([[1], [2], [1]]), matrix([[1], [1], [2]]), matrix([[2], [2], [1]]), matrix([[2], [1], [2]]), matrix([[1], [2], [2]]), matrix([[2], [2], [2]])}



Example 2

Cartesian powers of the set of complex numbers may occur as the result of a call to solve if every n-tuple of complex numbers is a solution of the given system:
solve([x+y = x+y], [x, y], VectorFormat)C_^2

Parameters

s

Set

n

Positive integer

Methods

Access Methods

baseSet `S`

`base(A)`

dimensionExponent `n`

`dimension(A)`

Technical Methods

printPrint a cartesian power

`print(A)`

solvelib::cartesianProduct

Purpose

Cartesian product of sets

Syntax

```
solvelib::cartesianProduct(S,  )
```

Description

`solvelib::cartesianProduct(S,...)` returns the cartesian product of its arguments.

The arguments may be sets of any type, consisting of complex numbers; the result is a set that consists of vectors, or a symbolic call to `solvelib::cartesianProduct`. See solve for an overview of the different kinds of sets in MuPAD.

Examples

Example 1

For finite sets, the result is similar to that of combinat::cartesianProduct but consists of vectors and not of lists:
S:= solvelib::cartesianProduct({1, 2}, {3, 4}){matrix([[1], [3]]), matrix([[2], [3]]), matrix([[1], [4]]), matrix([[2], [4]])}

$$\left\{\begin{pmatrix}1\\3\end{pmatrix}, \begin{pmatrix}2\\3\end{pmatrix}, \begin{pmatrix}1\\4\end{pmatrix}, \begin{pmatrix}2\\4\end{pmatrix}\right\}$$

solvelib::splitVectorSet(S)[{1, 2}, {3, 4}]

$$[\{1, 2\}, \{3, 4\}]$$

delete S:

Example 2

For infinite sets, results of various types are possible, e.g., solvelib::VectorImageSet or solvelib::cartesianPower:
solvelib::cartesianProduct(R_, R_)R_^2

$$\mathbb{R}^2$$

solvelib::cartesianProduct(PI*Z_, Z_)Dom::ImageSet(matrix([[PI*k], [l]]), [k, l], [Z_, Z_])

$$\left\{\binom{\pi k}{l} \middle| k \in \mathbb{Z}, l \in \mathbb{Z}\right\}$$

Parameters **s**

Set of complex numbers

Return Values Set

See Also combinat::cartesianProductsolvesolvelib::cartesianPowersolvelib::splitVectorSet

solvelib::conditionalSort

Purpose

Possible sortings of a list depending on parameters

Syntax

```
solvelib::conditionalSort(l)
```

Description

`solvelib::conditionalSort(l)` sorts the list `l` in ascending order. Unlike for sort, only the usual order on the real numbers and not the internal order (see sysorder) is used. `solvelib::conditionalSort` does a case analysis if list elements contain indeterminates.

`solvelib::conditionalSort` invokes the inequality solver to get simple conditions in the case analysis. The ability of `solvelib::conditionalSort` to recognize sortings as impossible is thus limited by the ability of the inequality solver to recognize an inequality as unsolvable. See “Example 3” on page 29-16.

Only expressions representing real numbers can be sorted. It is an error if non-real numbers occur in the list; it is implicitly assumed that all parameters take on only such values that cause all list elements to be real.

Sorting is unstable, i.e. equal elements may be placed in any order in the resulting list; these cases may be listed separately in the case analysis.

The usual simplifications for piecewise defined objects are applied, e.g., equalities that can be derived from a condition are applied (by substitution) to the list.

Environment Interactions

`solvelib::conditionalSort` takes into account the assumptions on all occurring identifiers.

Examples

Example 1

In the simplest case, sorting a two-element list `[a,b]` just amounts to solving the inequation `a<=b` w.r.t. all occuring parameters.

```
solvelib::conditionalSort([x,x^2])
```

```
piecewise([0 < x*(x - 1), [x, x^2]], [x*(x - 1) <= 0, [x^2, x]])
```

$$\begin{cases} [x, x^2] & \text{if } 0 < x\,(x-1) \\ [x^2, x] & \text{if } x\,(x-1) \le 0 \end{cases}$$

Example 2

If, by implicit or explicit assumptions on the parameters, no different sortings can occur, the result is just a list.

According to the implicit assumption that all list elements are real, x must be nonnegative.
solvelib::conditionalSort([sqrt(x), -3])[-3, sqrt(x)]

$$[-3, \sqrt{x}]$$

Example 3

Sometimes cases are not recognized as impossible.
assume(x>5): solvelib::conditionalSort([x,gamma(x)])piecewise([x < gamma(x), [x, gamma(x)]], [gamma(x) <= x, [gamma(x), x]])

$$\begin{cases} [x, \Gamma(x)] & \text{if } x < \Gamma(x) \\ [\Gamma(x), x] & \text{if } \Gamma(x) \le x \end{cases}$$

Parameters

l

List of arithmetical expressions

Return Values

List if the sorting is the same for all possible parameter values; or an object of type `piecewise` if some case analysis is necessary.

Algorithms

The complexity of sorting a list of n elements is up to n!$n!$.

See Also

sortpiecewise

solvelib::getElement

Purpose

Get one element of a set

Syntax

```
solvelib::getElement(S, <Random>)
```

Description

`solvelib::getElement(S)` returns an element of `S`.

`S` can be a set of any type; see solve for an overview of all sets.

`solvelib::getElement` returns the value `FAIL` if:

- `S` is the empty set
- the solver cannot find any element of the set due to the solver's limitations
- the solver cannot compute the first element of a set. You can use the `Random` option to check a random element of a set instead of the first element
- the answer depends on a case analysis on some parameter

With the option `Random`, the probability to get any particular element of a set is:

- Roughly equal for the elements of a finite set
- Proportional to the multiplicities for the elements of a finite multiset of type Dom::Multiset
- Unspecified for the elements of an infinite set. Practically, the same result does not occur twice for infinite sets.

Examples

Example 1

If `S` is a finite set, the solver returns just one of the elements:
solvelib::getElement({2, 7, a})2

```
2
```

Example 2

For image sets, the solver replaces every parameter by a constant:
S:=Dom::ImageSet(k*PI, k,
solvelib::BasicSet(Dom::Integer))Dom::ImageSet(PI*k, k, Z_)

$$\{\pi\, k \mid k \in \mathbb{Z}\}$$

solvelib::getElement(S)0

0

Example 3

If the set is empty, the solver cannot find any element:
solvelib::getElement({})FAIL

FAIL

`solvelib::getElement` might fail to find an element of a set although that set is not empty.
solvelib::getElement(solve(exp(x) + cos(x) = x^2,x))FAIL

FAIL

Example 4

Without the option `Random`, `solvelib::getElement` always produces the same result for a set:
solvelib::getElement({$1..5}) $i=1..51, 1, 1, 1, 1

1, 1, 1, 1, 1

With the option `Random`, the returned element varies randomly from call to call:
solvelib::getElement({$1..5}, Random) $i=1..152, 1, 3, 4, 2, 4, 1, 4, 2, 5, 1, 4, 3, 1, 5

```
2, 1, 3, 4, 2, 4, 1, 4, 2, 5, 1, 4, 3, 1, 5
```

The distribution of the returned values is close to the uniform distribution. For multisets, the multiplicity of elements is taken into account:
solvelib::getElement(Dom::Multiset(1$4, 2$2), Random) $i=1..181, 1, 1, 1, 2, 1, 1, 1, 1, 1, 1, 1, 2, 1, 2, 1, 1

```
1, 1, 1, 1, 2, 1, 1, 1, 1, 1, 1, 1, 1, 2, 1, 2, 1, 1
```

Example 5

For the following set parametrized by integers, the solver fails to find an element. This is because the solver tries only the first parameter-value pair `k = 0` for which the result is undefined. After that the solver does not try any other parameter-value pairs:
solvelib::getElement(1/Z_)FAIL

```
FAIL
```

For the sets with the undefined first element, you can get the result calling the solver with the option `Random`:
solvelib::getElement(1/Z_, Random)1/902

$$\frac{1}{902}$$

Parameters

S

Any set

Options

Random

Returns a random element of a set. Without this option, `solvelib::getElement(S)` always returns the same element.

Return Values `solvelib::getElement` returns a MuPAD object representing an element of `S`, or `FAIL` if no element could be determined.

Overloaded By `S`

See Also solve

solvelib::isEmpty

Purpose

Predicate expressing the emptyness of a set

Syntax

```
solvelib::isEmpty(S)
```

Description

`solvelib::isEmpty(S)` returns a boolean expression that is equivalent to the statement that `S` is the empty set.

Since functions operating on boolean expressions like assume, is, or solve cannot handle equations involving sets, it is not possible to pass the expression `S={}` to them. `solvelib::isEmpty(S)` helps to get around this problem, as it tries to express the emptyness of `S` in an equivalent way that can be handled by the aforementioned functions. If no suitable equivalen expression is found, the unevaluated call to `solvelib::isEmpty` is returned.

`S` may be a set of any type; see solve for an enumeration of the various types of sets.

The `solvelib::isEmpty` function always returns Boolean expressions, even if the function cannot resolve an expression. See “Example 4” on page 29-22.

Examples

Example 1

The emptyness of a DOM_SET can be decided immediately: solvelib::isEmpty({a, b}), solvelib::isEmpty({})FALSE, TRUE

FALSE, TRUE

Example 2

The intersection of a finite set with any other set is empty if and only if none of the elements of the finite set is in the other set: solvelib::isEmpty({a, b} intersect Z_)not a in Z_ and not b in Z_

$a \notin \mathbb{Z} \wedge b \notin \mathbb{Z}$

Example 3

The output of solve can be entered directly into `solvelib::isEmpty`:
solvelib::isEmpty(solve(a*x=b, x))a = 0 and b <> 0

$$a = 0 \wedge b \neq 0$$

Example 4

Sometimes, no simpler equivalent expression can be found:
result := solvelib::isEmpty(solve(x^2 = sin(x),
x))solvelib::isEmpty(solve(x^2 - sin(x) = 0, x))

$$\text{solvelib::isEmpty}\left(\text{solve}\left(x^2 - \sin(x) = 0,\ x\right)\right)$$

The returned expression is a Boolean expression:
testtype(result, Type::Boolean)TRUE

TRUE

Parameters

S

Any set

Return Values

Boolean expression

Overloaded By

S

See Also

solveassumeis

solvelib::isFinite

Purpose

Test whether a set is finite

Syntax

```
solvelib::isFinite(S)
```

Description

`solvelib::isFinite(S)` returns `TRUE`, `FALSE`, or `UNKNOWN` depending on whether `S` is finite, infinite, or the question could not be settled.

`S` may be a set of any type; see solve for an enumeration of the various types of sets.

Examples

Example 1

A DOM_SET is always finite:
solvelib::isFinite({2,5})TRUE

```
TRUE
```

Example 2

The set of integers is infinite.
solvelib::isFinite(Z_)FALSE

```
FALSE
```

Parameters

S

Any set

Return Values

Boolean value

Overloaded By

S

See Also

solve

solvelib::pdioe

Purpose

Solve polynomial Diophantine equations

Syntax

```
solvelib::pdioe(a, b, c)
solvelib::pdioe(aexpr, bexpr, cexpr, x)
```

Description

`solvelib::pdioe(a, b, c)` returns polynomials `u` and `v` that satisfy the equation `au + bv = c`.

`solvelib::pdioe(aexpr, bexpr, cexpr, x)` does the same after converting the arguments into univariate polynomials `a, b, c` in the variable `x`.

The coefficient ring of the polynomials `a`, `b`, and `c` must be either Expr, or IntMod(p) for some prime p, or a domain belonging to the category Cat::Field.

Examples

Example 1

If expressions are passed as arguments, a fourth argument must be provided:
solvelib::pdioe(x, 13*x + 22*x^2 + 18*x^3 + 7*x^4 + x^5 + 3, x^2 + 1, x)-
x^4/3 - (7*x^3)/3 - 6*x^2 - (19*x)/3 - 13/3, 1/3

$$-\frac{x^4}{3}-\frac{7x^3}{3}-6x^2-\frac{19x}{3}-\frac{13}{3},\ \frac{1}{3}$$

Example 2

x is not a multiple of the gcd of $x + 1$ and $x^2 - 1$. Hence the equation $u(x + 1) + v(x^2 - 1) = x$ has no solution for u and v:
solvelib::pdioe(x + 1, x^2 - 1, x, x)FAIL

FAIL

Example 3

If the arguments are polynomials, the fourth argument may be omitted:

solvelib::pdioe(poly(a + 1, [a]), poly(a^2 + 1, [a]), poly(a - 1, [a]))poly(a, [a]), poly(-1, [a])

Parameters

x

Identifier or indexed identifier

a

b

c

Univariate polynomials

aexpr

bexpr

cexpr

Polynomial expressions

Return Values

If the equation is solvable, `solvelib::pdioe` returns an expression sequence consisting of two operands of the same type as the input (expressions or polynomials). If the equation has no solution, `solvelib::pdioe` returns FAIL.

See Also

solve

solvelib::preImage

Purpose

Preimage of a set under a mapping

Syntax

```
solvelib::preImage(a, x, S)
```

Description

`solvelib::preImage(a, x, S)` returns the set of all numbers `y` such that substituting `y` for `x` in `a` gives an element of `S`.

`S` can be a set of any type (finite or infinite).

Examples

Example 1

In case of a finite set `S`, the preimage of S is just the union of all sets `solve(a=s, x)`, where `s` ranges over the elements of `S`.
solvelib::preImage(x^2+2, x, {11, 15});{-3, 3, sqrt(13), -sqrt(13)}

$$\{-3,\ 3,\ \sqrt{13},\ -\sqrt{13}\}$$

Note that computing this set may take a long time for large finite sets:
time(solvelib::preImage(x, x, Z_ intersect Dom::Interval(0, 1000000)))
14657

14657

Example 2

For intervals, the preimage is usually an interval or a union of intervals.
solvelib::preImage(x^2+2, x, Dom::Interval(3..7));Dom::Interval(1, sqrt(5)) union Dom::Interval(-sqrt(5), -1)

$$(1,\ \sqrt{5}) \cup (-\sqrt{5},\ -1)$$

Parameters

a

Arithmetic expression

x

Identifier

S

Set

Return Values

Set

See Also

solve

solvelib::splitVectorSet

Purpose

Factor a set of vectors into a cartesian product

Syntax

```
solvelib::splitVectorSet(S)
```

Description

`solvelib::splitVectorSet(S)` returns a list S_1, ..., S_n of sets of complex numbers such that `S` is the cartesian product of the S_i, or FAIL if such factorization could not be found.

The set `S` may be finite or infinite, of any type.

Examples

Example 1

We split a finite set of vectors into its factors:
solvelib::splitVectorSet({[1, 2], [1, 3], [0, 2], [0, 3]})[{0, 1}, {2, 3}]

[{0, 1}, {2, 3}]

The following set cannot be written as a cartesian product:
solvelib::splitVectorSet({[1, 2], [0, 2], [0, 3]})FAIL

FAIL

Example 2

Infinite sets can also be handled:
S:= Dom::ImageSet([k*PI, l*PI+2], [k, l], [Z_, Z_])Dom::ImageSet(matrix([[PI*k], [PI*l + 2]]), [k, l], [Z_, Z_])

$$\left\{\begin{pmatrix} \pi k \\ \pi l + 2 \end{pmatrix} \middle|\ k \in \mathbb{Z},\ l \in \mathbb{Z}\right\}$$

solvelib::splitVectorSet(S)[Dom::ImageSet(PI*k, k, Z_), Dom::ImageSet(PI*k + 2, k, Z_)]

$$[\{\pi k \mid k \in \mathbb{Z}\},\ \{\pi k + 2 \mid k \in \mathbb{Z}\}]$$

delete S:

Parameters **s**

Set of vectors

Return Values List of type DOM_LIST, or FAIL

See Also solve

solvelib::Union

Purpose

Union of a system of sets

Syntax

```
solvelib::Union(set, param, paramset)
solvelib::Union(set, paramlist, vectorset)
```

Description

`solvelib::Union (set, paramlist, vectorset)` returns the set of all objects that can be obtained by replacing, in some element of `set`, the list of free parameters `paramlist` by an element of `vectorset`.

`set` may be a set of any type; it need not depend on the parameter `param`, and it may also contain other free parameters.

`paramset` may be a set of any type and may depend on some free parameters. See "Example 1" on page 29-30.

If `paramset` is empty, the result is the empty set. Overloading has no effect in this case.

`vectorset` may be a set of any type, consisting of vectors whose dimension equals the number of variables in `paramlist`.

Examples

Example 1

We compute the set of all numbers that are equal to $k + 1$ or $k + 3$ for $k = 2$, $k = 4$, or $k = l$, where l is a free parameter.
solvelib::Union({k+1, k+3}, k, {2,4,l});{3, 5, 7, l + 1, l + 3}

$$\{3, 5, 7, l + 1, l + 3\}$$

Example 2

In the same way, we can let a pair of parameters range over a set of pairs:
solvelib::Union(Dom::ImageSet(PI*k + exp(x) + y, k, Z_), [x, y], {[3, 2], [1, 4]})Dom::ImageSet(exp(1) + PI*k + 4, k, Z_) union Dom::ImageSet(exp(3) + PI*k + 2, k, Z_)

$$\{e+\pi k+4 \mid k\in\mathbb{Z}\}\cup\{e^3+\pi k+2 \mid k\in\mathbb{Z}\}$$

Parameters

set

Set of any type

param

Identifier

paramset

Set of any type

paramlist

List of identifiers

vectorset

Set of vectors

Return Values

`solvelib::Union` returns a set of any type; see solve for an overview of the different types of sets. It may also return the unevaluated call if the union could not be computed.

solve

solvelib::VectorImageSet

Purpose

Domain of set of vectors that are images of sets under mappings

Syntax

Domain Creation

```
solvelib::VectorImageSet()
```

Element Creation

```
solvelib::VectorImageSet(v, x, S)
Dom::ImageSet(v, [x1,  ], [S1,  ])
```

Description

Domain Creation

`solvelib::VectorImageSet` is the domain of all sets of vectors of complex numbers that can be written as the set of all values taken on by some mapping, i.e., sets of the form ImageSet([f[1](x[1], Symbol::hellip, x[n]), Symbol::hellip, f[m](x[1], Symbol::hellip, x[n])], x[i] in S[i]) $\{[f_1(x_1, \ldots, x_n), \ldots, f_m(x_1, \ldots, x_n)] \mid x_i \in S_i\}$ for some complex-valued functions f_j and some sets S_1, …, S_n of complex numbers.

Sets of this type are used by solve to express solutions of systems of equations like ImageSet([k*PI, z], k in Z_, z in C_) $\{[k\pi, z] \mid k \in \mathbb{Z}, z \in \mathbb{C}\}$.

Element Creation

`solvelib::VectorImageSet(v, x, S)` represents the set of all vectors that can be obtained by substituting some element of `S` for `x` in the vector `v`.

`solvelib::VectorImageSet(v, [x1, ...], [S1, ...])` represents the set of all values that can be obtained by substituting, for each i, the identifier x_i by some element of S_i in the vector `v`.

The user never needs to call `solvelib::VectorImageSet` directly. Instead, Dom::ImageSet should be used; it will automatically create a vector image set if its first argument is a list or matrix. The entries and methods of the domain `solvelib::VectorImageSet` are the same as those of Dom::ImageSet, and may be found on that help page.

Superdomain

Dom::ImageSet

Categories

Cat::Set

Examples

Example 1

We create a set of two-dimensional vectors:
S:= Dom::ImageSet([k*PI, k*I*PI], k, Z_)Dom::ImageSet(matrix([[PI*k], [PI*k*I]]), k, Z_)

$$\left\{ \begin{pmatrix} \pi k \\ \pi k i \end{pmatrix} \middle| k \in \mathbb{Z} \right\}$$

Since this is a set of vectors, a `solvelib::VectorImageSet` is created automatically:
type(S)solvelib::VectorImageSet

DomImageSet

Set-theoretic operations (union, intersection, set difference) may be applied to `S`:
S intersect {[0, 0], [1, 1]}, S minus S{[0, 0]}, {}

$$\{[0, 0]\}, \varnothing$$

delete S:

Parameters

v

List or matrix

x

S

Set of any type

stats – Statistics

==REFNAME==

stats::betaCDF

Purpose

Cumulative distribution function of the beta distribution

Syntax

```
stats::betaCDF(a, b)
```

Description

`stats::betaCDF(a, b)` returns a procedure representing the cumulative distribution function

x->piecewise([x<=0, 0], [0<x and x<1, 1/beta(a,b)*int(t^(a-1)*(1-t)^(b-1), t=0..x)], [x>=1, 1])

$$x \to \begin{cases} 0 & \text{if } x \le 0 \\ \frac{1}{B(a,b)} \int_0^x t^{a-1} (1-t)^{b-1}\, dt & \text{if } 0 < x \wedge x < 1 \\ 1 & \text{if } x \ge 1 \end{cases}$$

of the beta distribution with shape parameters $a > 0$, $b > 0$.

The procedure `f := stats::betaCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

- If `x` can be converted to a real floating-point number and `a` and `b` can be converted to positive floating-point numbers, then the return value `f(x)` is a floating-point number.
- For numerical values $x \le 0$ and $x \ge 1$, the floating-point numbers `0.0`, respectively `1.0`, are returned even if `a` and `b` are symbolic quantities.
- The call `f(- infinity )` returns `0.0`; the call `f( infinity )` return `1.0`.
- In all other cases, `f(x)` returns the symbolic call `stats::betaCDF(a, b)(x)`.

Numerical values of `a` and `b` are only accepted if they are positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the cumulative distribution function with $a = 5$ and $b = 7$ at various points:
f := stats::betaCDF(5, 7): f(-infinity), f(-PI), f(1/sqrt(10)), f(0.75), f(1), f(infinity)0.0, 0.0, 0.247351489, 0.9924387932, 1.0, 1.0

0.0, 0.0, 0.247351489, 0.9924387932, 1.0, 1.0

Nonpositive numerical values of a or b lead to an error:
stats::betaCDF(-5, 7)(0.75) Error: The first shape parameter must be positive. [stats::betaCDF] Error: the first shape parameter must be positive [stats::betaCDF] delete f:

Example 2

For symbolic arguments, symbolic calls of `stats::betaCDF` are returned, unless $x \le 0$ or $x \ge 1$ can be decided:
f := stats::betaCDF(a, b): f(-2), f(0), f(1/3), f(0.4), f(1), f(PI), f(x)0.0, 0.0, stats::betaCDF(a, b)(1/3), stats::betaCDF(a, b)(0.4), 1.0, 1.0, stats::betaCDF(a, b)(x)

0.0, 0.0, stats::betaCDF(*a*, *b*)$\left(\frac{1}{3}\right)$, stats::betaCDF(*a*, *b*)(0.4), 1.0, 1.0, stats::betaCDF(*a*, *b*)(*x*)

When positive real numbers are assigned to a and b, the call $f(x)$ returns a floating-point number if x is numerical:
a := 2: b := PI: f(-2), f(1/3), f(0.4), f(PI)0.0, 0.4272662874, 0.5465772418, 1.0

0.0, 0.4272662874, 0.5465772418, 1.0

delete f, a, b:

Parameters

a

b

The shape parameters of the beta distribution: arithmetical expressions representing positive real values.

Return Values

procedure.

See Also

stats::betaPDFstats::betaQuantilestats::betaRandom

stats::betaPDF

Purpose

Probability density function of the beta distribution

Syntax

```
stats::betaPDF(a, b)
```

Description

`stats::betaPDF(a, b)` returns a procedure representing the probability density function

x->piecewise([x>0 and x<1, x^(a-1)*(1-x)^(b-1)/beta(a,b)], [x<=0 or x >=1, 0])

$$x \to \begin{cases} \frac{x^{a-1}\,(1-x)^{b-1}}{\beta(a,b)} & \text{if } x > 0 \wedge x < 1 \\ 0 & \text{if } x \le 0 \vee x \ge 1 \end{cases}$$

of the beta distribution with shape parameters $a > 0$ and $b > 0$

The procedure `f := stats::betaPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

- If `x` is a real floating-point number and `a` and `b` can be converted to positive floating-point numbers, then `f(x)` returns a floating-point number.
- If $0 < x < 1$ can be decided, the expression `x^(a-1)*(1-x)^(b-1)/beta(a, b)` is returned. If $x \le 0$ or $x \ge 1$ can be decided, then `0`, respectively `0.0`, is returned.
- The calls `f(- infinity )` and `f( infinity )` return 0.
- In all other cases, `f(x)` returns the symbolic call `stats::betaPDF(a, b)(x)`.

Numerical values of `a` and `b` are only accepted if they are positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure returned by `stats::betaPDF` reacts to properties of its argument.

Examples

Example 1

We evaluate the probability density function with $a = 3$ and $b = 4$ at various points:
f := stats::betaPDF(3, 4): f(-infinity), f(-1), f(1/2), f(0.7), f(infinity)0, 0, 15/8, 0.7938, 0

$$0,\ 0,\ \frac{15}{8},\ 0.7938,\ 0$$

delete f:

Example 2

If x is a symbolic object without properties, then it cannot be decided whether $0 < x < 1$ holds. A symbolic function call is returned:
f := stats::betaPDF(a, b): f(x)stats::betaPDF(a, b)(x)

$$\text{stats::betaPDF}(a, b)(x)$$

With suitable properties, an explicit expression is returned:
assume(0 < x < 1): f(x)(x^(a - 1)*(1 - x)^(b - 1))/beta(a, b)

$$\frac{x^{a-1}\,(1-x)^{b-1}}{\beta(a, b)}$$

assume(x > 1): f(x)0

$$0$$

unassume(x): delete f:

Parameters

a

b

The shape parameters of the beta distribution: arithmetical expressions representing positive real values.

Return Values procedure.

See Also stats::betaCDFstats::betaQuantilestats::betaRandom

stats::betaQuantile

Purpose

Quantile function of the beta distribution

Syntax

```
stats::betaQuantile(a, b)
```

Description

`stats::betaQuantile(a, b)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::betaCDF(a, b)`. For $0 \le x \le 1$, the solution of *stats*::*betaCDF*(*a*, *b*)(*y*) = *x* is given by *y* = *stats*::*betaQuantile*(*a*, *b*)(*x*).

The procedure `f := stats::betaQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, or a symbolic expression:

- If `a` and `b` can be converted to positive floating-point numbers and `x` is a real number between 0 and 1, then the return value `f(x)` is a floating-point number between 0.0 and 1.0 approximating the real solution *y* of *stats*::*betaCDF*(*a*, *b*)(*y*) = *x*.
- `f(0)`, `f(0.0)`, `f(1)`, and `f(1.0)` produce 0, 0.0, 1, and 1.0, respectively, for all values of `a` and `b`.
- In all other cases, `f(x)` returns the symbolic call `stats::betaQuantile(a, b)(x)`.

Numerical values of `a` and `b` are only accepted if they are positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with $a = \pi$ and $b = 11$ at the point x=9/10$x = \frac{9}{10}$:

```
f := stats::betaQuantile(PI, 11): f(9/10)0.368643722
```

```
0.368643722
```

The value `f(x)` satisfies `stats::betaCDF(PI, 11)(f(x)) = x`:
stats::betaCDF(PI, 11)(f(0.98765))0.98765

0.98765

delete f:

Example 2

For symbolic arguments, symbolic calls are returned:
f := stats::betaQuantile(a, b): f(x), f(0.9)stats::betaQuantile(a, b)(x), stats::betaQuantile(a, b)(0.9)

stats::betaQuantile(*a*, *b*)(*x*), stats::betaQuantile(*a*, *b*)(0.9)

If `a`, `b` evaluate to real numbers and `x` to a real number between 0 and 1, then the call `f(x)` produces a float:
a := 17: b := 6: f(0.9)0.8499783131

0.8499783131

Numerical values for x are only accepted if $0 \le x \le 1$:
f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, a, b:

Parameters

a

b

The shape parameters of the beta distribution: arithmetical expressions representing positive real values.

Return Values

procedure.

See Also

stats::betaCDFstats::betaPDFstats::betaRandom

stats::betaRandom

Purpose

Generate a random number generator for beta deviates

Syntax

```
stats::betaRandom(a, b, <Seed = n>)
```

Description

`stats::betaRandom(a, b)` returns a procedure that produces beta deviates (random numbers) with shape parameters $a > 0$, $b > 0$.

The procedure `f := stats::betaRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

- If `a` and `b` can be converted to positive floating-point numbers, then `f()` returns a random floating-point number between `0.0` and `1.0`.
- In all other cases, *f*() return the symbolic call `stats::betaRandom(a, b)()`.

Numerical values of `a` and `b` are only accepted if they are positive.

The values `X = f()` are distributed randomly according to the beta distribution with parameters `a` and `b`. For any $0 \le x \le 1$, the probability that $X \le x$ is given by

1/beta(a,b)*int(t^(a-1)*(1-t)^(b-1), t=0..x)

$$\frac{1}{\beta(a,b)} \int_0^x t^{a-1} (1-t)^{b-1} \, dt$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::betaRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::betaRandom(a, b): f() $ k = 1..K;
```

rather than by

```
stats::betaRandom(a, b)() $ k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::betaRandom(a, b, Seed = n)() $ k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate beta deviates with parameters a = 2 and b=3/4$b = \frac{3}{4}$:
f := stats::betaRandom(2, 3/4): f() $ k = 1..40.9454511844, 0.8615078721, 0.121495159, 0.379420364

```
0.9454511844, 0.8615078721, 0.121495159, 0.379420364
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::betaRandom(a, b): f()stats::betaRandom(a, b)()

```
stats::betaRandom(a, b)()
```

When a and b evaluate to positive real numbers, the generator starts to produce random numbers:
a := 1: b := 2: f() $ k = 1..40.1700845647, 0.1490672548, 0.6022714953, 0.2217977725

0.1700845647, 0.1490672548, 0.6022714953, 0.2217977725
delete f, a, b:

Example 3

We use the option Seed = s to reproduce a sequence of random numbers:
f := stats::betaRandom(1, 3, Seed = 1): f() $ k = 1..40.07584461034, 0.6146360615, 0.2188856232, 0.1020817554

0.07584461034, 0.6146360615, 0.2188856232, 0.1020817554
g := stats::betaRandom(1, 3, Seed = 1): g() $ k = 1..40.07584461034, 0.6146360615, 0.2188856232, 0.1020817554

0.07584461034, 0.6146360615, 0.2188856232, 0.1020817554
f() = g(), f() = g()0.3303369551 = 0.3303369551, 0.1975445744 = 0.1975445744

0.3303369551 = 0.3303369551, 0.1975445744 = 0.1975445744
delete f, g:

Parameters

a

b

The shape parameters of the beta distribution: arithmetical expressions representing positive real values.

Options

Seed

Option, specified as Seed = n

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the shape parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm for the computation of the beta deviates uses gamma deviates `x`, `y` to produce a beta deviate `x/(x + y)`. For more information see: D. Knuth, Seminumerical Algorithms (1998), Vol. 2, p. 134.

See Also

stats::betaCDFstats::betaPDFstats::betaQuantile

stats::binomialCDF

Purpose

The (discrete) cumulative distribution function of the binomial distribution

Syntax

```
stats::binomialCDF(n, p)
```

Description

`stats::binomialCDF(n, p)` returns a procedure representing the (discrete) cumulative distribution function

x->piecewise([x<0, 0], [x>=0 and x<1, sum(binomial(n,i)*p^i*(1-p)^(n-i), i=0..floor(x))], [x>=1, 1])

$$x \to \begin{cases} 0 & \text{if } x < 0 \\ \sum_{i=0}^{\lfloor x \rfloor} \binom{n}{i} p^i (1-p)^{n-i} & \text{if } x \geq 0 \wedge x < 1 \\ 1 & \text{if } x \geq 1 \end{cases}$$

of the binomial distribution with "trial parameter" `n` and "probability parameter" `p`.

The procedure `f := stats::binomialCDF(n, p)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

- If `x` is a numerical real value and `n` is a positive integer, then an explicit value is returned. If `p` is a numerical value satisfying $0 \leq p \wedge p \leq 1$, this is a numerical value. Otherwise, it is a symbolic expression in `p`.
- If `x` is a numerical value with $x < 0$, then `0`, respectively `0.0`, is returned for any value of `n` and `p`.
- For symbolic values of `n`, explicit results are returned if x is a numerical value with $x < 2$.
- For symbolic values of `n`, explicit results are returned if $n - x$ is a numerical value with $n - x \leq 2$.

- If `n - x` is a numerical value with $n - x \leq 0$, then `1`, respectively `1.0`, is returned for any value of `n` and `p`.
- In all other cases, `f(x)` returns the symbolic call `binomialCDF(n, p)(x)`.

Numerical values for `n` are only accepted if they are positive integers.

Numerical values for `p` are only accepted if they satisfy $0 \leq p \leq 1$.

If `x` is a real floating-point number, the result is a floating number provided n and p are numerical values. If `x` is an exact numerical value, the result is an exact number.

Note Note that for large n, floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number `x` to the procedure generated by `stats::binomialCDF`!

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the distribution function with n = 20 and p=3/4$p = \frac{3}{4}$ at various points:
f := stats::binomialCDF(5, 3/4): f(-1), f(2), f(PI), f(5), f(6)0, 53/512, 47/128, 1, 1

$$0, \frac{53}{512}, \frac{47}{128}, 1, 1$$

f(-1.2), f(2.0), f(float(PI)), f(5.5)0.0, 0.103515625, 0.3671875, 1.0

$$0.0, 0.103515625, 0.3671875, 1.0$$

delete f:

Example 2

We use symbolic arguments:
f := stats::binomialCDF(n, p): f(x), f(8), f(8.0)stats::binomialCDF(n, p)(x), stats::binomialCDF(n, p)(8), stats::binomialCDF(n, p)(8.0)

$$\text{stats::binomialCDF}(n, p)(x),\ \text{stats::binomialCDF}(n, p)(8),\ \text{stats::binomialCDF}(n, p)(8.0)$$

When numerical values are assigned to n and p, the function f starts to produce explicit results if the argument is numerical:
n := 3: p := 1/3: f(2), f(2.5), f(PI +1), f(4.0)26/27, 0.962962963, 1, 1.0

$$\frac{26}{27},\ 0.962962963,\ 1,\ 1.0$$

delete f, n, p:

Example 3

If n and x are numerical, symbolic expressions are returned for symbolic values of p:
f := stats::binomialCDF(3, p): f(-1), f(0), f(3/2), f(1 + sqrt(3)), f(2.999), f(3)0, -(p - 1)^3, 3*p*(p - 1)^2 - (p - 1)^3, 1 - p^3, 1.0 - 1.0*p^3, 1

$$0,\ -(p-1)^3,\ 3\,p\,(p-1)^2-(p-1)^3,\ 1-p^3,\ 1.0-1.0\,p^3,\ 1$$

delete f:

Parameters

n

The “trial parameter”: an arithmetical expression representing a positive integer

p

The “probability parameter”: an arithmetical expression representing a real number $0 \le p \le 1$.

Return Values

procedure.

See Also stats::binomialPFstats::binomialQuantilestats::binomialRandom

stats::binomialPF

Purpose

Probability function of the binomial distribution

Syntax

```
stats::binomialPF(n, p)
```

Description

`stats::binomialPF(n, p)` returns a procedure representing the probability function

x->binomial(n,x)*p^x*(1-p)^(n-x)

$$x \to \binom{n}{x} p^x (1-p)^{n-x}$$

for `x=0,1,..,n` of the binomial distribution with "trial parameter" `n` and "probability parameter" `p`.

The procedure `f := stats::binomialPF(n, p)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

- If `x` is a non-integer numerical value, *f*(*x*) returns `0` or `0.0`, respectively.
- If `x` is an integer or the floating point equivalent of an integer and `n` is a positive integer, then an explicit value is returned. If `p` is a numerical value satisfying $0 \le p \le 1$, this is a numerical value. Otherwise, it is a symbolic expression in `p`.

  For symbolic values of `n`, explicit results are returned if x is a numerical value with$x < 2$.
- For symbolic values of `n`, explicit results are returned if $n - x$ is a numerical value with$n - x < 2$.
- In all other cases, `f(x)` returns the symbolic call `stats::binomialPF(n,p)(x)`.

Numerical values for `n` are only accepted if they are positive integers.

Numerical values for p are only accepted if they satisfy $0 \le p \le 1$.

If x is a floating-point number, the result is a floating number provided n and p are numerical values. If x is an exact value, the result is an exact number.

Note that for large n, floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number x to the procedure created by `stats::binomialPF`.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We compute the probability function with n = 3 and p=3/4$p = \frac{3}{4}$ at various points:
f := stats::binomialPF(3, 3/4): f(-1/2), f(0), f(1/2), f(1), f(7/4), f(2), f(3), f(4)0, 1/64, 0, 9/64, 0, 27/64, 27/64, 0

$$0,\ \frac{1}{64},\ 0,\ \frac{9}{64},\ 0,\ \frac{27}{64},\ \frac{27}{64},\ 0$$

f(-0.2), f(0.0), f(0.7), f(1.0), f(2.0), f(2.7), f(3.0), f(4.0)0.0, 0.015625, 0.0, 0.140625, 0.421875, 0.0, 0.421875, 0.0

0.0, 0.015625, 0.0, 0.140625, 0.421875, 0.0, 0.421875, 0.0

delete f:

Example 2

We use symbolic arguments:
f := stats::binomialPF(n, p): f(x), f(8), f(8.0)stats::binomialPF(n, p)(x), stats::binomialPF(n, p)(8), stats::binomialPF(n, p)(8.0)

stats::binomialPF(n, p)(x), stats::binomialPF(n, p)(8), stats::binomialPF(n, p)(8.0)

When real numbers are assigned to n and p, the function f starts to produce explicit results if the argument is numerical:
n := 3: p := 1/3: f(0), f(1), f(2.0), f(3.5), f(4)8/27, 4/9, 0.2222222222, 0.0, 0

$\frac{8}{27}, \frac{4}{9}, 0.2222222222, 0.0, 0$
delete f, n, p, x:

Example 3

If n and x are numerical, symbolic expressions are returned for symbolic values of p:
f := stats::binomialPF(3, p): f(-1), f(0), f(3/2), f(2), f(3)0, -(p - 1)^3, 0, -3*p^2*(p - 1), p^3

$0, -(p-1)^3, 0, -3\,p^2\,(p-1), p^3$
delete f:

Parameters

n

The "trial parameter": an arithmetical expression representing a positive integer

p

The "probability parameter": an arithmetical expression representing a real number $0 \le p \le 1$.

Return Values

procedure.

See Also

stats::binomialCDFstats::binomialQuantilestats::binomialRandom

stats::binomialQuantile

Purpose

Quantile function of the binomial distribution

Syntax

```
stats::binomialQuantile(n, p)
```

Description

`stats::binomialQuantile(n, p)` returns a procedure representing the quantile function (discrete inverse) of the cumulative distribution function `stats::binomialCDF(n, p)`. For $0 \le x \le 1$, the quantile value $k = stats::binomialQuantile(n, p)(x)$ satisfies

stats::binomialCDF(n, p)(k - 1)<x and x <= stats::binomialCDF(n, p)(k)

$$\text{stats::binomialCDF}(n, p)(k-1) < x \wedge x \le \text{stats::binomialCDF}(n, p)(k)$$

The procedure `f := stats::binomialQuantile(n, p)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a natural number between 0 and n, or a symbolic expression:

- If n is a positive integer, p a real number satisfying $0 \le p \le 1$, and x a real number satisfying $0 \le x \le 1$, then $f(x)$ returns an integer between 0 and n.
- If $p = 0$, then $f(x)$ returns 0 for any values of n and x.
- If $p = 1$, then $f(x)$ returns n for any values of n and x.
- For $p \ne 1$, the call $f(0)$ returns 0 for any value of n.
- For $p \ne 0$, the call $f(1)$ returns n for any value of n.
- In all other cases, `f(x)` returns the symbolic call `stats::binomialQuantile(n, p)(x)`.

Numerical values for `n` are only accepted if they are positive integers.

Numerical values for `p` are only accepted if they satisfy $0 \le p \le 1$.

If floating-point arguments are passed to the quantile function f, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off

errors. In particular, round-off may be significant for arguments x close to 1. Cf. “Example 3” on page 30-23.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with n = 30 and p=1/3$p = \frac{1}{3}$ at some points:
f := stats::binomialQuantile(30, 1/3): f(0), f((2/3)^30), f(PI/10), f(0.5), f(1 - 1/10^10)0, 0, 9, 10, 27

0, 0, 9, 10, 27

The quantile value $f(x)$ satisfies

stats::binomialCDF(n, p)(f(x) - 1) < x and x <= stats::binomialCDF(n, p)(f(x))

$$\text{stats::binomialCDF}(n, p)(f(x) - 1) < x \wedge x \leq \text{stats::binomialCDF}(n, p)(f(x))$$

x := 0.7: f(x)11

11

stats::binomialCDF(30, 1/3)(float(f(x) - 1)), x, stats::binomialCDF(30, 1/3)(float(f(x)))0.5847595988, 0.7, 0.7238643653

0.5847595988, 0.7, 0.7238643653

delete f, x:

Example 2

We use symbolic arguments:
f := stats::binomialQuantile(n, p): f(x), f(9/10)stats::binomialQuantile(n, p)(x), stats::binomialQuantile(n, p)(9/10)

stats::binomialQuantile(*n*, *p*)(*x*), stats::binomialQuantile(*n*, *p*)$\left(\frac{9}{10}\right)$

When n and p evaluate to suitable numbers, the function f starts to produce quantile values:
n := 80: p := 1/10: f(1/2), f(999/1000), f(1 - 1/10^10), f(1 - 1/10^80)8, 17, 29, 79

8, 17, 29, 79

delete f, n, p:

Example 3

If floating-point arguments are passed to the quantile function, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors:
f := stats::binomialQuantile(1000, 1/30): f(1 - 1/10^16) <> f(float(1 - 1/10^16))89 <> 88

89 ≠ 88

delete f:

Parameters

n

The “trial parameter”: an arithmetical expression representing a positive integer

p

The “probability parameter”: an arithmetical expression representing a real number $0 \le p \le 1$.

Return Values

procedure.

See Also

stats::binomialCDFstats::binomialPFstats::binomialRandom

stats::binomialRandom

Purpose

Generate a random number generator for binomial deviates

Syntax

```
stats::binomialRandom(n, p, <Seed = s>)
```

Description

`stats::binomialRandom(n, p)` returns a procedure that produces binomial-deviates (random numbers) with trial parameter `n` and probability parameter `p`.

The procedure `f := stats::binomialRandom(n, p)` can be called in the form `f()`. The return value of `f()` is an integer between 0 and n or a symbolic expression:

- If `n` is a positive integer and `p` is a real value satisfying $0 \le p \le 1$, then `f()` returns an integer between 0 and n.
- If $p = 0$ or $p = 0.0$, then `f()` returns `0` for any value of n.
- If $p = 1$ or $p = 1.0$, then $f()$ returns `n` for any value of n.

  In all other cases, $f()$ return the symbolic call `stats::binomialRandom(n, p)()`.

Numerical values for `n` are only accepted if they are positive integers.

Numerical values for `p` are only accepted if they satisfy $0 \le p \le 1$.

The values `X = f()` are distributed randomly according to the binomial distribution with trial parameter `n` and probability parameter `p`. For any x in Dom::Interval([0],[1])$x \in [0, 1]$, the probability of $X \le x$ is given by

sum(binomial(n,i)*p^i*(1-p)^(n-i), i=0..floor(x))

$$\sum_{i=0}^{\lfloor x \rfloor} \binom{n}{i} p^i (1-p)^{n-i}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each

time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note With this option, the parameters `n` and `p` must evaluate to suitable numerical values at the time, when the generator is created.

Note In contrast to the function random, the generators produced by `stats::binomialRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::binomialRandom(n, p): f() $k = 1..K;
```

rather than by

```
stats::binomialRandom(n, p)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::binomialRandom(n, p, Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate binomial deviates with parameters n = 80 and p=1/7$p = \frac{1}{7}$:

f := stats::binomialRandom(80, 1/7): f() $ k = 1..109, 9, 16, 11, 8, 5, 11, 13, 14, 12

9, 9, 16, 11, 8, 5, 11, 13, 14, 12

delete f:

Example 2

With symbolic parameters, no random numbers can be produced:
f := stats::binomialRandom(n, p): f()stats::binomialRandom(n, p)()

stats::binomialRandom(*n*, *p*)()

When n and p evaluate to suitable numbers, the generator starts to produce random numbers:
n := 200: p := 1/PI: f() $ k= 1..1079, 69, 69, 64, 77, 70, 80, 66, 62, 69

79, 69, 69, 64, 77, 70, 80, 66, 62, 69

delete f, n, p:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:
f := stats::binomialRandom(70, 7/8, Seed = 1): f() $ k = 1..1063, 65, 60, 65, 60, 57, 58, 63, 57, 61

63, 65, 60, 65, 60, 57, 58, 63, 57, 61

g := stats::binomialRandom(70, 7/8, Seed = 1): g() $ k = 1..1063, 65, 60, 65, 60, 57, 58, 63, 57, 61

63, 65, 60, 65, 60, 57, 58, 63, 57, 61

f() = g(), f() = g()61 = 61, 63 = 63

61 = 61, 63 = 63

delete f, g:

Parameters

n

The “trial parameter”: an arithmetical expression representing a positive integer

p

The “probability parameter”: an arithmetical expression representing a real number $0 \leq p \leq 1$.

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `n` and `p` must be numerical values at the time when the random generator is generated.

Return Values

procedure.

stats::binomialCDFstats::binomialPFstats::binomialQuantile

stats::calc

Purpose

Apply functions to a sample

Syntax

```
stats::calc(s, c, f1, f2,  )
stats::calc(s, [c1, c2,  ], f1, f2,  )
```

Description

`stats::calc` applies functions to columns of the sample `s`.

In a call such as `stats::calc(s, c, f1)` the function `f1` is applied to the elements of the column `c` of `s`. This generates a new column which is appended to `s`. If present, the next function `f2` is applied to the new sample etc. Thus, a call of `stats::calc` with *m* functions appends *m* new columns to `s`.

Each function must accept exactly one parameter.

In a call such as `stats::calc(s, [c1, c2,  ], f1)` the *i*-th element of the new column is given by `f1(si, c1, si, c2,  )`.

Each function must accept as many parameters as specified by the second argument of `stats::calc`.

Examples

Example 1

We create a sample of three rows and three columns:
stats::sample([[1, a1, b1], [2, a2, b2], [3, a3, b3]]) 1 a1 b1 2 a2 b2 3 a3 b3

We add and multiply the elements of the columns 2 and 3 by applying the system functions _plus and _mult:
stats::calc(%, [2, 3], _plus, _mult) 1 a1 b1 a1 + b1 a1*b1 2 a2 b2 a2 + b2 a2*b2 3 a3 b3 a3 + b3 a3*b3

The following call maps each element of the second column of the original sample to its fourth power:
stats::calc(%2, 2, x -> x^4) 1 a1 b1 a1^4 2 a2 b2 a2^4 3 a3 b3 a3^4

The following call computes the mean values of the rows of the last sample:

stats::calc(%, [1, 2, 3, 4], (x1, x2, x3, x4) -> (x1 + x2 + x3 + x4)/4) 1 a1 b1 a1^4 a1^4/4 + a1/4 + b1/4 + 1/4 2 a2 b2 a2^4 a2^4/4 + a2/4 + b2/4 + 1/2 3 a3 b3 a3^4 a3^4/4 + a3/4 + b3/4 + 3/4

The same is achieved by the following call:
stats::calc(%2, [1, 2, 3, 4], stats::mean) 1 a1 b1 a1^4 a1^4/4 + a1/4 + b1/4 + 1/4 2 a2 b2 a2^4 a2^4/4 + a2/4 + b2/4 + 1/2 3 a3 b3 a3^4 a3^4/4 + a3/4 + b3/4 + 3/4

Parameters

s

A sample of domain type stats::sample

***c*, c_1, c_2, ...**

Positive integers representing column indices of the sample

f_1, f_2, ...

Procedures

Return Values

Sample of domain type stats::sample.

See Also

stats::tabulate

stats::cauchyCDF

Purpose

Cumulative distribution function of the Cauchy distribution

Syntax

```
stats::cauchyCDF(a, b)
```

Description

`stats::cauchyCDF(a, b)` returns a procedure representing the cumulative distribution function

x->1/PI*arctan((x-a)/b)+1/2

$$x \to \frac{1}{\pi}\arctan\left(\frac{x-a}{b}\right)+\frac{1}{2}$$

of the Cauchy distribution with median a and scale parameter $b > 0$.

The procedure `f := stats::cauchyCDF(a, b)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

- If `x` is a floating-point number and `a` and `b` can be converted to suitable floating-point numbers, then `f(x)` returns a floating-point number.
- In all other cases, the symbolic expression `arctan((x - a)/b)/PI + 1/2` is returned.

Numerical values of `a` and `b` are only accepted if they are real and `b` is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the cumulative distribution function with $a = 2$ and b=3/4$b = \frac{3}{4}$ at various points:
f := stats::cauchyCDF(2, 3/4): f(-infinity), f(-10), f(0.8), f(2), f(10.0^4), f(infinity)0, 1/2 - arctan(16)/PI, 0.1778076845, 1/2, 0.999976122, 1

$$0,\ \frac{1}{2}-\frac{\arctan(16)}{\pi},\ 0.1778076845,\ \frac{1}{2},\ 0.999976122,\ 1$$

delete f, x:

Example 2

We use symbolic arguments:
f := stats::cauchyCDF(a, b): f(x), f(sqrt(2)), f(0.9)1/2 - arctan((a - x)/b)/PI, 1/2 - arctan((a - sqrt(2))/b)/PI, 1/2 - arctan((a - 0.9)/b)/PI

$$\frac{1}{2}-\frac{\arctan\left(\frac{a-x}{b}\right)}{\pi},\ \frac{1}{2}-\frac{\arctan\left(\frac{a-\sqrt{2}}{b}\right)}{\pi},\ \frac{1}{2}-\frac{\arctan\left(\frac{a-0.9}{b}\right)}{\pi}$$

When numbers are assigned to a and b, the function f starts to produce corresponding numerical values:
a := PI: b := 1/8: f(sqrt(2)), f(0.9)arctan(8*sqrt(2) - 8*PI)/PI + 1/2, 0.01773184344

$$\frac{\arctan(8\sqrt{2}-8\pi)}{\pi}+\frac{1}{2},\ 0.01773184344$$

Parameters

a

The median: an arithmetical expression representing a real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::cauchyPDFstats::cauchyQuantilestats::cauchyRandom

stats::cauchyPDF

Purpose

Probability density function of the Cauchy distribution

Syntax

```
stats::cauchyPDF(a, b)
```

Description

`stats::cauchyPDF(a, b)` returns a procedure representing the probability density function

x->(b/PI) * (1/((x-a)^2+b^2))

$$x \to \frac{b}{\pi}\,\frac{1}{(x-a)^2+b^2}$$

of the Cauchy distribution with median a and scale parameter $b > 0$.

The procedure `f := stats::cauchyPDF(a, b)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

- If `x` is a floating-point number and `a` and `b` can be converted to suitable floating-point numbers, then `f(x)` returns a floating-point number.
- In all other cases, the symbolic expression `b/PI * 1/((x-a)^2 + b^2))` is returned.

Numerical values of `a` and `b` are only accepted if they are real and `b` is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We calculate the Cauchy density with a = 2 and b=3/4 $b = \frac{3}{4}$ at various points:
f := stats::cauchyPDF(2, 3/4): f(-infinity), f(9/10), f(0.9), f(2), f(infinity)0, 300/(709*PI), 0.1346868348, 4/(3*PI), 0

$$0,\ \frac{300}{\pi^2},\ 0.1346868348,\ \frac{4}{3\pi},\ 0$$

delete f:

Example 2

We use symbolic arguments:
f := stats::cauchyPDF(a, b): f(x), f(2), f(2.0)b/(PI*(b^2 + (a - x)^2)), b/(PI*((a - 2)^2 + b^2)), b/(PI*(b^2 + (a - 2.0)^2))

$$\frac{b}{\pi\left(b^2+(a-x)^2\right)},\ \frac{b}{\pi\left((a-2)^2+b^2\right)},\ \frac{b}{\pi\left(b^2+(a-2.0)^2\right)}$$

When a and b evaluate to numbers, the function f starts to produce numerical values:
a := PI: b:= 1/8: f(2), f(2.0)1/(8*PI*((PI - 2)^2 + 1/64)), 0.03016906448

$$\frac{1}{8\pi\left((\pi-2)^2+\frac{1}{64}\right)},\ 0.03016906448$$

delete f, a, b:

Parameters

a

The median: an arithmetical expression representing a real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::cauchyCDFstats::cauchyQuantilestats::cauchyRandom

stats::cauchyQuantile

Purpose

Quantile function of the Cauchy distribution

Syntax

```
stats::cauchyQuantile(a, b)
```

Description

`stats::cauchyQuantile(a, b)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::cauchyCDF(a, b)`: for $0 \le x \le 1$, the solution of *stats*::*cauchyCDF*(*a*, *b*)(*y*) = *x* is given by *y* = *stats*::*cauchyQuantile*(*a*, *b*)(*x*).

The procedure `f := stats::cauchyQuantile(a, b)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number, _outputSequence(Symbol::pm,infinity)$\pm\infty$ or a symbolic expression:

If `x` is a floating-point number between `0` and `1` and `a` and `b` can be converted to suitable floating-point numbers, then `f(x)` returns a floating-point number approximating the real solution *y* of *stats*::*cauchyCDF*(*a*, *b*)(*y*) = *x*.

For any value of `a` and `b`, the calls `f(0)` and `f(0.0)` produce $-\infty$. The calls `f(1)` and `f(1.0)` produce *infinity*.

In all other cases, the symbolic expression `a + b*tan(PI*(x - 1/2))` is returned.

Numerical values of `a` and `b` are only accepted, if they are real and `b` is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with $a = 2$ and b=3/4$b = \frac{3}{4}$ at various points:

```
f := stats::cauchyQuantile(2, 3/4): f(0), f(4/5), f(0.8), f(1)-infinity,
(3*sqrt(5)*sqrt(2*sqrt(5) + 5))/20 + 2, 3.03228644, infinity
```

$$-\infty,\ \frac{3\sqrt{5}\sqrt{2\sqrt{5}+5}}{20}+2,\ 3.03228644,\ \infty$$

delete f:

Example 2

We use symbolic arguments:
f := stats::cauchyQuantile(a, b): f(0), f(x), f(1/sqrt(2)), f(0.9), f(1)-infinity, a + b*tan(PI*(x - 1/2)), a + b*tan(PI*(sqrt(2)/2 - 1/2)), a + b*tan(0.4*PI), infinity

$$-\infty,\ a+b\tan\left(\pi\left(x-\frac{1}{2}\right)\right),\ a+b\tan\left(\pi\left(\frac{\sqrt{2}}{2}-\frac{1}{2}\right)\right),\ a+b\tan(0.4\,\pi),\ \infty$$

When numbers are assigned to a and b, the function f starts to produce numerical values when called with arguments between 0 and 1:
a := PI: b := 1/8: f(0), f(1/sqrt(2)), f(0.9), f(1)-infinity, PI + tan(PI*(sqrt(2)/2 - 1/2))/8, 3.526303096, infinity

$$-\infty,\ \pi+\frac{\tan\left(\pi\left(\frac{\sqrt{2}}{2}-\frac{1}{2}\right)\right)}{8},\ 3.526303096,\ \infty$$

Parameters

a

The median: an arithmetical expression representing a real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::cauchyPDFstats::cauchyCDFstats::cauchyRandom

stats::cauchyRandom

Purpose

Generate a random number generator for Cauchy deviates

Syntax

```
stats::cauchyRandom(a, b, <Seed = n>)
```

Description

`stats::cauchyRandom(a, b)` returns a procedure that produces Cauchy deviates (random numbers) with median a and scale parameter $b > 0$.

The procedure `f := stats::cauchyRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` can be converted to a real floating point number and `b` to a positive real floating point number, then `f()` returns a real floating point number.

In all other cases, *f*() returns the symbolic call `stats::cauchyRandom(a, b)()`.

Numerical values of `a` and `b` are only accepted, if they are real and b is positive.

The values `X = f()` are distributed randomly according to the the Cauchy distribution with parameters `a` and `b`. For any real `x`, the probability that $X \leq x$ is given by

1/PI*arctan((x-a)/b)+1/2

$$\frac{1}{\pi}\,\arctan\left(\frac{x-a}{b}\right)+\frac{1}{2}$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::cauchyRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::cauchyRandom(a, b): f() $ k = 1..K;
```

rather than by

```
stats::cauchyRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::cauchyRandom(a, b, Seed = n)() $ k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate Cauchy deviates with parameters a = 2 and b=3/4 $b = \frac{3}{4}$:
f := stats::cauchyRandom(2, 3/4): f() $ k = 1..41.340284406, 3.277664042, 0.5634392829, 48.01912393

```
1.340284406, 3.277664042, 0.5634392829, 48.01912393
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::cauchyRandom(a, b): f()stats::cauchyRandom(a, b)()

stats::cauchyRandom(*a*, *b*)()

When *a* and *b* evaluate to suitable real numbers, the generator starts to produce random numbers:
a := -PI: b := 1/2: f() $ k = 1..4-3.592915903, -3.928568815, -3.217434162, -2.82696038

$-3.592915903, -3.928568815, -3.217434162, -2.82696038$

delete f, a, b:

Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:
f := stats::cauchyRandom(PI, 3, Seed = 1): f() $ k = 1..43.786179405, 7.050017894, -4.775376375, -1.791650747

$3.786179405, 7.050017894, -4.775376375, -1.791650747$

g := stats::cauchyRandom(PI, 3, Seed = 1): g() $ k = 1..43.786179405, 7.050017894, -4.775376375, -1.791650747

$3.786179405, 7.050017894, -4.775376375, -1.791650747$

f() = g(), f() = g()8.362838563 = 8.362838563, -302.9342996 = -302.9342996

$8.362838563 = 8.362838563, -302.9342996 = -302.9342996$

delete f, g:

Parameters

a

The median: an arithmetical expression representing a real value

b

The scale parameter: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to suitable floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm for the computation of the Cauchy deviates uses the quantile function of the Cauchy distribution applied to uniformly distributed random numbers between 0 and 1.

See Also

stats::cauchyCDFstats::cauchyPDFstats::cauchyQuantile

stats::chisquareCDF

Purpose

Cumulative distribution function of the chi-square distribution

Syntax

```
stats::chisquareCDF(m)
```

Description

`stats::chisquareCDF(m)` returns a procedure representing the cumulative distribution function

x->piecewise([x>0, int(t^(m/2-1)*exp(-t/2)/(2^(m/2)*gamma(m/2)), t=0..x)], [x<=0, 0])

$$x \to \begin{cases} \int_0^x \frac{t^{\frac{m}{2}-1}\, e^{-\frac{t}{2}}}{2^{m/2}\,\Gamma\left(\frac{m}{2}\right)}\, dt & \text{if } x > 0 \\ 0 & \text{if } x \le 0 \end{cases}$$

of the chi-square distribution with mean $m > 0$.

The procedure `f := stats::chisquareCDF(m)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \le 0$ can be decided, then `f(x)` returns 0. If $x > 0$ can be decided, then `f(x)` returns the value 1 - igamma(m/2, x/2)/gamma(m/2) $1 - \frac{\Gamma\left(\frac{m}{2}, \frac{x}{2}\right)}{\Gamma\left(\frac{m}{2}\right)}$.

If x is a floating-point number and m can be converted to a positive floating-point number, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \le 0$ or $x \ge 0$, the corresponding values are returned.

`f(x)` returns the symbolic call `stats::chisquareCDF(m)(x)` if neither $x \le 0$ nor $x > 0$ can be decided.

Numerical values for `m` are only accepted if they are real and positive.

Note that, for large `m`, exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments `x` to `f` rather than to compute exact results `f(x)` and convert them via float. Cf. “Example 4” on page 30-42.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the cumulative distribution function with mean $m = 2$ at various points:

```
f := stats::chisquareCDF(2): f(-infinity), f(-3), f(1/2), f(0.5), f(PI), f(infinity)
```

0, 0, $1 - e^{-\frac{1}{4}}$, 0.2211992169, $1 - e^{-\frac{\pi}{2}}$, 1

delete f:

Example 2

If `x` is a symbolic object without properties, then it cannot be decided whether $x \geq 0$ holds. A symbolic function call is returned:

```
f := stats::chisquareCDF(m): f(x)
```

stats::chisquareCDF(m)(x)

With suitable properties, it can be decided whether $x \geq 0$ holds. An explicit expression is returned:

```
assume(0 <= x): f(x)
```

$$1 - \frac{\Gamma\left(\frac{m}{2}, \frac{x}{2}\right)}{\Gamma\left(\frac{m}{2}\right)}$$

For integer values of `m`, the special function igamma can be expressed in terms of more elementary functions:

```
m := 6: f(x)
```

1 - (exp(-x/2)*(x^2/4 + x + 2))/2

$$1 - \frac{e^{-\frac{x}{2}}\left(\frac{x^2}{4} + x + 2\right)}{2}$$

m := 5: f(x)1 - (4*((3*sqrt(PI)*erfc(sqrt(x/2)))/4 + exp(-x/2)*((3*sqrt(x/2))/2 + (x/2)^(3/2))))/(3*sqrt(PI))

$$1 - \frac{4\left(\frac{3\sqrt{\pi}\,\mathrm{erfc}\left(\sqrt{\frac{x}{2}}\right)}{4} + e^{-\frac{x}{2}}\left(\frac{3\sqrt{\frac{x}{2}}}{2} + \left(\frac{x}{2}\right)^{3/2}\right)\right)}{3\sqrt{\pi}}$$

unassume(x): delete f, m:

Example 3

We use a symbolic mean `m`:
f := stats::chisquareCDF(m): f(3), f(3.0)1 - igamma(m/2, 3/2)/gamma(m/2), 1.0 - (1.0*igamma(0.5*m, 1.5))/gamma(0.5*m)

$$1 - \frac{\Gamma\left(\frac{m}{2}, \frac{3}{2}\right)}{\Gamma\left(\frac{m}{2}\right)},\ 1.0 - \frac{1.0\,\Gamma(0.5\,m, 1.5)}{\Gamma(0.5\,m)}$$

When a numerical value is assigned to `m`, the function `f` starts to produce numerical values:
m := PI: f(3), f(3.0)1 - igamma(PI/2, 3/2)/gamma(PI/2), 0.5840678031

$$1 - \frac{\Gamma\left(\frac{\pi}{2}, \frac{3}{2}\right)}{\Gamma\left(\frac{\pi}{2}\right)},\ 0.5840678031$$

delete f, m:

Example 4

We consider a chi-square distribution with large mean `m` = 1000:
f := stats::chisquareCDF(1000):

For floating-point approximations, one should not compute an exact result and convert it via float. For large mean *m*, it is faster to pass a floating-point argument to `f`. The following call takes some time,

because an exact computation of the huge integer `gamma(m/2) = gamma(500) = 499!` is involved:
float(f(1023))0.7003071959

```
0.7003071959
```

The following call is much faster:
f(float(1023))0.7003071959

```
0.7003071959
```

delete f:

Parameters

m

The mean: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

gammaigammastats::chisquarePDFstats::chisquareQuantilestats::chisquareRandom

stats::chisquarePDF

Purpose

Probability density function of the chi-square distribution

Syntax

```
stats::chisquarePDF(m)
```

Description

`stats::chisquarePDF(m)` returns a procedure representing the probability density function

x->piecewise([x>0, x^(m/2-1)*exp(-x/2)/(2^(m/2)*gamma(m/2))], [x<=0, 0])

$$x \to \begin{cases} \dfrac{x^{\frac{m}{2}-1}\, e^{-\frac{x}{2}}}{2^{m/2}\,\Gamma\left(\frac{m}{2}\right)} & \text{if } x > 0 \\ 0 & \text{if } x \le 0 \end{cases}$$

of the chi-square distribution with mean $m > 0$.

The procedure `f := stats::chisquarePDF(m)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \le 0$ can be decided, then `f(x)` returns 0. If $x > 0$ can be decided, then `f(x)` returns the value x^(m/2 - 1)*exp(-x/2)/2^(m/2)/gamma(m/2) $\dfrac{x^{\frac{m}{2}-1}\, e^{-\frac{x}{2}}}{2^{m/2}\,\Gamma\left(\frac{m}{2}\right)}$.

If x is a floating-point number and m can be converted to a positive floating-point number, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \le 0$ or $x \ge 0$, the corresponding values are returned.

`f(x)` returns the symbolic call `stats::chisquarePDF(m)(x)` if neither $x \le 0$ nor $x > 0$ can be decided,

Numerical values of `m` are only accepted if they are positive.

Note that, for large m, exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments `x` to `f` rather than to compute exact results `f(x)` and convert them via float. Cf. “Example 4” on page 30-46.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the probability density function with $m = 2$ at various points:

```
f := stats::chisquarePDF(2): f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)
```

$$0.00765380452$$

The following call is much faster:
f(float(1023))0.00765380452

$$0.00765380452$$

delete f:

Parameters

m

The mean: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

gammastats::chisquareCDFstats::chisquareQuantilestats::chisquareRandom

stats::chisquareQuantile

Purpose

Quantile function of the chi-square distribution

Syntax

```
stats::chisquareQuantile(m)
```

Description

`stats::chisquareQuantile(m)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::chisquareCDF(m)`. For $0 \le x \le 1$, the solution of *stats*::*chisquareCDF*(*m*)(*y*) = *x* is given by *y* = *stats*::*chisquareQuantile*(*m*)(*x*).

The procedure `f := stats::chisquareQuantile(m)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, *infinity*, or a symbolic expression:

If `x` is a real number between `0` and `1` and `m` can be converted to a positive floating-point number, then `f(x)` returns a positive floating-point number approximating the solution *y* of *stats*::*chisquareCDF*(*m*)(*y*) = *x*.

The calls `f(0)` and `f(0.0)` produce `0.0` for all values of `m`.

The calls `f(1)` and `f(1.0)` produce *infinity* for all values of `m`.

In all other cases, `f(x)` returns the symbolic call `stats::chisquareQuantile(m)(x)`.

Numerical values of `m` are only accepted if they are real and positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with $m = \pi$ at various points:
f := stats::chisquareQuantile(PI): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)0.0, 0.6469867417, 2.505845123, 50.00263604, infinity

```
0.0, 0.6469867417, 2.505845123, 50.00263604, ∞
```

The value `f(x)` satisfies `stats::chisquareCDF(PI)(f(x)) = x`:

Der Wert `f(x)` erfüllt `stats::chisquareCDF(PI)(f(x)) = x`:
stats::chisquareCDF(PI)(f(0.987654))0.987654

0.987654

delete f:

Example 2

We use symbolic arguments:
f := stats::chisquareQuantile(m): f(x),
f(9/10)stats::chisquareQuantile(m)(x), stats::chisquareQuantile(m)(9/10)

$\text{stats::chisquareQuantile}(m)(x), \text{stats::chisquareQuantile}(m)\left(\frac{9}{10}\right)$

When a positive real value is assigned to `m`, the function `f` starts to produce floating-point values:
m := PI + 1: f(0.999), f(1 - sqrt(2)/10^5)18.76468483, 28.07485542

18.76468483, 28.07485542

Numerical values for x are only accepted if $0 \le x \le 1$:
f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, m:

Parameters

m

The mean: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::chisquareCDFstats::chisquarePDFstats::chisquareRandom

stats::chisquareRandom

Purpose

Generate a random number generator for chi-square deviates

Syntax

```
stats::chisquareRandom(m, <Seed = n>)
```

Description

`stats::chisquareRandom(m)` returns a procedure that produces chi-square deviates (random numbers) with mean $m > 0$.

The procedure `f := stats::chisquareRandom(m)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `m` can be converted to a positive floating point number, then `f()` returns a nonnegative floating point number.

In all other cases, `stats::chisquareRandom(m)()` is returned symbolically.

A numerical value of `m` is only accepted if it is positive.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the chi-square distribution with mean `m`. For any $x \geq 0$, the probability that $X \leq x$ is given by

1/(gamma(m/2) * 2^(m/2)) * int(t^(m/2-1)*exp(-t/2), t=0..x)

$$\frac{1}{\Gamma\left(\frac{m}{2}\right) 2^{\frac{m}{2}}} \int_0^x t^{\frac{m}{2}-1} e^{-\frac{t}{2}} \, dt$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::chisquareRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::chisquareRandom(m):  f() $k = 1..K;
```

rather than by

```
stats::chisquareRandom(m)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::chisquareRandom(m, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate chi-square deviates with mean $m = 12$:
f := stats::chisquareRandom(12): f() $ k = 1..417.54103319, 13.4630887, 17.34866815, 4.820644436

```
17.54103319, 13.4630887, 17.34866815, 4.820644436
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:

f := stats::chisquareRandom(m): f()stats::chisquareRandom(m)()

stats::chisquareRandom(*m*)()

When *m* evaluates to a positive real number, the generator starts to produce random numbers:
m := PI: f() $ k = 1..41.557180623, 0.3840766601, 0.5560473903, 3.185747198

1.557180623, 0.3840766601, 0.5560473903, 3.185747198

delete f, m:

Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:
f := stats::chisquareRandom(70, Seed = 1): f() $ k = 1..455.24812677, 78.10283482, 68.16283459, 80.01866787

55.24812677, 78.10283482, 68.16283459, 80.01866787

g := stats::chisquareRandom(70, Seed = 1): g() $ k = 1..455.24812677, 78.10283482, 68.16283459, 80.01866787

55.24812677, 78.10283482, 68.16283459, 80.01866787

f() = g(), f() = g()94.28358259 = 94.28358259, 57.54456 = 57.54456

94.28358259 = 94.28358259, 57.54456 = 57.54456

delete f, g:

Parameters

m

The mean: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the mean `m` must be convertible to a positive floating-point number at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm for the computation of the chi-square deviates uses a gamma deviate `x` with shape parameters `m/2` and `2`. For more information see: D. Knuth, Seminumerical Algorithms (1998), Vol. 2, p. 135.

See Also

stats::chisquareCDFstats::chisquarePDFstats::chisquareQuantile

stats::col

Purpose

Select and rearrange columns of a sample

Syntax

```
stats::col(s, c1, <c2,  >)
stats::col(s, c1 .. c2, <c3 .. c4,  >)
```

Description

`stats::col(s, ...)` creates a new sample from selected columns of the sample `s`.

`stats::col` is useful for selecting columns of interest or for rearranging columns.

The columns of `s` specified by the remaining arguments of `stats::col` are used to build a new sample. The new sample contains the columns of `s` in the order specified by the call to `stats::col`. Columns can be duplicated by specifying the column index more than once.

Examples

Example 1

The following sample contains columns for “gender”, “age”, “height”, the “number of yellow socks” and “eye color” of a person:
stats::sample([["m", 26, 180, 3, "blue"], ["f", 22, 160, 0, "brown"], ["f", 48, 155, 2, "green"], ["m", 30, 172, 1, "brown"]]) "m" 26 180 3 "blue" "f" 22 160 0 "brown" "f" 48 155 2 "green" "m" 30 172 1 "brown"

Since nobody is really interested in the yellow socks, we create a new sample without that column:
stats::col(%, 1..3, 5) "m" 26 180 "blue" "f" 22 160 "brown" "f" 48 155 "green" "m" 30 172 "brown"

We can use `stats::col` to rearrange the sample. As an illustrating example, we duplicate the first column:
stats::col(%, 1, 3, 2, 1, 4) "m" 180 26 "m" "blue" "f" 160 22 "f" "brown" "f" 155 48 "f" "green" "m" 172 30 "m" "brown"

Parameters

`s`

A sample of domain type stats::sample.

c_1, c_2, ...

Positive integers representing column indices of the sample `s`. A range `c_1 .. c_2` represents all columns from c_1 through c_2.

Return Values

Sample of domain type stats::sample.

See Also

stats::concatColstats::concatRowstats::row

stats::concatCol

Purpose

Concatenate samples column-wise

Syntax

`stats::concatCol(`s_1`, `s_2`, <`s_3`, >)`

Description

`stats::concatCol(`s_1`, `s_2`, )` creates a new sample consisting of the columns of the samples s_1, s_2 etc.

If the samples s_1, s_2 etc. have different numbers of rows, then the number of rows in the resulting sample is given by the "shortest" sample with the minimal number of rows. Elements below this row in "longer" samples are ignored.

Examples

Example 1

We create two samples:
s1 := stats::sample([[a1, a2], [b1, b2]]); s2 := stats::sample([[a3, a4], [b3, b4]]) a1 a2 b1 b2 a3 a4 b3 b4

Concatenation of the columns yields:
stats::concatCol(s1, s2) a1 a2 a3 a4 b1 b2 b3 b4 delete s1, s2:

Example 2

The following sample contains columns for "gender", "age" and "height" of a person:
stats::sample([["m", 26, 180], ["f", 22, 160], ["f", 48, 155], ["m", 30, 172]]) "m" 26 180 "f" 22 160 "f" 48 155 "m" 30 172

We append a further column "nationality", specified by a list:
stats::concatCol(%, ["German", "French", "Italian", "British", "German"]) "m" 26 180 "German" "f" 22 160 "French" "f" 48 155 "Italian" "m" 30 172 "British"

Parameters

s_1, s_2, ...

Samples of domain type stats::sample. Alternatively, lists may be entered, which are treated as columns of a sample.

Return Values Sample of domain type stats::sample.

See Also stats::colstats::concatRowstats::row

stats::concatRow

Purpose

Concatenate samples row-wise

Syntax

`stats::concatRow(`s_1`, `s_2`, <`s_3`, >)`

Description

`stats::concatRow(`s_1`, `s_2`, )` creates a new sample consisting of the rows of the samples s_1, s_2 etc.

All samples must have the same number of columns.

Examples

Example 1

We create a small sample:
stats::sample([[123, g], [442, f]]) 123 g 442 f

A list is concatenated to the sample as a row:
stats::concatRow(%, [x, y]) 123 g 442 f x y

Example 2

The following samples contain columns for “gender” and “age”:
s1 := stats::sample([["f", 36], ["m", 25]]); s2 := stats::sample([["m", 26], ["f", 22]]) "f" 36 "m" 25 "m" 26 "f" 22

We build a larger sample:
stats::concatRow(s1, s2) "f" 36 "m" 25 "m" 26 "f" 22 delete s1, s2:

Parameters

s_1, s_2, ...

Samples of domain type stats::sample. Alternatively, lists may be entered, which are treated as rows of a sample.

Return Values

Sample of domain type stats::sample.

See Also

stats::colstats::concatColstats::row

stats::correlation

Purpose

Correlation between data samples

Syntax

```
stats::correlation([x1, x2,  ], [y1, y2,  ],
<BravaisPearson | Fechner>)
stats::correlation([[x1, y1], [x2, y2],  ],
<BravaisPearson | Fechner>)
stats::correlation(s, <c1, c2>, <BravaisPearson | Fechner>)
stats::correlation(s, <[c1, c2]>, <BravaisPearson
| Fechner>)
stats::correlation(s1, <c1>, s2, <c2>, <BravaisPearson
| Fechner>)
```

Description

`stats::correlation([x1, x2,  ], [y1, y2,  ])` returns the linear (Bravais-Pearson) correlation coefficient

sum((x[i]-‘x‾‘)(y[i]-‘y‾‘), i) / sqrt(sum((x[i]-‘x‾‘)^2, i) * sum((y[i]-‘y‾‘)^2, i))

$$\frac{\sum_i (x_i(y_i-\overline{y}) - \overline{x}(y_i-\overline{y}))}{\sqrt{\left(\sum_i (x_i-\overline{x})^2\right)\left(\sum_i (y_i-\overline{y})^2\right)}}$$

where ‘x‾‘ $\overline{x}$ and ‘y‾‘ $\overline{y}$ are the means of the data x_i and y_i.

`stats::correlation([x1, x2,  ], [y1, y2,  ], Fechner)` returns the Fechner correlation (2/n*sum(v[i], i=1..n))-1 $\frac{2}{n}\left(\sum_{i=1}^{n} v_i\right) - 1$, where n is the sample size. The number v_i is 1, if x[i]-‘x‾‘ $x_i - \overline{x}$ and y[i]-‘y‾‘ $y_i - \overline{y}$ have the same sign or are both 0. It is 1/2 $\frac{1}{2}$, if either x[i]-‘x‾‘ $x_i - \overline{x}$ or y[i]-‘y‾‘ $y_i - \overline{y}$ is 0. Otherwise, v_i = 0.

Both the Bravais-Pearson correlation as well as the Fechner correlation are numbers between - 1 and 1.

The Bravais-Pearson correlation is close to 1 if the data pairs x_i, y_i are approximately related by a ’positive’ linear relation (i.e., $y_i \approx ax_i + b$ with

some positive coefficient a). It is close to - 1 if there is a 'negative' linear relation (with some negative coefficient a).

Correlation coefficients close to 0 correspond to non-linear relations or to unrelated data, respectively.

If the input data are floating-point numbers, the sums defining the Bravais-Pearson correlation are computed in a numerically stable way. If a floating-point result is desired, it is recommended to make sure that all input data are floats.

The Fechner correlation is always returned as a rational number.

The column indices c_1, c_2 are optional if the data are given by a stats::sample object `s` containing only two non-string data columns. If the data are provided by two samples s_1, s_2, the column indices are optional for samples containing only one non-string data column.

Note The Fechner correlation should not be computed for symbolic data. This may lead to unexpected results, if the sign of symbolic parameters cannot be determined.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We compute the correlation of samples passed as lists:
X := [7, 33/7, 3, 5, 2]: Y := [3, 5, 1, 7, 2]: stats::correlation(X, Y)(147*sqrt(26506))/53012

$$\frac{147\sqrt{26506}}{53012}$$

Alternatively, the data may be passed as a list of data pairs:

stats::correlation([[7, 3], [33/7, 5], [3, 1], [5, 7], [2, 2]])(147*sqrt(26506))/53012

$$\frac{147\sqrt{26506}}{53012}$$

If all data are floating-point numbers, the result is a float:
stats::correlation(float(X), float(Y))0.4514558056

0.4514558056

The Fechner correlation of the data is always returned as a rational number:
stats::correlation(X, Y, Fechner), stats::correlation(float(X), float(Y), Fechner)3/5, 3/5

$$\frac{3}{5}, \frac{3}{5}$$

The following exact result indicates an exact linear between the data pairs:
stats::correlation([0, 1, 2, 3], [7, 5, 3, 1])-1

$$-1$$

Indeed, there is the 'negative' linear relation $y = 7 - 2x$ between the data pairs.
delete X, Y:

Example 2

We create a sample of type stats::sample:
s := stats::sample([[1.0, 2.4, 3.0], [7.0, 4.8, 4.0], [3.3, 3.0, 5.0]]) 1.0 2.4 3.0 7.0 4.8 4.0 3.3 3.0 5.0

We compute the correlation between the data of the first and the third column in several equivalent ways:

stats::correlation(s, 1, 3), stats::correlation(s, [1, 3]), stats::correlation(s, 1, s, 3)0.3799015783, 0.3799015783, 0.3799015783

0.3799015783, 0.3799015783, 0.3799015783

stats::correlation(s, 1, 3, Fechner), stats::correlation(s, [1, 3], Fechner), stats::correlation(s, 1, s, 3, Fechner)0, 0, 0

0, 0, 0

delete s:

Example 3

With symbolic data, the Bravais-Pearson correlation is returned as a symbolic expression:

stats::correlation([x1, x2], [y1, y2])(x1*y1 + x2*y2 - 2*(x1/2 + x2/2)*(y1/2 + y2/2))/sqrt((x1^2 - 2*(x1/2 + x2/2)^2 + x2^2)*(y1^2 - 2*(y1/2 + y2/2)^2 + y2^2))

$$\frac{x1\,y1 + x2\,y2 - 2\left(\frac{x1}{2} + \frac{x2}{2}\right)\left(\frac{y1}{2} + \frac{y2}{2}\right)}{\sqrt{\left(x1^2 - 2\left(\frac{x1}{2} + \frac{x2}{2}\right)^2 + x2^2\right)\left(y1^2 - 2\left(\frac{y1}{2} + \frac{y2}{2}\right)^2 + y2^2\right)}}$$

simplify(%)((x1 - x2)*(y1 - y2))/sqrt((x1 - x2)^2*(y1 - y2)^2)

$$\frac{(x1 - x2)\,(y1 - y2)}{\sqrt{(x1 - x2)^2\,(y1 - y2)^2}}$$

Parameters

x_1, y_1, x_2, y_2, ...

The statistical data: arithmetical expressions. The number of data x_i must coincide with the number of data y_i.

s

s_1

s_2

Samples of type stats::sample

c_1

c_2

Column indices: positive integers. Column c_1 of `s` or s_1, respectively, provides the data x_i. Column c_2 of `s` or `s_2`, respectively, provides the data y_i.

mode

Either `BravaisPearson` or `Fechner`. The default is the linear (Bravais-Pearson) correlation.

Options

BravaisPearson

Fechner

Linear (Bravais-Pearson) or Fechner's correlation coefficient. Bravais-Pearson coefficient is the default, but may in some cases where the data is not normally distributed be less useful than Fechner's correlation.

Return Values

The Bravais-Pearson correlation is returned as an arithmetical expression. `FAIL` is returned if the variance of one of the data samples vanishes (the Bravais-Pearson correlation does not exist).

The Fechner correlation is returned as a rational number.

`FAIL` is returned if the data samples are empty.

See Also

stats::correlationMatrixstats::covariancestats::stdevplot::Scatterplot

stats::correlationMatrix

Purpose

Compute the correlation matrix associated with a covariance matrix

Syntax

```
stats::correlationMatrix(cov)
```

Description

`stats::correlationMatrix(cov)` returns to correlation matrix `cor` of the variance-covariance matrix `cov`. It is given by:

cor[i,j]=cov[i,j]/(sqrt(cov[i,i])*sqrt(cov[j,j]))

$$\mathrm{cor}_{i,j} = \frac{\mathrm{cov}_{i,j}}{\sqrt{\mathrm{cov}_{i,i}}\sqrt{\mathrm{cov}_{j,j}}}$$

A covariance matrix C should be positive (semi-)definite and hence satisfies $|C_{ij}|^2 \le C_{ii}C_{jj}$ for all indices i, j. Consequently, the absolute values of the entries of the corresponding correlation matrix do not exceed 1.

With the option `CovarianceMatrix`, the routine stats::reg returns the variance-covariance matrix of the fit parameters in a regression analysis. The corresponding correlation matrix of the fit parameters is computed conveniently by applying `stats::correlationMatrix` to this matrix. Cf. “Example 2” on page 30-65.

Examples

Example 1

We generate a positive definite matrix that may serve as a covariance matrix:

```
A := matrix([[4, -3, 2], [-1, 2, 1], [0, 1, 1]]): cov :=
A*linalg::transpose(A)matrix([[29, -8, -1], [-8, 6, 3], [-1, 3,
2]])
```

$$\begin{pmatrix} 29 & -8 & -1 \\ -8 & 6 & 3 \\ -1 & 3 & 2 \end{pmatrix}$$

The corresponding correlation matrix is:

stats::correlationMatrix(cov)matrix([[1, -(4*sqrt(6)*sqrt(29))/87, -(sqrt(2)*sqrt(29))/58], [-(4*sqrt(6)*sqrt(29))/87, 1, (sqrt(2)*sqrt(6))/4], [-(sqrt(2)*sqrt(29))/58, (sqrt(2)*sqrt(6))/4, 1]])

$$\begin{pmatrix} 1 & -\frac{4\sqrt{6}\sqrt{29}}{87} & -\frac{\sqrt{2}\sqrt{29}}{58} \\ -\frac{4\sqrt{6}\sqrt{29}}{87} & 1 & \frac{\sqrt{2}\sqrt{6}}{4} \\ -\frac{\sqrt{2}\sqrt{29}}{58} & \frac{\sqrt{2}\sqrt{6}}{4} & 1 \end{pmatrix}$$

If the input matrix consists of floating-point data, the result is a matrix of floats:

stats::correlationMatrix(float(cov))matrix([[1.0, -0.6064784349, -0.1313064329], [-0.6064784349, 1.0, 0.8660254038], [-0.1313064329, 0.8660254038, 1.0]])

$$\begin{pmatrix} 1.0 & -0.6064784349 & -0.1313064329 \\ -0.6064784349 & 1.0 & 0.8660254038 \\ -0.1313064329 & 0.8660254038 & 1.0 \end{pmatrix}$$

delete A, cov:

Example 2

We consider a covariance matrix arising in a non-linear regression problem. The model function $y = a + b\cos(x - c)$ is to be fit to the following randomized data:

r := stats::uniformRandom(-0.1, 0.1): xdata := [i $i = 1..100]: ydata := [1 + 2*cos(x - 3) + r() $ x in xdata]:

By construction, the variance of the y values is the variance of the uniformly distributed random data on the interval [- 0.1, 0.1] generated by the random generator r. This variance is Symbol::sigma^2=1/300$\sigma^2 = \frac{1}{300}$. We use stats::reg to obtain estimates of the fit parameters a, b, c of the model. Appropriate weights for the regression are given by 1/Symbol::sigma^2=300 $\frac{1}{\sigma^2} = 300$. The option `CovarianceMatrix` makes stats::reg include the covariance matrix `cov` of the fit parameters in its return list:

weights := [300 $ i = 1..100]: DIGITS:= 4: [abc, chisquare, cov] := stats::reg(xdata, ydata, weights, a + b*cos(x - c), [x], [a, b, c], StartingValues = [1, 2, 3], CovarianceMatrix)[[1.004, 1.998, 3.0], 107.4, matrix([[3.334e-5, -3.414e-7, -6.749e-8], [-3.414e-7, 6.697e-5, 1.379e-7], [-6.749e-8, 1.379e-7, 1.663e-5]])]

$$\left[[1.004,\ 1.998,\ 3.0],\ 107.4,\ \begin{pmatrix} 0.00003334 & -0.0000003414 & -0.00000006749 \\ -0.0000003414 & 0.00006697 & 0.0000001379 \\ -0.00000006749 & 0.0000001379 & 0.00001663 \end{pmatrix}\right]$$

The correlation matrix of the parameters *a*, *b*, *c* is obtained via `stats::correlationMatrix` applied to the covariance matrix `cov` returned by stats::reg:
stats::correlationMatrix(cov)matrix([[1.0, -0.007226, -0.002866], [-0.007226, 1.0, 0.004132], [-0.002866, 0.004132, 1.0]])

$$\begin{pmatrix} 1.0 & -0.007226 & -0.002866 \\ -0.007226 & 1.0 & 0.004132 \\ -0.002866 & 0.004132 & 1.0 \end{pmatrix}$$

delete r, xdata, ydata, weights, DIGITS, abc, chisquare, cov:

Parameters

cov

The covariance matrix: a square matrix of category Cat::Matrix, or an array.

Return Values

Matrix of the same dimension and type as the input matrix `cov`. `FAIL` is returned if at least one of the diagonal elements of the input matrix `cov` is zero.

See Also

stats::correlationstats::covariancestats::regstats::stdev

stats::covariance

Purpose

Covariance of data samples

Syntax

```
stats::covariance([x1, x2,  ], [y1, y2,  ],
<Sample | Population>)
stats::covariance([[x1, y1], [x2, y2],  ],
<Sample | Population>)
stats::covariance(s, <c1, c2>, <Sample | Population>)
stats::covariance(s, <[c1, c2]>, <Sample | Population>)
stats::covariance(s1, <c1>, s2, <c2>, <Sample | Population>)
```

Description

`stats::covariance([x1, x2,  , xn], [y1, y2,  , yn])` returns the covariance

1/(n-1)*sum((x[i]-‘x‾’)*(y[i]-‘y‾’), i=1..n) = 1/(n-1)*sum(x[i]*y[i], i=1..n) - n/(n-1)*‘x‾’*‘y‾’

$$\frac{1}{n-1}\left(\sum_{i=1}^{n}(x_i-\overline{x})\,(y_i-\overline{y})\right)=\frac{1}{n-1}\left(\sum_{i=1}^{n}x_i\,y_i\right)-\frac{n}{n-1}\,\overline{x}\,\overline{y}$$

where ‘x‾’ $\overline{x}$ and ‘y‾’ $\overline{y}$ are the arithmetic means of the data x_i and y_i, respectively.

`stats::covariance([x1, x2,  , xn], [y1, y2,  , yn], Population)` returns

1/n*sum((x[i]-‘x‾’)*(y[i]-‘y‾’), i=1..n) = 1/n*sum(x[i]*y[i], i=1..n) - ‘x‾’*‘y‾’

$$\frac{1}{n}\left(\sum_{i=1}^{n}(x_i-\overline{x})\,(y_i-\overline{y})\right)=\frac{1}{n}\left(\sum_{i=1}^{n}x_i\,y_i\right)-\overline{x}\,\overline{y}$$

If the input data are floating-point numbers, the sums defining the covariance are computed in a numerically stable way. If a floating point result is desired, it is recommended to make sure that all input data are floats.

For exact input data, exact symbolic expressions are returned.

The column indices c_1, c_2 are optional if the data are given by a stats::sample object s containing only two non-string data columns. If the data are provided by two samples s_1, s_2, the column indices are optional for samples containing only one non-string data column.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We compute the covariance of samples passed as lists:
X := [2, 33/7, 21/9, PI]: Y := [3, 5, 1, 7]: stats::covariance(X, Y)PI - 10/7

$$\pi - \frac{10}{7}$$

Alternatively, the data may be passed as a list of data pairs:
stats::covariance([[2, 3], [33/7, 5], [21/9, 1], [PI, 7]])PI - 10/7

$$\pi - \frac{10}{7}$$

If all data are floating-point numbers, the result is a float:
stats::covariance(float(X), float(Y))1.713021225

$$1.713021225$$

delete X, Y:

Example 2

We create a sample of type stats::sample:
s := stats::sample([[1.0, 2.4, 3.0], [7.0, 4.8, 4.0], [3.3, 3.0, 5.0]]) 1.0 2.4 3.0 7.0 4.8 4.0 3.3 3.0 5.0

We compute the covariance of the first column and the third column in several equivalent ways:
stats::covariance(s, 1, 3), stats::covariance(s, [1, 3]), stats::covariance(s, 1, s, 3)1.15, 1.15, 1.15

1.15, 1.15, 1.15
delete s:

Example 3

The covariance of symbolic data is returned as a symbolic expression:
stats::covariance([x1, x2], [y1, y2])x1*y1 + x2*y2 - 2*(x1/2 + x2/2)*(y1/2 + y2/2)

$$x1\,y1 + x2\,y2 - 2\left(\frac{x1}{2} + \frac{x2}{2}\right)\left(\frac{y1}{2} + \frac{y2}{2}\right)$$

expand(%)(x1*y1)/2 - (x1*y2)/2 - (x2*y1)/2 + (x2*y2)/2

$$\frac{x1\,y1}{2} - \frac{x1\,y2}{2} - \frac{x2\,y1}{2} + \frac{x2\,y2}{2}$$

Parameters

x_1, y_1, x_2, y_2, ...

The statistical data: arithmetical expressions. The number of data x_i must coincide with the number of data y_i.

s

s_1

s_2

Samples of type stats::sample

c_1

c_2

Column indices: positive integers. Column c_1 of s or s_1, respectively, provides the data x_i. Column c_2 of s or s_2, respectively, provides the data y_i.

Options

Sample

The data are regarded as a “sample”, not as a full population. This is the default.

Population

The data are regarded as the whole population, not as a sample.

Return Values

arithmetical expression.

See Also

stats::correlationstats::correlationMatrixstats::stdev

stats::cutoff

Purpose

Discard outliers

Syntax

```
stats::cutoff([x_1, x_2,  ], Æ)
stats::cutoff([[x_11, x_12,  ], [x_21, x_22,  ],  ], Æ, i)
stats::cutoff(s, Æ, i)
```

Description

`stats::cutoff([x_1, x_2,  ], Æ)` returns those elements of [x_1, x_2, ...] larger than the a quantile and smaller than the 1 - a quantile of this list.

`stats::cutoff([[x_11, x_12,  ], [x_21, x_22,  ],  ], Æ, i)` and `stats::cutoff(stats::sample([[x_11, x_12,  ], [x_21, x_22,  ], ]), Æ, i)` perform the operations described above on the i-th entries of the input rows.

Measurement data often contains "outliers," sample points rather far outside the range containing the majority of the points. While expected both from theory and experience, these outliers, for small or medium-sized samples, tend to distort statistical data such as the mean value.

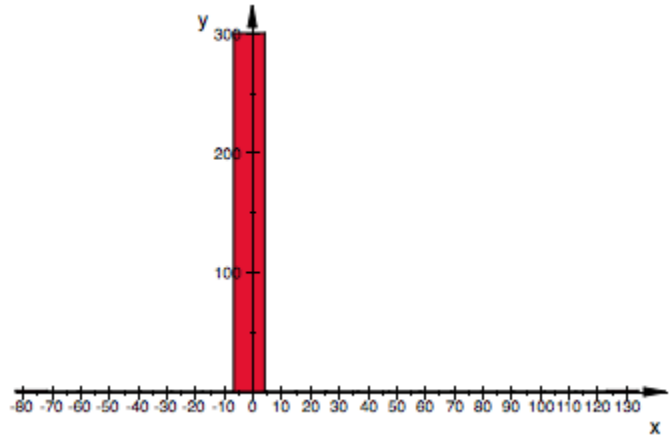
One of the standard methods dealing with this problem for (real) continuous scales is discarding the outliers. `stats::cutoff` discards all data points below or above a given quantile.

Examples

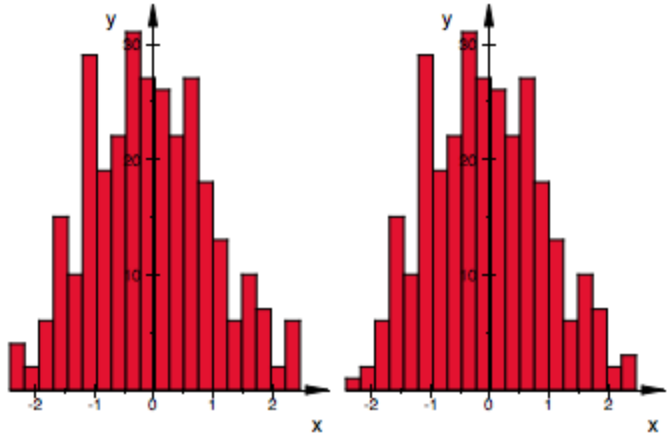
Example 1

We create a normally distributed sample, slightly contaminated:
r := stats::normalRandom(0, 1, Seed=2): data := [r() $ i = 1..300, 100*r() $ i = 1..2]:

The two extra points distort the data significantly:
plot(plot::Histogram2d(data, Cells=20))

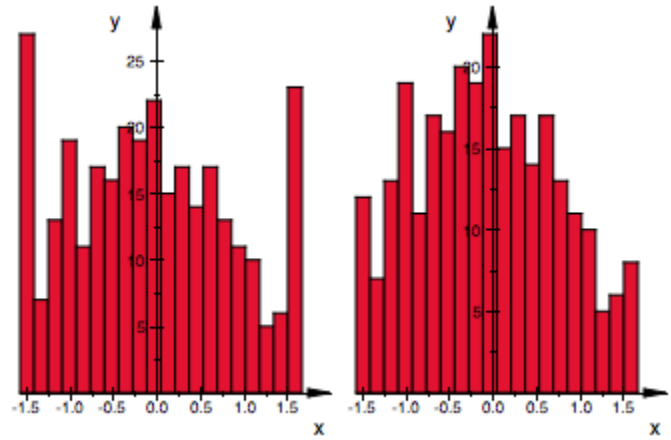


Using either stats::winsorize or `stats::cutoff` removes this noise and the image shows more detail:
plot(plot::Scene2d(plot::Histogram2d (stats::winsorize(data, 1/100), Cells=20)), plot::Scene2d(plot::Histogram2d (stats::cutoff(data, 1/100), Cells=20)))



With larger values of a, the difference between the two is easier to see:

plot(plot::Scene2d(plot::Histogram2d (stats::winsorize(data, 1/20), Cells=20)), plot::Scene2d(plot::Histogram2d (stats::cutoff(data, 1/20), Cells=20)))



Both stats::winsorize and `stats::cutoff` reduce the standard deviation of the sample. This effect is considerably stronger for `stats::cutoff`, though. Keeping in mind that the standard deviation of our random number generator is 1, we compute that of the data in its various forms: stats::stdev(data), stats::stdev(stats::winsorize(data, 1/20)), stats::stdev(stats::cutoff(data, 1/20))9.133931298, 0.9276576788, 0.8142529511

```
9.133931298, 0.9276576788, 0.8142529511
```

Parameters

x_1, x_2, x_{11}, ...

The statistical data: arithmetical expressions. The data to filter on must be real-valued.

s

Sample of type stats::sample

Cutoff parameter: a real-valued expression 0 <= Symbol::alpha <= 1/2$0 \le \alpha \le \frac{1}{2}$.

i

Column index: positive integer. The nested list or the sample is filtered on its *i*-th column.

Return Values

The input data with outliers being removed.

See Also

stats::winsorizestats::sample

Concepts

- “Handle Outliers”

stats::winsorize

Purpose

Clamp (winsorize) extremal values

Syntax

```
stats::winsorize([x_1, x_2,  ], Æ)
stats::winsorize([[x_11, x_12,  ], [x_21, x_22,  ],  ], Æ, i)
stats::winsorize(s, Æ, i)
```

Description

`stats::winsorize([x_1, x_2,  ], Æ)` returns a copy of $[x_1, x_2, \ldots]$ in which all entries smaller than the a quantile have been replaced by this value and likewise for all entries larger than the 1 - a quantile.

`stats::winsorize([[x_11, x_12,  ], [x_21, x_22,  ],  ], Æ, i)` and `stats::winsorize(stats::sample([[x_11, x_12,  ], [x_21, x_22,  ], ]), Æ, i)` perform the operations described above on the i-th entries of the input rows.

Measurement data often contains "outliers," sample points rather far outside the range containing the majority of the points. While expected both from theory and experience, these outliers, for small or medium-sized samples, tend to distort statistical data such as the mean value.

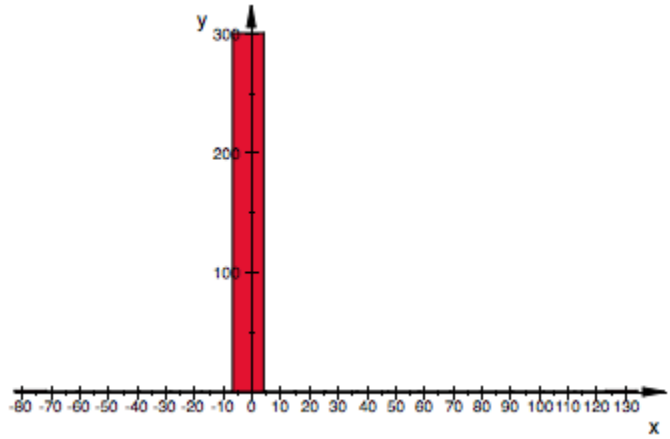
One of the standard methods dealing with this problem for (real) continuous scales is clamping the outliers. `stats::winsorize` sets all data points below or above a given quantile to these quantiles. (This operation is named after its inventor, Charles P. Winsor.)

Examples

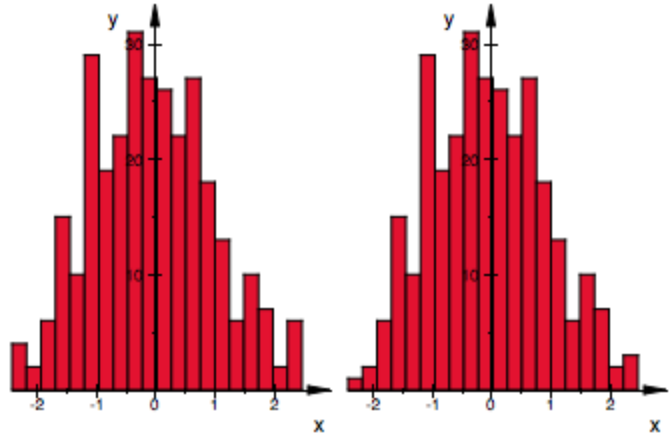
Example 1

We create a normally distributed sample, slightly contaminated:
r := stats::normalRandom(0, 1, Seed=2): data := [r() $ i = 1..300, 100*r() $ i = 1..2]:

The two extra points distort the data significantly:
plot(plot::Histogram2d(data, Cells=20))

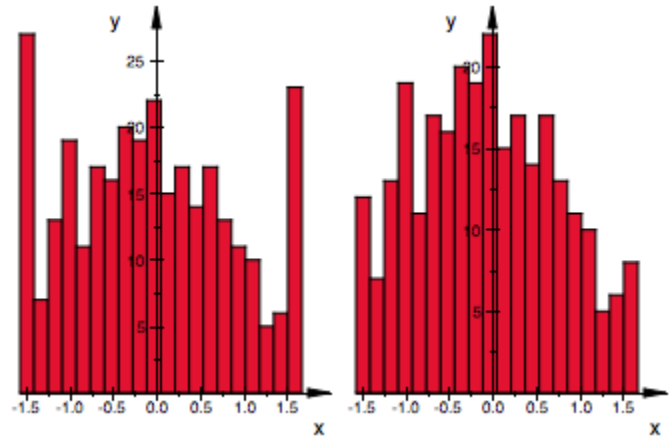


Using either `stats::winsorize` or stats::cutoff removes this noise and the image shows more detail:
plot(plot::Scene2d(plot::Histogram2d (stats::winsorize(data, 1/100), Cells=20)), plot::Scene2d(plot::Histogram2d (stats::cutoff(data, 1/100), Cells=20)))



With larger values of a, the difference between the two is easier to see:

plot(plot::Scene2d(plot::Histogram2d (stats::winsorize(data, 1/20), Cells=20)), plot::Scene2d(plot::Histogram2d (stats::cutoff(data, 1/20), Cells=20)))



Both `stats::winsorize` and stats::cutoff reduce the standard deviation of the sample. This effect is considerably stronger for stats::cutoff, though. Keeping in mind that the standard deviation of our random number generator is 1, we compute that of the data in its various forms: stats::stdev(data), stats::stdev(stats::winsorize(data, 1/20)), stats::stdev(stats::cutoff(data, 1/20))9.133931298, 0.9276576788, 0.8142529511

```
9.133931298, 0.9276576788, 0.8142529511
```

Parameters

x_1, x_2, x_{11}, ...

The statistical data: arithmetical expressions. The data to filter on must be real-valued.

s

Sample of type stats::sample

Cut-off parameter: a real-valued expression 0 <= Symbol::alpha <= 1/2$0 \le \alpha \le \frac{1}{2}$.

i

Column index: positive integer. The nested list or the sample is winsorized on its *i*-th column.

Return Values

The input data with outliers being replaced by the values of quantiles.

stats::csGOFT

Purpose

Classical chi-square goodness-of-fit test

Syntax

```
stats::csGOFT(x1, x2,  , [[a1, b1], [a2, b2],  ],
CDF = f | PDF = f | PF = f)
stats::csGOFT([x1, x2,  ], [[a1, b1], [a2, b2],  ],
CDF = f | PDF = f | PF = f)
stats::csGOFT(s, <c>, [[a1, b1], [a2, b2],  ], CDF
= f | PDF = f | PF = f)
```

Description

`stats::csGOFT(data, cells, CDF = f)` applies the classical chi-square goodness-of-fit test for the null hypothesis: "the data are f-distributed".

The chi-square goodness-of-fit test divides the real line into k intervals c[i]=Interval(a[i], [b[i]]) $c_i = (a_i, b_i]$ ('the cells'). It computes the number of data x_j falling into the cells c_i and compares these 'empirical cell frequencies' with the 'expected cell frequencies' np_i, where n is the sample size and $p_i = Pr(a_i < x \le b_i)$ are the 'cell probabilities' of a random variable with the hypothesized distribution specified by `X = f`.

All data `x1`, `x2` etc. must be convertible to real floating-point numbers. The data do not have to be sorted on input: `stats::csGOFT` automatically converts the data to floats and sorts them internally.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Finite cell boundaries a_i, b_i must be convertible to real floating-point numbers satisfying $a_1 < b_1 \le a_2 < b_2 \le a_3 < \ldots$. They define *semiopen* intervalls c[i]=Interval(a[i], [b[i]]) $c_i = (a_i, b_i]$.

When the hypothesized distribution f is specified as a cumulative distribution function (`CDF = f`), the left boundary of the first cell and the right boundary of the last cell are ignored. They are replaced by $-\infty$ and *infinity*, respectively, i.e., the cell partitioning

Interval(-infinity, [b[1]]), Interval(a[2], [b[2]]), Symbol::hellip, Interval(a[k-1], [b[k-1]]), Interval(a[k], infinity)

$(-\infty, b_1], (a_2, b_2], \ldots, (a_{k-1}, b_{k-1}], (a_k, \infty)$

is used internally.

The cells must be disjoint. Their union must cover the support area of the distribution, i.e., the 'cell probabilities' $p_i = Pr(a_i < x \le b_i)$ must add up to 1 for a random variable x with the hypothesized distribution given by `f`. For continuous distributions, adjacent cells with $b_1 = a_2$, $b_2 = a_3$, … are appropriate.

You may use $a_1 = -\infty$ and $b_k = \infty$ for distributions supported on the entire real line.

Note The cells must be chosen such that no cell probability p_i vanishes!

See the 'Background' section of this help page for recommendations on the cell partitioning. In particular, the use of equiprobable cells (with constant p_i) is recommended. For convenience, a utility function stats::equiprobableCells is provided to generate such cells. See "Example 1" on page 30-83, "Example 3" on page 30-86, and "Example 4" on page 30-89.

The distribution the data are tested for is specified by the equation `X = f`, where `X` is one of the flags `CDF`, `PDF` or `PF`.

For efficiency, it is recommended to specify a cumulative distribution function (`CDF = f`).

The function `f` can be a procedure provided by the MuPAD `stats` library. Specifications such as `CDF = stats::normalCDF(m, v)` or `CDF = stats::poissonCDF(m)` with suitable numerical values of `m`, `v` are possible and recommended.

Distributions that are not provided by the `stats`-package can be implemented easily by the user. A user defined procedure *f* can implement any distribution function. In the CDF case, `stats::csGOFT` calls `f` with the boundary values a_i, b_i of the cells to compute the cell probabilities via $p_i = f(b_i) - f(a_i)$ (automatically setting $f(a_1) = 0$ and $f(b_k) = 1$).

The function `f` must return a numerical real value between 0 and 1. See "Example 5" on page 30-90 and "Example 6" on page 30-91.

Alternatively, the function `f` can be specified by a univariate arithmetical expression $g(x)$ depending on a symbolic variable `x`. It is interpreted as the function _outputSequence(f, Symbol::colon, Symbol::NonBreakingSpace, x->g(x)) $f: x \to g(x)$. Cf. "Example 6" on page 30-91.

See the 'Background' section of this help page for further information on the specification of the distribution via `CDF = f`, `PDF = f` or `PF = f`.

The call `stats::csGOFT(data, cells, X = f)` returns the list [*PValue* = *p*, *StatValue* = *s*, *MinimalExpectedCellFrequency* = *m*]:

- `s` is the observed value of the chi-square statistic

  s=sum((fenced(y[(i)]-n*p[(i)])^(2))/(n*p[(i)]), i=1..k)

  $$s = \sum_{i=1}^{k} \frac{(y_i - n\,p_i)^2}{n\,p_i}$$

  where n is the sample size, k is the number of cells, y_i is the observed cell frequency of the data (i.e., y_i is the number of data x_j falling into the cell c_i), and p_i is the cell probabilitiy corresponding to the hypothesized distribution *f*.

- *p* is the observed significance level of the chi-square statistic with *k* - 1 degrees of freedom, i.e., *p* = 1 - *stats*::*chisquareCDF*(*k* - 1)(*s*)

- m=min(n*p[i], i=1..k) $m = \min(n\,p_i,\ i = 1..k)$ is the minimum of the expected cell frequencies np_i. This information is provided by the test

to make sure that the boundary conditions for a “reasonable” cell partitioning are met (see the “Background” section of this help page).

The most relevant information returned by `stats::csGOFT` is the observed significance level `PValue = p`. It has to be interpreted in the following way: Under the null hypothesis, the chi-square statistic

S=sum((fenced(y[(i)]-n*p[(i)])^(2))/(n*p[(i)]), i=1..k)

$$S = \sum_{i=1}^{k} \frac{(y_i - n\,p_i)^2}{n\,p_i}$$

is approximately chi-square distributed (for large samples):

Pr(S<=s)=stats::chisquareCDF(k-1)(s)

$$\Pr(S \le s) = \text{stats::chisquareCDF}(k-1)(s)$$

Under the null hypothesis, the probability $p = Pr(S > s)$ should not be small, where `s` is the value of the statistic attained by the sample.

Specifically, $p = Pr(S > s) \geq \alpha$ should hold for a given significance level $0 < \alpha < 1$, If this condition is violated, the hypothesis may be rejected at level α.

Thus, if the PValue (observed significance level) `p` = $Pr(S > s)$ satisfies $p < \alpha$, the sample leading to the observed value `s` of the statistic S represents an unlikely event, and the null hypothesis may be rejected at level α.

On the other hand, values of p close to 1 should raise suspicion about the randomness of the data: they indicate a fit that is *too good*.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We consider random data that should be normally distributed with mean 15 and variance 2:
f := stats::normalRandom(15, 2, Seed = 0): data := [f() $ i = 1..1000]:

According to the recommendations in the 'Background' section of this help page, the number of cells should be approximately 2 * n^(2/5)
approx $31.72\, n^{2/5} \approx 31.7$, where n = 1000 is the sample size.

We wish to use 32 cells that are equiprobable with respect to the hypothesized normal distribution. We estimate the mean m and the variance v of the data:
[m, v] := [stats::mean(data), stats::variance(data, Sample)][14.94011963, 2.014256118]

[14.94011963, 2.014256118]

The utility function stats::equiprobableCells is used to compute an equiprobable cell partitioning via the quantile function of the normal distribution with the empirical parameters:
cells := stats::equiprobableCells(32, stats::normalQuantile(m, v)):
stats::csGOFT(data, cells, CDF = stats::normalCDF(m, v))[PValue = 0.6359912784, StatValue = 27.712, MinimalExpectedCellFrequency = 31.25]

[PValue = 0.6359912784, StatValue = 27.712, MinimalExpectedCellFrequency = 31.25]

The observed significance level _outputSequence(0.635, dots)0.635... attained by the sample is not small. Hence, one should not reject the hypothesis that the sample is normally distributed with mean _outputSequence(14.94, dots)14.94... and variance _outputSequence(2.014, dots)2.014....

In the following, we impurify the sample by appending some uniformly distributed numbers. A new equiprobable cell partitioning appropriate for the new data is computed:

```
r := stats::uniformRandom(10, 20, Seed = 0): data := append(data,
r() $ 40): [m, v] := [stats::mean(data), stats::variance(data, Sample)]:
k := round(2*nops(data)^(2/5)): cells := stats::equiprobableCells(k,
stats::normalQuantile(m, v)): stats::csGOFT(data, cells, CDF =
stats::normalCDF(m, v))[PValue = 0.007653320709, StatValue =
53.29230769, MinimalExpectedCellFrequency = 32.5]
```

```
[PValue = 0.007653320709, StatValue = 53.29230769, MinimalExpectedCellFrequency = 32.5]
```

The impure data may be rejected as a normally distributed sample at levels as small as _outputSequence(0.0076, dots)0.0076....
delete f, data, m, v, k, cells, r:

Example 2

We create a sample of random data that should be binomially distributed with trial parameter 70 and probability parameter 1/2$\frac{1}{2}$:

```
r := stats::binomialRandom(70, 1/2, Seed = 123): data := [r() $ k =
1..1000]:
```

With the expectation value of 35 and the standard deviation of sqrt(70)/2 approx 4.18$\frac{\sqrt{70}}{2} \approx 4.18$ of this distribution, we expect most of the data to have values between 30 and 40. Thus, a cell partitioning consisting of 12 cells corresponding to the intervals

Interval(0, [30]), Interval(30, [31]), Interval(31, [32]), Symbol::hellip, Interval(39, [40]), Interval(40, [70])

```
(0, 30], (30, 31], (31, 32], ..., (39, 40], (40, 70]
```

should be appropriate. Note that all cells are interpreted as the intervals Interval(a[i], [b[i]])$(a_i, b_i]$, i.e., the left boundary is not included in the interval. Strictly speaking, the value 0 is not covered by these cells. However, with a `CDF` specification, `stats::csGOFT` ignores the leftmost boundary and replaces it by -infinity. Thus, the union of the cells does cover all integers 0, …, 70 that can be attained by the hypothesized binomial distribution with 'trial parameter' 70:

```
cells := [[0, 30], [i, i + 1] $ i = 30..39, [40, 70]][[0, 30], [30, 31], [31, 32],
[32, 33], [33, 34], [34, 35], [35, 36], [36, 37], [37, 38], [38, 39], [39, 40],
[40, 70]]
```

```
[[0, 30], [30, 31], [31, 32], [32, 33], [33, 34], [34, 35], [35, 36], [36, 37], [37, 38], [38, 39], [39, 4
```

We apply the χ^2 test with various specifications of the binomial distribution. They all produce the same result. However, the first call using a `CDF` specification is the most efficient (fastest) call:

```
stats::csGOFT(data, cells, CDF = stats::binomialCDF(70,
1/2));[PValue = 0.4810610726, StatValue = 10.55729362,
MinimalExpectedCellFrequency = 46.88135939]
```

```
[PValue = 0.4810610726, StatValue = 10.55729362, MinimalExpectedCellFrequency = 46.8813593
```

```
stats::csGOFT(data, cells, PF = stats::binomialPF(70,
1/2));[PValue = 0.4810610726, StatValue = 10.55729362,
MinimalExpectedCellFrequency = 46.88135939]
```

```
[PValue = 0.4810610726, StatValue = 10.55729362, MinimalExpectedCellFrequency = 46.8813593
```

```
f := binomial(70, x)*(1/2)^x*(1/2)^(70 - x): stats::csGOFT(data,
cells, PF = f)[PValue = 0.4810610726, StatValue = 10.55729362,
MinimalExpectedCellFrequency = 46.88135939]
```

```
[PValue = 0.4810610726, StatValue = 10.55729362, MinimalExpectedCellFrequency = 46.8813593
```

The observed significance level _outputSequence(0.481, dots)`0.481...` indicates that the data pass the test well.

Next, we dote the sample by appending the value 35 fourty times:

```
data := data . [35 $ 40]: stats::csGOFT(data, cells, CDF =
stats::binomialCDF(70, 1/2));[PValue = 0.0098099163, StatValue =
24.78215227, MinimalExpectedCellFrequency = 48.75661376]
```

```
[PValue = 0.0098099163, StatValue = 24.78215227, MinimalExpectedCellFrequency = 48.7566137
```

Now, the data may be rejected as a binomial sample with the specified parameters at levels as small as _outputSequence(0.0098, dots)0.0098.... delete r, data, cells, f:

Example 3

We test data that purport to be a sample of beta distributed numbers with scale parameters 3 and 2. Since beta deviates attain values between 0 and 1, we choose an equidistant cell partitioning of the interval [0, 1] consisting of 10 cells. Various equivalent calls to `stats::csGOFT` are demonstrated:
r := stats::betaRandom(3, 2, Seed = 1): data := [r() $ i = 1..100]: cells := [[(i - 1)/10, i/10] $ i = 1..10]: stats::csGOFT(data, cells, CDF = stats::betaCDF(3, 2)); stats::csGOFT(data, cells, CDF = (x -> stats::betaCDF(3, 2)(x)))[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.37]

[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.37]
[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.37]

[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.37]

Alternatively, the beta destribution may be passed by a `PDF` specification. This, however, is less efficient than the `CDF` specification used before:
stats::csGOFT(data, cells, PDF = stats::betaPDF(3, 2)); stats::csGOFT(data, cells, PDF = (x -> stats::betaPDF(3, 2)(x)));[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.37]

[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.37]
[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.37]

[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.37]

The observed significance level _outputSequence(0.732, dots)0.732... is not small. Hence, this test does not indicate that the data should be rejected as a beta distributed sample with the specified parameters. Note, however, that the minimal expected cell frequency given by the third element of the returned list is rather small. This indicates that the cell partitioning is not very fortunate. We investigate the expected cell frequencies by computing $np_i = n(f(b_i) - f(a_i))$, where f is the cumulative distribution function of the beta distribution and n is the sample size:
f:= stats::betaCDF(3, 2): map(cells, cell -> 100*(f(cell[2]) - f(cell[1])))[0.37, 2.35, 5.65, 9.55, 13.33, 16.27, 17.65, 16.75, 12.85, 5.23]

[0.37, 2.35, 5.65, 9.55, 13.33, 16.27, 17.65, 16.75, 12.85, 5.23]

These values show that the first two or three cells should be joined to a single cell. We modify the cell partitioning by joining the first three and the last two cells:
cells := [[0, 3/10], [(i - 1)/10, i/10] $ i = 4..8, [8/10, 1]][[0, 3/10], [3/10, 2/5], [2/5, 1/2], [1/2, 3/5], [3/5, 7/10], [7/10, 4/5], [4/5, 1]]

$$\left[\left[0, \frac{3}{10}\right], \left[\frac{3}{10}, \frac{2}{5}\right], \left[\frac{2}{5}, \frac{1}{2}\right], \left[\frac{1}{2}, \frac{3}{5}\right], \left[\frac{3}{5}, \frac{7}{10}\right], \left[\frac{7}{10}, \frac{4}{5}\right], \left[\frac{4}{5}, 1\right]\right]$$

For this cell partitioning, the expected frequencies in a random sample of size 100 are sufficiently large for all cells:
map(cells, cell -> 100*(f(cell[2]) - f(cell[1])))[8.37, 9.55, 13.33, 16.27, 17.65, 16.75, 18.08]

[8.37, 9.55, 13.33, 16.27, 17.65, 16.75, 18.08]

We apply another χ^2 test with this improved partitioning:
stats::csGOFT(data, cells, CDF = f)[PValue = 0.9023533657, StatValue = 2.180685972, MinimalExpectedCellFrequency = 8.37]

[PValue = 0.9023533657, StatValue = 2.180685972, MinimalExpectedCellFrequency = 8.37]

Again, with the observed significance level _outputSequence(0.902, dots)0.902..., the test does not give any hint that the data are not beta distributed with the specified parameters.

Now, we test whether the data can be regarded as being normally distributed. First, we estimate the parameters (mean and variance) required for the normal distribution:
[m, v] := [stats::mean(data), stats::variance(data, Sample)][0.6101560142, 0.03595065085]

[0.6101560142, 0.03595065085]

The cell partitioning used before was a partitioning of the interval [0, 1], because beta deviates attain values in this interval. Now we construct a partitioning of 7 equiprobable cells using the quantile function of the normal distribution:
k := 7: cells := stats::equiprobableCells(7, stats::normalQuantile(m, v))[[-infinity, 0.4077376304], [0.4077376304, 0.5028484001], [0.5028484001, 0.5760244864], [0.5760244864, 0.6442875419], [0.6442875419, 0.7174636283], [0.7174636283, 0.8125743979], [0.8125743979, infinity]]

[[−∞, 0.4077376304], [0.4077376304, 0.5028484001], [0.5028484001, 0.5760244864], [0.5760244
[0.6442875419, 0.7174636283], [0.7174636283, 0.8125743979], [0.8125743979, ∞]]

Indeed, theses cells are equiprobable:
f:= stats::normalCDF(m, v): map(cells, cell -> f(cell[2]) - f(cell[1]))[0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429]

[0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.14

We test for normality with the estimated mean and variance:
stats::csGOFT(data, cells, CDF = f)[PValue = 0.7118124259, StatValue = 3.74, MinimalExpectedCellFrequency = 14.28571429]

[PValue = 0.7118124259, StatValue = 3.74, MinimalExpectedCellFrequency = 14.28571429]

With the observed significance level of _outputSequence(0.711, dots)0.711..., the data should not be rejected as a normally distributed sample. We note that the nonparametric Shapiro-Wilk test implemented in stats::swGOFT does detect nonnormality of the sample:
stats::swGOFT(data)[PValue = 0.04753801335, StatValue = 0.97429647]

[PValue = 0.04753801335, StatValue = 0.97429647]

With the observed significance level of _outputSequence(0.0475, dots)0.0475..., normality can be rejected at levels as low as _outputSequence(0.0475, dots)0.0475....
delete r, data, cells, f, m, v, k, boundaries:

Example 4

We demonstrate the use of samples of type stats::sample. We create a sample consisting of one string column and two non-string columns:
s := stats::sample([["1996", 1242, 156], ["1997", 1353, 162], ["1998", 1142, 168], ["1999", 1201, 182], ["2001", 1201, 190], ["2001", 1201, 190], ["2001", 1201, 205], ["2001", 1201, 210], ["2001", 1201, 220], ["2001", 1201, 213], ["2001", 1201, 236], ["2001", 1201, 260], ["2001", 1201, 198], ["2001", 1201, 236], ["2001", 1201, 245], ["2001", 1201, 188], ["2001", 1201, 177], ["2001", 1201, 233], ["2001", 1201, 270]]) "1996" 1242 156 "1997" 1353 162 "1998" 1142 168 "1999" 1201 182 "2001" 1201 190 "2001" 1201 190 "2001" 1201 205 "2001" 1201 210 "2001" 1201 220 "2001" 1201 213 "2001" 1201 236 "2001" 1201 260 "2001" 1201 198 "2001" 1201 236 "2001" 1201 245 "2001" 1201 188 "2001" 1201 177 "2001" 1201 233 "2001" 1201 270

We consider the data in the third column. The mean and the variance of these data are computed:
[m, v] := float([stats::mean(s, 3), stats::variance(s, 3, Sample)])[207.3157895, 1082.672515]

[207.3157895, 1082.672515]

We check whether the data of the third column are normally distributed with the empirical mean and variance computed above. We compute an appropriate cell partitioning in the same way as explained in "Example 1" on page 30-83:

```
samplesize := s::dom::size(s): k := round(2*samplesize^(2/5)):
cells := stats::equiprobableCells(k, stats::normalQuantile(m,
v)): stats::csGOFT(s, 3, cells, CDF = stats::normalCDF(m,
v))[PValue = 0.9100131461, StatValue = 1.526315789,
MinimalExpectedCellFrequency = 3.166666667]
```

```
[PValue = 0.9100131461, StatValue = 1.526315789, MinimalExpectedCellFrequency = 3.166666667]
```

Thus, the data pass the test.

```
delete s, m, v, samplesize, k, cells:
```

Example 5

We demonstrate how user-defined distribution functions can be used. A die is rolled 60 times. The following frequencies of the scores 1, 2, …, 6 are observed:

```
score | 1 | 2 | 3 | 4 | 5 | 6 ----------+---+----+---+----+---+-- frequency
| 7 | 16 | 8 | 17 | 3 | 9
```

We test the null hypothesis that the dice is fair. Under this hypothesis, the variable X given by the score of a single roll attains the values 1 through 6 with constant probability 1/6. Presently, the `stats`-package does not provide a discrete uniform distribution, so we implement a corresponding cumulative discrete distribution function `f`:

```
f := proc(x) begin if x < 0 then 0 elif x <= 6 then trunc(x)/6 else 1 end_if;
end_proc:
```

We create the data representing the 60 rolls:

```
data := [ 1 $ 7, 2 $ 16, 3 $ 8, 4 $ 17, 5 $ 3, 6 $ 9]:
```

We choose a collection of cells, each of which contains exactly one of the integers 1, …, 6:

Wir wählen sodann eine Zellzerlegung, so dass jede Zelle genau eine der ganzen Zahlen 1, …, 6 enthält:

cells := [[i - 1/2, i + 1/2] $ i = 1..6][[1/2, 3/2], [3/2, 5/2], [5/2, 7/2], [7/2, 9/2], [9/2, 11/2], [11/2, 13/2]]

$$\left[\left[\frac{1}{2}, \frac{3}{2}\right], \left[\frac{3}{2}, \frac{5}{2}\right], \left[\frac{5}{2}, \frac{7}{2}\right], \left[\frac{7}{2}, \frac{9}{2}\right], \left[\frac{9}{2}, \frac{11}{2}\right], \left[\frac{11}{2}, \frac{13}{2}\right]\right]$$

stats::csGOFT(data, cells, CDF = f)[PValue = 0.01125197903, StatValue = 14.8, MinimalExpectedCellFrequency = 10.0]

[PValue = 0.01125197903, StatValue = 14.8, MinimalExpectedCellFrequency = 10.0]

At a significance level as small as _outputSequence(0.011, dots)0.011..., the null hypothesis 'the dice is fair' should be rejected.
delete f, data, cells:

Example 6

We give a further demonstration of user-defined distribution functions. The following procedure represents the cumulative distribution function _outputSequence(f, Symbol::colon, Symbol::NonBreakingSpace, x->Pr(X<=x)=x^2)$f: x \to \Pr(X \le x) = x^2$ of a variable *X* supported on the interval Interval([0], [1])$[0, 1]$. It will be called with values from the cell boundaries and must return numerical values between 0 and 1:
f := proc(x) begin if x <= 0 then return(0) elif x <= 1 then return(x^2) else return(1) end_if end_proc:

We test the hypothesis that the following data are *f*-distributed. The cells form an equidistant partitioning of the interval [0, 1]:
data := [sqrt(frandom()) $ i = 1..10^3]: k := 10: cells := [[(i - 1)/k, i/k] $ i = 1..k]: stats::csGOFT(data, cells, CDF = f)[PValue = 0.5637573509, StatValue = 7.708606165, MinimalExpectedCellFrequency = 10.0]

[PValue = 0.5637573509, StatValue = 7.708606165, MinimalExpectedCellFrequency = 10.0]

The test does not disqualify the sample as being *f*-distributed. Indeed, for a uniform deviate *Y* on the interval [0, 1] (as produced by frandom), the cumulative distribution function of sqrt(Y)$\sqrt{Y}$ is indeed given by *f*.

We note that the previous function yields the correct CDF values for all real arguments. The chosen cell partitioning indicates that only values from the interval Interval(0, [1])(0, 1] are considered. Since `stats::csGOFT` just evaluates the CDF on the cell boundaries to compute the cell probability of the cell Interval(a, [b])(*a*, *b*] by $f(b) - f(a)$, it suffices to restrict f to the interval Interval(0, [1])(0, 1]. Hence, for the chosen cells, the symbolic expression `f = x^2` can also be used to specify the distribution:
stats::csGOFT(data, cells, CDF = x^2)[PValue = 0.5637573509, StatValue = 7.708606165, MinimalExpectedCellFrequency = 10.0]

[PValue = 0.5637573509, StatValue = 7.708606165, MinimalExpectedCellFrequency = 10.0]
delete f, data, k, cells:

Parameters

x_1, x_2, ...

The statistical data: real numerical values

s

A sample of domain type stats::sample

c

An integer representing a column index of the sample `s`. This column provides the data x_1, x_2 etc. There is no need to specify a column `c` if the sample has only one column.

a_1, b_1, a_2, b_2, ...

Cell boundaries: real numbers satisfying $a_1 < b_1 \le a_2 < b_2 \le a_3 <$ .... Also _outputSequence(Symbol::pm,infinity)$\pm\infty$ is admitted as a cell boundary. At least 3 cells have to be specified.

f

A procedure representing the hypothesized distribution: either a cumulative distribution function (`CDF = f`), a probability density function (`PDF = f`), or a (discrete) probability function (`PF = f`). Typically, `f` is one of the distribution functions of the `stats`

package such as `stats::normalCDF(m, v)` etc. Instead of a procedure, also an arithmetical expression in some indeterminate `x` may be specified which will be interpreted as a function of `x`.

Options

CDF

PDF

PF

This determines how the procedure `f` is interpreted by `stats::csGOFT`.

Return Values

a list of three equations

`[PValue = p, StatValue = s, MinimalExpectedCellFrequency = m]`

with floating-point values `p`, `s`, `m`. See the "Details" section below for the interpretation of these values.

Algorithms

In R.B. D'Agostino and M.A. Stephens, "Goodness-Of-Fit Techniques", Marcel Dekker, 1986, p. 70-71, one finds the following recommendations for choosing the cell partitioning:

- The number of cells used should be approximately 2 * n^(2/5) $2\,n^{2/5}$, where n is the sample size.
- The cells should have equal probabilities p_i under the hypothesized distribution.
- With equiprobable cells, the average of the expected cell frequencies np_i should be at least 1 when testing at the significance level α = 0.05. For α = 0.01, the average expected cell frequency should be at least 2. When cells are not approximately equiprobable, the average expected cell frequency for the significance levels above should be doubled. For example, the average expected cell frequency at the significance level α = 0.01 should be at least 4.

The distribution function *f* passed to `stats::csGOFT` via `X = f` is only used to compute the cell probabilities $p_i = Pr(a_i < x \le b_i)$ of the cells c[i]=Interval(a[i], [b[i]]) $c_i = (a_i, b_i]$.

A cumulative distribution function `f` specified by `CDF = f` is used to compute the cell probabilities via $p_i = f(b_i) - f(a_i)$.

A probability density function `f` specified via `PDF = f` is used to compute the cell probabilities via numerical integration: p[i]=numeric::int(f(x), x=a[i]..b[i]) $p_i = \text{numeric::int}(f(x),\ x = a_i .. b_i)$. This is rather expensive!

A discrete probability function specified via `PF = f` is used to compute the cell probabilities via the summation p[i]=sum(f(x), x=floor(a_i)+1..b[i]) $p_i = \sum_{x=\lfloor a_i \rfloor + 1}^{b_i} f(x)$.

Note Thus, with the specification `PF = f`, the distribution is implicitly supposed to be supported on the integers in the cells c[i]=Interval(a[i], [b[i]]) $c_i = (a_i, b_i]$. Do not use `PF = f` if the discrete probability function is not supported on the integers! Use `CDF = f` with an appropriate (discrete) cumulative distribution function instead!

With the specification `PF = f`, the value $-\infty$ is not admitted for the left boundary a_1 of the first cell $c_1 = Intval([a_1], [b_1])$.

stats::equiprobableCellsstats::ksGOFTstats::swGOFTstats::tTest

stats::empiricalCDF

Purpose

Empirical (discrete) cumulative distribution function of a finite data sample

Syntax

```
stats::empiricalCDF(x1, x2,  )
stats::empiricalCDF([x1, x2,  ])
stats::empiricalCDF(s, c)
```

Description

`stats::empiricalCDF(x1, x2,  , xn)` returns a procedure representing the empirical (discrete) cumulative distribution function x->1/n * abs(ImageSet(i, x[i] <= x)) $x \to \frac{1}{n}\left|\{i \mid x_i \le x\}\right|$ (the relative frequency of data elements x_i less than or equal to x).

All data `x1, x2,` must be convertible to real floating-point numbers.

The procedure `f := stats::empiricalCDF(x1, x2,  )` can be called in the form `f(x)` with an arithmetical expression `x`.

If `x` is a numerical value, `f(x)` returns a rational number from the interval [0, 1].

The call `f(- infinity )` produces 0; the call `f( infinity )` produces 1.

Otherwise, if `x` is a symbolic expression that cannot be converted to a real floating-point number, `f(x)` returns the symbolic call `stats::empiricalCDF([x1, x2,  ])(x)` with the data `x1, x2,` in ascending order.

For a sample of size n, the call `f := stats::empiricalCDF(x1, x2, )` needs a run time of $O(nln(n))$ due to internal sorting of the data. Each call to `f` needs a run time of $O(ln(n))$. If several evaluations of the distribution function are needed, a calling sequence such as

```
f := stats::empiricalCDF(x1, x2,  ); f(a1); f(a2); dots
```

is more efficient than

```
stats::empiricalCDF(x1, x2,  )(a1);
```

```
stats::empiricalCDF(x1, x2,  )(a2);
```

dots.

stats::empiricalCDF is generalized by stats::finiteCDF, which allows to specify different probabilities for the elements of the sample. The call stats::empiricalCDF([x_1, , x_n]) corresponds to stats::finiteCDF([x_1, dots, x_n], [1/n, dots, 1/n]).

Further, stats::finiteCDF does not only allow numerical values x_1, x_2, , but arbitrary MuPAD objects.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. Note, however, that this function is implemented with option remember. After the first call it does not react to changes of DIGITS unless the input parameters are changed.

Examples

Example 1

We evaluate the empirical distribution function of the data -1, 0, 2.3, PI, 8 at various points:
f := stats::empiricalCDF(-1, 0, 2.3, PI, 8): f(-infinity), f(-3), f(2.4), f(PI), f(10), f(infinity)0, 0, 3/5, 4/5, 1, 1

$$0,\ 0,\ \frac{3}{5},\ \frac{4}{5},\ 1,\ 1$$

Alternatively, the data may be passed as a list:
f := stats::empiricalCDF([-1, 0, 2.3, PI, 8]): f(-infinity), f(-3), f(2.4), f(PI), f(10), f(infinity)0, 0, 3/5, 4/5, 1, 1

$$0,\ 0,\ \frac{3}{5},\ \frac{4}{5},\ 1,\ 1$$

delete f:

Example 2

We use a symbolic argument. In the symbolic return value, the input data appear as a sorted list:

stats::empiricalCDF(PI, -3, 25, PI, 4/3)(x)stats::empiricalCDF([-3, 4/3, PI, PI, 25])(x)

$$\text{stats::empiricalCDF}\left(\left[-3, \frac{4}{3}, \pi, \pi, 25\right]\right)(x)$$

Example 3

We create a sample consisting of one string column and two non-string columns:
s := stats::sample([["1996", 1242, PI - 1/2], ["1997", 1353, PI + 0.3], ["1998", 1142, PI + 0.5], ["1999", 1201, PI - 1], ["2001", 1201, PI]]) "1996" 1242 PI - 1/2 "1997" 1353 PI + 0.3 "1998" 1142 PI + 0.5 "1999" 1201 PI - 1 "2001" 1201 PI

We compute values of the empirical distributions of the data in the second and third column, respectively:
f2 := stats::empiricalCDF(s, 2): f2(1000), f2(1200), f2(1201)0, 1/5, 3/5

$$0, \frac{1}{5}, \frac{3}{5}$$

f3 := stats::empiricalCDF(s, 3): f3(0.7), f3(3), f3(PI), f3(4)0, 2/5, 3/5, 1

$$0, \frac{2}{5}, \frac{3}{5}, 1$$

delete s, f2, f3:

Parameters

x_1, x_2, ...

The statistical data: real numerical values

s

A sample of domain type stats::sample

c

A column index of the sample `s`: a positive integer. This column provides the data x_1, x_2 etc. There is no need to specify a column number `c` if the sample has only one non-string column.

Return Values procedure.

See Also stats::empiricalPFstats::empiricalQuantilestats::empiricalRandomstats::finiteCDFstats::finite

stats::empiricalPF

Purpose

Probability function of a finite data sample

Syntax

```
stats::empiricalPF(x1, x2,  )
stats::empiricalPF([x1, x2,  ])
stats::empiricalPF(n, <c>)
stats::empiricalPF(n, <[c]>)
```

Description

`stats::empiricalPF([x1, x2,  , xn])` returns a procedure representing the probability function

(x) -> piecewise([x = x[i], 1/n], [Otherwise, 0])

$$x \to \begin{cases} \frac{1}{n} & \text{if } x = x_i \\ 0 & \text{otherwise} \end{cases}$$

of the sample given by the data `x1, x2,  `.

The procedure `f := stats::empiricalPF([x1, x2,  ])` can be called in the form `f(x)` with an arithmetical expression `x` or sets of lists of such expressions.

If `x` is a numerical expression that is contained in the data `x1, x2,  `, then the corresponding probability value 1/n $\frac{1}{n}$ is returned (n is the size of the sample).

If `x` is a numerical expression that is not contained in the data `x1, x2,  `, then `0` is returned.

If `x` is a symbolic expression that cannot be converted to a real floating-point number, `f(x)` returns the symbolic call `stats::empiricalPF([x1, x2,  ])(x)` with the data `x1, x2,  ` in ascending order.

If `x` is a set, the sum of the probability values of its elements is returned.

If `x` is a list, it is treated like a set (i.e., duplicate entries in `x` are eliminated). The sum of the probability values of the elements in `x` is returned.

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values. Cf. “Example 4” on page 30-101.

`stats::empiricalPF` is generalized by stats::finitePF, which allows to specify different probabilities for the elements of the sample. The call `stats::empiricalPF([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalPF([x_1, , x_n])`.

Further, stats::finitePF does not only allow numerical values x_1, x_2, , but arbitrary MuPAD objects.

Examples

Example 1

We demonstrate the basic usage of this function:
f := stats::empiricalPF(1, 3, PI, 4.0): f(0), f(1), f(1.0), f(3), f(PI), f(float(PI)), f(4), f(4.0)0, 1/4, 0, 1/4, 1/4, 0, 0, 1/4

$$0, \frac{1}{4}, 0, \frac{1}{4}, \frac{1}{4}, 0, 0, \frac{1}{4}$$

Alternatively, the data may be passed as a list:
f := stats::empiricalPF(1, 3, PI, 4.0): f(0), f(1), f(1.0), f(3), f(PI), f(float(PI)), f(4), f(4.0)0, 1/4, 0, 1/4, 1/4, 0, 0, 1/4

$$0, \frac{1}{4}, 0, \frac{1}{4}, \frac{1}{4}, 0, 0, \frac{1}{4}$$

A symbolic value of the argument in `f` leads to a symbolic return value:
f(x)stats::empiricalPF([1, 3, PI, 4.0])(x)

$$\text{stats::empiricalPF}([1, 3, \pi, 4.0])(x)$$

Symbolic data are not accepted:
stats::empiricalPF(1, 3, x, 4.0): Error: Some data cannot be converted to floating-point numbers. [stats::empiricalPF] delete f:

Example 2

We create a sample of type stats::sample consisting of one string column and two non-string columns:
s := stats::sample([["1996", 1242, 2/5], ["1997", 1353, 0.1], ["1998", 1142, 0.2], ["1999", 1201, 0.2], ["2001", 1201, 0.1]]) "1996" 1242 2/5 "1997" 1353 0.1 "1998" 1142 0.2 "1999" 1201 0.2 "2001" 1201 0.1

We use the data in the first and third column:
f := stats::empiricalPF(s, 2): f(1242), f(1353), f(1200), f(1201)1/5, 1/5, 0, 2/5

$\frac{1}{5}, \frac{1}{5}, 0, \frac{2}{5}$

delete s, f:

Example 3

We consider a fair die:
f:= stats::empiricalPF([1, 2, 3, 4, 5, 6]):

What is the probabiliy that tossing the die produces a score more than or equal to 4?
f({4, 5, 6})1/2

$\frac{1}{2}$

delete f:

Example 4

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values:
f:= stats::empiricalPF([1, 2, 1, 1, 2]): f(1), f(2)3/5, 2/5

$\frac{3}{5}, \frac{2}{5}$

delete f:

Parameters

x_1, x_2, ...

The statistical data: real numerical values

s

A sample of domain type stats::sample

c

A column index of the sample s: a positive integer. This column provides the data x_1, x_2 etc. There is no need to specify a column number c if the sample has only one non-string column.

Return Values

procedure.

stats::empiricalCDFstats::empiricalQuantilestats::empiricalRandomstats::finiteCDFstats::fini

stats::empiricalQuantile

Purpose

Quantile function of the empirical distribution

Syntax

```
stats::empiricalQuantile(x1, x2,  )
stats::empiricalQuantile([x1, x2,  ])
stats::empiricalQuantile(s, c)
```

Description

`stats::empiricalQuantile(x1, x2,  )` returns a procedure representing the quantile function of the data `x1, x2` etc. It is the (discrete) inverse of the empirical cumulative distribution function `stats::empiricalCDF(x1, x2,  )`. For $0 \le x \le 1$, the `x`-quantile y = *stats*::*empiricalQuantile*(x_1, x_2, ...)(x) is the smallest of the data elements `x1, x2,` satisfying

stats::empiricalCDF(x_1, x_2, dots)(y)>=x

stats::empiricalCDF(x_1, x_2, ...)(y) ≥ x

All data `x1, x2,` must be convertible to real floating-point numbers. The data do not have to be sorted on input.

The procedure `f := stats::empiricalQuantile(x1, x2,  )` can be called in the form `f(x)` or `f(x, Averaged)` with an arithmetical expression `x`.

If x is a real number satisfying $0 \le x \le 1$, then `f(x)` returns one of the data elements; `f(x, Averaged)` uses interpolation of adjacent data elements:

The x-quantile of n sorted values $x_1 \le \ldots \le x_n$ is computed as follows.

- `f(x)` returns x_k with `k = ceil(n*x)`.
- `f(x, Averaged)` returns x_k with `k = ceil(n*x)` if nx is not an integer. Otherwise, it returns fenced(x[(k)]+x[(k+1)])/2 $\frac{(x_k + x_{k+1})}{2}$.

If `x` is a symbolic expression that cannot be converted to a real floating-point number, `f( x , <Averaged>)` returns the symbolic call

`stats::empiricalQuantile([x_1, x_2, ...])(x, <Averaged>)` with the data `x_1, x_2, ...` in ascending order.

Numerical values of x are only accepted if $0 \le x \le 1$.

$y = stats::empiricalQuantile(x_1, x_2, \ldots)(x)$ satisfies

stats::empiricalCDF(x_1, x_2, dots)(z) <x<=stats::empiricalCDF(x_1, x_2, dots)(y)

$$\text{stats::empiricalCDF}(x_1, x_2, \ldots)(z) < x \le \text{stats::empiricalCDF}(x_1, x_2, \ldots)(y)$$

for all data elements z in the sample satisfying $z < y$.

For a sample of size n, the call `f := stats::empiricalQuantile(x_1, x_2, ...)` needs a run time of $O(nln(n))$ due to internal sorting of the data. The costs of a call to `f` are essentially dependent of n. If several evaluations of the quantile function are needed, a calling sequence such as

```
f := stats::empiricalQuantile(x_1, x_2, ...); f(a_1); f(a_2); dots
```

is more efficient than

```
stats::empiricalQuantile(x_1, x_2, ...)(a_1);
```

```
stats::empiricalQuantile(x_1, x_2, ...)(a_2);
```

```
dots
```

The (1)/(2) $\frac{1}{2}$-quantile is called “median”. The function stats::median implements this special quantile.

`stats::empiricalQuantile` is generalized by stats::finiteQuantile, which allows to specify different probabilities for the elements of the sample. The call `stats::empiricalQuantile([x_1, ..., x_n])` corresponds to `stats::finiteQuantile([x_1, dots, x_n], [1/n, dots, 1/n])`.

Further, stats::finiteQuantile does not only allow numerical values `x_1, x_2, ...`, but arbitrary MuPAD objects.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. Note, however, that this function is implemented with option remember. After the first call it does not react to changes of DIGITS unless the input parameters are changed.

Examples

Example 1

We compute various quantiles of the data `-1, 0, 0, 2.3, PI, PI, 8`:
f := stats::empiricalQuantile(-1, 0, 0, 2.3, PI, PI, 8): f(0), f(0.1), f(3/10), f(0.5), f(1/sqrt(2)), f(99/100), f(1)-1, -1, 0, 2.3, PI, 8, 8

$$-1,\ -1,\ 0,\ 2.3,\ \pi,\ 8,\ 8$$

Alternatively, the data may be passed as a list:
f := stats::empiricalQuantile([-1, 0, 2.3, PI, 8]): f(0), f(0.1), f(3/10), f(0.5), f(1/sqrt(2)), f(99/100), f(1)-1, -1, 0, 2.3, PI, 8, 8

$$-1,\ -1,\ 0,\ 2.3,\ \pi,\ 8,\ 8$$

delete f:

Example 2

We use a symbolic argument. In the symbolic return value, the input data appear as a sorted list:
f := stats::empiricalQuantile(3, 25, PI, 4/3):
f(x)stats::empiricalQuantile([4/3, 3, PI, 25])(x)

$$\text{stats::empiricalQuantile}\left(\left[\frac{4}{3},\ 3,\ \pi,\ 25\right]\right)(x)$$

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)3

$$3$$

f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f:

Example 3

We create a sample of type stats::sample consisting of one string column and two non-string columns:
s := stats::sample([["1996", 1242, PI - 1/2], ["1997", 1353, PI + 0.3], ["1998", 1142, PI + 0.5], ["1999", 1201, PI - 1/3], ["2001", 1201, PI + 0.5]])
"1996" 1242 PI - 1/2 "1997" 1353 PI + 0.3 "1998" 1142 PI + 0.5 "1999" 1201 PI - 1/3 "2001" 1201 PI + 0.5

We compute quantile values of the data in the second and third column, respectively:
f2 := stats::empiricalQuantile(s, 2): f2(0.1), f2(1/4), f2(0.7), f2(99/100)1142, 1201, 1242, 1353

1142, 1201, 1242, 1353

f3 := stats::empiricalQuantile(s, 3): f3(0.1), f3(1/4), f3(0.7), f3(99/100)PI - 1/2, PI - 1/3, PI + 0.5, PI + 0.5

$\pi - \frac{1}{2}, \pi - \frac{1}{3}, \pi + 0.5, \pi + 0.5$

delete s, f2, f3:

Parameters

x_1, x_2, ...

The statistical data: real numerical values

s

A sample of domain type stats::sample

c

A column index of the sample s: a positive integer. This column provides the data x_1, x_2 etc. There is no need to specify a column number c if the sample has only one non-string column.

Return Values

procedure.

See Also stats::empiricalCDFstats::empiricalPFstats::empiricalRandomstats::finiteCDFstats::finite

stats::empiricalRandom

Purpose

Generate a random generator for uniformly distributed elements of a data sample

Syntax

```
stats::empiricalRandom(x1, x2,  , <Seed = n>)
stats::empiricalRandom([x1, x2,  ], <Seed = n>)
stats::empiricalRandom(n, <c>, <Seed = n>)
stats::empiricalRandom(n, <[c]>, <Seed = n>)
```

Description

`stats::empiricalRandom([x1, x2,  , xn])` returns a procedure that picks out random elements from the data `x1, x2` etc.

All data `x1, x2,` must be convertible to real floating-point numbers.

The procedure `f := stats::empiricalRandom([x1, x2,  ])` can be called in the form `f()`. The call `f()` returns one of the data elements `x1, x2,  .`

The values produced by `f()` are distributed randomly. Each element of the sample is chosen with the same probability.

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::empiricalRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random elements via

```
f := stats::empiricalRandom([x1, x2,  ]):
f() $k = 1..K;
```

rather than by

```
stats::empiricalRandom([x_1, x_2, dots])() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::empiricalRandom([x_1, x_2, dots], Seed = s)() $k =
1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

`stats::empiricalRandom` is generalized by stats::finiteRandom, which allows to specify different probabilities for the elements of the sample. The call `stats::empiricalRandom([x_1, dots, x_n])` corresponds to `stats::finiteRandom([x_1, dots, x_n], [1/n, dots, 1/n])`.

Further, stats::finiteRandom does not only allow numerical values x_1, x_2, , but arbitrary MuPAD objects.

Examples

Example 1

We pick out random elements of some data:
f := stats::empiricalRandom(1, 7, 4, PI, Seed = 234): f(), f(), f(), f(), f(), f(), f(), f(), f()1, 1, PI, 7, 7, PI, PI, 7, 7

1, 1, π, 7, 7, π, π, 7, 7

Alternatively, the data may be passed as a list:
f := stats::empiricalRandom([1, 7, 4, PI], Seed = 234): f(), f(), f(), f(), f(), f(), f(), f(), f()1, 1, PI, 7, 7, PI, PI, 7, 7

1, 1, π, 7, 7, π, π, 7, 7

Symbolic data are not accepted:
stats::empiricalRandom(1, 7, 4, x): Error: Some data cannot be converted to floating-point numbers. [stats::empiricalRandom] delete f:

Example 2

We create a sample of type stats::sample consisting of one string column and two non-string columns:
s := stats::sample([["1996", 1242, 2/5], ["1997", 1353, 0.1], ["1998", 1142, 0.2], ["1999", 1201, 0.2], ["2001", 1201, 0.1]]) "1996" 1242 2/5 "1997" 1353 0.1 "1998" 1142 0.2 "1999" 1201 0.2 "2001" 1201 0.1

We pick random values using the data in the second and third column, respectively:
f := stats::empiricalRandom(s, 2, Seed = 12345): f(), f(), f(), f(), f(), f(), f()1353, 1142, 1142, 1201, 1142, 1142, 1353

1353, 1142, 1142, 1201, 1142, 1142, 1353

f := stats::empiricalRandom(s, 3, Seed = 12345): f(), f(), f(), f(), f(), f(), f()2/5, 0.1, 0.1, 0.1, 0.1, 0.1, 2/5

$\frac{2}{5}$, 0.1, 0.1, 0.1, 0.1, 0.1, $\frac{2}{5}$

delete s, f:

Example 3

We toss a fair die:
f:= stats::empiricalRandom([1, 2, 3, 4, 5, 6], Seed = 12345): f(), f(), f(), f(), f(), f(), f(), f(), f(), f()5, 1, 2, 3, 1, 1, 6, 3, 1, 2

5, 1, 2, 3, 1, 1, 6, 3, 1, 2

We toss the die 6000 times and count the frequencies of the scores 1 through 6:
t := [f() $ k = 1..6000]: i = nops(select(t, _equal, i)) $ i = 1..61 = 982, 2 = 1006, 3 = 911, 4 = 1037, 5 = 1021, 6 = 1043

1 = 982, 2 = 1006, 3 = 911, 4 = 1037, 5 = 1021, 6 = 1043

The routine stats::finiteRandom allows to model a loaded die:

```
f:= stats::finiteRandom( [[1, 0.1], [2, 0.1], [3, 0.1], [4, 0.1], [5, 0.1], [6,
0.5]], Seed = 12345): t := [f() $ k = 1..6000]: i = nops(select(t, _equal, i)) $
i = 1..61 = 572, 2 = 611, 3 = 614, 4 = 548, 5 = 554, 6 = 3101
```

```
1 = 572, 2 = 611, 3 = 614, 4 = 548, 5 = 554, 6 = 3101
```

```
delete f, t:
```

Parameters

x_1, x_2, ...

The statistical data: real numerical values

s

A sample of domain type stats::sample

c

A column index of the sample `s`: a positive integer. This column provides the data x_1, x_2 etc. There is no need to specify a column number `c` if the sample has only one non-string column.

Options

Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random values. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of values.

Return Values

procedure.

stats::empiricalCDFstats::empiricalPFstats::empiricalQuantilestats::finiteCDFstats::finit

stats::equiprobableCells

Purpose

Divide the real line into equiprobable intervals

Syntax

```
stats::equiprobableCells(k, q, <NoWarning>)
```

Description

`stats::equiprobableCells` is a utility function for the classical chi-square test implemented by stats::csGOFT. The call `stats::equiprobableCells(k, q)` creates a list of intervals ("cells") that are equiprobable with respect to the statistical distribution corresponding to the quantile function `q`.

The chi-square goodness-of-fit test needs a cell partitioning of the real line to compare the empirical frequencies of data falling into the cells with the expected frequencies corresponding to a hypothesized statistical distribution. It is recommended to use equiprobable cells in this test. `stats::equiprobableCells` is a utility function to compute such a partitioning.

The cell boundaries b_i of the returned cell partitioning $[[b_0, b_1], \ldots, [b_{k-1}, b_k]]$ are computed via b[i]=float(q(float(i/k))) $b_i = \mathrm{float}(q(\mathrm{float}(\frac{i}{k})))$. Mathematically, each cell $[b_{i-1}, b_i]$ corresponds to a semi-open interval Interval(b[i-1], [b[i]]) $(b_{i-1}, b_i]$.

If `q` is the quantile function of a *continuous* statistical distribution, all cells have the same cell probability Pr(b[i-1]<x<=b[i])=1/k $\Pr(b_{i-1} < x \le b_i) = \frac{1}{k}$.

The function `q` can be a quantile procedure provided by the MuPAD `stats`-library.

Quantile functions not provided by the `stats`-package can be implemented easily by the user. A user defined quantile procedure q can correspond to any statistical distribution. Quantile functions must accept one numerical floating-point parameter x satisfying $0.0 \le x \le 1.0$. The call `q(x)` must produce a real value. In particular, the return values `q(0.0)` = -infinity and `q(1.0)` = infinity are allowed.

Quantile functions must be monotonically increasing. `stats::equiprobableCells` issues warnings if the computed

quantile values b[i]=float(q(float(i/k))) $b_i = \mathrm{float}(q(\mathrm{float}(\frac{i}{k})))$ are not real or _outputSequence(Symbol::pm, infinity) $\pm\infty$, or if these values do not increase monotonically.

`stats::equiprobableCells` also accepts quantile functions of *discrete* distributions such as `stats::empiricalQuantile(data)` or `stats::binomialQuantile(n, p)`.

Note Note, however, that in general, there are no equiprobable cell partitionings for discrete distributions. Consequently, equiprobability of the cells returned by `stats::equiprobableCells` is not guaranteed if q is not a continuous function.

In particular, it may happen for large k, that q((i-1)/k) $q(\frac{i-1}{k})$ coincides with q(i/k) $q(\frac{i}{k})$, i.e., the corresponding cell is empty. This will always happen, when k exceeds the number of possible discrete values the random variable can attain.

In such a case, a warning is issued. Passing such a cell partitioning to stats::csGOFT raises an error.

Further to the examples on this help page, see also the examples on the help page of stats::csGOFT.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We divide the real line into 4 intervals that are equiprobable with respect to the standard normal distribution:

```
k:= 4: q := stats::normalQuantile(0, 1): cells :=
stats::equiprobableCells(k, q)[[-infinity, -0.6744897502],
[-0.6744897502, 0.0], [0.0, 0.6744897502], [0.6744897502, infinity]]
```

[[−∞, −0.6744897502], [−0.6744897502, 0.0], [0.0, 0.6744897502], [0.6744897502, ∞]]

We check equiprobability by applying the function `stats::normalCDF(0, 1)` to the cell boundaries:
cdf := stats::normalCDF(0, 1): p := map(cells, map, cdf)[[0, 0.25], [0.25, 0.5], [0.5, 0.75], [0.75, 1]]

[[0, 0.25], [0.25, 0.5], [0.5, 0.75], [0.75, 1]]

The cell probabilities are given by the differences of the CDF function applied to the cell boundaries:
(p[i][2] - p[i][1]) $ i = 1..k0.25, 0.25, 0.25, 0.25

0.25, 0.25, 0.25, 0.25

We use these cells for a chi-square test for normality of some random data:
r := stats::normalRandom(0, 1, Seed = 0): data := [r() $ i = 1..1000]: stats::csGOFT(data, cells, CDF = cdf)[PValue = 0.8398775533, StatValue = 0.84, MinimalExpectedCellFrequency = 250.0]

[PValue = 0.8398775533, StatValue = 0.84, MinimalExpectedCellFrequency = 250.0]

With the observed significance level _outputSequence(0.839, dots)0.839..., the data pass this test well. We experiment with other equiprobable cell partitionings:
for k in [20, 30, 40, 50] do cells := stats::equiprobableCells(k, q); print(stats::csGOFT(data, cells, CDF = cdf)); end_for:[PValue = 0.1798122173, StatValue = 24.44, MinimalExpectedCellFrequency = 50.0]

[PValue = 0.1798122173, StatValue = 24.44, MinimalExpectedCellFrequency = 50.0]
[PValue = 0.713000696, StatValue = 24.32, MinimalExpectedCellFrequency = 33.33333333]

[PValue = 0.713000696, StatValue = 24.32, MinimalExpectedCellFrequency = 33.33333333]
[PValue = 0.7039429342, StatValue = 33.84,
MinimalExpectedCellFrequency = 25.0]

[PValue = 0.7039429342, StatValue = 33.84, MinimalExpectedCellFrequency = 25.0]
[PValue = 0.932574698, StatValue = 35.1,
MinimalExpectedCellFrequency = 20.0]

[PValue = 0.932574698, StatValue = 35.1, MinimalExpectedCellFrequency = 20.0]
delete k, cells, p, cdf, r, data:

Example 2

We create a sample of 1000 random integers between 0 and 100:
SEED := 10^2: r := random(0 .. 100): data := [r() $ i = 1..1000]:

We construct an 'equiprobable' cell partitioning of 10 cells using the (discrete) empirical distribution of the data. I.e., each of the following cells should contain approximately the same number of data from the random sample:
k := 10: quantile := stats::empiricalQuantile(data): cells := stats::equiprobableCells(k, quantile)[[0.0, 9.0], [9.0, 19.0], [19.0, 31.0], [31.0, 38.0], [38.0, 49.0], [49.0, 59.0], [59.0, 69.0], [69.0, 78.0], [78.0, 91.0], [91.0, 100.0]]

[[0.0, 9.0], [9.0, 19.0], [19.0, 31.0], [31.0, 38.0], [38.0, 49.0], [49.0, 59.0], [59.0, 69.0], [69.0, 78.0

For discrete distributions, 'equiprobability' can only be achieved approximately. We compute the cell probabilities with respect to the empirical cumulative distribution function (CDF), by subtracting the CDF value of the left boundary from the CDF value of the right boundary:
cdf := stats::empiricalCDF(data): map(cells, cell -> cdf(cell[2]) - cdf(cell[1]))[12/125, 99/1000, 14/125, 89/1000, 51/500, 103/1000, 103/1000, 23/250, 21/200, 93/1000]

$$\left[\frac{12}{125}, \frac{99}{1000}, \frac{14}{125}, \frac{89}{1000}, \frac{51}{500}, \frac{103}{1000}, \frac{103}{1000}, \frac{23}{250}, \frac{21}{200}, \frac{93}{1000}\right]$$

The actual empirical frequency of the data in each cell is the cell probability times the sample size (1000):
map(cells, cell -> 1000*(cdf(cell[2]) - cdf(cell[1])))[96, 99, 112, 89, 102, 103, 103, 92, 105, 93]

[96, 99, 112, 89, 102, 103, 103, 92, 105, 93]

When computing the probability of the cell `[b[i-1], b[i]]` via $cdf(b_i)$ - $cdf(b_{i-1})$, the cell is regarded as the semiopen interval Interval(b[i - 1], [b[i]])$(b_{i-1}, b_i]$ mathematically. For this reason, the data points `0` contained in the sample are not counted, and the cell frequencies do not quite add up to the sample size:
_plus(op(%))994

994

For the Symbol::chi^2 test, this does not matter because it replaces the left boundary of the first cell by -infinity, anyway. With an observed significance level of _outputSequence(0.161, dots)0.161..., the data pass the test for a uniform distribution at levels as high as _outputSequence(0.161, dots)0.161...:
stats::csGOFT(data, cells, CDF = stats::uniformCDF(0, 100))[PValue = 0.1619543558, StatValue = 13.01443112, MinimalExpectedCellFrequency = 70.0]

[PValue = 0.1619543558, StatValue = 13.01443112, MinimalExpectedCellFrequency = 70.0]

We test whether the data fit a normal distribution with the empirical mean and variance:
[m, v] := [stats::mean(data), stats::variance(data)]; stats::csGOFT(data, cells, CDF = stats::normalCDF(m, v))[9863/200, 1221413/1480]

$$\left[\frac{9863}{200}, \frac{1221413}{1480}\right]$$

[PValue = 0.00000000207226197, StatValue = 59.0175707, MinimalExpectedCellFrequency = 65.3983756]

[PValue = 0.00000000207226197, StatValue = 59.0175707, MinimalExpectedCellFrequency = 65.39

With the observed significance level _outputSequence(0.00000000207, dots)0.00000000207..., the hypothesis of a normal distribution clearly has to be rejected.
delete r, data, k, quantile, cells, cdf, m, v:

Example 3

We consider a binomial distribution with 'trial parameter' n = 100 and 'probability parameter' p=1/2$p = \frac{1}{2}$. It is the distribution of the number of successes in n = 100 independent Bernoulli experiments, each with success probability p=1/2$p = \frac{1}{2}$. This random variable can attain the discrete values 0, 1, ..., 100. We create a cell partitioning of 4 cells:
n := 100: p := 1/2: quantile := stats::binomialQuantile(n, p): cells := stats::equiprobableCells(4, quantile)[[0.0, 47.0], [47.0, 50.0], [50.0, 53.0], [53.0, 100.0]]

[[0.0, 47.0], [47.0, 50.0], [50.0, 53.0], [53.0, 100.0]]

Because of discreteness, an exact equiprobable cell partitioning does not exist. We compute the expected cell frequencies in the same way as in the previous example:
cdf := stats::binomialCDF(n, p): map(cells, cell -> n*(cdf(cell[2]) - cdf(cell[1])))[30.86497068, 23.11449119, 21.81461745, 24.20592068]

[30.86497068, 23.11449119, 21.81461745, 24.20592068]

We create a random sample and apply the Symbol::chi^2 test:
r := stats::binomialRandom(n, p, Seed = 123): data := [r() $ i = 1..100]: stats::csGOFT(data, cells, CDF = cdf)[PValue = 0.3394635837,

StatValue = 3.359377148, MinimalExpectedCellFrequency = 21.81461745]

[PValue = 0.3394635837, StatValue = 3.359377148, MinimalExpectedCellFrequency = 21.81461745]

The observed significance level _outputSequence(0.339, dots)0.339... is not small, i.e., the data pass the test well.

The 'trial parameter' $n = 100$ is large enough for the binomial distribution to be approximated by a normal distribution with mean np and variance $np(1 - p)$. The data pass the test for a normal distribution, too:
cdf := stats::normalCDF(n*p, n*p*(1 - p)): stats::csGOFT(data, cells, CDF = cdf)[PValue = 0.1547938521, StatValue = 5.243756673, MinimalExpectedCellFrequency = 22.57468822]

[PValue = 0.1547938521, StatValue = 5.243756673, MinimalExpectedCellFrequency = 22.57468822]

We repeat the test with another cell partitioning:
quantile := stats::normalQuantile(n*p, n*p*(1 - p)): cells := stats::equiprobableCells(4, quantile)[[-infinity, 46.62755125], [46.62755125, 50.0], [50.0, 53.37244875], [53.37244875, infinity]]

[[−∞, 46.62755125], [46.62755125, 50.0], [50.0, 53.37244875], [53.37244875, ∞]]
stats::csGOFT(data, cells, CDF = cdf)[PValue = 0.1422716505, StatValue = 5.44, MinimalExpectedCellFrequency = 25.0]

[PValue = 0.1422716505, StatValue = 5.44, MinimalExpectedCellFrequency = 25.0]
delete k, quantile, cells, cdf, r, data:

Example 4

We demonstrate user-defined quantile functions. We consider the following distribution of a random variable X supported on the interval [0, 1]:

Pr(X<=x)=piecewise([x<0, 0], [0<=x<=1, x^2], [x>1, 1])

$$\Pr(X \le x) = \begin{cases} 0 & \text{if } x < 0 \\ x^2 & \text{if } 0 \le x \le 1 \\ 1 & \text{if } x > 1 \end{cases}$$

The quantile function q is given by q(x)=sqrt(x)$q(x) = \sqrt{x}$ for $0 \le x \le 1$:
quantile := x -> sqrt(x):

We test the hypothesis that the following data are distributed as defined above.
cells := stats::equiprobableCells(6, quantile)[[0.0, 0.4082482905], [0.4082482905, 0.5773502692], [0.5773502692, 0.7071067812], [0.7071067812, 0.8164965809], [0.8164965809, 0.9128709292], [0.9128709292, 1.0]]

[[0.0, 0.4082482905], [0.4082482905, 0.5773502692], [0.5773502692, 0.7071067812], [0.7071
[0.8164965809, 0.9128709292], [0.9128709292, 1.0]]

data := [sqrt(frandom()) $ i = 1..10^3]: cdf := proc(x) begin if x <= 0 then return(0) elif x <= 1 then return(x^2) else return(1) end_if end_proc:
stats::csGOFT(data, cells, CDF = cdf)[PValue = 0.2230310886, StatValue = 6.968, MinimalExpectedCellFrequency = 166.6666667]

[PValue = 0.2230310886, StatValue = 6.968, MinimalExpectedCellFrequency = 166.6666667]

The data pass the test well. In fact, for a uniform deviate Y on the interval [0, 1] (as produced by frandom), the cumulative distribution function of sqrt(Y)$\sqrt{Y}$ is indeed given by *cdf*.
delete quantile, cells, data, cdf:

Parameters

k

The number of cells: a positive integer

q

A procedure representing a quantile function of a statistical distribution. Typically, q is one of the quantile functions of

the stats-package such as `stats::normalQuantile(m, v)`, `stats::empiricalQuantile(data)` etc. Alternatively, user defined procedures may be passed if the `stats`-package does not provide a suitable quantile function.

Options

NoWarning

`stats::equiprobableCells` issues warnings if the computed cell partitioning is not suitable for stats::csGOFT. These warnings may be switched off with this option.

Return Values

List of *k* "cells"

[[b[0], b[1]], [b[1], b[2]], Symbol::hellip, [b[(k-1)], b[k]]]

$[[b_0, b_1], [b_1, b_2], \ldots, [b_{k-1}, b_k]]$

with floating-point values b[i]=q(i/k), i=0, Symbol::hellip, k $b_i = q(\frac{i}{k}),\ i = 0, \ldots, k$. This 'cell partitioning' is suitable as input parameter for stats::csGOFT.

See Also

stats::csGOFT

stats::erlangCDF

Purpose

Cumulative distribution function of the Erlang distribution

Syntax

```
stats::erlangCDF(a, b)
```

Description

`stats::erlangCDF(a, b)` returns a procedure representing the cumulative distribution function

x->piecewise([x>0, b^a/gamma(a)*int(t^(a-1)*exp(-t*b), t=0..x)], [x<=0, 0])

$$x \to \begin{cases} \frac{b^a}{\Gamma(a)} \int_0^x t^{a-1} e^{-t\,b}\, d\,t & \text{if } x > 0 \\ 0 & \text{if } x \le 0 \end{cases}$$

of the Erlang distribution with shape parameter $a > 0$ and scale parameter $b > 0$.

The procedure `f := stats::erlangCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \le 0$ can be decided, then `f(x)` returns 0. If $x \ge 0$ can be decided, then `f(x)` returns the value 1 - igamma(a, x*b)/gamma(a) $1 - \frac{\Gamma(a,\, x\,b)}{\Gamma(a)}$.

If x is a floating-point number and both a and b can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \le 0$ or $x \ge 0$, the corresponding values are returned.

The call `f(- infinity )` returns 0.

The call `f( infinity )` returns 1.

`f(x)` returns the symbolic call `stats::erlangCDF(a, b)(x)` if neither $x \le 0$ nor $x \ge 0$ can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

Note that, for large a, exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments `x` to `f` rather than to compute exact results `f(x)` and convert them via float. Cf. “Example 4” on page 30-123.

Note that stats::erlangCDF(a, b) = stats::gammaCDF(a, 1/b)$\text{stats::erlangCDF}(a, b) = \text{stats::gammaCDF}(a, \frac{1}{b})$.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure generated by `stats::erlangCDF` reacts to properties of identifiers set via assume.

Examples

Example 1

We evaluate the cumulative probability function with $a = 2$ and $b = 1$ at various points:
f := stats::erlangCDF(2, 1): f(-infinity), f(-3), f(0.5), f(2/3), f(PI), f(infinity)0, 0, 0.09020401043, 1 - (5*exp(-2/3))/3, 1 - exp(-PI)*(PI + 1), 1

$$0,\ 0,\ 0.09020401043,\ 1 - \frac{5\,e^{-\frac{2}{3}}}{3},\ 1 - e^{-\pi}\,(\pi + 1),\ 1$$

delete f:

Example 2

If `x` is a symbolic object without properties, then it cannot be decided whether $x \geq 0$ holds. A symbolic function call is returned:
f := stats::erlangCDF(a, b): f(x)stats::erlangCDF(a, b)(x)

$$\text{stats::erlangCDF}(a, b)(x)$$

With suitable properties, it can be decided whether $x \geq 0$ holds. An explicit expression is returned:
assume(0 <= x): f(x)1 - igamma(a, b*x)/gamma(a)

$$1 - \frac{\Gamma(a, b\,x)}{\Gamma(a)}$$

unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::erlangCDF(a, b): f(3), f(3.0)1 - igamma(a, 3*b)/gamma(a), 1.0 - (1.0*igamma(a, 3.0*b))/gamma(a)

$$1 - \frac{\Gamma(a, 3\,b)}{\Gamma(a)},\ 1.0 - \frac{1.0\,\Gamma(a, 3.0\,b)}{\Gamma(a)}$$

When numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
a := 2: b := 4: f(3), f(3.0)1 - 13*exp(-12), 0.9999201252

$$1 - 13\,e^{-12},\ 0.9999201252$$

delete f, a, b:

Example 4

We consider an Erlang distribution with large shape parameter:
f := stats::erlangCDF(2000, 2):

For floating-point approximations, one should not compute an exact result and convert it via float. For large shape parameter, it is faster to pass a floating-point argument to `f`. The following call takes some time, because an exact computation of the huge integer gamma(2000) = 1999!$\Gamma(2000) = 1999!$ is involved:
float(f(1010))0.6747900654

$$0.6747900654$$

The following call is much faster:
f(float(1010))0.6747900654

```
0.6747900654
delete f:
```

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

gammaigammastats::erlangPDFstats::erlangQuantilestats::erlangRandomstats::gammaCDFs

stats::erlangPDF

Purpose

Probability density function of the Erlang distribution

Syntax

```
stats::erlangPDF(a, b)
```

Description

`stats::erlangPDF(a, b)` returns a procedure representing the probability density function

x->piecewise([x>0, b^a/gamma(a)*x^(a-1)*exp(-x*b)], [x<=0, 0])

$$x \to \begin{cases} \frac{b^a}{\Gamma(a)}\, x^{a-1}\, e^{-x\,b} & \text{if } x > 0 \\ 0 & \text{if } x \le 0 \end{cases}$$

of the Erlang distribution with shape parameter $a > 0$ and scale parameter $b > 0$.

The procedure `f := stats::erlangPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \le 0$ can be decided, then `f(x)` returns 0. If $x > 0$ can be decided, then `f(x)` returns the value x^(a-1)*b^a*exp^(-x*b)/gamma(a) $\frac{x^{a-1}\, b^a}{\exp^{b\,x}\, \Gamma(a)}$.

If x is a floating-point number and both a and b can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \le 0$ or $x > 0$, the corresponding values are returned.

`f(- infinity )` and `f( infinity )` return 0.

`f(x)` returns the symbolic call `stats::erlangPDF(a, b)(x)` if neither $x \le 0$ nor $x > 0$ can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

Note that, for large a, exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments `x` to `f` rather than to compute exact results `f(x)` and convert them via float. Cf. “Example 4” on page 30-127.

Note that stats::erlangPDF(a, b) = stats::gammaPDF(a, 1/b)$\text{stats::erlangPDF}(a,\ b) = \text{stats::gammaPDF}(a,\ \frac{1}{b})$.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure generated by `stats::erlangPDF` reacts to properties of identifiers set via assume.

Examples

Example 1

We evaluate the probability density function with $a = 2$ and $b = 1$ at various points:
f := stats::erlangPDF(2, 1): f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)0, 0, exp(-1/2)/2, 0.3032653299, PI*exp(-PI), 0

$$0,\ 0,\ \frac{e^{-\frac{1}{2}}}{2},\ 0.3032653299,\ \pi\, e^{-\pi},\ 0$$

delete f:

Example 2

If `x` is a symbolic object without properties, then it cannot be decided whether $x > 0$ holds. A symbolic function call is returned:
f := stats::erlangPDF(a, b): f(x)stats::erlangPDF(a, b)(x)

$$\text{stats::erlangPDF}(a,\ b)(x)$$

With suitable properties, it can be decided whether $x > 0$ holds. An explicit expression is returned:
assume(0 < x): f(x)(b^a*x^(a - 1)*exp(-b*x))/gamma(a)

$$\frac{b^a\, x^{a-1}\, e^{-b\,x}}{\Gamma(a)}$$

unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::erlangPDF(a, b): f(x), f(3)stats::erlangPDF(a, b)(x), (3^(a - 1)*b^a*exp(-3*b))/gamma(a)

$$\text{stats::erlangPDF}(a,\ b)(x),\ \frac{3^{a-1}\, b^a\, e^{-3\,b}}{\Gamma(a)}$$

When numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
a := 2: b := 1: f(3), f(3.0)3*exp(-3), 0.1493612051

$$3\, e^{-3},\ 0.1493612051$$

delete f, a, b:

Example 4

We consider an Erlang distribution with large shape parameter:
f := stats::erlangPDF(2000, 1):

For floating-point approximations, one should not compute an exact result and convert it via float. For large shape parameter, it is faster to pass a floating-point argument to `f`. The following call takes some time, because an exact computation of the huge integer gamma(2000) = 1999!$\Gamma(2000) = 1999!$ is involved:
float(f(2010))0.008657442277

$$0.008657442277$$

The following call is much faster:
f(float(2010))0.008657442277

```
0.008657442277
```

delete f:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

gammastats::erlangCDFstats::erlangQuantilestats::erlangRandomstats::gammaCDFstats::ga

stats::erlangQuantile

Purpose

Quantile function of the Erlang distribution

Syntax

```
stats::erlangQuantile(a, b)
```

Description

`stats::erlangQuantile(a, b)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::erlangCDF(a, b)`. For $0 \le x \le 1$, the solution of *stats*::*erlangCDF*(*a*, *b*)(*y*) = *x* is given by

y=stats::erlangQuantile(a, b)(x)

$y = \text{stats::erlangQuantile}(a, b)(x)$

The procedure `f := stats::erlangQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, *infinity*, or a symbolic expression:

If `x` is a real number between 0 and 1 and `a` and `b` can be converted to positive floating-point numbers, then `f(x)` returns a positive floating-point number approximating the solution *y* of `stats::erlangCDF(a, b)(y) = x`.

The calls `f(0)` and `f(0.0)` produce `0.0` for all values of `a` and `b`.

The calls `f(1)` and `f(1.0)` produce *infinity* for all values of `a` and `b`.

In all other cases, `f(x)` returns the symbolic call `stats::erlangQuantile(a, b)(x)`.

Numerical values of *x* are only accepted if $0 \le x \le 1$.

Numerical values of `a` and `b` are only accepted if they are real and positive.

Note that stats::erlangQuantile(a, b) = stats::gammaQuantile(a, 1/b)$\text{stats::erlangQuantile}(a, b) = \text{stats::gammaQuantile}(a, \frac{1}{b})$.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with $a = \pi$ and $b = 11$ at various points:
f := stats::erlangQuantile(PI, 1/11): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)0.0, 13.08489993, 30.96813726, 324.7230043, infinity

0.0, 13.08489993, 30.96813726, 324.7230043, ∞

The value `f(x)` satisfies `stats::erlangCDF(PI, 1/11)(f(x)) = x`:
stats::erlangCDF(PI, 1/11)(f(0.987654))0.987654

0.987654

delete f:

Example 2

We use symbolic arguments:
f := stats::erlangQuantile(a, b): f(x), f(9/10)stats::erlangQuantile(a, b)(x), stats::erlangQuantile(a, b)(9/10)

$\text{stats::erlangQuantile}(a, b)(x)$, $\text{stats::erlangQuantile}(a, b)\left(\frac{9}{10}\right)$

When positive real values are assigned to `a` and `b`, the function `f` starts to produce floating-point values:
a := 17: b := 1/6: f(0.999), f(1 - sqrt(2)/10^5)195.7416524, 240.0294477

195.7416524, 240.0294477

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)100.0071221

100.0071221

f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, a, b:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::erlangCDFstats::erlangPDFstats::erlangRandomstats::gammaCDFstats::gammaPD

stats::erlangRandom

Purpose

Generate a random number generator for Erlang deviates

Syntax

```
stats::erlangRandom(a, b, <Seed = n>)
```

Description

`stats::erlangRandom(a, b)` returns a procedure that produces Erlang deviates (random numbers) with shape parameter $a > 0$ and scale parameter $b > 0$.

The procedure `f := stats::erlangRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` and `b` can be converted to positive floating-point numbers, then `f()` returns a nonnegative floating-point number.

In all other cases, `stats::erlangRandom(a, b)()` is returned symbolically.

Numerical values of `a` and `b` are only accepted if they are real and positive.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the Erlang distribution with parameters a and b. For any $0 \le x$, the probability that $X \le x$ is given by

```
b^(a)/gamma(a)*int(t^(a-1)*exp(-t*b), t=0..x)
```

$$\frac{b^a}{\Gamma(a)} \int_0^x t^{a-1} e^{-t\,b}\, d\,t$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::erlangRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::erlangRandom(a, b):  f() $k = 1..K;
```

rather than by

```
stats::erlangRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::erlangRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Note that `stats::erlangRandom(a, b)` = `stats::gammaRandom(a, 1/b)`.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate Erlang deviates with parameters a = 2 and b=3/4 $b = \frac{3}{4}$:
f := stats::erlangRandom(2, 3/4): f() $ k = 1..43.958784095, 3.891811185, 6.046842446, 3.142485711

```
3.958784095, 3.891811185, 6.046842446, 3.142485711
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::erlangRandom(a, b): f()stats::erlangRandom(a, b)()

stats::erlangRandom(*a*, *b*)()

When positive real numbers are assigned to `a` and `b`, the function `f` starts to produce random floating point numbers:
a := PI: b := 1/8: f() $ k = 1..419.74371462, 12.37357049, 13.40137346, 29.97534861

19.74371462, 12.37357049, 13.40137346, 29.97534861
delete f, a, b:

Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:
f := stats::erlangRandom(PI, 3, Seed = 1): f() $ k = 1..40.125771079, 1.179788536, 0.7213738523, 1.268143263

0.125771079, 1.179788536, 0.7213738523, 1.268143263
g := stats::erlangRandom(PI, 3, Seed = 1): g() $ k = 1..40.125771079, 1.179788536, 0.7213738523, 1.268143263

0.125771079, 1.179788536, 0.7213738523, 1.268143263
f() = g(), f() = g()1.926015116 = 1.926015116, 1.1178812 = 1.1178812

1.926015116 = 1.926015116, 1.1178812 = 1.1178812
delete f, g:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

See Also

stats::erlangCDFstats::erlangPDFstats::erlangQuantilestats::gammaCDFstats::gammaPI

stats::exponentialCDF

Purpose

Cumulative distribution function of the exponential distribution

Syntax

```
stats::exponentialCDF(a, b)
```

Description

`stats::exponentialCDF(a, b)` returns a procedure representing the cumulative distribution function

x->piecewise([x>a, 1-exp(-b*(x-a))], [x<=0, 0])

$$x \to \begin{cases} 1 - e^{-b\,(x-a)} & \text{if } x > a \\ 0 & \text{if } x \le 0 \end{cases}$$

of the exponential distribution with real location parameter a and scale parameter $b > 0$.

The procedure `f := stats::exponentialCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \le a$ can be decided, then `f(x)` returns 0. If $x > a$ can be decided, then `f(x)` returns the value 1 - exp(b*(a - x)) $1 - e^{b\,(a-x)}$.

If x is a floating-point number and both a and b can be converted to floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \le a$ or $x \le a$, the corresponding values are returned.

`f(x)` returns the symbolic call `stats::exponentialCDF(a, b)(x)` if neither $x \le a$ nor $x > a$ can be decided.

Numerical values for a and b are only accepted if they are real and b is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the cumulative distribution function with $a = 0$ and $b = 1$ at various points:
f := stats::exponentialCDF(0, 1): f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)0, 0, 1 - exp(-1/2), 0.3934693403, 1 - exp(-PI), 1

$$0,\ 0,\ 1 - e^{-\frac{1}{2}},\ 0.3934693403,\ 1 - e^{-\pi},\ 1$$

delete f:

Example 2

If `a` or `x` are symbolic objects without properties, then it cannot be decided whether $x \geq a$ holds. A symbolic function call is returned:
f := stats::exponentialCDF(a, b): f(x)stats::exponentialCDF(a, b)(x)

$$\text{stats::exponentialCDF}(a,\ b)(x)$$

With suitable properties, it can be decided whether $x \geq a$ holds. An explicit expression is returned:
assume(a <= x): f(x)1 - exp(b*(a - x))

$$1 - e^{b\,(a-x)}$$

Note that `assume(a <= x)` attached properties both to `a` and `x`. When cleaning up, the properties have to be removed separately for `a` and `x` via unassume:
unassume(a): unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::exponentialCDF(a, b): f(x)stats::exponentialCDF(a, b)(x)

$$\text{stats::exponentialCDF}(a,\ b)(x)$$

When numerical values are assigned to a and b, the function `f` starts to produce numerical values:
a := 0: b := 2: f(3), f(3.0)1 - exp(-6), 0.9975212478

delete f, a, b:

Parameters

a

The location parameter: an arithmetical expression representing a real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

stats::exponentialPDF

Purpose

Probability density function of the exponential distribution

Syntax

```
stats::exponentialPDF(a, b)
```

Description

`stats::exponentialPDF(a, b)` returns a procedure representing the probability density function

x->piecewise([x>=a, b*exp(-b*(x-a))], [x<a, 0])

$$x \to \begin{cases} b\,e^{-b\,(x-a)} & \text{if } x \geq a \\ 0 & \text{if } x < a \end{cases}$$

of the exponential distribution with real location parameter a and scale parameter $b > 0$.

The procedure `f := stats::exponentialPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x < a$ can be decided, then `f(x)` returns 0. If $x \geq a$ can be decided, then `f(x)` returns the value b*exp(b*(a - x))$b\,e^{b\,(a-x)}$.

If x is a floating-point number and both a and b can be converted to floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x < a$ or $x \geq a$, the corresponding values are returned.

`f(x)` returns the symbolic call `stats::exponentialPDF(a, b)(x)` if neither $x < a$ nor $x \geq a$ can be decided.

Numerical values for a and b are only accepted if they are real and b is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the probability density function with $a = 0$ and $b = 1$ at various points:
f := stats::exponentialPDF(0, 1): f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)0, 0, exp(-1/2), 0.6065306597, exp(-PI), 0

$$0,\ 0,\ e^{-\frac{1}{2}},\ 0.6065306597,\ e^{-\pi},\ 0$$

delete f:

Example 2

If `a` or `x` are symbolic objects without properties, then it cannot be decided whether $x \geq a$ holds. A symbolic function call is returned:
f := stats::exponentialPDF(a, b): f(x)stats::exponentialPDF(a, b)(x)

$$\text{stats::exponentialPDF}(a,\ b)(x)$$

With suitable properties, it can be decided whether $x \geq a$ holds. An explicit expression is returned:
assume(a <= x): f(x)b*exp(b*(a - x))

$$b\,e^{b\,(a-x)}$$

Note that `assume(a <= x)` attached properties both to `a` and `x`. When cleaning up, the properties have to be removed separately for `a` and `x` via unassume:
unassume(a): unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::exponentialPDF(a, b): f(x)stats::exponentialPDF(a, b)(x)

$$\text{stats::exponentialPDF}(a,\ b)(x)$$

When numerical values are assigned to a and b, the function `f` starts to produce numerical values:
a := 0: b := 2: f(3), f(3.0)2*exp(-6), 0.004957504353

delete f, a, b:

Parameters

a

stats::exponentialCDFstats::exponentialQuantilestats::exponentialRandom

stats::exponentialQuantile

Purpose

Quantile function of the exponential distribution

Syntax

```
stats::exponentialQuantile(a, b)
```

Description

`stats::exponentialQuantile(a, b)` returns a procedure representing the quantile function (inverse)

x->a-ln(1-x)/b

$$x \to a - \frac{\ln(1-x)}{b}$$

of the cumulative distribution function `stats::exponentialCDF(a, b)`. For $0 \le x \le 1$, the solution of *stats*::*exponentialCDF*(a, b)(y) = x is given by

y=stats::exponentialQuantile(a, b)(x)

$$y = \text{stats::exponentialQuantile}(a, b)(x)$$

The procedure `f := stats::exponentialQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, infinity, or a symbolic expression:

If `x` is a real floating-point number between 0 and 1 and `a` and `b` can be converted to suitable real floating-point numbers, then `f(x)` returns a floating-point number.

The calls `f(1)` and `f(1.0)` produce *infinity*.

In all other cases, $f(x)$ returns the symbolic expression `a-ln(1-x)/b`.

Numerical values of x are only accepted if $0 \le x \le 1$.

Numerical values of a and b are only accepted if they are real and b is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS. which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with $a = 2$ and $b = 3$ at various points:
f := stats::exponentialQuantile(2, 3): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)2, 2 - ln(9/10)/3, 2.23104906, ln(10000000000)/3 + 2, infinity

$$2,\ 2-\frac{\ln\left(\frac{9}{10}\right)}{3},\ 2.23104906,\ \frac{\ln(10000000000)}{3}+2,\ \infty$$

The value `f(x)` satisfies `stats::exponentialCDF(2, 3)(f(x)) = x`:
stats::exponentialCDF(2, 3)(f(0.987654))0.987654

$$0.987654$$

delete f:

Example 2

We use symbolic arguments:
f := stats::exponentialQuantile(a, b): f(x), f(1/3), f(0.4)a - ln(1 - x)/b, a - ln(2/3)/b, a + 0.5108256238/b

$$a-\frac{\ln(1-x)}{b},\ a-\frac{\ln\left(\frac{2}{3}\right)}{b},\ a+\frac{0.5108256238}{b}$$

When suitable numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
a := 7: b := 1/8: f(0.999), f(999/1000)62.26204223, 8*ln(1000) + 7

$$62.26204223,\ 8\ln(1000)+7$$

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)12.54517744

```
12.54517744
```
f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, a, b:

```

Description

`stats::exponentialRandom(a, b)` returns a procedure that produces exponential deviates (random numbers) with real location parameter a and scale parameter $b > 0$.

The procedure `f := stats::exponentialRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` can be converted to a real floating point number and `b` to a positive floating-point number, then `f()` returns nonnegative floating-point number.

In all other cases, `stats::exponentialRandom(a, b)()` is returned symbolically.

Numerical values of `a` and `b` are only accepted if they are real and `b` is positive.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the exponential distribution with parameters `a` and `b`. For real $x \geq a$, the probability that $X \leq x$ is given by

1-e^(-b*fenced(x-a))

$$1 - \frac{1}{b\,(x-a+x)}$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::exponentialRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::exponentialRandom(a, b):  f() $k = 1..K;
```

rather than by

```
stats::exponentialRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::exponentialRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate exponential deviates with parameters $a = 2$ and b=3/4$b = \frac{3}{4}$:
f := stats::exponentialRandom(2, 3/4): f() $ k = 1..43.744010213, 2.246774327, 4.501726533, 2.006934293

```
3.744010213, 2.246774327, 4.501726533, 2.006934293
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:

f := stats::exponentialRandom(a, b): f()stats::exponentialRandom(a, b)()

stats::exponentialRandom(*a*, *b*)()

When a and b evaluate to suitable real numbers, `f` starts to produce random floating-point numbers:
a := PI: b := 1/8: f() $ k = 1..413.72746104, 16.8526844, 9.492707582, 6.241235276

13.72746104, 16.8526844, 9.492707582, 6.241235276

delete f, a, b:

Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:
f := stats::exponentialRandom(PI, 1/2, Seed = 1): f() $ k = 1..44.275085081, 3.608946643, 7.462091361, 6.63997707

4.275085081, 3.608946643, 7.462091361, 6.63997707

g := stats::exponentialRandom(PI, 1/2, Seed = 1): g() $ k = 1..44.275085081, 3.608946643, 7.462091361, 6.63997707

4.275085081, 3.608946643, 7.462091361, 6.63997707

f() = g(), f() = g()3.504644667 = 3.504644667, 14.68155806 = 14.68155806

3.504644667 = 3.504644667, 14.68155806 = 14.68155806

delete f, g:

Parameters

a

The location parameter: an arithmetical expression representing a real value

b

The scale parameter: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to suitable floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm for the computation of the exponential deviates uses the quantile function of the exponential distribution applied to uniformly distributed random numbers between 0 and 1.

See Also

stats::exponentialCDFstats::exponentialPDFstats::exponentialQuantile

stats::fCDF

Purpose

Cumulative distribution function of Fisher's f-distribution (fratio distribution)

Syntax

```
stats::fCDF(a, b)
```

Description

`stats::fCDF(a, b)` returns a procedure representing the cumulative distribution function

x->piecewise([x>0,
(a/b)^(a/2)/beta(a/2,b/2)*int(t^(a/2-1)*(1+(a*t)/b)^(-(a+b)/2),
t=0..x)], [x<=0, 0])

$$x \to \begin{cases} \frac{\left(\frac{a}{b}\right)^{a/2}}{\beta\left(\frac{a}{2},\frac{b}{2}\right)} \int_0^x \frac{t^{\frac{a}{2}-1}}{\left(\frac{a\,t}{b}+1\right)^{\frac{a}{2}+\frac{b}{2}}}\,dt & \text{if } x>0 \\ 0 & \text{if } x \le 0 \end{cases}$$

of Fisher's f-distribution with shape parameters $a > 0$, $b > 0$.

The procedure `f:=stats::fCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `x` can be converted to a real floating point number and the shape parameters can be converted to positive floating-point numbers, then `f(x)` returns a floating point number between 0.0 and 1.0.

For all values of `a` and `b`, the call `f(x)` returns `0.0` if `x` is a nonpositive numerical value or a symbolic expression with the property$x \le 0$.

The call `f(- infinity )` returns 0.0.

The call `f( infinity )` returns 1.0.

In all other cases, `f(x)` returns the symbolic call `stats::fCDF(a, b)(x)`.

Numerical values for `a` and `b` are only accepted if they are real and positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. It reacts to properties of identifiers set via assume.

Examples

Example 1

We evaluate the cumulative distribution function with $a = 2$ and $b = 1$ at various points:
f := stats::fCDF(2, 1): f(-infinity), f(-3), f(0.5), f(2/3), f(PI), f(infinity)0.0, 0.0, 0.2928932188, 0.3453463293, 0.629456397, 1.0

```
0.0, 0.0, 0.2928932188, 0.3453463293, 0.629456397, 1.0
```

delete f:

Example 2

If x is a symbolic object without properties, then it cannot be decided whether $x \leq 0$ holds. A symbolic function call is returned:
f := stats::fCDF(a, b): f(x)stats::fCDF(a, b)(x)

```
stats::fCDF(a, b)(x)
```

With suitable properties, it can be decided whether $x \leq 0$ holds. The value 0.0 is returned:
assume(x <= 0): f(x)0.0

```
0.0
```

MuPAD does not provide a special function to represent the cumulative distribution function for positive arguments. A symbolic call is returned:
assume(x > 0): f(x)stats::fCDF(a, b)(x)

```
stats::fCDF(a, b)(x)
```

unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::fCDF(a, b): f(x), f(2)stats::fCDF(a, b)(x), stats::fCDF(a, b)(2)

$$\text{stats::fCDF}(a, b)(x),\ \text{stats::fCDF}(a, b)(2)$$

When numerical values are assigned to `a` and `b`, the function `f` starts to produce floating-point numbers for numerical arguments:
a := 2: b := 1: f(2)0.5527864045

$$0.5527864045$$

delete f, a, b:

Parameters

a

b

The shape parameters: arithmetical expressions representing positive real values

Return Values

procedure.

See Also

stats::fPDFstats::fQuantilestats::fRandom

stats::fPDF

Purpose

Probability density function of Fisher's f-distribution (fratio distribution)

Syntax

```
stats::fPDF(a, b)
```

Description

`stats::fPDF(a, b)` returns a procedure representing the probability density function

x->piecewise([x>0,
(a/b)^(a/2)/beta(a/2,b/2)*x^(a/2-1)*(1+(a*x)/b)^(-(a+b)/2)], [x<=0, 0])

$$x \to \begin{cases} \dfrac{\left(\frac{a}{b}\right)^{a/2}\, x^{\frac{a}{2}-1}}{\beta\left(\frac{a}{2},\frac{b}{2}\right)\left(\frac{a\,x}{b}+1\right)^{\frac{a}{2}+\frac{b}{2}}} & \text{if } x>0 \\ 0 & \text{if } x\le 0 \end{cases}$$

of Fisher's f-distribution with shape parameters $a > 0$, $b > 0$.

The procedure `f:=stats::fPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \le 0$ can be decided, then `f(x)` returns 0 If $x > 0$ can be decided, then `f(x)` returns the value

(a/b)^(a/2)/beta(a/2,b/2) * x^(a/2-1) * (1+a/b*x)^(-(a+b)/2)

$$\frac{\left(\frac{a}{b}\right)^{a/2}\, x^{\frac{a}{2}-1}}{\beta\left(\frac{a}{2},\frac{b}{2}\right)\left(\frac{a\,x}{b}+1\right)^{\frac{a}{2}+\frac{b}{2}}}$$

If x is a floating-point number and both a and b can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \leq 0$ or $x \geq 0$, the corresponding values are returned.

`f(- infinity )` and `f( infinity )` return 0.

`f(x)` returns the symbolic call `stats::fPDF(a, b)(x)` if neither $x \leq 0$ nor $x > 0$ can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. It reacts to properties of identifiers set via assume.

Examples

Example 1

We evaluate the probability density function with $a = 2$ and $b = 4$ at various points:
f := stats::fPDF(2, 4): f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)0, 0, 64/125, 0.512, 1/(PI/2 + 1)^3, 0

$$0,\ 0,\ \frac{64}{125},\ 0.512,\ \frac{1}{\left(\frac{\pi}{2}+1\right)^3},\ 0$$

delete f:

Example 2

If `x` is a symbolic object without properties, then it cannot be decided whether $x \geq 0$ holds. A symbolic function call is returned:
f := stats::fPDF(a, b): f(x)stats::fPDF(a, b)(x)

$$\text{stats::fPDF}(a, b)(x)$$

With suitable properties, it can be decided whether $x \geq 0$ holds. An explicit expression is returned:
assume(0 <= x): f(x)(x^(a/2 - 1)*(a/b)^(a/2))/(((a*x)/b + 1)^(a/2 + b/2)*beta(a/2, b/2))

$$\frac{x^{\frac{a}{2}-1}\left(\frac{a}{b}\right)^{a/2}}{\left(\frac{a\,x}{b}+1\right)^{\frac{a}{2}+\frac{b}{2}}\,\beta\left(\frac{a}{2},\frac{b}{2}\right)}$$

unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::fPDF(a, b): f(x)stats::fPDF(a, b)(x)

$$\text{stats::fPDF}(a,\ b)(x)$$

When numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
a := 2: b := 1: f(3), f(3.0)sqrt(7)/49, 0.05399492472

$$\frac{\sqrt{7}}{49},\ 0.05399492472$$

delete f, a, b:

Parameters

a

b

The shape parameters: arithmetical expressions representing positive real values

Return Values

procedure.

See Also

stats::fCDFstats::fQuantilestats::fRandom

stats::fQuantile

Purpose

Quantile function of Fisher's f-distribution (fratio distribution)

Syntax

```
stats::fQuantile(a, b)
```

Description

`stats::fQuantile(a, b)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::fCDF(a, b)`. For $0 \le x \le 1$, the solution of *stats*::*fCDF*(a, b)(y) = x is given by y = *stats*::*fQuantile*(a, b)(x).

The procedure `f:=stats::fQuantile(a, b)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number, *infinity*, or a symbolic expression:

If `x` is a real number between 0 and 1 and `a` and `b` can be converted to positive floating-point numbers, then `f(x)` returns a positive floating-point number approximating the solution y of *stats*::*fCDF*(a, b)(y) = x.

The calls `f(0)` and `f(0.0)` produce 0.0 for all values of `a` and `b`.

The calls `f(1)` and `f(1.0)` produce *infinity* for all values of `a` and `b`.

In all other cases, `f(x)` returns the symbolic call `stats::fQuantile(a, b)(x)`.

Numerical values of x are only accepted if $0 \le x \le 1$.

Numerical values of `a` and `b` are only accepted if they are real and positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure generated by `stats::fQuantile` is sensitive to properties of identifiers, which can be set via assume.

Examples

Example 1

We evaluate the quantile function with $a = \pi$ and $b = 11$ at various points:

f := stats::fQuantile(PI, 11): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)0.0, 0.2017865341, 0.8492236618, 280.937214, infinity

$$0.0,\ 0.2017865341,\ 0.8492236618,\ 280.937214,\ \infty$$

The value `f(x)` satisfies *stats*::*fCDF*(π, 11)(*f*(*x*)) = *x*:
stats::fCDF(PI, 11)(f(0.987654321))0.987654321

$$0.987654321$$

delete f:

Example 2

We use symbolic arguments:
f := stats::fQuantile(a, b): f(x), f(9/10)stats::fQuantile(a, b)(x), stats::fQuantile(a, b)(9/10)

$$\text{stats::fQuantile}(a,\ b)(x),\ \text{stats::fQuantile}(a,\ b)\left(\frac{9}{10}\right)$$

When positive real values are assigned to `a` and `b`, the function `f` starts to produce floating-point values:
a := 17: b := 6: f(0.999), f(1 - sqrt(2)/10^5)17.35343418, 75.00107347

$$17.35343418,\ 75.00107347$$

Numerical values for *x* are only accepted if $0 \le x \le 1$:
f(0.5)1.077968248

$$1.077968248$$

f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, a, b:

Parameters

a

b

The shape parameters: arithmetical expressions representing positive real values

Return Values procedure.

See Also stats::fCDFstats::fPDFstats::fRandom

stats::fRandom

Purpose

Generate a random number generator for Fisher's f-deviates (fratio deviates)

Syntax

```
stats::fRandom(a, b, <Seed = n>)
```

Description

`stats::fRandom(a, b)` returns a procedure that produces f-deviates (random numbers) with shape parameters $a > 0$, $b > 0$.

The procedure `f:=stats::fRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` and `b` can be converted to positive floating-point numbers, then `f()` returns a positive floating-point number.

In all other cases, `stats::fRandom(a, b)()` is returned symbolically.

Numerical values of `a` and `b` are only accepted if they are real and positive.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the f-distribution with shape parameters a and b. For $0 \le x$, the probability that $X \le x$ is given by

(a/b)^(a/2)/beta(a/2,b/2)*int(t^(a/2-1)*(1+(a*t)/b)^(-(a+b)/2), t=0..x)

$$\frac{\left(\frac{a}{b}\right)^{a/2}}{\beta\left(\frac{a}{2},\frac{b}{2}\right)}\int_0^x \frac{t^{\frac{a}{2}-1}}{\left(\frac{a\,t}{b}+1\right)^{\frac{a}{2}+\frac{b}{2}}}\,dt$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::fRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::fRandom(a, b):  f() $k = 1..K;
```

rather than by

```
stats::fRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::fRandom(a, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate f-deviates with shape parameters a = 2 and b=3/4$b = \frac{3}{4}$:
f := stats::fRandom(2, 3/4): f() $ k = 1..40.06381499229, 4.951243823, 4.433412266, 2.189546079

```
0.06381499229, 4.951243823, 4.433412266, 2.189546079
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::fRandom(a, b): f()stats::fRandom(a, b)()

stats::fRandom(*a*, *b*)()

When the shape parameters evaluate to positive real numbers, `f` starts to produce random floating-point numbers:
a := PI: b := 8: f()1.641736211

1.641736211

delete f, a, b:

Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:
f := stats::fRandom(4, 5, Seed = 1): f() $ k = 1..40.002660717454, 1.586532187, 0.6498965358, 0.8953358537

0.002660717454, 1.586532187, 0.6498965358, 0.8953358537

g := stats::fRandom(4, 5, Seed = 1): g() $ k = 1..40.002660717454, 1.586532187, 0.6498965358, 0.8953358537

0.002660717454, 1.586532187, 0.6498965358, 0.8953358537

f() = g(), f() = g()1.672785971 = 1.672785971, 0.5207718594 = 0.5207718594

1.672785971 = 1.672785971, 0.5207718594 = 0.5207718594

delete f, g:

Parameters

a

b

The shape parameters: arithmetical expressions representing positive real values

Options

Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the shape parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm uses independent gamma deviates `X` and `Y` to produce an f-deviate (b/a)*(X/Y)$_{b,a}$. For more information see: D. Knuth, Seminumerical Algorithms (1998), Vol. 2, p. 135.

See Also

stats::fCDFstats::fPDFstats::fQuantile

stats::finiteCDF

Purpose

Cumulative distribution function of a finite sample space

Syntax

```
stats::finiteCDF([x1, x2,  ], [p1, p2,  ])
stats::finiteCDF([[x1, p1], [x2, p2],  ])
stats::finiteCDF(s, <c1, c2>)
stats::finiteCDF(s, <[c1, c2]>)
```

Description

`stats::finiteCDF([x1, x2,  , xn], [p1, p2,  , pn])` returns a procedure representing the cumulative distribution function x-> sum(p[i], i = 1.. k) $x \to \sum_{i=1}^{k} p_i$ of the finite sample space consisting of the data elements $x_1, \ldots, x_n$ with the probabilities $p_1, \ldots, p_n$. Here, k = abs(ImageSet(j, x[j] <= x)) $k = |\{j \mid x_j \le x\}|$, i.e., x_k is the largest element of the data sample less or equal to x (the data elements are assumed to be ordered: $x_1 < x_2 < x_3$ etc.)

The procedure `f := stats::finiteCDF([x1, x2,  ], [p1, p2,  ])` can be called in the form `f(x)` with an arithmetical expression `x`.

If `x` is a numerical value and the data elements $x_1, x_2, \ldots$ are all numerical, then `f(x)` returns an arithmetical expression (the sum of the probabilities of all data elements smaller or equal to `x`).

The call `f(- infinity )` produces 0; the call `f( infinity )` produces 1.

Otherwise, if `x` is a symbolic expression that cannot be converted to a real floating-point number or if the data $x_1, x_2, \ldots$ contain elements that cannot be converted to real floating-point numbers, then `f(x)` returns the symbolic call `stats::finiteCDF([x1, x2,  ], [p1, p2,  ])(x)` with the data $x_1, x_2, \ldots$ in ascending order.

If all probability values $p_1, p_2, \ldots$ are numerical, they must add up to 1. Otherwise, an error is raised.

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values. Cf. “Example 5” on page 30-165.

The data elements x_1, x_2, are assumed to be in ascending order: $x_1 < x_2 <$. If all data elements are numerical, they are re-ordered automatically, if they are not ascending. If the data contain symbolic elements that cannot be converted to floating-point numbers, the ordering is assumed implicitly.

`stats::finiteCDF` generalizes stats::empiricalCDF, which assumes equiprobable data. For numerical data x_1, x_2, , the call `stats::finiteCDF([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalCDF([`x_1, , x_n`])`.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. Note, however, that this function is implemented with option remember. After the first call it does not react to changes of DIGITS unless the input parameters are changed.

Examples

Example 1

We evaluate the finite distribution function of some numerical data at various points:
f := stats::finiteCDF([1, 0, 2.3, PI], [p1, p0, 0.2, 0.3]): f(-infinity), f(0.1), f(2.3), f(PI), f(10), f(infinity)0, p0, p0 + p1 + 0.2, p0 + p1 + 0.5, p0 + p1 + 0.5, 1

```
0, p0, p0 + p1 + 0.2, p0 + p1 + 0.5, p0 + p1 + 0.5, 1
```

Alternatively, the data may be passed as a list:
f := stats::finiteCDF([[1, p1], [0, p0], [2.3, 0.2], [PI, 0.3]]): f(-infinity), f(0.1), f(2.3), f(PI), f(10), f(infinity)0, p0, p0 + p1 + 0.2, p0 + p1 + 0.5, p0 + p1 + 0.5, 1

```
0, p0, p0 + p1 + 0.2, p0 + p1 + 0.5, p0 + p1 + 0.5, 1
```

delete f:

Example 2

We use symbolic arguments. In the symbolic return value, the input data appear as a sorted list:
stats::finiteCDF([3, 4, PI], [0.2, 0.5, 0.3])(x)stats::finiteCDF([3, PI, 4], [0.2, 0.3, 0.5])(x)

stats::finiteCDF([3, π, 4], [0.2, 0.3, 0.5])(x)

If the data contain symbolic elements, the return value is again a symbolic call:
stats::finiteCDF([3, x, PI], [0.2, 0.5, 0.3])(0.7)stats::finiteCDF([3, x, PI], [0.2, 0.5, 0.3])(0.7)

stats::finiteCDF([3, x, π], [0.2, 0.5, 0.3])(0.7)

Example 3

We create a sample consisting of one string column and two non-string columns:
s := stats::sample([["1996", 1242, 2/5], ["1997", 1353, 0.1], ["1998", 1142, 0.2], ["1999", 1201, 0.2], ["2001", 1201, 0.1]]) "1996" 1242 2/5 "1997" 1353 0.1 "1998" 1142 0.2 "1999" 1201 0.2 "2001" 1201 0.1

We compute values of the finite distributions of the data in the second and third column:
f := stats::finiteCDF(s, 2, 3): f(1000), f(1200), f(1201)0, 0.2, 0.5

0, 0.2, 0.5

delete s, f:

Example 4

If numerical probability values are given, they must add up to 1:
f := stats::finiteCDF([Head, TAIL], [0.45, 0.54]): Error: The probabilities do not add up to one. [stats::finiteCDF]

Symbolic probability values are not checked for consistency:

f := stats::finiteCDF([Head, TAIL], [0.45, p]): f(x)stats::finiteCDF([Head, TAIL], [0.45, p])(x)

stats::finiteCDF([Head, TAIL], [0.45, *p*])(*x*)

However, when the probabilities are set to numerical values, they are checked:
p:= 0.7: f(x) Error: The probabilities do not add up to one. [f] delete f, p:

Example 5

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values:
f:= stats::finiteCDF([x1, x2, x1, x2], [0.1, 0.2, 0.3, 0.4]):
f(3)stats::finiteCDF([x1, x2], [0.4, 0.6])(3)

stats::finiteCDF([x1, x2], [0.4, 0.6])(3)

x1 := 1: x2 := 3: f(2)0.4

0.4

delete f, x1, x2:

Parameters

x_1, x_2, ...

The statistical data: arbitrary MuPAD objects

p_1, p_2, ...

Probability values: arithmetical expressions

s

A sample of domain type stats::sample

c_1, c_2

Column indices of the sample s: positive integers. Column c_1 provides the data x_1, x_2 etc. Column c_2 provides the data p_1, p_2 etc. There is no need to specify column numbers if the sample has only two columns.

Return Values procedure.

See Also stats::empiricalCDFstats::empiricalPFstats::empiricalQuantilestats::empiricalRandomstats::f

stats::finitePF

Purpose

Probability function of a finite sample space

Syntax

```
stats::finitePF([x_1, x_2,  ], [p_1, p_2,  ])
stats::finitePF([[x_1, p_1], [x_2, p_2],  ])
stats::finitePF(n, <c_1, c_2>)
stats::finitePF(n, <[c_1, c_2]>)
```

Description

`stats::finitePF([x_1, x_2, , x_n], [p_1, p_2, , p_n])` returns a procedure representing the probability function

(x) -> piecewise([x = x[i], p[i]], [Otherwise, 0])

$$x \to \begin{cases} p_i & \text{if } x = x_i \\ 0 & \text{otherwise} \end{cases}$$

of the sample space given by the data $x_1, x_2,$ with the probabilities $p_1, p_2,$.

The procedure `f := stats::finitePF([x_1, x_2, ], [p_1, p_2, ])` can be called in the form `f(x)` with an arithmetical expression `x` or sets of lists of such expressions.

If `x` is an expression that is contained in the data $x_1, x_2,$, then the corresponding probability value is returned.

If `x` is an expression that is not contained in the data $x_1, x_2,$, then `0` is returned.

If `x` is a set, the sum of the probability values of its elements is returned.

If `x` is a list, it is treated like a set (i.e., duplicate entries in `x` are eliminated). The sum of the probability values of the elements in `x` is returned.

If all probability values $p_1, p_2,$ are numerical, they must add up to 1. Otherwise, an error is raised. Cf. “Example 4” on page 30-169.

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values. Cf. “Example 5” on page 30-169.

`stats::finitePF` generalizes stats::empiricalPF, which assumes equiprobable data. For numerical data $x_1, x_2, \ldots$, the call `stats::finitePF([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalPF([`$x_1, \ldots, x_n$`])`.

Examples

Example 1

We demonstrate the basic usage of this function:
f := stats::finitePF([1, x, y, PI], [1/4, px, py, 0.25]): f(0), f(1), f(1.0), f(x), f(y), f(PI), f(float(PI)), f(10)0, 1/4, 0, px, py, 0.25, 0, 0

$$0, \frac{1}{4}, 0, px, py, 0.25, 0, 0$$

Alternatively, the data may be passed as a list:
f := stats::finitePF([[1, 1/4], [x, px], [y, py], [PI, 0.25]]): f(0), f(1), f(1.0), f(x), f(y), f(PI), f(float(PI)), f(10)0, 1/4, 0, px, py, 0.25, 0, 0

$$0, \frac{1}{4}, 0, px, py, 0.25, 0, 0$$

delete f:

Example 2

We create a sample of type stats::sample consisting of one string column and two non-string columns:
s := stats::sample([["1996", 1242, 2/5], ["1997", 1353, 0.1], ["1998", 1142, 0.2], ["1999", 1201, 0.2], ["2001", 1201, 0.1]]) "1996" 1242 2/5 "1997" 1353 0.1 "1998" 1142 0.2 "1999" 1201 0.2 "2001" 1201 0.1

We use the data in the first and third column:
f := stats::finitePF(s, 1, 3): f("1995"), f("1998"), f("2000"), f("2001")0, 0.2, 0, 0.1

0, 0.2, 0, 0.1

delete s, f:

Example 3

We consider a loaded die:
f:= stats::finitePF([1, 2, 3, 4, 5, 6], [0.1, 0.1, 0.1, 0.2, 0.2, 0.3]):

What is the probabiliy that tossing the die produces a score more than or equal to 4?
f({4, 5, 6})0.7

0.7

delete f:

Example 4

The probability values must add up to 1:
stats::finitePF([Head, TAIL], [0.45, 0.54]): Error: The probabilities do not add up to one. [stats::finitePF]

Example 5

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values:
f:= stats::finitePF([x1, x2, x1, x2], [0.1, 0.2, 0.3, 0.4]): f(x1), f(x2)0.4, 0.6

0.4, 0.6

delete f:

Parameters

stats::finiteQuantile

Purpose

Quantile function of a finite sample space

Syntax

```
stats::finiteQuantile([x_1, x_2,  ], [p_1, p_2,  ])
stats::finiteQuantile([[x_1, p_1], [x_2, p_2],  ])
stats::finiteQuantile(s, <c_1, c_2>)
stats::finiteQuantile(s, <[c_1, c_2]>)
```

Description

`stats::finiteQuantile([x_1, x_2,  , x_n], [p_1, p_2,  , p_n])` returns a procedure representing the quantile function of the data `x_1, x_2` etc. with the probabilities `p_1, p_2` etc. It is the (discrete) inverse of the cumulative distribution function `stats::finiteCDF([x_1, x_2,  ], [p_1, p_2,  ])`. For $0 \le x \le 1$, the x-quantile $y = stats::finiteQuantile([x_1, x_2, \ldots], [p_1, p_2, \ldots])(x)$ is the smallest of the data elements `x_1, x_2,` satisfying

stats::finiteCDF([x_1, x_2, dots], [p_1, p_2, dots])(y)>=x

$$stats::finiteCDF([x_1, x_2, \ldots], [p_1, p_2, \ldots])(y) \ge x$$

(The data elements are assumed to be ordered: $x_1 < x_2 < x_3$ etc.)

The procedure `f := stats::finiteQuantile([x_1, x_2,  ], [p_1, p_2, ])` can be called in the form `f(x)` with an arithmetical expression `x`.

If x is a real number satisfying $0 \le x \le 1$ and all probability values `p_1, p_2,` are numerical, then `f(x)` returns one of the data elements `x_1, x_2,  .`

Otherwise, if `x` is a symbolic expression that cannot be converted to a real floating-point number or if the probabilities `p_1, p_2,` contain elements that cannot be converted to real floating-point numbers, then `f(x)` returns the symbolic call `stats::finiteQuantile([x_1, x_2,  ], [p1, p2,  ])(x)` with the data `x_1, x_2,` in ascending order.

Numerical values of x are only accepted if $0 \le x \le 1$.

If all probability values `p_1, p_2,` are numerical, they must add up to 1. Otherwise, an error is raised.

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values. Cf. “Example 5” on page 30-174.

y = *stats*::*finiteQuantile*([x_1, x_2, …], [p_1, p_2, …])(x) satisfies

stats::finiteCDF([x_1, x_2, dots], [p_1, p_2, dots])(x[i]) <x<= stats::finiteCDF([x_1, x_2, dots], [p_1, p_2, dots])(y)

$$\text{stats::finiteCDF}([x_1, x_2, \ldots], [p_1, p_2, \ldots])(x_i) < x \le \text{stats::finiteCDF}([x_1, x_2, \ldots], [p_1, p_2, \ldots])(y)$$

for all data elements x_i in the sample satisfying $x_i < y$.

The data elements x_1, x_2, … are assumed to be in ascending order: $x_1 < x_2 < \ldots$. If all data elements are numerical, they are re-ordered automatically, if they are not ascending. If the data contain symbolic elements that cannot be converted to floating-point numbers, the ordering is assumed implicitly.

`stats::finiteQuantile` generalizes stats::empiricalQuantile, which assumes equiprobable data. For numerical data x_1, x_2, …, the call `stats::finiteQuantile([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalQuantile([`x_1, …, x_n`])`.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. Note, however, that this function is implemented with option remember. After the first call it does not react to changes of DIGITS unless the input parameters are changed.

Examples

Example 1

We compute various quantiles of some numerical data:
f := stats::finiteQuantile([1, x, y, PI], [1/4, 3/8, 1/4, 1/8]): f(0), f(0.1), f(3/10), f(0.5), f(1/sqrt(2)), f(99/100), f(1)1, 1, x, x, y, PI, PI

$$1, 1, x, x, y, \pi, \pi$$

Alternatively, the data may be passed as a list:

f := stats::finiteQuantile([[1, 1/4], [x, 3/8], [y, 1/4], [PI, 1/8]]): f(0), f(0.1), f(3/10), f(0.5), f(1/sqrt(2)), f(99/100), f(1)1, 1, x, x, y, PI, PI

$1, 1, x, x, y, \pi, \pi$

delete f:

Example 2

We use symbolic arguments. In the symbolic return value, the input data appear as a sorted list:
f:= stats::finiteQuantile([3, 4, PI], [0.2, 0.5, 0.3]):
f(x)stats::finiteQuantile([3, PI, 4], [0.2, 0.3, 0.5])(x)

$\text{stats::finiteQuantile}([3, \pi, 4], [0.2, 0.3, 0.5])(x)$

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)PI

π

f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f:

Example 3

We create a sample of type stats::sample consisting of one string column and two non-string columns:
s := stats::sample([["1996", 1242, 2/5], ["1997", 1353, 0.1], ["1998", 1142, 0.2], ["1999", 1201, 0.2], ["2001", 1201, 0.1]]) "1996" 1242 2/5 "1997" 1353 0.1 "1998" 1142 0.2 "1999" 1201 0.2 "2001" 1201 0.1

We compute quantile values of the data in the second and third column:
f := stats::finiteQuantile(s, 2, 3): f(0.1), f(1/4), f(0.7), f(99/100)1142, 1201, 1242, 1353

1142, 1201, 1242, 1353

delete s, f:

Example 4

If numerical probability values are given, they must add up to 1:
f := stats::finiteQuantile([Head, TAIL], [0.45, 0.54]): Error: The probabilities do not add up to one. [stats::finiteQuantile]

Symbolic probability values are not checked for consistency:
f := stats::finiteQuantile([Head, TAIL], [0.45, p]):
f(x)stats::finiteQuantile([Head, TAIL], [0.45, p])(x)

```
stats::finiteQuantile([Head, TAIL], [0.45, p])(x)
```

However, when the probabilities are set to numerical values, they are checked:
p:= 0.7: f(x) Error: The probabilities do not add up to one. [f] delete f, p:

Example 5

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values:
f:= stats::finiteQuantile([x1, x2, x1, x2], [p1, p2, 0.3, 0.4]):
f(0.5)stats::finiteQuantile([x1, x2], [p1 + 0.3, p2 + 0.4])(0.5)

```
stats::finiteQuantile([x1, x2], [p1 + 0.3, p2 + 0.4])(0.5)
```

p1 := 0.1: p2 := 0.2: f(0.5)x2

```
x2
```

delete f, p1, p2:

Parameters

x_1, x_2, ...

The statistical data: arbitrary MuPAD objects

p_1, p_2, ...

Probability values: arithmetical expressions

s

A sample of domain type stats::sample

c_1, c_2

Column indices of the sample `s`: positive integers. Column c_1 provides the data x_1, x_2 etc. Column c_2 provides the data p_1, p_2 etc. There is no need to specify column numbers if the sample has only two columns.

Return Values

procedure.

stats::empiricalCDFstats::empiricalPFstats::empiricalQuantilestats::empiricalRandomsta

stats::finiteRandom

Purpose

Generate a random generator for elements of a finite sample space

Syntax

```
stats::finiteRandom([x1, x2,  ], [p1, p2,  ], <Seed = n>)
stats::finiteRandom([[x1, p1], [x2, p2],  ], <Seed = n>)
stats::finiteRandom(n, <c1, c2>, <Seed = n>)
stats::finiteRandom(n, <[c1, c2]>, <Seed = n>)
```

Description

`stats::finiteRandom([x1, x2,  , xn], [p1, p2,  , pn])` returns a procedure that picks out random elements from the data `x1, x2` etc. The chances of picking out elements are given by the probabilities `p1, p2` etc.

The procedure `f := stats::finiteRandom([x1, x2,  ], [p1, p2,  ])` can be called in the form `f()`. The call `f()` returns one of the data elements `x1, x2,  `.

The values `X = f()` are distributed randomly according to the discrete distribution function of the sample space, i.e., the probability of $X \leq x$ is given by `stats::finiteCDF([x1, x2,  ], [p1, p2,  ])(x)`.

All probability values `p1, p2,  ` must be convertible to floating-point numbers. They must add up to 1.

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::finiteRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::finiteRandom([x1, x2,  ], [p1, p2,  ]):
f() $k = 1..K;
```

rather than by

```
stats::finiteRandom([x_1, x_2, dots], [p_1, p_2, dots])()
$k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::finiteRandom([x_1, x_2, dots], [p_1, p_2, dots],
Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

`stats::finiteRandom` generalizes stats::empiricalRandom, which assumes equiprobable data. For numerical data $x_1, x_2, \ldots$, the call `stats::finiteRandom([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalRandom([`$x_1, \ldots, x_n$`])`.

Examples

Example 1

We pick out random elements of some data:
f := stats::finiteRandom([1, x, y, PI], [1/4, 3/8, 1/4, 1/8], Seed = 234): f(), f(), f(), f(), f(), f(), f(), f(), f()1, 1, x, y, y, x, x, y, PI

$1, 1, x, y, y, x, x, y, \pi$

Alternatively, the data may be passed as a list:
f := stats::finiteRandom([[1, 1/4], [x, 3/8], [y, 1/4], [PI, 1/8]], Seed = 234): f(), f(), f(), f(), f(), f(), f(), f(), f()1, 1, x, y, y, x, x, y, PI

$1, 1, x, y, y, x, x, y, \pi$

delete f:

Example 2

We create a sample of type stats::sample consisting of one string column and two non-string columns:

s := stats::sample([["1996", 1242, 2/5], ["1997", 1353, 0.1], ["1998", 1142, 0.2], ["1999", 1201, 0.2], ["2001", 1201, 0.1]]) "1996" 1242 2/5 "1997" 1353 0.1 "1998" 1142 0.2 "1999" 1201 0.2 "2001" 1201 0.1

We pick random values using the data in the first and third column: f := stats::finiteRandom(s, 1, 3, Seed = 123): f(), f(), f(), f(), f(), f(), f()"1996", "1998", "1997", "1996", "1998", "1996", "1996"

"1996", "1998", "1997", "1996", "1998", "1996", "1996"

delete s, f:

Example 3

We toss a loaded coin:
f:= stats::finiteRandom([Head, Tail], [0.4, 0.6], Seed = 123): f(), f(), f(), f(), f(), f(), f(), f(), f(), f()Head, Tail, Tail, Head, Tail, Head, Head, Tail, Head, Tail

Head, Tail, Tail, Head, Tail, Head, Head, Tail, Head, Tail

We toss the coin 10000 times and count the number of Heads and Tails: t := [f() $ k = 1..10^4]: NumberOfHeads = nops(select(t, _equal, Head)), NumberOfTails = nops(select(t, _equal, Tail))NumberOfHeads = 3975, NumberOfTails = 6025

NumberOfHeads = 3975, NumberOfTails = 6025

delete f, t:

Example 4

The probability values must add up to 1:
stats::finiteRandom([Head, TAIL], [0.45, 0.54]): Error: The probabilities do not add up to one. [stats::finiteRandom]

Parameters

x_1, x_2, ...

The statistical data: arbitrary MuPAD objects

p_1, p_2, ...

Probability values: real numerical values

s

A sample of domain type stats::sample

c_1, c_2

Column indices of the sample `s`: positive integers. Column c_1 provides the data x_1, x_2 etc. Column c_2 provides the data p_1, p_2 etc. There is no need to specify column numbers if the sample has only two columns.

Options

Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random values. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of values.

Return Values

procedure.

Algorithms

The random values are chosen by applying the quantile function to uniformly distributed random numbers between 0 and 1.

stats::frequency

Purpose

Tally numerical data into classes and count frequencies

Syntax

```
stats::frequency(data, <ClassesClosed = Left | Right>)
stats::frequency(data, n, <ClassesClosed = Left | Right>)
stats::frequency(data, [n], <ClassesClosed = Left | Right>)
stats::frequency(data, [a_1 .. b_1, a_2 .. b_2,  ],
<ClassesClosed = Left | Right>)
stats::frequency(data, [[a_1, b_1], [a_2, b_2],  ],
<ClassesClosed = Left | Right>)
stats::frequency(data, Classes = n, <ClassesClosed
= Left | Right>)
stats::frequency(data, Classes = [n], <ClassesClosed
= Left | Right>)
stats::frequency(data, Classes = [a_1 .. b_1, a_2 .. b_2,
 ], <ClassesClosed = Left | Right>)
stats::frequency(data, Classes = [[a_1, b_1], [a_2, b_2],
 ], <ClassesClosed = Left | Right>)
stats::frequency(data, Cells = n, <CellsClosed
= Left | Right>)
stats::frequency(data, Cells = [n], <CellsClosed
= Left | Right>)
stats::frequency(data, Cells = [a_1 .. b_1, a_2 .. b_2,
 ], <CellsClosed = Left | Right>)
stats::frequency(data, Cells = [[a_1, b_1], [a_2, b_2],
 ], <CellsClosed = Left | Right>)
```

Description

`stats::frequency(data, [[a_1, b_1], [a_2, b_2],  ])` tallies numerical data into different classes given by semiopen intervals Interval(a[i], [b[i]])$(a_i, b_i]$. It counts how many data elements fall into each class.

All data elements must be real numerical values. Exact numerical values such as π, sqrt(3)$\sqrt{3}$ etc. are allowed if they can be converted to real floating-point numbers via float. An error is raised if symbolic data are found that cannot be converted to real floating point numbers.

Note Note that `stats::frequency` is fast if all data elements are integers, rational numbers, or floating point numbers. Exact numerical values such as π, sqrt(3)$\sqrt{3}$ etc. are processed, but have a noticeable impact on the efficiency of `stats::frequency`.

Data given by an array, a table etc. are internally treated like a list containing all operands of the data container. In particular, all rows and columns of arrays, matrices and stats::sample objects are taken into account. A stats::sample object must not contain any text entries.

For the specification of the classes, `stats::frequency` accepts either a single positive integer (or, equivalently, a list of one positive integer), or a list of classes given as ranges or lists of two elements.

A single integer n in the specification `Classes= n` or `Classes= [n]` is interpreted as "subdivide the range from $min(data)$ to $max(data)$ into n classes of equal size". The left border of the first class is set to - ∞.

The classes may be specified directly as in `Classes = [[a1, b1], [a2, b2], ]` or `Classes=[a_1..b_1, a_2..b_2, dots]`.

Note With the default setting `ClassesClosed = Right`, the i-th class is the *semi-open* interval Interval(a[i], [b[i]])$(a_i, b_i]$, i.e., a datum x is tallied into the i-th class if $a_i < x \le b_i$ is satisfied.

With `ClassesClosed = Left`, the i-th class is the semi-open interval Interval([a[i]], b[i])$[a_i, b_i)$, i.e., a datum x is tallied into the i-th class if $a_i \le x < b_i$ is satisfied.

The class boundaries must be numerical real values satisfying $a_1 \le b_1 \le a_2 \le b_2 \le a_3 \le \ldots$. In most applications, $b_1 = a_2$, $b_2 = a_3$ etc. is appropriate.

Exact values such as π, sqrt(3)$\sqrt{3}$ etc. are accepted and processed.

The classes need not cover the entire data range. Data are ignored if they do not fall into one of the specified classes.

If giving classes directly, the leftmost border may be - ∞ and the rightmost border may be *infinity*.

Examples

Example 1

We split the following data into 10 classes of equal size (default). The first class covers the values from - ∞ to 2:

```
data := [0, 1, 2, PI, 4, 5, 6, 7, 7.1, 20]: T := stats::frequency(data)table(10 = [[18, 20], 1, [20]], 9 = [[16, 18], 0, []], 8 = [[14, 16], 0, []], 7 = [[12, 14], 0, []], 6 = [[10, 12], 0, []], 5 = [[8, 10], 0, []], 4 = [[6, 8], 2, [7, 7.1]], 3 = [[4, 6], 2, [5, 6]], 2 = [[2, 4], 2, [PI, 4]], 1 = [[-infinity, 2], 3, [0, 1, 2]])
```

1	[[−∞, 2], 3, [0, 1, 2]]
2	[[2, 4], 2, [π, 4]]
3	[[4, 6], 2, [5, 6]]
4	[[6, 8], 2, [7, 7.1]]
5	[[8, 10], 0, []]
6	[[10, 12], 0, []]
7	[[12, 14], 0, []]
8	[[14, 16], 0, []]
9	[[16, 18], 0, []]
10	[[18, 20], 1, [20]]

We split the information on the classes into 3 separate tables:

```
TheClasses := map(T, op, 1)TheClasses = table(10 = [18, 20], 9 = [16, 18], 8 = [14, 16], 7 = [12, 14], 6 = [10, 12], 5 = [8, 10], 4 = [6, 8], 3 = [4, 6], 2 = [2, 4], 1 = [-infinity, 2])
```

TheClasses =

1	[−∞, 2]
2	[2, 4]
3	[4, 6]
4	[6, 8]
5	[8, 10]
6	[10, 12]
7	[12, 14]
8	[14, 16]
9	[16, 18]

TheFrequencies = map(T, op, 2)TheFrequencies = table(10 = 1, 9 = 0, 8 = 0, 7 = 0, 6 = 0, 5 = 0, 4 = 2, 3 = 2, 2 = 2, 1 = 3)

TheFrequencies =

1	3
2	2
3	2
4	2
5	0
6	0
7	0
8	0
9	0
10	1

TheValues = map(T, op, 3)TheValues = table(10 = [20], 9 = [], 8 = [], 7 = [], 6 = [], 5 = [], 4 = [7, 7.1], 3 = [5, 6], 2 = [PI, 4], 1 = [0, 1, 2])

1	[0, 1, 2]
2	[π, 4]
3	[5, 6]
4	[7, 7.1]
5	[]
6	[]
7	[]
8	[]
9	[]

The classes are specified explicitly:

```
classes:= [[0, 5], [5, 10], [10, 20]]: stats::frequency(data, classes)table(3 = [[10, 20], 1, [20]], 2 = [[5, 10], 3, [6, 7, 7.1]], 1 = [[0, 5], 5, [1, 2, PI, 4, 5]])
```

1	[[0, 5], 5, [1, 2, π, 4, 5]]
2	[[5, 10], 3, [6, 7, 7.1]]
3	[[10, 20], 1, [20]]

Note that the value 0 is not tallied into any of the classes (the first class represents the semi-open interval Interval(0, [5])(0, 5])! In order to include all values, we use _outputSequence(Symbol::pm,infinity)±∞ as class boundaries:

```
classes:= [[-infinity, 5], [5, 10], [10, infinity]]: stats::frequency(data, classes)table(3 = [[10, infinity], 1, [20]], 2 = [[5, 10], 3, [6, 7, 7.1]], 1 = [[-infinity, 5], 6, [0, 1, 2, PI, 4, 5]])
```

```
[[-∞, 5], 6, [0, 1, 2, π, 4, 5]]
[[5, 10], 3, [6, 7, 7.1]]
[[10, ∞], 1, [12]]
```

delete data, T, classes:

Example 2

We demonstrate the difference between the options `ClassesClosed = Left` and `ClassesClosed = Right`. In the first case, the value 1 is tallied into the second class:
stats::frequency([0, 1, 2], Classes = [-infinity..1, 1..infinity], ClassesClosed = Left)table(2 = [[1, infinity], 2, [1, 2]], 1 = [[-infinity, 1], 1, [0]])

```
[[-∞, 1], 1, [0]]
[[1, ∞], 2, [1, 2]]
```

With `ClassesClosed = Right`, the value 1 is tallied into the first class:
stats::frequency([0, 1, 2], Classes = [-infinity..1, 1..infinity], ClassesClosed = Right)table(2 = [[1, infinity], 1, [2]], 1 = [[-infinity, 1], 2, [0, 1]])

```
[[-∞, 1], 2, [0, 1]]
[[1, ∞], 1, [2]]
```

The default setting is `ClassesClosed = Right`:
stats::frequency([0, 1, 2], Classes = [-infinity..1, 1..infinity])table(2 = [[1, infinity], 1, [2]], 1 = [[-infinity, 1], 2, [0, 1]])

```
[[-∞, 1], 2, [0, 1]]
[[1, ∞], 1, [2]]
```

Example 3

We create a sample of 1000 normally distributed data points:
X := stats::normalRandom(0, 10): data := [X() $ i = 1..1000]:

These data are tallied into 5 different classes of equal width:
T := stats::frequency(data, 5):

We determine the number of data values in each class:
for i from 1 to 5 do print(Class = T[i][1], NumberOfElements = T[i][2]);
end_for:Class = [-infinity, -5.982260368], NumberOfElements = 23

Class = [−∞, −5.982260368], NumberOfElements = 23
Class = [-5.982260368, -1.635193057], NumberOfElements = 300

Class = [−5.982260368, −1.635193057], NumberOfElements = 300
Class = [-1.635193057, 2.711874254], NumberOfElements = 485

Class = [−1.635193057, 2.711874254], NumberOfElements = 485
Class = [2.711874254, 7.058941565], NumberOfElements = 182

Class = [2.711874254, 7.058941565], NumberOfElements = 182
Class = [7.058941565, 11.40600888], NumberOfElements = 10

Class = [7.058941565, 11.40600888], NumberOfElements = 10

We determine the outliers of the data sample by collecting the values smaller than - 9 and the values larger than 10:
classes := [[-infinity, -9], [10, infinity]]: T := stats::frequency(data, classes);table(2 = [[10, infinity], 1, [11.40600888]], 1 = [[-infinity, -9], 2, [-10.32932768, -9.707360153]])

1	[[−∞, −9], 2, [−10.32932768, −9.707360153]]
2	[[10, ∞], 1, [11.40600888]]

delete X, data, T, i, classes:

Parameters

data

The statistical data: a list, a set, a table, an array, a matrix, or an object of type stats::sample containing numerical real data values

n

The number of classes (cells): a positive integer. If not specified, $n = 10$ is used.

a_1, b_1, a_2, ...

The class boundaries: real numerical values satisfying

a[1]<=b[1]<=a[2]<=b[2]<=Symbol::hellip

$a_1 \le b_1 \le a_2 \le b_2 \le \ldots$

Also _outputSequence(Symbol::pm,infinity)$\pm\infty$ are allowed as class boundaries.

Return Values

table is returned with integer indices from 1 through the number of classes. The i-th entry of the table `T = stats::frequency(data, ...)` is the list `T[i]` = [[a_i, b_i], n_i, [v_1, v_2, ...]], where [a_i, b_i] is the i-th class, n_i is the number of data falling in this class, and [v_1, v_2, ...] is the sorted list of all data in this class (i.e., $a_i < v_j \le b_j$ for all j from 1 through n_i).

See Also

stats::meanstats::stdevplot::Histogram2d

stats::gammaCDF

Purpose

Cumulative distribution function of the gamma distribution

Syntax

```
stats::gammaCDF(a, b)
```

Description

`stats::gammaCDF(a, b)` returns a procedure representing the cumulative distribution function

x->piecewise([x>0, 1/(b^a*gamma(a))*int(t^(a-1)*exp(-t/b), t=0..x)], [x<=0, 0])

$$x \to \begin{cases} \frac{1}{b^a\,\Gamma(a)} \int_0^x t^{a-1}\, e^{-\frac{t}{b}}\, dt & \text{if } x > 0 \\ 0 & \text{if } x \le 0 \end{cases}$$

of the gamma distribution with shape parameter $a > 0$ and scale parameter $b > 0$.

The procedure `f:=stats::gammaCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \le 0$ can be decided, then `f(x)` returns 0. If $x \ge 0$ can be decided, then `f(x)` returns the value 1 - igamma(a, x/b)/gamma(a) $1 - \frac{\Gamma\left(a, \frac{x}{b}\right)}{\Gamma(a)}$.

If x is a floating-point number and both a and b can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \le 0$ or $x \ge 0$, the corresponding values are returned.

The call `f(- infinity )` returns 0.

The call `f( infinity )` returns 1.

`f(x)` returns the symbolic call `stats::gammaCDF(a, b)(x)` if neither $x \le 0$ nor $x \ge 0$ can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

Note that, for large a, exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments `x` to `f` rather than to compute exact results `f(x)` and convert them via float. Cf. "Example 4" on page 30-190.

Note that stats::gammaCDF(a, b) = stats::erlangCDF(a, 1/b)stats::gammaCDF(a, b) = stats::erlangCDF(a, $\frac{1}{b}$).

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure generated by `stats::gammaCDF` reacts to properties of identifiers set via assume.

Examples

Example 1

We evaluate the cumulative distribution function with $a = 2$ and $b = 1$ at various points:
f := stats::gammaCDF(2, 1): f(-infinity), f(-3), f(0.5), f(2/3), f(PI), f(infinity)0, 0, 0.09020401043, 1 - (5*exp(-2/3))/3, 1 - exp(-PI)*(PI + 1), 1

$$0,\ 0,\ 0.09020401043,\ 1-\frac{5\,e^{-\frac{2}{3}}}{3},\ 1-e^{-\pi}\,(\pi+1),\ 1$$

delete f:

Example 2

If `x` is a symbolic object without properties, then it cannot be decided whether $x \geq 0$ holds. A symbolic function call is returned:
f := stats::gammaCDF(a, b): f(x)stats::gammaCDF(a, b)(x)

stats::gammaCDF(a, b)(x)

With suitable properties, it can be decided whether $x \geq 0$ holds. An explicit expression is returned:
assume(0 <= x): f(x)1 - igamma(a, x/b)/gamma(a)

$1 - \frac{\Gamma(a, \frac{x}{b})}{\Gamma(a)}$
unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::gammaCDF(a, b): f(x)stats::gammaCDF(a, b)(x)

$\text{stats::gammaCDF}(a, b)(x)$

When numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
a := 2: b := 4: f(3), f(3.0)1 - (7*exp(-3/4))/4, 0.1733585327

$1 - \frac{7\,e^{-\frac{3}{4}}}{4}$, 0.1733585327
delete f, a, b:

Example 4

We consider a gamma distribution with large shape parameter:
f := stats::gammaCDF(2000, 2):

For floating-point approximations, one should not compute an exact result and convert it via float. For large shape parameter, it is faster to pass a floating-point argument to `f`. The following call takes some time, because an exact computation of the huge integer gamma(2000) = 1999!$\Gamma(2000) = 1999!$ is involved:
float(f(4010))0.5474266776

0.5474266776

The following call is much faster:
f(float(4010))0.5474266776

0.5474266776
delete f:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

stats::gammaPDF

Purpose

Probability density function of the gamma distribution

Syntax

```
stats::gammaPDF(a, b)
```

Description

`stats::gammaPDF(a, b)` returns a procedure representing the probability density function

x->piecewise([x>0, 1/(b^a*gamma(a))*x^(a-1)*exp(-t*b)], [x<=0, 0])

$$x \to \begin{cases} \frac{1}{b^a\,\Gamma(a)}\,x^{a-1}\,e^{-t\,b} & \text{if } x > 0 \\ 0 & \text{if } x \le 0 \end{cases}$$

of the gamma distribution with shape parameter $a > 0$ and scale parameter $b > 0$.

The procedure `f:=stats::gammaPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \le 0$ can be decided, then `f(x)` returns 0. If $x > 0$ can be decided, then `f(x)` returns the value (x^(a - 1)*exp^(-x/b)/b^a)*(1/gamma(a)) $\frac{x^{a-1}}{\frac{\exp^{x/b}}{b^a}}\,\frac{1}{\Gamma(a)}$.

If x is a floating-point number and both a and b can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \le 0$ or $x \ge 0$, the corresponding values are returned.

`f(- infinity )` and `f( infinity )` return 0.

`f(x)` returns the symbolic call `stats::gammaPDF(a, b)(x)` if neither $x \le 0$ nor $x > 0$ can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

Note that, for large a, exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments `x` to `f` rather than to compute exact results `f(x)` and convert them via float. Cf. "Example 4" on page 30-194.

Note that stats::gammaPDF(a, b) = stats::erlangPDF(a, 1/b)stats::gammaPDF(a, b) = stats::erlangPDF(a, $\frac{1}{b}$).

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure generated by `stats::gammaPDF` reacts to properties of identifiers set via assume.

Examples

Example 1

We evaluate the probability density function with $a = 2$ and $b = 1$ at various points:
f := stats::gammaPDF(2, 1): f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)0, 0, exp(-1/2)/2, 0.3032653299, PI*exp(-PI), 0

$$0,\ 0,\ \frac{e^{-\frac{1}{2}}}{2},\ 0.3032653299,\ \pi\, e^{-\pi},\ 0$$

delete f:

Example 2

If `x` is a symbolic object without properties, then it cannot be decided whether $x \geq 0$ holds. A symbolic function call is returned:
f := stats::gammaPDF(a, b): f(x)stats::gammaPDF(a, b)(x)

$$\text{stats::gammaPDF}(a,\ b)(x)$$

With suitable properties, it can be decided whether $x \geq 0$ holds. An explicit expression is returned:
assume(0 < x): f(x)(x^(a - 1)*exp(-x/b))/(b^a*gamma(a))

$$\frac{x^{a-1}\,e^{-\frac{x}{b}}}{b^a\,\Gamma(a)}$$

unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::gammaPDF(a, b): f(x), f(3)stats::gammaPDF(a, b)(x), (3^(a - 1)*exp(-3/b))/(b^a*gamma(a))

$$\text{stats::gammaPDF}(a,\ b)(x),\ \frac{3^{a-1}\,e^{-\frac{3}{b}}}{b^a\,\Gamma(a)}$$

When numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical results:
a := 2: b := 4: f(3), f(3.0)(3*exp(-3/4))/16, 0.08856872864

$$\frac{3\,e^{-\frac{3}{4}}}{16},\ 0.08856872864$$

delete a, b, f:

Example 4

We consider a gamma distribution with large shape parameter:
f := stats::gammaPDF(2000, 2):

For floating-point approximations, one should not compute an exact result and convert it via float. For large shape parameter, it is faster to pass a floating-point argument to `f`. The following call takes some time, because an exact computation of the huge integer gamma(2000) = 1999!$\Gamma(2000) = 1999!$ is involved:
float(f(4050))0.00377271215

$$0.00377271215$$

The following call is much faster:

f(float(4050))0.00377271215

delete f:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

gammaigammastats::erlangCDFstats::erlangPDFstats::erlangQuantilestats::erlangRando

stats::gammaQuantile

Purpose

Quantile function of the gamma distribution

Syntax

```
stats::gammaQuantile(a, b)
```

Description

`stats::gammaQuantile(a, b)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::gammaCDF(a, b)`. For $0 \le x \le 1$, the solution of *stats*::*gammaCDF*(*a*, *b*)(*y*) = *x* is given by *y* = *stats*::*gammaQuantile*(*a*, *b*)(*x*).

The procedure `f:=stats::gammaQuantile(a, b)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number, *infinity*, or a symbolic expression:

If `x` is a real number between 0 and 1 and `a` and `b` can be converted to positive floating-point numbers, then `f(x)` returns a positive floating-point number approximating the solution *y* of *stats*::*gammaCDF*(*a*, *b*)(*y*) = *x*.

The calls `f(0)` and `f(0.0)` produce 0.0 for all values of `a` and `b`.

The calls `f(1)` and `f(1.0)` produce *infinity* for all values of `m`.

In all other cases, `f(x)` returns the symbolic call `stats::gammaQuantile(a, b)(x)`.

Numerical values of *x* are only accepted if $0 \le x \le 1$.

Numerical values of `a` and `b` are only accepted if they are real and positive.

Note that stats::gammaQuantile(a, b) = stats::erlangQuantile(a, 1/b)$\mathrm{stats::gammaQuantile}(a, b) = \mathrm{stats::erlangQuantile}(a, \frac{1}{b})$.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with $a = \pi$ and $b = 11$ at various points:
f := stats::gammaQuantile(PI, 11): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)0.0, 13.08489993, 30.96813726, 324.7230043, infinity

$$0.0,\ 13.08489993,\ 30.96813726,\ 324.7230043,\ \infty$$

The value `f(x)` satisfies $stats::gammaCDF(\pi, 11)(f(x)) = x$:
stats::gammaCDF(PI, 11)(f(0.987654))0.987654

$$0.987654$$

delete f:

Example 2

We use symbolic arguments:
f := stats::gammaQuantile(a, b): f(x), f(9/10)stats::gammaQuantile(a, b)(x), stats::gammaQuantile(a, b)(9/10)

$$\text{stats::gammaQuantile}(a,\ b)(x),\ \text{stats::gammaQuantile}(a,\ b)\left(\frac{9}{10}\right)$$

When positive real values are assigned to `a` and `b`, the function `f` starts to produce floating-point values:
a := 17: b := 6: f(0.999), f(1 - sqrt(2)/10^5)195.7416524, 240.0294477

$$195.7416524,\ 240.0294477$$

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)100.0071221

$$100.0071221$$

f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, a, b:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::erlangCDFstats::erlangPDFstats::erlangQuantilestats::erlangRandomstats::gammaCDI

stats::gammaRandom

Purpose

Generate a random number generator for gamma deviates

Syntax

```
stats::gammaRandom(a, b, <Seed = n>)
```

Description

`stats::gammaRandom(a, b)` returns a procedure that produces gamma deviates (random numbers) with shape parameter $a > 0$ and scale parameter $b > 0$.

The procedure `f:=stats::gammaRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` and `b` can be converted to positive floating-point numbers, then `f()` returns a nonnegative floating-point number.

In all other cases, `stats::gammaRandom(a, b)()` is returned symbolically.

Numerical values of `a` and `b` are only accepted if they are real and positive.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the gamma distribution with parameters a and b. For any $0 \le x$, the probability that $X \le x$ is given by

```
1/(b^a*gamma(a))*int(t^(a-1)*exp(-b*t), t=0..x)
```

$$\frac{1}{b^a\,\Gamma(a)}\int_0^x t^{a-1}\,e^{-b\,t}\,dt$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::gammaRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::gammaRandom(a, b):  f() $k = 1..K;
```

rather than by

```
stats::gammaRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::gammaRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Note that stats::gammaRandom(a, b) = stats::erlangRandom(a, 1/b)$\text{stats::gammaRandom}(a, b) = \text{stats::erlangRandom}(a, \frac{1}{b})$.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate gamma deviates with parameters a = 2 and b=4/3$b = \frac{4}{3}$:
f := stats::gammaRandom(2, 4/3): f() $ k = 1..43.958784095, 3.891811185, 6.046842446, 3.142485711

```
3.958784095, 3.891811185, 6.046842446, 3.142485711
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::gammaRandom(a, b): f()stats::gammaRandom(a, b)()

```
stats::gammaRandom(a, b)()
```

When a and b evaluate to positive real numbers, the result is evaluated to a real floating point number:
a := PI: b := 8: f() $ k = 1..419.74371462, 12.37357049, 13.40137346, 29.97534861

```
19.74371462, 12.37357049, 13.40137346, 29.97534861
```

delete f, a, b:

Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:
f := stats::gammaRandom(PI, 1/3, Seed = 10^3): f() $ k = 1..40.3631090007, 0.8803177461, 0.9712460319, 1.740056499

```
0.3631090007, 0.8803177461, 0.9712460319, 1.740056499
```

g := stats::gammaRandom(PI, 1/3, Seed = 10^3): g() $ k = 1..40.3631090007, 0.8803177461, 0.9712460319, 1.740056499

```
0.3631090007, 0.8803177461, 0.9712460319, 1.740056499
```

f() = g(), f() = g()1.561212345 = 1.561212345, 0.4650866732 = 0.4650866732

```
1.561212345 = 1.561212345, 0.4650866732 = 0.4650866732
```

delete f:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm for the computation of gamma deviates uses a rejection method applied to uniform random numbers. For more information see: D. Knuth, Seminumerical Algorithms (1998), Vol. 2, pp. 133.

stats::geometricMean

Purpose

Geometric mean of a data sample

Syntax

```
stats::geometricMean(x1, x2,  )
stats::geometricMean([x1, x2,  ])
stats::geometricMean(s, <c>)
```

Description

`stats::geometricMean(x1, x2,  , xn)` returns the geometric mean fenced(x[1]*x[2]* dots * x[n])^(1/n)$(x_1\ x_2\ \ldots\ x_n)^{1/n}$ of the data x_i.

The column index `c` is optional, if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-204.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the geometric mean of three values:
stats::geometricMean(a, b, c)(a*b*c)^(1/3)

$$(a\ b\ c)^{1/3}$$

Alternatively, the data may be passed as a list:
stats::geometricMean([2, 3, 5])30^(1/3)

$$30^{1/3}$$

Example 2

We create a sample:
stats::sample([[a1, b1, c1], [a2, b2, c2]]) a1 b1 c1 a2 b2 c2

The geometric mean of the second column is:
stats::geometricMean(%, 2)sqrt(b1*b2)

$\sqrt{b1\ b2}$

Example 3

We create a sample consisting of one string column and one non-string column:
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]]) "1996" 1242 "1997" 1353 "1998" 1142

We compute the geometric mean of the second column. In this case this column does not have to be specified, since it is the only non-string column in the sample:
float(stats::geometricMean(%))1242.68722

1242.68722

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions.

s

A sample of domain type stats::sample.

c

An integer representing a column index of the sample `s`. This column provides the data `x1`, `x2` etc.

Return Values

arithmetical expression.

See Also

stats::harmonicMeanstats::meanstats::medianstats::modalstats::quadraticMeanstats::stdevst

stats::geometricCDF

Purpose

The (discrete) cumulative distribution function of the geometric distribution

Syntax

```
stats::geometricCDF(p)
```

Description

`stats::geometricCDF(p)` returns a procedure representing the (discrete) cumulative distribution function

x->piecewise([x<1, 0], [x>=1, 1-(1-p)^floor(x)])

$$x \to \begin{cases} 0 & \text{if } x < 1 \\ 1-(1-p)^{\lfloor x \rfloor} & \text{if } x \geq 1 \end{cases}$$

of the geometric distribution with 'probability parameter' `p`.

The procedure `f:=stats::geometricCDF(p)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a number or a symbolic expression:

If $x < 1$ can be decided, then `f(x)` returns 0. If $x \geq 1$ can be decided, then `f(x)` returns the value 1 - (1-p)^floor(x)$1-(1-p)^{\lfloor x \rfloor}$.

If x is a floating-point number and p can be converted to a floating-point number, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x < 1$ or $x \geq 1$, the corresponding values are returned.

`f(x)` returns the symbolic call `stats::geometricCDF(p)(x)` if neither $x < 1$ nor $x \geq 1$ can be decided.

If $p = 0$ or $p = 0.0$, then $f(x)$ returns 0 or 0.0, respectively, for any value of x.

Numerical values for `p` are only accepted if they satisfy $0 \leq p \leq 1$.

If x is a real floating-point number, $f(x)$ produces a floating number provided p is a numerical value. If x is an exact numerical value, no internal floating-point conversion of the parameter p is attempted.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the distribution function with p=1/3$p = \frac{1}{3}$ at various points:
f := stats::geometricCDF(1/3): f(-PI) = f(float(-PI)), f(1) = f(1.0), f(103/10) = f(10.3)0 = 0.0, 1/3 = 0.3333333333, 58025/59049 = 0.9826584701

$$0 = 0.0,\ \frac{1}{3} = 0.3333333333,\ \frac{58025}{59049} = 0.9826584701$$

delete f:

Example 2

If x is a symbolic object without properties, then it cannot be decided whether $x \geq 1$ holds. A symbolic function call is returned:
f := stats::geometricCDF(p): f(x)stats::geometricCDF(p)(x)

$$\text{stats::geometricCDF}(p)(x)$$

With suitable properties, it can be decided whether $x \geq 1$ holds. An explicit expression is returned:
assume(1 <= x): f(x)1 - (1 - p)^floor(x)

$$1 - (1 - p)^{\lfloor x \rfloor}$$

unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::geometricCDF(p): f(x)stats::geometricCDF(p)(x)

stats::geometricCDF(*p*)(*x*)

If x is a numerical value, symbolic expressions in p are returned:
f(-1), f(1), f(5/2), f(PI)0, p, 1 - (p - 1)^2, (p - 1)^3 + 1

$0, p, 1-(p-1)^2, (p-1)^3+1$

When numerical values are assigned to *p*, the function *f* starts to produce numbers if the argument is numerical:
p := 1/3: f(-1), f(1), f(5/2), f(PI)0, 1/3, 5/9, 19/27

$0, \frac{1}{3}, \frac{5}{9}, \frac{19}{27}$

delete f, p:

Parameters

p

The 'probability parameter': an arithmetical expression representing a real number $0 \le p \le 1$.

Return Values

procedure.

Algorithms

The geometric distribution describes the number of Bernoulli trials with success probability *p* up to and including the first success.

See Also

stats::geometricPFstats::geometricQuantilestats::geometricRandom

stats::geometricPF

Purpose

Probability function of the geometric distribution

Syntax

```
stats::geometricPF(p)
```

Description

`stats::geometricPF(p)` returns a procedure representing the probability function

x -> p * (1-p)^(x-1)

$$x \mapsto p\,(1-p)^{x-1}$$

for $x = 1, 2, 3, \ldots$ of the geometric distribution with 'probability parameter' `p`.

The procedure `f:=stats::geometricPF(p)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a number or a symbolic expression:

If `x` is a non-integer numerical value, $f(x)$ returns 0 or 0.0, respectively.

If `x` is a positive integer or the floating point equivalent of such an integer, then an explicit value is returned.

In all other cases, `f(x)` returns the symbolic call `stats::geometricPF(n,p)(x)`.

Numerical values for `p` are only accepted if they satisfy $0 \le p \le 1$.

If `x` is a floating-point number, the result is a floating-point number provided p can be converted to a floating-point number between 0.0 and 1.0. If `x` is an exact numerical value, no internal floating point conversion of the parameter p is attempted.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We calculate the geometric probability with p=1/8$p = \frac{1}{8}$ at various points:
f := stats::geometricPF(1/8): f(-1), f(0.5), f(1), f(3/2), f(3) = f(float(3))0, 0.0, 1/8, 0, 49/512 = 0.095703125

$$0,\ 0.0,\ \frac{1}{8},\ 0,\ \frac{49}{512} = 0.095703125$$

delete f:

Example 2

We use symbolic arguments:
f := stats::geometricPF(p): f(x)stats::geometricPF(p)(x)

$$\text{stats::geometricPF}(p)(x)$$

If x is a numerical value, symbolic expressions in p are returned:
f(17/2), f(8), f(9.0), f(9.2)0, -p*(p - 1)^7, p*(1.0 - 1.0*p)^8.0, 0.0

$$0,\ -p\,(p-1)^{7},\ p\,(1.0-1.0\,p)^{8.0},\ 0.0$$

When numerical values are assigned to p, the function f starts to produce numbers if the argument is numerical:
p := 1/3: f(17/2), f(8), f(9.0), f(9.2)0, 128/6561, 0.01300614744, 0.0

$$0,\ \frac{128}{6561},\ 0.01300614744,\ 0.0$$

delete f, p:

Parameters

p

The 'probability parameter': an arithmetical expression representing a real number $0 \le p \le 1$.

Return Values

procedure.

See Also stats::geometricCDFstats::geometricQuantilestats::geometricRandom

stats::geometricQuantile

Purpose

Quantile function of the geometric distribution

Syntax

```
stats::geometricQuantile(p)
```

Description

`stats::geometricQuantile(p)` returns a procedure representing the quantile function (discrete inverse) of the cumulative distribution function `stats::geometricCDF(p)`. For $0 \le x \le 1$, k = *stats*::*geometricQuantile*(p)(x) is the smallest positive integer satisfying

stats::geometricCDF(p)(k)=1-(1-p)^k>=x

$$\text{stats::geometricCDF}(p)(k) = 1 - (1-p)^k \ge x$$

The procedure `f:=stats::geometricQuantile(p)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of the call `f(x)` is either a positive integer, *infinity*, or a symbolic expression:

If p is a real number satisfying $0 < p \le 1$ and x is a real number satisfying $0 \le x < 1$, then $f(x)$ returns a positive integer.

If $p = 0$, then $f(x)$ returns *infinity* for any x.

If $p = 1$, then $f(x)$ returns 1 for any x.

If $p \ne 0$, then $f(0)$ and $f(0.0)$ return 1.

If $p \ne 1$, then $f(1)$ and $f(1.0)$ return *infinity*.

In all other cases, `f(x)` returns the symbolic call `stats::geometricQuantile(p)(x)`.

Numerical values for `p` are only accepted if they satisfy $0 \le p \le 1$.

If floating-point arguments are passed to the quantile function f, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors. In particular, round-off may be significant for arguments x close to 1. Cf. “Example 3” on page 30-213.

Finite quantile values k = *stats*::*geometricQuantile*(p)(x) satisfy

stats::geometricCDF(p)(k - 1) < x <= stats::geometricCDF(p)(k)

$$\text{stats::geometricCDF}(p)(k-1) < x \le \text{stats::geometricCDF}(p)(k)$$

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with p=1/PI$p = \frac{1}{\pi}$ at various points:
f := stats::geometricQuantile(1/PI): f(0), f(1/20), f(PI/6), f(0.7), f(1-1/10^10), f(1)1, 1, 2, 4, 61, infinity

$$1,\ 1,\ 2,\ 4,\ 61,\ \infty$$

The value `f(x)` satisfies

stats::geometricCDF(p)(f(x) -1) < x <= stats::geometricCDF(p)(f(x))

$$\text{stats::geometricCDF}(p)(f(x)-1) < x \le \text{stats::geometricCDF}(p)(f(x))$$

x := 0.98: k := f(x)11

$$11$$

float(stats::geometricCDF(1/PI)(k - 1)), x, float(stats::geometricCDF(1/PI)(k))0.9783294488, 0.98, 0.9852273995

$$0.9783294488,\ 0.98,\ 0.9852273995$$

delete f, x, k:

Example 2

We use symbolic arguments:
f := stats::geometricQuantile(p): f(x), f(9/10)stats::geometricQuantile(p)(x), stats::geometricQuantile(p)(9/10)

stats::geometricQuantile(*p*)(*x*), stats::geometricQuantile(*p*)$\left(\frac{9}{10}\right)$

When p evaluates to a suitable real number, the function f starts to produce quantile values:
p := 1/sqrt(2): f(1/2), f(999/1000), f(1 - 1/10^10), f(1 - 1/10^80)1, 6, 19, 151

1, 6, 19, 151

delete f, p:

Example 3

If floating-point arguments are passed to the quantile function, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors:
f := stats::geometricQuantile(1/123): f(1 - 1/10^19) <> f(float(1 - 1/10^19))5360 <> infinity

5360 ≠ ∞

delete f:

Parameters

p

The “probability parameter”: an arithmetical expression representing a real number $0 \le p \le 1$.

Return Values

procedure.

See Also

stats::geometricCDFstats::geometricPFstats::geometricRandom

stats::geometricRandom

Purpose

Generate a random number generator for geometric deviates

Syntax

```
stats::geometricRandom(p, <Seed = s>)
```

Description

`stats::geometricRandom(p)` returns a procedure that produces geometric deviates (random numbers) with 'probability parameter' `p`.

The procedure `f:=stats::geometricRandom(p)` can be called in the form `f()`. The return value of `f()` is a positive integer if `p` is a real number satisfying $0 \le p \le 1$.

Otherwise, `stats::geometricRandom(p)()` is returned symbolically.

Numerical values for `p` are only accepted if they satisfy $0 \le p \le 1$.

The values $X = f()$ are distributed randomly according to the discrete distribution function of the geometric distribution with parameter p, i.e., for $1 \le x$, the probability of $X \le x$ is given by 1-(1-p)^floor(x)$1 - (1 - p)^{\lfloor x \rfloor}$.

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note With this option, the parameter `p` must evaluate to a numerical value at the time, when the generator is created.

Note In contrast to the function random, the generators produced by `stats::geometricRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::geometricRandom(p):  f() $k = 1..K;
```

rather than by

```
stats::geometricRandom(p)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::geometricRandom(p, Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate geometric deviates with p=1/3$p = \frac{1}{3}$:
f := stats::geometricRandom(1/3): f() $ k = 1..10
4, 1, 5, 1, 1, 4, 5, 2, 1, 3, 1

```
4, 1, 5, 1, 1, 4, 5, 2, 1, 3, 1
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::geometricRandom(p): f()stats::geometricRandom(p)()

```
stats::geometricRandom(p)()
```

When p evaluates to a real number between 0 and 1, the generator starts to produce random numbers:
p := 1/sqrt(70): f(), f(), f()3, 6, 2

```
3, 6, 2
```

delete f, p:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:
f := stats::geometricRandom(1/10, Seed = 1): f() $ k = 1..106, 3, 21, 17, 2, 55, 7, 16, 26, 11

```
6, 3, 21, 17, 2, 55, 7, 16, 26, 11
```

g := stats::geometricRandom(1/10, Seed = 1): g() $ k = 1..106, 3, 21, 17, 2, 55, 7, 16, 26, 11

```
6, 3, 21, 17, 2, 55, 7, 16, 26, 11
```

f() = g(), f() = g()9 = 9, 8 = 8

```
9 = 9, 8 = 8
```

delete f, g:

Parameters

p

The "probability parameter": an arithmetical expression representing a real number $0 \le p \le 1$.

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameter p must be convertible to a floating-point number between 0.0 and 1.0 at the time when the random generator is generated.

Return Values procedure.

See Also stats::geometricCDFstats::geometricPFstats::geometricQuantile

stats::harmonicMean

Purpose

Harmonic mean of a data sample

Syntax

```
stats::harmonicMean(x1, x2,  )
stats::harmonicMean([x1, x2,  ])
stats::harmonicMean(s, <c>)
```

Description

`stats::harmonicMean(x1, x2,  , xn)` returns the harmonic mean

fenced(1/n * sum(1/x[i], i))^(-1) $\left(\frac{1}{n}\left(\sum \frac{1}{x_i}\right)\right)^{-1}$ of the data x_i.

The column index `c` is optional, if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-219.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the harmonic mean of three values:
stats::harmonicMean(a, b, c)3/(1/a + 1/b + 1/c)

$$\frac{3}{\frac{1}{a}+\frac{1}{b}+\frac{1}{c}}$$

Alternatively, data may be passed as a list:
stats::harmonicMean([2, 3, 5])90/31

$$\frac{90}{31}$$

Example 2

We create a sample:
stats::sample([[a1, b1, c1], [a2, b2, c2]]) a1 b1 c1 a2 b2 c2

The harmonic mean of the second column is:

stats::harmonicMean(%, 2)2/(1/b1 + 1/b2)

$$\frac{2}{\frac{1}{b1}+\frac{1}{b2}}$$

Example 3

We create a sample consisting of one string column and one non-string column:
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]]) "1996" 1242 "1997" 1353 "1998" 1142

We compute the harmonic mean of the second column. In this case this column does not have to be specified, since it is the only non-string column:
float(stats::harmonicMean(%))1239.71654

1239.71654

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions.

s

A sample of domain type stats::sample.

c

An integer representing a column index of the sample *s*. This column provides the data x_1, x_2 etc.

Return Values

arithmetical expression. `FAIL` is returned, if one of the data values is zero (the harmonic mean does not exist).

See Also

stats::geometricMeanstats::meanstats::medianstats::modalstats::quadraticMeanstats::std

stats::hodrickPrescottFilter

Purpose

The Hodrick-Prescott filter

Syntax

```
stats::hodrickPrescottFilter([x1, x2,  ], p)
stats::hodrickPrescottFilter(s, <c>, p)
```

Description

`stats::hodrickPrescottFilter([x1, x2,  ], p)` returns a list of data from which cyclic variations of the time series given by the input data x_1, x_2 etc. are eliminated using the Hodrick-Prescott filter process.

The Hodrick-Prescott filter scheme tries to split a time series consisting of the data x_1, x_2 etc. into a "trend" that is approximately linear in time plus a "cyclic" contribution. The data returned by `stats::hodrickPrescottFilter` describe the trend. The cyclic part c may be computed by

```
x := [x1, x2, ...]:
y := stats::HodrickPrescottFilter(x, p):
c := zip(x, y, _subtract):
```

Thus, $x_i = y_i + c_i$.

Large values of the penalty parameter p lead to smooth straight trend curves. Cf. "Example 5" on page 30-224.

If the data are provided by a stats::sample object containing only one non-string column, the column index `c` is optional. Cf. "Example 3" on page 30-221.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We apply the Hodrick-Prescott filter to some data. The result shows an obvious trend towards increasing data values:

stats::hodrickPrescottFilter([1, 2, 3, 2, 3, 4, 3, 4, 5], 10)[1.356447588, 1.819582682, 2.247073017, 2.621315566, 3.0, 3.378684434, 3.752926983, 4.180417318, 4.643552412]

[1.356447588, 1.819582682, 2.247073017, 2.621315566, 3.0, 3.378684434, 3.752926983, 4.18

Example 2

We create a sample:
s := stats::sample([[i + frandom() - 0.5, -i + frandom() - 0.5] $ i = 1..10])
0.7703581656 -0.6689628213 1.653156516 -1.505187219 2.766272902 -3.319835772 3.952083055 -3.821218044 4.854984926 -4.818141187 6.221918655 -6.026170226 7.288981492 -7.288474164 8.355687175 -8.455102606 9.379160127 -8.580615152 10.23505742 -9.712454973

The Hodrick-Prescott filter process applied to the data in the first column yields:
p := 10: stats::hodrickPrescottFilter(s, 1, p)[0.7163345093, 1.721715792, 2.781120731, 3.880013706, 4.989011271, 6.150799324, 7.274037423, 8.338504453, 9.338923372, 10.28719986]

[0.7163345093, 1.721715792, 2.781120731, 3.880013706, 4.989011271, 6.150799324, 7.2740
10.28719986]

-8.896213527, -9.700312476]

delete s, p:

Example 3

We create a sample consisting of one string column and one non-string column:

s := stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142], ["1999", 1255], ["2000", 1417], ["2001", 1312], ["2002", 1440], ["2003", 1422], ["2004", 1470]]) "1996" 1242 "1997" 1353 "1998" 1142 "1999" 1255 "2000" 1417 "2001" 1312 "2002" 1440 "2003" 1422 "2004" 1470

We apply the Hodrick-Prescott filter to the second column. In this case, this column needs not be specified, since it is the only non-string column:
y := stats::hodrickPrescottFilter(s, 10)[1239.848378, 1255.015604, 1270.397993, 1296.009146, 1329.022865, 1362.512038, 1398.347268, 1433.347951, 1468.498758]

[1239.848378, 1255.015604, 1270.397993, 1296.009146, 1329.022865, 1362.512038, 1398.347268

We convert this list to a sample object:
y := stats::sample(y) 1239.848378 1255.015604 1270.397993 1296.009146 1329.022865 1362.512038 1398.347268 1433.347951 1468.498758

We create a new sample consisting of the filtered data:
stats::concatCol(stats::col(s, 1), y) "1996" 1239.848378 "1997" 1255.015604 "1998" 1270.397993 "1999" 1296.009146 "2000" 1329.022865 "2001" 1362.512038 "2002" 1398.347268 "2003" 1433.347951 "2004" 1468.498758 delete s, y:

Example 4

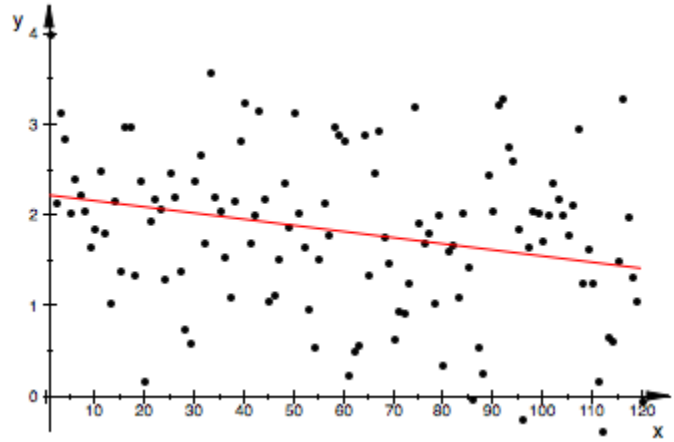
We model monthly data with a decaying trend of

1/fenced(1+0.01*i) $\frac{1}{(1+0.01\,i)}$, where *i* is the index of the month.
These trend data are obscured by cyclic contributions and random noise:
monthlyData:= i -> (1/(1 + 0.01*i) // the trend + 0.7*cos(i * 1.12*2*float(PI)) // cycle + 0.3*sin(i * 2.04*4*float(PI)) // cycle + 0.2*cos(i * 1.01*6*float(PI)) // cycle + 2.3*frandom() // random noise):

We provide monthly data for 10 years, i.e., 120 months. The cyclic contributions and the noise are eliminated from the time series by the Hodrick-Prescott filter process:
n := 120: x := [monthlyData(i) $ i = 1..n]: trend := stats::hodrickPrescottFilter(x, 10^5): cycle := zip(x, trend, _subtract):

We visualize the splitting of the time series (black) into the approximately linear trend contribution (red) plus the cyclic part (blue):
plot(plot::Listplot([[i, x[i]] $ i = 1..n], Color = RGB::Black), plot::Listplot([[i, trend[i]] $ i = 1..n], Color = RGB::Red), plot::Listplot([[i, cycle[i]] $ i = 1..n], Color = RGB::Blue))

We use a scatterplot to visualize a linear regression of the unfiltered data. The regression line is in good accordance with the trend line above:
plot(plot::Scatterplot([[i, x[i]] $ i = 1..n]))

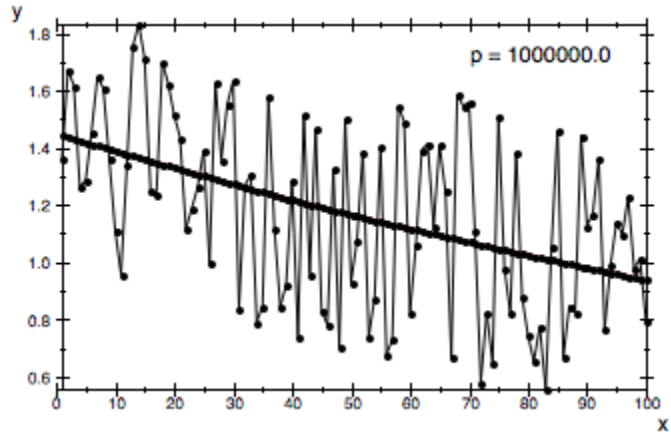


delete monthlyData, n, x, trend, cycle:

Example 5

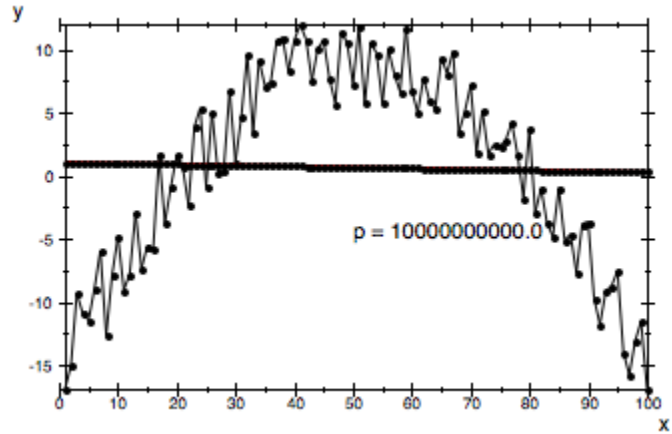
We demonstrate the effect of the penalty parameter *p* by an animated plot:

```
delete p: n := 100: data := [1/(1 + 0.01*i) + frandom() $ i = 1..n]: for
i from 0 to 30 step 1/5 do trend := stats::hodrickPrescottFilter(data,
10^(0.2*i)); L[i] := plot::Listplot([[i, trend[i]] $ i = 1..n], Color =
RGB::Red, VisibleFromTo = i .. i + 0.2); T[i] := plot::Text2d(expr2text(p
= 10^(0.2*i)), [70, 1.7], VisibleFromTo = i .. i + 0.2); end_for:
plot(plot::Listplot([[i, data[i]] $ i= 1..n], Color=RGB::Black), L[i] $ i =
0..30 step 1/5, T[i] $ i = 0..30 step 1/5)
```



Large penalty parameters *p* result in trend curves that are close to a straight line. This is not always the desired information. The following animation features a time series with a parabolic trend curve obscured by random noise. Too large values of *p* produce a trend curve that just displays the mean of the data:

```
data := [8*frandom() + 5 - (i - 50)^2/100 $ i = 1..n]: for i from 0 to
50 do trend := stats::hodrickPrescottFilter(data, 10^(0.2*i)); L[i] :=
plot::Listplot([[i, trend[i]] $ i = 1..n], Color = RGB::Red, VisibleFromTo
= i/5 .. (i + 1)/5); T[i] := plot::Text2d(expr2text(p = 10^(0.2*i)), [50, -5],
VisibleFromTo = i/5 .. (i + 1)/5); end_for: plot(plot::Listplot([[i, data[i]] $
i= 1..n], Color=RGB::Black), L[i] $ i = 0..50, T[i] $ i = 0..50)
```



delete n, data, i, trend, L, T:

Parameters

x_1, x_2, ...

The statistical data (time series): arithmetical expressions.

s

A sample of domain type stats::sample.

c

An integer representing a column index of the sample *s*. This column provides the data x_1, x_2 etc.

p

The penalty parameter of the Hodrick-Prescott scheme: a real positive numerical value.

If the data x_1, x_2 etc. represent monthly measurements, the literature recommends values of p between 1000 and 1400.

If the data represent quaterly measurements, values of p around 1600 are recommended.

If the data represent yearly measurements, values of p between 6 and 14 are recommended.

Return Values

List of floating-point data.

stats::linRegstats::regplot::Listplotplot::Scatterplot

stats::hypergeometricCDF

Purpose

The (discrete) cumulative probability function of the hypergeometric distribution

Syntax

```
stats::hypergeometricCDF(N, X, n)
```

Description

`stats::hypergeometricCDF(N, X, n)` returns a procedure representing the probability function

x->piecewise([x<max(0,n+X-N), 0], [max(0,n+X-N)<=x<=min(n,X), sum(binomial(X,i)*binomial(N-X,n-i)/binomial(N,n), i=max(0,n+X-N)..floor(x))], [x>min(n,X), 1])

$$x \to \begin{cases} 0 & \text{if } x < \max(0,\, n+X-N) \\ \sum_{i=\max(0,\, n+X-N)}^{\lfloor x \rfloor} \frac{\binom{X}{i}\binom{N-X}{n-i}}{\binom{N}{n}} & \text{if } \max(0,\, n+X-N) \le x \le \min(n,\, X) \\ 1 & \text{if } x > \min(n,\, X) \end{cases}$$

of the hypergeometric distribution with "population size" `N`, "success population size" `X` and "sample size" `n`.

The procedure `f:=stats::hypergeometricCDF(N, X, n)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

If `x` is an integer, a rational or a floating point number, while `N` is a positive integer and both `X` and `n` are nonnegative integers, then an explicit numerical value is returned.

The function `f` reacts to properties of identifiers set via assume.

If any of the parameters is symbolic with properties as follows, then 0, 1 or a symbolic result is returned:

If $x < max(0, n + X - N)$, then $f(x) = 0$.

If $x \geq min(n, X)$, then $f(x) = 1$.

If $X = N$, then $f(x) = 0$ for $x < n$ and $f(x) = 1$ for $x \geq n$.

If $n = N$, then $f(x) = 0$ for $x < X$ and $f(x) = 1$ for $x \geq X$.

If $X = N - 1$, then $f(x) = 0$ for $x < n - 1$, f(x) = n/N$f(x) = \frac{n}{N}$ for $n - 1 \leq x < n$ and $f(x) = 1$ for $x \geq n$.

If $n = N - 1$, then $f(x) = 0$ for $x < X - 1$, f(x) = X/N$f(x) = \frac{X}{N}$ for $X - 1 \leq x < X$ and $f(x) = 1$ for $x \geq X$.

If $X = 1$, then f(x) = (N - n)/N$f(x) = \frac{N-n}{N}$ for $0 \leq x < 1$ and $f(x) = 1$ for $x \geq 1$.

If $n = 1$, then f(x) = (N - X)/N$f(x) = \frac{N-X}{N}$ for $0 \leq x < 1$ and $f(x) = 1$ for $x \geq 1$.

If $X = 0$ or $n = 0$, then $f(x) = 1$ for $x \geq 0$.

If `x` and all parameters but `N` are numerical and the assumption on N is `assume(N > X)`, then symbolic values are returned.

`f(x)` returns the symbolic call `stats::hypergeometricCDF(N, X, n)(x)` in all other cases.

Numerical values for `N` are only accepted if they are positive integers.

Numerical values for `X` are only accepted if they are nonnegative integers.

Numerical values for `n` are only accepted if they are nonnegative integers.

Note If `x` is a floating-point number, the result is a floating number provided N, X and n are numerical values. If `x` is an exact value, the result is a rational number.

Note that for large numbers, floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number `x` to `stats::hypergeometricCDF`.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We compute the distribution function with $N = 20$, $X = 4$ and $n = 3$ at various points:
f := stats::hypergeometricCDF(20, 4, 3): f(-1), f(0), f(1/2), f(1), f(2), f(PI), f(5)0, 28/57, 28/57, 52/57, 284/285, 1, 1

$$0, \frac{28}{57}, \frac{28}{57}, \frac{52}{57}, \frac{284}{285}, 1, 1$$

f(-infinity), f(infinity)0, 1

$$0, 1$$

f(-0.2), f(0.0), f(0.7), f(1.0), f(float(PI)), f(4.0)0.0, 0.4912280702, 0.4912280702, 0.9122807018, 1.0, 1.0

$$0.0, 0.4912280702, 0.4912280702, 0.9122807018, 1.0, 1.0$$

delete f:

Example 2

We use symbolic arguments:
f := stats::hypergeometricCDF(N, X, n): f(x), f(8), f(8.0)stats::hypergeometricCDF(N, X, n)(x), stats::hypergeometricCDF(N, X, n)(8), stats::hypergeometricCDF(N, X, n)(8.0)

$$\text{stats::hypergeometricCDF}(N, X, n)(x), \text{stats::hypergeometricCDF}(N, X, n)(8), \text{stats::hypergeometricCDF}(N$$

When real numbers are assigned to N, X and n, the function f starts to produce explicit results if the argument is numerical:
N := 15: X := 6: n := 5: f(0), f(1), f(2.0), f(3.5), f(4)6/143, 42/143, 0.7132867133, 0.953046953, 999/1001

$\frac{6}{143}, \frac{42}{143}, 0.7132867133, 0.953046953, \frac{999}{1001}$

delete f, N, X, n:

Example 3

If one or more parameters are symbolic, usually a symbolic call is returned. Some combinations of symbolic and numeric values for *N*, *X*, *n* and *x*, however, may yield symbolic or numeric results:

f := stats::hypergeometricCDF(N, X, n): X := 1: f(-1), f(0), f(1/2), f(0.5), f(3/2), f(2.0)0, (N - n)/N, (N - n)/N, (N - 1.0*n)/N, 1, 1.0

$0, \frac{N-n}{N}, \frac{N-n}{N}, \frac{N-1.0\,n}{N}, 1, 1.0$

X := N - 1: f(1), f(n-1), f(n)stats::hypergeometricCDF(N, N - 1, n)(1), n/N, 1

$\text{stats::hypergeometricCDF}(N, N-1, n)(1), \frac{n}{N}, 1$

delete X:

Example 4

If *x* and all parameters but *N* are numerical and *N* is assumed to be greater than *X*, a symbolic expression is returned:

X := 6: assume(N > X): f := stats::hypergeometricCDF(N, X, 5): f(1), f(2), f(3)1 - (15*N + 20*binomial(N - 6, 2) + 15*binomial(N - 6, 3) - 84)/binomial(N, 5), 1 - (15*N + 20*binomial(N - 6, 2) - 84)/binomial(N, 5), 1 - (15*N - 84)/binomial(N, 5)

$1 - \frac{15\,N + 20\binom{N-6}{2} + 15\binom{N-6}{3} - 84}{\binom{N}{5}}, 1 - \frac{15\,N + 20\binom{N-6}{2} - 84}{\binom{N}{5}}, 1 - \frac{15\,N - 84}{\binom{N}{5}}$

delete f, N, X:

Parameters

N

The “population size”: an arithmetical expression representing a positive integer

X

The “success population size”: an arithmetical expression representing a nonnegative integer

n

The “sample size”: an arithmetical expression representing a nonnegative integer

Return Values

procedure.

See Also

stats::hypergeometricPFstats::hypergeometricQuantilestats::hypergeometricRandom

stats::hypergeometricPF

Purpose

Probability function of the hypergeometric distribution

Syntax

```
stats::hypergeometricPF(N, X, n)
```

Description

`stats::hypergeometricPF(N, X, n)` returns a procedure representing the probability function

x->binomial(X,x)*binomial(N-X,n-x)/binomial(N,n)

$$x \to \frac{\binom{X}{x}\binom{N-X}{n-x}}{\binom{N}{n}}$$

for x in N_ intersect Interval([max(0, n+X-N)], [min(n, X)]) $x \in \mathbb{N} \cap [\max(0,\ n+X-N),\ \min(n,\ X)]$ of the hypergeometric distribution with "population size" `N`, "success population size" `X` and "sample size" `n`.

The procedure `f:=stats::hypergeometricPF(N, X, n)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

If `x` is a noninteger numerical value, `f(x)` returns 0 or 0.0, respectively.

If `x` is an integer or the floating-point equivalent of an integer, while `N` is a positive integer and both `X` and `n` are nonnegative integers, then an explicit numerical value is returned.

The function `f` reacts to properties of identifiers set via assume.

If any of the parameters is symbolic with properties as follows, then 0, 1 or a symbolic result is returned:

If $X = N$, then $f(x) = 1$ for $x = n$ and $f(x) = 0$ for $x \neq n$. If $n = N$, then $f(x) = 1$ for $x = X$ and $f(x) = 0$ for $x \neq X$.

If $X = N - 1$, then f(x) = (N - n)/N $f(x) = \frac{N-n}{N}$ for $x = n$, f(x) = n/N $f(x) = \frac{n}{N}$ for $x = n - 1$ and $f(x) = 0$ for $x \neq n,\ n - 1$.

If $n = N - 1$, then f(x) = (N - X)/N $f(x) = \frac{N-X}{N}$ for $x = X$, f(x) = X/N $f(x) = \frac{X}{N}$ for $x = X - 1$ and $f(x) = 0$ for $x \neq X, X - 1$.

If $X = 1$, then f(x) = (N - n)/N $f(x) = \frac{N-n}{N}$ for $x = 0$, f(x) = n/N $f(x) = \frac{n}{N}$ for $x = 1$ and $f(x) = 0$ for $x \neq 0, 1$.

If $n = 1$, then f(x) = (N - X)/N $f(x) = \frac{N-X}{N}$ for $x = 0$, f(x) =X/N $f(x) = \frac{X}{N}$ for $x = 1$ and $f(x) = 0$ for $x \neq 0, 1$.

If $X = 0$ or $n = 0$, then $f(x) = 1$ for $x = 0$ and $f(x) = 0$ for $x \neq 0$.

If `x` and all parameters but `N` are numerical and the assumption on `N` is `assume(N > X)`, then symbolic values are returned.

`f(x)` returns the symbolic call `stats::hypergeometricPF(N, X, n)(x)` in all other cases.

Numerical values for `N` are only accepted if they are positive integers.

Numerical values for `X` are only accepted if they are nonnegative integers.

Numerical values for `n` are only accepted if they are nonnegative integers.

Note If `x` is a floating-point number, the result is a floating number provided `N`, `X` and `n` are numerical values. If `x` is an exact value, the result is a rational number.

Note that for large numbers, floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number `x` to `stats::hypergeometricPF`.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We compute the probability function with $N = 20$, $X = 4$ and $n = 3$ at various points:
f := stats::hypergeometricPF(20, 4, 3): f(-infinity), f(0), f(1/2), f(1), f(2), f(4), f(infinity)0, 28/57, 0, 8/19, 8/95, 0, 0

$$0, \frac{28}{57}, 0, \frac{8}{19}, \frac{8}{95}, 0, 0$$

Example 2

We use symbolic arguments:
f := stats::hypergeometricPF(N, X, n): f(x), f(8), f(8.0)stats::hypergeometricPF(N, X, n)(x), stats::hypergeometricPF(N, X, n)(8), stats::hypergeometricPF(N, X, n)(8.0)

stats::hypergeometricPF(*N*, *X*, *n*)(*x*), stats::hypergeometricPF(*N*, *X*, *n*)(8), stats::hypergeometricPF(*N*,

When real numbers are assigned to N, X and n, the function f starts to produce explicit results if the argument is numerical:
N := 15: X := 6: n := 5: f(0), f(1), f(2.0), f(3.5), f(4)6/143, 36/143, 0.4195804196, 0.0, 45/1001

$$\frac{6}{143}, \frac{36}{143}, 0.4195804196, 0.0, \frac{45}{1001}$$

delete f, N, X, n, x:

Example 3

If one or more parameters are symbolic, usually a symbolic call is returned. Some combinations of symbolic and numeric values for N, X, n and x, however, may yield symbolic or numeric results:

```
f := stats::hypergeometricPF(N, X, n): X := 1: f(-1), f(0), f(1), f(3/2), f(2),
f(3)0, (N - n)/N, n/N, 0, 0, 0
```

$$0, \frac{N-n}{N}, \frac{n}{N}, 0, 0, 0$$

```
X := N: f(-1), f(n), f(n + 1)0, 1, 0
```

$$0, 1, 0$$

```
delete f, X:
```

Example 4

If x and all parameters but N are numerical and N is assumed to be greater than X, a symbolic expression is returned:

```
X := 6: assume(N > X): f := stats::hypergeometricPF(N, X, 5): f(2), f(4),
f(5.0)(15*binomial(N - 6, 3))/binomial(N, 5), (15*N - 90)/binomial(N, 5),
6.0/binomial(N, 5.0)
```

$$\frac{15\binom{N-6}{3}}{\binom{N}{5}}, \frac{15N-90}{\binom{N}{5}}, \frac{6.0}{\binom{N}{5.0}}$$

```
delete f, N, X:
```

Parameters

N

The “population size”: an arithmetical expression representing a positive integer

X

The “success population size”: an arithmetical expression representing a nonnegative integer

n

The “sample size”: an arithmetical expression representing a nonnegative integer

Return Values procedure.

See Also stats::hypergeometricCDFstats::hypergeometricQuantilestats::hypergeometricRandom

stats::hypergeometricQuantile

Purpose

Quantile function of the hypergeometric distribution

Syntax

```
stats::hypergeometricQuantile(N, X, n)
```

Description

`stats::hypergeometricQuantile(N, X, n)` returns a procedure representing the quantile function (discrete inverse) of the cumulative distribution function `stats::hypergeometricCDF(N, X, n)`. For $0 \le x \le 1$, k = *stats*::*hypergeometricQuantile*(N, X, n)(x) is the smallest nonnegative integer satisfying

stats::hypergeometricCDF(N, X, n)(k)=sum(binomial(X,i)*binomial(N-X,n-i)/binomial(N,n), i=0..k)>=x

$$\text{stats::hypergeometricCDF}(N, X, n)(k) = \sum_{i=0}^{k} \frac{\binom{X}{i}\binom{N-X}{n-i}}{\binom{N}{n}} \ge x$$

The procedure `f:=stats::hypergeometricQuantile(N, X, n)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a natural number between 0 and $min(X, n)$, or a symbolic expression:

If x is a real number satisfying $0 \le x \le 1$, while `N` is a positive integer and both `X` and `n` are nonnegative integers, then an explicit numerical value is returned.

The function `f` reacts to properties of identifiers set via assume.

If any of the parameters is symbolic, then in some cases a symbolic result will be returned:

0 will be returned if either any of x, n or X is zero or if n = 1 and x<=(N-X)/N$_{x \le \frac{N-X}{N}}$ or if X = 1 and x<=(N-n)/N$_{x \le \frac{N-n}{N}}$.

1 will be returned if n = 1 and x>(N-X)/N$_{x > \frac{N-X}{N}}$ or if X = 1 and x>(N-n)/N$_{x > \frac{N-n}{N}}$.

n will be returned if $X = N - 1$ and x>n/N$_{x > \frac{n}{N}}$ or if $X = N$ and $x > 0$.

X will be returned if $n = N - 1$ and x>X/N$_{x > \frac{X}{N}}$ or if $n = N$ and $x > 0$.

$n - 1$ will be returned if $X = N - 1$ and x=n/N$_{x = \frac{n}{N}}$ provided that n is symbolic, whereas $X - 1$ will be returned if $n = N - 1$ and x=X/N$_{x = \frac{X}{N}}$ provided that X is symbolic.

Finally $min(X, n)$ will be returned if $x = 1$.

The symbolic call `stats::hypergeometricQuantile(N, X, n)(x)` is returned by `f(x)` in all other cases.

Numerical values for `N` are only accepted if they are positive integers.

Numerical values for `X` are only accepted if they are nonnegative integers.

Numerical values for `n` are only accepted if they are nonnegative integers.

If `x` is a floating-point number, the result is a floating number provided N, X and n are numerical values. If `x` is an exact value, the result is a rational number.

Note Note that if floating-point arguments are passed to the quantile function f, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors. In particular, round-off may be significant for arguments x close to 1. Cf. "Example 4" on page 30-241.

The quantile value $k = stats::hypergeometricQuantile(N, X, n)(x)$ satisfies

cdf(k-1)<x<=cdf(k)

$$\mathrm{cdf}(k-1) < x \le \mathrm{cdf}(k)$$

where $cdf = stats::hypergeometricCDF(N, X, n)$.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with $N = 50$, $X = 30$ and $n = 10$ at some points:

```
f := stats::hypergeometricQuantile(50, 30, 10): f(0), f((2/3)^30), f(PI/10), f(0.5), f(1 - 1/10^10)0, 0, 5, 6.0, 10
```

0, 0, 5, 6.0, 10

With *cdf* = *stats*::*hypergeometricCDF*(*N*, *X*, *n*), the quantile value $f(x)$ satisfies the inequalities $cdf(f(x) - 1) < x \le cdf(f(x))$:

```
x := 0.7: f(x)7.0
```

7.0

```
stats::hypergeometricCDF(50, 30, 10)(float(f(x) - 1)), x, stats::hypergeometricCDF(50, 30, 10)(float(f(x)))0.6350317132, 0.7, 0.8609613426
```

0.6350317132, 0.7, 0.8609613426

```
delete f, x:
```

Example 2

We use symbolic arguments:

```
f := stats::hypergeometricQuantile(N, X, n): f(x), f(9/10)stats::hypergeometricQuantile(N, X, n)(x), stats::hypergeometricQuantile(N, X, n)(9/10)
```

stats::hypergeometricQuantile(*N*, *X*, *n*)(*x*), stats::hypergeometricQuantile(*N*, *X*, *n*)$\left(\frac{9}{10}\right)$

When `N`, `X` and `n` evaluate to suitable numbers, the function `f` starts to produce quantile values:

```
N := 500: X := 80: n := 18: f(1/2), f(999/1000), f(1 - 1/10^10), f(1 - 1/10^80)
```

3, 8, 15, 18

```
delete f, N, X, n:
```

Example 3

If one or more parameters are symbolic, usually a symbolic call is returned. Some combinations of symbolic and numeric values for *N*, *X*, *n* and *x*, however, may yield symbolic or numeric results:

```
f := stats::hypergeometricQuantile(N, X, n): f(0), f(1)
```

0, min(*X*, *n*)

```
0, min(X, n)
X := N - 1: f(n/N), f(7/10)
```

n − 1, stats::hypergeometricQuantile(*N*, *N* − 1, *n*)$\left(\frac{7}{10}\right)$

```
n - 1, stats::hypergeometricQuantile(N, N - 1, n)(7/10)
assume(x > n/N): f(0.5), f(x)
```

stats::hypergeometricQuantile(*N*, *N* − 1, *n*)(0.5), *n*

```
stats::hypergeometricQuantile(N, N - 1, n)(0.5), n
delete f, X, x:
```

Example 4

If floating-point arguments are passed to the quantile function, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors:

```
f := stats::hypergeometricQuantile(10000, 2000, 30): f(1 - 1/10^18) <> f(float(1 - 1/10^18))
```

28 ≠ 27.0

```
28 <> 27.0
delete f:
```

Parameters

N

The “population size”: an arithmetical expression representing a positive integer

X

The “success population size”: an arithmetical expression representing a nonnegative integer

n

The “sample size”: an arithmetical expression representing a nonnegative integer

Return Values

procedure.

See Also

stats::hypergeometricCDFstats::hypergeometricPFstats::hypergeometricRandom

stats::hypergeometricRandom

Purpose

Generate a random number generator for hypergeometric deviates

Syntax

```
stats::hypergeometricRandom(N, X, n, <Seed = s>)
```

Description

`stats::hypergeometricRandom(N, X, n)` returns a procedure that produces hypergeometric-deviates (random numbers) with population size `N`, success population size `X` and sample size `n`.

The procedure `f:=stats::hypergeometricRandom(N, X, n)` can be called in the form `f()`.

The return value of `f(x)` is either an integer between $max(0, X + n - N)$ and $min(X, n)$ or a symbolic expression:

If `N` is a positive integer and both `X` and `n` are nonnegative integers, then an explicit numerical value is returned.

If any of the parameters is symbolic, then in some cases numerical or symbolic result will be returned:

0 will be returned if either n or X is zero, n will be returned if $N = X$ and X will be returned if $N = n$.

The symbolic call `stats::hypergeometricRandom(N, X, n)()` is returned in all other cases.

Numerical values for `N` are only accepted if they are positive integers.

Numerical values for `X` and `n` are only accepted if they are integers that satisfy $0 \le X$, $n \le N$.

The values $R = f()$ are distributed randomly according to the hypergeometric distribution with poupulation size `N`, success population size `X` and sample size `n`.

For any $max(0, X + n - N) \le x \le min(X, n)$, the probability of $R \le x$ is given by

sum(binomial(X,i)*binomial(N-X,n-i)/binomial(N,n), i=max(0,n+X-N)..floor(x))

$$\sum_{i=\max(0,\,x+n-N)}^{\lfloor x \rfloor} \frac{\binom{X}{i}\binom{N-X}{n-i}}{\binom{N}{n}}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note With this option, the parameters `N`, `X` and `n` must evaluate to suitable numerical values at the time, when the generator is created.

Note In contrast to the function random, the generators produced by `stats::hypergeometricRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::hypergeometricRandom(N, X, n):  f() $k = 1..K;
```

rather than by

```
stats::hypergeometricRandom(N, X, n)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::hypergeometricRandom(N, X, n, Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate hypergeometric deviates with parameters $N = 100$, $X = 30$, and $n = 7$:
f := stats::hypergeometricRandom(100, 30, 7): f() $ k = 1..102, 2, 6, 2, 2, 3, 0, 3, 4, 4

```
2, 2, 6, 2, 2, 3, 0, 3, 4, 4
```

delete f:

Example 2

With symbolic parameters, no random numbers can be produced:
f := stats::hypergeometricRandom(N, X, n):
f()stats::hypergeometricRandom(N, X, n)()

```
stats::hypergeometricRandom(N, X, n)()
```

When N, X and n evaluate to suitable numbers, the generator starts to produce random numbers:
N := 200: X := 80: n := 20: f() $ k= 1..106, 4, 12, 5, 10, 5, 11, 5, 9, 7

```
6, 4, 12, 5, 10, 5, 11, 5, 9, 7
```

delete f, N, X, n:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:
f := stats::hypergeometricRandom(500, 100, 50, Seed = 1): f() $ k = 1..106, 10, 4, 13, 8, 5, 12, 12, 11, 11

```
6, 10, 4, 13, 8, 5, 12, 12, 11, 11
```

g := stats::hypergeometricRandom(500, 100, 50, Seed = 1): g() $ k = 1..106, 10, 4, 13, 8, 5, 12, 12, 11, 11

```
6, 10, 4, 13, 8, 5, 12, 12, 11, 11
```

f() = g(), f() = g()5 = 5, 10 = 10

```
5 = 5, 10 = 10
```

delete f, g:

Parameters

N

The “population size”: an arithmetical expression representing a positive integer

X

The “success population size”: an arithmetical expression representing a nonnegative integer

n

The “sample size”: an arithmetical expression representing a nonnegative integer

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `N`, `X` and `n` must be numerical values at the time when the random generator is generated.

Return Values

procedure.

See Also stats::hypergeometricCDFstats::hypergeometricPFstats::hypergeometricQuantile

stats::ksGOFT

Purpose

The Kolmogorov-Smirnov goodness-of-fit test

Syntax

```
stats::ksGOFT(x1, x2,  , CDF = f)
stats::ksGOFT([x1, x2,  ], CDF = f)
stats::ksGOFT(s, <c>, CDF = f)
```

Description

`stats::ksGOFT`([x_1, x_2, ...], *CDF* = *f*) applies the Kolmogorov-Smirnov goodness-of-fit test for the null hypothesis: "x_1, x_2, ... is an `f`-distributed sample".

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

An error is raised if any of the data cannot be converted to a real floating-point number.

Let y_1, ..., y_n be the input data x_1, ..., x_n arranged in ascending order. `stats::ksGOFT` returns the list

([PValue1=p1, StatValue1=K1, PValue2=p2, StatValue2=K2])

[PValue1 = p1, StatValue1 = K1, PValue2 = p2, StatValue2 = K2]

containing the following information:

1. `K1` is the Kolmogorov-Smirnov statistic sqrt(n)*max(ImageSet(j/n-f(y[j]), 1<= j<=n))$\sqrt{n}\max(\{\frac{j}{n} - f(y_j) \mid 1 \le j \le n\})$.

2. `p1` is the observed significance level exp(-2*K1^2) * (1 -2*K1/(3*sqrt(n)) + (2*K1^2)/(3*n) - (4*K1^4/(9*n)))$e^{-2\,K1^2}\left(1 - \frac{2\,K1}{3\sqrt{n}} + \frac{2\,K1^2}{3\,n} - \frac{4\,K1^4}{9\,n}\right)$ of the statistic `K1`.

3 `K2` is the Kolmogorov-Smirnov statistic sqrt(n)*max(ImageSet(f(y[j])-(j-1)/n, 1<= j<=n))$\sqrt{n}\max(\{f(y_j) - \frac{j-1}{n} \mid 1 \le j \le n\})$.

4 `p2` is the observed significance level exp(-2*K2^2) * (1 -2*K2/(3*sqrt(n)) + (2*K2^2)/(3*n) - (4*K2^4/(9*n)))$e^{-2\,K2^2}\left(1 - \frac{2\,K2}{3\sqrt{n}} + \frac{2\,K2^2}{3\,n} - \frac{4\,K2^4}{9\,n}\right)$ of the statistic `K2`.

For the Kolmogorov-Smirnov statistic *K* corresponding to *K1* or *K2*, respectively, the observed significance levels `p1`, `p2` are computed by an asymptotic approximation of the exact probability

Pr(K>k)=(k)/(n^(n-1/2)) * sum(binomial(n,i) *((i - sqrt(n) *k)^i * (sqrt(n) *k + n - i)^(n - i - 1)), i=1..floor(sqrt(n) * k))

$$\Pr(K > k) = \frac{k}{n^{n-\frac{1}{2}}}\left(\sum_{i=1}^{\lfloor\sqrt{n}\,k\rfloor}\binom{n}{i}\left((i-\sqrt{n}\,k)^i\,(\sqrt{n}\,k+n-i)^{n-i-1}\right)\right)$$

For large n, these probabilities are approximated by

exp(-2*k^2) * (1 -2*k/(3*sqrt(n)) + (2*k^2)/(3*n) - (4*k^4/(9*n)))

$$e^{-2\,k^2}\left(1 - \frac{2\,k}{3\sqrt{n}} + \frac{2\,k^2}{3\,n} - \frac{4\,k^4}{9\,n}\right)$$

Thus, the observed significance levels returned by `stats::ksGOFT` approximate the exact probabilities for large *n*. Roughly speaking, for *n* = 10, the 3 leading digits of `p1`, `p2` correspond to the exact probabilities. For *n* = 100, the 4 leading digits of `p1`, `p2` correspond to the exact probabilities. For *n* = 1000, the 6 leading digits of `p1`, `p2` correspond to the exact probabilities.

The observed significance level `PValue1 = p1` returned by `stats::ksGOFT` has to be interpreted in the following way:

Under the null hypothesis, the probability $p1 = Pr(K > K1)$ should not be small. Specifically, $p1 = Pr(K > K1) \geq \alpha$ should hold for a given significance level _outputSequence(0, '<', Symbol::alpha, '<', 1)0 <α <<1. If this condition is violated, the hypothesis may be rejected at level α.

Thus, if the observed significance level `p1` = $Pr(K > K1)$ satisfies $p1 <$ α, the sample leading to the value `K1` of the statistic K represents an unlikely event and the null hypotheses may be rejected at level α.

The corresponding interpretation holds for `PValue2 = p2`: if `p2 = Pr(K > K2)` satisfies $p2 <$ α, the null hypotheses may be rejected at level α.

Note that *both* observed significance levels `p1`, `p2` must be sufficiently large to make the data pass the test. The null hypothesis may be rejected at level α if any of the two values is smaller than α.

If $p1$ and $p2$ are both close to 1, this should raise suspicion about the randomness of the data: they indicate a fit that is *too good*.

Distributions that are not provided by the `stats`-package can be implemented easily by the user. A user defined procedure f can implement any cumulative distribution function; `stats::ksGOFT` calls $f(x)$ with real floating-point arguments from the data sample. The function f must return a numerical real value between 0 and 1. Cf. "Example 3" on page 30-252.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We create a sample of 1000 normally distributed random numbers: r := stats::normalRandom(0, 1, Seed = 123): data := [r() $ i = 1 .. 1000]:

We test whether these data are indeed normally distributed with mean 0 und variance 1. We pass the corresponding cumulative distribution function `stats::normalCDF(0, 1)` to `stats::ksGOFT`:

stats::ksGOFT(data, CDF = stats::normalCDF(0, 1))[PValue1 = 0.722852785, StatValue1 = 0.397634617, PValue2 = 0.2073651285, StatValue2 = 0.8816932145]

[PValue1 = 0.722852785, StatValue1 = 0.397634617, PValue2 = 0.2073651285, StatValue2 = 0.881

The result shows that the data can be accepted as a sample of normally distributed numbers: both observed significance levels _outputSequence(0.722, dots)0.722... and _outputSequence(0.207, dots)0.207... are not small.

Next, we inject some further data into the sample:
data := data . [frandom() $ i = 1..100]: stats::ksGOFT(data, CDF = stats::normalCDF(0, 1))[PValue1 = 0.7520868926, StatValue1 = 0.3724682725, PValue2 = 0.00006540335794, StatValue2 = 2.188978212]

[PValue1 = 0.7520868926, StatValue1 = 0.3724682725, PValue2 = 0.00006540335794, StatValue2

Now, the data should not be accepted as a sample of normal deviates with mean 0 and variance 1, because the second observed significance level `PValue2 = 0.000065..` is very small.
delete r, data:

Example 2

We create a sample consisting of one string column and two non-string columns:
s := stats::sample([["1996", 1242, PI - 1/2], ["1997", 1353, PI + 0.3], ["1998", 1142, PI + 0.5], ["1999", 1201, PI - 1], ["2001", 1201, PI]]) "1996" 1242 PI - 1/2 "1997" 1353 PI + 0.3 "1998" 1142 PI + 0.5 "1999" 1201 PI - 1 "2001" 1201 PI

We consider the data in the third column. The mean and the variance of these data are computed:
[m, v] := [stats::mean(s, 3), stats::variance(s, 3)][PI - 0.14, 0.373]

[π – 0.14, 0.373]

We check whether the data of the 3rd column are normally distributed with the mean and variance computed above:
stats::ksGOFT(s, 3, CDF = stats::normalCDF(m, v))[PValue1 = 0.7366062033, StatValue1 = 0.3294603834, PValue2 = 0.6216810571, StatValue2 = 0.4263183582]

[PValue1 = 0.7366062033, StatValue1 = 0.3294603834, PValue2 = 0.6216810571, StatValue2 = 0.4263

Both observed significance levels _outputSequence(0.736, dots)0.736... and _outputSequence(0.621, dots)0.621... returned by the test are not small. There is no reason to reject the null hypothesis that the data are normally distributed.
delete s, m, v:

Example 3

We demonstrate how user-defined distribution functions can be used. The following function represents the cumulative distribution function $Pr(X \le x) = x^2$ of a variable X supported on the interval [0, 1]. It will be called with floating-point arguments x and must return numerical values between 0 and 1:
f := proc(x) begin if x <= 0 then return(0) elif x < 1 then return(x^2) else return(1) end_if end_proc:

We test the hypothesis that the following data are f-distributed:
data := [sqrt(frandom()) $ k = 1..10^2]: stats::ksGOFT(data, CDF = f)[PValue1 = 0.366526126, StatValue1 = 0.692353403, PValue2 = 0.8844815733, StatValue2 = 0.2318684139]

[PValue1 = 0.366526126, StatValue1 = 0.692353403, PValue2 = 0.8844815733, StatValue2 = 0.231868

At a given significance level of 0.1, say, the hypothesis should not be rejected: both observed significance levels p1 = _outputSequence(0.366, dots)0.366... and p2 = _outputSequence(0.884, dots)0.884... exceed 0.1.
delete f, data:

Parameters

x_1, x_2, ...

The statistical data: real numerical values

f

A procedure representing a cumulative distribution function. Typically, one of the distribution functions of the `stats`-package such as stats::normalCDF(n, v) etc.

s

A sample of domain type stats::sample

c

An integer representing a column index of the sample `s`. This column provides the data `x1`, `x2` etc. There is no need to specify a column number `c` if the sample has only one column.

Return Values

List with four equations `[PValue1 = p1, StatValue1 = K1, PValue2 = p2, StatValue2 = K2]`, with floating-point values `p1`, `K1`, `p2`, `K2`. See the "Details" section below for the interpretation of these values.

stats::csGOFTstats::samplestats::swGOFTstats::tTest

stats::kurtosis

Purpose

Kurtosis (excess) of a data sample

Syntax

```
stats::kurtosis(x1, x2,  )
stats::kurtosis([x1, x2,  ])
stats::kurtosis(s, <c>)
```

Description

`stats::kurtosis`(x_1, x_2, ..., x_n) returns the kurtosis (the coefficient of excess)

1/n*sum((x[i]-‘x‾‘)^4, i=1..n)/(1/n*sum((x[i]-‘x‾‘)^2, i=1..n)^2)-3

$$\frac{\frac{1}{n}\left(\sum_{i=1}^{n}(x_i-\overline{x})^4\right)}{\frac{1}{n}\left(\sum_{i=1}^{n}(x_i-\overline{x})^2\right)^2}-3$$

where x‾‘ $\overline{x}$ is the mean of the data x_i.

The kurtosis measures whether a distribution is “flat” or “peaked”. For normally distributed data, the kurtosis is zero. If the distribution function of the data has a flatter top than the normal distribution, then the kurtosis is negative. The kurtosis is positive, if the distribution function has a high peak compared to the normal distribution.

The column index `c` is optional, if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-255.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the kurtosis of some values:

```
stats::kurtosis(0, 7, 7, 6, 6, 6, 5, 5, 4, 1)-74146/271441
```

$$-\frac{74146}{271441}$$

Alternatively, data may be passed as a list:
stats::kurtosis([2, 2, 4, 6, 8, 10, 10])-85/54

$$-\frac{85}{54}$$

Example 2

We create a sample:
stats::sample([[a, 5, 8], [b, 3, 7], [c, d, 0]]) a 5 8 b 3 7 c d 0

The kurtosis of the second column is:
stats::kurtosis(%, 2)(3*(d/3 - 1/3)^4 + 3*(d/3 - 7/3)^4 + 3*((2*d)/3 - 8/3)^4)/((d/3 - 1/3)^2 + (d/3 - 7/3)^2 + ((2*d)/3 - 8/3)^2)^2 - 3

$$\frac{3\left(\frac{d}{3}-\frac{1}{3}\right)^4+3\left(\frac{d}{3}-\frac{7}{3}\right)^4+3\left(\frac{2\,d}{3}-\frac{8}{3}\right)^4}{\left(\left(\frac{d}{3}-\frac{1}{3}\right)^2+\left(\frac{d}{3}-\frac{7}{3}\right)^2+\left(\frac{2\,d}{3}-\frac{8}{3}\right)^2\right)^2}-3$$

Example 3

We create a sample consisting of one string column and one non-string column:
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]]) "1996" 1242 "1997" 1353 "1998" 1142

We compute the kurtosis of the second column. In this case this column does not have to be specified, since it is the only non-string column:
stats::kurtosis(%)-3/2

$$-\frac{3}{2}$$

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions.

s

A sample of domain type stats::sample.

c

An integer representing a column index of the sample `s`. This column provides the data `x1`, `x2` etc.

Return Values

Arithmetical expression. `FAIL` is returned, if the kurtosis does not exist.

See Also

stats::obliquity

stats::linReg

Purpose

Linear regression (least squares fit)

Syntax

```
stats::linReg([x1, x2,  ], [y1, y2,  ], <[w1, w2,
 ]>, <CovarianceMatrix>)
stats::linReg([[x1, y1, <w1>], [x2, y2, <w2>],  ],
<CovarianceMatrix>)
stats::linReg(s, <cx, cy, <cw>>, <CovarianceMatrix>)
stats::linReg(s, <[cx, cy, <cw>]>, <CovarianceMatrix>)
```

Description

`stats::linReg([x1, x2,  ], [y1, y2,  ], [w1, w2,  ])` computes the least squares estimators a, b of a linear relation $y_i = a + bx_i$ between the data pairs (x_i, y_i) by minimizing

Symbol::chi^2=sum(w[i]*abs(y[i]-a-b*x[i])^2, i)

$$\chi^2 = \sum w_i \left| y_i - a - b\, x_i \right|^2$$

A linear relation $y_i = a + bx_i + e_i$ between the data pairs (x_i, y_i) is assumed.

The column indices `cx`, `cy` are optional if the data are given by a stats::sample object containing only two non-string columns. Cf. "Example 2" on page 30-259.

Multivariate linear regression and non-linear regression is provided by stats::reg.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the least square estimators of four pairs of values given in two lists. Note that there is a linear relation $y = 1 + 2x$ between the entries of the lists. The minimized quadratic deviation is 0 indicating a perfect fit:

stats::linReg([0, 1, 2, 3], [1, 3, 5, 7])[[1, 2], 0]

[[1, 2], 0]

Alternatively, data may be specified by a list of pairs:
stats::linReg([[1, 1.0], [2, 1.2], [3, 1.3], [4, 1.5]])[[0.85, 0.16], 0.002]

[[0.85, 0.16], 0.002]

We assume that the variable y in the previous example is Poissonian, i.e. that the measurements (y_i) = (1.0, 1.2, 1.3, 1.5) have errors given by the standard deviation Symbol::sigma(y[i])=sqrt(y[i])$\sigma(y_i) = \sqrt{y_i}$. We provide

corresponding weights w[i]=1/Symbol::sigma(y[i])^2=1/y[i]$w_i = \frac{1}{\sigma(y_i)^2} = \frac{1}{y_i}$ and estimate confidence intervals for the least squares estimators by using the option `CovarianceMatrix`:
stats::linReg([[1, 1.0, 1/1.0], [2, 1.2, 1/1.2], [3, 1.3, 1/1.3], [4, 1.5, 1/1.5]], CovarianceMatrix)[[0.8491476359, 0.1601801222], 0.001608234159, matrix([[1.650048247, -0.5751045352], [-0.5751045352, 0.2460598263]])]

$$\left[[0.8491476359, 0.1601801222], 0.001608234159, \begin{pmatrix} 1.650048247 & -0.5751045352 \\ -0.5751045352 & 0.2460598263 \end{pmatrix}\right]$$

The square roots of the diagonal elements of the covariance matrix provide standard deviations for the estimated parameters:
sqrt(%[3][1,1]), sqrt(%[3][2,2])1.284542038, 0.4960441778

1.284542038, 0.4960441778

Thus, we obtain the estimates _outputSequence(a, Symbol::pm, Symbol::sigma(a)) = _outputSequence(0.849, Symbol::pm, 1.28)$a \pm \sigma(a) = 0.849 \pm 1.28$, _outputSequence(b, Symbol::pm, Symbol::sigma(b)) = _outputSequence(0.160, Symbol::pm, 0.496)$b \pm \sigma(b) = 0.16 \pm 0.496$.

Example 2

We create a sample consisting of one string column and two non-string columns:
stats::sample([["1", 0, 0], ["2", 10, 15], ["3", 20, 30]]) "1" 0 0 "2" 10 15 "3" 20 30

The least square estimators are calculated using the data columns 2 and 3. In this example there are only two non-string columns, so the column indices do not have to be specified:
stats::linReg(%)[[0, 3/2], 0]

$$\left[\left[0, \frac{3}{2}\right], 0\right]$$

Example 3

We create a sample consisting of three data columns:
stats::sample([[1, 0, 0], [2, 10, 15], [3, 20, 30]]) 1 0 0 2 10 15 3 20 30

We compute the least square estimators for the data pairs given by the first and the second column:
stats::linReg(%, 1, 2)[[-10, 10], 0]

$$[[-10, 10], 0]$$

Example 4

We create a sample of three columns containing symbolic data:
stats::sample([[x, y, 0], [2, 4, 15], [3, 20, 30]]) x y 0 2 4 15 3 20 30

We compute the symbolic least square estimators for the data pairs given by the first and the second column. Here we specify these columns by a list of column indices:
map(stats::linReg(%, [1, 2], CovarianceMatrix), normal)[[-(68*x - 13*y + 5*x*y - 24*x^2 + 28)/(2*(x^2 - 5*x + 7)), -(24*x + 5*y - 2*x*y - 84)/(2*(x^2 - 5*x + 7))], (256*x^2 - 32*x*y - 896*x + y^2 + 56*y + 784)/(2*(x^2 - 5*x + 7)), matrix([[(x^2 + 13)/(2*(x^2 - 5*x + 7)), -(x + 5)/(2*(x^2 - 5*x + 7))], [-(x + 5)/(2*(x^2 - 5*x + 7)), 3/(2*(x^2 - 5*x + 7))]])]

$$\left[\left[-\frac{68x-13y+5xy-24x^2+28}{2(x^2-5x+7)}, -\frac{24x+5y-2xy-84}{2(x^2-5x+7)}\right], \frac{256x^2-32xy-896x+y^2+56y+78}{2(x^2-5x+7)}\right.$$

Example 5

We create data (x_i, y_i) with a randomized relation $y_i = a + bx_i$:
DIGITS := 5: r := stats::normalRandom(0, 5): X := [i $ i = 0..100]: Y := [12 + 17*x + r() $ x in X]:

By construction, the variances $\sigma(y_i)^2$ for the data y_i in the list Y is 5.

We use the weights w[i]=1/Symbol::sigma(y[i])^2=1/5 $w_i = \frac{1}{\sigma(y_i)^2} = \frac{1}{5}$ for all data:
W := [1/5 $ i = 0..100]: [ab, chisquared, C]:= stats::linReg(X, Y, W, CovarianceMatrix)[[12.065, 16.998], 87.997, matrix([[335/1717, -5/1717], [-5/1717, 1/17170]])]

$$\left[[12.065, 16.998], 87.997, \begin{pmatrix} \frac{335}{1717} & -\frac{5}{1717} \\ -\frac{5}{1717} & \frac{1}{17170} \end{pmatrix}\right]$$

The standard deviations of the estimators a, b are the square roots of the diagonal elements of C:
sqrt(float(C[1,1])), sqrt(float(C[2,2]))0.44171, 0.0076316

$$0.44171, 0.0076316$$

Thus, the estimate for a is _outputSequence(a, Symbol::pm, Symbol::sigma(a)) approx _outputSequence(11.93, Symbol::pm, 0.44) $a \pm \sigma(a) \approx 11.93 \pm 0.44$, the estimate for b is _outputSequence(b, Symbol::pm, Symbol::sigma(b)) approx _outputSequence(17.003, Symbol::pm, 0.0076) $b \pm \sigma(b) \approx 17.003 \pm 0.0076$.
delete r, X, Y, W, ab, chisquared, C:

Parameters

x_1, x_2, ...

Statistical data: arithmetical expressions

y_1, y_2, ...

Statistical data: arithmetical expressions

w_1, w_2, ...

Weights: arithmetical expressions. If no weights are provided, $w_1 = w_2 = \ldots = 1$ is used.

s

A sample of domain type stats::sample.

cx

cy

cw

Integers representing column indices of the sample `s`. Column `cx` provides the data $x_1, x_2, \ldots$, column `cy` provides the data $y_1, y_2, \ldots$. Column `cw`, if present, provides the weights $w_1, w_2, \ldots$. If no index for the weights is provided, $w_1 = w_2 = \ldots = 1$ is used.

Options

CovarianceMatrix

Changes the return value from `[[a, b], chisquared]` to `[[a, b], chisquared, C]`, where C is the covariance matrix

matrix([[_outputSequence(Symbol::sigma(a)^2), cov(a, b)], [cov(a, b), _outputSequence(Symbol::sigma(b)^2)]])

$$\begin{pmatrix} \sigma(a)^2 & \mathrm{cov}(a, b) \\ \mathrm{cov}(a, b) & \sigma(b)^2 \end{pmatrix}$$

Of the estimators a, b.

With this option, information on confidence intervals for the least squares estimators are provided. In particular, the return value includes the covariance matrix

matrix([[_outputSequence(Symbol::sigma(a)^2), cov(a, b)], [cov(a, b), _outputSequence(Symbol::sigma(b)^2)]])

$$\begin{pmatrix} \sigma(a)^2 & \mathrm{cov}(a,\, b) \\ \mathrm{cov}(a,\, b) & \sigma(b)^2 \end{pmatrix}$$

Of type `Dom::Matrix()`. Assuming that the data (y_i) are randomly perturbed with stochastic variations _outputSequence(Symbol::sigma(y[i])^2)$\sigma(y_i)^2$, the quadratic error to be minimized is

Symbol::chi^2=sum(w[i]*abs(y[i]-a-b*x[i])^2, i)

$$\chi^2 = \sum_i w_i \left| y_i - a - b\, x_i \right|^2$$

With

w[i] = 1/_outputSequence(Symbol::sigma(y[i])^2)

$$w_i = \frac{1}{\sigma(y_i)^2}$$

The covariance matrix of the least squares estimators is given by

_outputSequence(Symbol::sigma(a)^2)=(sum(w[i]*x[i]^2, i))/(sum(w[i], i)*sum(w[i]*x[i]^2, i) - (sum((w[i] * x[i]), i))^2)

$$\sigma(a)^2 = \frac{\sum_i w_i x_i^2}{\left(\sum_i w_i\right)\left(\sum_i w_i x_i^2\right) - \left(\sum_i w_i x_i\right)^2}$$

_outputSequence(Symbol::sigma(b)^2)=(sum(w[i], i))/(sum(w[i], i)*sum(w[i]*x[i]^2, i) - (sum((w[i] * x[i]), i))^2)

$$\sigma(b)^2 = \frac{\sum_i w_i}{\left(\sum_i w_i\right)\left(\sum_i w_i x_i^2\right) - \left(\sum_i w_i x_i\right)^2}$$

cov(a,b)=(sum(w[i]*x[i], i))/(sum(w[i], i)*sum(w[i]*x[i]^2, i) - (sum((w[i] * x[i]), i))^2)

$$\mathrm{cov}(a,\,b) = \frac{\sum_i w_i\, x_i}{\left(\sum_i w_i\right)\left(\sum_i w_i\, x_i^2\right) - \left(\sum_i w_i\, x_i\right)^2}$$

Return Values

Without the option `CovarianceMatrix`, a list `[[a, b], chisquared]` is returned. The arithmetical expressions *a* and *b* are estimators of the the offset and the slope of the linear relation. The arithmetical expression `chisquared` is the quadratic deviation

Symbol::chi^2=sum(w[i]*abs(y[i]-a-b*x[i])^2, i)

$$\chi^2 = \sum_i w_i \left| y_i - a - b\, x_i \right|^2$$

where *a*, *b* are the optimized estimators.

With the option `CovarianceMatrix`, a list `[[a, b], chisquared, C]` is returned. The matrix `C` is the covariance matrix of the optimized estimators *a* and *b*.

`FAIL` is returned if the estimators *a* and *b* do not exist.

stats::regstats::sampleplot::Scatterplot

stats::logisticCDF

Purpose

Cumulative distribution function of the logistic distribution

Syntax

```
stats::logisticCDF(m, s)
```

Description

`stats::logisticCDF(m, s)` returns a procedure representing the cumulative distribution function

(x) -> 1/2*(1+ tanh (PI*(x-m)/(2*sqrt(3)*s)))

$$x \to \frac{1}{2}\left(1 + \tanh\left(\frac{\pi\,(x-m)}{2\cdot\sqrt{3}\cdot s}\right)\right)$$

of the logistic distribution with mean `m` and standard deviation `s` > 0 as a procedure.

The procedure `f := stats::logisticCDF(m, s)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `x` is a floating-point number and `m` and `s` can be converted to floating-point numbers, then `f(x)` returns a floating-point number between 0.0 and 1.0.

The call `f(- infinity )` returns `0`; the call `f( infinity )` returns `1`.

In all other cases, the expression `1/2*(1 + tanh(PI*(x - m)/(2*sqrt(3)*s)))` is returned symbolically.

Numerical values for `m` and `s` are only accepted if they are real and `s` is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the cumulative distribution function with `m` = 0 and `s` = 1 at various points:

```
f := stats::logisticCDF(0, 1): f(-infinity), f(-3), f(0.5), f(2/3),
f(PI), f(infinity)0, 1/2 - tanh((PI*sqrt(3))/2)/2, 0.7123653231,
tanh((PI*sqrt(3))/9)/2 + 1/2, tanh((sqrt(3)*PI^2)/6)/2 + 1/2, 1
```

$$0,\ \frac{1}{2}-\frac{\tanh\left(\frac{\pi\sqrt{3}}{2}\right)}{2},\ 0.7123653231,\ \frac{\tanh\left(\frac{\pi\sqrt{3}}{9}\right)}{2}+\frac{1}{2},\ \frac{\tanh\left(\frac{\sqrt{3}\,\pi^2}{6}\right)}{2}+\frac{1}{2},\ 1$$

```
delete f:
```

Example 2

We use symbolic arguments:

```
f := stats::logisticCDF(m, s): f(x)1/2 - tanh((PI*sqrt(3)*(m - x))/(6*s))/2
```

$$\frac{1}{2}-\frac{\tanh\left(\frac{\pi\sqrt{3}\,(m-x)}{6\,s}\right)}{2}$$

When numerical values are assigned to `m` and `s`, the function `f` starts to produce numerical values:

```
m := 0: s := 1: f(3), f(3.0)tanh((PI*sqrt(3))/2)/2 + 1/2, 0.995685277
```

$$\frac{\tanh\left(\frac{\pi\sqrt{3}}{2}\right)}{2}+\frac{1}{2},\ 0.995685277$$

```
delete f, m, s:
```

Parameters

m

The mean: an arithmetical expression representing a real value

s

The standard deviation: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also stats::logisticPDFstats::logisticQuantilestats::logisticRandom

stats::logisticPDF

Purpose

Probability density function of the logistic distribution

Syntax

```
stats::logisticPDF(m, s)
```

Description

`stats::logisticPDF(m, s)` returns the probability density function

(x) -> (PI)/(4*s * sqrt(3)) * sech (PI*(x-m)/(4*sqrt(3)*s))^2

$$x \to \frac{\pi}{4\,s\,\sqrt{3}}\,\operatorname{sech}\left(\frac{\pi\,(x-m)}{4\,\sqrt{3}\,s}\right)^2$$

of the logistic distribution with mean `m` and standard deviation `s` > 0.

The procedure `f := stats::logisticPDF(m, s)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `x` is a floating-point number and `m` and `s` can be converted to floating-point numbers, then `f(x)` returns a positive floating-point number.

`f( infinity )` and `f(- infinity )` return `0`.

In all other cases, the expression (PI)/(4*s * sqrt(3)) * sech(PI*(x-m)/(4*sqrt(3)*s))^2$\frac{\pi}{4\,s\,\sqrt{3}}\,\operatorname{sech}\left(\frac{\pi\,(x-m)}{4\,\sqrt{3}\,s}\right)^2$ is returned symbolically.

Numerical values for `m` and `s` are only accepted if they are real and `s` is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the probability density function with `m` = 0 and `s` = 1 at various points:

```
f := stats::logisticPDF(0, 1): f(1/2), f(0.5),
f(x)(PI*sqrt(3))/(12*cosh((PI*sqrt(3))/12)^2), 0.3716492483,
(PI*sqrt(3))/(12*cosh((PI*sqrt(3)*x)/6)^2)
```

$$\frac{\pi\sqrt{3}}{12\cosh\left(\frac{\pi\sqrt{3}}{12}\right)^2},\ 0.3716492483,\ \frac{\pi\sqrt{3}}{12\cosh\left(\frac{\pi\sqrt{3}\,x}{6}\right)^2}$$

delete f:

```
delete f:
```

Example 2

We use symbolic arguments:

```
f := stats::logisticPDF(m, s): f(x),
f(3)(PI*sqrt(3))/(12*s*cosh((PI*sqrt(3)*(m - x))/(6*s))^2),
(PI*sqrt(3))/(12*s*cosh((PI*sqrt(3)*(m - 3))/(6*s))^2)
```

$$\frac{\pi\sqrt{3}}{12\cosh\left(\frac{\pi\sqrt{3}\,(m-x)}{6\,s}\right)^2},\ \frac{\pi\sqrt{3}}{12\,s\cosh\left(\frac{\pi\sqrt{3}\,(m-3)}{6\,s}\right)^2}$$

When numerical values are assigned to `m` and `s`, the function `f` starts to produce numerical values:

```
m := 0: s := 1: f(3), f(3.0)(PI*sqrt(3))/(12*cosh((PI*sqrt(3))/2)^2),
0.007792274633
```

$$\frac{\pi\sqrt{3}}{12\cosh\left(\frac{3}{2}\right)^2},\ 0.007792274633$$

delete f, m, s:

```
delete f, m, s:
```

Parameters

m

The mean: an arithmetical expression representing a real value

s

The standard deviation: an arithmetical expression representing a positive real value

Return Values procedure.

See Also stats::logisticCDFstats::logisticQuantilestats::logisticRandom

stats::logisticQuantile

Purpose

Quantile function of the logistic distribution

Syntax

```
stats::logisticQuantile(m, s)
```

Description

`stats::logisticQuantile(m, s)` returns a procedure representing the quantile function (inverse)

x -> m+(sqrt(3)*s)/Symbol::pi * ln(x/(1-x))

$$x \to m + \frac{\sqrt{3}\,s}{\pi} \ln\left(\frac{x}{1-x}\right)$$

of the cumulative distribution function `stats::logisticCDF(m, s)`. For $0 \le x \le 1$, the solution of `stats::logisticCDF`$(m, s)(y) = x$ is given by

y= stats::logisticQuantile(m, s)(x)

$$y = \text{stats::logisticQuantile}(m, s)(x)$$

The procedure `f := stats::logisticQuantile(m, s)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, ±infinity, or a symbolic expression:

The call `f(x)` returns a real floating-point number if `x` is a floating-point number between `0.0` and `1.0`, `m` can be converted to a real floating-point number, and `s` can be converted to a positive real floating-point number.

The calls `f(0)` and `f(0.0)` produce `- infinity`; the calls `f(1)` and `f(1.0)` produce infinity.

In all other cases, the symbolic expression `m + sqrt(3)*s*ln(x/(1-x))/PI` is returned.

Numerical values of x are only accepted if $0 \le x \le 1$.

Numerical values of m and s are only accepted if they are real and s is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with mean `m` = 0 and standard deviation `s` = 1 at various points:
f := stats::logisticQuantile(0, 1): f(0), f(1/10), f(0.7), f(0.999999999), f(1)-infinity, -(sqrt(3)*ln(9))/PI, 0.4671397935, 11.42533526, infinity

$$-\infty,\ -\frac{\sqrt{3}\ln(9)}{\pi},\ 0.4671397935,\ 11.42533526,\ \infty$$

The value `f(x)` satisfies `stats::logisticCDF(0, 1)(f(x))` = `x`:
stats::logisticCDF(0, 1)(f(0.987654321))0.987654321

$$0.987654321$$

delete f:

Example 2

We use symbolic arguments:
f := stats::logisticQuantile(m, s): f(x), f(1/3), f(0.4)m + (sqrt(3)*s*ln(-x/(x - 1)))/PI, m - (sqrt(3)*s*ln(2))/PI, m - 0.2235446302*s

$$m+\frac{\sqrt{3}\ s\ \ln\left(-\frac{x}{x-1}\right)}{\pi},\ m-\frac{\sqrt{3}\ s\ \ln(2)}{\pi},\ m-0.2235446302\ s$$

When suitable numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
m := 0: s := 1: f(0.999), f(999/1000)3.807893483, (sqrt(3)*ln(999))/PI

$$3.807893483,\ \frac{\sqrt{3}\ln(999)}{\pi}$$

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)0.0

```
0.0
f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, m, s:
```

Parameters

m

The mean: an arithmetical expression representing a real value

s

The standard deviation: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::logisticCDFstats::logisticPDFstats::logisticRandom

stats::logisticRandom

Purpose

Generate a random number generator for logistic deviates

Syntax

```
stats::logisticRandom(m, s, <Seed = s>)
```

Description

`stats::logisticRandom(m, s)` returns a procedure that produces logistic deviates (random numbers) with mean `m` and standard deviation `b` > 0.

The procedure `f := stats::logisticRandom(m, s)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `m` can be converted to a floating-point number and `s` can be converted to a positive floating point number, then `f(x)` returns a real floating point number.

Otherwise, `stats::logisticRandom(m, s)()` is returned symbolically.

Numerical values of `m` and `s` are only accepted if they are real and `s` is positive.

The values `X = f()` are distributed randomly according to the logistic distribution with mean `m` and standard deviation `s`. For any real `x`, the probability that $X \leq x$ is given by

1/2 * (1 + tanh(Symbol::pi*(x-m)/(2*sqrt(3)*s)))

$$\frac{1 + \tanh\left(\frac{\pi\,(x-m)}{2\sqrt{3}\,s}\right)}{2}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::logisticRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::logisticRandom(m, s):  f() $k = 1..K;
```

rather than by

```
stats::logisticRandom(m, s)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::logisticRandom(m, s, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate logistic deviates with mean `m` = 0 and standard deviation `s` = 1:
f := stats::logisticRandom(0, 1): f() $ k = 1..4-0.5473627217, 0.8782646344, -0.9428030153, 2.897981396

```
-0.5473627217, 0.8782646344, -0.9428030153, 2.897981396
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::logisticRandom(m, s): f()stats::logisticRandom(m, s)()

stats::logisticRandom(*m*, *s*)()

When numbers are assigned to `m` and `s`, the function `f` starts to produce random floating point numbers:
m := PI: s := 1/8: f() $ k = 1..43.071738219, 3.037168533, 3.128342993, 3.193154296

3.071738219, 3.037168533, 3.128342993, 3.193154296

delete f, m, s:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:
f := stats::logisticRandom(PI, 3, Seed = 1): f() $ k = 1..43.590026186, 5.349173335, -0.228813398, 0.5644575096

3.590026186, 5.349173335, −0.228813398, 0.5644575096

g := stats::logisticRandom(PI, 3, Seed = 1): g() $ k = 1..43.590026186, 5.349173335, -0.228813398, 0.5644575096

3.590026186, 5.349173335, −0.228813398, 0.5644575096

f() = g(), f() = g()5.811492258 = 5.811492258, -6.396713726 = -6.396713726

5.811492258 = 5.811492258, −6.396713726 = −6.396713726

delete f, g:

Parameters

m

The mean: an arithmetical expression representing a real value

s

The standard deviation: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `m` and `s` must be convertible to floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm for the computation of the logistic deviates uses the quantile function of the logistic distribution applied to unformly distributed random numbers on the interval Interval([0], 1)[0, 1).

See Also

stats::logisticCDFstats::logisticPDFstats::logisticQuantile

stats::lognormalCDF

Purpose

Cumulative distribution function of the log-normal distribution

Syntax

```
stats::lognormalCDF(m, v)
```

Description

`stats::lognormalCDF(m, v)` returns a procedure representing the cumulative distribution function

(x) -> 1/(sqrt(2*PI*v)) * int(exp(-ln(t-m)^2/(2*v)), t=-infinity..x)

$$x \to \frac{1}{\sqrt{2\,\pi\,v}} \int_{-\infty}^{x} e^{-\frac{\ln(t-m)^2}{2\,v}}\,dt$$

of the log-normal distribution with location parameter `m` and shape parameter `v`.

A random variable X is log-normally distributed if $ln(X)$ is a normally distributed variable. The "location parameter" m of X is the mean of $ln(X)$ and the "shape parameter" v is the variance of $ln(X)$.

The procedure `f := stats::lognormalCDF(m, v)` can be called in the form `f(x)` with an arithmetical expression `x`. The value 1/2 + 1/2*erf((ln(x) - m)/sqrt(2*v^3)) $\frac{1}{2} + \frac{\mathrm{erf}\left(\frac{\ln(x)-m}{\sqrt{2\,v^3}}\right)}{2}$ is returned.

If x is a floating-point number and both m and v can be converted to floating-point numbers, this value is returned as a floating-point number. Otherwise, a symbolic expression is returned.

Numerical values for m and v are only accepted if they are real and v is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the CDF of a lognormal distribution for some arbitrary parameter values:
f := stats::lognormalCDF(1/2, 3/4): f(0.1), f(10.3)0.0006057758986, 0.9828096232

0.0006057758986, 0.9828096232

delete f:

Example 2

We use symbolic arguments:
f := stats::lognormalCDF(m, v): f(3), f(x)1/2 - erf((sqrt(2)*(m - ln(3)))/(2*sqrt(v)))/2, 1/2 - erf((sqrt(2)*(m - ln(x)))/(2*sqrt(v)))/2

$$\frac{1}{2}-\frac{\operatorname{erf}\left(\frac{\sqrt{2}\,(m-\ln(3))}{2\sqrt{v}}\right)}{2},\ \frac{1}{2}-\frac{\operatorname{erf}\left(\frac{\sqrt{2}\,(m-\ln(x))}{2\sqrt{v}}\right)}{2}$$

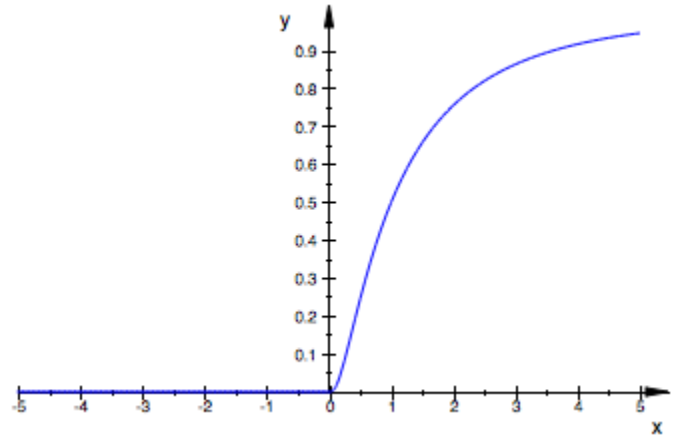
When numerical values are assigned to m and v, the function f starts to produce numerical values:
m := 4: v := PI: f(3), f(3.0)erf((sqrt(2)*(ln(3) - 4))/(2*sqrt(PI)))/2 + 1/2, 0.05082226366

$$\frac{\operatorname{erf}\left(\frac{\sqrt{2}\,(\ln(3)-4)}{2\sqrt{\pi}}\right)}{2}+\frac{1}{2},\ 0.05082226366$$

delete f, m, v:

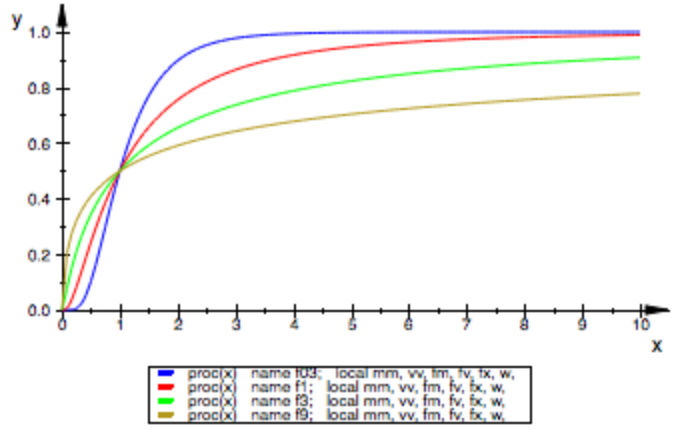
Example 3

From the definition of “lognormal” above it is clear that the probability of $X < 0$ is zero for X lognormally distributed:
plotfunc2d(stats::lognormalCDF(0,1))

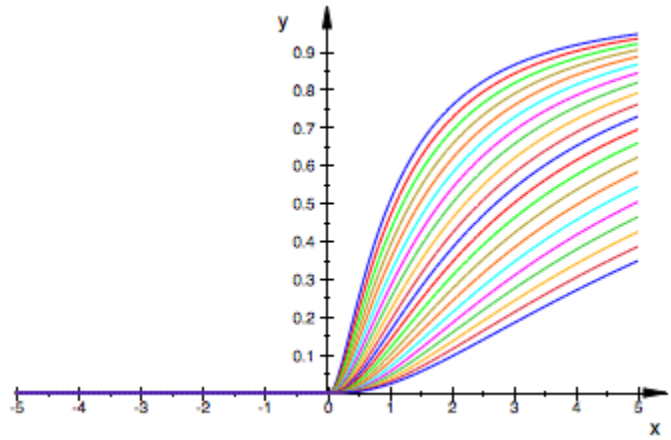


The following plot shows the influence of the shape parameter on the shape of the lognormal distribution:

```
f03 := stats::lognormalCDF(0, 0.3): f1 := stats::lognormalCDF(0, 1):
f3 := stats::lognormalCDF(0, 3): f9 := stats::lognormalCDF(0, 9):
plotfunc2d(f03, f1, f3, f9, x = 0..10)
```



As for the normal distribution, a larger value of the shape parameter stretches the lognormal distribution, also changing its shape in the process:
plotfunc2d(stats::lognormalCDF(m, 1)$ m = 0..2 step .1, LegendVisible = FALSE)



Parameters

m

The location parameter: an arithmetical expression representing a real value

v

The shape parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

erfstats::normalCDFstats::lognormalPDFstats::lognormalQuantilestats::lognormalRandom

stats::lognormalPDF

Purpose

Probability density function of the log-normal distribution

Syntax

```
stats::lognormalPDF(m, v)
```

Description

`stats::lognormalPDF(m, v)` returns a procedure representing the probability density function

(x) -> exp(-((ln(x)-m)^2/(2*v)))/(sqrt(2*PI)*v*x)

$$x \to \frac{e^{-\frac{(\ln(x)-m)^2}{2\,v}}}{\sqrt{2\,\pi\,v\,x}}$$

of the log-normal distribution with location parameter `m` and shape parameter `v`.

A random variable X is log-normally distributed if $ln(X)$ is a normally distributed variable. The "location parameter" m of X is the mean of $ln(X)$ and the "shape parameter" v is the variance of $ln(X)$.

The procedure `f := stats::lognormalPDF(m, v)` can be called in the form `f(x)` with an arithmetical expression `x`. The value

exp(-((ln(x)-m)^2/(2*v)))/(sqrt(2*PI)*v*x) $\left(= \frac{e^{-\frac{(\ln(x)-m)^2}{2\,v}}}{\sqrt{2\,\pi\,v\,x}}\right)$ is returned.

If `x` is a floating-point number and both `m` and `v` can be converted to floating-point numbers, this value is returned as a floating-point number. Otherwise, a symbolic expression is returned.

Numerical values for m and v are only accepted if they are real and v is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We compute the probability density with location parameter $m = 2$ and shape parameter $v = 4$ at various points:

```
f := stats::lognormalPDF(2, 4): f(-infinity), f(-3), f(2.0), f(PI), f(infinity)0, 0, 0.08056298881, (sqrt(2)*exp(-(ln(PI) - 2)^2/8))/(4*PI^(3/2)), 0
```

$$0,\ 0,\ 0.08056298881,\ \frac{\sqrt{2}\,e^{-\frac{(\ln(\pi)-2)^2}{8}}}{4\,\pi^{3/2}},\ 0$$

delete f:

Example 2

We use symbolic arguments:

```
f := stats::lognormalPDF(m, v): f(x), f(0.4)(sqrt(2)*exp(-(m - ln(x))^2/(2*v)))/(2*sqrt(PI)*sqrt(v)*x), (1.25*sqrt(2)*exp(-(m + 0.9162907319)^2/(2*v)))/(sqrt(PI)*sqrt(v))
```

$$\frac{\sqrt{2}\,e^{-\frac{(m-\ln(x))^2}{2\,v}}}{2\,\sqrt{\pi}\,\sqrt{v}\,x},\ \frac{1.25\,\sqrt{2}\,e^{-\frac{(m+0.9162907319)^2}{2\,v}}}{\sqrt{\pi}\,\sqrt{v}}$$

When numerical values are assigned to m and v, the function f starts to produce numerical values:

```
m := PI: v := 2: f(3), f(3.0)exp(-(PI - ln(3))^2/4)/(6*sqrt(PI)), 0.03312170057
```

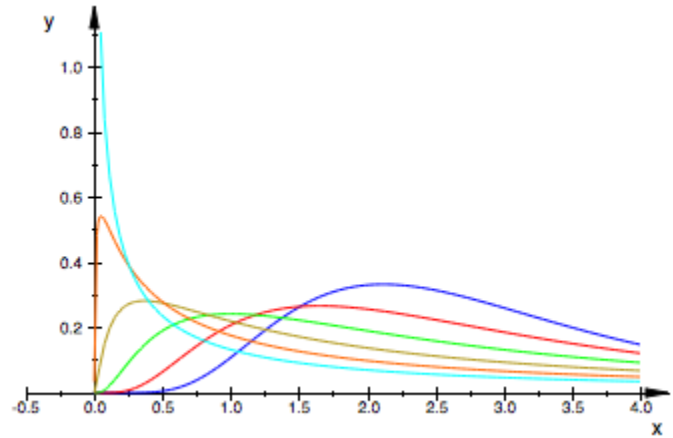
$$\frac{e^{-\frac{(\pi-\ln(3))^2}{4}}}{6\,\sqrt{\pi}},\ 0.03312170057$$

delete f, m, v:

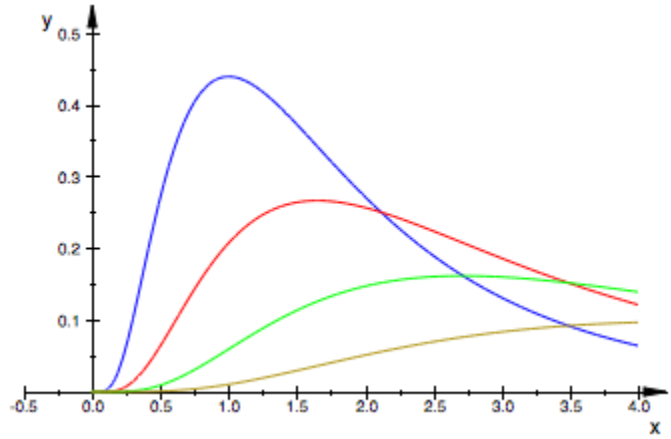
Example 3

The following plot shows the influence of the shape parameter on the log-normal distribution:

plotfunc2d(stats::lognormalPDF(1, 0.25)(x), stats::lognormalPDF(1, 0.5)(x), stats::lognormalPDF(1, 1)(x), stats::lognormalPDF(1, 2)(x), stats::lognormalPDF(1, 4)(x), stats::lognormalPDF(1, 8)(x), x = -0.5 .. 4, ViewingBoxYRange = 0 .. 1.1, LegendVisible = FALSE)



Due to its logarithmic influence, the location parameter changes the shape of the distribution, too:
plotfunc2d(stats::lognormalPDF(m, 0.5)(x) $ m = 0.5..2 step 0.5, x = -0.5 ..4, ViewingBoxYRange = 0 .. 0.5, LegendVisible = FALSE)



Parameters

m

The location parameter: an arithmetical expression representing a real value

v

The shape parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

expstats::normalPDFstats::lognormalCDFstats::lognormalQuantilestats::lognormalRandom

stats::lognormalQuantile

Purpose

Quantile function of the log-normal distribution

Syntax

```
stats::lognormalQuantile(m, v)
```

Description

`stats::normalQuantile(m, v)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::lognormalCDF(m, v)` of the log-normal distribution with location parameter m and shape parameter $v > 0$: For $0 \le x \le 1$, the solution of *stats*::*lognormalCDF*(m, v)(y) = x is given by y = *stats*::*lognormalQuantile*(m, v)(x).

The procedure `f := stats::lognormalQuantile(m, v)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, 0, infinity, or a symbolic expression:

If `x` is a real number between 0 and 1 and both `m` and `v` can be converted to floating-point numbers, then `f(x)` returns a real floating-point number approximating the solution `y` of `stats::lognormalCDF(m, v)(y) = x`.

The call `f(0)` returns `0`.

The calls `f(1)` and `f(1.0)` produce infinity for all values of `m` and `v`.

In all other cases, `f(x)` returns the symbolic call `stats::lognormalQuantile(m, v)(x)`.

Numerical values for m and v are only accepted if they are real and v is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with location parameter $m = \pi$ and shape parameter $v = 11$ at various points:

f := stats::lognormalQuantile(PI, 11): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)0, 0.3299437681, 23.14069263, 33666650688.0, infinity

$$0,\ 0.3299437681,\ 23.14069263,\ 33666650688.0,\ \infty$$

The value `f(x)` satisfies `stats::lognormalCDF(PI, 11)(f(x)) = x`: stats::lognormalCDF(PI, 11)(f(0.987654))0.987654

$$0.987654$$

delete f:

Example 2

We use symbolic arguments:
f := stats::lognormalQuantile(m, v): f(x), f(9/10)stats::lognormalQuantile(m, v)(x), stats::lognormalQuantile(m, v)(9/10)

$$\text{stats::lognormalQuantile}(m,\ v)(x),\ \text{stats::lognormalQuantile}(m,\ v)\left(\frac{9}{10}\right)$$

When numerical values are assigned to `m` and `v`, the function `f` starts to produce floating-point values:
m := 17: v := 6: f(9/10), f(0.999)557597210.5, 46816069055.0

$$557597210.5,\ 46816069055.0$$

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)24154952.75

$$24154952.75$$

f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, m, v:

Parameters

m

The location parameter: an arithmetical expression representing a real value

v

The shape parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::lognormalCDFstats::lognormalPDFstats::lognormalRandom

stats::lognormalRandom

Purpose

Generate a random number generator for log-normal deviates

Syntax

```
stats::lognormalRandom(m, v, <Seed = s>)
```

Description

`stats::normalRandom(m, v)` returns a procedure that produces lognormal deviates (random numbers) with location parameter m and shape parameter $v > 0$.

A random variable X is log-normally distributed if $ln(X)$ is a normally distributed variable. The "location parameter" m of X is the mean of $ln(X)$ and the "shape parameter" v is the variance of $ln(X)$.

The procedure `f := stats::lognormalRandom(m, v)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `m` and `v` can be converted to floating-point numbers, `f()` returns a real floating point number. Otherwise, the symbolic call `stats::lognormalRandom(m, v)()` is returned.

Numerical values of `m` and `v` are only accepted if they are real and v is positive.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the log-normal distribution with parameters `m` and `v`. For any real x, the probability that $X \leq x$ is given by

1/2 + 1/2*erf((ln(x) - m)/sqrt(2*v^3))

$$\frac{1}{2} + \frac{\mathrm{erf}\left(\frac{\ln(x) - m}{\sqrt{2}\,\sqrt{v^3}}\right)}{2}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by stats::normalRandom do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via `f := stats::lognormalRandom(m, v): f() $k = 1..K` rather than by `stats::lognormalRandom(m, v)() $k = 1..K`. The latter call produces a sequence of generators each of which is called once. Also note that `stats::lognormalRandom(m, v, Seed = n)() $k = 1..K` does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate log-normal deviates with location parameter 2 and shape parameter 3/4:

```
f := stats::normalRandom(2, 3/4): f() $ k = 1..4
```

1.541231663, 1.506864857, 1.553005641, 1.055326957

```
delete f:
```

Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::lognormalRandom(m, v): f()
```

stats::lognormalRandom(*m*, *v*)()

When m and v evaluate to real numbers, `f` starts to produce random floating point numbers:

m := PI/10: v := 1/8: f() $ k = 1..42.57120706, 1.714950915, 1.747513452, 1.543972889

2.57120706, 1.714950915, 1.747513452, 1.543972889

delete f, m, v:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:
f := stats::lognormalRandom(1, 3, Seed = 1): f() $ k = 1..42.745783212, 0.566509847, 0.8352884053, 6.981716268

2.745783212, 0.566509847, 0.8352884053, 6.981716268

g := stats::lognormalRandom(1, 3, Seed = 1): g() $ k = 1..42.745783212, 0.566509847, 0.8352884053, 6.981716268

2.745783212, 0.566509847, 0.8352884053, 6.981716268

f() = g(), f() = g()2.891620861 = 2.891620861, 0.547178586 = 0.547178586

2.891620861 = 2.891620861, 0.547178586 = 0.547178586

delete f, g:

Parameters

m

The location parameter: an arithmetical expression representing a real value

v

The shape parameter: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `m` and `v` must be convertible to suitable floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implementation uses stats::normalRandom.

See Also

stats::lognormalCDFstats::lognormalPDFstats::lognormalQuantile

stats::mean

Purpose

Arithmetic mean of a data sample

Syntax

```
stats::mean(x_1, x_2,  )
stats::mean([x_1, x_2,  ])
stats::mean(s, <c>)
```

Description

`stats::mean`(x_1, x_2, ..., x_n) returns the arithmetic mean (1)/(n) * sum(x[i], i=1..n) $\frac{1}{n}\left(\sum_{i=1}^{n} x_i\right)$ of the data x_i.

The column index `c` is optional if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-293.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the arithmetic mean of three values:
stats::mean(a, b, c)a/3 + b/3 + c/3

$$\frac{a}{3} + \frac{b}{3} + \frac{c}{3}$$

Alternatively, data may be passed as a list:
stats::mean([2, 3, 5])10/3

$$\frac{10}{3}$$

Example 2

We create a sample:
stats::sample([[a1, b1, c1], [a2, b2, c2]]) a1 b1 c1 a2 b2 c2

The arithmetic mean of the second column is:
stats::mean(%, 2)b1/2 + b2/2

$$\frac{b1}{2} + \frac{b2}{2}$$

Example 3

We create a sample consisting of one string column and one non-string column:
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]]) "1996" 1242 "1997" 1353 "1998" 1142

We compute the arithmetic mean of the second column. In this case, this column does not have to be specified, since it is the only non-string column:
float(stats::mean(%))1245.666667

```
1245.666667
```

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions.

s

A sample of domain type stats::sample.

c

An integer representing a column index of the sample `s`. This column provides the data `x1`, `x2` etc.

Return Values

Arithmetical expression.

See Also

stats::geometricMeanstats::harmonicMeanstats::medianstats::modalstats::quadraticMean

stats::meandev

Purpose

Mean deviation of a data sample

Syntax

```
stats::meandev(x1, x2,  )
stats::meandev([x1, x2,  ])
stats::meandev(s, <c>)
```

Description

`stats::meandev( x1, x2,  , xn)` returns the mean deviation

(1)/(n) * sum(abs(x[(i)]-‘x‾’), i=1..n)

$$\frac{1}{n}\left(\sum_{i=1}^{n}|x_i-\overline{x}|\right)$$

where ‘x‾’ $\overline{x}$ is the mean of the data x_i.

If all data are floating-point numbers, a float is returned. For symbolic data, the mean is returned as a symbolic expression.

The column index `c` is optional if the data are given by a stats::sample object containing only one non-string column.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the mean deviation of some data:
stats::meandev(2, 33/7, PI)104/63 - (2*PI)/9

$$\frac{104}{63}-\frac{2\,\pi}{9}$$

Alternatively, the data may be passed as a list:
data:=[2, 33/7, PI]: stats::meandev(data)104/63 - (2*PI)/9

$\frac{104}{63} - \frac{2\,\pi}{9}$

If all data are floating-point numbers, the result is a float:
stats::meandev(float(data))0.95266195

0.95266195

delete data:

Example 2

We create a sample of type stats::sample:
s := stats::sample([[22, 4, 1], [9, 8/3, 1], [2.0, 3, x]]) 22 4 1 9 8/3 1 2.0 3 x

The mean deviations of the columns are computed:
stats::meandev(s, 1), stats::meandev(s, 2), stats::meandev(s, 3)7.333333333, 14/27, (2*abs(x/3 - 1/3))/3 + abs((2*x)/3 - 2/3)/3

$7.333333333,\ \frac{14}{27},\ \frac{2\left|\frac{x}{3}-\frac{1}{3}\right|}{3}+\frac{\left|\frac{2\,x}{3}-\frac{2}{3}\right|}{3}$

delete s:

Example 3

With symbolic arguments, the mean deviation is returned as a symbolic expression:
stats::meandev(x1, x2, x3)abs(x1/3 + x2/3 - (2*x3)/3)/3 + abs(x1/3 - (2*x2)/3 + x3/3)/3 + abs(x2/3 - (2*x1)/3 + x3/3)/3

$\frac{\left|\frac{x1}{3}+\frac{x2}{3}-\frac{2\,x3}{3}\right|}{3}+\frac{\left|\frac{x1}{3}-\frac{2\,x2}{3}+\frac{x3}{3}\right|}{3}+\frac{\left|\frac{x2}{3}-\frac{2\,x1}{3}+\frac{x3}{3}\right|}{3}$

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions

s

A sample of domain type stats::sample

c

A column index of the sample `s`: a positive integer. This column provides the data `x1`, `x2` etc.

Return Values

arithmetical expression.

See Also

stats::momentstats::stdevstats::variance

stats::median

Purpose

Median value of a data sample

Syntax

```
stats::median(x1, x2,  , <Averaged>)
stats::median([x1, x2,  ], <Averaged>)
stats::median(s, <c>, <Averaged>)
```

Description

`stats::median`(x_1, x_2, ...) returns the median of the data x_i.

The median of n sorted values $x_1 \le \ldots \le x_n$ is x[ceil(n/2)] $x_{\lceil \frac{n}{2} \rceil}$.

The averaged median of n sorted values $x_1 \le \ldots \le x_n$ is (1)/(2)*fenced(x[ceil(n/2)] + x[ceil((n+1)/2)]) $\frac{\left(x_{\lceil \frac{n}{2} \rceil} + x_{\lceil \frac{n+1}{2} \rceil}\right)}{2}$.

For odd n, both the median and the averaged median coincide with the element x[(fenced(n+1)/2)] $x_{\frac{(n+1)}{2}}$ of the sorted data list. For even n, the median is x[(n/2)] $x_{\frac{n}{2}}$, whilst the averaged median is (1)/(2)*fenced(x[(n/2)]+x[(fenced(n+2)/2)]) $\frac{\left(x_{\frac{n}{2}} + x_{\frac{(n+2)}{2}}\right)}{2}$.

The median coincides with the (1)/(2) $\frac{1}{2}$-quantile of the data: the calls `stats::median(data <Averaged>)` and `stats::empiricalQuantile(data)(1/2 <Averaged>)` are equivalent. See the help page of stats::empiricalQuantile for details on the parameters specifying the data.

The column index `c` is optional if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-298.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the median of a sequence of five values:

stats::median(3, 8, 5, 9/2, 11)5

5

Alternatively, data may be passed as a list:
stats::median([2, 7, 3, 9/2, 11, 12]), stats::median([2, 7, 3, 9/2, 11, 12], Averaged)9/2, 23/4

$\frac{9}{2}, \frac{23}{4}$

Example 2

We create a sample:
stats::sample([[4, 7, 5], [3, 6, 17], [8, 2, 2]]) 4 7 5 3 6 17 8 2 2

The median of the second column is 6:
stats::median(%, 2)6

6

Example 3

We create a sample consisting of one string column and one non-string column:
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]]) "1996" 1242 "1997" 1353 "1998" 1142

The median of the second column is calculated. In this case, there is no need to specify the index of the column, since it is the only non-string data column in the sample:
stats::median(%)1242

1242

Parameters

x_1, x_2, ...

The statistical data: real numerical values.

s

A sample of domain type stats::sample

c

A column index of the sample `s`: a positive integer. This column provides the data `x1`, `x2` etc.

Options

Averaged

Return the averaged median value

Return Values

arithmetical expression. `FAIL` is returned if the data sample is empty.

See Also

stats::empiricalQuantilestats::geometricMeanstats::harmonicMeanstats::meanstats::moda

stats::modal

Purpose

Modal (most frequent) value(s) in a data sample

Syntax

```
stats::modal(x1, x2,  )
stats::modal([x1, x2,  ])
stats::modal(s, <c>)
```

Description

`stats::modal`(x_1, x_2, ...) returns the most frequent value(s) of the data x_i.

The column index `c` is optional, if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-301.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the modal value of a data sequence:
stats::modal(2, a, b, c, b, 10, 12, 2, b)[b], 3

[*b*], 3

Alternatively, data may be passed as a list:
stats::modal([a, a, a, b, c, b, 10, 12, 2, b])[a, b], 3

[*a*, *b*], 3

Example 2

We create a sample containing “age” and “gender”:
stats::sample([[32, "f"], [25, "m"], [40, "f"], [23, "f"]]) 32 "f" 25 "m" 40 "f" 23 "f"

The modal value of the second column (the most frequent “gender”) is calculated:

stats::modal(%, 2)["f"], 3

["f"], 3

Example 3

We create a sample consisting of only one column:
stats::sample([4, 6, 2, 6, 8, 3, 2, 1, 7, 9, 3, 6, 5, 1, 6, 8]):

The modal value of these data is calculated. In this case, the column does not have to be specified, since there is only one column:
stats::modal(%)[6], 4

[6], 4

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions.

s

A sample of domain type stats::sample.

c

An integer representing a column index of the sample `s`. This column provides the data `x1`, `x2` etc.

Return Values

Sequence consisting of a list and an integer. The list contains the most frequent element(s) in the data, the integer specifies the number of occurrences. E.g., the result `[x5, x10], 21` means that `x5` and `x10` are the most frequent data items, each occurring 21 times.

See Also

stats::empiricalQuantilestats::geometricMeanstats::harmonicMeanstats::meanstats::medi

stats::moment

Purpose

The K-th moment of a data sample

Syntax

```
stats::moment(k, X, x_1, x_2,  )
stats::moment(k, X, [x_1, x_2,  ])
stats::moment(k, X, s, <c>)
```

Description

`stats::moment`(k, X, [x_1, x_2, …, x_n]) returns the k-th moment

(1)/(n) * sum(fenced(x[(i)]-X)^(k), i=1..n)

$$\frac{1}{n}\left(\sum_{i=1}^{n}(x_i - X)^k\right)$$

of the data x_i centered around `X`.

If k is an integer, rational or float, and all data `X`, x_1, x_2, … are floating-point numbers, then the moment is returned as a floating-point number. For symbolic data, a symbolic expression is returned.

The column index `c` is optional if the data are given by a stats::sample object containing only one non-string column.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We calculate the third moment of some data centered around `0`:
stats::moment(3, 0, 2, 33/7, 21/9, PI)PI^3/4 + 290509/9261

$$\frac{\pi^3}{4} + \frac{290509}{9261}$$

Alternatively, the data may be passed as a list:
data := [2, 33/7, 21/9, PI]: stats::moment(3, 0, data)PI^3/4 + 290509/9261

$$\frac{\pi^3}{4} + \frac{290509}{9261}$$

If all data are floating-point numbers, the result is a float:
data := float(data): stats::moment(3, 0, data)39.12064378

39.12064378

We use `stats::moment` to compute the variance of the data:
m := stats::mean(data): stats::moment(2, m, data) = stats::variance(data, Population)1.098579542 = 1.098579542

1.098579542 = 1.098579542

delete data, m:

Example 2

We create a sample of type stats::sample:
s := stats::sample([[22, 4, 1], [9, 8/3, 1], [0.1, 2, 3]]) 22 4 1 9 8/3 1 0.1 2 3

The fourth moment around a symbolic center `X` is computed for all columns in the sample:
stats::moment(4, X, s, i) $ i = 1..3(X - 9)^4/3 + (X - 22)^4/3 + (X - 0.1)^4/3, (X - 2)^4/3 + (X - 4)^4/3 + (X - 8/3)^4/3, (2*(X - 1)^4)/3 + (X - 3)^4/3

$$\frac{(X-9)^4}{3} + \frac{(X-22)^4}{3} + \frac{(X-0.1)^4}{3}, \frac{(X-2)^4}{3} + \frac{(X-4)^4}{3} + \frac{\left(X-\frac{8}{3}\right)^4}{3}, \frac{2\,(X-1)^4}{3} + \frac{(X-3)^4}{3}$$

delete s:

Example 3

For symbolic arguments, the moment is returned as a symbolic expression:
stats::moment(k, X, [x1, x2, x3, x4])(x1 - X)^k/4 + (x2 - X)^k/4 + (x3 - X)^k/4 + (x4 - X)^k/4

$$\frac{(x1 - X)^k}{4} + \frac{(x2 - X)^k}{4} + \frac{(x3 - X)^k}{4} + \frac{(x4 - X)^k}{4}$$

Parameters

k

An arithmetical expression

X

The center: an arithmetical expression

x_1, x_2, ...

The statistical data: arithmetical expressions

s

A sample of domain type stats::sample

c

A column index of the sample `s`: a positive integer. This column provides the data x_1, x_2, ...

Return Values

arithmetical expression.

See Also

stats::quadraticMeanstats::variance

stats::normalCDF

Purpose

Cumulative distribution function of the normal distribution

Syntax

```
stats::normalCDF(m, v)
```

Description

`stats::normalCDF(m, v)` returns a procedure representing the cumulative distribution function

(x) -> (1)/(sqrt(2*PI*v)) * int(exp(-(t-m)^2/(2*v)), t=-infinity..x)

$$x \to \frac{1}{\sqrt{2\pi v}} \int_{-\infty}^{x} e^{-\frac{(t-m)^2}{2v}}\, dt$$

of the normal distribution with mean `m` and variance `v`.

The procedure `f := stats::normalCDF(m, v)` can be called in the form `f(x)` with an arithmetical expression `x`. The value `1/2 + 1/2* erf((x - m)/sqrt(2*v))` is returned.

If x is a floating-point number and both m and v can be converted to floating-point numbers, this value is returned as a floating-point number. Otherwise, a symbolic expression is returned.

Numerical values for m and v are only accepted if they are real and v is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the cumulative distribution function with mean $m = 2$ and variance v=3/4$v = \frac{3}{4}$ at various points:
f := stats::normalCDF(2, 3/4): f(-infinity), f(-3), f(PI), f(infinity)0, 1/2 - erf((5*sqrt(2)*sqrt(3))/3)/2, erf((sqrt(2)*sqrt(3)*(PI - 2))/3)/2 + 1/2, 1

$$0,\ \frac{1}{2}-\frac{\mathrm{erf}\left(\frac{5\sqrt{2}\sqrt{3}}{3}\right)}{2},\ \frac{\mathrm{erf}\left(\frac{\sqrt{2}\sqrt{3}(\pi-2)}{3}\right)}{2}+\frac{1}{2},\ 1$$

f(-100.0), f(-3.0), f(float(PI)), f(10.0), f(100.0)1.833507721e-3015, 0.000000003882018269, 0.9062812543, 1.0, 1.0

$$1.833507721\ 10^{-3015},\ 0.000000003882018269,\ 0.9062812543,\ 1.0,\ 1.0$$

delete f:

Example 2

We use symbolic arguments:

f := stats::normalCDF(m, v): f(3), f(x)1/2 - erf((sqrt(2)*(m - 3))/(2*sqrt(v)))/2, 1/2 - erf((sqrt(2)*(m - x))/(2*sqrt(v)))/2

$$\frac{1}{2}-\frac{\mathrm{erf}\left(\frac{\sqrt{2}\,(m-3)}{2\sqrt{v}}\right)}{2},\ \frac{1}{2}-\frac{\mathrm{erf}\left(\frac{\sqrt{2}\,(m-x)}{2\sqrt{v}}\right)}{2}$$

When numerical values are assigned to *m* and *v*, the function *f* starts to produce numerical values:

m := 4: v := PI: f(3), f(3.0)1/2 - erf(sqrt(2)/(2*sqrt(PI)))/2, 0.286312558

$$\frac{1}{2}-\frac{\mathrm{erf}\left(\frac{\sqrt{2}}{2\sqrt{\pi}}\right)}{2},\ 0.286312558$$

delete f, m, v:

Parameters

m

The mean: an arithmetical expression representing a real value

v

The variance: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also erfstats::normalPDFstats::normalQuantilestats::normalRandom

stats::normalPDF

Purpose

Probability density function of the normal distribution

Syntax

```
stats::normalPDF(m, v)
```

Description

`stats::normalPDF(m, v)` returns a procedure representing the probability density function

(x) -> (e^(-(fenced(x-m)^(2))/(2*v)))/(sqrt(2*PI*v))

$$x \to \frac{e^{-\frac{(x-m)^2}{2\,v}}}{\sqrt{2\,\pi\,v}}$$

of the normal distribution with mean `m` and variance `v`.

The procedure `f := stats::normalPDF(m, v)` can be called in the form `f(x)` with an arithmetical expression `x`. The value `exp(-(x - m)^2/(2*v))/sqrt(2*PI*v)` is returned.

If `x` is a floating-point number and both `m` and `v` can be converted to floating-point numbers, this value is returned as a floating-point number. Otherwise, a symbolic expression is returned.

Numerical values for m and v are only accepted if they are real and v is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We compute the probability density with mean $m = 2$ and variance $v = 4$ at various points:

f := stats::normalPDF(2, 4): f(-infinity), f(-3), f(2.0), f(PI), f(infinity)0, (sqrt(2)*exp(-25/8))/(4*sqrt(PI)), 0.1994711402, (sqrt(2)*exp(-(PI - 2)^2/8))/(4*sqrt(PI)), 0

$$0,\ \frac{\sqrt{2}\,e^{-\frac{25}{8}}}{4\sqrt{\pi}},\ 0.1994711402,\ \frac{\sqrt{2}\,e^{-\frac{(\pi-2)^2}{8}}}{4\sqrt{\pi}},\ 0$$

delete f:

Example 2

We use symbolic arguments:

```
f := stats::normalPDF(m, v): f(x), f(0.4)(sqrt(2)*exp(-(m
- x)^2/(2*v)))/(2*sqrt(PI)*sqrt(v)), (sqrt(2)*exp(-(m -
0.4)^2/(2*v)))/(2*sqrt(PI)*sqrt(v))
```

$$\frac{\sqrt{2}\,e^{-\frac{(m-x)^2}{2v}}}{2\sqrt{\pi}\sqrt{v}},\ \frac{\sqrt{2}\,e^{-\frac{(m-0.4)^2}{2v}}}{2\sqrt{\pi}\sqrt{v}}$$

When numerical values are assigned to m and v, the function f starts to produce numerical values:

```
m := PI: v := 2: f(3), f(3.0)exp(-(PI - 3)^2/4)/(2*sqrt(PI)), 0.2806844362
```

$$\frac{e^{-\frac{(\pi-3)^2}{4}}}{2\sqrt{\pi}},\ 0.2806844362$$

delete f, m, v:

Parameters

m

The mean: an arithmetical expression representing a real value

v

The variance: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also expstats::normalCDFstats::normalQuantilestats::normalRandom

stats::normalQuantile

Purpose

Quantile function of the normal distribution

Syntax

```
stats::normalQuantile(m, v)
```

Description

`stats::normalQuantile(m, v)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::normalCDF(m, v)` of the normal distribution with mean m and variance $v > 0$: For $0 \le x \le 1$, the solution of *stats*::*normalCDF*(m, v)(y) = x is given by y = *stats*::*normalQuantile*(m, v)(x).

The procedure `f := stats::normalQuantile(m, v)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, ±infinity, or a symbolic expression:

If `x` is a real number between `0` and `1` and both `m` and `v` can be converted to floating-point numbers, then `f(x)` returns a real floating-point number approximating the solution `y` of `stats::normalCDF(m, v)(y) = x`.

The calls `f(0)` and `f(0.0)` produce -infinity for all values of `m` and `v`.

The calls `f(1)` and `f(1.0)` produce infinity for all values of `m` and `v`.

In all other cases, `f(x)` returns the symbolic call `stats::normalQuantile(m, v)(x)`.

Numerical values for m and v are only accepted if they are real and v is positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with mean $m = \pi$ and variance $v = 11$ at various points:

f := stats::normalQuantile(PI, 11): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)-infinity, -1.108833039, 3.141592654, 24.23977359, infinity

$-\infty, -1.108833039, 3.141592654, 24.23977359, \infty$

The value `f(x)` satisfies `stats::normalCDF(PI, 11)(f(x)) = x`: stats::normalCDF(PI, 11)(f(0.987654))0.987654

0.987654

delete f:

Example 2

We use symbolic arguments:
f := stats::normalQuantile(m, v): f(x), f(9/10)stats::normalQuantile(m, v)(x), stats::normalQuantile(m, v)(9/10)

$\text{stats::normalQuantile}(m, v)(x), \text{stats::normalQuantile}(m, v)\left(\frac{9}{10}\right)$

When numerical values are assigned to `m` and `v`, the function `f` starts to produce floating-point values:
m := 17: v := 6: f(9/10), f(0.999)20.13914741, 24.56949234

20.13914741, 24.56949234

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)17.0

17.0

f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, m, v:

Parameters

m

The mean: an arithmetical expression representing a real value

v

The variance: an arithmetical expression representing a positive real value

Return Values procedure.

See Also stats::normalCDFstats::normalPDFstats::normalRandom

stats::normalRandom

Purpose

Generate a random number generator for normal deviates

Syntax

```
stats::normalRandom(m, v, <Seed = s>)
```

Description

`stats::normalRandom(m, v)` returns a procedure that produces normal deviates (random numbers) with mean m and variance $v > 0$.

The procedure `f := stats::normalRandom(m, v)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `m` and `v` can be converted to floating-point numbers, `f()` returns a real floating point number. Otherwise, the symbolic call `stats::normalRandom(m, v)()` is returned.

Numerical values of `m` and `v` are only accepted if they are real and v is positive.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the normal distribution with parameters `m` and `v`. For any real x, the probability that $X \le x$ is given by

```
1/(sqrt(2*PI*v)) * int( exp(-(t-m)^2/(2*v) ), t=-infinity..x )
```

$$\frac{1}{\sqrt{2\pi v}} \int_{-\infty}^{x} e^{-\frac{(t-m)^2}{2v}}\, dt$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::normalRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::normalRandom(m, v):  f() $k = 1..K;
```

rather than by

```
stats::normalRandom(m, v)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::normalRandom(m, v, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate normal deviates with mean 2 and variance 3/4:
f := stats::normalRandom(2, 3/4): f() $ k = 1..41.541231663, 1.506864857, 1.553005641, 1.055326957

1.541231663, 1.506864857, 1.553005641, 1.055326957

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::normalRandom(m, v): f()stats::normalRandom(m, v)()

stats::normalRandom(*m*, *v*)()

When m and v evaluate to real numbers, `f` starts to produce random floating point numbers:

m := PI: v := 1/8: f() $ k = 1..43.77180885, 3.366817847, 3.385627281, 3.261792281

3.77180885, 3.366817847, 3.385627281, 3.261792281

delete f, m, v:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers: f := stats::normalRandom(PI, 3, Seed = 1): f() $ k = 1..43.151659011, 1.573331837, 1.961614435, 4.084887424

3.151659011, 1.573331837, 1.961614435, 4.084887424

g := stats::normalRandom(PI, 3, Seed = 1): g() $ k = 1..43.151659011, 1.573331837, 1.961614435, 4.084887424

3.151659011, 1.573331837, 1.961614435, 4.084887424

f() = g(), f() = g()3.20340985 = 3.20340985, 1.538612606 = 1.538612606

3.20340985 = 3.20340985, 1.538612606 = 1.538612606

delete f, g:

Parameters

m

The mean: an arithmetical expression representing a real value

v

The variance: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `m` and `v` must be convertible to suitable floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm for the computation of the normal deviates uses the Box-Mueller method. For more information see: D. Knuth, Seminumerical Algorithms (1998), Vol. 2, pp. 122.

See Also

stats::normalCDFstats::normalPDFstats::normalQuantile

stats::obliquity

Purpose

Obliquity (skewness) of a data sample

Syntax

```
stats::obliquity(x1, x2,  )
stats::obliquity([x1, x2,  ])
stats::obliquity(s, <c>)
```

Description

stats::*obliquity*(x_1, x_2, …, x_n) returns the obliquity (skewness)

(1/n*sum((x[i]-‘x‾’)^3, i=1..n))/(1/n*sum((x[i]-‘x‾’)^2, i=1..n)^(3/2))

$$\frac{\frac{1}{n}\left(\sum_{i=1}^{n}(x_i-\overline{x})^3\right)}{\frac{1}{n}\left(\sum_{i=1}^{n}(x_i-\overline{x})^2\right)^{3/2}}$$

where ‘x‾’ $\overline{x}$ is the mean of the data x_i.

The obliquity is a measure for the symmetry of a distribution. It is zero, if the distribution of the data is symmetric around the mean. Positive values indicate that the distribution function has a “longer tail” to the right of the mean than to the left. Negative values indicate a “longer tail” to the left.

The column index `c` is optional, if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-319.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the obliquity of a data sequence:
float(stats::obliquity(0, 7, 7, 6, 6, 6, 5, 5, 4, 1))-1.041368312

```
-1.041368312
```

Alternatively, data may be passed as a list:
stats::obliquity([2, 2, 4, 6, 8, 10, 10])0

0

Example 2

We create a sample:
stats::sample([[a, 5, 8], [b, 3, 7], [c, d, 0]]) a 5 8 b 3 7 c d 0

The obliquity of the second column is:
stats::obliquity(%, 2)-(sqrt(3)*((d/3 - 1/3)^3 + (d/3 - 7/3)^3 - ((2*d)/3 - 8/3)^3))/((d/3 - 1/3)^2 + (d/3 - 7/3)^2 + ((2*d)/3 - 8/3)^2)^(3/2)

$$-\frac{\sqrt{3}\left(\left(\frac{d}{3}-\frac{1}{3}\right)^3+\left(\frac{d}{3}-\frac{7}{3}\right)^3-\left(\frac{2\,d}{3}-\frac{8}{3}\right)^3\right)}{\left(\left(\frac{d}{3}-\frac{1}{3}\right)^2+\left(\frac{d}{3}-\frac{7}{3}\right)^2+\left(\frac{2\,d}{3}-\frac{8}{3}\right)^2\right)^{3/2}}$$

Example 3

We create a sample consisting of one string column and one non-string column:
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]]) "1996" 1242 "1997" 1353 "1998" 1142

We compute the obliquity of the second column. In this case this column does not have to be specified, since it is the only non-string column:
float(stats::obliquity(%))0.06374333648

0.06374333648

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions.

s

A sample of domain type stats::sample.

c

An integer representing a column index of the sample `s`. This column provides the data `x1`, `x2` etc.

Return Values Arithmetical expression. `FAIL` is returned, if the obliquity does not exist.

See Also stats::kurtosis

stats::poissonCDF

Purpose

The (discrete) cumulative distribution function of the Poisson distribution

Syntax

```
stats::poissonCDF(m)
```

Description

`stats::poissonCDF(m)` returns a procedure representing the (discrete) cumulative distribution function

(x) -> piecewise([x < 0, 0], [x >= 0, sum(m^i*exp(-m)/(i!), i=0..floor(x))])

$$x \to \begin{cases} 0 & \text{if } x < 0 \\ \sum_{i=0}^{\lfloor x \rfloor} \frac{m^i \cdot e^{-m}}{i!} & \text{if } x \geq 0 \end{cases}$$

of the Poisson distribution with mean `m`.

The procedure `f := stats::poissonCDF(m)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

If `x` is a numerical real value, then an explicit value is returned. It is a floating-point number if `x` is a floating-point number and `m` can be converted to a positive real float. Otherwise, an exact expression is returned.

If `x` is a numerical value `< 0`, then `0`, respectively `0.0`, is returned for any value of `m`.

For symbolic values of `x`, `f(x)` returns the symbolic call `stats::poissonCDF(m)(x)`.

Numerical values for `m` are only accepted if they are nonnegative.

If `x` is a real floating-point number, the result is a floating number provided *m* is a nonnegative numerical value. If both `x` and `m` are exact numerical values, the result is an exact number.

Note Note that for large *m*, floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number `x` to `stats::poissonCDF`!

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the distribution function with `m` = 1/2 at various points:
f := stats::poissonCDF(1/2): f(-PI) = f(float(-PI)), f(0) = f(0.0), f(4) = f(4.0)0 = 0.0, exp(-1/2) = 0.6065306597, (211*exp(-1/2))/128 = 0.9998278844

$$0 = 0.0,\ e^{-\frac{1}{2}} = 0.6065306597,\ \frac{211\,e^{-\frac{1}{2}}}{128} = 0.9998278844$$

delete f:

Example 2

We use symbolic arguments. If `x` is symbolic, a symbolic call is returned:
f := stats::poissonCDF(m): f(x)stats::poissonCDF(m)(x)

$$\text{stats::poissonCDF}(m)(x)$$

If `x` is a numerical value, symbolic expressions in `m` are returned:
f(-1), f(0), f(5/2), f(PI)0, exp(-m), exp(-m)*(m^2/2 + m + 1), exp(-m)*(m^3/6 + m^2/2 + m + 1)

$$0,\ e^{-m},\ e^{-m}\left(\frac{m^2}{2}+m+1\right),\ e^{-m}\left(\frac{m^3}{6}+\frac{m^2}{2}+m+1\right)$$

When numerical values are assigned to *m*, the function *f* starts to produce explicit results if the argument is numerical:
m := 3: f(-1), f(0), f(5/2), f(PI)0, exp(-3), (17*exp(-3))/2, 13*exp(-3)

$0, e^{-3}, \frac{17\,e^{-3}}{2}, 13\,e^{-3}$
delete f, m:

Parameters

m

The mean: an arithmetical expression representing a nonnegative real number

Return Values

procedure.

See Also

stats::poissonPFstats::poissonQuantilestats::poissonRandom

stats::poissonPF

Purpose

Probability function of the Poisson distribution

Syntax

```
stats::poissonPF(m)
```

Description

`stats::poissonPF(m)` returns a procedure representing the probability function

(x) -> (m^x * e^(-m))/(x!)

$$x \to \frac{m^x e^{-m}}{x!}$$

of the Poisson distribution with mean `m`.

The procedure `f := stats::poissonPF(m)` can be called in the form `f(x)` with arithmetical expressions `x`. The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

If `x` is a non-integer numerical value, $f(x)$ returns `0` or `0.0`, respectively.

If `x` is an integer or the floating-point equivalent of an integer, then an explicit value is returned.

In all other cases, `f(x)` returns the symbolic call `stats::poissonPF(n,p)(x)`.

Numerical values for `m` are only accepted if they are nonnegative.

If `x` is a floating-point number, the result is a floating-point number provided m is a nonnegative numerical value. If both `x` and `m` are exact values then the result is an exact number.

Note that for large m, floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number `x` to the procedure generated by `stats::poissonPF`.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We calculate the Poisson probability with $m = 8$ at various points:
f := stats::poissonPF(8): f(-1), f(-1.0), f(0), f(1/2), f(1), f(3/2), f(3) = f(float(3))0, 0.0, exp(-8), 0, 8*exp(-8), 0, (256*exp(-8))/3 = 0.02862614425

$$0,\ 0.0,\ e^{-8},\ 0,\ 8\,e^{-8},\ 0,\ \frac{256\,e^{-8}}{3} = 0.02862614425$$

delete f:

Example 2

We use symbolic arguments:
f := stats::poissonPF(m): f(x)stats::poissonPF(m)(x)

$$\text{stats::poissonPF}(m)(x)$$

If `x` is a numerical value, symbolic expressions in `m` are returned:
f(8), f(17/2), f(9.0), f(9.2)(m^8*exp(-m))/40320, 0, 0.000002755731922*m^9.0*exp(-1.0*m), 0.0

$$\frac{m^8\,e^{-m}}{40320},\ 0,\ 0.000002755731922\,m^{9.0}\,e^{-1.0\,m},\ 0.0$$

When numerical values are assigned to m, the function f starts to produce numbers if the argument is numerical:
m := 3: f(8), f(17/2), f(9.0), f(9.2)(729*exp(-3))/4480, 0, 0.002700503932, 0.0

$$\frac{729\,e^{-3}}{4480},\ 0,\ 0.002700503932,\ 0.0$$

delete f, m:

Parameters

m

The mean: an arithmetical expression representing a nonnegative real number

Return Values

procedure.

See Also

stats::poissonCDFstats::poissonQuantilestats::poissonRandom

stats::poissonQuantile

Purpose

Quantile function of the Poisson distribution

Syntax

```
stats::poissonQuantile(m)
```

Description

`stats::poissonQuantile(m)` returns a procedure representing the quantile function (discrete inverse) of the cumulative distribution function `stats::poissonCDF(m)`. For $0 \le x \le 1$, k = `stats::poissonQuantile(m)(x)` is the smallest nonnegative integer satisfying

stats::poissonCDF(m)(k) = sum((m^i * e^(-m))/(i!), i=0..k) >= x

$$\text{stats::poissonCDF}(m)(k) = \sum_{i=0}^{k} \frac{m^i}{e^m\, i!} \ge x$$

The procedure `f := stats::poissonQuantile(m)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of the call `f(x)` is either a nonnegative integer, infinity, or a symbolic expression:

If m is a nonnegative real number and x a real number satisfying $0 \le x < 1$, then $f(x)$ returns a nonnegative integer.

If $m = 0$, then $f(x)$ returns `0` for any x.

If $m \neq 0$, then $f(1)$ and $f(1.0)$ return infinity.

In all other cases, `f(x)` returns the symbolic call `stats::poissonQuantile(m)(x)`.

Numerical values for `m` are only accepted if they are positive.

If floating-point arguments are passed to the quantile function f, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors. In particular, round-off may be significant for arguments x close to 1. Cf. "Example 3" on page 30-329.

Finite quantile values k = `stats::poissonQuantile(m)(x)` satisfy

stats::poissonCDF(m)(k - 1) < x <= stats::poissonCDF(m)(k)

$$\text{stats::poissonCDF}(m)(k-1) < x \le \text{stats::poissonCDF}(m)(k)$$

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with $m = \pi$ at various points:
f := stats::poissonQuantile(PI): f(0), f(1/20), f(0.3), f(PI/6), f(0.7), f(1-1/10^10), f(1)0, 1, 2, 3, 4, 20, infinity

$$0,\ 1,\ 2,\ 3,\ 4,\ 20,\ \infty$$

The value `f(x)` satisfies

stats::poissonCDF(Symbol::pi)(f(x) -1) < x <= stats::poissonCDF(Symbol::pi)(f(x))

$$\text{stats::poissonCDF}(\pi)(f(x)-1) < x \le \text{stats::poissonCDF}(\pi)(f(x))$$

x := 0.98: k := f(x)7

$$7$$

float(stats::poissonCDF(PI)(k - 1)), x, float(stats::poissonCDF(PI)(k))0.9588410737, 0.98, 0.9847376421

$$0.9588410737,\ 0.98,\ 0.9847376421$$

delete f, x, k:

Example 2

We use symbolic arguments:

f := stats::poissonQuantile(m): f(x), f(9/10)stats::poissonQuantile(m)(x), stats::poissonQuantile(m)(9/10)

$$\text{stats::poissonQuantile}(m)(x),\ \text{stats::poissonQuantile}(m)\left(\frac{9}{10}\right)$$

When `m` evaluates to a positive real number, the function `f` starts to produce quantile values:
m := 17: f(1/2), f(999/1000), f(1 - 1/10^10), f(1 - 1/10^80)17, 31, 49, 144

$$17,\ 31,\ 49,\ 144$$

delete f, m:

Example 3

If floating-point arguments are passed to the quantile function, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors:
f := stats::poissonQuantile(123): f(1 - 1/10^19) <> f(float(1 - 1/10^19))236 <> infinity

$$236 \neq \infty$$

delete f:

Parameters

m

The mean: a arithmetical expression representing a nonnegative real number

Return Values

procedure.

See Also

stats::poissonCDFstats::poissonPFstats::poissonRandom

stats::poissonRandom

Purpose

Generate a random number generator for Poisson deviates

Syntax

```
stats::poissonRandom(m, <Seed = s>)
```

Description

`stats::poissonRandom(m)` returns a procedure that produces poisson-deviates (random numbers) with mean *m*.

The procedure `f := stats::poissonRandom(m)` can be called in the form `f()`. The return value of `f()` is a nonnegative integer if `m` is a nonnegative numerical value.

Otherwise, `stats::poissonRandom(m)()` is returned symbolically.

Numerical values for `m` are only accepted if they are nonnegative.

The values `X = f()` are distributed randomly according to the discrete distribution function of the Poisson distribution with mean `m`, i.e., for $0 \le x$, the probability of $X \le x$ is given by

sum((m^i*e^(-m))/(i!), i=0..floor(x))

$$\sum_{i=0}^{\lfloor x \rfloor} \frac{m^i}{e^m\, i!}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note With this option, the mean `m` must evaluate to a nonnegative numerical value at the time, when the generator is created.

Note In contrast to the function random, the generators produced by `stats::poissonRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::poissonRandom(m):  f() $k = 1..K;
```

rather than by

```
stats::poissonRandom(m)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::poissonRandom(m, Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate Poisson deviates with mean m = 80:
f := stats::poissonRandom(80): f() $ k = 1..1069, 105, 77, 81, 71, 79, 86, 77, 87, 97

```
69, 105, 77, 81, 71, 79, 86, 77, 87, 97
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::poissonRandom(m): f()stats::poissonRandom(m)()

stats::poissonRandom(*m*)()

When *m* evaluates to a positive real number, the generator starts to produce random numbers:
m := 80: f(), f(), f()89, 76, 82

89, 76, 82
delete f, m:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:
f := stats::poissonRandom(12, Seed = 1): f() $ k = 1..1012, 15, 8, 9, 15, 4, 12, 9, 7, 10

12, 15, 8, 9, 15, 4, 12, 9, 7, 10
g := stats::poissonRandom(12, Seed = 1): g() $ k = 1..1012, 15, 8, 9, 15, 4, 12, 9, 7, 10

12, 15, 8, 9, 15, 4, 12, 9, 7, 10
f() = g(), f() = g()11 = 11, 11 = 11

11 = 11, 11 = 11
delete f, g:

Parameters

m

The mean: an arithmetical expression representing a nonnegative real number

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the mean `m` must be convertible to a positive floating-point number at the time when the random generator is generated.

Return Values

procedure.

See Also

stats::poissonCDFstats::poissonPFstats::poissonQuantile

stats::quadraticMean

Purpose

Quadratic mean of a data sample

Syntax

```
stats::quadraticMean(x1, x2,  )
stats::quadraticMean([x1, x2,  ])
stats::quadraticMean(s, <c>)
```

Description

`stats::quadraticMean`(x_1, x_2, ..., x_n) returns the quadratic mean

sqrt(1/(n) * sum(x[i]^2, i=1..n))

$$\sqrt{\frac{1}{n}\left(\sum_{i}^{n} x_i^2\right)}$$

of the data x_i.

The column index `c` is optional, if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-335.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the quadratic mean of three values:
stats::quadraticMean(a, b, c)sqrt(a^2/3 + b^2/3 + c^2/3)

$$\sqrt{\frac{a^2}{3} + \frac{b^2}{3} + \frac{c^2}{3}}$$

Alternatively, data may be passed as a list:
stats::quadraticMean([2, 3, 5])(sqrt(3)*sqrt(38))/3

$$\frac{\sqrt{3}\,\sqrt{38}}{3}$$

Example 2

We create a sample:
stats::sample([[a1, b1, c1], [a2, b2, c2]]) a1 b1 c1 a2 b2 c2

The quadratic mean of the second column is:
stats::quadraticMean(%, 2)sqrt(b1^2/2 + b2^2/2)

$$\sqrt{\frac{b1^2}{2} + \frac{b2^2}{2}}$$

Example 3

We create a sample consisting of one string column and one non-string column:
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]]) "1996" 1242 "1997" 1353 "1998" 1142

We compute the quadratic mean of the second column. In this case this column does not have to be specified, since it is the only non-string column:
float(stats::quadraticMean(%))1248.644198

1248.644198

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions.

s

A sample of domain type stats::sample.

c

An integer representing a column index of the sample `s`. This column provides the data `x1`, `x2` etc.

Return Values

arithmetical expression.

See Also stats::geometricMeanstats::harmonicMeanstats::meanstats::medianstats::modalstats::stdevst

stats::reg

Purpose

Regression (general linear and nonlinear least squares fit)

Syntax

```
stats::reg([x_1,1,  ,x_k,1], ,[x_1,m,  ,x_k,m], [y_1,  ,y_k],
<[w_1,  ,w_k]>, f, [x_1, x_m], [p_1,  ,p_n], <StartingValues =
[p_1(0),  ,p_n(0)]>, <CovarianceMatrix>)
stats::reg([[x_1,1,  ,x_1,m, y_1, <w_1>], ,[x_k,1,  ,x_k,m,
y_k, <w_k>]], f, [x_1,  ,x_m], [p_1,  ,p_m], <StartingValues =
[p_1(0),  ,p_n(0)]>, <CovarianceMatrix>)
stats::reg(s, c_1,  ,c_m, cy, <cw>, f, [x_1,  ,x_m], [p_1,  ,p_n],
<StartingValues = [p_1(0),  ,p_n(0)]>, <CovarianceMatrix>)
stats::reg(s, [c_1, c_m], cy, <cw>, f, [x_1,  ,x_m], [p_1,  ,p_n],
<StartingValues = [p_1(0),  ,p_n(0)]>, <CovarianceMatrix>)
```

Description

Consider a "model function" f with n parameters p_1, ..., p_n relating a dependent variable y and m independent variables x_1, ..., x_m: $y = f(x_1, ..., x_m, p_1, ..., p_n)$. Given k different measurements x_{1j}, ..., x_{kj} for the independent variables x_j and corresponding measurements y_1, ..., y_k for the dependent variable y, one fits the parameters p_1, ..., p_n by minimizing the "weighted quadratic deviation" ("chi-squared")

_outputSequence(Symbol::chi^2, fenced (p[1], Symbol::hellip, p[n]))=sum(w[i] * abs(y[i]-f(x[(i1)], Symbol::hellip, x[(im)], p[1], Symbol::hellip ,p[n]))^2, i=1..k)

$$\chi^2(p_1, ..., p_n) = \sum_{i}^{k} w_i \left| y_i - f(x_{i1}, ..., x_{im}, p_1, ..., p_n) \right|^2$$

`stats::reg(..data.., f, [x.1, ...  , x.m], [p.1, ...  , p.n], [w.1, ..., w.n])` computes numerical approximations of the fit parameters p_1, ..., p_n.

All data must be convertible to real or complex floating-point values via float.

The number of measurements k must not be less than the number n of parameters p_i.

The model function f may be non-linear in the independent variables x_i and the fit parameters p_i. E.g., a model function such as `p1 + p2*x1^2 + exp(p3 + p4*x2)` with the independent variables `x1, x2` and the fit parameters `p1, p2, p3, p4` is accepted.

Note that the fitting of model functions with a non-linear dependence on the parameters p_i is much more costly than a linear regression, where the p_i enter linearly. The functional dependence of the model function on the variables x_i is of no relevance.

Note There are rare cases where the implemented algorithm converges to a local minimum rather than to a global minimum. In particular, this problem may arise when the model involves periodic functions. It is recommended to provide suitable starting values for the fit parameters in this case. Cf. "Example 4" on page 30-340.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We fit a linear function $y = p_1 + p_2 x_1$ to four data pairs (x_{i1}, y_i) given by two lists:

```
stats::reg([0, 1, 2, 3], [1, 3, 5, 7], p1 + p2*x1, [x1], [p1, p2])[[1.0, 2.0], 0.0]
```

```
[[1.0, 2.0], 0.0]
```

The parameter values $p_1 = 1.0$, $p_2 = 2.0$ provide a perfect fit: up to numerical round-off, the quadratic deviation vanishes.

Example 2

We fit an exponential function $y = ae^{bx}$ to five data pairs (x_i, y_i). Weights are used to decrease the influence of the "exceptional pair" $(x, y) = (5.0, 6.5\ 10^6)$ on the fit:
stats::reg([[1.1, 54, 1], [1.2, 73, 1], [1.3, 98, 1], [1.4, 133, 1], [5.0, 6.5*10^6, 10^(-4)]], a*exp(b*x), [x], [a, b])[[1.992321622, 2.999602426], 0.2001899629]

```
[[1.992321622, 2.999602426], 0.2001899629]
```

Example 3

We create a sample with four columns. The first column is a counter labeling the measurements. This column is of no further relevance here. The second and third column provide measured data of two variables x_1 and x_2, respectively. The last column provides corresponding measurements of a dependent variable.
s := stats::sample([[1, 0, 0, 1.1], [2, 0, 1, 5.4], [3, 1, 1, 8.5], [4, 1, 2, 18.5], [5, 2, 1, 15.0], [6, 2, 2, 24.8]]) 1 0 0 1.1 2 0 1 5.4 3 1 1 8.5 4 1 2 18.5 5 2 1 15.0 6 2 2 24.8

First, we try to model the data provided by the columns 2, 3, 4 by a function that is linear in the variables x_1, x_2. We specify the data columns by a list of column indices:
stats::reg(s, [2, 3, 4], p1 + p2*x1 + p3*x2, [x1, x2], [p1, p2, p3])[[-0.9568181818, 4.688636364, 7.272727273], 15.23613636]

```
[[-0.9568181818, 4.688636364, 7.272727273], 15.23613636]
```

The quadratic deviation is rather large, indicating that a linear function is inappropriate to fit the data. Next, we extend the model and consider a polynomial fit function of degree 2. This is still a linear regression problem, because the fit parameters enter the model function linearly. We specify the data columns by a sequence of column indices:
stats::reg(s, 2, 3, 4, p1 + p2*x1 + p3*x2 + p4*x1^2 + p5*x2^2, [x1, x2], [p1, p2, p3, p4, p5])[[1.1, 1.525, 1.5, 1.625, 2.8], 0.01]

[[1.1, 1.525, 1.5, 1.625, 2.8], 0.01]

Finally, we include a further term `p6*x1*x2` in the model, obtaining a perfect fit:
stats::reg(s, 2, 3, 4, p1 + p2*x1 + p3*x2 + p4*x1^2 + p5*x2^2 + p6*x1*x2, [x1, x2], [p1, p2, p3, p4, p5, p6])[[1.1, 1.6, 1.35, 1.7, 2.95, -0.2], 1.796307589e-27]

$$\left[[1.1,\ 1.6,\ 1.35,\ 1.7,\ 2.95,\ -0.2],\ 1.796307589\ 10^{-27}\right]$$

delete s:

Example 4

We create a sample of two columns:
s := stats::sample([[1, -1.44], [2, -0.82], [3, 0.97], [4, 1.37]]) 1 -1.44 2 -0.82 3 0.97 4 1.37

The data are to be modeled by a function of the form $y = p_1 sin(p_2 x)$, where the first column contains measurements of x and the second column contains corresponding data for y. Note that in this example there is no need to specify column indices, because the sample contains only two columns:
stats::reg(s, a*sin(b*x), [x], [a, b])[[-1.499812823, 1.281963381], 0.00001255632629]

[[-1.499812823, 1.281963381], 0.00001255632629]

Fitting a periodic function may be problematic. We provide starting values for the fit parameters and obtain a quite different set of parameters approximating the data with the same quality:
stats::reg(s, a*sin(b*x), [x], [a, b], StartingValues = [2, 5])[[1.499812823, 5.001221926], 0.00001255632629]

[[1.499812823, 5.001221926], 0.00001255632629]

delete s:

Example 5

The blood sugar level y (in mmol/L) of a diabetic is measured over a period of 10 days with 5 measurements per day at x1 = 7 (o'clock a.m.), x1 = 12 (noon), x1 = 15 (afternoon), x1 = 19 (before dinner), and x1 = 23 (bed time). These are the measurements:
Y:= //hour: 7 12 15 19 23 [[7.2, 5.5, 6.8, 5.4, 6.0], // day 1 [6.3, 5.0, 5.5, 5.8, 4.9], // day 2 [6.5, 6.3, 4.8, 4.5, 5.0], // day 3 [4.3, 5.2, 4.3, 4.7, 4.0], // day 4 [7.1, 7.2, 6.7, 7.2, 5.5], // day 5 [5.8, 5.5, 4.9, 5.0, 6.2], // day 6 [6.2, 4.8, 5.0, 5.2, 5.3], // day 7 [4.8, 5.8, 5.7, 6.2, 5.0], // day 8 [5.2, 3.8, 4.8, 5.8, 4.7], // day 9 [5.8, 4.7, 5.0, 6.5, 6.3] // day 10]:

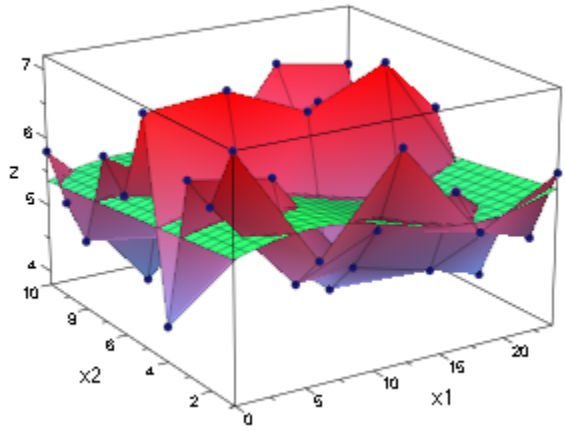
We have a total of 50 measurements. Each measurement is a triple [x1, x2, y], where *x1* is the hour of the day, *x2* is the day number, and y is the blood sugar level:
data:= [([7, x2, Y[x2][1]], [12, x2, Y[x2][2]], [15, x2, Y[x2][3]], [19, x2, Y[x2][4]], [23, x2, Y[x2][5]]) $ x2 = 1 .. 10]:

We model the blood sugar y as a function of the hour of the day x1 and the day number x2 (trying to detect a general tendency). We assume a periodic dependence on x1 with a period of 24 hours:
y := y0 + a*x2 + b*sin(2*PI/24*x1 + c):

A least squares fit of the given data leads to the following parameters y0, a, b, c:
[y0abc, residue]:= stats::reg(data, y, [x1, x2], [y0, a, b, c]): [y0, a, b, c]:= y0abc[5.809945498, -0.04618181818, 0.2055298076, 0.07751988162]

```
[5.809945498, -0.04618181818, 0.2055298076, 0.07751988162]
```

The average blood sugar level is y0 = _outputSequence(5.8, dots)5.8... with an improvement of a = _outputSequence(-0.046, dots)-0.046... per day. The amplitude of the daily variation of y is b = _outputSequence(0.205, dots)0.205.... We visualize the measurements Y by a plot::Matrixplot. The least squares fit of our model function y is added as a function graph:
plot(plot::Matrixplot(Y, x1 = 0..24, x2 = 1..10), plot::Function3d(y, x1 = 0..24, x2 = 1..10, Color = RGB::Green))



delete Y, data, y, y0abc, y0, a, b, c, residue:

Example 6

We consider a decaying radioactive source, whose activity N ("counts") is measured at intervals of 1 second. The physical model for the decay

is N(t)=N[0]*e^(-t/Symbol::tau) $N(t) = \frac{N_0}{e^{\frac{t}{\tau}}}$, where $N(t)$ is the count rate at time t, N_0 is the base rate at time $t = 0$ and τ is the lifetime of the radioactive source. Instead of taking data from an actual physical experiment, we create artificial data with a base rate $N_0 = 100$ and a lifetime $\tau = 300$:

```
T := [i $ i= 0 .. 100]: N := [100*exp(-t/300) $ t in T]:
```

By construction, we obtain a perfect fit when estimating the paramaters N_0 and τ of the model:

```
stats::reg(T, N, N0*exp(-t/tau), [t], [N0, tau]);[[100.0, 300.0],
1.133987551e-30]
```

$$\left[[100.0,\ 300.0],\ 1.133987551\ 10^{-30}\right]$$

We perturb the data:

```
N := [stats::poissonRandom(n)() $ n in N]:
```

Since the data n_i in N are Poissonian, their standard deviation is the square root of their mean: Symbol::sigma(n[i]) approx sqrt(n[i])$\sigma(n_i) \approx \sqrt{n_i}$. Thus, suitable weights for a least squares estimation of the parameters

are given by w[i]=1/Symbol::sigma(n[i])^2=1/n[i]$w_i = \frac{1}{\sigma(n_i)^2} = \frac{1}{n_i}$:
W := [1/n $ n in N]:

With these weights, a least squares fit of the model parameters N_0 and τ is computed. The option `CovarianceMatrix` is used to get information on confidence intervals for the parameters:
[p, chisquared, C] := stats::reg(T, N, W, N0*exp(-t/tau), [t], [N0, tau], CovarianceMatrix)[[95.43096895, 309.3571484], 87.4642626, matrix([[3.998386217, -61.38541859], [-61.38541859, 1302.650416]])]

$$\left[[95.43096895,\ 309.3571484],\ 87.4642626,\ \begin{pmatrix} 3.998386217 & -61.38541859 \\ -61.38541859 & 1302.650416 \end{pmatrix}\right]$$

The square roots of the diagonal elements of the covariance matrix provides the statistical standard deviations of the fit parameters:
sqrt(float(C[1,1])), sqrt(float(C[2,2]))1.999596513, 36.0922487

1.999596513, 36.0922487

Thus, the estimate for the base rate N_0 is _outputSequence(N[0], Symbol::pm, Symbol::sigma(N[0])) approx _outputSequence(95.4, Symbol::pm, 2.0) $N_0 \pm \sigma(N_0) \approx 95.4 \pm 2.0$, the estimate for the lifetime τ is _outputSequence(Symbol::tau, Symbol::pm, Symbol::sigma(Symbol::tau)) approx _outputSequence(309.4, Symbol::pm, 36.1) $\tau \pm \sigma(\tau) \approx 309.4 \pm 36.1$. The correlation matrix of the fit parameters is obtained from the covariance matrix via stats::correlationMatrix:
stats::correlationMatrix(C)matrix([[1.0, -0.8505677452], [-0.8505677452, 1.0]])

$$\begin{pmatrix} 1.0 & -0.8505677452 \\ -0.8505677452 & 1.0 \end{pmatrix}$$

delete T, N, W, p, chisquared, C:

Parameters

$x_{1,1}, \ldots, x_{k,m}$

Numerical sample data for the independent variables. The entry $x_{i,j}$ represents the i-th measurement of the independent variable x_j.

$y_1, \ldots, y_k$

Numerical sample data for the dependent variable. The entry y_i represents the i-th measurement of the dependent variable.

$w_1, \ldots, w_k$

Weight factors: positive real numerical values. The entry w_i is used as a weight for the data $x_{i,1}, \ldots, x_{i,m}, y_i$ of the i-th measurement. If no weights are provided, then $w_i = 1$ is used.

f

The model function: an arithmetical expression representing a function of the independent variables $x_1, \ldots, x_m$ and the fit parameters $p_1, \ldots, p_n$. The expression must not contain any symbolic objects apart from $x_1, \ldots, x_m, p_1, \ldots, p_n$.

$x_1, \ldots, x_m$

The independent variables: identifiers or indexed identifiers.

$p_1, \ldots, p_n$

The fit parameters: identifiers or indexed identifiers.

$p_1(0), \ldots, p_n(0)$

The user can assist the internal numerical search by providing numerical starting values $p_i(0)$ for the fit parameters p_i. These should be reasonably close to the optimal fit values. The starting values $p_i(0) = 1.0$ are used if no starting values are provided by the user.

s

A sample of domain type stats::sample containing the data $x_{i,j}$ for the independent variables, the data y_i for the dependent variable and, optionally, the weights w_i.

cy

A positive integer representing a column index of the sample `s`. This column provides the measurements y_i for the dependent variable.

cw

A positive integer representing a column index of the sample `s`. This column provides the weight factors w_i.

Options

StartingValues

Option, specified as `StartingValues = [p1(0),  ,pn(0)]`

Positive integers representing column indices of the sample `s`. Column p_j provides the measurements $x_{i,j}$ for the independent variable x_j.

If the model function depends linearly on the fit parameters p_j ("linear regression"), then the optimized parameters are the solution of a linear system of equations. In this case there is no need to provide starting values for a numerical search. In fact, initial values provided by the user are ignored.

If the model function depends non-linearly on the fit parameters p_j ("non-linear regression"), then the optimized fitting parameters are the solution of a non-linear optimization problem. There is no guarantee that the internal search for a numerical solution will succeed. It is recommended to assist the internal solver by providing reasonably good estimates for the optimal fit parameters.

CovarianceMatrix

Changes the return value from $[[p_1, ..., p_n], \chi^2]$ to $[[p_1, ..., p_n], \chi^2, C]$, where C is the covariance matrix of the estimators p_i given by $C_{i,i} = \sigma(p_i)^2$ and $C_{i,j} = cov(p_i, p_j)$ for $i \neq j$.

With this option, information on confidence intervals for the least squares estimators p_i are provided. In particular, the return value includes the covariance matrix C of type `Dom::Matrix()`. This matrix provides the variances $C_{ii} = \sigma(p_i)^2$ of the least squares estimators p_i and their covariances $C_{ij} = cov(p_i, p_j)$. The covariance matrix is defined via its inverse

(C^(-1))[i,j] = 1/2 * diff(Symbol::chi^2, p[i], p[j])

$$\left(\frac{1}{C}\right)_{i,j} = \frac{\frac{\partial}{\partial p_j}\frac{\partial}{\partial p_i}\chi^2}{2}$$

Where

_outputSequence(Symbol::chi^2, fenced (p[1], Symbol::hellip, p[n]))=sum(w[i] * abs(y[i]-f(x[(i1)], Symbol::hellip, x[(im)], p[1], dots, p[n]))^2, i=1..k)

$$\chi^2(p_1, \ldots, p_n) = \sum_{i=1}^{k} w_i \left| y_i - f(x_{i1}, \ldots, x_{im}, p_1, \ldots, p_n) \right|^2$$

The covariance matrix of the least squares estimators only has a statistical meaning if the stochastic variances $\sigma(y_i)^2$ of the measurements y_i are known. These variances are to be included in the computation by choosing the weights

w[i]=1/Symbol::sigma(y[i])^2 $w_i = \frac{1}{\sigma(y_i)^2}$. Cf. “Example 6” on page 30-342.

The function stats::correlationMatrix serves for converting the covariance matrix to the corresponding correlation matrix. See “Example 6” on page 30-342

Return Values

Without the option `CovarianceMatrix`, a list $[[p_1, \ldots, p_n], \chi^2]$ is returned. It contains the optimized fit parameters p_i minimizing the quadratic deviation. The minimized value of this deviation is given by χ^2, it indicates the quality of the fit.

With the option `CovarianceMatrix`, a list [[p_1, ..., p_n], χ^2, C] is returned. The n n matrix `C` is the covariance matrix of the fit parameters.

All returned data are floating-point values. `FAIL` is returned if a least square fit of the data is not possible with the given model function or if the internal numerical search failed.

Algorithms

`stats::reg` uses a Marquardt-Levenberg gradient expansion algorithm. Searching for the minimum of _outputSequence(Symbol::chi^2, fenced(p[1], Symbol::hellip, p[n]))$\chi^2(p_1, ..., p_n)$, the algorithm does not simply follow the negative gradient, but the diagonal terms of the curvature matrix are increased by a factor that is optimized in each step of the search.

stats::correlationMatrixstats::linRegstats::sample

stats::row

Purpose

Select and re-arrange rows of a sample

Syntax

```
stats::row(s, r1, <r2,  >)
stats::row(s, r1 .. r2, <r3 .. r4,  >)
```

Description

`stats::row(s, ..)` creates a new sample from selected rows of the sample `s`.

`stats::row` is useful for selecting rows of interest or for re-arranging rows.

The rows of `s` specified by the remaining arguments of `stats::row` are used to build a new sample. The new sample contains the rows of `s` in the order specified by the call to `stats::row`. Rows can be duplicated by specifying the row index more than once.

Examples

Example 1

The following sample represents the “population” of a small town:
stats::sample([["1990", 10564], ["1991", 10956], ["1992", 11007], ["1993", 11123], ["1994", 11400], ["1995", 11645]]) "1990" 10564 "1991" 10956 "1992" 11007 "1993" 11123 "1994" 11400 "1995" 11645

We are only interested in the years 1990, 1991, 1992 and 1995. We create a new sample containing the rows of interest:
stats::row(%, 1..3, 6) "1990" 10564 "1991" 10956 "1992" 11007 "1995" 11645

We reorder the sample:
stats::row(%, 4, 3, 2, 1) "1995" 11645 "1992" 11007 "1991" 10956 "1990" 10564

Parameters

s

A sample of domain type stats::sample.

r_1, r_2, ...

Positive integers representing row indices of the sample `s`. A range r[1] .. r[2] $r_1 .. r_2$ represents all rows from r_1 through r_2.

Return Values Sample of domain type stats::sample.

See Also stats::colstats::concatColstats::concatRowstats::selectRow

stats::sample

Purpose

Domain of statistical samples

Syntax

```
stats::sample([[a1,1, a1,2,  ], [a2,1, a2,2,  ],  ])
stats::sample([a1,1, a2,1,  ])
```

Description

sample represents a collection of statistical data, organized as a matrix. Usually, each row refers to an individual of the population described by the sample. Each column represents an attribute.

`stats::sample( [[a1,1,  , a1,n],  , [am,1,  , am,n]] )` creates a sample with m rows and n columns, $a_{i,j}$ being the entry in the i-th row, j-th column.

`stats::sample( [a1,1,  , am,1] )` creates a sample with m rows and one column.

Each row $[a_{i,1}, \ldots, a_{i,n}]$ must contain the same number of entries.

Elements of domain type DOM_COMPLEX, DOM_EXPR, DOM_FLOAT, DOM_IDENT, DOM_INT, or DOM_RAT are regarded as "data" and are stored in a sample as on input. All other types of input parameters are converted to strings (DOM_STRING).

If one element in a column is a string or is converted to a string, then all elements of that column are converted to strings.

This produces two kinds of columns: data columns and string columns.

Superdomain

Dom::BaseDomain

Axioms

Ax::canonicalRep

Categories

Cat::Set

Examples

Example 1

A sample is created from a list of rows:
stats::sample([[5, a], [b, 7.534], [7/4, c+d]]) 5 a b 7.534 7/4 c + d

For a sample with only one column one can use a flat list instead of a list of rows:
stats::sample([5, 3, 8]) 5 3 8

Example 2

The following input creates a small sample with columns for “gender”, “age” and “height”, respectively:
stats::sample([["m", 26, 180], ["f", 22, 160], ["f", 48, 155], ["m", 30, 172]]) "m" 26 180 "f" 22 160 "f" 48 155 "m" 30 172

Note that all entries in a column are automatically converted to strings, if one entry of that column is a string:
stats::sample([[m, 26, 180], [f, 22, 160], ["f", 48, 155], [m, 30, 172]]) "m" 26 180 "f" 22 160 "f" 48 155 "m" 30 172

Example 3

The functions float, has, map, nops, op, and subsop are overloaded to work on samples as on lists of lists:
s := stats::sample([[a, 1], [b, 2], [c, 3]]) a 1 b 2 c 3 float(s), has(s, a), map(s, list -> [list[1], list[2]^2]), nops(s), subsop(s, 1 = [d, 4]), op(s, [1, 2]) a 1.0 a 1 d 4 b 2.0 , TRUE, b 4 , 3, b 2 , 1 c 3.0 c 9 c 3

Indexing works like on arrays:
s[1, 2] := x : s a x b 2 c 3 delete s:

Example 4

The dot operator may be used to concatenate samples and lists (regarded a samples with one row):
s := stats::sample([[1, a], [2, b]]): s.[X, Y].s 1 a 2 b X Y 1 a 2 b delete s:

Parameters

$a_{1,1}$, $a_{1,2}$, ...

Arithmetical expressions or strings.

Methods

Mathematical Methods
equalTest for equality

```
equal(s1, s2)
```

Conversion Methods

convertConvert a list to a sample

```
convert(x)
```

convert_toConvert a sample to a list of lists

```
convert_to(s, T)
```

exprConvert a sample to a list of lists of expressions

```
expr(s)
```

Access Methods

sizeReturn the number of rows

```
size(s)
```

col2listReturn a particular column as a list

```
col2list(s, c,  )
```

appendAppend a row

```
append(s, row)
```

_concatCreate a sample from the rows of several samples

```
_concat(s, s1,  )
```

delColDelete one or more columns

```
delCol(s, c)
```

delRowDelete one or more rows

```
delRow(s, r)
```

floatMap the float function to all entries

```
float(s)
```

hasTest for the occurrence of elements

```
has(s, e)
```

If `e` is a list or a set, then this method tests, whether at least one of its elements is among the entries of `s`.

_indexReturn a particular entry

```
_index(s, i, j)
```

Indexed calls such as `s[i, j]` call this method.

set_indexAssign a new value to an entry

```
set_index(s, i, j, x)
```

This method is called by indexed assignments of the form `s[i, j] := x`.

mapMap a function to the rows

```
map(s, f)
```

nopsNumber of rows

```
nops(s)
```

opGet the operands (rows)

```
op(s, i)
```

```
op(s, [i, j])
```

subsopReplace a row

```
subsop(s, i = newrow,  )
```

row2listReturn a particular row as a list

```
row2list(s, r,  )
```

Technical Methods

printOutput

```
print(s)
```

fastprintFast output

```
fastprint(s)
```

stats::sample2list

Purpose

Convert a sample to a list of lists

Syntax

```
stats::sample2list(s)
```

Description

`stats::sample2list(s)` converts the sample `s` to a list of lists.

The sub-lists of the list returned by `stats::sample2list(s)` are the rows of the sample `s`.

Examples

Example 1

First we create a sample from a list of lists:
stats::sample([[123, s, 1/2], [442, s, -1/2], [322, p, -1/2]]) 123 s 1/2 442 s -1/2 322 p -1/2

The input list may be recovered by `stats::sample2list`:
stats::sample2list(%)[[123, s, 1/2], [442, s, -1/2], [322, p, -1/2]]

$$\left[\left[123,\ s,\ \frac{1}{2}\right],\ \left[442,\ s,\ -\frac{1}{2}\right],\ \left[322,\ p,\ -\frac{1}{2}\right]\right]$$

Parameters

s

A sample of domain type stats::sample.

Return Values

List of lists.

See Also

stats::unzipColstats::zipCol

stats::selectRow

Purpose

Select rows of a sample

Syntax

```
stats::selectRow(s, c, x, <Not>)
stats::selectRow(s, [c1, c2,  ], [x1, x2,  ], <Not>)
```

Description

`stats::selectRow(s, ...)` selects rows of the sample `s` having specific entries in specific places.

`stats::selectRow(s, c, x)` returns a sample consisting of all rows in `s`, which contain the data element `x` at the position `c`.

`stats::selectRow(s, [c1, c2,  ], [x1, x2,  ] )` returns a sample consisting of all rows in `s`, which contain the data element x_1 at the position c_1 *and* x_2 at the position c_2 etc. There must be as many positions c_1, c_2, ... as data elements x_1, x_2, ...

Examples

Example 1

We create a sample with two columns:
stats::sample([[a, 5], [c, 1], [a, 2], [b, 3]]) a 5 c 1 a 2 b 3

We select all rows with `a` as their first entry:
stats::selectRow(%, 1, a) a 5 a 2

Example 2

We create a sample containing income and costs in the years 1997 and 1998:
stats::sample([[123, "costs", "97"], [442, "income", "98"], [11, "costs", "98"], [623, "income", "97"]]) 123 "costs" "97" 442 "income" "98" 11 "costs" "98" 623 "income" "97"

We select the row which has `"income"` in the second and `"97"` in the third column:
stats::selectRow(%, [2, 3], ["income", "97"]) 623 "income" "97"

We select the remaining rows:
stats::selectRow(%2, [2, 3], ["income", "97"], Not) 123 "costs" "97" 442 "income" "98" 11 "costs" "98"

Parameters

s

A sample of domain type stats::sample.

c, c_1, c_2, ...

Integers representing column indices of the sample s.

x, x_1, x_2, ...

Arithmetical expressions.

Options

Not

Causes `stats::selectRow` to select those rows which do *not* have the specified entries.

Return Values

Sample of domain type stats::sample.

See Also

stats::row

stats::sortSample

Purpose

Sort the rows of a sample

Syntax

```
stats::sortSample(s)
stats::sortSample(s, c1, c2,  )
stats::sortSample(s, [c1, c2,  ])
```

Description

`stats::sortSample(s, ...)` sorts the rows of the sample `s`.

The sorting of rows only uses the entries of the specified columns. First, rows are sorted according to the elements of the first specified column. Those rows with identical elements in the first specified column are then ordered according to the elements in the second specified column etc.

If no columns are specified, then column 1 is used for sorting. In case of a tie, column 2 is used etc.

Numbers are sorted numerically, strings are sorted lexicographically. Identifiers are sorted according to the strategy used by the MuPAD sort command. Numbers come first, identifiers second.

Examples

Example 1

We create a sample with one column and sort it:
stats::sortSample(stats::sample([x, g2, 3, g1, 8/5, 2])) 8/5 2 3 g1 g2 x

Example 2

We create a sample with two columns:
stats::sample([[b, 2], [a, 5], [a, 2], [c, 1], [b, 3]]) b 2 a 5 a 2 c 1 b 3

Note the different sorting priorities specified by the column indices:
stats::sortSample(%, 1), stats::sortSample(%, 2), stats::sortSample(%, 1, 2), stats::sortSample(%, 2, 1) a 2 c 1 a 2 c 1 a 5 a 2 a 5 a 2 b 3 , b 2 , b 2 , b 2 b 2 b 3 b 3 b 3 c 1 a 5 c 1 a 5

Example 3

We create a sample containing income and costs in the years 1997 and 1998:

stats::sample([[123, "costs", "97"], [720, "income", "98"], [623, "income", "97"], [150, "costs", "98"]]) 123 "costs" "97" 720 "income" "98" 623 "income" "97" 150 "costs" "98"

We sort according to the year (third column):
stats::sortSample(%, 3) 623 "income" "97" 123 "costs" "97" 150 "costs" "98" 720 "income" "98"

We sort with priority on the year. Items of the same year are then sorted lexicographically ("costs" before "income"):
stats::sortSample(%2, 3, 2) 123 "costs" "97" 623 "income" "97" 150 "costs" "98" 720 "income" "98"

Parameters

s

A sample of domain type stats::sample.

c_1, c_2, ...

Integers representing column indices of the sample s.

Return Values

Sample of domain type stats::sample.

See Also

stats::selectRow

stats::stdev

Purpose

Standard deviation of a data sample

Syntax

```
stats::stdev(x1, x2,  , <Sample | Population>)
stats::stdev([x1, x2,  ], <Sample | Population>)
stats::stdev(s, <c>, <Sample | Population>)
```

Description

`stats::stdev( x1, x2, ..., xn)` returns the standard deviation

sqrt(1/(n-1) * sum((x[i]-‘x‾’)^2, i=1..n))

$$\sqrt{\frac{1}{n-1}\left(\sum_{i=1}^{n}(x_i-\overline{x})^2\right)}$$

where ‘x‾’ $\overline{x}$ is the arithmetic mean of the data x_i.

`stats::stdev( x1, x2, ..., xn, Population)` returns

sqrt(1/n * sum((x[i]-‘x‾’)^2, i=1..n))

$$\sqrt{\frac{1}{n}\left(\sum_{i=1}^{n}(x_i-\overline{x})^2\right)}$$

The standard deviation is the square root of the variance.

The column index `c` is optional, if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-360.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the standard deviation of three values:
stats::stdev(2, 3, 5)(sqrt(3)*sqrt(7))/3

$$\frac{\sqrt{3}\,\sqrt{7}}{3}$$

Alternatively, the data may be passed as a list:
stats::stdev([2, 3, 5])(sqrt(3)*sqrt(7))/3

$$\frac{\sqrt{3}\,\sqrt{7}}{3}$$

Example 2

We create a sample:
stats::sample([[a1, b1, c1], [a2, b2, c2]]) a1 b1 c1 a2 b2 c2

The standard deviation of the second column is:
expand(stats::stdev(%, 2))sqrt(2)*sqrt(b1^2/4 - (b1*b2)/2 + b2^2/4)

$$\sqrt{2}\,\sqrt{\frac{b1^2}{4} - \frac{b1\,b2}{2} + \frac{b2^2}{4}}$$

Example 3

We create a sample consisting of one string column and one non-string column:
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]]) "1996" 1242 "1997" 1353 "1998" 1142

We compute the standard deviation of the second column. In this case this column does not have to be specified, since it is the only non-string column:
float(stats::stdev(%))105.5477775

105.5477775

We repeat the computation with the option `Population`:
float(stats::stdev(%2, Population))86.17939945

86.17939945

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions

s

A sample of domain type stats::sample

c

An integer representing a column index of the sample `s`. This column provides the data x_1, x_2 etc.

Options

Population

Sample

With `Sample`, the data are regarded as a "sample", not as a full population. The default is `Sample`.

Return Values

Arithmetical expression.

See Also

stats::geometricMeanstats::harmonicMeanstats::meanstats::medianstats::modalstats::qua

stats::swGOFT

Purpose

The Shapiro-Wilk goodness-of-fit test for normality

Syntax

```
stats::swGOFT(x1, x2,  )
stats::swGOFT([x1, x2,  ])
stats::swGOFT(s, <c>)
```

Description

`stats::swGOFT`([x_1, x_2, ...]) applies the Shapiro-Wilk goodness-of-fit test for the null hypothesis: "the data x_1, x_2, ... are normally distributed (with unknown mean and variance)". The sample size must not be larger than 5000 and not smaller than 3.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

An error is raised by `stats::swGOFT` if any of the data cannot be converted to a real floating-point number or if the sample size is too large or too small.

Let y_1, ..., y_n be the input data x_1, ..., x_n arranged in ascending order. `stats::swGOFT` returns the list `[PValue = p, StatValue = w]` containing the following information:

- `w` is the attained value of the Shapiro-Wilk statistic

  W=sum(a[i]*y[i], i=1..n)^2/ (n*S^2) =
  sum(a[(n+1-i)]*(y[(n+1-i)]-y[i]),i=1..floor(n/2))^2/ (n*S^2)

$$W = \frac{\left(\sum_{i=1}^{n} a_i y_i\right)^2}{n S^2} = \frac{\left(\sum_{i=1}^{\lfloor \frac{n}{2} \rfloor} a_{n+1-i}\,(y_{n+1-i} - y_i)\right)^2}{n S^2}$$

  Here, the a_i are the Shapiro-Wilk coefficients, and `S^2` is the statistical variance of the sample.

- `p` is the observed significance level of the Shapiro-Wilk statistic W.

The observed significance level `PValue = p` returned by `stats::swGOFT` has to be interpreted in the following way: If `p` is smaller than a given significance level α<<1, the null hypothesis may be rejected at level α. If `p` is larger than α, the null hypothesis should not be rejected at level α.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We test a list of random data that purport to be a sample of normally distributed numbers:

```
f := stats::normalRandom(0, 1, Seed = 123): data := [f() $ i = 1..400]: stats::swGOFT(data)[PValue = 0.4902802259, StatValue = 0.9963301659]
```

```
[PValue = 0.4902802259, StatValue = 0.9963301659]
```

The observed significance level _outputSequence(0.490, dots)0.49... is not small. Consequently, one should not reject the null hypothesis that the data are normally distributed.

Next, we dote the data with some uniformly continuous deviates:

```
impuredata := data . [frandom() $ i = 1..101]: stats::swGOFT(impuredata)[PValue = 0.00001713272044, StatValue = 0.9833725964]
```

```
[PValue = 0.00001713272044, StatValue = 0.9833725964]
```

The doted data may be rejected as a sample of normal deviates at significance levels as small as _outputSequence(0.000017, dots)0.000017....

```
delete f, data, impuredata:
```

Example 2

We create a sample consisting of one string column and two non-string columns:

```
s := stats::sample( [["1996", 1242, PI - 1/2], ["1997", 1353, PI + 0.3],
["1998", 1142, PI + 0.5], ["1999", 1201, PI - 1], ["2001", 1201, PI] ])
"1996" 1242 PI - 1/2 "1997" 1353 PI + 0.3 "1998" 1142 PI + 0.5 "1999"
1201 PI - 1 "2001" 1201 PI
```

We check whether the data of the third column are normally distributed:

```
stats::swGOFT(s, 3)[PValue = 0.7314967372, StatValue = 0.9492034961]
```

```
[PValue = 0.7314967372, StatValue = 0.9492034961]
```

The observed significance level returned by the test is not small: the test does not indicate that the data are not normally distributed.

delete s:

Parameters

x_1, x_2, ...

The statistical data: real numerical values

s

A sample of domain type stats::sample

c

An integer representing a column index of the sample `s`. This column provides the data x_1, x_2 etc. There is no need to specify a column number `c` if the sample has only one column.

Return Values

List of two equations `[PValue = p, StatValue = w]` with floating-point values `p` and `w`. See the 'Details' section below for the interpretation of these values.

Algorithms

The implemented algorithm for the computation of the Shapiro-Wilk coefficients, the Shapiro-Wilk statistic and the observed significance level is based on: Patrick Royston, "Algorithm AS R94", Applied Statistics, Vol.44, No.4 (1995).

Following Royston, the Shapiro-Wilk coefficients a_i are computed by an approximation of

a=M*V^(-1)*fenced(fenced(M^T*V^(-1))*fenced(V^(-1)*M))^(-1)

$$a = \frac{M}{V\left(\left(M^T\right)\left(M\right)\right)}$$

where M denotes the expected values of standard normal order statistic for a sample, V is the corresponding covariance matrix, and M^T is the transpose of M.

stats::csGOFTstats::ksGOFTstats::tTest

stats::tabulate

Purpose

Statistics of duplicate rows in a sample

Syntax

```
stats::tabulate(s)
stats::tabulate(s, c1, c2,  , <f>)
stats::tabulate(s, c1 .. c2, c3 .. c4,  , <f>)
stats::tabulate(s, [c1, f1], [c2, f2],  )
stats::tabulate(s, [c1, c2,  , f1], [c3, c4,  , f2],  )
```

Description

`stats::tabulate(s)` eliminates duplicate rows in the sample `s` and appends a column containing the multiplicities.

`stats::tabulate( s, c1, c2,  , f )` combines all rows that are identical except for entries in the specified columns c_1, c_2 etc. The function `f` is applied to these columns, its result replaces the values in these columns.

`stats::tabulate( s, [c1, f1], [c2, f2],  )` combines all rows that are identical except for entries in the columns c_1, c_2 etc. The functions f_1, f_2 etc. are applied to these columns, the results replace the values in these columns.

`stats::tabulate` regards rows as duplicates if they have identical entries in the columns that are *not* specified.

With `stats::tabulate( s, c1, c2,  , f )` the function `f` is applied to the entries of the duplicate rows in the specified columns. Duplicates are eliminated and replaced by a single instance of the row, the result of `f` is inserted into the corresponding columns.

The function `f` must accept as many parameters as there are duplicates. Typical applications involve functions such as stats::mean which accept arbitrarily many arguments.

E.g., with stats::mean duplicate rows are replaced by a single row, in which the entries of the columns c_1, c_2 etc. are replaced by the mean values of the corresponding entries of the duplicates.

If no function `f` is specified, then the default function _plus is used.

If column indices are specified more than once, extra columns with the result of the specified function are inserted into the sample.

Consecutive columns may be specified by ranges. E.g., the call `stats::tabulate(s, c[1]..c[2], dots, f)` is a short hand notation for `stats::tabulate(s, c1, c1 + 1, , c2, , f)`.

With `stats::tabulate(s, [c1, f1], [c2, f2], )` pairs of columns and corresponding procedures are specified. Again, rows are regarded as duplicates if they have identical entries in the columns that are *not* specified. Duplicates are eliminated and replaced by a single instance of the row, the result of f_1 is inserted in column c_1, the result of f_2 is inserted in column c_2 etc.

If column indices are specified more than once, then extra columns with the result of the specified functions are inserted into the sample.

With `stats::tabulate(s, [c1, c2, , f1], )` it is possible to apply functions that act on several columns. The procedure f_1 has to accept a sequence of lists (each representing a column). The specified columns are replaced by a single column containing the result of f_1. If column indices are specified more than once, then extra columns with the result of the specified function(s) are inserted into the sample. See "Example 2" on page 30-368 and "Example 3" on page 30-368.

Examples

Example 1

We create a sample:
s := stats::sample([[a, A, 1], [a, A, 1], [a, A, 2], [b, B, 5], [b, B, 10]]) a A 1 a A 1 a A 2 b B 5 b B 10

Duplicate rows of the sample are counted. There are four unique rows, one occurring twice:
stats::tabulate(s) a A 1 2 a A 2 1 b B 5 1 b B 10 1

In the following call, rows are regarded as duplicates if the entries in the first two columns coincide. We compute the mean value of the third entry of the duplicates:
stats::tabulate(s, 3, stats::mean) a A 4/3 b B 15/2

We compute both the mean and the standard deviation of the data in the third column for the sub-samples labeled ‘a A’ and ‘b B’ by the first two columns:
stats::tabulate(s, [3, stats::mean], [3, stats::stdev]) a A 4/3 3^(1/2)/3 b B 15/2 (5*2^(1/2))/2 delete s:

Example 2

We create a sample containing columns for “gender”, “age” and “size”:
s := stats::sample([["f", 25, 166], ["m", 30, 180], ["f", 54, 160], ["m", 40, 170], ["f", 34, 170], ["m", 20, 172]]) "f" 25 166 "m" 30 180 "f" 54 160 "m" 40 170 "f" 34 170 "m" 20 172

We use stats::mean on the second and third column to calculate the average “age” and “size” of each gender:
stats::tabulate(s, 2..3, float@stats::mean) "f" 37.66666667 165.3333333 "m" 30.0 174.0

With the next call both the mean and the standard deviation of “age” and “size” for each gender are inserted into the sample.
stats::tabulate(s, [2, float@stats::mean], [2, float@stats::stdev], [3, float@stats::mean], [3, float@stats::stdev]) "f" 37.66666667 14.84362939 165.3333333 5.033222957 "m" 30.0 10.0 174.0 5.291502622

We compute the Bravais-Pearson correlation coefficient between “age” and “size” for each gender:
stats::tabulate(s, [2, 3, float@stats::correlation]) "f" -0.7540135991 "m" -0.1889822365 delete s:

Example 3

We create a sample:
s := stats::sample([[a, x1, 1, 2], [b, x2, 2, 4], [b, x1, 2, 4], [e, x2, 3, 5.5]]) a x1 1 2 b x2 2 4 b x1 2 4 e x2 3 5.5

We regard rows with the same entry in the second column as “of the same kind”. We tabulate the sample using different functions on the remaining columns:
stats::tabulate(s, [1, _plus], [3, _mult], [4, stats::mean]) a + b x1 2 3 b + e x2 6 4.75

One can apply customized procedures. In the following we define the procedure `plusmult`, which sums up the elements of two lists (representing columns) and then multiplies the sums.
plusmult := proc(x, y) begin _plus(op(x))*_plus(op(y)) end_proc:

This procedure is then used to combine the first and the third column. Simultaneously, the mean and the standard deviation of the fourth column is inserted into the sample.
stats::tabulate(s, [1, 3, plusmult], [4, stats::mean], [4, stats::stdev]) 3*a + 3*b x1 3 2^(1/2) 5*b + 5*e x2 4.75 1.060660172 delete plusmult, s:

Parameters

s

A sample of domain type stats::sample

c_1, c_2, ...

Integers representing column indices of the sample `s`

f, f_1, f_2, ...

Procedures

Return Values

Sample of domain type stats::sample.

See Also

stats::calc

stats::tCDF

Purpose

Cumulative distribution function of Student's t-distribution

Syntax

```
stats::tCDF(a)
```

Description

`stats::tCDF(a)` returns a procedure representing the cumulative distribution function

x -> gamma((a+1)/2)/(gamma(a/2)*sqrt(a*PI)) * int((1+t^2/a)^(-(a+1)/2), t=-infinity..x)

$$x \to \frac{\Gamma\left(\frac{a+1}{2}\right)}{\Gamma\left(\frac{a}{2}\right)\sqrt{a\pi}} \int_{-\infty}^{x} \frac{1}{\left(1+\frac{t^2}{a}\right)^{\frac{a+1}{2}}}\, dt$$

of Student's t-distribution with shape parameter ('degrees of freedom') `a>0`.

The procedure `f := stats::tCDF(a)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `a` can be converted to a positive floating point number `x` is a real number, the return value `f(x)` is a floating-point number.

`f(infinity)` produces `0.0`; `f(-infinity)` produces `1.0`.

In all other cases, `f(x)` returns the symbolic call `stats::tCDF(a)(x)`.

The procedure `f := stats::tCDF(a)` can also be called in the form `f(x, Symbolic)` with arithmetical expressions `x`.

If `a` is a positive integer, explicit symbolic expressions in `x` are returned. Otherwise, the function behaves as if called without the option `Symbolic`. Cf. "Example 3" on page 30-371.

Numerical values of `a` are only accepted if they are positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the cumulative distribution function with a = 3/4 $\frac{3}{4}$ at various points:
f := stats::tCDF(3/4): f(-infinity), f(-4), f(0), f(1/2), f(0.75), f(PI), f(infinity)0.0, 0.1085580939, 0.5, 0.6374082038, 0.689341961, 0.8707365121, 1.0

0.0, 0.1085580939, 0.5, 0.6374082038, 0.689341961, 0.8707365121, 1.0

Nonpositive numerical values of the shape parameter lead to an error:
stats::tCDF(-1)(0.75) Error: The shape parameter must be positive.
[stats::tCDF] delete f:

Example 2

We use symbolic arguments:
f := stats::tCDF(a): f(x), f(1/3), f(0.4)stats::tCDF(a)(x), stats::tCDF(a)(1/3), stats::tCDF(a)(0.4)

stats::tCDF(*a*)(*x*), stats::tCDF(*a*)$\left(\frac{1}{3}\right)$, stats::tCDF(*a*)(0.4)

When a positive real number is assigned to a, the call *f*(*x*) returns a floating-point number if *x* is numerical:
a := sqrt(10): f(PI)0.9759846335

0.9759846335

delete f, a:

Example 3

We demonstrate the option `Symbolic`. Without this option, the CDF function only produces explicit results if both a and x are numerical values:
stats::tCDF(3)(x)stats::tCDF(3)(x)

stats::tCDF(3)(*x*)

If the shape parameter is a positive integer, an explicit symbolic representation of the t-distribution exists for any *x*:
f := stats::tCDF(3): f(x, Symbolic)arctan((sqrt(3)*x)/3)/PI + (sqrt(3)*x)/(3*((PI*x^2)/3 + PI)) + 1/2

$$\frac{\arctan\left(\frac{\sqrt{3}\,x}{3}\right)}{\pi} + \frac{\sqrt{3}\,x}{3\left(\frac{x^2}{3}+1\right)\pi} + \frac{1}{2}$$

No internal floating-point conversions occur even if all input parameters are exact numerical values:
f(sqrt(2), Symbolic) = f(sqrt(2))arctan((sqrt(2)*sqrt(3))/3)/PI + (sqrt(2)*sqrt(3))/(5*PI) + 1/2 = 0.8738922518

$$\frac{\arctan\left(\frac{\sqrt{2}\,\sqrt{3}}{3}\right)}{\pi} + \frac{\sqrt{2}\,\sqrt{3}}{5\,\pi} + \frac{1}{2} = 0.8738922518$$

If the shape parameter is not a positive integer, the option `Symbolic` has no effect. The function *f* behaves as if called without this option:
f := stats::tCDF(PI): f(sqrt(2), Symbolic) = f(sqrt(2))0.8758345238 = 0.8758345238

$$0.8758345238 = 0.8758345238$$

f := stats::tCDF(PI): f(x, Symbolic)stats::tCDF(PI)(x, Symbolic)

$$\text{stats::tCDF}(\pi)(x, \text{Symbolic})$$

delete f:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also stats::tPDFstats::tQuantilestats::tRandom

stats::tPDF

Purpose

Probability density function of Student's t-distribution

Syntax

```
stats::tPDF(a)
```

Description

`stats::tPDF(a)` returns a procedure representing the probability density function

x -> gamma((a+1)/2)/(gamma(a/2)*sqrt(a*PI)) * (1+x^2/a)^(-(a+1)/2)

$$x \to \frac{\Gamma\left(\frac{a+1}{2}\right)}{\Gamma\left(\frac{a}{2}\right)\sqrt{a\,\pi}\left(\frac{x^2}{a}+1\right)^{\frac{a}{2}+\frac{1}{2}}}$$

of Student's t-distribution with shape parameter ('degrees of freedom') `a` > 0.

The procedure `f := stats::tPDF(a)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `x` is a floating-point number and `a` can be converted to a floating-point number, then `f(x)` returns a floating-point number.

`f(infinity)` and `f(-infinity)` produce the result `0.0`.

In all other cases, the expression gamma((a+1)/2)/(gamma(a/2)*sqrt(a)*sqrt(PI)) * (1+x^2/a)^(-(a+1)/2) is returned.

$$\frac{\Gamma\left(\frac{a+1}{2}\right)}{\Gamma\left(\frac{a}{2}\right)\sqrt{a}\,\sqrt{\pi}\left(\frac{x^2}{a}+1\right)^{\frac{a}{2}+\frac{1}{2}}}$$

If floating-point results are desired, call `f(x)` with a floating-point value `x`.

Numerical values for `a` are only accepted if they are real and positive.

Examples

Example 1

We evaluate the probability density function with a = 3/4 at various points:

f := stats::tPDF(3/4): f(-infinity), f(-PI), f(1/2), f(0.5), f(3), f(infinity)0.0, (2*sqrt(3)*gamma(7/8))/(3*sqrt(PI)*gamma(3/8)*((4*PI^2)/3 + 1)^(7/8)), (3^(3/8)*4^(1/8)*gamma(7/8))/(2*sqrt(PI)*gamma(3/8)), 0.232826673, (2*sqrt(3)*13^(1/8)*gamma(7/8))/(39*sqrt(PI)*gamma(3/8)), 0.0

$$0.0, \frac{2\sqrt{3}\,\Gamma\left(\frac{7}{8}\right)}{3\sqrt{\pi}\,\Gamma\left(\frac{3}{8}\right)\left(\frac{4\pi^2}{3}+1\right)^{7/8}}, \frac{3^{3/8}\,4^{1/8}\,\Gamma\left(\frac{7}{8}\right)}{2\sqrt{\pi}\,\Gamma\left(\frac{3}{8}\right)}, 0.232826673, \frac{2\sqrt{3}\,13^{1/8}\,\Gamma\left(\frac{7}{8}\right)}{39\sqrt{\pi}\,\Gamma\left(\frac{3}{8}\right)}, 0.0$$

delete f:

Example 2

We use symbolic arguments:

f := stats::tPDF(a): f(x), f(0.3)gamma(a/2 + 1/2)/(sqrt(PI)*sqrt(a)*gamma(a/2)*(x^2/a + 1)^(a/2 + 1/2)), (0.5641895835*gamma(a/2 + 1/2))/(sqrt(a)*gamma(a/2)*(0.09/a + 1)^(a/2 + 1/2))

$$\frac{\Gamma\left(\frac{a}{2}+\frac{1}{2}\right)}{\sqrt{\pi}\sqrt{a}\,\Gamma\left(\frac{a}{2}\right)\left(\frac{x^2}{a}+1\right)^{\frac{a}{2}+\frac{1}{2}}}, \frac{0.5641895835\,\Gamma\left(\frac{a}{2}+\frac{1}{2}\right)}{\sqrt{a}\,\Gamma\left(\frac{a}{2}\right)\left(\frac{0.09}{a}+1\right)^{\frac{a}{2}+\frac{1}{2}}}$$

When numerical values are assigned to a, the function f starts to produce floating-point values for floating-point arguments:

a := PI: f(0.3)0.347916859

$$0.347916859$$

delete f, a:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

Return Values procedure.

See Also stats::tCDFstats::tQuantilestats::tRandom

stats::tQuantile

Purpose

Quantile function of Student's t-distribution

Syntax

```
stats::tQuantile(a)
```

Description

`stats::tQuantile(a)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::tCDF(a)`. For $0 \le x \le 1$, the solution of *stats*::*tCDF*(*a*)(*y*) = *x* is given by *y* = *stats*::*tQuantile*(*a*)(*x*).

The procedure `f := stats::tQuantile(a)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, ±infinity, or a symbolic expression:

If `x` is a real number between `0` and `1` and the shape parameter `a` can be converted to a positive real floating-point number, then `f(x)` returns a real floating-point number approximating the solution `y` of `stats::tCDF(a)(y) = x`.

The calls `f(1/2)` and `f(0.5)` produce `0.0` for all values of `a`.

The calls `f(0)` and `f(0.0)` produce -infinity for all values of `a`.

The calls `f(1)` and `f(1.0)` produce infinity for all values of `a`.

In all other cases, `f(x)` returns the symbolic call `stats::tQuantile(a)(x)`.

Numerical values of *x* are only accepted if $0 \le x \le 1$.

Numerical values of the shape parameter `a` are only accepted if they are real and positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with `a` = π at various points:

f := stats::tQuantile(PI): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)-infinity, -1.618021174, 0.0, 1639.390923, infinity

$-\infty, -1.618021174, 0.0, 1639.390923, \infty$

The value `f(x)` satisfies `stats::tCDF(PI)(f(x)) = x`:
stats::tCDF(PI)(f(0.987654))0.987654

0.987654

delete f:

Example 2

We use symbolic arguments:
f := stats::tQuantile(a): f(x), f(9/10)stats::tQuantile(a)(x), stats::tQuantile(a)(9/10)

$\text{stats::tQuantile}(a)(x), \text{stats::tQuantile}(a)\left(\frac{9}{10}\right)$

When a positive real value is assigned to the shape parameter `a`, the function `f` starts to produce floating-point values:
a := 17: f(0.999), f(1 - sqrt(2)/10^5)3.64576738, 5.65913443

3.64576738, 5.65913443

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)0.0

0.0

f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, a:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

Return Values procedure.

See Also stats::tCDFstats::tPDFstats::tRandom

stats::tRandom

Purpose

Generate a random number generator for Student deviates (t-deviates)

Syntax

```
stats::tRandom(a, <Seed = s>)
```

Description

`stats::tRandom(a)` returns a procedure that produces t-deviates (random numbers) with shape parameter ('degrees of freedom') `a>0`.

The procedure `f := stats::tRandom(a)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` can be converted to a positive floating point number, then `f()` returns a real floating point number.

In all other cases, `stats::tRandom(a)()` is returned symbolically.

Numerical values of `a` are only accepted if they are real and positive.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the t-distribution with shape parameter `a`. For any real x, the probability that $X \le x$ is given by

```
gamma((a+1)/2)/(gamma(a/2)*sqrt(a*PI)) *
int((1+t^2/a)^(-(a+1)/2),t=-infinity..x)
```

$$\frac{\Gamma\left(\frac{a+1}{2}\right)}{\Gamma\left(\frac{a}{2}\right)\sqrt{a\pi}} \int_{-\infty}^{x} \frac{1}{\left(1+\frac{t^2}{a}\right)^{\frac{a+1}{2}}}\, dt$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::tRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::tRandom(a):  f() $k = 1..K;
```

rather than by

```
stats::tRandom(a)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::tRandom(a, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate t-deviates with shape parameter a = 23:
f := stats::tRandom(23): f() $ k = 1..4-0.4417960021, 0.8951424894, 1.291568047, -0.8938637441

```
-0.4417960021, 0.8951424894, 1.291568047, -0.8938637441
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::tRandom(a): f()stats::tRandom(a)()

```
stats::tRandom(a)()
```

When the shape parameter a evaluates to a positive real number, f starts to produce random floating-point numbers:

a := sqrt(99): f() $ k = 1..40.2115095721, 0.3326980658, 0.6483250281, 4.341741815

```
0.2115095721, 0.3326980658, 0.6483250281, 4.341741815
```

delete f, a:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers: f := stats::tRandom(PI, Seed = 1): f() $ k = 1..40.006866430292, -1.483500533, -0.6688788771, 0.4017860587

```
0.006866430292, -1.483500533, -0.6688788771, 0.4017860587
```

g := stats::tRandom(PI, Seed = 1): g() $ k = 1..40.006866430292, -1.483500533, -0.6688788771, 0.4017860587

```
0.006866430292, -1.483500533, -0.6688788771, 0.4017860587
```

f() = g(), f() = g()0.03860593782 = 0.03860593782, -1.259521158 = -1.259521158

```
0.03860593782 = 0.03860593782, -1.259521158 = -1.259521158
```

delete f, g:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the shape parameter `a` must be convertible to a positive floating-point number at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm for the computation of the t-deviates uses a gamma deviate `X` with shape parameter `a/2` and a normal deviate `Y` to arrive at a t-deviate `X/sqrt(Y/a)`. For more information see: D. Knuth, Seminumerical Algorithms (1998), Vol. 2, p. 135.

stats::tCDFstats::tPDFstats::tQuantile

stats::tTest

Purpose

T-test for a mean

Syntax

```
stats::tTest(x1, x2,  , m, <Normal>)
stats::tTest([x1, x2,  ], m, <Normal>)
stats::tTest(s, <c>, m, <Normal>)
```

Description

`stats::tTest( [x1, x2,  ], m )` tests the null hypothesis: "the true mean of the data x_i is larger than `m`".

`stats::tTest` accepts numerical data as well as symbolic data.

If all data are real floating-point numbers, the returned values `p` and `t` are floating-point numbers.

If `m` is a floating-point number, the sample data are converted to floating-point numbers automatically.

For a sample x_1, x_2, ... of size n, `stats::tTest` computes t=sqrt((n)/(v)) * (X - m)$t = \sqrt{\frac{n}{v}}(X - m)$, where

X = 1/n*sum(x[i],i=1..n)

$$X = \frac{1}{n}\left(\sum_{i=1}^{n} x_i\right)$$

is the empirical mean of the data and

v=(1)/(n-1) * sum((x[i]-X)^2, i=1..n)

$$v = \frac{1}{n-1}\left(\sum_{i=1}^{n} (x_i - X)^2\right)$$

is the empirical variance.

`stats::tTest(data, m)` returns the list `[PValue = p, StatValue = t]`, where the observed significance level `p` is computed as `p = stats::tCDF(n - 1)(t)`.

`stats::tTest(data, m, Normal)` returns the list `[PValue = p, StatValue = t]`, where the observed significance level `p` is computed as `p` = stats::normalCDF`(0, 1)(t)`. For large n, this is an approximation of stats::tCDF`(n - 1)(t)`.

Intuitively, `p` corresponds to the "probability" that the true mean of the data (the expectation value of the underlying distribution) is larger than m.

The most relevant information returned by `stats::tTest` is the observed significance level `PValue = p`. It has to be interpreted in the following way:

The t-test may be used as a one-tailed test of the null hypothesis: "the true mean of the data is larger than m". In this case, the null hypothesis may be rejected at level α if the observed significance level p satisfies $p < \alpha$.

Alternatively, the t-test may also be used as a one-tailed test of the null hypothesis: "the true mean of the data is smaller than m". In this case, the null hypothesis may be rejected at level α if the observed "significance level" p satisfies $p > 1 - \alpha$.

Alternatively, the t-test may also be used as a two-tailed test of the null hypothesis: "the true mean of the data is m". If the observed "significance level" `p` returned by `stats::tTest` satisfies either (p)<Symbol::alpha/2$p < \frac{\alpha}{2}$ or (p)>1-Symbol::alpha/2$p > 1 - \frac{\alpha}{2}$ for some given level $0 < \alpha < 1$, this null hypothesis may be rejected at level α.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

10 experiments produced the values 1, - 2, 3, - 4, 5, - 6, 7, - 8, 9, 10, which are assumed to be normally distributed with unknown mean and

variance. The empirical mean of the sample data is 1.5. There is only a small probability p = _outputSequence(0.057 , Symbol::hellip)0.057... that the true mean is larger than 5.0:
data := [1, -2, 3, -4, 5, -6, 7, -8, 9, 10]: stats::tTest(data, 5.0)[PValue = 0.05756660092, StatValue = -1.743955077]

[PValue = 0.05756660092, StatValue = -1.743955077]

We compare this result with the observed significance level computed via a standard normal distribution:
stats::tTest(data, 5.0, Normal)[PValue = 0.04058346175, StatValue = -1.743955077]

[PValue = 0.04058346175, StatValue = -1.743955077]

The approximation of the observed significance level p by the standard normal distribution is rather poor because of the small sample size. Next, we consider a larger sample. The true mean of the random data should be 10:
r := stats::normalRandom(10, 12, Seed = 0): data := [r() $ i = 1..100]: stats::tTest(data, 10);[PValue = 0.2129644942, StatValue = -0.7994751641]

[PValue = 0.2129644942, StatValue = -0.7994751641]
stats::tTest(data, 10, Normal)[PValue = 0.212007471, StatValue = -0.7994751641]

[PValue = 0.212007471, StatValue = -0.7994751641]

With the observed significance level of p = _outputSequence(0.212, dots)0.212..., the data are not disqualified as having the true mean 10. For samples of this size, the normal distribution approximates the t-distribution well.
delete data, r:

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions

m

The estimate for the true mean of the data: an arithmetical expression

s

A sample of domain type stats::sample.

c

An integer representing a column index of the sample `s`. This column provides the data x_1, x_2 etc. There is no need to specify a column number `c` if the sample has only one non-string column.

Options

Normal

Compute the observed significance level by a standard normal distribution instead of a t-distribution.

Return Values

a list of two equations `[PValue = p, StatValue = t]` with numerical values `p` and `t`. See the 'Details' section below for the interpretation of these values.

If the variance of the data vanishes, FAIL is returned.

Algorithms

If the data are normally distributed with expectation value ('true mean') μ, the variable T=sqrt((n)/(v)) * (X - Symbol::mu) $T = \sqrt{\frac{n}{v}}(X-\mu)$ is t-distributed with n - 1 degrees of freedom. The probability of the event that T attains values not larger than t is $Pr(T \le t)$=stats::tCDF`(n - 1)(t)`.

stats::csGOFTstats::ksGOFTstats::meanstats::normalCDFstats::stdevstats::swGOFTstats

stats::uniformCDF

Purpose

Cumulative distribution function of the uniform distribution

Syntax

```
stats::uniformCDF(a, b)
```

Description

`stats::uniformCDF(a, b)` returns a procedure representing the cumulative distribution function

x -> (x-a)/(b-a)

$$x \to \frac{x-a}{b-a}$$

of the uniform distribution on the interval $[a, b]$.

The procedure `f := stats::uniformCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x < a$ can be decided, then `f(x)` returns 0. If $x > b$ can be decided, then `f(x)` returns the value 1. If $a \le x$ and $x \le b$ can be decided, then `f(x)` returns the value `(x - a)/(b - a)`.

If x is a real floating-point number and both a and b can be converted to real floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \le a$, or $x \ge b$, or $a \le x$ and $x \le b$, then the corresponding values are returned.

`f(x)` returns the symbolic call `stats::uniformCDF(a, b)(x)` if it cannot be decided whether x lies in the interval $[a, b]$.

Numerical values for `a` and `b` are only accepted if they are real and $a \le b$.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the cumulative distribution function on the interval [- 3, 2π] at various points:
f := stats::uniformCDF(-3, 2*PI): f(-infinity), f(-3), f(0.5), f(2/3), f(3.0), f(PI), f(infinity)0, 0, 0.3770257605, 11/(3*(2*PI + 3)), 0.6463298751, (PI + 3)/(2*PI + 3), 1

$$0,\ 0,\ 0.3770257605,\ \frac{11}{3\,(2\,\pi+3)},\ 0.6463298751,\ \frac{\pi+3}{2\,\pi+3},\ 1$$

delete f:

Example 2

If x is a symbolic object without properties, then it cannot be decided whether $a \le x \le b$ holds. A symbolic function call is returned:
f := stats::uniformCDF(a, b): f(x)stats::uniformCDF(a, b)(x)

$$\text{stats::uniformCDF}(a,\ b)(x)$$

With suitable properties, it can be decided whether $a \le x \le b$ holds. An explicit expression is returned:
assume(x < a): f(x)0

$$0$$

Note that `assume(x < a)` attached properties both to a and x. With the next call, we overwrite the property attached to x. However, the property attached to a has to be 'unassumed' as well to avoid inconsistent assumptions $x < a$ and $x > b$:
unassume(a): assume(x > b): f(x)1

$$1$$

assume(a <= x <= b): f(x)(a - x)/(a - b)

$\frac{a - x}{a - b}$ assume(b > a): f(a + (b - a)/3)1/3

$\frac{1}{3}$ unassume(x): unassume(a): unassume(b): delete f:

Example 3

We use symbolic arguments:
f := stats::uniformCDF(a, b): f(3), f(3.0)stats::uniformCDF(a, b)(3), stats::uniformCDF(a, b)(3.0)

stats::uniformCDF(*a*, *b*)(3), stats::uniformCDF(*a*, *b*)(3.0)

When numerical values are assigned to a and b, the function `f` starts to produce numerical values:
a := 0: b := PI: f(3), f(3.0)3/PI, 0.9549296586

$\frac{3}{\pi}$, 0.9549296586
delete f, a, b:

Parameters

a

b

arithmetical expressions representing real values; $a \le b$ is assumed.

Return Values

procedure.

stats::uniformPDFstats::uniformQuantilestats::uniformRandom

stats::uniformPDF

Purpose

Probability density function of the uniform distribution

Syntax

```
stats::uniformPDF(a, b)
```

Description

`stats::uniformPDF(a, b)` returns a procedure representing the probability density function

x -> 1/(b - a)

$$x \to \frac{1}{b-a}$$

of the uniform distribution on the interval $[a, b]$.

The procedure `f := stats::uniformPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x < a$ or $x > b$ can be decided, then `f(x)` returns 0. If $a \le x$ and $x \le b$ can be decided, then `f(x)` returns the value `1/(b - a)`.

If x is a real floating-point number and both a and b can be converted to real floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x < a$, or $x > b$, or $a \le x$ and $x \le b$, then the corresponding values are returned.

`f(x)` returns the symbolic call `stats::uniformPDF(a, b)(x)` if it cannot be decided whether x lies in the interval $[a, b]$.

Numerical values for `a` and `b` are only accepted if they are real and $a \le b$.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the probability density function on the interval [- 3, 2π] at various points:
f := stats::uniformPDF(-3, 2*PI): f(-infinity), f(-PI), f(-3.0), f(1/2), f(0.5), f(PI), f(infinity)0, 0, 0.1077216458, 1/(2*PI + 3), 0.1077216458, 1/(2*PI + 3), 0

$$0,\ 0,\ 0.1077216458,\ \frac{1}{2\,\pi + 3},\ 0.1077216458,\ \frac{1}{2\,\pi + 3},\ 0$$

delete f:

Example 2

If x is a symbolic object without properties, then it cannot be decided whether $a \le x \le b$ hold. A symbolic function call is returned:
f := stats::uniformPDF(a, b): f(x)stats::uniformPDF(a, b)(x)

$$\text{stats::uniformPDF}(a,\ b)(x)$$

With suitable properties, it can be decided whether $a \le x \le b$ holds. An explicit expression is returned:
assume(x < a): f(x)0

$$0$$

Note that `assume(x < a)` attached properties both to a and x. With the next call, we overwrite the property attached to x. However, the property attached to a has to be 'unassumed' as well to avoid inconsistent assumptions $x < a$ and $x > b$:
unassume(a): assume(x > b): f(x)0

$$0$$

assume(a <= x <= b): f(x)-1/(a - b)

$$-\frac{1}{a - b}$$

```
assume(b > a): f(a + (b - a)/3)-1/(a - b)
```

$$-\frac{1}{a-b}$$

```
unassume(x): unassume(a): unassume(b): delete f:
```

Example 3

We use symbolic arguments:

```
f := stats::uniformPDF(a, b): f(x)stats::uniformPDF(a, b)(x)
```

$$\text{stats::uniformPDF}(a,\ b)(x)$$

When numerical values are assigned to a and b, the function `f` starts to produce numerical values:

```
a := 0: b := PI: f(3), f(3.0)1/PI, 0.3183098862
```

$$\frac{1}{\pi},\ 0.3183098862$$

```
delete f, a, b:
```

Parameters

a

b

arithmetical expressions representing real values; $a \le b$ is assumed.

Return Values

procedure.

See Also

stats::uniformCDFstats::uniformQuantilestats::uniformRandom

stats::uniformQuantile

Purpose

Quantile function of the uniform distribution

Syntax

```
stats::uniformQuantile(a, b)
```

Description

`stats::uniformQuantile(a, b)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::uniformCDF(a, b)` of the uniform distribution on the interval $[a, b]$. For $0 \le x \le 1$, the quantile function is given by (x) -> a+x*fenced(b-a)$x \to a + x\,(b - a)$.

The procedure `f := stats::uniformQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `x` is a real number between `0` and `1` and `a` and `b` can be converted to floating-point numbers, then `f(x)` returns the value $a + x(b - a)$ as a floating-point number. Otherwise, this value is returned as a symbolic expression.

Numerical values of x are only accepted if $0 \le x \le 1$.

Numerical values for `a` and `b` are only accepted if they are real and $a \le b$.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function over the interval [2, 11/4]$[2, \frac{11}{4}]$ at various points:
f := stats::uniformQuantile(2, 11/4): f(0), f(1/10), f(0.5), f(1 - 10^(-5)), f(1)2, 83/40, 2.375, 1099997/400000, 11/4

$$2, \frac{83}{40}, 2.375, \frac{1099997}{400000}, \frac{11}{4}$$

delete f:

Example 2

We use symbolic arguments:
f := stats::uniformQuantile(a, b): f(x), f(9/10)a - x*(a - b), a/10 + (9*b)/10

$$a - x\,(a - b),\ \frac{a}{10} + \frac{9\,b}{10}$$

When positive real values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
a := 3: b := 11/2: f(0.999), f(1 - sqrt(2)/10^5)5.4975, 11/2 - sqrt(2)/40000

$$5.4975,\ \frac{11}{2} - \frac{\sqrt{2}}{40000}$$

delete f, a, b:

Parameters

a

b

arithmetical expressions representing real values; $a \le b$ is assumed.

Return Values

procedure.

See Also

stats::uniformCDFstats::uniformPDFstats::uniformRandom

stats::uniformRandom

Purpose

Generate a random number generator for uniformly continous deviates

Syntax

```
stats::uniformRandom(a, b, <Seed = s>)
```

Description

`stats::uniformRandom(a, b)` returns a procedure that produces uniformly continous deviates (random numbers) on the interval Interval([a], b)$[a, b)$.

The procedure `f := stats::uniformRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` and `b` can be converted to floating-point numbers, then `f()` returns a floating point number between a and b.

In all other cases, `stats::uniformRandom(a, b)()` is returned symbolically.

Numerical values of `a` and `b` are only accepted if they are real and $a \le b$.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the uniform distribution on the interval Interval([a], b)$[a, b)$. For any $a \le x \le b$, the probability that $X \le x$ is given by fenced(x-a)/fenced(b-a) $\frac{(x-a)}{(b-a)}$.

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::uniformRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via `f := stats::uniformRandom(a, b): f() $ k = 1..K` rather than by `stats::uniformRandom(a, b)() $ k = 1..K` The

latter call produces a sequence of generators each of which is called once. Also note that

```
stats::uniformRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate uniform deviates on the interval Interval([2], 7)[2, 7):
f := stats::uniformRandom(2, 7): f() $ k = 1..43.351790828, 6.155185894, 2.76578258, 6.974063904

```
3.351790828, 6.155185894, 2.76578258, 6.974063904
```

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::uniformRandom(a, b): f()stats::uniformRandom(a, b)()

```
stats::uniformRandom(a, b)()
```

When a and b evaluate to real numbers, `f` starts to produce random floating point numbers:
a := PI: b := 10: f() $ k = 1..44.967800682, 4.377232316, 6.242162399, 7.796955809

```
4.967800682, 4.377232316, 6.242162399, 7.796955809
```

delete f, a, b:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers: f := stats::uniformRandom(0, 10, Seed = 10^3): f() $ k = 1..48.633422729, 0.1225672185, 6.622938516, 5.069443372

8.633422729, 0.1225672185, 6.622938516, 5.069443372

g := stats::uniformRandom(0, 10, Seed = 10^3): g() $ k = 1..48.633422729, 0.1225672185, 6.622938516, 5.069443372

8.633422729, 0.1225672185, 6.622938516, 5.069443372

f() = g(), f() = g()0.6809567809 = 0.6809567809, 0.0395345751 = 0.0395345751

0.6809567809 = 0.6809567809, 0.0395345751 = 0.0395345751

delete f, g:

Parameters

a

b

arithmetical expressions representing real values; $a \le b$ is assumed.

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

Uniform deviates on the interval Interval([a], b)$[a, b)$ are produced via `a + (b - a)*frandom()`.

stats::unzipCol

Purpose

Extract columns from a list of lists

Syntax

```
stats::unzipCol(list)
```

Description

`stats::unzipCol` extracts the columns of a matrix structure encoded by a list of lists.

`stats::unzipCol` treats a list of lists like a list of rows of a stats::sample and extracts the columns. In conjunction with stats::sample2list it is useful for extracting the columns of a stats::sample.

`stats::unzipCol` is the inverse of stats::zipCol.

Examples

Example 1

We extract the columns from a list of rows representing a matrix structure:
stats::unzipCol([[a11, a12], [a21, a22], [a31, a32]])[a11, a21, a31], [a12, a22, a32]

[a11, a21, a31], [a12, a22, a32]

Example 2

A list of rows is used to create a sample:
stats::sample([[123, s, 1/2], [442, s, -1/2], [322, p, -1/2]]) 123 s 1/2 442 s -1/2 322 p -1/2

We re-convert the sample to a list of lists:
stats::sample2list(%)[[123, s, 1/2], [442, s, -1/2], [322, p, -1/2]]

$$\left[\left[123, s, \frac{1}{2}\right], \left[442, s, -\frac{1}{2}\right], \left[322, p, -\frac{1}{2}\right]\right]$$

Finally, we extract the columns:
stats::unzipCol(%)[123, 442, 322], [s, s, p], [1/2, -1/2, -1/2]

$$[123, 442, 322], [s, s, p], \left[\frac{1}{2}, -\frac{1}{2}, -\frac{1}{2}\right]$$

Parameters

list

A list of lists.

Return Values

Sequence of lists to be regarded as columns.

See Also

stats::colstats::sample2liststats::zipCol

stats::variance

Purpose

Variance of a data sample

Syntax

```
stats::variance(x1, x2,  , <Sample | Population>)
stats::variance([x1, x2,  ], <Sample | Population>)
stats::variance(s, <c>, <Sample | Population>)
```

Description

`stats::variance( x1, x2, ..., xn)` returns the variance

1/(n-1)*sum((x[i]-‘x‾‘)^2, i=1..n)

$$\frac{1}{n-1}\left(\sum_{i=1}^{n}(x_i-\overline{x})^2\right)$$

where ‘x‾‘ $\overline{x}$ is the arithmetic mean of the data x_i.

`stats::variance( x1, x2, ..., xn, Population)` returns

1/n*sum((x[i] - ‘x‾‘)^2, i = 1..n)

$$\frac{1}{n}\left(\sum_{i=1}^{n}(x_i-\overline{x})^2\right)$$

The variance is the square of the standard deviation.

The column index `c` is optional, if the data are given by a stats::sample object containing only one non-string column. Cf. “Example 3” on page 30-403.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Examples

Example 1

We calculate the variance of three values:
stats::variance(2, 3, 5)7/3

$\frac{7}{3}$

Alternatively, the data may be passed as a list:
stats::variance([2, 3, 5])7/3

$\frac{7}{3}$

Example 2

We create a sample:
stats::sample([[a1, b1, c1], [a2, b2, c2]]) a1 b1 c1 a2 b2 c2

The variance of the second column is:
expand(stats::variance(%, 2))b1^2/2 - b1*b2 + b2^2/2

$\frac{b1^2}{2} - b1\ b2 + \frac{b2^2}{2}$

Example 3

We create a sample consisting of one string column and one non-string column:
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]]) "1996" 1242 "1997" 1353 "1998" 1142

We compute the variance of the second column. In this case this column does not have to be specified, since it is the only non-string column:
float(stats::variance(%))11140.33333

11140.33333

We repeat the computation with the option `Population`:
float(stats::variance(%2, Population))7426.888889

7426.888889

Parameters

x_1, x_2, ...

The statistical data: arithmetical expressions

s

A sample of domain type stats::sample

c

An integer representing a column index of the sample `s`. This column provides the data x_1, x_2, ...

Options

Population

Sample

With `Sample`, the data are regarded as a "sample", not as a full population. The default is `Sample`.

Return Values

Arithmetical expression.

See Also

stats::geometricMeanstats::harmonicMeanstats::meanstats::medianstats::modalstats::quadra

stats::weibullCDF

Purpose

Cumulative distribution function of the Weibull distribution

Syntax

```
stats::weibullCDF(a, b)
```

Description

`stats::weibullCDF(a, b)` returns a procedure representing the cumulative distribution function

(x) -> 1-exp(-(x/b)^a)

$$x \to 1 - e^{-\left(\frac{x}{b}\right)^a}$$

of the Weibull distribution with shape parameter $a > 0$ and scale parameter $b > 0$.

The procedure `f := stats::weibullCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \leq 0$ can be decided, then `f(x)` returns `0`. If $x \geq 0$ can be decided, then `f(x)` returns the value `1 - exp(-(x/b)^a)`.

If x is a floating-point number and both a and b can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \leq 0$ or $x \geq 0$, the corresponding values are returned.

The call `f(- infinity )` returns `0`.

The call `f( infinity )` returns `1`.

`f(x)` returns the symbolic call `stats::weibullCDF(a, b)(x)` if neither $x \leq 0$ nor $x \geq 0$ can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure generated by `stats::weibullCDF` reacts to properties of identifiers set via assume.

Examples

Example 1

We evaluate the cumulative distribution function with `a` = 2 and `b` = 1 at various points:
f := stats::weibullCDF(2, 1): f(-infinity), f(-3), f(0.5), f(2/3), f(PI), f(infinity)0, 0, 0.2211992169, 1 - exp(-4/9), 1 - exp(-PI^2), 1

$$0,\ 0,\ 0.2211992169,\ 1-e^{-\frac{4}{9}},\ 1-e^{-\pi^2},\ 1$$

delete f:

Example 2

If `x` is a symbolic object without properties, then it cannot be decided whether $x \geq 0$ holds. A symbolic function call is returned:
f := stats::weibullCDF(a, b): f(x)stats::weibullCDF(a, b)(x)

$$\text{stats::weibullCDF}(a,\ b)(x)$$

With suitable properties, it can be decided whether $x \geq 0$ holds. An explicit expression is returned:
assume(0 < x): f(x)1 - exp(-(x/b)^a)

$$1-e^{-\left(\frac{x}{b}\right)^a}$$

unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::weibullCDF(a, b): f(x)stats::weibullCDF(a, b)(x)

$$\text{stats::weibullCDF}(a,\ b)(x)$$

When numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
a := 2: b := 1: f(3), f(3.0)1 - exp(-9), 0.9998765902

delete f, a, b:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::weibullPDFstats::weibullQuantilestats::weibullRandom

stats::weibullPDF

Purpose

Probability density function of the Weibull distribution

Syntax

```
stats::weibullPDF(a, b)
```

Description

`stats::weibullPDF(a, b)` returns a procedure representing the probability density function

x -> a*b^(-a)*x^(a-1)*exp(-(x/b)^a)

$$x \to \frac{a\,x^{a-1}\,e^{-\left(\frac{x}{b}\right)^a}}{b^a}$$

of the Weibull distribution with shape parameter `a` > 0 and scale parameter `b` > 0.

The procedure `f := stats::weibullPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If $x \leq 0$ can be decided, then `f(x)` returns `0`. If $x > 0$ can be decided, then `f(x)` returns the value `a*x^(a-1)/b^a*exp^(-(x/b)^a)`.

If x is a floating-point number and both a and b can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via assume. If x is a symbolic expression with the property $x \leq 0$ or $x > 0$, the corresponding values are returned.

`f(- infinity )` and `f( infinity )` return `0`.

`f(x)` returns the symbolic call `stats::weibullPDF(a, b)(x)` if neither $x \leq 0$ nor $x > 0$ can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure generated by `stats::weibullPDF` reacts to properties of identifiers set via assume.

Examples

Example 1

We evulate the probability density function with `a` = 2 and `b` = 1 at various points:
f := stats::weibullPDF(2, 1): f(1/5), f(0.5), f(-1), f(x)(2*exp(-1/25))/5, 0.7788007831, 0, stats::weibullPDF(2, 1)(x)

$$\frac{2\,e^{-\frac{1}{25}}}{5},\ 0.7788007831,\ 0,\ \text{stats::weibullPDF}(2,\ 1)(x)$$

delete f:

Example 2

If `x` is a symbolic object without properties, then it cannot be decided whether $x > 0$ holds. A symbolic function call is returned:
f := stats::weibullPDF(a, b): f(x)stats::weibullPDF(a, b)(x)

$$\text{stats::weibullPDF}(a,\ b)(x)$$

With suitable properties, it can be decided whether $x > 0$ holds. An explicit expression is returned:
assume(0 < x): f(x)(a*x^(a - 1)*exp(-(x/b)^a))/b^a

$$\frac{a\,x^{a-1}\,e^{-\left(\frac{x}{b}\right)^a}}{b^a}$$

unassume(x): delete f:

Example 3

We use symbolic arguments:
f := stats::weibullPDF(a, b): f(x), f(3)stats::weibullPDF(a, b)(x), (3^(a - 1)*a*exp(-(3/b)^a))/b^a

stats::weibullPDF(a, b)(x), $\frac{3^{a-1}\, a\, e^{-\left(\frac{3}{b}\right)^a}}{b^a}$

When numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
a := 2: b := 1: f(3), f(3.0)6*exp(-9), 0.0007404588245

$6\, e^{-9}$, 0.0007404588245

delete f, a, b:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::weibullCDFstats::weibullQuantilestats::weibullRandom

stats::weibullQuantile

Purpose

Quantile function of the Weibull distribution

Syntax

```
stats::weibullQuantile(a, b)
```

Description

`stats::weibullQuantile(a, b)` returns a procedure representing the quantile function (inverse)

(x) -> b * (-ln(1-x))^(1/a)

$$x \to b\,(-\ln(1-x))^{1/a}$$

of the cumulative distribution function `stats::weibullCDF(a, b)`. For $0 \le x \le 1$, the solution of *stats*::*weibullCDF*(*a*, *b*)(*y*) = *x* is given by

y=stats::weibullQuantile(a, b)(x)

y = stats::weibullQuantile(*a*, *b*)(*x*)

The procedure `f := stats::weibullQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, infinity, or a symbolic expression:

If `x` is a real float point number between `0` and `1` and `a` and `b` can be converted to positive floating-point numbers, then `f(x)` returns a floating-point number.

The calls `f(1)` and `f(1.0)` produce infinity.

In all other cases, *f*(*x*) returns the symbolic expression `a - ln(1 - x)/b`.

Numerical values of *x* are only accepted if $0 \le x \le 1$.

Numerical values of *a* and *b* are only accepted if they are real and positive.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We evaluate the quantile function with `a` = 2 and `b` = 3/4$\frac{3}{4}$ at various points:
f := stats::weibullQuantile(2, 3/4): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)0, (3*sqrt(-ln(9/10)))/4, 0.6244159584, (3*sqrt(ln(10000000000)))/4, infinity

$$0,\ \frac{3\sqrt{-\ln\left(\frac{9}{10}\right)}}{4},\ 0.6244159584,\ \frac{3\sqrt{\ln(10000000000)}}{4},\ \infty$$

The value `f(x)` satisfies `stats::weibullCDF(2, 3)(f(x)) = x`:
stats::weibullCDF(2, 3/4)(f(0.987654321))0.987654321

$$0.987654321$$

delete f:

Example 2

We use symbolic arguments:
f := stats::weibullQuantile(a, b): f(x), f(1/PI), f(0.99)b*(-ln(1 - x))^(1/a), b*(-ln(1 - 1/PI))^(1/a), 4.605170186^(1/a)*b

$$b\,(-\ln(1-x))^{1/a},\ b\left(-\ln\left(1-\frac{1}{\pi}\right)\right)^{1/a},\ 4.605170186^{1/a}\,b$$

When suitable numerical values are assigned to `a` and `b`, the function `f` starts to produce numerical values:
a := 7: b := 1/8: f(0.999), f(999/1000)0.1647461562, ln(1000)^(1/7)/8

$$0.1647461562,\ \frac{\ln(1000)^{1/7}}{8}$$

Numerical values for x are only accepted if $0 \le x \le 1$:
f(0.5)0.1186235162

```
0.1186235162
```

f(2) Error: An argument x with 0 <= x <= 1 is expected. [f] delete f, a, b:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Return Values

procedure.

See Also

stats::weibullCDFstats::weibullPDFstats::weibullRandom

stats::weibullRandom

Purpose

Generate a random number generator for Weibull deviates

Syntax

```
stats::weibullRandom(a, b, <Seed = s>)
```

Description

`stats::weibullRandom(a, b)` returns a procedure that produces Weibull deviates (random numbers) with shape parameter `a` > 0 and scale parameter `b` > 0.

The procedure `f := stats::weibullRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` and `b` can be converted to positive floating-point numbers, then `f()` returns a nonnegative floating-point number.

In all other cases, `stats::weibullRandom(a, b)()` is returned symbolically.

Numerical values of `a` and `b` are only accepted if they are real and positive.

The values `X = f()` are distributed randomly according to the cumulative distribution function of the Weibull distribution with parameters `a` and `b`. For any $0 \le x$, the probability that $X \le x$ is given by

1-e^(-fenced(x/b)^a)$1 - \frac{1}{\left(\frac{x}{b}\right)^a}$.

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the reset function, random generators produce the same sequences of numbers.

Note In contrast to the function random, the generators produced by `stats::weibullRandom` do not react to the environment variable SEED.

For efficiency, it is recommended to produce sequences of K random numbers via

```
f := stats::weibullRandom(a, b):  f() $k = 1..K;
```

rather than by

```
stats::weibullRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::weibullRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We generate Weibull deviates with parameters `a` = 2 and `b` = 3/4:
f := stats::weibullRandom(2, 3/4): f() $ k = 1..40.8577612188, 0.3226575883, 1.027334357, 0.05408701056

0.8577612188, 0.3226575883, 1.027334357, 0.05408701056

delete f:

Example 2

With symbolic parameters, no random floating-point numbers can be produced:
f := stats::weibullRandom(a, b): f()stats::weibullRandom(a, b)()

stats::weibullRandom(*a*, *b*)()

When positive real numbers are assigned to `a` and `b`, the function `f` starts to produce random floating point numbers:

a := PI: b := 1/8: f() $ k = 1..40.1366558143, 0.148384594, 0.1161455634, 0.09243509442

```
0.1366558143, 0.148384594, 0.1161455634, 0.09243509442
```

delete f, a, b:

Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers: f := stats::weibullRandom(PI, 3, Seed = 1): f() $ k = 1..42.503931345, 1.888623862, 3.833514832, 3.584419593

```
2.503931345, 1.888623862, 3.833514832, 3.584419593
```

g := stats::weibullRandom(PI, 3, Seed = 1): g() $ k = 1..42.503931345, 1.888623862, 3.833514832, 3.584419593

```
2.503931345, 1.888623862, 3.833514832, 3.584419593
```

f() = g(), f() = g()1.742746285 = 1.742746285, 5.240957365 = 5.240957365

```
1.742746285 = 1.742746285, 5.240957365 = 5.240957365
```

delete f, g:

Parameters

a

The shape parameter: an arithmetical expression representing a positive real value

b

The scale parameter: an arithmetical expression representing a positive real value

Options

Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

Return Values

procedure.

Algorithms

The implemented algorithm for the computation of the Weibull deviates uses the quantile function of the Weibull distribution applied to unformly distributed random numbers on the interval Interval([0], 1)[0, 1).

stats::weibullCDFstats::weibullPDFstats::weibullQuantile

stats::zipCol

Purpose

Convert a sequence of columns to a list of lists

Syntax

```
stats::zipCol(column1, column2,  )
```

Description

`stats::zipCol(..)` converts a sequence of columns to a format suitable for creating a stats::sample.

`stats::zipCol` is useful for converting column data given in lists to a list of lists accepted by stats::sample.

`stats::zipCol` is the inverse of stats::unzipCol.

Examples

Example 1

We convert a single column to a nested list:
stats::zipCol([a, b, c])[[a], [b], [c]]

[[*a*], [*b*], [*c*]]

This list is accepted by stats::sample:
stats::sample(%) a b c

Example 2

We build a sample consisting of two columns:
column1 := [122, 442, 322]: column2 := [s, s, p]: stats::zipCol(column1, column2)[[122, s], [442, s], [322, p]]

[[122, *s*], [442, *s*], [322, *p*]]

stats::sample(%) 122 s 442 s 322 p

Parameters

column1, column2, ...

Lists.

Return Values

List of lists.

See Also stats::sample2liststats::unzipCol

Ground

stringlib – Manipulating Strings

==REFNAME==

stringlib::collapseWhitespace

Purpose

Collapse whitespace in strings

Syntax

```
stringlib::collapseWhitespace(string)
```

Description

`stringlib::collapseWhitespace(string)` replaces each whitespace sequence in `string` by one space.

The characters `" "` (space), `"\n"` (newline), `"\t"` (tabulator) and `"\r"` (return) are called whitespace.

`stringlib::collapseWhitespace(string)` replaces all whitespace characters by one space and following all sequences of spaces by one space in `string`.

When `string` contains no whitespace or only single space characters, the string is returned without changes.

`stringlib::collapseWhitespace` is a function of the system kernel.

Examples

Example 1

In the following examples all whitespace is collapsed:
stringlib::collapseWhitespace(" ")" "

" "

stringlib::collapseWhitespace("MuPAD is nice.")"MuPAD is nice."

"MuPAD is nice."
stringlib::collapseWhitespace(" ")" "

" "

In this example no whitespace can be collapsed:
stringlib::collapseWhitespace(""),
stringlib::collapseWhitespace("12345"),

stringlib::collapseWhitespace("MuPAD is nice.")"", "12345", "MuPAD is nice."

"", "12345", "MuPAD is nice."

Example 2

`stringlib::collapseWhitespace` can be useful for output MuPAD code. The procedure is only an expample:
f:= proc(x) local y; begin y:= 2*x; x + y end‘proc f(x) ... end‘

proc f(x) ... end

print(f)‘proc f(x) ... end‘

proc f(x) ... end

expr2text(f)"proc(x)\n name f;\n local y;\nbegin\n y := 2*x; \n x + y\nend_proc"

"proc(x) name f; local y; begin y := 2*x; x + y end_proc"

stringlib::collapseWhitespace(%)"proc(x) name f; local y; begin y := 2*x; x + y end_proc"

"proc(x) name f; local y; begin y := 2*x; x + y end_proc"

Parameters

string

Any MuPAD string

Return Values

Given string with collapsed whitespace

See Also

subsstringlib::subsstringlib::remove

stringlib::contains

Purpose

Test for substring

Syntax

```
stringlib::contains(string1, string2, options)
```

Description

`stringlib::contains(string1, string2)` checks, whether `string1` contains another string `string2`.

Examples

Example 1

If called without options, `stringlib::contains` simply returns `TRUE` or `FALSE`.

stringlib::contains("abcdeabcdeabcde", "bc")TRUE

```
TRUE
```

stringlib::contains("abcdeabcdeabcde", "cb")FALSE

```
FALSE
```

stringlib::contains("abcdeabcdeabcde", "bc", Index)2

```
2
```

stringlib::contains("abcdeabcdeabcde", "cb", Index)FALSE

```
FALSE
```

stringlib::contains("abcdeabcdeabcde", "bc", IndexList)[2, 7, 12]

```
[2, 7, 12]
```

stringlib::contains("abcdeabcdeabcde", "cb", IndexList)[]

```
[]
```

Example 2

The following call does *not* return `[1,2]` because the first matching substring has not ended when the second begins.
stringlib::contains("aaa", "aa", IndexList)[1]

[1]

Parameters

string1

string2

Non empty string

Options

Index

Causes the first index position at which `string2` appears in `string1` to be returned as integer. The return value is `FALSE`, if `string2` occurs nowhere in `string1`.

IndexList

Causes the list of all positions at which `string2` appears in `string1` to be returned. The returned list is empty if `string2` occurs nowhere in `string1`.

An occurrence of `string2` is not detected if overlapped by the tail of a previously detected occurrence. See “Example 2” on page 31-5.

Return Values

`TRUE`, an integer, or a list of integers that determines the position (if an option is given), when `string1` contains `string2`, otherwise `FALSE` or an empty list.

See Also

containsstringlib::posstrmatch

stringlib::format

Purpose

Formatting a string

Syntax

```
stringlib::format(string1, width, <Left | Center
| Right>, <fill_char>)
```

Description

`stringlib::format` adjusts the length of a string.

If `width` is less than the length of the given string `string1`, the substring consisting of the first `width` characters of `string1` is returned.

If `width` exceeds the length of `string1`, the given string will be filled with the necessary number of spaces or the optional `fill_char`. These are inserted at the end in case of left alignment, or at the beginning in case of right alignment. In case of centering, the same number of filling characters is placed at the beginning and at the end, but one more is placed at the end if their total number is odd.

If `alignment` is not given, left alignment is used by default.

Examples

Example 1

By default, a string of length 5 is adjusted to length 10 by inserting five space characters at the end. Since white spaces are collapsed in typesetting output, we use print:
print(Plain, stringlib::format("abcde", 10)) "abcde "

In the case of centering, three spaces are inserted at the end and two at the beginning.
print(Plain, stringlib::format("abcde", 10, Center)) " abcde "

Instead of the space character, also any other character may be used as a filling character.
stringlib::format("abcde", 10, Right, ".")".....abcde"

".....abcde"
stringlib::format("abcde", 10, ".")"abcde....."

"abcde....."

Parameters

string1

String

width

Integer that determines the length of the returned string

fill_char

One-character string to fill up the result string

Options

Left

Determines that the string will be aligned left

Center

Determines that the string will be centered

Right

Determines that the string will be aligned right

Return Values

String of length `width` containing the given string

See Also

stringlib::formatf

stringlib::formatf

Purpose

Convert a floating-point number to a string

Syntax

```
stringlib::formatf(f, digits, <strlength>)
```

Description

`stringlib::formatf(f, d)` converts the floating point number `f` into a string after rounding it to `d` digits after the decimal point.

If `d` is a positive integer, a rounded fixed-point representation with `d` digits after the decimal point is returned. If `d` is zero, then a rounded fixed-point representation with one zero after the decimal point is returned. If `d` is negative, then `f` is rounded to `-d` digits before the decimal point and a fixed-point representation with one zero after the decimal point is returned.

The representation of a negative number starts with the sign and no additional spaces. The representation of a nonnegative number starts with a single space character.

If a third argument is specified, then the string returned consists of exactly `strlength` characters. If the converted number `f` requires less room, then it is padded on the left with spaces. If the converted number `f` requires more room, then the last characters are truncated.

Examples

Example 1

Convert the number `123.456` with two characters after the point into a string. Since white spaces are collapsed in typesetting output, we use print:
print(Plain, stringlib::formatf(123.456, 2)) " 123.46"

The same for `-123.456`:
print(Plain, stringlib::formatf(-123.456, 2)) "-123.46"

Convert the number `123.456` with two characters after the point into a string of the length `10`:
print(Plain, stringlib::formatf(123.456, 2, 10)) " 123.46"

If the string should only have the length `3`, the whole number does not fit into the string:

print(Plain, stringlib::formatf(123.456, 2, 3)) " 12"

Rounding to no number after point:
print(Plain, stringlib::formatf(123.456, 0)) " 123.0"

Rounding to one number in front of point:
print(Plain, stringlib::formatf(123.456, -1)) " 120.0"

Parameters

f

Floating point number

digits

Integer which determines the precision of the number

strlength

Integer which determines the length of the returned string

Return Values

`stringlib::formatf` returns a string.

See Also

stringlib::format

stringlib::formatTime

Purpose

Textual description of a time length

Syntax

```
stringlib::formatTime(t)
```

Description

`stringlib::formatTime` returns a textual description such as “5 minutes, 20 seconds” of a time value such as `320 * unit::sec` given as its argument.

When given an integer or floating-point number, `stringlib::formatTime` interprets it as milliseconds, for compatibility with time. Cf. “Example 2” on page 31-10.

`stringlib::formatTime` rounds its input to only use two types of unit, cf. “Example 1” on page 31-10.

Examples

Example 1

`stringlib::formatTime` takes a time description and renders it as English text:
stringlib::formatTime(1234*unit::sec)"20 minutes, 34.0 seconds"

```
"20 minutes, 34.0 seconds"
```

Excessive precision is avoided:
stringlib::formatTime(12345678*unit::sec)"4 months, 3.26 weeks"

```
"4 months, 3.26 weeks"
```

Example 2

time and rtime return integers interpreted as milliseconds. `stringlib::formatTime` thus interprets integers (and, for consistency, floating-point numbers) as milliseconds:
stringlib::formatTime(1)"0.001 seconds"

```
"0.001 seconds"
```

stringlib::formatTime(rtime(system("sleep 2")))"2.411 seconds"

"2.411 seconds"

Parameters

t

The time to convert: An integer or floating-point value (regarded as milliseconds) or an expression involving time units.

Return Values

string.

See Also

rtimetime

stringlib::lower

Purpose

Convert to lower-case

Syntax

```
stringlib::lower(string1)
```

Description

`stringlib::lower(string1)` converts each upper-case letter in the string `string1` to lower-case. All other characters remains unchanged.

If the string contains no upper-case letters, the given string is returned unchanged.

Examples

Example 1

Convert a string to lower-case:
stringlib::lower("MuPAD"), stringlib::lower("Mupad"), stringlib::lower("MUPAD"), stringlib::lower("mupad")"mupad", "mupad", "mupad", "mupad"

"mupad", "mupad", "mupad", "mupad"

Example 2

Compare strings not case sensitive:
str_eq:= (str1, str2) -> bool(stringlib::lower(str1) = stringlib::lower(str2)):
str_eq("MuPAD", "mupad"), str_eq("Mupad", "MUPAD")TRUE, TRUE

TRUE, TRUE

Parameters

string1

Any string

Return Values

String

See Also

stringlib::formatstringlib::upper

stringlib::maskMeta

Purpose

Mask regular expression special characters

Syntax

```
stringlib::maskMeta(str)
```

Description

`stringlib::maskMeta(str)` generates a regular expression (for use with strmatch) that matches exactly the string `str`.

As of MuPAD version 3.2, strmatch uses regular expression matching. To search for some verbatim substring therefore requires “escaping” special characters such as `*` or `()`. `stringlib::maskMeta` performs this task.

Examples

Example 1

Trying to find `"a+b"` in the string `"a+b+c"` via strmatch fails due to the special nature of `"+"` in regular expressions, but, for almost the same reason, `"a*b"` is found:
strmatch("a+b+c", "a+b"), strmatch("a+b+c", "a*b")FALSE, TRUE

FALSE, TRUE

Using `stringlib::maskMeta`, we lose the ability of using regular expressions, but can easily search for verbatim strings:
strmatch("a+b+c", stringlib::maskMeta("a+b")), strmatch("a+b+c", stringlib::maskMeta("a*b"))TRUE, FALSE

TRUE, FALSE

The output of `stringlib::maskMeta` is just another string, so combinations with other strings (containing regular expression meta-characters) is possible:
strmatch("a+b+c", "^".stringlib::maskMeta("a+b")), strmatch("a+b+c", "^".stringlib::maskMeta("b+c"))TRUE, FALSE

TRUE, FALSE

Parameters ***str***

Non empty string

Return Values String

See Also strmatchstringlib::subsstringlib::pos

stringlib::order

Purpose

Sorting procedure for Sort

Syntax

```
stringlib::order(options)
```

Description

`stringlib::order()` returns a procedure that compares two strings and returns TRUE when they are in lexicographical order, otherwise FALSE. This procedure can be used as second argument or sort.

Examples

Example 1

Sort strings in lexicographical order:
sort(["ab", "a", "abc", "B", "ba", "Ca", "bB", "bb"], stringlib::order())["B", "Ca", "a", "ab", "abc", "bB", "ba", "bb"]

```
["B", "Ca", "a", "ab", "abc", "bB", "ba", "bb"]
```

Sort strings in lexicographical order without case sensitivity:
sort(["ab", "a", "abc", "B", "ba", "Ca", "bB", "bb"], stringlib::order(Nocase))["a", "ab", "abc", "B", "ba", "bb", "bB", "Ca"]

```
["a", "ab", "abc", "B", "ba", "bb", "bB", "Ca"]
```

Sort strings in reverse lexicographical order:
sort(["ab", "a", "abc", "B", "ba", "Ca", "bB", "bb"], stringlib::order(Reverse))["bb", "ba", "bB", "abc", "ab", "a", "Ca", "B"]

```
["bb", "ba", "bB", "abc", "ab", "a", "Ca", "B"]
```

Sort strings in reverse lexicographical order without case sensitivity:
sort(["ab", "a", "abc", "B", "ba", "Ca", "bB", "bb"], stringlib::order(ReverseNocase))["Ca", "bB", "bb", "ba", "B", "abc", "ab", "a"]

```
["Ca", "bB", "bb", "ba", "B", "abc", "ab", "a"]
```

Options

Lexicographical

Return a procedure that yields TRUE when the two given strings are in lexicographical order.

Nocase

Return a procedure that yields TRUE when the two given strings are in lexicographical order without case sensitivity.

Reverse

Return a procedure that yields TRUE when the two given strings are in reverse lexicographical order.

ReverseNocase

Return a procedure that yields TRUE when the two given strings are in reverse lexicographical order without case sensitivity.

Return Values

Procedure that can be used as second argument of sort

See Also

sortstringlib

stringlib::pos

Purpose

Position of a substring

Syntax

```
stringlib::pos(string1, string2, <pos>)
```

Description

`stringlib::pos` returns the position of a substring in a string.

The third optional argument must be less than the length of `string1`.

If `string1` does not contain `string2`, then `FAIL` will be returned.

Examples

Example 1

In case of several occurrences of the substring, the position of the first is returned.

```
stringlib::pos("abcdeabcdeabcde", "bc")2
```

```
2
```

Example 2

If a starting point for the search is given, `stringlib::pos` returns the first position at which the substring occurs after that starting point.

```
stringlib::pos("abcdeabcdeabcde", "bc", 5)7
```

```
7
```

Example 3

The result is `FAIL` if the substring does not occur at all or after the given starting point.

```
stringlib::pos("abcdeabcdeabcde", "bc", 14)FAIL
```

```
FAIL
```

Parameters

string1

string2

Non empty string

pos

Integer that determines the first position to search

Return Values

Integer that determines the position or `FAIL`.

See Also

stringlib::containslength

stringlib::random

Purpose

Create a random string

Syntax

```
stringlib::random(<l>, <characters>, options)
```

Description

`stringlib::random()` returns a random string of the default length 7.

`stringlib::random(l)` with a number or a range `l` returns a random string with length `l` or length in the given range. When the prefix and/or suffix is longer than the given length, `stringlib::random` raises an error message.

`stringlib::random(characters)` with a given list oder set of characters builds the random string of the given characters. When the characters are strings, they are used as single characters, however, the length is exceeded.

`stringlib::random(l, characters)` is a combination of the both last calls. When both parameters are given, the order is significant.

`stringlib` defines the lists `stringlib::lowerLetters`, `stringlib::upperLetters`, `stringlib::digits` and `stringlib::punctuation` with the characters lower letters, upper letters, digits and punctuation.

Examples

Example 1

Create a random string of the default length 7:
stringlib::random()"jaR<2oH"

```
"jaR<2oH"
```

Create a random string of the length 3:
stringlib::random(3)"uRT"

```
"uRT"
```

Create a random string of the length 2 only of digits:

stringlib::random(2, stringlib::digits)"53"

"53"

Create a random string of the length 3 only of digits with prefix "+":
stringlib::random(3, stringlib::digits, Prefix = "+")"+70"

"+70"

Create a random string of the length 5 only of digits with suffix ".0":
stringlib::random(5, stringlib::digits, Suffix = ".0")"456.0"

"456.0"

Create a random strings of the length 3 to 8 only of letters:
stringlib::random(3..8, stringlib::lowerLetters. stringlib::upperLetters)
$ k = 1..5"BDkkIz", "zkkvYp", "mFobeC", "Vxsjuk", "HHTJbWh"

"BDkkIz", "zkkvYp", "mFobeC", "Vxsjuk", "HHTJbWh"

Create a random string of the length 2 to 8 with letters and casual
a punctuation:
stringlib::random(2..8, (stringlib::lowerLetters. stringlib::upperLetters
$ 4). stringlib::punctuation) $ k = 1..12"<vlvl<a", "rFxvu", "GUHEBR",
"fP", "dIqxr", "wO\"Md", "RdFdRlqH", "nv)", "Bo", "HGaiqPt&", "AqnF",
"do"

"<vlvl<a", "rFxvu", "GUHEBR", "fP", "dIqxr", "wO"Md", "RdFdRlqH", "nv)", "Bo", "HGaiqPt&", "AqnF", "do"

Create a random string of the length 6 to 8 with letters and equivalent
punctuation:
stringlib::random(6..8, (stringlib::lowerLetters. stringlib::upperLetters).
(stringlib::punctuation $ 2)) $ k = 1..10"n^iY)E", "=l_?sZ", "{i^(Gh>h",
"/A+#}/", "L-DM&G-U", "(,^JzNL;", "ZH;|%;i", ")t^.[^}T", "-v*Es=Z>",
"\\:AdF{R"

"n^iY)E", "=l_?sZ", "{i^(Gh>h", "/A+#}/", "L-DM&G-U", "(,^JzNL;", "ZH;|%;i", ")t^.[^]T", "-v*Es=Z>", "

Create random names of the length 4 to 6:
stringlib::random(4..6, Name) $ k = 1..12"pbg1", "A98HWb", "eAaR1", "ve_6", "rtxoi", "Iwaw", "Td8cQR", "PAsudJ", "a4AN", "d2ixaC", "DvLXzh", "yTMCa5"

"pbg1", "A98HWb", "eAaR1", "ve_6", "rtxoi", "Iwaw", "Td8cQR", "PAsudJ", "a4AN", "d2ixaC", "DvLXzh",

Create a random password of the length 8 to 10, but without some special characters:
EX := {"\\", "\"", "|", "'", "?", "*", "[", "]"}: stringlib::random(8..10, Exclude = EX)"NRpjhuRkc"

"NRpjhuRkc"

Parameters

l

The length of the returned string: a nonnegative integer or a range of nonnegative integers

characters

A list or set of characters

options

Any of the described options

Options

Exclude

Option, specified as `Exclude = characters`

The returned string does not contain characters given in the set or list `characters`.

Name

The returned string is a valid MuPAD object name.

Prefix

Option, specified as `Prefix = string`

Adds `string` in front of each random string. The length of the returned string is the given length or the default length including the prefix.

Suffix

Option, specified as `Suffix = string`

Appends `string` to each random string. The length of the returned string is the given length or the default length including the suffix.

Return Values

Random string of the given length or the default length including the prefix resp. suffix.

See Also

randomSEEDstringlib::lowerstringlib::uppersubstring

stringlib::readText

Purpose

Reading text file

Syntax

```
stringlib::readText(filename)
stringlib::readText(filename, String, <NoNL>)
stringlib::readText(filename, String, <Separator = string>)
```

Description

`stringlib::readText(filename)` reads all lines of the text file with name `filename` and returns a list of strings, one string per line. The linebreaks are not included at the end of each string.

The file must be a text file, otherwise the file cannot be read.

Examples

Example 1

First create a text file that can be read:
fprint(Unquoted, Text, "test.txt", "This file contains three lines.\n", "// this line is a MuPAD comment\n", "..........\n"):

By default, `stringlib::readText` returns a list of all lines:
stringlib::readText("test.txt")["This file contains three lines.", "// this line is a MuPAD comment", "..........", ""]

["This file contains three lines.", "// this line is a MuPAD comment", "..........", ""]

Because the third line was ended by a newline, the file contains four lines, the last line is empty.

The file can be read as *one* string:
stringlib::readText("test.txt", String)"This file contains three lines.\n// this line is a MuPAD comment\n..........\n"

"This file contains three lines. // this line is a MuPAD comment .... "

When the newlines should be removed, option `NoNL` can be used:
stringlib::readText("test.txt", String, NoNL)"This file contains three lines.// this line is a MuPAD comment.........."

"This file contains three lines.// this line is a MuPAD comment....."

Otherwise the newlines can be replaced by another separator: stringlib::readText("test.txt", String, Separator = " ;; ")"This file contains three lines. ;; // this line is a MuPAD comment ;; ..... ;; "

"This file contains three lines. ;; // this line is a MuPAD comment ;; ..... ;; "

Parameters

filename

The name of a file as string

string

Any string

Options

String

With this option, `stringlib::readText` returns *one* string that contains all contents of the read file, including the line breaks as separator of the lines.

NoNL

With option `NoNL`, the returned string does not contain the linebreaks between the lines.

Separator

Option, specified as `Separator = string`

This option causes `stringlib::readText`, to separate each all lines by `string`, instead of the line break `"\n"`.

Return Values

List of strings, or one string

See Also

ftextinputfprintstringlib::subs

stringlib::remove

Purpose

Delete substrings

Syntax

```
stringlib::remove(string1, string2, <First>)
```

Description

With `stringlib::remove`, a substring can be deleted from another string.

After `string2` has been found, the search for further occurrences of it continues after its last letter; hence only the first of several overlapping occurrences is detected. See “Example 3” on page 31-25.

Examples

Example 1

By default, out of several occurrences of the given substring *all* are removed.
stringlib::remove("abcdeabcdeabcde", "bc")"adeadeade"

"adeadeade"

Example 2

Using the option `First` causes `stringlib::remove` to remove only the first occurrence of the given substring.
stringlib::remove("abcdeabcdeabcde", "bc", First)"adeabcdeabcde"

"adeabcdeabcde"

Example 3

In the following example, the given substring occurs twice, where both instances of it do overlap. Only the first occurrence is removed.
stringlib::remove("aaa", "aa")"a"

"a"

Parameters

string1

string2

Non empty string

Options

First

Determines that only the first appearance of `string2` in `string1` will be deleted

Return Values

Given string without the deleted parts

See Also

deletestringlib::subsstringlib::subsop

stringlib::split

Purpose

Split a string

Syntax

```
stringlib::split(string, <separator>)
```

Description

`stringlib::split(string, separator)` splits `string` in all parts separated by the string given as `separator`, that is not included in the returned strings.

If no separator is given, a single space is used as separator.

A returned part can be the empty string.

When the given string does not contain the separator, a list with the unchanged string is returned.

Examples

Example 1

The given string is splitted into the numbers separated by comma:
stringlib::split("1,2,3,4,5", ",")["1", "2", "3", "4", "5"]

```
["1", "2", "3", "4", "5"]
```

In the next example is the separator a comma followed by a space:
stringlib::split("1, 2, 3, 4, 5", ", ")["1", "2", "3", "4", "5"]

```
["1", "2", "3", "4", "5"]
```

Without separator a single space is used as separator:
stringlib::split("1, 2, 3, 4, 5")["1,", "2,", "3,", "4,", "5"]

```
["1,", "2,", "3,", "4,", "5"]
```

Example 2

The parts can be empty strings – five empty strings separated by four single spaces:
stringlib::split(" ", " ")["", "", "", "", ""]

```
["", "", "", "", ""]
```

The following string (five spaces) consists of two empty strings and a single space separated by two double spaces:
stringlib::split(" ", " ")["", "", " "]

```
["", "", " "]
```

Example 3

When the string does not contain the separator, a list with the unchanged string is returned:
stringlib::split("1,2,3,4,5", ".")["1,2,3,4,5"]

```
["1,2,3,4,5"]
```

Parameters

string

separator

Any non-empty MuPAD string

Return Values

List of all parts of `string` without all parts `separator`; the string itself, if `string` does not contain `separator`.

See Also

stringlib::collapseWhitespacestringlib::containsstrmatchsubstring

stringlib::subs

Purpose

Substitution in a string

Syntax

```
stringlib::subs(string, substring = replacement, <First>)
```

Description

`stringlib::subs` substitutes a substring by another string.

By default, every occurrence of the string `substring` in `string` is replaced by `replacement`. The option `First` causes only the first appearance of `substring` to be replaced.

The result is not searched again for instances of `substring`. See “Example 3” on page 31-30.

Among several overlapping occurrences of `substring`, the leftmost one is replaced.

Examples

Example 1

The string `replacement` may be empty.
stringlib::subs("abcdeabcdeabcde", "bc" = "")"adeadeade"

```
"adeadeade"
```

Example 2

Every `substring` is replaced unless the option `First` is given.
stringlib::subs("abcdeabcdeabcde", "bc" = "xxx")"axxxdeaxxxdeaxxxde"

```
"axxxdeaxxxdeaxxxde"
```

stringlib::subs("abcdeabcdeabcde", "bc" = "xxx",
First)"axxxdeabcdeabcde"

```
"axxxdeabcdeabcde"
```

Example 3

The substitution may produce a new instance of `substring`, but this one is not replaced.
stringlib::subs("aab", "ab"="b")"ab"

```
"ab"
```

Example 4

Collapse all whitespace in strings (see stringlib::collapseWhitespace):
f := proc(x) local y; begin y := 2*x; x + y end_proc: string := expr2text(f)"proc(x)\n name f;\n local y;\nbegin\n y := 2*x; \n x + y\nend_proc"

```
"proc(x)   name f;   local y; begin   y := 2*x;    x + y end_proc"
```

string := stringlib::subs(string, "\n" = " "): string := stringlib::subs(string, " " = " "): string := stringlib::subs(string, " " = " ")"proc(x) name f; local y; begin y := 2*x; x + y end_proc"

```
"proc(x) name f; local y; begin y := 2*x; x + y end_proc"
```

Parameters

string

Non empty string

substring

Non empty string that should be replaced

replacement

Any string that replaced `substring`

Options

First

Determines that only the first appearance of `substring` in `string` will be replaced

Return Values Given string with `substring` replaced by `replacement`

See Also subsstringlib::subsopstringlib::posstringlib::remove

stringlib::subsop

Purpose

Substitution in a string

Syntax

```
stringlib::subsop(string, index = replacement)
```

Description

`stringlib::subsop` removes one or more characters at a given position and inserts another substring at that position instead.

The char with index `index` in `string` (if `index` is an integer) or the range of chars (if `index` is a range of integers) is removed. Instead `replacement` is inserted at that position. The inserted string need not have the same length.

Examples

Example 1

Delete the first character:
stringlib::subsop("abcdeabcdeabcde", 1 = "")"bcdeabcdeabcde"

"bcdeabcdeabcde"

The 2nd to 3rd character will be replaced by `"xxx"`:
stringlib::subsop("abcdeabcdeabcde", 2..3 = "xxx")"axxxdeabcdeabcde"

"axxxdeabcdeabcde"

Delete the characters 2 to 11:
stringlib::subsop("abcdeabcdeabcde", 2..11 = "")"abcde"

"abcde"

Parameters

string

Non empty string

index

Integer or range of integers that determines the chars to be replaced

replacement

Any string to replace the given char or range

Return Values

Given string with the replacement

See Also

subsopstringlib::posstringlib::removestringlib::subs

stringlib::upper

Purpose

Convert to upper-case

Syntax

```
stringlib::upper(string1)
```

Description

`stringlib::upper(string1)` converts each lower-case letter in the string `string1` to upper-case. All other characters remains unchanged.

If the string contains no lower-case letters, the given string is returned unchanged.

Examples

Example 1

Convert a string to upper-case:
stringlib::upper("MuPAD"), stringlib::upper("Mupad"), stringlib::upper("MUPAD"), stringlib::upper("mupad")"MUPAD", "MUPAD", "MUPAD", "MUPAD"

"MUPAD", "MUPAD", "MUPAD", "MUPAD"

Example 2

Compare strings not case sensitive:
str_eq:= (str1, str2) -> bool(stringlib::upper(str1) = stringlib::upper(str2)): str_eq("MuPAD", "mupad"), str_eq("Mupad", "MUPAD")TRUE, TRUE

TRUE, TRUE

Parameters

string1

Any string

Return Values

String

See Also

stringlib::formatstringlib::lower

stringlib::validIdent

Purpose

Validate identifier name

Syntax

```
stringlib::validIdent(string)
```

Description

`stringlib::validIdent(string)` returns TRUE, when `string` is a valid identifier name, otherwise FALSE.

A valid identifier name in MuPAD must follow the rules:

- The first character must be a letter or the character `"_"`.
- All following characters must be letters or digits or the character `"_"`.
- An identifier consists of at least one character up to `512` characters.

Names in backticks ` are not determined as valid names.

Examples

Example 1

The example splits a set of names into valid identifier names and invalid identifier names:

```
split({"a", "1", "_111", "____", "A0b.C", "MuPAD", "1ABCDE", "xyz00"},
stringlib::validIdent)[{"MuPAD", "_111", "____", "a", "xyz00"}, {"1",
"1ABCDE", "A0b.C"}, {}]
```

```
[{"MuPAD", "_111", "____", "a", "xyz00"}, {"1", "1ABCDE", "A0b.C"}, ∅]
```

stringlib::random called with option `Name` returns always valid identifier names. The function map applies `stringlib::validIdent` to each of the `1000` generated random names:

```
map({stringlib::random(1..10, Name) $ k = 1..1000},
stringlib::validIdent){TRUE}
```

```
{TRUE}
```

Parameters

string

A string

Return Values TRUE or FALSE

See Also domtypestringlib::random

Symbol – Typesetting Symbols

==REFNAME==

Symbol::accentPrime

Purpose

Adds a prime accent to an identifier

Syntax

```
Symbol::accentPrime(a)
```

Description

Creates a new identifier with a prime accent, such as ‘a′‘$a_{\prime}$.

Examples

Example 1

`Symbol::accentPrime` adds a “prime” to an identifier:
Symbol::accentPrime(x) = x + f(x)‘x′‘ = x + f(x)

$$x_{\prime} = x + f(x)$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::accentAsterisk

Purpose

Adds an asterisk accent to an identifier

Syntax

```
Symbol::accentAsterisk(a)
```

Description

Creates a new identifier with an asterisk accent, such as ‘a*‘a^*.

Examples

Example 1

Asterisk accents are often used to denote special values:
f(Symbol::accentAsterisk(x)) = 0f(‘x*‘) = 0

$$f(x^*) = 0$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::accentTilde

Purpose

Adds a tilde accent to an identifier

Syntax

```
Symbol::accentTilde(a)
```

Description

Creates a new identifier with a tilde accent, such as ‘a˜‘ã.

Examples

Example 1

The most common use of the tilde accent is to denote an approximation:
x = Symbol::accentTilde(x) + O(h^2)x = ‘x˜‘ + O(h^2)

$$x = \tilde{x} + O(h^2)$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::accentHat

Purpose

Adds a hat accent to an identifier

Syntax

```
Symbol::accentHat(a)
```

Description

Creates a new identifier with a hat accent, such as ‘aˆ‘â.

Examples

Example 1

One of the common uses of the hat (or circumflex) accents is to denote Laplace transforms:
f = sin(x) ==> Symbol::accentHat(f) = laplace(sin(x), x, t)f = sin(x) ==> ‘fˆ‘ = 1/(t^2 + 1)

$$f = \sin(x) \Rightarrow \hat{f} = \frac{1}{t^2 + 1}$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::accentRightArrow

Purpose

Adds a right arrow accent to an identifier

Syntax

```
Symbol::accentRightArrow(a)
```

Description

Creates a new identifier with a right arrow accent, such as ‘a→‘ $\vec{a}$.

Examples

Example 1

Arrow accents are usually used to denote vectors:
Symbol::accentRightArrow(b) = matrix([1, 2, Symbol::dots, n])‘b→‘ = matrix([[1], [2], [‘&dots;‘], [n]])

$$\vec{b} = \begin{pmatrix} 1 \\ 2 \\ \vdots \\ n \end{pmatrix}$$

To denote ‘0→‘ $\vec{0}$, the null vector, start with the *identifier* `0`:
Symbol::accentRightArrow(‘0‘)‘0→‘

$$\vec{0}$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::accentDot

Purpose

Adds a dot accent to an identifier

Syntax

```
Symbol::accentDot(a)
```

Description

Creates a new identifier with a dot accent, such as ‘a˙‘ȧ

Examples

Example 1

In physics, a dot accent is often used as a shorthand for the derivative with respect to time:
Symbol::accentDot(y) = - Symbol::omega^2 * sin(x)‘y˙‘ = -‘ω‘^2*sin(x)

$$\dot{y} = -\omega^2 \sin(x)$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::accentDoubleDot

Purpose

Adds a double dot accent to an identifier

Syntax

```
Symbol::accentDoubleDot(a)
```

Description

Creates a new identifier with a double dot accent, such as $a\ddot{}$.

Examples

Example 1

In physics, the double dot accent usually denotes the second derivative with respect to time:
Symbol::accentDoubleDot(x) = -x‘x¨‘ = -x

$$\ddot{x} = -x$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::accentTripleDot

Purpose

Adds a triple dot accent to an identifier

Syntax

```
Symbol::accentTripleDot(a)
```

Description

Creates a new identifier with a triple dot accent, such as ‘a⃛“$\dddot{a}$.

Examples

Example 1

Triple dots, where used, usually denote the third derivative with repect to time:
Symbol::accentTripleDot(x)(t) = diff(x(t), t$3)‘x⃛‘(t) = diff(x(t), t, t, t)

$$\dddot{x}(t) = \frac{\partial^3}{\partial t^3} x(t)$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::accentOverBar

Purpose

Adds an overbar to an identifier

Syntax

```
Symbol::accentOverBar(a)
```

Description

Creates a new identifier with an overbar, such as ‘a‾‘ $\bar{a}$.

Examples

Example 1

The overbar is used in statistics to denote the arithmetical mean of an observable quantity:
Symbol::accentOverBar(x) = sum(x[i], i=1..n)/n‘x‾‘ = sum(x[i], i = 1..n)/n

$$\bar{x} = \frac{\sum_{i=1}^{n} x_i}{n}$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::accentUnderBar

Purpose

Adds an underbar to an identifier

Syntax

```
Symbol::accentUnderBar(a)
```

Description

Creates a new identifier with an underbar, such as ‘a_‘a.

Examples

Example 1

One of the areas where the underbar is used frequently is interval analysis, where an interval is usually given as follows:
x = [Symbol::accentUnderBar(x), Symbol::accentOverBar(x)]x = [‘x_‘, ‘x‾‘]

$$x = [\underline{x}, \overline{x}]$$

Parameters

a

An identifier

Return Values

Identifier

Symbol::new

Purpose

Functional access to symbols

Syntax

```
Symbol(x)
```

Description

`Symbol::new(symname)` or simply `Symbol(symname)` creates the typesetting symbol corresponding to `symname`.

The typesetting symbols can be accessed in two different ways: Most symbols can be input by typing `Symbol::symname`, where `symname` is taken from the lists in the introduction. For some symbol names (such as `not` or `I`), this is not possible in the MuPAD language. What is possible in any case is to invoke `Symbol` as a function, taking a string representation as its argument, as in `Symbol("not")`.

Examples

Example 1

The symbols accessed via `Symbol` can be used like ordinary identifiers:
Symbol::heartsuit in {Symbol::heartsuit, Symbol::spades}‘♥‘ in {‘♥‘, ‘♠‘}

$$\heartsuit \in \{\heartsuit, \spadesuit\}$$

expand((Symbol::alpha + Symbol::beta)^4);‘α‘^4 + 4*‘α‘^3*‘β‘ + 6*‘α‘^2*‘β‘^2 + 4*‘α‘*‘β‘^3 + ‘β‘^4

$$\alpha^4 + 4\,\alpha^3\,\beta + 6\,\alpha^2\,\beta^2 + 4\,\alpha\,\beta^3 + \beta^4$$

Some symbol names are MuPAD keywords and can not be accessed via slot calls. They can be given as function calls:
Symbol("minus"), Symbol("div"), Symbol("in"), Symbol("and"), Symbol("subset"), Symbol("NIL"), Symbol("UNKNOWN"), Symbol("FAIL"), Symbol("E"), Symbol("I"), Symbol("not")‘−‘, ‘÷‘, ‘∈‘, ‘∧‘, ‘⊂‘, ‘&NIL;‘, ‘&UNKNOWN;‘, ‘&FAIL;‘, ‘&E;‘, ‘&I;‘, ‘¬‘

–, /, ∈, ∧, ⊂, Nil, unknown, Fail, *E*, *I*, ¬

Parameters

symname

A symbol name: a string

Return Values

identifier

See Also

print

Symbol::subScript

Purpose

Combines two expressions to a new subscripted identifier

Syntax

```
Symbol::subScript(a, b)
```

Description

Creates a new subscripted identifier, such as a_b. If the arguments are not yet identifiers, they are first converted into identifiers. You can also use _,^,*$*,*{*, and *}* to create arguments with superscript and subscript. For these arguments a new subscripted identifier appears on top of the existing ones: a_{b_c} or ‘a_{b$cd}‘ $a_{b_{c^d}}$. If you want to create identifiers in which these five special characters appear explicitly, use string arguments:
Symbol::subScript("a","b_c")‘{a}_{b{_}c}‘

a_{b_c}

Examples

Example 1

Even if *X1* and *X2* look identical, only *X1* is an identifier whereas *X2* is an _index-expression:
X1 := Symbol::subScript(x, 1): X2 := x[1]: X1, X2; domtype(X1), domtype(X2)‘{x}_{1}‘, x[1]

x_1, x_1
DOM_IDENT, DOM_EXPR

DOM_IDENT, DOM_EXPR

Pre-scripts are possible by subscripting the empty identifier `` and appending an identifer:
Symbol::subScript(“, 1).x‘{}_{1}x‘

${}_1x$

Example 2

You can use the nested form of the function:
Symbol::subScript(x, Symbol::subScript(i, j))‘{x}_{{i}_{j}}‘

Parameters

a, b

Arbitrary expressions

Return Values

Identifier

Symbol::subSuperScript

Purpose

Combines three expressions to a new combined sub- and superscripted identifier

Syntax

```
Symbol::subSuperScript(a, b, c)
```

Description

Creates a new combined sub- and superscripted identifier, such as ‘a$bc‘$a_b^c$. If the arguments are not yet identifiers, they are first converted into identifiers. You can also use _,^,*$*,*{*, and *}* to create arguments with superscript and subscript. For these arguments a new indexed identifier appears on top of the existing ones: ‘a${b_c}{d_e}‘$a_{b_c}^{d_e}$ or ‘a${b$cd}{e}‘$a_{b_{cd}}^{e}$. If you want to create identifiers in which these five special characters appear explicitly, use string arguments: Symbol::subSuperScript("a","b_c","d_e")‘{a}${b{_}c}{d{_}e}‘

$a_{b\_c}^{d\_e}$

Examples

Example 1

Input of an identifier with sub- and superscript:
X1 := Symbol::subSuperScript(x, 1, 2): X1, domtype(X1)‘{x}${1}{2}‘, DOM_IDENT

x_1^2, DOM_IDENT

Pre-scripts are possible by subsuperscripting the empty identifier ``` and appending an identifer:
Symbol::subSuperScript(“, 1, 2).X‘{}${1}{2}X‘

${}_1^2X$

And at last scripts all around `X`:
Symbol::subSuperScript(“, 1, 2).Symbol::subSuperScript(X, 3, 4)‘{}${1}{2}{X}${3}{4}‘

Example 2

You can use the nested form of the function: Symbol::subSuperScript(x, a, Symbol::subSuperScript(b, i, j))‘{x}${a}{{b}${i}{j}}‘

Parameters

a, b, c

Arbitrary expressions

Return Values

Identifier

Symbol::superScript

Purpose

Combines two expressions to a new superscripted identifier

Syntax

```
Symbol::superScript(a, b)
```

Description

Creates a new superscripted identifier, such as ‘a^b‘a^b. If the arguments are not yet identifiers, they are first converted into identifiers. You can also use _,^,*$*,*{*, and *}* to create arguments with superscript and subscript. For these arguments a new superscripted identifier appears on top of the existing ones: ‘a^{b^c}‘a^{b^c} or ‘a^{b$cd}‘$a^{b_c^d}$. If you want to create identifiers in which these five special characters appear explicitly, use string arguments:
Symbol::superScript("a","b^c")‘{a}^{b{ˆ}c}‘

$a^{b\hat{}c}$

Examples

Example 1

Even if *X1* and *X2* look identical, only *X1* is an identifier whereas *X2* is a _power-expression:
X1 := Symbol::superScript(x, 2): X2 := x^2: X1, X2; domtype(X1), domtype(X2)‘{x}^{2}‘, x^2

x^2, x^2

DOM_IDENT, DOM_EXPR

DOM_IDENT, DOM_EXPR

Pre-scripts are possible by superscripting the empty identifier `` and appending an identifer:
Symbol::superScript(“, 1).x‘{}^{1}x‘

${}^1x$

Example 2

You can use the nested form of the function:
Symbol::superScript(x, Symbol::superScript(i, j))‘{x}^{{i}^{j}}‘

Parameters

a, b

Arbitrary expressions

Return Values

Identifier

transform – Integral and other Transforms

==REFNAME==

transform::fourier

Purpose

Fourier transform

Note `transform::fourier` will be removed in a future release. Use fourier instead. To get the same result as in `transform::fourier`, call Pref::fourierParameters`(1, 1)`, and then call fourier .

Syntax

```
transform::fourier(f, t, s)
```

Description

`transform::fourier(f, t, s)` computes the Fourier transform int(f*exp(I*s*t), t=(-infinity)..(infinity)) $\int_{-\infty}^{\infty} f e^{i s t} \, dt$ of the expression $f = f(t)$ with respect to the variable t at the point s.

Note Symbolic Math Toolbox™ uses a different definition of the Fourier transforms. The new fourier function uses the same definitions as Symbolic Math Toolbox.

An unevaluated function call is returned, if no explicit representation of the transform is found.

The discrete Fourier transform is implemented by numeric::fft.

If `f` is a matrix, the Fourier transform is applied to all components of the matrix.

Parameters

f

Arithmetical expressions or matrices of such expressions

t

The transformation variables: identifiers

s

The evaluation points: arithmetical expressions

Return Values Arithmetical expression or a matrix of such expressions.

Overloaded By `f`

References [1] Reference: F. Oberhettinger, “Tables of Fourier Transforms and Fourier Transforms of Distributions”, Springer, 1990.

See Also transform::invfourierfourierfourier::addpatternifourierifourier::addpatternnumeric::fftnur

Concepts

- “Integral Transforms”

Purpose

transform::invfourier

Inverse Fourier transform

Note `transform::invfourier` will be removed in a future release. Use ifourier instead. To get the same result as in `transform::invfourier`, call Pref::fourierParameters(1, 1), and then call ifourier.

Syntax

```
transform::invfourier(F, S, T)
```

Description

`transform::invfourier(F, S, T)` computes the inverse Fourier transform (1)/(2*PI) * int(F * exp(-I*S*T), S=-infinity..infinity) $\frac{1}{2\pi}\int_{-\infty}^{\infty} F e^{-i S T} d S$ of the expression $F = F(S)$ with respect to the variable S at the point T.

Note Symbolic Math Toolbox uses a different definition of the inverse Fourier transforms. The new ifourier function uses the same definitions as Symbolic Math Toolbox.

`transform::invfourier(F, S, T)` is computed as

transform::fourier(F, S, -T)/(2*PI)

$$\frac{\text{transform::fourier}(F, S, -T)}{2\pi}$$

This result is returned, if no explicit representation of the transformation is found.

The inverse discrete Fourier transform is implemented by numeric::invfft.

If `F` is a matrix, the inverse Fourier transform is applied to all components of the matrix.

Parameters

F

Arithmetical expressions or matrices of such expressions

S

The transformation variables: identifiers

T

The evaluation points: arithmetical expressions

Return Values

Arithmetical expression or a matrix of such expressions.

transform::fourierfourierfourier::addpatternifourierifourier::addpatternnumeric::fftnumer

Concepts

- “Integral Transforms”

transform::fourier::addpattern

Purpose

Add patterns for the Fourier transform

Note `transform::fourier::addpattern` will be removed in a future release. Use fourier::addpattern instead. To get the same result as in `transform::fourier::addpattern`, call Pref::fourierParameters(`1, 1`), and then call fourier::addpattern.

Syntax

```
transform::fourier::addpattern(pat, t, s, res,
<[param,  ], <[cond,  ]>>)
```

Description

`transform::fourier::addpattern(pat, t, s, res)` teaches transform::fourier to return transform::fourier(pat, t, s) = int(pat*exp(I*s*t), t=(-infinity)..(infinity))=res

$$\text{transform::fourier}(\text{pat}, t, s) = \int_{-\infty}^{\infty} \text{pat}\, e^{i\,s\,t}\, d\,t = \text{res}.$$

Note Symbolic Math Toolbox uses a different definition of the Fourier transforms. The new fourier and fourier::addpattern functions use the same definitions as Symbolic Math Toolbox.

In MuPAD, you can add your own patterns for Fourier transform computations. To add a new pattern to the pattern matcher, use `transform::fourier::addpattern`.

You can include free parameters and conditions on these parameters using additional arguments. These conditions and the result are protected from premature evaluation. That means you can use `not iszero(a^2-b)` instead of `hold( _not @ iszero )(a^2-b)`.

The following conditions treat assumptions on identifiers differently:

- `a^2-b <> 0` takes into account assumptions on the identifiers.
- `not  iszero(a^2-b)` disregards assumptions on identifiers.

Recursive calls of transform::fourier can use patterns introduced by `transform::fourier::addpattern`.

Environment Interactions

Calling `transform::fourier::addpattern` or transform::invfourier::addpattern changes the expressions returned by future calls to transform::fourier or transform::invfourier, respectively.

Parameters

pat

The pattern to match: an arithmetical expression in `t` or `s`.

t

s

The indeterminates used in pattern and result: identifiers.

res

The pattern for the result: an arithmetical expression in `s` or `t`.

[param, ...]

"pattern variables": identifiers. Pattern variables serve as placeholders in `pat` and `res`. They represent arbitrary MuPAD objects restricted by the conditions `cond`. The expressions must not contain the indeterminate `s` (or `t`, respectively).

cond, ...

Conditions on the pattern variables.

Return Values

Object of type DOM_NULL.

Concepts

- "Use Custom Patterns for Transforms"

transform::invfourier::addpattern

Purpose

Add patterns for the inverse Fourier transform

Note `transform::invfourier::addpattern` will be removed in a future release. Use ifourier::addpattern instead. To get the same result as in `transform::invfourier::addpattern`, call Pref::fourierParameters`(1, 1)`, and then call ifourier::addpattern.

Syntax

```
transform::invfourier::addpattern(pat, s, t, res,
<[param,  ], <[cond,  ]>>)
```

Description

`transform::invfourier::addpattern(pat, s, t, res)` teaches transform::invfourier to return *transform*::*invfourier*(*pat*, *s*, *t*) = *res*.

Note Symbolic Math Toolbox uses a different definition of the inverse Fourier transforms. The new ifourier and ifourier::addpattern functions use the same definitions as Symbolic Math Toolbox.

In MuPAD, you can add your own patterns for inverse Fourier transform computations. To add a new pattern to the pattern matcher, use `transform::invfourier::addpattern`.

You can include free parameters and conditions on these parameters using additional arguments. These conditions and the result are protected from premature evaluation. That means you can use `not iszero(a^2-b)` instead of `hold( _not @ iszero )(a^2-b)`.

The following conditions treat assumptions on identifiers differently:

- `a^2-b <> 0` takes into account assumptions on the identifiers.
- `not  iszero(a^2-b)` disregards assumptions on identifiers.

Recursive calls of transform::invfourier can use patterns introduced by `transform::invfourier::addpattern`.

Environment Interactions

Calling transform::fourier::addpattern or `transform::invfourier::addpattern` changes the expressions returned by future calls to transform::fourier or transform::invfourier, respectively.

Parameters

pat

The pattern to match: an arithmetical expression in `t` or `s`.

t

s

The indeterminates used in pattern and result: identifiers.

res

The pattern for the result: an arithmetical expression in `s` or `t`.

Concepts

- "Use Custom Patterns for Transforms"

transform::laplace

Purpose

Laplace transform

> **Note** `transform::laplace` will be removed in a future release. Use laplace instead.

Syntax

```
transform::laplace(f, t, s)
```

Description

`transform::laplace(f, t, s)` computes the Laplace transform

int(f*e^(-s*t), t=(0)..(infinity)) $\int_0^\infty f\,e^{-s\,t}\,dt$ of the expression $f = f(t)$ with respect to the variable t at the point s.

An unevaluated function call is returned, if no explicit representation of the transform is found.

If `f` is a matrix, the Laplace transform is applied to all components of the matrix.

Parameters

f

Arithmetical expressions or matrices of such expressions

t

The transformation variables: identifiers

s

The evaluation points: arithmetical expressions

Return Values

Arithmetical expression or an unevaluated function call of domain type `transform::laplace`. If the first argument is a matrix, the result is returned as a matrix.

Overloaded By

`f`

See Also transform::invlaplacelaplacelaplace::addpatternilaplaceilaplace::addpattern

Concepts

- “Integral Transforms”

transform::invlaplace

Purpose

Inverse Laplace transform

Note `transform::invlaplace` will be removed in a future release. Use ilaplace instead.

Syntax

```
transform::invlaplace(F, S, T)
```

Description

`transform::invlaplace(F, S, T)` computes the inverse Laplace transform of the expression $F = F(S)$ with respect to the variable S at the point T.

An unevaluated function call is returned, if no explicit representation of the transform is found.

If `F` is a matrix, the inverse Laplace transform is applied to all components of the matrix.

Parameters

F

Arithmetical expressions or matrices of such expressions

S

The transformation variables: identifiers

T

The evaluation points: arithmetical expressions

Return Values

Arithmetical expression or an unevaluated function call of domain type `transform::invlaplace`. If the first argument is a matrix, the result is returned as a matrix.

Overloaded By

`F`

See Also transform::laplacelaplacelaplace::addpatternilaplaceilaplace::addpattern

Concepts

- “Integral Transforms”

Purpose

transform::laplace::addpattern

Add patterns for the Laplace transform

Note `transform::laplace::addpattern` will be removed in a future release. Use laplace::addpattern instead.

Syntax

```
transform::laplace::addpattern(pat, t, s, res,
<[var,  ], <[cond,  ]>>)
```

Description

`transform::laplace::addpattern(pat, t, s, res)` teaches transform::laplace to return transform::laplace(pat, t, s) = int(pat*exp(-s*t), t=0..(infinity))=res$\text{transform::laplace}(\text{pat}, t, s) = \int_0^{\infty} \text{pat}\, e^{-s\,t}\, d\,t = \text{res}$.

A part of a computer algebra system's abilities computing a Laplace transform stems from mathematical pattern matching. The MuPAD pattern matcher can be extended at runtime with `transform::laplace::addpattern`.

You can include placeholders in the pattern and conditions on the expressions matched by these placeholders by giving additional arguments. These conditions, as well as the result, are protected from premature evaluation, i.e., it is not necessary to write `hold(_not @ iszero)(a^2 - b)`, a simple `not iszero(a^2-b)` suffices.

The difference between `not iszero(a^2-b)` and `a^2-b <> 0` when given as a condition is that the latter takes into account assumptions on the identifiers encountered, while the first does not.

Patterns introduced by `transform::laplace::addpattern` are also used in recursive calls of transform::laplace.

Environment Interactions

Calling `transform::laplace::addpattern` changes the expressions returned by future calls to transform::laplace.

Parameters

pat

The pattern to match: an arithmetical expression in `t` or `s`, respectively. See below for implicit assumptions on other identifiers.

t

s

The indeterminates used in pattern and result: identifiers.

res

The pattern for the result of the transformation: an arithmetical expression in `s` or `t`, respectively.

[var, ...]

"pattern variables": placeholders in `pat` and `ret`, i.e., identifiers that do not represent themselves but almost arbitrary MuPAD expressions not containing `s` and `t` and restricted by the conditions in the fifth parameter.

cond, ...

Conditions on the pattern variables

Return Values

Object of type DOM_NULL

See Also

transform::invlaplace::addpatternlaplacelaplace::addpatternilaplaceilaplace::addpattern

Concepts

- "Use Custom Patterns for Transforms"

Purpose

transform::invlaplace::addpattern

Add patterns for the inverse Laplace transform

Note `transform::invlaplace::addpattern` will be removed in a future release. Use ilaplace::addpattern instead.

Syntax

```
transform::invlaplace::addpattern(pat, t, s, res,
<[var,  ], <[cond,  ]>>)
```

Description

`transform::invlaplace::addpattern(pat, s, t, res)` teaches transform::invlaplace to return *transform*::*invlaplace*(*pat*, *s*, *t*) = *res*.

A part of a computer algebra system's abilities computing an inverse Laplace transform stems from mathematical pattern matching. The MuPAD pattern matcher can be extended at runtime with `transform::invlaplace::addpattern`.

You can include placeholders in the pattern and conditions on the expressions matched by these placeholders by giving additional arguments. These conditions, as well as the result, are protected from premature evaluation, i.e., it is not necessary to write `hold(_not @ iszero)(a^2 - b)`, a simple `not iszero(a^2-b)` suffices.

The difference between `not iszero(a^2-b)` and `a^2-b <> 0` when given as a condition is that the latter takes into account assumptions on the identifiers encountered, while the first does not.

Patterns introduced by `transform::invlaplace::addpattern` are also used in recursive calls of transform::invlaplace.

Environment Interactions

Calling `transform::invlaplace::addpattern` changes the expressions returned by future calls to `transform::invlaplace`.

Parameters

pat

The pattern to match: an arithmetical expression in `t` or `s`, respectively. See below for implicit assumptions on other identifiers.

t

s

The indeterminates used in pattern and result: identifiers.

res

The pattern for the result of the transformation: an arithmetical expression in `s` or `t`, respectively.

Purpose

transform::ztrans

Z transform

Note `transform::ztrans` will be removed in a future release. Use ztrans instead.

Syntax

```
transform::ztrans(f, k, z)
```

Description

`transform::ztrans(f, k, z)` computes the Z transform sum(f(k)/z^k, k = (0) ..(infinity)) $\sum_{k=0}^{\infty} \frac{f(k)}{z^k}$ of the expression $f = f(k)$ with respect to the summation index k at the point z.

An unevaluated function call is returned, if no explicit representation of the transform is found.

If `f` is a matrix, the Z transform is applied to all components of the matrix.

Parameters

f

Arithmetical expressions or matrices of such expressions

k

Identifiers or indexed identifiers

z

The evaluation points: arithmetical expressions

Return Values

An explicit arithmetical expression or an unevaluated function call of domain type `transform::ztrans`.

An explicit result may be a piecewise object.

If the first argument is a matrix, the result is returned as a matrix.

Overloaded By f

See Also transform::invztransztransztrans::addpatterniztransiztrans::addpattern

Concepts

- "Z-Transforms"

Purpose

transform::invztrans

Inverse Z transform

Note `transform::invztrans` will be removed in a future release. Use iztrans instead.

Syntax

```
transform::invztrans(F, Z, K)
```

Description

`transform::invztrans(F, Z, K)` computes the inverse Z transform of the expression $F = F(Z)$ with respect to the variable Z at the point K.

An unevaluated function call is returned, if no explicit representation of the transform is found.

If `F` is a matrix, the inverse Z transform is applied to all components of the matrix.

Parameters

F

Arithmetical expressions or matrices of such expressions

Z

Identifiers or indexed identifiers

K

The evaluation points: arithmetical expressions

Return Values

An explicit arithmetical expression or an unevaluated function call of domain type `transform::invztrans`, respectively.

An explicit result may be a piecewise object.

If the first argument is a matrix, the result is returned as a matrix.

transform::ztrans::addpattern

Add patterns for the Z transform

Note `transform::ztrans::addpattern` will be removed in a future release. Use ztrans::addpattern instead.

Syntax

```
transform::ztrans::addpattern(pat, k, z, res,
<[var,  ], <[cond,  ]>>)
```

Description

`transform::ztrans::addpattern(pat, k, z, res)` teaches transform::ztrans to return transform::ztrans(pat, k, z) = sum(pat/z^k, k = 0 ..infinity)=res $\text{transform::ztrans}(\text{pat}, k, z) = \sum_{k=0}^{\infty} \frac{\text{pat}}{z^k} = \text{res}$.

A part of a computer algebra system's abilities computing a Z transform stems from mathematical pattern matching. The MuPAD pattern matcher can be extended at runtime with `transform::ztrans::addpattern`.

Users can include placeholders (pattern variables) in the pattern and conditions on the expressions inserted for these placeholders by giving additional arguments. These conditions, as well as the result, are protected from premature evaluation, i.e., it is not necessary to write `hold( _not @ iszero )(a^2-b)`, a simple `not iszero(a^2-b)` suffices.

The difference between `not iszero(a^2-b)` and `a^2-b <> 0` when given as a condition is that the latter takes into account assumptions on the identifiers encountered, while the first does not.

Patterns introduced by `transform::ztrans::addpattern` are also used in recursive calls of transform::ztrans.

Environment Interactions

Calling `transform::ztrans::addpattern` changes the expressions returned by future calls to transform::ztrans.

Parameters

pat

The pattern to match: an arithmetical expression in `k` or `z`, respectively.

k

z

The indeterminates used in pattern and result: identifiers.

res

The pattern for the result of the transformation: an arithmetical expression in `z` or `k`, respectively.

[var, ...]

"pattern variables": placeholders in `pat` and `ret`, i.e., identifiers that do not represent themselves but almost arbitrary MuPAD expressions not containing `k` (or `z`, respectively) and restricted by the conditions in the fifth parameter.

cond, ...

Conditions on the pattern variables

Return Values

Object of type DOM_NULL

See Also

transform::invztrans::addpatternztransztrans::addpatterniztransiztrans::addpattern

Concepts

- "Use Custom Patterns for Transforms"

transform::invztrans::addpattern

Purpose

Add patterns for the inverse Z transform

Note `transform::invztrans::addpattern` will be removed in a future release. Use iztrans::addpattern instead.

Syntax

```
transform::invztrans::addpattern(pat, z, k, res,
<[var,  ], <[cond,  ]>>)
```

Description

`transform::invztrans::addpattern(pat, z, k, res)` teaches transform::invztrans to return *transform*::*invztrans*(*pat*, *z*, *k*) = *res*.

A part of a computer algebra system's abilities computing a Z transform stems from mathematical pattern matching. The MuPAD pattern matcher can be extended at runtime with `transform::invztrans::addpattern`.

Users can include placeholders (pattern variables) in the pattern and conditions on the expressions inserted for these placeholders by giving additional arguments. These conditions, as well as the result, are protected from premature evaluation, i.e., it is not necessary to write `hold( _not @ iszero )(a^2-b)`, a simple `not iszero(a^2-b)` suffices.

The difference between `not iszero(a^2-b)` and `a^2-b <> 0` when given as a condition is that the latter takes into account assumptions on the identifiers encountered, while the first does not.

Patterns introduced by `transform::invztrans::addpattern` are also used in recursive calls of transform::invztrans.

Environment Interactions

Calling `transform::invztrans::addpattern` changes the expressions returned by future calls to transform::invztrans.

Parameters

pat

The pattern to match: an arithmetical expression in `k` or `z`, respectively.

k

z

The indeterminates used in pattern and result: identifiers.

res

The pattern for the result of the transformation: an arithmetical expression in `z` or `k`, respectively.

[var, ...]

"pattern variables": placeholders in `pat` and `ret`, i.e., identifiers that do not represent themselves but almost arbitrary MuPAD expressions not containing `k` (or `z`, respectively) and restricted by the conditions in the fifth parameter.

cond, ...

Conditions on the pattern variables

Return Values

Object of type DOM_NULL

Type – Type Checking and Mathematical Properties

==REFNAME==

Type::AlgebraicConstant

Purpose

Type representing algebraic constants

Syntax

```
testtype(obj, Type::AlgebraicConstant)
```

Description

`Type::AlgebraicConstant` represents algebraic constants.

In MuPAD, algebraic constants are characterized as follows: a complex number is an algebraic constant, if both its real part and its imaginary part are rational. Sums and products of algebraic constants are again algebraic constants. Further, rational powers of algebraic constants are again algebraic constants.

Taken together, these rules characterize algebraic constants over the rationals defined as usual, i.e., as roots of polynomial expressions.

This type does not represent a property: it cannot be used in assume to mark an identifier as an algebraic constant.

Examples

Example 1

The following number is composed of radicals involving rational numbers and therefore is an algebraic constant:
testtype((3^(1/2)*I + 1/8)^(1/7), Type::AlgebraicConstant)TRUE

```
TRUE
```

The following objects are not algebraic constants:
testtype(2^I, Type::AlgebraicConstant), testtype(PI, Type::AlgebraicConstant)FALSE, FALSE

```
FALSE, FALSE
```

Example 2

Symbolic objects cannot represent algebraic constants:
testtype(x, Type::AlgebraicConstant)FALSE

FALSE

Example 3

The following call selects the algebraic constants in an expression:
select(x + PI + 2^(1/2) + I, testtype, Type::AlgebraicConstant)sqrt(2) + I

$\sqrt{2} + i$

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also

testtypeType::Constant

Type::AnyType

Purpose

Type representing arbitrary MuPAD objects

Syntax

```
testtype(obj, Type::AnyType)
```

Description

`Type::AnyType` represents arbitrary MuPAD objects.

This type is meant to represent arbitrary MuPAD objects in constructors of composite types such as Type::ListOf.

This type does not represent a property: it cannot be used in assume.

Examples

Example 1

Any object matches this type:
testtype(3, Type::AnyType), testtype(x, Type::AnyType), testtype(array(1..1, [x]), Type::AnyType), testtype(Dom::Matrix(), Type::AnyType)TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE

This type is meant for constructing composite types. The following call tests, whether an object is a list with arbitrary elements:
testtype([3, x, array(1..1, [x]), Dom::Matrix()], Type::ListOf(Type::AnyType))TRUE

TRUE

Parameters

obj

Any MuPAD object

Return Values

testtype always returns TRUE

See Also

testtype

Type::Arithmetical

Purpose

Type representing arithmetical objects

Syntax

```
testtype(obj, Type::Arithmetical)
```

Description

`Type::Arithmetical` represents arithmetical objects.

In MuPAD, arithmetical objects are objects that represent complex numbers if all identifiers in them also represent complex numbers. Arithmetical objects include numbers, most expressions, and elements of certain library domains. In particular, the latter include rectform objects and series expansions of domain type Series::Puiseux.

Certain infinite objects such as `dirac(0)`, infinity, or complexInfinity are also defined to be arithmetical expressions.

The following objects are *not* regarded as arithmetical objects:

- equations and inequalities,
- Boolean objects and Boolean expressions involving and, `or`, `not`,
- lists,
- sets and set expressions involving union, intersect, minus,
- polynomials of domain type DOM_POLY,
- functions and procedures,
- arrays and tables.

This type does not represent a property: it cannot be used in assume to mark an identifier as an arithmetical object.

Examples

Example 1

The expression A^(-1) * BAB may represent a matrix if A and B are matrices, or it may represent a number if A and B are numbers. However, MuPAD regards identifiers as numbers: hence they commute with each other, and a product of identifiers represents a number, too:

A^(-1) * B * A * BB^2

testtype(%, Type::Arithmetical)TRUE

TRUE

Example 2

Numbers and expressions are regarded as arithmetical objects: testtype(3 + I, Type::Arithmetical), testtype(x + sqrt(2) + I*PI, Type::Arithmetical), testtype(x/y + y/x, Type::Arithmetical)TRUE, TRUE, TRUE

TRUE, TRUE, TRUE

Equations and inequalities are not regarded as arithmetical objects: testtype(x^2 = 2, Type::Arithmetical), testtype(x <> 2, Type::Arithmetical), testtype(x < 2, Type::Arithmetical), testtype(x >= 2, Type::Arithmetical)FALSE, FALSE, FALSE, FALSE

FALSE, FALSE, FALSE, FALSE

Sets, lists, tables and arrays are not arithmetical: testtype({a, b, c}, Type::Arithmetical), testtype(array(1..1, [x]), Type::Arithmetical)FALSE, FALSE

FALSE, FALSE

Most domain objects such as matrices of some matrix domain are not arithmetical:
testtype(Dom::Matrix()([[1, 2], [3, 4]]), Type::Arithmetical)FALSE

FALSE

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also

testtype

Type::Boolean

Purpose

Type representing boolean expressions

Syntax

```
testtype(obj, Type::Boolean)
```

Description

`Type::Boolean` represents logical formulas.

Boolean expressions are all of the following objects: the Boolean constants TRUE, FALSE, and UNKNOWN; identifiers; equations and inqualities; expressions with operator and, or, not, xor, _implies, _equiv if each operand is a Boolean expression; or results returned by solvelib::isEmpty.

Examples

Example 1

Identifiers and boolean constants are Boolean expressions: testtype(TRUE, Type::Boolean), testtype(a, Type::Boolean)TRUE, TRUE

```
TRUE, TRUE
```

Example 2

In order that an expression be Boolean, it is not sufficient that only its operator is a logical operator; also its operands must be Boolean expressions.
testtype(a >= 3 and b, Type::Boolean); testtype(a+b and c, Type::Boolean)TRUE

```
TRUE
```

FALSE

```
FALSE
```

Parameters

obj

Any MuPAD object

Return Values See testtype

See Also testtype

Type::Complex

Purpose

Type and property representing complex numbers

Syntax

```
testtype(obj, Type::Complex)
assume(x, Type::Complex)
is(ex, Type::Complex)
```

Description

`Type::Complex` represents complex numbers. This type can also be used as a property to mark identifiers as complex numbers.

The call `testtype(obj, Type::Complex)` checks, whether `obj` is a complex number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT, DOM_RAT, DOM_FLOAT and DOM_COMPLEX. This does not include arithmetical expressions such as `exp(1)`, which are not identified as of type `Type::Complex`.

The call `assume(x, Type::Complex)` marks the identifier `x` as a complex number.

The call `is(ex, Type::Complex)` derives, whether the expression `ex` is a complex number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::Complex`:
testtype(2, Type::Complex), testtype(3/4, Type::Complex), testtype(0.123, Type::Complex), testtype(1 + I/3, Type::Complex), testtype(1.0 + 2.0*I, Type::Complex)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

The following expressions are exact representations of complex numbers. Syntactically, however, they are not of type `Type::Complex`:
testtype(exp(3), Type::Complex), testtype(PI^2 + 5, Type::Complex), testtype(sin(2) + PI*I, Type::Complex)FALSE, FALSE, FALSE

FALSE, FALSE, FALSE

Example 2

Identifiers may be assumed to represent a complex number:
assume(x, Type::Complex): is(x, Type::Complex)TRUE

TRUE

The real numbers are a subset of the complex numbers:
assume(x, Type::Real): is(x, Type::Complex)TRUE

TRUE

Without further information, it cannot be decided whether a complex number is real:
assume(x, Type::Complex): is(x, Type::Real)UNKNOWN

UNKNOWN
unassume(x):

Parameters

obj

Any MuPAD object

x

An identifier

ex

An arithmetical expression

Return Values

See assume, is and testtype

See Also

assumeistesttypeType::ImaginaryType::PropertyType::Real

Type::ConstantIdents

Purpose

Set of constant identifiers in MuPAD

Syntax

```
contains(Type::ConstantIdents, obj)
```

Description

`Type::ConstantIdents` is the set `{ CATALAN , E , EULER , I , PI }`.

`Type::ConstantIdents` is the set of identifiers that represent constants. As of version 4.0, these are CATALAN, E (= `exp(1)`), EULER, I, PI.

These constants will be returned by the function indets, but they cannot be treated like other identifiers. For example, they cannot have properties or be the left-hand side of an assignment.

See “Example 1” on page 34-12 for an application.

Type::Constant makes use of `Type::ConstantIdents`, see “Example 2” on page 34-13.

Examples

Example 1

MuPAD implements π as the identifier PI.
domtype(PI)DOM_IDENT

DOM_IDENT

However, `PI` is constant (although rumors keep raising their heads that China, Alabama, or whoever it may be next time had tried to change its value by means of a legislative process):
testtype(PI, Type::Constant)TRUE

TRUE

Still, indets regards `PI` as an identifier with no value (which is syntactically correct), and you can even use `PI` as an indeterminate of a polynomial:
indets(PI/2*x); poly(PI/2*x){PI, x}

$\{\pi, x\}$

poly((PI*x)/2, [PI, x])

$\text{poly}\left(\frac{\pi x}{2}, [\pi, x]\right)$

To find the "real" indeterminates, use the following call:
indets(PI/2*x) minus Type::ConstantIdents{x}

$\{x\}$

Example 2

In the following, the solve command solves for all identifiers found in the equation:
solve(x^2 = KHINTCHINE){[KHINTCHINE = z^2, x = z]}

$\{[\text{KHINTCHINE} = z^2, x = z]\}$

Assume you want MuPAD to regard the identifier `KHINTCHINE` as a constant. (Probably, it should represent the Khintchine constant *K*, which is approximately 2.685452, but we will not implement this.) First of all, you should make sure that the identifier does not have a value yet and protect it:
testtype(KHINTCHINE, DOM_IDENT); protect(KHINTCHINE, ProtectLevelError)TRUE

TRUE

ProtectLevelNone

ProtectLevelNone

Next, add `KHINTCHINE` to `Type::ConstantIdents` (note that we have to unprotect the identifier `Type`, because `Type::ConstantIdents` is a slot of it):

old_protection := unprotect(Type): Type::ConstantIdents := Type::ConstantIdents union {KHINTCHINE}: protect(Type, old_protection): Type::ConstantIdents{I, CATALAN, EULER, KHINTCHINE, PI, exp(1)}

$$\{i, \text{CATALAN}, \text{EULER}, \text{KHINTCHINE}, \pi, e\}$$

Now, MuPAD regards `KHINTCHINE` as a constant: testtype(sin(PI + KHINTCHINE), Type::Constant)TRUE

$$\text{TRUE}$$

After clearing the remember table of `solve`, we now obtain: solve(Remember, Clear): solve(x^2 = KHINTCHINE){[x = sqrt(KHINTCHINE)], [x = -sqrt(KHINTCHINE)]}

$$\{[x = \sqrt{\text{KHINTCHINE}}], [x = -\sqrt{\text{KHINTCHINE}}]\}$$

Parameters

obj

Any MuPAD object

Return Values

See contains

See Also

containsindetsType::ConstantType::Indeterminate

Type::Constant

Purpose

Type representing constant objects

Syntax

```
testtype(obj, Type::Constant)
```

Description

`Type::Constant` represents constant objects, i.e., objects not containing symbolic identifiers.

Numbers, strings, Boolean constants, NIL, FAIL and the identifiers PI, EULER and CATALAN in the set Type::ConstantIdents are regarded as constant objects. A composite object is constant, if all its operands are constant.

Any function is identified as a constant, if all arguments are constant, also if the function is not defined (e.g., an identifier).

This type does not represent a property: it cannot be used in assume to mark an identifier as a constant.

Examples

Example 1

The following objects are elementary constants:
testtype(3, Type::Constant), testtype(sin(3/2), Type::Constant), testtype(TRUE, Type::Constant), testtype("MuPAD", Type::Constant), testtype(FAIL, Type::Constant)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

The following expression contains an indeterminate *x* and, consequently, is not a constant object:
testtype(exp(x + 1), Type::Constant)FALSE

FALSE

All constant operands of an expression are selected:
select(x^2 + 3*x - 2, testtype, Type::Constant)-2

```
-2
```

Any function call is considered constant, if the arguments are constant: testtype(f(1, 2, 3, 4), Type::Constant)TRUE

```
TRUE
```

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also

testtype

Type::Equation

Purpose

Type representing equations

Syntax

```
testtype(obj, Type::Equation(<lhs_type, <rhs_type>>))
```

Description

`Type::Equation` represents equations. The types of the left hand side and the right hand side can be specified.

The call `testtype(obj, Type::Equation(lhs_type,rhs_type))` checks whether `type(obj)` yields `" _equal "` and `testtype(lhs(obj), lhs_type)` and `testtype(rhs(obj), rhs_type)` both yield TRUE and returns TRUE, if all holds, otherwise FALSE.

The two optional parameters `lhs_type` and `rhs_type` determine the types of the left hand side and the right hand side, respectively.

The default values of `lhs_type` and `rhs_type` are Type::AnyType.

Note The equations `lhs=rhs` and `rhs=lhs` are considered different! E.g., the equation `x=3` matches the type `Type::Equation(DOM_IDENT,DOM_INT)`, but it does not match the type `Type::Equation(DOM_INT,DOM_IDENT)`.

This type does not represent a property, it cannot be used in an assume call.

Examples

Example 1

The following object is an equation:
testtype(x = 3, Type::Equation())TRUE

```
TRUE
```

The following calls test, whether the object is an equation with an unknown on the left hand side and a positive integer on the right hand side:

testtype(x = 3, Type::Equation(Type::Unknown, Type::PosInt)),
testtype(x = 0, Type::Equation(Type::Unknown, Type::PosInt))TRUE,
FALSE

TRUE, FALSE

Parameters

obj

Any MuPAD object

lhs_type

The type of the left hand side; a type can be an object of the library `Type` or one of the possible return values of domtype and type

rhs_type

The type of the right hand side

Return Values

See testtype

See Also

testtype

Type::Even

Purpose

Type and property representing even integers

Syntax

```
testtype(obj, Type::Even)
assume(x, Type::Even)
is(ex, Type::Even)
```

Description

`Type::Even` represents even integers. This type can also be used as a property to mark identifiers as even integers.

The call `testtype(obj, Type::Even)` checks, whether `obj` is an even number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT and checks, if `bool(domtype(x/2) = DOM_INT)` holds.

The call `assume(x, Type::Even)` marks the identifier `x` as an even number.

The call `is(ex, Type::Even)` derives, whether the expression `ex` is an even number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::Even`:
testtype(2, Type::Even), testtype(-4, Type::Even),
testtype(8, Type::Even), testtype(-11114, Type::Even),
testtype(4185296581467695598, Type::Even)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

Example 2

We use this type as a property:
assume(x, Type::Even):

The following calls to is derive the properties of a composite expression from the properties of its indeterminates:
is(3*x^2, Type::Even), is(x + 1, Type::Even)TRUE, FALSE

TRUE, FALSE
is(x, Type::Integer), is(2*x, Type::Integer), is(x/2, Type::Integer), is(x/3, Type::Integer)TRUE, TRUE, TRUE, UNKNOWN

TRUE, TRUE, TRUE, UNKNOWN
assume(y, Type::Odd): is(x + y, Type::Even)FALSE

FALSE
is(2*(x + y), Type::Even)TRUE

TRUE
delete x, y:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See assume, is and testtype

See Also

isassumetesttypeType::OddType::Property

Type::Function

Purpose

Type representing functions

Syntax

```
testtype(obj, Type::Function)
```

Description

`Type::Function` represents all MuPAD functions (procedures, executable objects etc).

The call `testtype(obj, Type::Function)` checks, whether `obj` is an executable MuPAD object. The call returns TRUE or FALSE, respectively.

"Executable objects" in MuPAD are procedures (of type DOM_PROC), function environments (of type DOM_FUNC_ENV), and pure kernel functions (of type DOM_EXEC).

Additionally, symbolic function iterates`f@@n` (representing the map `x -> f(..(f(x))..)`) and symbolic function compositions`f@g` (representing the function `x -> f(g(x))` are regarded as executable objects.

This type does not represent a property.

Examples

Example 1

`Type::Function` accepts procedures:
testtype(proc(x) begin x^2 end, Type::Function)TRUE

```
TRUE
```

`Type::Function` accepts simple procedures generated with the "arrow operator" `->`, too:
testtype(x -> x^2, Type::Function)TRUE

```
TRUE
```

sin is a function environment, accepted by `Type::Function`:
testtype(sin, Type::Function)TRUE

```
TRUE
```

The first operand of the function environment print is a pure kernel function, accepted by `Type::Function`:
testtype(op(print, 1), Type::Function)TRUE

```
TRUE
```

The 3-fold iterate of the function diff is accepted by `Type::Function`:
testtype(diff@@3, Type::Function)TRUE

```
TRUE
```

The composition of functions is accepted by `Type::Function`:
testtype(f@g, Type::Function)TRUE

```
TRUE
```

Any other MuPAD object is determined as non executable object by `Type::Function`:
map([1, TRUE, x, {}], testtype, Type::Function)[FALSE, FALSE, FALSE, FALSE]

```
[FALSE, FALSE, FALSE, FALSE]
```

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also

testtype

Type::Imaginary

Purpose

Type and property representing imaginary numbers

Syntax

```
testtype(obj, Type::Imaginary)
assume(x, Type::Imaginary)
is(ex, Type::Imaginary)
```

Description

`Type::Imaginary` represents complex numbers with vanishing real part. This type can also be used as a property to mark identifiers as imaginary numbers.

The call `testtype(obj, Type::Imaginary)` checks, whether `obj` is an imaginary number (or zero) and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_COMPLEX and checks, whether `iszero(Re(obj))` holds, or whether `iszero(obj)` is TRUE. This does not include arithmetical expressions such as `I*exp(1)`, which are not identified as of type `Type::Imaginary`.

The call `assume(x, Type::Imaginary)` marks the identifier `x` as an imaginary number.

The call `is(ex, Type::Imaginary)` derives, whether the expression `ex` is an imaginary number (or this property can be derived).

This type represents a property that can be used in assume and is.

The call `assume(Re(x) = 0)` has the same meaning as `assume(x, Type::Imaginary)`.

Examples

Example 1

The following numbers are of type `Type::Imaginary`: testtype(5*I, Type::Imaginary), testtype(3/2*I, Type::Imaginary), testtype(-1.23*I, Type::Imaginary)TRUE, TRUE, TRUE

```
TRUE, TRUE, TRUE
```

The following expressions are exact representations of imaginary numbers. However, syntactically they are not of type `Type::Imaginary`, because their domain type is not DOM_COMPLEX: testtype(exp(3)*I, Type::Imaginary), testtype(PI*I, Type::Imaginary), testtype(sin(2*I), Type::Imaginary)FALSE, FALSE, FALSE

FALSE, FALSE, FALSE

In contrast to testtype, the function is performs a semantical test: is(exp(3)*I, Type::Imaginary), is(PI*I, Type::Imaginary), is(sin(2*I), Type::Imaginary)TRUE, TRUE, TRUE

TRUE, TRUE, TRUE

Example 2

Identifiers may be assumed to represent an imaginary number: assume(x, Type::Imaginary): is(x, Type::Imaginary), Re(x), Im(x)TRUE, 0, -x*I

TRUE, 0, $-x\,i$

The imaginary numbers are a subset of the complex numbers: is(x, Type::Complex)TRUE

TRUE

unassume(x):

Parameters

obj

Any MuPAD object

x

An identifier

ex

An arithmetical expression

obj

Any MuPAD object

Return Values

See assume, is and testtype

See Also

assumeistesttypeType::ComplexType::Property

Type::IndepOf

Purpose

Type representing objects that do not contain given identifiers

Syntax

```
testtype(obj, Type::IndepOf(x))
testtype(obj, Type::IndepOf({x1, x2,  }))
```

Description

`Type::IndepOf(x)` represents objects that do not contain the identifier `x`.

`Type::IndepOf({x1, x2, ...})` represents objects that do not contain any of the identifiers `x1`, `x2` etc.

The call `testtype(obj, Type::IndepOf(x))` checks, whether `obj` does not contain the identifier `x` and returns a corresponding TRUE or FALSE.

`Type::IndepOf` uses has to check whether the object contains at least one of the specified identifiers.

This type does not represent a property.

Examples

Example 1

The following expression depends on `x`:
testtype(x^2 - x + 3, Type::IndepOf(x))FALSE

```
FALSE
```

It is independend of `y`:
testtype(x^2 - x + 3, Type::IndepOf(y))TRUE

```
TRUE
```

The following expression is independend of `x` and `y`:
testtype(2*(a + b)/c, Type::IndepOf({x, y}))TRUE

```
TRUE
```

The following call selects all operands of the expression that are independend of x:
select(sin(y) + x^2 - 3*x + 2, testtype, Type::IndepOf(x))sin(y) + 2

$$\sin(y) + 2$$

Parameters

obj

Any MuPAD object

x

x1

x2

Identifiers of domain type DOM_IDENT

Return Values

See testtype

See Also

hasindetstesttypeType::Indeterminate

Type::Indeterminate

Purpose

Type representing indeterminates

Syntax

```
testtype(obj, Type::Indeterminate)
```

Description

`Type::Indeterminate` represents all objects that MuPAD regards as indeterminates: identifiers except those in Type::ConstantIdents, plus indexed identifiers.

This type does not represent a property: it cannot be used in assume to mark an identifier as an algebraic constant.

Examples

Example 1

The following call selects all indeterminates from a list:
delete x: testtype(x, Type::Indeterminate), testtype(sqrt(2), Type::Indeterminate);TRUE, FALSE

TRUE, FALSE

l := [x, x[2], x[sqrt(2) + I], x[x], PI, PI[1], sin(x), 3.0]; select(l, testtype, Type::Indeterminate)[x, x[2], x[sqrt(2) + I], x[x], PI, PI[1], sin(x), 3.0]

$[x, x_2, x_{\sqrt{2}+i}, x_x, \pi, \pi_1, \sin(x), 3.0]$

[x, x[2], x[sqrt(2) + I], x[x], PI[1]]

$[x, x_2, x_{\sqrt{2}+i}, x_x, \pi_1]$

Note that testtype evaluates its arguments:
y := 5; testtype(y, Type::Indeterminate), testtype(hold(y), Type::Indeterminate);5

5

FALSE, TRUE

```
FALSE, TRUE
```

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also

DOM_IDENTindets_indextesttypeType::ConstantIdentsType::IndepOf

Type::Integer

Purpose

Type and property representing integers

Syntax

```
testtype(obj, Type::Integer)
assume(x, Type::Integer)
is(ex, Type::Integer)
```

Description

`Type::Integer` represents integers. This type can also be used as a property to mark identifiers as integers.

The call `testtype(obj, Type::Integer)` checks, whether `obj` is an integer number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT.

The call `assume(x, Type::Integer)` marks the identifier `x` as an integer number.

The call `is(ex, Type::Integer)` derives, whether the expression `ex` is an integer number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::Integer`:
testtype(0, Type::Integer), testtype(55, Type::Integer), testtype(-111, Type::Integer)TRUE, TRUE, TRUE

```
TRUE, TRUE, TRUE
```

Example 2

We use this type as a property:
assume(x, Type::Integer):

The following calls to is derive the properties of a composite expression from the properties of its indeterminates:

is(3*x, Type::Real), is(2*x, Type::Even), is(x/2, Type::Integer)TRUE, TRUE, UNKNOWN

```
TRUE, TRUE, UNKNOWN
```

assume(y, Type::Integer): is(x + y^2, Type::Integer)TRUE

```
TRUE
```

unassume(x), unassume(y):

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See assume, is and testtype

See Also

assumeistesttypeType::RealType::Property

Type::Intersection

Purpose

Type representing the intersection of several types

Syntax

```
testtype(obj, (obj_type,  ))
```

Description

`Type::Intersection(type1, type2, ...)` represents all objects having all of the types `type1, type2, ...`

The call `testtype(obj, Type::Intersection(obj_types, ...))` checks, whether `obj` has all the given types obj_types, ...

The call `testtype(obj, Type::Intersection(obj_types, ...))` is thus equivalent to the call `_lazy_and(map(obj_types, x -> testtype(obj, x)))`, testing `obj` against all types in turn.

obj_types, ... must be a (nonempty) sequence of types (see testtype).

This type does not represent a property.

Examples

Example 1

Check, whether the given object is a positive and odd integer:
testtype(1, Type::Intersection(Type::PosInt, Type::Odd))TRUE

```
TRUE
```

2 however, is not a positive and a odd number:
testtype(2, Type::Intersection(Type::PosInt, Type::Odd))FALSE

```
FALSE
```

Example 2

testtype is used to select positive and odd integers:
SET:= {-2, -1.5, -1, -0.5, 0, 0.5, 1, 1.5, 2, 3}: select(SET, testtype, Type::Intersection(Type::PosInt, Type::Odd)){1, 3}

```
{1, 3}
```

delete SET:

Parameters

obj

Any MuPAD object

obj_type, ...

A sequence of types; a type can be an object of the library Type or one of the possible return values of domtype and type

Return Values

See testtype

See Also

testtype

Type::Interval

Purpose

Property representing intervals

Syntax

```
Type::Interval(a, b, <ndomain>)
Type::Interval([a], b, <ndomain>)
Type::Interval(a, [b], <ndomain>)
Type::Interval([a], [b], <ndomain>)
Type::Interval([a, b], <ndomain>)
```

Description

`Type::Interval(a, b, ...)` represents the interval Interval(a, b)(a, b).

`Type::Interval([a], b, ...)` represents the interval Interval([a], b)$[a, b)$.

`Type::Interval(a, [b], ...)` represents the interval Interval(a, [b])$(a, b]$.

`Type::Interval([a], [b], ...)` represents the interval Interval([a], [b])$[a, b]$.

`Type::Interval([a, b], ...)` represents the interval Interval([a], [b])$[a, b]$.

With the default domain Type::Real, the type object created by `Type::Interval` represents a real interval, i.e., the set of all real numbers between the border points `a` and `b`. If another domain is specified, then the type object represents the intersection of the real interval with the set represented by the domain. E.g., `Type::Interval(a, b, Type::Rational)` represents the set of all rational numbers between `a` and `b`, and `Type::Interval([a, b], Type::Residue(0, 2))` represents the set of all even integers between `a` and `b` including `a` and `b`.

The type object represents a property that may be used in assume and is. With

```
assume(x, Type::Interval(a, b, ndomain))
```

the identifier `x` is marked as a number from the interval represented by the type object. With

```
is(x, Type::Interval(a, b, ndomain))
```

one queries, whether `x` is contained in the interval.

Interval types should not be used in testtype. No MuPAD object matches these types syntactically, i.e., testtype always returns FALSE.

Examples

Example 1

The following type object represents the open interval (- 1, 1):
Type::Interval(-1, 1)Type::Interval(-1, 1, Type::Real)

```
Type::Interval(-1, 1, Type::Real)
```

The following calls are equivalent: both create the type representing a closed interval:
Type::Interval([-1], [1]), Type::Interval([-1, 1])Type::Interval([-1], [1], Type::Real), Type::Interval([-1], [1], Type::Real)

```
Type::Interval([-1], [1], Type::Real), Type::Interval([-1], [1], Type::Real)
```

The following call creates the type representing the set of all integers from -10 to 10:
Type::Interval([-10, 10], Type::Integer)Type::Interval([-10], [10], Type::Integer)

```
Type::Interval([-10], [10], Type::Integer)
```

The following call creates the type representing the set of all rational numbers in the interval Interval([0],1)[0, 1):
Type::Interval([0], 1, Type::Rational)Type::Interval([0], 1, Type::Rational)

```
Type::Interval([0], 1, Type::Rational)
```

The following calls create the types representing the sets of all even/odd integers in the interval Interval([-10], [10])[-10, 10]:
Type::Interval([-10], [10], Type::Even), Type::Interval([-10], [10], Type::Odd)Type::Interval([-10], [10], Type::Residue(0, 2, Type::Integer)), Type::Interval([-10], [10], Type::Residue(1, 2, Type::Integer))

Type::Interval([-10], [10], Type::Residue(0, 2, Type::Integer)), Type::Interval([-10], [10], Type::Residue

Example 2

We use intervals as a property. The following call marks x as a real number from the interval Interval([0], 2)[0, 2):
assume(x, Type::Interval([0], 2)):

Consequently, $x^2 + 1$ lies in the interval Interval([1], 5)[1, 5):
is(x^2 + 1 >= 1), is(x^2 + 1 < 5)TRUE, TRUE

TRUE, TRUE

The following call marks x as an integer larger than -10 and smaller than 100:
assume(x, Type::Interval(-10, 100, Type::Integer)):

Consequently, x^3 is an integer larger than -730 and smaller than 970300:
is(x^3, Type::Integer), is(x^3 >= -729), is(x^3 < 970300), is(x^3, Type::Interval(-10^3, 100^3, Type::Integer))TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE

is(x <= -730), is(x^3 >= 970300)FALSE, FALSE

FALSE, FALSE

is(x > 0), is(x^3, Type::Interval(0, 10, Type::Integer))UNKNOWN, UNKNOWN

UNKNOWN, UNKNOWN

unassume(x):

Parameters

a

b

The borders of the interval: arithmetical objects

ndomain

A type object such as Type::Real, Type::Integer or Type::Rational representing a subset of the real numbers or a property representing a residue class as `Type::Residue(0, 2)`. The default domain is Type::Real.

Return Values

`Type` object

See Also

assumeistesttypeType::IntegerType::RationalType::RealType::Residue

Type::ListOf

Purpose

Type representing lists of objects with the same type

Syntax

```
testtype(obj, (obj_type, <min_nr, <max_nr>>))
```

Description

`Type::ListOf` describes lists of objects of a specified type.

The call `testtype(obj, Type::ListOf(obj_types, ...))` checks, whether `obj` is a list with elements of the given type obj_type, ... and returns TRUE, if it holds, otherwise FALSE.

The two optional parameters `min_nr` and `max_nr` determine the minimum and maximum number of elements in the analyzed list. If the numbers are not be given, the number of elements in the list will not be checked. If only the minimum is given, only the minimal number of elements in the list is checked.

Note especially that Type::Union provides a way to allow more than one type for the list elements.

This type does not represent a property.

Examples

Example 1

Is the given list a list of identifiers?
testtype([a, b, c, d, e, f], Type::ListOf(DOM_IDENT))TRUE

```
TRUE
```

Is the given list a list of at least five real numbers?
testtype([0, 0.5, 1, 1.5, 2, 2.5, 3], Type::ListOf(Type::Real, 5))TRUE

```
TRUE
```

Example 2

testtype is used to select lists with exactly two identifiers:
S := {[a], [a, b], [d, 1], [0, d], [e], [d, e]}: select(S, testtype, Type::ListOf(DOM_IDENT, 2, 2)){[a, b], [d, e]}

$$\{[a, b], [d, e]\}$$

Parameters

obj

Any MuPAD object

obj_type

The type of the objects; a type can be an object of the library Type or one of the possible return values of domtype and type

min_nr

The minimal number of objects as nonnegative integer

max_nr

The maximal number of objects as nonnegative integer

Return Values

See testtype

See Also

DOM_LISTtesttypeType::ListProductType::SetOfType::Union

Type::ListProduct

Purpose

Type representing lists

Syntax

```
testtype(obj, Type::ListProduct(typedef,  ))
```

Description

With `Type::ListProduct`, lists with different object types can be identified.

The call `testtype(obj, Type::ListProduct(typedef))` checks, whether `obj` is a list of objects, which have the types given by `typedef` and returns TRUE, if it holds, otherwise FALSE.

`obj` must have the same number of arguments as the sequence `typedef`. The elements of `obj` are checked one after another: the first element of `obj` is checked against the type given by the first element of `typedef`, and so on. All elements and types must match.

typedef, ... must be a nonempty sequence of types. A type can be an object of the library Type or one of the possible return values of domtype and type.

This type does not represent a property.

Examples

Example 1

The argument is a list of a positive integer followed by an identifier:
testtype([5, x], Type::ListProduct(Type::PosInt, Type::Unknown))TRUE

```
TRUE
```

Is the argument is a sequence of five positive integers?
testtype([5, 3, 5, -1, 0], Type::ListProduct(Type::PosInt $ 5))FALSE

```
FALSE
```

Parameters

obj

Any MuPAD object

typedef

A sequence of types; a type can be an object of the library Type or one of the possible return values of domtype and type

Return Values

See testtype

See Also

testtypeType::ListOfType::Product

Type::NegInt

Purpose

Type and property representing negative integers

Syntax

```
testtype(obj, Type::NegInt)
assume(x, Type::NegInt)
is(ex, Type::NegInt)
```

Description

`Type::NegInt` represents negative integers. `Type::NegInt` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::NegInt)` checks, whether `obj` is a negative integer number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT and checks, if `bool(obj < 0)` holds.

The call `assume(x, Type::NegInt)` marks the identifier `x` as a negative integer number.

The call `is(ex, Type::NegInt)` derives, whether the expression `ex` is a negative integer number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::NegInt`:
testtype(-2, Type::NegInt), testtype(-3, Type::NegInt), testtype(-55, Type::NegInt), testtype(-1, Type::NegInt), testtype(-111111111, Type::NegInt)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

Example 2

Assume an identifier is a negative integer:
assume(x, Type::NegInt): is(x, Type::NegInt)TRUE

TRUE

Negative integers are integers, of course:
assume(x, Type::NegInt): is(x, Type::Integer)TRUE

TRUE

However, integers can be negative or not:
assume(x, Type::Integer): is(x, Type::NegInt)UNKNOWN

UNKNOWN
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See testtype, assume and is

See Also

testtypeisassumeType::Property

Type::NegRat

Purpose

Type and property representing negative rational numbers

Syntax

```
testtype(obj, Type::NegRat)
assume(x, Type::NegRat)
is(ex, Type::NegRat)
```

Description

`Type::NegRat` represents negative rational numbers. `Type::NegRat` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::NegRat)` checks, whether `obj` is a negative rational number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT and DOM_RAT and checks, if `bool(obj < 0)` holds.

The call `assume(x, Type::NegRat)` marks the identifier `x` as a negative rational number.

The call `is(ex, Type::NegRat)` derives, whether the expression `ex` is a negative rational number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::NegRat`:
testtype(-2, Type::NegRat), testtype(-3/4, Type::NegRat), testtype(-55/111, Type::NegRat), testtype(-1, Type::NegRat), testtype(-111/111111, Type::NegRat)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

Example 2

Assume an identifier is negative rational:
assume(x, Type::NegRat): is(x, Type::NegRat)TRUE

TRUE

Also negative rational numbers are rational:
assume(x, Type::NegRat): is(x, Type::Rational)TRUE

TRUE

However, rational numbers can be negative rational or not:
assume(x, Type::Rational): is(x, Type::NegRat)UNKNOWN

UNKNOWN
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See testtype, assume and is

See Also

testtypeisassumeType::Property

Type::Negative

Purpose

Type and property representing negative numbers

Syntax

```
testtype(obj, Type::Negative)
assume(x, Type::Negative)
is(ex, Type::Negative)
```

Description

`Type::Negative` represents negative numbers. `Type::Negative` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::Negative)` checks, whether `obj` is a negative real number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT, DOM_RAT and DOM_FLOAT and checks, if `bool(obj < 0)` holds. This does not include arithmetical expressions such as `-exp(1)`, which are not identified as of type `Type::Negative`.

The call `assume(x, Type::Negative)` marks the identifier `x` as a negative real number.

The call `is(ex, Type::Negative)` derives, whether the expression `ex` is a negative real number (or this property can be derived).

This type represents a property that can be used in assume and is.

Instead of `Type::Negative` the assumption can also be `assume(x < 0)`.

Examples

Example 1

The following numbers are of type `Type::Negative`:
testtype(-2, Type::Negative), testtype(-3/4, Type::Negative), testtype(-0.123, Type::Negative), testtype(-1, Type::Negative), testtype(-1.02, Type::Negative)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

The following expressions are exact representations of negative numbers, but syntactically they are not of `Type::Negative`:

testtype(-exp(1), Type::Negative), testtype(-PI^2 - 5, Type::Negative), testtype(-sin(2), Type::Negative)FALSE, FALSE, FALSE

FALSE, FALSE, FALSE

Example 2

Assume an identifier is negative:
assume(x, Type::Negative): is(x, Type::Negative)TRUE

TRUE

This is equal to:
assume(x < 0): is(x < 0)TRUE

TRUE

Also negative numbers are real:
assume(x, Type::Negative): is(x, Type::Real)TRUE

TRUE

However, real numbers can be negative or not:
assume(x, Type::Real): is(x, Type::Negative)UNKNOWN

UNKNOWN
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values See testtype, assume and is

See Also testtypeisassumeType::RealType::Property

Type::NonNegInt

Purpose

Type and property representing nonnegative integers

Syntax

```
testtype(obj, Type::NonNegInt)
assume(x, Type::NonNegInt)
is(ex, Type::NonNegInt)
```

Description

`Type::NonNegInt` represents nonnegative integers. `Type::NonNegInt` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::NonNegInt)` checks, whether `obj` is a nonnegative integer number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT and checks, if `bool(obj >= 0)` holds.

The call `assume(x, Type::NonNegInt)` marks the identifier `x` as a nonnegative integer number.

The call `is(ex, Type::NonNegInt)` derives, whether the expression `ex` is a nonnegative integer number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::NonNegInt`:
testtype(2, Type::NonNegInt), testtype(3/4, Type::NonNegInt), testtype(55/111, Type::NonNegInt), testtype(1, Type::NonNegInt), testtype(111/111111, Type::NonNegInt)TRUE, FALSE, FALSE, TRUE, FALSE

```
TRUE, FALSE, FALSE, TRUE, FALSE
```

Example 2

Assume an identifier is nonnegative rational:
assume(x, Type::NonNegInt): is(x, Type::NonNegInt)TRUE

TRUE

Also nonnegative integers are integers:
assume(x, Type::NonNegInt): is(x, Type::Integer)TRUE

TRUE

However, integers can be nonnegative or not:
assume(x, Type::Integer): is(x, Type::NonNegInt)UNKNOWN

UNKNOWN
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See testtype, assume and is

See Also

testtypeisassumeType::IntegerType::Property

Type::NonNegRat

Purpose

Type and property representing nonnegative rational numbers

Syntax

```
testtype(obj, Type::NonNegRat)
assume(x, Type::NonNegRat)
is(ex, Type::NonNegRat)
```

Description

`Type::NonNegRat` represents nonnegative rational numbers. `Type::NonNegRat` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::NonNegRat)` checks, whether `obj` is a nonnegative rational number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT and DOM_RAT and checks, if `bool(obj >= 0)` holds.

The call `assume(x, Type::NonNegRat)` marks the identifier `x` as a nonnegative rational number.

The call `is(ex, Type::NonNegRat)` derives, whether the expression `ex` is a nonnegative rational number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::NonNegRat`:
testtype(2, Type::NonNegRat), testtype(3/4, Type::NonNegRat), testtype(55/111, Type::NonNegRat), testtype(0, Type::NonNegRat), testtype(111/111111, Type::NonNegRat)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

Example 2

Assume an identifier is nonnegative rational:
assume(x, Type::NonNegRat): is(x, Type::NonNegRat)TRUE

TRUE

Also nonnegative rational numbers are rational:
assume(x, Type::NonNegRat): is(x, Type::Rational)TRUE

TRUE

However, rational numbers can be nonnegative rational or not:
assume(x, Type::Rational): is(x, Type::NonNegRat)UNKNOWN

UNKNOWN
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See testtype, assume and is

See Also

testtypeisassumeType::RationalType::Property

Type::NonNegative

Purpose

Type and property representing nonnegative numbers

Syntax

```
testtype(obj, Type::NonNegative)
assume(x, Type::NonNegative)
is(ex, Type::NonNegative)
```

Description

`Type::NonNegative` represents nonnegative numbers. `Type::NonNegative` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::NonNegative)` checks, whether `obj` is a nonnegative real number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT, DOM_RAT and DOM_FLOAT and checks, if `bool(obj >= 0)` holds. This does not include arithmetical expressions such as `exp(1)`, which are not identified as of type `Type::NonNegative`.

The call `assume(x, Type::NonNegative)` marks the identifier `x` as a nonnegative real number.

The call `is(ex, Type::NonNegative)` derives, whether the expression `ex` is a nonnegative real number (or this property can be derived).

This type represents a property that can be used in assume and is.

Instead of `Type::NonNegative` the assumption can also be `assume(x >= 0)`.

Examples

Example 1

The following numbers are of type `Type::NonNegative`: testtype(2, Type::NonNegative), testtype(3/4, Type::NonNegative), testtype(0.123, Type::NonNegative), testtype(0, Type::NonNegative), testtype(1.02, Type::NonNegative)TRUE, TRUE, TRUE, TRUE, TRUE

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

The following expressions are exact representations of nonnegative numbers, but syntactically they are not of `Type::NonNegative`: testtype(exp(1), Type::NonNegative), testtype(PI^2 + 5, Type::NonNegative), testtype(sin(2), Type::NonNegative)FALSE, FALSE, FALSE

FALSE, FALSE, FALSE

The function is, however, can find these expressions to be nonnegative: is(exp(1), Type::NonNegative), is(PI^2 + 5, Type::NonNegative), is(sin(2), Type::NonNegative)TRUE, TRUE, TRUE

TRUE, TRUE, TRUE

Example 2

Assume an identifier is nonnegative:
assume(x, Type::NonNegative): is(x, Type::NonNegative)TRUE

TRUE

This is equal to:
assume(x >= 0): is(x >= 0)TRUE

TRUE

Also nonnegative numbers are real:
assume(x, Type::NonNegative): is(x, Type::Real)TRUE

TRUE

But real numbers can be nonnegative or not:
assume(x, Type::Real): is(x, Type::NonNegative)UNKNOWN

UNKNOWN

delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See testtype, assume and is

See Also

testtypeisassumeType::RealType::Property

Type::NonZero

Purpose

Type and property representing “unequal to zero”

Syntax

```
testtype(obj, Type::NonZero)
assume(x, Type::NonZero)
is(ex, Type::NonZero)
```

Description

`Type::NonZero` is a type of objects unequal to zero. `Type::NonZero` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::NonZero)` checks, whether `obj` is *not* zero and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test and uses the function iszero to determine, whether the object is not zero. This implies that identifiers without a value, for example, are considered as being different from zero, see “Example 1” on page 34-56.

The call `assume(x, Type::NonZero)` marks the identifier `x` as a complex number unequal to zero.

The call `is(ex, Type::NonZero)` derives, whether the expression `ex` is a complex number unequal to zero (or this property can be derived).

This type represents a property that can be used in assume and is.

The call `assume(x <> 0)` has the same meaning as `assume(x, Type::NonZero)`.

Examples

Example 1

Usage of `Type::NonZero` whith testtype:
testtype(1.0, Type::NonZero)TRUE

```
TRUE
```

Since `iszero(x)` returns FALSE, the following call returns TRUE:
testtype(x, Type::NonZero)TRUE

TRUE

Example 2

Usage of `Type::NonZero` whith assume and is:
is(x, Type::NonZero)UNKNOWN

UNKNOWN

Assumption: `x` is `Type::NonZero`:
assume(x, Type::NonZero): is(x, Type::NonZero)TRUE

TRUE

The same again:
assume(x <> 0): is(x <> 0)TRUE

TRUE

The difference between testtype and is:
delete x: is(x, Type::NonZero), testtype(x, Type::NonZero)UNKNOWN, TRUE

UNKNOWN, TRUE

`x` could be zero:
assume(x >= 0): is(x, Type::NonZero), testtype(x, Type::NonZero)UNKNOWN, TRUE

UNKNOWN, TRUE
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values See testtype, assume and is

See Also testtypeisassumeType::Zero

Type::Numeric

Purpose

Type representing numerical objects

Syntax

```
testtype(obj, Type::Numeric)
```

Description

With `Type::Numeric`, numeric objects (numbers) can be identified.

The call `testtype(obj, Type::Numeric)` checks, whether `obj` is a number and returns TRUE, if it holds, otherwise FALSE.

A number has the domain type DOM_INT, DOM_RAT, DOM_FLOAT or DOM_COMPLEX.

This type does not represent a property.

Examples

Example 1

The following objects are numbers.
testtype(2, Type::Numeric), testtype(3/4, Type::Numeric), testtype(0.123, Type::Numeric), testtype(1 + I/3, Type::Numeric), testtype(1.0 + 2.0*I, Type::Numeric)TRUE, TRUE, TRUE, TRUE, TRUE

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

The following objects are not numerical objects.
testtype(ln(2), Type::Numeric), testtype(sin(3/4), Type::Numeric), testtype(x + I/3, Type::Numeric)FALSE, FALSE, FALSE

```
FALSE, FALSE, FALSE
```

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also assumeistesttypeType::Complex

Type::Odd

Purpose

Type and property representing odd integers

Syntax

```
testtype(obj, Type::Odd)
assume(x, Type::Odd)
is(ex, Type::Odd)
```

Description

`Type::Odd` represents odd integers. `Type::Odd` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::Odd)` checks, whether `obj` is an odd number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT and checks, if `bool(domtype((x-1)/2) = DOM_INT)` holds.

The call `assume(x, Type::Odd)` marks the identifier `x` as an odd number.

The call `is(ex, Type::Odd)` derives, whether the expression `ex` is an odd number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::Odd`:
testtype(1, Type::Odd), testtype(-3, Type::Odd), testtype(7, Type::Odd), testtype(-11113, Type::Odd), testtype(41852965814676955597, Type::Odd)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

Example 2

Assume an identifier is odd:
assume(x, Type::Odd): is(x, Type::Odd)TRUE

TRUE

All odd numbers are integer:
assume(x, Type::Odd): is(x, Type::Integer)TRUE

TRUE

However, integers can be odd or not:
assume(x, Type::Integer): is(x, Type::Odd)UNKNOWN

UNKNOWN

However, even numbers are not odd:
assume(x, Type::Odd): is(2*x, Type::Odd)FALSE

FALSE
assume(n, Type::Even): is(x*n, Type::Odd)FALSE

FALSE
is(x*n + 1, Type::Odd)TRUE

TRUE
delete x, n:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values See testtype, assume and is

See Also testtypeisassumeType::EvenType::Property

Type::PolyExpr

Purpose

Type representing polynomial expressions

Syntax

```
testtype(obj, Type::PolyExpr(unknowns, <coeff_type>))
```

Description

With `Type::PolyExpr`, polynomial expressions can be identified.

The call `testtype(obj, Type::PolyExpr(unknowns))` checks, whether `obj` is a polynomial expression in the indeterminates `unknowns` and, if so, returns TRUE, otherwise FALSE.

A polynomial expression in `indet` is an expression, where `indet` occurs only as operand of _plus or _mult expressions and in the base of _power with a positive integer exponent.

A polynomial expression is a representation of a polynomial, but it has the MuPAD type DOM_EXPR and is not produced by the function poly.

`indets` must be an identifier or a list of identifiers.

The optional argument `coeff_type` determines the type of the coefficients. If it is not given, Type::AnyType will be used.

This type does not represent a property.

Examples

Example 1

Is the object a polynomial expression with variable `x`?
X := -x^2 - x + 3: testtype(X, Type::PolyExpr(x))TRUE

```
TRUE
```

But `X` is not a MuPAD polynomial in `x`:
testtype(X, Type::PolyOf(x))FALSE

```
FALSE
```

Is the object a polynomial expression with variables `x` and `y` and with integer coefficients?

```
X := -x^2 - x + 3: testtype(X, Type::PolyExpr([x, y], Type::Integer))TRUE
```

```
TRUE
```

The next example too?

```
X := -x^2 - y^2 + 3*x + 3*y - 1: testtype(X, Type::PolyExpr([x, y],
Type::Integer))TRUE
```

```
TRUE
```

delete X:

Parameters

obj

Any MuPAD object

unknowns

An indeterminate or a list of indeterminates

coeff_type

The type of the coefficients; a type can be an object of the library Type or one of the possible return values of domtype and type

Return Values

See testtype

See Also

testtypeType::PolyOfpolyindets

Type::PolyOf

Purpose

Type representing polynomials

Syntax

```
testtype(obj, Type::PolyOf(coeff_type, <num_ind>))
```

Description

With `Type::PolyOf`, polynomials can be identified.

The call `testtype(obj, Type::PolyOf(coeff_type))` checks, whether `obj` is a polynomial with coefficients of type `coeff_type` and, if so, returns TRUE, otherwise FALSE.

Note Only polynomials of type DOM_POLY can be identified with `Type::PolyOf`, see Type::PolyExpr for polynomial expressions.

`coeff_type` determines the type of the coefficients.

The optional argument `num_ind` determines the number of indeterminates. If this argument is not given, the polynomial may have any number of indeterminates.

This type does not represent a property.

Examples

Example 1

Is the object a polynomial with integer coefficients?
P := poly(-x^2 - x + 3): testtype(P, Type::PolyOf(Type::Integer))TRUE

TRUE

Is the object a polynomial with integer coefficients and two indets?
P := poly(-x^2 - x + 3, [x, y]): testtype(P, Type::PolyOf(Type::Integer, 2))TRUE

TRUE
delete P:

Parameters

obj

Any MuPAD object

coeff_type

The type of the coefficientes; a type can be an object of the library `Type` or one of the possible return values of domtype and type

num_ind

The number of indeterminates

Return Values

See testtype

testtypepolyindets

Type::PosInt

Purpose

Type and property representing positive integers

Syntax

```
testtype(obj, Type::PosInt)
assume(x, Type::PosInt)
is(ex, Type::PosInt)
```

Description

`Type::PosInt` represents positive integers. `Type::PosInt` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::PosInt)` checks, whether `obj` is a positive integer number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT and checks, if `bool(obj > 0)` holds.

The call `assume(x, Type::PosInt)` marks the identifier `x` as a positive integer number.

The call `is(ex, Type::PosInt)` derives, whether the expression `ex` is a positive integer number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::PosInt`:
testtype(2, Type::PosInt), testtype(3, Type::PosInt), testtype(55, Type::PosInt), testtype(1, Type::PosInt), testtype(111, Type::PosInt)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

Example 2

Assume an identifier is positive integer:
assume(x, Type::PosInt): is(x, Type::PosInt)TRUE

TRUE

Also positive integers are integers:
assume(x, Type::PosInt): is(x, Type::Integer)TRUE

TRUE

However, integers can be positive or not:
assume(x, Type::Integer): is(x, Type::PosInt)UNKNOWN

UNKNOWN
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See testtype, assume and is

See Also

testtypeisassumeType::Property

Type::PosRat

Purpose

Type and property representing positive rational numbers

Syntax

```
testtype(obj, Type::PosRat)
assume(x, Type::PosRat)
is(ex, Type::PosRat)
```

Description

`Type::PosRat` represents positive rational numbers. `Type::PosRat` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::PosRat)` checks, whether `obj` is a positive rational number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT and DOM_RAT and checks, if `bool(obj > 0)` holds.

The call `assume(x, Type::PosRat)` marks the identifier `x` as a positive rational number.

The call `is(ex, Type::PosRat)` derives, whether the expression `ex` is a positive rational number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::PosRat`:
testtype(2, Type::PosRat), testtype(3/4, Type::PosRat), testtype(55/111, Type::PosRat), testtype(1, Type::PosRat), testtype(111/111111, Type::PosRat)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

Example 2

Assume an identifier is positive rational:
assume(x, Type::PosRat): is(x, Type::PosRat)TRUE

TRUE

Also positive rational numbers are rational:
assume(x, Type::PosRat): is(x, Type::Rational)TRUE

TRUE

However, rational numbers can be positive rational or not:
assume(x, Type::Rational): is(x, Type::PosRat)UNKNOWN

UNKNOWN
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See testtype, assume and is

See Also

testtypeisassumeType::Property

Type::Positive

Purpose

Type and property representing positive numbers

Syntax

```
testtype(obj, Type::Positive)
assume(x, Type::Positive)
is(ex, Type::Positive)
```

Description

`Type::Positive` represents positive numbers. `Type::Positive` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::Positive)` checks, whether `obj` is a positive real number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT, DOM_RAT and DOM_FLOAT and checks, if `bool(obj > 0)` holds. This does not include arithmetical expressions such as `exp(1)`, which are not identified as of type `Type::Positive`.

The call `assume(x, Type::Positive)` marks the identifier `x` as a positive real number.

The call `is(ex, Type::Positive)` derives, whether the expression `ex` is a positive real number (or this property can be derived).

This type represents a property that can be used in assume and is.

Instead of `Type::Positive` the assumption can also be `assume(x > 0)`.

Examples

Example 1

The following numbers are of type `Type::Positive`:
testtype(2, Type::Positive), testtype(3/4, Type::Positive), testtype(0.123, Type::Positive), testtype(1, Type::Positive), testtype(1.02, Type::Positive)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

The following expressions are exact representations of positive numbers, but syntactically they are not of `Type::Positive`:

testtype(exp(1), Type::Positive), testtype(PI^2 + 5, Type::Positive), testtype(sin(2), Type::Positive)FALSE, FALSE, FALSE

FALSE, FALSE, FALSE

Ths function is, however, realizes that they are, indeed, positive: is(exp(1), Type::Positive), is(PI^2 + 5, Type::Positive), is(sin(2), Type::Positive)TRUE, TRUE, TRUE

TRUE, TRUE, TRUE

Example 2

Assume an identifier is positive:
assume(x, Type::Positive): is(x, Type::Positive)TRUE

TRUE

This is equivalent to:
assume(x > 0): is(x > 0)TRUE

TRUE

Also positive numbers are real:
assume(x, Type::Positive): is(x, Type::Real)TRUE

TRUE

But real numbers can be positive or not:
assume(x, Type::Real): is(x, Type::Positive)UNKNOWN

UNKNOWN
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See testtype, assume and is

See Also

testtypeisassumeType::Property

Type::Predicate

Purpose

Type for testing object satisfying a given predicate

Syntax

```
testtype(obj, Type::Predicate(<pname>, predicate,
<p1, p2,  >))
```

Description

`Type::Predicate(predicate)` represents the MuPAD objects which satisfy the predicate `predicate`.

The call `testtype(obj, pname, Type::Predicate(< pname >, predicate , < p1 , p2 >))` test whether `obj` satisfies `predicate`; that is it returns `predicate(obj, p1, p2, ...)`.

`Type::Predicate(predicate)`, `Type::Predicate(name, predicate)`, `Type::Predicate ( predicate( p1 , p2 ,  ))`, and `Type::Predicate(name, predicate p1 , p2 , ,  )` are respectively pretty printed as `Type::Predicate(predicate)`, `Type::name`, `Type::Predicate(p, p1, p2, ...)`, and `Type::name(p1, p2, ...)`.

Examples

Example 1

We define a type which contains any MuPAD object:
t := Type::Predicate(x -> TRUE): testtype(1, t), testtype(2, t), testtype(x, t)TRUE, TRUE, TRUE

TRUE, TRUE, TRUE

We define a type which contains all the MuPAD object which are solution of `(x-1)*(x+1)=0`:
t := Type::Predicate(x -> bool((x - 1)*(x + 1) = 0)): testtype(1, t), testtype(2, t), testtype(x, t)TRUE, FALSE, FALSE

TRUE, FALSE, FALSE

We define a type for partitions, that is, decreasing lists of integers:

```
part := Type::Predicate(l -> _lazy_and(testtype(l,
Type::ListOf(Type::Integer)), bool(revert(sort(l)) = l))): testtype(a, part),
testtype([3, 6, 1], part), testtype([3, 2, 2], part)FALSE, FALSE, TRUE
```

```
FALSE, FALSE, TRUE
```

Using the naming facility is recommended to improve the readability of error messages:

```
part := Type::Predicate("Partition", l -> _lazy_and(testtype(l,
Type::ListOf(Type::Integer)), bool(revert(sort(l)) = l))): f := proc(p:
part) begin end: f(3); Error: The type of argument number 1 must be
'Type::Partition'. The object '3' is incorrect. Evaluating: f
```

Parameters

pname

A string which will be used for pretty printing the type

predicate

A function of one argument which can return TRUE, FALSE or FAIL

obj, p1, p2, ...

Any MuPAD objects

Return Values

See testtype

See Also

testtype

Type::Prime

Purpose

Type representing prime numbers

Syntax

```
testtype(obj, Type::Prime)
```

Description

`Type::Prime` represents prime numbers.

The call `testtype(obj, Type::Prime)` returns TRUE if `obj` is a prime number, and FALSE otherwise.

testtype only performs a syntactical test whether `obj` is an integer and `isprime(obj)` holds.

Examples

Example 1

The following numbers are of type `Type::Prime`:
testtype(2, Type::Prime), testtype(3, Type::Prime), testtype(7, Type::Prime), testtype(11113, Type::Prime), testtype(4185296581467695597, Type::Prime)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also

testtypeisprime

Type::Product

Purpose

Type representing sequences

Syntax

```
testtype(obj, Type::Product(typedef,  ))
```

Description

`Type::Product` is the type of sequences of objects of different types.

The call `testtype(obj, Type::Product( typedef ,  ))` checks, whether `obj` is a sequence of objects, which have the types given by `typedef` and returns TRUE, if it holds, otherwise FALSE.

`obj` must have the same number of arguments as the sequence `typedef`. The elements of `obj` are checked one after another: the first element of `obj` is checked against the type given by the first element of `typedef` and so on. All elements and types must match.

`typedef`, ... must be a nonempty sequence of types. A type can be an object of the library Type or one of the possible return values of domtype and type.

This type does not represent a property.

Examples

Example 1

The argument is a sequence of a positive integer followed by an identifier:
testtype((5, x), Type::Product(Type::PosInt, Type::Unknown))TRUE

```
TRUE
```

Is the argument is a sequence of five positive integers?
testtype((5, 3, 5, -1, 0), Type::Product(Type::PosInt $ 5))FALSE

```
FALSE
```

Parameters

obj

Any MuPAD object

typedef

A sequence of types; a type can be an object of the library Type or one of the possible return values of domtype and type

Return Values

See testtype

See Also

testtypeType::ListProduct

Type::Property

Purpose

Type representing any property

Syntax

```
testtype(obj, Type::Property)
```

Description

With `Type::Property`, properties can be identified.

The call `testtype(obj, Type::Property)` checks, whether the MuPAD object `obj` is a property and returns TRUE, if it holds, otherwise FALSE.

Some elements of the library `Type` serve two functions. One is to perform syntactical tests to identify the type of an object (with testtype), the other is to occur as a property within assume and is.

Note `Type::Property` itself is not a property.

To determine whether an element of `Type` is a property, `Type::Property` can be used with testtype.

This type does not represent a property.

Examples

Example 1

Is Type::PosInt a property?
testtype(Type::PosInt, Type::Property)TRUE

```
TRUE
```

Also an interval created with Type::Interval is a property:
testtype(Type::Interval(0, 1), Type::Property)TRUE

```
TRUE
```

Is Type::Constant a property?
testtype(Type::Constant, Type::Property)FALSE

```
FALSE
```

Type::Constant is not a property and cannot be used as argument of assume:
assume(x, Type::Constant) Error: The second argument must be a property. [assume]

The next example shows the usage of testtype to select properties among operands of `Type`:
T := Type::Numeric, Type::PosInt, Type::Unknown, Type::Zero: select(T, testtype, Type::Property)Type::PosInt, Type::Zero

```
Type::PosInt, Type::Zero
```

delete x, T:

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also

testtypeis

Type::RatExpr

Purpose

Type representing rational expressions

Syntax

```
testtype(obj, Type::RatExpr(indet, <coeff_type>))
```

Description

With `Type::RatExpr`, rational expressions can be identified.

The call `testtype(obj, Type::RatExpr(indet))` checks, whether `obj` is a rational expression in the indeterminante `indet`, i.e., the quotient of two polynomial expressions in `indet`. If it is, the result is TRUE, otherwise FALSE.

A rational expression in `indet` is a expression, and `indet` occurs only as operand of _plus or _mult expressions and in _power with an integer exponent.

`indet` must be an identifier, and `coeff_type` a type for the coefficients of the rational expression.

This type does not represent a property.

Examples

Example 1

A polynomial expression in `x` is also a rational expression in `x`:
testtype(-x^2 - x + 3, Type::RatExpr(x))TRUE

TRUE

testtype is used to select all rational operands in `x` with positive integer coefficients:
EX := sin(x) + x^2 - 3*x + 2 + 3/x: select(EX, testtype, Type::RatExpr(x, Type::PosInt))3/x + x^2 + 2

$\frac{3}{x} + x^2 + 2$
delete EX:

Parameters

obj

Any MuPAD object

indet

An indeterminante

coeff_type

A type for the coefficientes; a type can be an object of the library Type or one of the possible return values of domtype and type

Return Values

See testtype

See Also

testtypeindets

Type::Rational

Purpose

Type and property representing rational numbers

Syntax

```
testtype(obj, Type::Rational)
assume(x, Type::Rational)
is(ex, Type::Rational)
```

Description

`Type::Rational` represents rational numbers. `Type::Rational` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::Rational)` checks, whether `obj` is a rational number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT and DOM_RAT.

The call `assume(x, Type::Rational)` marks the identifier `x` as a rational number.

The call `is(ex, Type::Rational)` derives, whether the expression `ex` is a rational number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::Rational`:
testtype(2, Type::Rational), testtype(3/4, Type::Rational), testtype(-1/2, Type::Rational), testtype(-1, Type::Rational), testtype(1024/11111, Type::Rational)TRUE, TRUE, TRUE, TRUE, TRUE

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

Example 2

Integers are rational:
assume(x, Type::Integer): is(x, Type::Rational)TRUE

```
TRUE
```

However, rational numbers can be integer or not:
assume(x, Type::Rational): is(x, Type::Integer)UNKNOWN

UNKNOWN
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values

See testtype, assume and is

See Also

testtypeisassumeType::Property

Type::Real

Purpose

Type and property representing real numbers

Syntax

```
testtype(obj, Type::Real)
assume(x, Type::Real)
is(ex, Type::Real)
```

Description

`Type::Real` represents real numbers. `Type::Real` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::Real)` checks, whether `obj` is a real number and, if it is, returns TRUE, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM_INT, DOM_RAT and DOM_FLOAT. This does not include arithmetical expressions such as `exp(1)`, which are not identified as of type `Type::Real`.

The call `assume(x, Type::Real)` marks the identifier `x` as a real number.

The call `is(ex, Type::Real)` derives, whether the expression `ex` is a real number (or this property can be derived).

This type represents a property that can be used in assume and is.

Examples

Example 1

The following numbers are of type `Type::Real`:
testtype(2, Type::Real), testtype(3/4, Type::Real), testtype(0.123, Type::Real), testtype(-1, Type::Real), testtype(-1.02, Type::Real)TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

The following expressions are exact representations of real numbers, but syntactically they are not of `Type::Real`:
testtype(exp(1), Type::Real), testtype(PI^2 + 5, Type::Real), testtype(sin(2), Type::Real)FALSE, FALSE, FALSE

FALSE, FALSE, FALSE

The function is performs a semantical, mathematically more useful check:
is(exp(1), Type::Real), is(PI^2 + 5, Type::Real), is(sin(2), Type::Real)TRUE, TRUE, TRUE

TRUE, TRUE, TRUE

Example 2

Integers are real numbers:
assume(x, Type::Integer): is(x, Type::Real)TRUE

TRUE

But real numbers can be integer or not:
assume(x, Type::Real): is(x, Type::Integer)UNKNOWN

UNKNOWN

The sine of a real number is a real number in the interval [- 1, 1]:
getprop(sin(x))Dom::Interval([-1], [1])

[– 1, 1]

delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values See testtype, assume and is

See Also testtypeisassumeType::Property

Type::Relation

Purpose

Type representing relations

Syntax

```
testtype(obj, Type::Relation)
```

Description

With `Type::Relation`, relational expression can be identified.

The call `testtype(obj, Type::Relation)` checks, whether `obj` is a relational expression and returns TRUE, if it is, otherwise FALSE.

A relation in MuPAD is an expression of the type `" _equal "`, `" _unequal "`, `" _less "` and `" _leequal "`.

Note Expressions with the operations >= and > will be interpreted as expressions with <= and < by exchanging the operands (see “Example 2” on page 34-89).

This type does not represent a property.

Examples

Example 1

`x > 3` is a relation, while `TRUE` is not:
testtype(x > 3, Type::Relation), testtype(TRUE, Type::Relation)TRUE, FALSE

```
TRUE, FALSE
```

Example 2

MuPAD always interprets expressions with the operations >= and > as expressions with <= and < with the operands exchanged:
x > 3; prog::exprtree(x > 3):3 < x

```
3 < x
  _less | +-- 3 | `-- x
```

The operator is *not* >, but <, and the operands have been swapped:
op(x > 3, 0..2)_less, 3, x

```
_less, 3, x
```

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also

testtype

Type::Residue

Purpose

Property representing a residue class

Syntax

```
assume(x, (rem, class, <sub_set>))
is(ex, (rem, class, <sub_set>))
testtype(ex, (rem, class, <sub_set>))
```

Description

`Type::Residue(rem, class)` represents the integers *n* for which *n* - *rem* is divisible by *class*.

The call `assume(x, Type::Residue(rem, class))` marks the identifier `x` as an integer divisible by `class` with remainder `rem`.

The call `is(ex, Type::Residue(rem, class))` derives, whether the expression `ex` is an integer divisible by `class` with remainder `rem` (or this property can be derived).

This type represents a property that can be used in assume and is.

Type::Even and Type::Odd are objects created by `Type::Residue`.

The call `testtype(obj, Type::Residue(rem, class))` checks, whether `obj` is an integer and is divisible by `class` with remainder `rem`. If the optional argument `sub_set` is given, testtype checks additionally `testtype(obj, sub_set)`.

Examples

Example 1

`Type::Residue` can be used in testtype:
testtype(6, Type::Residue(2, 4)), testtype(13, Type::Residue(1, 20))TRUE, FALSE

```
TRUE, FALSE
```

Example 2

`x` is assumed to be divisible by `3` with remainder `1`:
assume(x, Type::Residue(1, 3))

Which properties has `x + 2` got?

getprop(x + 2)Dom::ImageSet(3*k, k, Z_)

$\{3\,k \mid k \in \mathbb{Z}\}$

x is an integer, but it may be odd or not:
is(x, Type::Integer), is(x, Type::Odd)TRUE, UNKNOWN

TRUE, UNKNOWN

This example restricts possible values of x to odd integers:
assume(x, Type::Residue(1, 4)); is(x, Type::Odd), is((-1)^x < 0)TRUE, TRUE

TRUE, TRUE

Parameters

x

An identifier or a mathematical expression containing identifiers

rem

Remainder as integer number between `0` and `class - 1`; an integer larger than `class - 1` will be divided by `class` and `rem` gets the remainder of this division

class

The divider as positive integer

sub_set

A subset of the integers (e.g., Type::PosInt); otherwise Type::Integer is used

ex

An arithmetical expression

obj

Any MuPAD object

Return Values See assume, is and testtype

See Also assumeistesttypeType::EvenType::IntegerType::Odd

Type::SequenceOf

Purpose

Type representing sequences

Syntax

```
testtype(obj, (obj_type, <min_nr, <max_nr>>))
```

Description

With `Type::SequenceOf`, sequences with specified objects can be identified.

The call `testtype(obj, Type::SequenceOf(obj_type))` checks, whether `obj` is a sequence with elements of the given type `obj_type`. In that case, it TRUE, otherwise FALSE.

A sequence has the domain type DOM_EXPR and the type `"_exprseq"`.

The two optional parameters `min_nr` and `max_nr` determine the minimum and maximum number of arguments of the analysed sequence, respectively. If the numbers are not be given, the number of elements of the sequence will not be checked. If only the minimum is given, the sequence must have at least `min_nr` elements for the test to succeed.

This type does not represent a property.

Examples

Example 1

Is the given sequence a sequence of identifiers?
testtype((a, b, c, d, e, f), Type::SequenceOf(DOM_IDENT))TRUE

```
TRUE
```

Is the given sequence a sequence of at least five real numbers?
testtype((0, 0.5, 1, 1.5, 2, 2.5, 3), Type::SequenceOf(Type::Real, 5))TRUE

```
TRUE
```

Parameters

obj

Any MuPAD object

obj_type

The type of the objects; a type can be an object of the library Type or one of the possible return values of domtype and type

min_nr

The minimal number of objects as nonnegative integer

max_nr

The maximal number of objects as nonnegative integer

Return Values

See testtype

See Also

_exprseqtesttypeType::ListOf

Type::Series

Purpose

Type representing truncated Puiseux, Laurent, and Taylor series expansions

Syntax

```
testtype(obj, (Puiseux | Laurent | Taylor))
testtype(obj, (Puiseux | Laurent | Taylor, x))
testtype(obj, (Puiseux | Laurent | Taylor, x = x0))
testtype(obj, (Puiseux | Laurent | Taylor, x, Undirected
| Real | Right | Left))
testtype(obj, (Puiseux | Laurent | Taylor, x = x0,
Undirected | Real | Right | Left))
```

Description

`Type::Series(Puiseux)`, `Type::Series(Laurent)`, and `Type::Series(Taylor)` represent truncated Puiseux series, Laurent series, and Taylor series, respectively.

The call `testtype(obj, Type::Series(T))` checks, whether `obj` is a truncated series expansion of domain type Series::Puiseux and of mathematical type `T`.

The call `testtype(obj, Type::Series(T, x = x0))` checks in addition, whether the series variable is `x` and the expansion point is `x0`. If `x0` is omitted, `x0 = 0` is assumed.

The call `testtype(obj, Type::Series(T, x = x0, dir))` checks in addition, whether the direction of expansion is compatible with the specified direction `dir`. See the help pages of series and Series::Puiseux for more details about the direction.

See “Example 1” on page 34-97 and “Example 3” on page 34-99.

If `obj` is of domain type Series::Puiseux, but not a Puiseux expansion in the mathematical sense, then `testtype(obj, Type::Series(T))` returns FALSE. This is the case if the coefficients of `obj` depend on the series variable, or if the type flag of `obj` is 1. See “Example 2” on page 34-98, and the help page of Series::Puiseux for more details.

A Laurent series is a Puiseux series with integral exponents. If the expansion point is finite, then a Taylor series is a Puiseux

series with nonnegative integral exponents. If the expansion point is complexInfinity, then a Taylor series is a Puiseux series with nonpositive integral exponents. See “Example 1” on page 34-97 and “Example 4” on page 34-101.

For the expansion points infinity and -infinity, the directions `Left` and `Right`, respectively, are implicitly assumed.

Specifying `x0 = infinity` is equivalent to `x0 = complexInfinity` and `dir = Left`, and similarly `x0 = -infinity` is equivalent to `x0 = complexInfinity` and `dir = Right`.

See “Example 4” on page 34-101.

This type does not represent a property: it cannot be used in assume to mark an identifier as a truncated series expansion.

Examples

Example 1

The following call returns a Puiseux series:
s := series(sin(sqrt(x)), x); domtype(s);sqrt(x) - x^(3/2)/6 + x^(5/2)/120 + O(x^(7/2))

$$\sqrt{x} - \frac{x^{3/2}}{6} + \frac{x^{5/2}}{120} + O\left(x^{7/2}\right)$$

“Series::Puiseux”

Series::Puiseux

However, `s` is not a Laurent series:
testtype(s, Type::Series(Puiseux)), testtype(s, Type::Series(Laurent)), testtype(s, Type::Series(Taylor))TRUE, FALSE, FALSE

TRUE, FALSE, FALSE

A Laurent series that is not a Taylor series:
s := series(1/sin(x), x); domtype(s);1/x + x/6 + (7*x^3)/360 + O(x^5)

$$\frac{1}{x} + \frac{x}{6} + \frac{7\,x^3}{360} + O(x^5)$$

'Series::Puiseux'

Series::Puiseux

testtype(s, Type::Series(Puiseux)), testtype(s, Type::Series(Laurent)), testtype(s, Type::Series(Taylor))TRUE, TRUE, FALSE

TRUE, TRUE, FALSE

The inverse of `s` is a Taylor series:
1/s; testtype(1/s, Type::Series(Puiseux)), testtype(1/s, Type::Series(Laurent)), testtype(1/s, Type::Series(Taylor))x - x^3/6 + x^5/120 + O(x^7)

$$x - \frac{x^3}{6} + \frac{x^5}{120} + O(x^7)$$

TRUE, TRUE, TRUE

TRUE, TRUE, TRUE

Example 2

`Type::Series` represents only objects of domain type Series::Puiseux:
s := 1 + x + 2*x^2 + O(x^3); domtype(s), testtype(s, Type::Series(Puiseux));x + 2*x^2 + 1 + O(x^3)

$$x + 2\,x^2 + 1 + O(x^3)$$

DOM_EXPR, FALSE

DOM_EXPR, FALSE

s := series(exp(x + 1/x), x = infinity, 3); domtype(s), testtype(s, Type::Series(Puiseux));exp(x) + exp(x)/x + exp(x)/(2*x^2) + O(exp(x)/x^3)

$$e^x + \frac{e^x}{2} + \frac{e^x}{2x^2} + O\left(\frac{e^x}{x^3}\right)$$

"Series::gseries", FALSE

Series::gseries, FALSE

For objects of domain type Series::Puiseux, whose coefficients contain the series variable or whose type flag is 1, the result is FALSE as well: s := series(psi(x), x = infinity); domtype(s), coeff(s, 0), testtype(s, Type::Series(Puiseux));ln(x) - 1/(2*x) - 1/(12*x^2) + 1/(120*x^4) + O(1/x^6)

$$\ln(x) - \frac{1}{2x} - \frac{1}{12x^2} + \frac{1}{120x^4} + O\left(\frac{1}{x^6}\right)$$

"Series::Puiseux", ln(x), FALSE

Series::Puiseux, ln(x), FALSE

s := series(sin(sqrt(-x)), x); domtype(s), testtype(s, Type::Series(Puiseux));sqrt(-x) - (-x)^(3/2)/6 + (-x)^(5/2)/120 + O(x^(7/2))

$$\sqrt{-x} - \frac{(-x)^{3/2}}{6} + \frac{(-x)^{5/2}}{120} + O\left(x^{7/2}\right)$$

"Series::Puiseux", FALSE

Series::Puiseux, FALSE

Example 3

By specifying further arguments, you can check for the series variable, the expansion point, and the direction of expansion as well: s := series(sin(sqrt(-x)), x, Left); testtype(s, Type::Series(Puiseux, y)), testtype(s, Type::Series(Puiseux, x)), testtype(s, Type::Series(Puiseux, x

= 0)), testtype(s, Type::Series(Puiseux, x = 2));- sqrt(x)*I - (x^(3/2)*I)/6 - (x^(5/2)*I)/120 + O(x^(7/2))

$$-\sqrt{x}\,i-\frac{x^{3/2}\,i}{6}-\frac{x^{5/2}\,i}{120}+O\left(x^{7/2}\right)$$

FALSE, TRUE, TRUE, FALSE

FALSE, TRUE, TRUE, FALSE

Series::Puiseux::direction(s), testtype(s, Type::Series(Puiseux, x, Undirected)), testtype(s, Type::Series(Puiseux, x, Real)), testtype(s, Type::Series(Puiseux, x, Right)), testtype(s, Type::Series(Puiseux, x, Left));Left, FALSE, FALSE, FALSE, TRUE

Left, FALSE, FALSE, FALSE, TRUE

s := series(x^5/(x - 2), x = 2, 3); testtype(s, Type::Series(Laurent, x)), testtype(s, Type::Series(Laurent, x = 2)), testtype(s, Type::Series(Laurent, x = 3));32/(x - 2) + 80 + 80*(x - 2) + O((x - 2)^2)

$$\frac{32}{x-2}+80+80\,(x-2)+O\left((x-2)^2\right)$$

FALSE, TRUE, FALSE

FALSE, TRUE, FALSE

If you specify a direction, testtype checks whether it is compatible with the direction of the series:
Series::Puiseux::direction(s), testtype(s, Type::Series(Puiseux, x = 2, Undirected)), testtype(s, Type::Series(Puiseux, x = 2, Real)), testtype(s, Type::Series(Puiseux, x = 2, Right)), testtype(s, Type::Series(Puiseux, x = 2, Left));Undirected, TRUE, TRUE, TRUE, TRUE

Undirected, TRUE, TRUE, TRUE, TRUE

Example 4

The following example is a Laurent series around infinity, but not a Taylor series:
s := series(z*exp(1/z), z = infinity); testtype(s, Type::Series(Puiseux)), testtype(s, Type::Series(Laurent)), testtype(s, Type::Series(Taylor))z + 1 + 1/(2*z) + 1/(6*z^2) + 1/(24*z^3) + 1/(120*z^4) + O(1/z^5)

$$z+1+\frac{1}{2\,z}+\frac{1}{6\,z^2}+\frac{1}{24\,z^3}+\frac{1}{120\,z^4}+O\left(\frac{1}{z^5}\right)$$

TRUE, TRUE, FALSE

TRUE, TRUE, FALSE

The expansion point is infinity, or equivalently, complexInfinity from the left:
Series::Puiseux::point(s), Series::Puiseux::direction(s); testtype(s, Type::Series(Laurent, z)), testtype(s, Type::Series(Laurent, z = 0)), testtype(s, Type::Series(Laurent, z = infinity)), testtype(s, Type::Series(Laurent, z = -infinity)), testtype(s, Type::Series(Laurent, z = complexInfinity));complexInfinity, Left

complexInfinity, Left

FALSE, FALSE, TRUE, FALSE, TRUE

FALSE, FALSE, TRUE, FALSE, TRUE

testtype(s, Type::Series(Laurent, z = complexInfinity, Undirected)), testtype(s, Type::Series(Laurent, z = complexInfinity, Real)), testtype(s, Type::Series(Laurent, z = complexInfinity, Right)), testtype(s, Type::Series(Laurent, z = complexInfinity, Left));FALSE, FALSE, FALSE, TRUE

FALSE, FALSE, FALSE, TRUE

Mathematically, the expression is even an undirected expansion around complexInfinity:
s := series(z*exp(1/z), z = complexInfinity); Series::Puiseux::point(s), Series::Puiseux::direction(s);z + 1 + 1/(2*z) + 1/(6*z^2) + 1/(24*z^3) + 1/(120*z^4) + O(1/z^5)

$$z + 1 + \frac{1}{2z} + \frac{1}{6z^2} + \frac{1}{24z^3} + \frac{1}{120z^4} + O\left(\frac{1}{z^5}\right)$$

complexInfinity, Undirected

complexInfinity, Undirected
testtype(s, Type::Series(Laurent, z)), testtype(s, Type::Series(Laurent, z = infinity)), testtype(s, Type::Series(Laurent, z = -infinity)), testtype(s, Type::Series(Laurent, z = complexInfinity));FALSE, TRUE, TRUE, TRUE

FALSE, TRUE, TRUE, TRUE
testtype(s, Type::Series(Laurent, z = complexInfinity, Undirected)), testtype(s, Type::Series(Laurent, z = complexInfinity, Real)), testtype(s, Type::Series(Laurent, z = complexInfinity, Right)), testtype(s, Type::Series(Laurent, z = complexInfinity, Left));TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE

Parameters

obj

Any MuPAD object

x

The series variable: an identifier

x0

The expansion point: an arithmetical expression

Options

Laurent

Puiseux

Taylor

The type of series

Left

Real

Right

Undirected

The direction of the expansion

Return Values

See testtype

See Also

seriesSeries::PuiseuxtesttypeType::PolyExprType::PolyOf

Type::SetOf

Purpose

Type representing sets

Syntax

```
testtype(obj, (obj_type, <min_nr, <max_nr>>))
```

Description

`Type::SetOf(obj_type)` describes sets of elements of type `obj_type`.

The call `testtype(obj, Type::SetOf(obj_type))` checks, whether `obj` is a set with elements of the given type `obj_type`. If it is, the function returns TRUE, otherwise FALSE.

A set has the domain type DOM_SET.

The two optional parameters `min_nr` and `max_nr` determine the minimum and maximum number of elements in the analysed set. If the numbers are not be given, the number of elements in the set will not be checked. If only the minimum is given, the set must contain at least `min_nr` elements for the test to succeed.

This type does not represent a property.

Examples

Example 1

Is the given set a set of identifiers?
testtype({a, b, c, d, e, f}, Type::SetOf(DOM_IDENT))TRUE

TRUE

Is the given set a set of at least five real numbers?
testtype({0, 0.5, 1, 1.5, 2, 2.5, 3}, Type::SetOf(Type::Real, 5))TRUE

TRUE

Example 2

testtype is used to select sets with exactly two idetifiers:
S := {{a}, {a, b}, {d, 1}, {0, d}, {e}, {d, e}}: select(S, testtype, Type::SetOf(DOM_IDENT, 2, 2))
{{d, e}, {a, b}}

$\{\{d, e\}, \{a, b\}\}$

Parameters

obj

Any MuPAD object

obj_type

The type of the objects; a type can be an object of the library `Type` or one of the possible return values of domtype and type

min_nr

The minimal number of objects as nonnegative integer

max_nr

The maximal number of objects as nonnegative integer

Return Values

See testtype

See Also

DOM_SETtesttypeType::ListOfType::Union

Type::Set

Purpose

Type representing set-theoretic expressions

Syntax

```
testtype(obj, Type::Set)
```

Description

`Type::Set` comprises all expressions in which the operators are set-theoretic operations

A set-theoretic expression is defined to be any of the following: a set constant, an identifier, an unevaluated call to a set-valued function, or the composition of set-theoretic expressions by the operator union, intersect, or minus.

The following objects are set constants: finite sets of type DOM_SET, intervals, the universe, and every object that belongs to a domain of category Cat::Set.

The following functions are set-valued: solve, discont, RootOf, and solvelib::Union.

The union, intersection, or difference of objects is not a set-theoretic expression unless each of the objects is. See “Example 2” on page 34-106.

Examples

Example 1

Sets are set-theoretic expressions.
testtype({3}, Type::Set)TRUE

TRUE

Example 2

Unions, intersections, and differences are set-theoretic expressions if and only if all operands are.
testtype(a union {4}, Type::Set)TRUE

TRUE
testtype(a+1 union {4}, Type::Set)FALSE

FALSE

Example 3

If the call to a set-valued function as solve returns unevaluated, then the result is a set-theoretic expression.
solve(x^2 = sin(x + 1), x)solve(x^2 - sin(x + 1) = 0, x)

$$\mathrm{solve}\left(x^2 - \sin(x+1) = 0,\ x\right)$$

testtype(%, Type::Set)TRUE

TRUE

Parameters

obj

Any MuPAD object

Return Values

See testtype

See Also

testtype

Type::Singleton

Purpose

Type representing exactly one object

Syntax

```
testtype(obj, (t_obj))
```

Description

`testtype(x, Type::Singleton(y))` is equivalent to `bool(x = y)`.

The call `testtype(obj, Type::Singleton(t_obj))` is equivalent to `bool(x = y)`, but the latter is faster.

`Type::Singleton` can be used to create combined types, especially in conjunction with Type::Union, Type::Equation and other types expecting type information for subexpressions (see “Example 2” on page 34-108).

This type does not represent a property.

Examples

Example 1

Check, if `x` is really `x`:
testtype(x, Type::Singleton(x))TRUE

```
TRUE
```

But the next call does the same:
bool(x = x)TRUE

```
TRUE
```

Example 2

`Type::Singleton` exists to create special testing expressions:
T := Type::Union(Type::Singleton(hold(All)), Type::Constant):

With the type `T` the option `All` and any constant can be identified with one call of testtype:
testtype(4, T), testtype(hold(All), T), testtype(x, T)TRUE, TRUE, FALSE

```
TRUE, TRUE, FALSE
```

But (e.g., in procedures) the following example works faster:
test := X -> testtype(X, Type::Constant) or bool(X = hold(All)): test(4), test(hold(All)), test(x)TRUE, TRUE, FALSE

TRUE, TRUE, FALSE

One way to test a list of options for syntactical correctness is the following:
T := Type::Union(// Name = "..." Type::Equation(Type::Singleton(hold(Name)), DOM_STRING), // Mode = n, n in {1, 2, 3} Type::Equation(Type::Singleton(hold(Mode)), Type::Interval([1,3], Type::Integer)), // Quiet Type::Singleton(hold(Quiet))):testtype((Name = "abcde", Quiet), Type::SequenceOf(T))TRUE

TRUE

We only allow the values 1, 2, and 3 for `Mode`, however:
testtype((Quiet, Mode = 0), Type::SequenceOf(T))FALSE

FALSE

Obviously, it would be a good idea to tell the user which options we could not grok:
error("Unknown option(s): ".expr2text(select((Quiet, Mode = 0), not testtype, Type::SequenceOf(T)))) Error: Unknown option(s): Mode = 0 delete T, test:

Parameters

obj

Any MuPAD object

t_obj

Any object to identify

Return Values See testtype

See Also _equalbooltesttypeType::Union

Type::TableOfEntry

Purpose

Type representing tables with specified entries

Syntax

```
testtype(obj, (obj_type))
```

Description

`Type::TableOfEntry(obj_type)` describes tables with *entries* of type `obj_type`.

The call `testtype(obj, Type::TableOfEntry(obj_type))` checks, whether `obj` is a table and all entries of this table are of the type `obj_type`. If both conditions are met, the call returns TRUE, otherwise FALSE.

The entries of a table are the right hand sides of the operands of a table.

This type does not represent a property.

Examples

Example 1

The following table uses identifiers as keys and integers as entries:
T := table(a = 1, b = 2, c = 3, d = 4): testtype(T, Type::TableOfEntry(DOM_INT))TRUE

```
TRUE
```

`Type::TableOfEntry` only checks the type of the entries, not the keys:
T := table(a = 1, b = 2, c = 3, d = 4): testtype(T, Type::TableOfEntry(DOM_IDENT))FALSE

```
FALSE
```

delete T:

Parameters

obj

Any MuPAD object

obj_type

The type of the entries; can be an object of the library Type or one of the possible return values of domtype and type

Return Values See testtype

See Also testtypetableType::TableOfIndex

Type::TableOfIndex

Purpose

Type representing tables with specified indices

Syntax

```
testtype(obj, (obj_type))
```

Description

`Type::TableOfIndex(obj_type)` represents tables with *indices* (keys) of type `obj_type`.

The call `testtype(obj, Type::TableOfIndex(obj_type))` checks, whether `obj` is a table and all indices (keys) are of the type `obj_type`. If both conditions are met, the call returns TRUE, otherwise FALSE.

The indices of a table are the left hand sides of the operands of a table.

This type does not represent a property.

Examples

Example 1

The following table uses identifiers as keys and integers as values:
T := table(a = 1, b = 2, c = 3, d = 4): testtype(T, Type::TableOfIndex(DOM_IDENT))TRUE

```
TRUE
```

`Type::TableOfIndex` only checks the types of the keys of the table, so the following call returns `FALSE`:
T := table(a = 1, b = 2, c = 3, d = 4): testtype(T, Type::TableOfIndex(DOM_INT))FALSE

```
FALSE
```

delete T:

Parameters

obj

Any MuPAD object

obj_type

The type of the indices; can be an object of the library Type or one of the possible return values of domtype and type

Return Values See testtype

See Also testtypetableType::TableOfEntry

Type::TableOf

Purpose

Type representing tables

Syntax

```
testtype(obj, (<indices_type, <entries_type>>))
```

Description

`Type::TableOf` represents tables; the types of the *indices* and of the *entries* can be specified.

The call `testtype(obj, Type::TableOf(indices_type, entries_type))` checks, whether `obj` is a table with indices of type `indices_type` and entries of type `entries_type`.

The *indices* (resp. the *entries*) of a table are the left (resp. right) hand sides of the operands of a table.

`indices_type` and `entries_type` default to Type::AnyType

This type does not represent a property.

Examples

Example 1

We test if the following objects are tables:
testtype(x, Type::TableOf()); testtype(table(), Type::TableOf())FALSE

```
FALSE
```

TRUE

```
TRUE
```

We test if the following objects are tables with integer indexes:
testtype(table(a = 1), Type::TableOf(Type::Integer)); testtype(table(1 = 2), Type::TableOf(Type::Integer))FALSE

```
FALSE
```

TRUE

```
TRUE
```

We test if the following objects are tables with integer entries:
testtype(table(a = a), Type::TableOf(Type::AnyType,
Type::Integer)); testtype(table(a = 2), Type::TableOf(Type::AnyType,
Type::Integer))FALSE

FALSE
TRUE

TRUE

We test if the following objects are tables with integer indexes and entries:
testtype(table(a = a), Type::TableOf(Type::Integer,
Type::Integer)); testtype(table(1 = 2), Type::TableOf(Type::Integer,
Type::Integer))FALSE

FALSE
TRUE

TRUE

Example 2

Test if the following table uses identifiers as indexes:
T := table(a = 1, b = 2, c = 3, d = 4): testtype(T,
Type::TableOf(DOM_IDENT))TRUE

TRUE

Test if the following table uses integers as indexes:
T := table(a = 1, b = 2, c = 3, d = 4): testtype(T,
Type::TableOf(DOM_INT))FALSE

FALSE
delete T:

Example 3

The following table uses identifiers as keys and integers as entries:
T := table(a = 1, b = 2, c = 3, d = 4): testtype(T, Type::TableOf(Type::AnyType, DOM_INT))TRUE

TRUE

`Type::TableOf` only checks the type of the entries, not the keys:
T := table(a = 1, b = 2, c = 3, d = 4): testtype(T, Type::TableOf(Type::AnyType, DOM_IDENT))FALSE

FALSE

delete T:

Parameters

obj

Any MuPAD object

indices_type

The type of the indices. It can be an object of the library Type or one of the possible return values of domtype and type

entries_type

The type of the entries.

Return Values

See testtype

See Also

testtypetableType::TableOfIndexType::TableOfEntry

Type::Union

Purpose

Type representing several types as one type object

Syntax

```
testtype(obj, (obj_types,  ))
```

Description

`Type::Union ( type1 , type2 ,  )` represents all objects having at least one of the types `type1`, `type2`, ...

The call `testtype(obj, Type::Union( obj_types ,  ))` checks, whether `obj` has the type of at least one of the given types `obj_types`, ... If such a type is found, the call returns TRUE, otherwise FALSE.

The call `testtype(Type::Union( obj , obj_types ,  ))` is thus equivalent to the call `_lazy_or(map(obj_types, x -> testtype(obj, x)))`, testing `obj` against all types in turn until one is found which matches.

`obj_types`, ... must be a (nonempty) sequence of types (see testtype).

This type does not represent a property.

Examples

Example 1

Check, whether the given object is a positive or negative integer:
testtype(2, Type::Union(Type::PosInt, Type::NegInt))TRUE

```
TRUE
```

`x` however, is neither a positive nor a negative number:
testtype(x, Type::Union(Type::Positive, Type::Negative))FALSE

```
FALSE
```

Example 2

testtype is used to select positive and negative integers:
SET:= {-2, -1.5, -1, -0.5, 0, 0.5, 1, 1.5, 2}: select(SET, testtype, Type::Union(Type::PosInt, Type::NegInt)){-2, -1, 1, 2}

```
{-2, -1, 1, 2}
```
delete SET:

Parameters

obj

Any MuPAD object

obj_types

A sequence of types; a type can be an object of the library Type or one of the possible return values of domtype and type

Return Values

See testtype

See Also

testtype

Type::Unknown

Purpose

Type representing variables

Syntax

```
testtype(obj, Type::Unknown)
```

Description

`Type::Unknown` represents identifiers and indexed identifiers.

The call `testtype(obj, Type::Unknown)` checks, whether `obj` is an identifier or an indexed identifier with an integer index. If it is, the call returns TRUE, otherwise FALSE.

An identifier has the domain type DOM_IDENT. An indexed identifier is an expression with type_index and two operands, the first of which is an identifier and the second one is an integer. A local variable is not of type `Type::Unknown`.

This type does not represent a property.

Examples

Example 1

`Type::Unknown` accepts identifiers:
testtype(x, Type::Unknown)TRUE

```
TRUE
```

`x[0]` is an indexed identifier accepted by `Type::Unknown`:
testtype(x[0], Type::Unknown)TRUE

```
TRUE
```

The index must be an integer:
testtype(x[-1], Type::Unknown), testtype(x[1.0], Type::Unknown)TRUE, FALSE

```
TRUE, FALSE
```

Parameters

obj

Any MuPAD object

Return Values See testtype

See Also testtypeindets

Type::Zero

Purpose

Type and property representing zero

Syntax

```
testtype(obj, Type::Zero)
assume(x, Type::Zero)
is(ex, Type::Zero)
```

Description

`testtype(obj, Type::Zero )` is equivalent to `iszero(obj)`. `Type::Zero` is a property, too, which can be used in an assume call.

The call `testtype(obj, Type::Zero)` is equivalent to `iszero(obj)`, which performs a syntactical test if `obj` is zero. If it is, the call returns TRUE, otherwise, FALSE is returned.

The call `assume(x, Type::Zero)` marks the identifier `x` as zero.

The call `is(ex, Type::Zero)` derives, whether the expression `ex` is zero (or this property can be derived).

This type represents a property that can be used in assume and is.

The call `assume(x = 0)` has the same meaning as `assume(x, Type::Zero)`.

Examples

Example 1

testtype determines the syntactical equality to zero:
testtype(0.0, Type::Zero)TRUE

```
TRUE
```

testtype(x, Type::Zero)FALSE

```
FALSE
```

Example 2

`Type::Zero` can be used within assume and is:
is(x, Type::Zero)UNKNOWN

UNKNOWN

Assumption that x is zero:
assume(x, Type::Zero): is(x^2, Type::Zero)TRUE

TRUE

The next example shows the difference between testtype and is:
is(x, Type::Zero), testtype(x, Type::Zero)TRUE, FALSE

TRUE, FALSE

Now the property of x is removed:
delete x: is(x, Type::Zero), testtype(x, Type::Zero)UNKNOWN, FALSE

UNKNOWN, FALSE

A positive number cannot be zero:
assume(x > 0): is(x, Type::Zero), testtype(x, Type::Zero)FALSE, FALSE

FALSE, FALSE

But in the next example x could be zero:
assume(x >= 0): is(x, Type::Zero), testtype(x, Type::Zero)UNKNOWN, FALSE

UNKNOWN, FALSE
delete x:

Parameters

obj

Any MuPAD object

x

An identifier or a mathematical expression containing identifiers

ex

An arithmetical expression

Return Values See testtype, assume and is

See Also testtypeisassumeType::NonZero
