`dsp.util.SignalPath` objects contain path information for signals in `Simulink.SimulationData.Dataset` objects. You get `Simulink.SimulationData.Dataset` objects when you use `Dataset` logging to log signals from a Simulink model.

## Construction

`dsp.util.SignalPath` objects are returned by the `dsp.util.getSignalPath` function and can be used as input to the `dsp.util.getLogArrays` function.

## Properties

### SignalName

Contains the name of the signal output by the block at the specified `BlockPath`.

### BlockPath

Provides the `Simulink.SimulationData.BlockPath` to the block in the Simulink model from which the signal originates.

### PortIndex

Provides the output port index of the block from which the logged signal `SignalName` originates.

### BusElement

Provides a string description of a signal in a logged bus. When `SignalPath` is not a logged bus, this property will be an empty string.

If the `SignalPath` object is a logged bus signal, the `BusElement` string will be formatted as follows:

- When the bus contains a nonbus signal, `BusElement` is the name of that signal.
- When the bus contains a nested bus that contains a nonbus signal, `BusElement` will be a dot-separated string consisting of

## dsp.util.SignalPath

---

the name of the nested bus followed by the name of the non-bus signal. For example: `nestbus.signal1`

- When the bus contains nested busses within nested busses to any depth, `BUSElement` will be a dot-separated string. This string contains each of the nested bus names, and ends with the nonbus signal name. For example: `outernestedbus.innernestedbus.signal1`

<b>Purpose</b>	Identify whether blocks in model are current, deprecated, or obsolete
<b>Syntax</b>	<pre>dsp_links dsp_links('modelname')</pre>
<b>Description</b>	<p>dsp_links returns a structure with three elements that identify whether the DSP System Toolbox blocks in the current model are current, deprecated, or obsolete. Each element is one of the three block categories and contains a cell array of strings. Each string is the name of a library block in the current model.</p> <p>dsp_links('modelname') returns the three-element structure for the specified model.</p>
<b>Definitions</b>	<p><b>Obsolete Blocks</b></p> <p><i>Obsolete blocks</i> are blocks that the toolbox no longer supports. In some cases, these blocks no longer function properly.</p> <p><b>Deprecated Blocks</b></p> <p><i>Deprecated blocks</i> are blocks that the toolbox still supports but are likely to become obsolete in a future release. Refer to the block reference page for suggested replacements.</p> <p><b>Current Blocks</b></p> <p><i>Current blocks</i> are blocks that the toolbox supports and that represent the latest block functionality.</p>
<b>Examples</b>	<p>Display block support information for the specified model, and then find the name of the first current block:</p> <pre>sys = 'dspcochlear'; load_system(sys)      % Load the dspcochlear model links = dsp_links(sys) % Run dsp_links on the model links.current{1}     % Find the name of the first current block</pre>
<b>See Also</b>	liblinks

# dsplib

---

**Purpose** Open top-level DSP System Toolbox library

**Syntax** `dsplib`

**Description** `dsplib` opens the top-level DSP System Toolbox block library model.

**Examples** View and gain access to the DSP System Toolbox blocks:

```
dsplib
```

**Alternatives** To view and gain access to the DSP System Toolbox blocks using the Simulink library browser:

- Type `simulink` at the MATLAB command line, and then expand the DSP System Toolbox node in the library browser.

- Click the Simulink icon from the MATLAB Toolstrip.

**Purpose** Configure Simulink environment for signal processing systems

**Syntax** dspstartup

**Description** dspstartup configures Simulink environment parameters with settings appropriate for a typical signal processing project. You can use the dspstartup function in the following ways:

- At the MATLAB command line. Doing so configures the Simulink environment in your current session for signal processing projects.
- By adding a call to the dspstartup function from your startup.m file. When you do so, MATLAB configures your Simulink environment for typical signal processing projects each time you launch MATLAB.

When the function successfully configures your Simulink environment, MATLAB displays the following message in the command window.

```
Changed default Simulink settings for signal processing
systems (dspstartup.m).
```

The dspstartup.m file executes the following commands.

```
set_param(0, ...
    'SingleTaskRateTransMsg', 'error', ...
    'multiTaskRateTransMsg', 'error', ...
    'Solver',                  'fixedstepdiscrete', ...
    'SolverMode',              'SingleTasking', ...
    'StartTime',                '0.0', ...
    'StopTime',                 'inf', ...
    'FixedStep',                'auto', ...
    'SaveTime',                 'off', ...
    'SaveOutput',               'off', ...
    'AlgebraicLoopMsg',         'error', ...
    'SignalLogging',            'off');
```

## Examples

Add a call to the `dspstartup` function from your `startup.m` file:

- 1 To find out if there is a `startup.m` file on your MATLAB path, run the following code at the MATLAB command line:

```
which startup.m
```

- 2 If MATLAB returns '`startup.m`' not found., see “Startup Options” in the MATLAB documentation to learn more about the `startup.m` file.

If MATLAB returns a path to your `startup.m` file, open that file for editing.

```
edit startup.m
```

- 3 Add a call to the `dspstartup` function. Your `startup.m` file now resembles the following code sample:

```
%STARTUP Startup file
% This file is executed when MATLAB starts up, if it exists
% anywhere on the path. In this case, the startup.m file
% runs the dspstartup.m file to configure the Simulink
% environment with settings appropriate for typical
% signal processing projects.

dspstartup;
```

## How To

- “Configure the Simulink Environment for Signal Processing Models”

**Purpose**

Elliptic filter using specification object

**Syntax**

```
hd = design(d,'ellip')
hd = design(d,'ellip',designoption,value,designoption,...
value,...)
```

**Description**

`hd = design(d,'ellip')` designs an elliptical IIR digital filter using the specifications supplied in the object `h`.

`hd = design(d,'ellip',designoption,value,designoption,... value,...)` returns an elliptical or Causer FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `ellip`, refer to the command line help system. For example, to get specific information about using `ellip` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'ellip')
```

**Examples**

These examples demonstrate how to use `ellip` to design filters based on filter specification objects.

**Example 1**

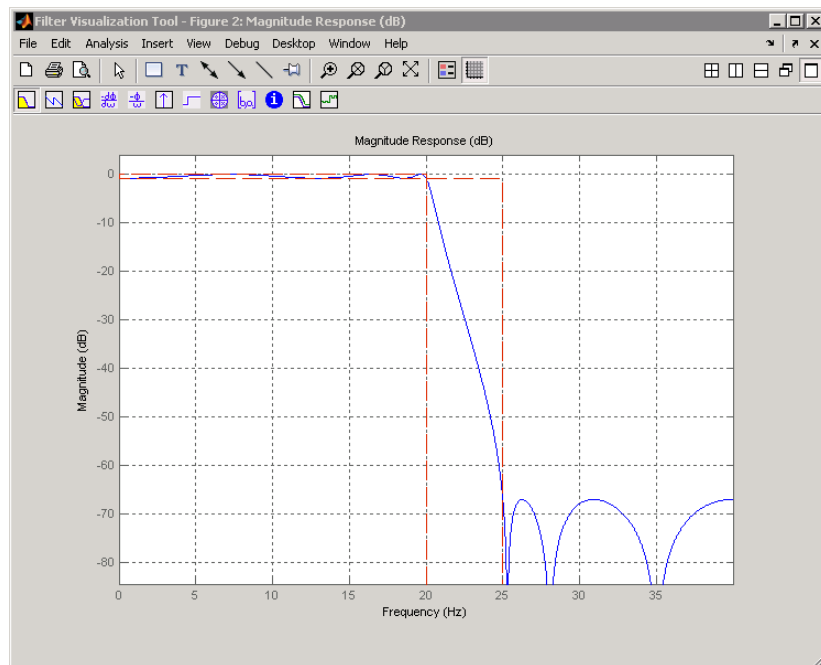

Construct the default bandpass filter specification object and design an elliptic filter.

```
d = fdesign.bandpass;
hd = design(d,'ellip','matchexactly','both');
```

## Example 2

Construct a lowpass object with order, passband-edge frequency, stopband-edge frequency, and passband ripple specifications, and then design an elliptic filter.

```
d = fdesign.lowpass('n,fp,fst,ap',6,20,25,.8,80);
design(d,'ellip'); % Starts FVtool to display the filter.
```

## Example 3

Construct a lowpass object with filter order, passband edge frequency, passband ripple, and stopband attenuation specifications, and then design an elliptic filter.

```
d = fdesign.lowpass('n,fp,ap,ast',6,20,.8,60,80);
design(d,'ellip'); % Starts FVTool to display the filter.
```

# euclidfactors

---

**Purpose** Euclid factors for multirate filter

**Syntax** `[lo,mo] = euclidfactors(hm)`

**Description** `[lo,mo] = euclidfactors(hm)` returns integer factors `lo` and `mo` such that  $(lo * L) - (mo * M) = -1$ . `L` and `M` are relatively prime and represent the interpolation and decimation factors of the multirate filter `hm`.

`euclidfactors` works with the multirate filters `mfilt.firfracdecim` and `mfilt.firfracinterp`. You cannot return `lo` and `mo` for decimators or interpolators.

**Examples** Use an FIR fractional decimator, with `L = 5` and `M = 7`, to show what `euclidfactors` does.

Indeed,  $(lo * L) - (mo * M) = (4 * 5) - (3 * 7) = -1$ .

**See Also** `polyphase` | `nstates`

**Purpose** Equiripple single-rate or multirate FIR filter from specification object

**Syntax**

```
hd = design(d,'equiripple')
hd = design(d,'equiripple',designoption,value,designoption,
...value,...)
```

**Description** `hd = design(d,'equiripple')` designs an equiripple FIR digital filter or multirate filter using the specifications supplied in the object `d`. Equiripple filter designs minimize the maximum ripple in the passbands and stopbands.

`hd` is either a `dfilt` object (a single-rate digital filter) or an `mfilt` object (a multirate digital filter) depending on the `Specification` property of the filter specification object `d` and the specifications object type — halfband or interpolator.

When you use `equiripple` with Nyquist filter specification objects, you might encounter design cases where the filter design does not converge. Convergence errors occur mostly at large filter orders, or small transition widths, or large stopband attenuations. These specifications, alone or combined, can cause design failures. For more information, refer to `fdesign.nyquist` in the online Help system.

`hd = design(d,'equiripple',designoption,value,designoption,...value,...)` returns an equiripple FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `equiripple`, refer to the command line help system. For example, to get specific information about using `equiripple` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'equiripple')
```

## Examples

Here is an example of designing a single-rate equiripple filter from a halfband filter specification object. Notice the `help` command used to learn about the options for the specification object and method.

```
d = fdesign.halfband('tw,ast',0.1,80);  
designmethods(d)  
help(d,'equiripple')  
designopts(d,'equiripple')  
hd = design(d,'equiripple','stopbandshape','flat');  
fvtool(hd);
```

Displaying the filter in FVTool shows the equiripple nature of the filter.

`equiripple` also designs multirate filters. This example generates a halfband interpolator filter.

```
d = fdesign.interpolator(2); % Interpolation factor = 2.  
hd = design(d,'equiripple');
```

This final example designs an equiripple filter with a direct-form structure by specifying the **filterstructure** argument. To set the design options for the filter, use the `designopts` method and options object `opts`.

```
d = fdesign.lowpass('fp,fst,ap,ast');  
opts=designopts(d,'equiripple')  
opts.FilterStructure='dffirt'  
opts.MinPhase=1;  
opts.DensityFactor=20;  
opts  
hd=design(d,'equiripple',opts)
```

---

**Note** The `MaxPhase` design option for equiripple FIR filters is currently only available for lowpass, highpass, bandpass, and bandstop filters.

`fdesign.nyquist` | `firls` | `kaiserwin`

# fcfwrite

---

**Purpose** Write file containing filter coefficients

**Syntax**

```
fcfwrite(h)
fcfwrite(h,filename)
fcfwrite(...,'fmt')
```

**Description** `fcfwrite(h)` writes a filter coefficient ASCII file in a folder you choose, or your current MATLAB working folder. `h` can be a single filter object or a vector of filter objects. On execution, `fcfwrite` opens the **Export Filter Coefficients to .FCF File** dialog box to let you assign a file name for the output file. You can choose the destination folder within this dialog as well.

The default file name is `untitled.fcf`. When you have DSP System Toolbox software, you can use `fcfwrite(h)` to write filter coefficient files for multirate filters, adaptive filters, and discrete-time filters.

`fcfwrite(h,filename)` writes the filter coefficients and general information to a text file called `filename` in your present MATLAB working folder and opens the file in the MATLAB editor for you to review or modify.

If you do not include a file extension in `filename`, `fcfwrite` adds the extension `fcf` to `filename`.

`fcfwrite(...,'fmt')` writes the filter coefficients in the format specified by the input argument `fmt`. Valid `fmt` values are `hex` for hexadecimal, `dec` for decimal, or `bin` for binary representation of the filter coefficients.

**Examples** To demonstrate `fcfwrite`, create a fixed-point IIR filter at the command line, and then write the filter coefficients to a file named `iirfilter.fcf`.

```
d=fdesign.lowpass;
hd=design(d,'butter');
set(hd,'arithmetic','fixed');
fcfwrite(hd,'iirfilter.fcf');
```

Here is the output from fcfwrite as it appears in the MATLAB editor. Not shown here is the filename — `iirfilter.fcf` as specified and some comments at the top of the file.

```

---

<b>Purpose</b>	Open Filter Design and Analysis Tool
<b>Syntax</b>	<code>fdatool</code>
<b>Description</b>	<p><code>fdatool</code> opens the Filter Design and Analysis Tool (FDATool). Use this tool to:</p> <ul style="list-style-type: none"><li>• Design filters</li><li>• Quantize filters (with DSP System Toolbox software installed)</li><li>• Analyze filters</li><li>• Modify existing filter designs</li><li>• Create multirate filters (with DSP System Toolbox software installed)</li><li>• Realize Simulink models of quantized, direct-form, FIR filters (with DSP System Toolbox software installed)</li><li>• Perform digital frequency transformations of filters (with DSP System Toolbox software installed)</li></ul> <p>Refer to “Use FDATool with DSP System Toolbox Software” for more information about using the analysis, design, and quantization features of FDATool. For general information about using FDATool, refer to “Using FDATool”.</p> <p>When you open FDATool and you have DSP System Toolbox software installed, FDATool incorporates features that are added by DSP System Toolbox software. With DSP System Toolbox software installed, FDATool lets you design and analyze quantized filters, as well as convert quantized filters to various filter structures, transform filters, design multirate filters, and realize models of filters.</p>

Use the buttons on the sidebar to configure the design area to use various tools in FDATool.

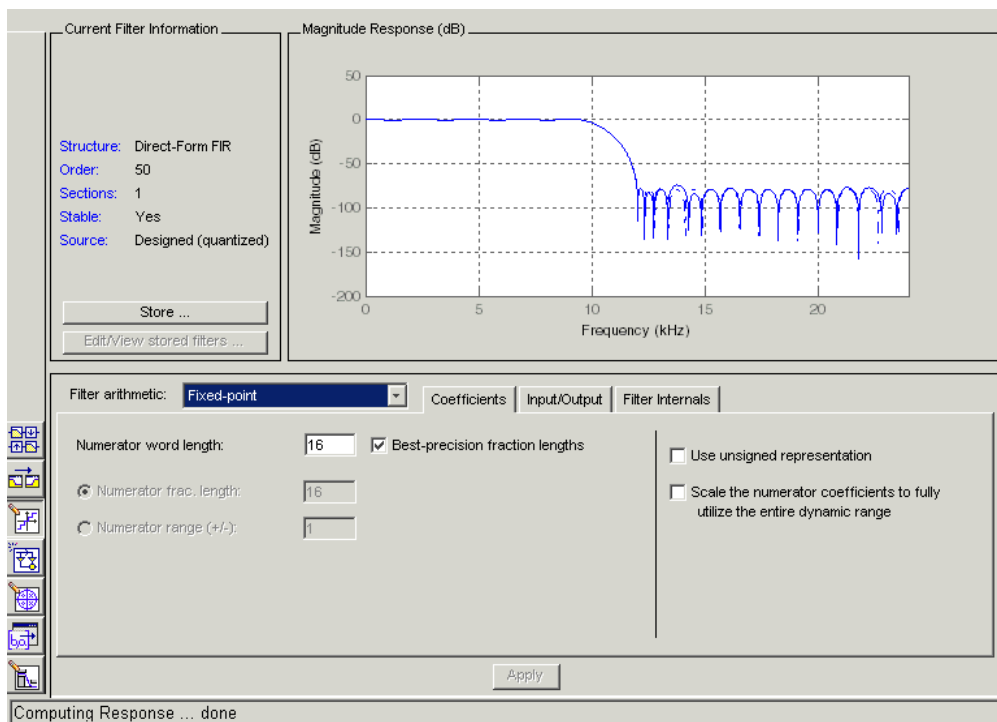

**Set Quantization Parameters** — provides access to the properties of the quantizers that compose a quantized filter. When you click **Set Quantization Parameters**, you see FDATool displaying the

quantization options at the bottom of the dialog box (the design area), as shown in the figure.

**Transform Filter** — clicking this button opens the *Frequency Transformations* pane so you can use digital frequency transformations to change the magnitude response of your filter.

**Create a multirate filter** — clicking this button switches FDATool to multirate filter design mode so you can design interpolators, decimators, and fractional rate change filters.

**Realize Model** — starting from your quantized, direct-form, FIR filter, clicking this button creates a Simulink model of your filter structure in new model window.

Other options in the menu bar let you convert the filter structure to a new structure, change the order of second-order sections in a filter, or change the scaling applied to the filter, among many possibilities.

## **Tips**

By incorporating many advanced filter design methods from DSP System Toolbox software, FDATool provides more design methods than the SPTool Filter Designer.

## **See Also**

`fdatool` | `fvtool` | `sptool`

**Purpose** Filter specification object

**Syntax**

```
d = fdesign.response  
d = fdesign.response(spec)  
d = fdesign.response(...,Fs)  
d = fdesign.response(...,magunits)
```

**Description** **Filter Specification Objects**

`d = fdesign.response` returns a filter specification object `d`, of filter response `response`. To create filters from `d`, use one of the design methods listed in “Using Filter Design Methods with Specification Objects” on page 4-488

---

**Note** Several of the filter response types described below are only available if your installation includes the DSP System Toolbox. The DSP System Toolbox significantly expands the functionality available for the specification, design, and analysis of filters.

---

Here is how you design filters using `fdesign`.

- 1** Use `fdesign.response` to construct a filter specification object.
- 2** Use `designmethods` to determine which filter design methods work for your new filter specification object.
- 3** Use `design` to apply your filter design method from step 2 to your filter specification object to construct a filter object.
- 4** Use `FVTool` to inspect and analyze your filter object.

---

**Note** `fdesign` does not create filters. `fdesign` returns a filter specification object that contains the specifications for a filter, such as the passband cutoff or attenuation in the stopband. To design a filter `hd` from a filter specification object `d`, use `d` with a filter design method such as `butter` —`hd = design(d, 'butter')`.

---

*response* can be one of the entries in the following table that specify the filter response desired, such as a bandstop filter or an interpolator.

<b>fdesign Response String</b>	<b>Description</b>
<code>arbgrpdelay</code>	<code>fdesign.arbgrpdelay</code> creates an object to specify allpass arbitrary group delay filters. Requires the DSP System Toolbox
<code>arbmag</code>	<code>fdesign.arbmag</code> creates an object to specify IIR filters that have arbitrary magnitude responses defined by the input arguments.
<code>arbmagnphase</code>	<code>fdesign.arbmagnphase</code> creates an object to specify IIR filters that have arbitrary magnitude and phase responses defined by the input arguments. Requires the DSP System Toolbox.
<code>audioweighting</code>	<code>fdesign.audioweighting</code> creates a filter specification object for audio weighting filters. The supported audio weighting types are: A, C, C-message, ITU-T 0.41, and ITU-R 468-4 weighting. Requires the DSP System Toolbox
<code>bandpass</code>	<code>fdesign.bandpass</code> creates an object to specify bandpass filters.
<code>bandstop</code>	<code>fdesign.bandstop</code> creates an object to specify bandstop filters.

<b>fdesign Response String</b>	<b>Description</b>
<code>ciccomp</code>	<code>fdesign.ciccomp</code> creates an object to specify filters that compensate for the CIC decimator or interpolator response curves. Requires the DSP System Toolbox.
<code>comb</code>	<code>fdesign.comb</code> creates an object to specify a notching or peaking comb filter. Requires the DSP System Toolbox.
<code>decimator</code>	<code>fdesign.decimator</code> creates an object to specify decimators. Requires the DSP System Toolbox.
<code>differentiator</code>	<code>fdesign.differentiator</code> creates an object to specify an FIR differentiator filter.
<code>fracdelay</code>	<code>fdesign.fracdelay</code> creates an object to specify fractional delay filters. Requires the DSP System Toolbox.
<code>halfband</code>	<code>fdesign.halfband</code> creates an object to specify halfband filters. Requires the DSP System Toolbox.
<code>highpass</code>	<code>fdesign.highpass</code> creates an object to specify highpass filters.
<code>hilbert</code>	<code>fdesign.hilbert</code> creates an object to specify an FIR Hilbert transformer.
<code>interpolator</code>	<code>fdesign.interpolator</code> creates an object to specify interpolators. Requires the DSP System Toolbox.
<code>isinchp</code>	<code>fdesign.isinchp</code> creates an object to specify an inverse sinc highpass filter. Requires the DSP System Toolbox.

<b>fdesign Response String</b>	<b>Description</b>
isinclp	<code>fdesign.isinclp</code> creates an object to specify an inverse sinc lowpass filters. Requires the DSP System Toolbox.
lowpass	<code>fdesign.lowpass</code> creates an object to specify lowpass filters.
notch	<code>fdesign.notch</code> creates an object to specify notch filters. Requires the DSP System Toolbox.
nyquist	<code>fdesign.nyquist</code> creates an object to specify nyquist filters. Requires the DSP System Toolbox.
octave	<code>fdesign.octave</code> creates an object to specify octave and fractional octave filters. Requires the DSP System Toolbox.
parameq	<code>fdesign.parameq</code> creates an object to specify parametric equalizer filters. Requires the DSP System Toolbox.
peak	<code>fdesign.peak</code> creates an object to specify peak filters. Requires the DSP System Toolbox.
polysrc	<code>fdesign.polysrc</code> creates an object to specify polynomial sample-rate converter filters. Requires the DSP System Toolbox.
pulseshaping	<code>fdesign.pulseshaping</code> creates an object to specify pulse-shaping filters.
rsrc	<code>fdesign.rsrc</code> creates an object to specify rational-factor sample-rate converters. Requires the DSP System Toolbox.

Use the doc `fdesign.response` syntax at the MATLAB prompt to get help on a specific structure. Using `doc` in a syntax like

```
doc fdesign.lowpass
doc fdesign.bandstop
```

gets more information about the lowpass or bandstop structure objects.

Each response has a property `Specification` that defines the specifications to use to design your filter. You can use defaults or specify the `Specification` property when you construct the specifications object.

With the strings for the `Specification` property, you provide filter constraints such as the filter order or the passband attenuation to use when you construct your filter from the specification object.

## Properties

`fdesign` returns a filter specification object. Every filter specification object has the following properties.

Property Name	Default Value	Description
Response	Depends on the chosen type	Defines the type of filter to design, such as an interpolator or bandpass filter. This is a read-only value.
Specification	Depends on the chosen type	Defines the filter characteristics used to define the desired filter performance, such as the cutoff frequency $F_c$ or the filter order $N$ .

Property Name	Default Value	Description
Description	Depends on the filter type you choose	Contains descriptions of the filter specifications used to define the object, and the filter specifications you use when you create a filter from the object. This is a read-only value.
NormalizedFrequency	Logical true	Determines whether the filter calculation uses normalized frequency from 0 to 1, or the frequency band from 0 to $F_s/2$ , the sampling frequency. Accepts either true or false without single quotation marks. Audio weighting filters do not support normalized frequency.

In addition to these properties, filter specification objects may have other properties as well, depending on whether they design `dfilt` objects or `mfilt` objects.

Added Properties for <code>mfilt</code> Objects	Description
DecimationFactor	Specifies the amount to decrease the sampling rate. Always a positive integer.
InterpolationFactor	Specifies the amount to increase the sampling rate. Always a positive integer.
PolyphaseLength	Polyphase length is the length of each polyphase subfilter that composes the decimator or interpolator or rate-change

Added Properties for mfilt Objects	Description
	factor filters. Total filter length is the product of p1 and the rate change factors. p1 must be an even integer.

`d = fdesign.response(spec)`. In `spec`, you specify the variables to use that define your filter design, such as the passband frequency or the stopband attenuation. The specifications are applied to the filter design method you choose to design your filter.

For example, when you create a default lowpass filter specification object, `fdesign.lowpass` sets the passband frequency `Fp`, the stopband frequency `Fst`, the stopband attenuation `Ast`, and the passband ripple `Ap` :

```
H = fdesign.lowpass
% Without a terminating semicolon
% the filter specifications are displayed
```

The default specification '`Fp,Fst,Ap,Ast`' is only one of the possible specifications for `fdesign.lowpass`. To see all available specifications:

```
H = fdesign.lowpass;
set(H, 'specification')
```

The DSP System Toolbox software supports all available specification strings. The Signal Processing Toolbox supports a subset of the specification strings. See the reference pages for the filter specification object to determine which specification strings your installation supports.

One important note is that the specification string you choose determines which design methods apply to the filter specifications object.

Specifications that do not contain the filter order result in minimum order designs when you invoke the `design` method:

```
d = fdesign.lowpass;
% Specification is Fp,Fst,Ap,Ast
Hd = design(d,'equiripple');
length(Hd.Numerator) % returns 43
% Filter order is 42
fvtool(Hd) %view magnitude
```

`d = fdesign.response(...,Fs)` specifies the sampling frequency in Hz to use in the filter specifications. The sampling frequency is a scalar trailing all other input arguments. If you specify a sampling frequency, all frequency specifications are in Hz.

`d = fdesign.response(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of the following strings:

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in decibels
- 'squared' — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Using Filter Design Methods with Specification Objects

After you create a filter specification object, you use a filter design method to implement your filter with a selected algorithm. Use `designmethods` to determine valid design methods for your filter specification object.

```
d = fdesign.lowpass('N,Fc,Ap,Ast',10,0.2,0.5,40);
designmethods(d)
% Design FIR equiripple filter
hd = design(d,'equiripple');
```

When you use any of the design methods without providing an output argument, the resulting filter design appears in FVTool by default.

Along with filter design methods, `fdesign` works with supporting methods that help you create filter specification objects or determine which design methods work for a given specifications object.

<b>Supporting Function</b>	<b>Description</b>
<code>setspecs</code>	Set all of the specifications simultaneously.
<code>designmethods</code>	Return the design methods.
<code>designopts</code>	Return the input arguments and default values that apply to a specifications object and method

You can set filter specification values by passing them after the `Specification` argument, or by passing the values without the `Specification` string.

Filter object constructors take the input arguments in the same order as `setspecs` and the order in the strings for `Specification`. Enter `doc setspecs` at the prompt for more information about using `setspecs`.

When the first input to `fdesign` is not a valid `Specification` string like `'n,fc'`, `fdesign` assumes that the input argument is a filter specification and applies it using the default `Specification` string —`fp,fst,ap,ast` for a lowpass object, for example.

## Examples

The following examples require only the Signal Processing Toolbox.

### Example 1—Bandstop Filter

A bandstop filter specification object for data sampled at 8 kHz. The stopband between 2 and 2.4 kHz is attenuated at least 80 dB:

```
H = fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2',...
    1600,2000,2400,2800,1,80,1,8000);
```

### Example 2—Lowpass Filter

A lowpass filter specification object for data sampled at 10 kHz. The passband frequency is 500 Hz and the stopband frequency is 750 Hz.

The passband ripple is set to 1 dB and the required attenuation in the stopband is 80 dB.

```
H = fdesign.lowpass('Fp,Fst,Ap,Ast',500,750,1,80,10000);
```

### Example 3—Highpass Filter

A default highpass filter specification object.

```
H = fdesign.highpass % Creates specifications object.  
H.Description
```

Notice the correspondence between the property values in **Specification** and **Description** — in **Description** you see in words the definitions of the variables shown in **Specification**.

### Example 4—Filter Specification and Design

Lowpass Butterworth filter specification object

Use a filter specification object to construct a lowpass Butterworth filter with default **Specification** 'Fp,Fst,Ap,Ast'. Set the passband edge frequency to  $0.4\pi$  radians/sample, a stopband frequency of  $0.5\pi$  radians/sample, a passband ripple of 1 dB, and 80 dB of stopband attenuation.

```
d = fdesign.lowpass(0.4,0.5,1,80);
```

Determine which design methods apply to d.

```
designmethods(d)
```

You can use d and the butter design method to design a Butterworth filter.

```
hd = design(d,'butter','matchexactly','passband');  
fvtool(hd);
```

The resulting filter magnitude response shown by FVTool appears in the following figure.

If you have the DSP System Toolbox software installed, the preceding figure appears with the filter specification mask.

# fdesign.arbgrpdelay

---

**Purpose** Arbitrary group delay filter specification object

**Syntax**

```
D = fdesign.arbgrpdelay(SPEC)
D = fdesign.arbgrpdelay(SPEC,SPEC1,SPEC2,...)
D = fdesign.arbgrpdelay(N,F,Gd)
D = fdesign.arbgrpdelay(...,Fs)
```

**Description** Arbitrary group delay filters are allpass filters you can use for correcting phase distortion introduced by other filters. `fdesign.arbgrpdelay` uses an iterative least  $p$ -th norm optimization procedure to minimize the phase response error [1].

`D = fdesign.arbgrpdelay(SPEC)` specifies an allpass arbitrary group delay filter with the `Specification` property set to `SPEC`. See “Input Arguments” on page 4-493 for a description of supported specifications.

`D = fdesign.arbgrpdelay(SPEC,SPEC1,SPEC2,...)` initializes the allpass arbitrary group delay filter specification object with specifications `SPEC1,SPEC2,...`. See `SPEC` for a description of supported specifications.

`D = fdesign.arbgrpdelay(N,F,Gd)` specifies an allpass arbitrary group delay filter. The filter order is equal to `N`, frequency vector equal to `F`, and group delay vector equal to `Gd`. See `SPEC` for a description of the filter order, frequency vector, and group delay vector inputs. See the example Allpass Filter with Arbitrary Group Delay for an example using this syntax.

`D = fdesign.arbgrpdelay(...,Fs)` specifies the sampling frequency in hertz as a trailing scalar. If you do not specify a sampling frequency, all frequencies are normalized frequencies and group delay values are in samples. If you specify a sampling frequency, group delay values are in seconds.

**Tips** If your arbitrary group delay design produces the error `Poorly conditioned Hessian matrix`, attempt one or more of the following:

- Set the `MaxPoleRadius` IIR lp norm design option to some number less than 1. Set this option when you design your filter with the syntax:

```
design(d, 'iirlpnorm', 'MaxPoleRadius', 0.95)
```

See the Frequency Dispersion and Multiband Delay Equalization examples for the use of the `MaxPoleRadius` design option.

- Reduce the order of your filter design.

## Input Arguments

### SPEC

Specification string. SPEC is one of the following two strings. The entries are not case sensitive.

- 'N,F,Gd'
- 'N,B,F,Gd'

The string entries are defined as follows:

- N — Filter order. This value must be an even positive integer. The numerator and denominator orders are both equal to N. “Allpass Systems” on page 4-495 explains why the numerator and denominator filter orders are equal and the order must be even in `fdesign.arbgrpdelay`.
- F — Frequency vector for the group delay specifications. The elements of the frequency vector must increase monotonically. If you do not specify a sampling frequency, `Fs`, in hertz, the frequencies are normalized frequencies. For a single-band design, the first element of the normalized frequency vector must be zero and the last element must be 1. These correspond to 0 and  $\pi$  radians/sample respectively. For multiband designs, the union of the frequency vectors must range from [0,1].

If you specify a sampling frequency, `Fs`, the first element of the frequency vector in a single-band design must be 0. The last element must be the Nyquist frequency, `Fs/2`. For multiband designs, the union of the frequency vectors must range from [0,`Fs/2`].

- **Gd** — Group delay vector. A vector with nonnegative elements equal in length to the frequency vector, **F**. The elements of **Gd** specify the nonnegative group delay at the corresponding element of the frequency vector, **F**.

If you do not specify a sampling frequency, **F<sub>s</sub>**, in Hertz, the group delays are in samples. If you specify a sampling frequency, the group delays are in seconds.

- **B** — Number of frequency bands. If you use this specification, you must specify a frequency and group delay vector for each band. The union of the frequency vectors must range from [0,1] in normalized frequency, or [0,**F<sub>s</sub>/2**] when a sampling frequency is specified. The elements in the union of the frequency bands must be monotonically increasing.

For example:

```
filterorder = 14;
freqband1 = [0 0.1 0.4]; grpdelay1 = [1 2 3];
freqband2 = [0.5 0.8 1]; grpdelay2 = [3 2 1];
D = fdesign.arbgrpdelay('N,B,F,Gd',filterorder,2,freqband1,grpdelay1,freqband2,grpdelay2)
```

**Default:** 'N,F,Gd'

## **F<sub>s</sub>**

Sampling frequency. Specify the sampling frequency as a trailing positive scalar after all other input arguments. Specifying a sampling frequency forces the group delay units to be in seconds. If you specify a sampling frequency, the first element of the frequency vector must be 0. The last element must be the Nyquist frequency, **F<sub>s</sub>/2**.

## **Output Arguments**

### **D**

Filter specification object. An allpass arbitrary group delay filter specification object containing the following modifiable properties: **Specification**, **NormalizedFrequency**, **FilterOrder**, **Frequencies**, and **GroupDelay**.

Use the `normalizefreq` method to change the `NormalizedFrequency` property after construction.

## Definitions **Group Delay in Discrete-Time Filter Design**

The frequency response of a rational discrete-time filter is:

$$H(e^{j\omega}) = \frac{B(e^{j\omega})}{A(e^{j\omega})}$$

The argument of the frequency response as a function of the angle,  $\omega$ , is referred to as the *phase response*.

The negative of the first derivative of the argument with respect to  $\omega$  is the group delay.

$$\tau(\omega) = -\frac{d}{d\omega} \text{Arg}(H(e^{j\omega}))$$

Systems with nonlinear phase responses have nonconstant group delay, which causes dispersion of the frequency components of the signal. You may not want this phase distortion even if the magnitude distortion introduced by the filter produces the desired effect. See [Frequency Dispersion](#) for an illustration of frequency dispersion resulting from nonconstant group delay.

In these cases, you can cascade the frequency-selective filter with an allpass filter that compensates for the group delay. This process is often referred to as *delay equalization*.

### Allpass Systems

The general form of an allpass system function with a real-valued impulse response is:

$$H_{ap}(z) = \prod_{k=1}^M \frac{z^{-1} - d_k}{1 - d_k z^{-1}} \prod_{k=1}^N \frac{(z^{-1} - c_k)(z^{-1} - c_k^*)}{(1 - c_k z^{-1})(1 - c_k^* z^{-1})}$$

where the  $d_k$  denote the real-valued poles and the  $c_k$  denote the complex-valued poles, which occur in conjugate pairs.

The preceding equation demonstrates that allpass systems with real-valued impulse responses have  $2N+M$  zeros and poles. The poles and zeros occur in pairs with reciprocal magnitudes. The filter order is always the same for the numerator and denominator.

Because `fdesign.arbgrpdelay` uses robust second-order section (biquad) filter structures to implement the allpass arbitrary group delay filter, the filter order must be even.

## Examples

Construct a signal consisting of two discrete-time windowed sinusoids (wave packets) with disjoint time support to illustrate frequency dispersion. One discrete-time sinusoid has a frequency of  $\pi/2$  radians/sample and the other has a frequency of  $\pi/4$  radians/sample. There are 9 periods of the higher-frequency sinusoid that precede 5 periods of the lower-frequency signal.

Create the signal.

```
x = zeros(300,1);
x(1:36) = cos(pi/2*(0:35)).*hamming(36)';
x(40:40+39) = cos(pi/4*(0:39)).*hamming(40)';
```

Create an arbitrary group delay filter that delays the higher-frequency wave packet by approximately 100 samples.

```
N = 18;
f = 0:.1:1;
gd = ones(size(f));
% Delay pi/2 radians/sample by 100 samples
gd(6) = 100;
d = fdesign.arbgrpdelay(N,f,gd);
Hd = design(d,'iirlpnorm','MaxPoleRadius',0.9);
% Visualize the group delay
fvtool(Hd,'analysis','grpdelay');
```

Filter the input signal with the arbitrary group delay filter and illustrate the frequency dispersion. The high-frequency wave packet, which initially preceded the low-frequency wave packet, now occurs later because of the nonconstant group delay.

```
y = filter(Hd,x);
subplot(211)
plot(x); title('Input Signal');
grid on; ylabel('Amplitude');
subplot(212);
plot(y); title('Output Signal'); grid on;
```

# fdesign.arbgrpdelay

---

```
xlabel('Samples'); ylabel('Amplitude');
```

---

Design an allpass filter with an arbitrary group delay.

```
N = 10;  
f = [0 0.02 0.04 0.06 0.08 0.1 0.25 0.5 0.75 1];  
g = [5 5 5 5 5 5 4 3 2 1];  
w = [2 2 2 2 2 2 1 1 1 1];  
hgd = fdesign.arbgrpdelay(N,f,g);  
Hgd = design(hgd,'iirlpnorm','Weights',w,'MaxPoleRadius',0.95);
```

```
fvtool(Hgd,'Analysis','grpdelay') ;
```

Perform multiband delay equalization outside the stopband.

```
Fs = 1e3;  
Hcheby2 = design(fdesign.bandstop('N,Fst1,Fst2,Ast',10,150,400,60,Fs));  
f1 = 0.0:0.5:150; % Hz  
g1 = grpdelay(Hcheby2,f1,Fs) ./ Fs; % seconds  
f2 = 400:0.5:500; % Hz  
g2 = grpdelay(Hcheby2,f2,Fs) ./ Fs; % seconds
```

# fdesign.arbgrpdelay

```
maxg = max([g1 g2]);  
% Design an arbitrary group delay allpass filter to equalize the group  
% delay of the bandstop filter. Use an order 18 multiband design and spec  
% two bands.  
hgd = fdesign.arbgrpdelay('N,B,F,Gd',18,2,f1,maxg-g1,f2,maxg-g2,Fs);  
Hgd = design(hgd,'iirlpnorm','MaxPoleRadius',0.95);  
Hcascade = cascade(Hcheby2,Hgd);  
hft = fvtool(Hcheby2,Hgd,Hcascade,'Analysis','grpdelay','Fs',Fs);  
legend(hft,'Original Bandstop Filter','Allpass Arbitrary Group Delay  
'Delay Equalization','Location','North');
```

## Algorithms

fdesign.arbgrpdelay uses a least  $p$ -th norm iterative optimization described in [1].

## References

[1] Antoniou, A. *Digital Signal Processing: Signals, Systems, and Filters.*, New York:McGraw-Hill, 2006, pp. 719–771.

## Alternatives

iirgrpdelay — Returns an allpass arbitrary group delay filter. The iirgrpdelay function returns the numerator and denominator coefficients. This behavior differs from that of fdesign.arbgrpdelay, which returns the filter in second-order sections. iirgrpdelay accepts only normalized frequencies.

fdesign | design | iirgrpdelay

## How To

- “Design a Filter in Fdesign — Process Overview”

# fdesign.arbmag

---

**Purpose** Arbitrary response magnitude filter specification object

**Syntax**

```
D = fdesign.arbmag
D = fdesign.arbmag(SPEC)
D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)
D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)
D = fdesign.arbmag(...,Fs)
```

**Description** D = fdesign.arbmag constructs an arbitrary magnitude filter specification object D.

D = fdesign.arbmag(SPEC) initializes the Specification property to SPEC. The input argument SPEC must be one of the strings shown in the following table. Specification strings are not case sensitive.

---

**Note** Specifications strings marked with an asterisk require the DSP System Toolbox software.

---

- 'N,F,A' — Single band design (default)
- 'F,A,R' — Single band minimum order design \*
- 'N,B,F,A' — Multiband design
- 'N,B,F,A,C' — Constrained multiband design \*
- 'B,F,A,R' — Multiband minimum order design \*
- 'Nb,Na,F,A' — Single band design \*
- 'Nb,Na,B,F,A' — Multiband design \*

The string entries are defined as follows:

- A — Amplitude vector. Values in A define the filter amplitude at frequency points you specify in f, the frequency vector. If you use A, you must use F as well. Amplitude values must be real. For complex values designs, use fdesign.arbmagnphase.
- B — Number of bands in the multiband filter

- **C** — Constrained band flag. This enables you to constrain the passband ripple in your multiband design. You cannot constrain the passband ripple in all bands simultaneously.
- **F** — Frequency vector. Frequency values in specified in **F** indicate locations where you provide specific filter response amplitudes. When you provide **F**, you must also provide **A**.
- **N** — Filter order for FIR filters and the numerator and denominator orders for IIR filters.
- **Nb** — Numerator order for IIR filters
- **Na** — Denominator order for IIR filter designs
- **R** — Ripple

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

### Specifying Frequency and Amplitude Vectors

**F** and **A** are the input arguments you use to define the filter response desired. Each frequency value you specify in **F** must have a corresponding response value in **A**. The following table shows how **F** and **A** are related.

Define the frequency vector **F** as [0 0.25 0.3 0.4 0.5 0.6 0.7 0.75 1.0]

Define the response vector **A** as [1 1 0 0 0 0 1 1]

These specifications connect **F** and **A** as shown here:

<b>F (Normalized Frequency)</b>	<b>A (Response Desired at F)</b>
0	1
0.25	1
0.3	0
0.4	0

<b>F (Normalized Frequency)</b>	<b>A (Response Desired at F)</b>
0.5	0
0.6	0
0.7	0
0.75	1
1.0	1

Different specifications can have different design methods available. Use `designmethods` to get a list of design methods available for a given specification string and filter specification object.

Use `designopts` to get a list of design options available for a filter specification object and a given design method. Enter `help(D,METHOD)` to get detailed help on the available design options for a given design method.

`D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)` initializes the specifications with `specvalue1`, `specvalue2`. Use `get(D,'Description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ... `specvalueN`.

`D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)` uses the default specification string 'N,F,A', setting the filter order, filter frequency vector, and the amplitude vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`D = fdesign.arbmag(...,Fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `Fs`.

## Examples

### Design of a multiband arbitrary-magnitude filter

Use `fdesign.arbmag` to design a 3-band filter.

Use the given frequency and amplitude vectors in “Specifying Frequency and Amplitude Vectors” on page 4-503.

```
N = 150;
B = 3;
F = [0 .25 .3 .4 .5 .6 .7 .75 1];
A = [1 1 0 0 0 0 0 1 1];
A1 = A(1:2);
A2 = A(3:7);
A3 = A(8:end);
F1 = F(1:2);
F2 = F(3:7);
F3 = F(8:end);
d = fdesign.arbmag('N,B,F,A',N,B,F1,A1,F2,A2,F3,A3);
Hd = design(d);
fvtool(Hd)
```

A response with two passbands — one roughly between 0 and 0.25 and the second between 0.75 and 1 — results from the mapping between F and A.

## Design of a single band arbitrary-magnitude filter

Use `fdesign.arbmag` to design a single band equiripple filter.

```
n = 120;  
f = linspace(0,1,100); % 100 frequency points.  
as = ones(1,100)-f*0.2;  
absorb = [ones(1,30), (1-0.6*bohmanwin(10))', ...  
ones(1,5), (1-0.5*bohmanwin(8))', ones(1,47)];  
a = as.*absorb;  
d = fdesign.arbmag('N,F,A',n,f,a);  
hd1 = design(d,'equiripple');
```

If you have the DSP System Toolbox, you can design a minimum-phase equiripple filter.

```
hd2 = design(d,'equiripple','MinPhase',true);  
hfvt = fvtool([hd1 hd2],'analysis','polezero');  
legend(hfvt,'Equiripple Filter','Minimum-phase Equiripple Filter');
```

## Design of a multiband minimum order arbitrary-magnitude filter

Use `fdesign.arbmag` to design a multiband minimum order filter.

This example requires the DSP System Toolbox.

Place the notches at  $0.25\pi$  and  $0.55\pi$  radians/sample

```
d = fdesign.arbmag('B,F,A,R');  
d.NBands = 5;  
d.B1Frequencies = [0 0.2];  
d.B1Amplitudes = [1 1];  
d.B1Ripple = 0.25;  
d.B2Frequencies = 0.25;  
d.B2Amplitudes = 0;  
d.B3Frequencies = [0.3 0.5];  
d.B3Amplitudes = [1 1];  
d.B3Ripple = 0.25;  
d.B4Frequencies = 0.55;  
d.B4Amplitudes = 0;  
d.B5Frequencies = [0.6 1];  
d.B5Amplitudes = [1 1];  
d.B5Ripple = 0.25;  
Hd = design(d,'equiripple');  
fvtool(Hd)
```

## Design of a multiband constrained arbitrary-magnitude filter

Use `fdesign.arbmag` to design a multiband constrained FIR filter.

This example requires the DSP System Toolbox.

Force the frequency response at  $0.15\pi$  radians/sample to 0 dB.

```
d = fdesign.arbmag('N,B,F,A,C',82,2);  
d.B1Frequencies = [0 0.06 .1];  
d.B1Amplitudes = [0 0 0];  
d.B2Frequencies = [.15 1];  
d.B2Amplitudes = [1 1];
```

```
% Design a filter with no constraints
Hd1 = design(d,'equiripple','B2ForcedFrequencyPoints',0.15);
% Add a constraint to the first band to increase attenuation
d.B1Constrained = true;
d.B1Ripple = .001;
Hd2 = design(d,'equiripple','B2ForcedFrequencyPoints',0.15);
hfvtool(Hd1,Hd2);
legend(hfvtool,'Original Design','Design with Constrained Stopband Ripple');
```

**See Also**

[design](#) | [designmethods](#) | [fdesign](#)

# fdesign.arbmagnphase

**Purpose** Arbitrary response magnitude and phase filter specification object

**Syntax**

```
d = fdesign.arbmagnphase
d = fdesign.arbmagnphase(specification)
d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,
    ...)
d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)
d = fdesign.arbmagnphase(...,fs)
```

**Description** `d = fdesign.arbmagnphase` constructs an arbitrary magnitude filter specification object `d`.

`d = fdesign.arbmagnphase(specification)` initializes the `Specification` property for specifications object `d` to the string in `specification`. The input argument `specification` must be one of the strings shown in the following table. Specification strings are not case sensitive.

Specification String	Description of Resulting Filter
<code>n, f, h</code>	Single band design (default). FIR and IIR ( <code>n</code> is the order for both numerator and denominator).
<code>n, b, f, h</code>	FIR multiband design where <code>b</code> defines the number of bands.
<code>nb, na, f, h</code>	IIR single band design.

The following table describes the arguments in the strings.

Argument	Description
<code>b</code>	Number of bands in the multiband filter.
<code>f</code>	Frequency vector. Frequency values specified in <code>f</code> indicate locations where you provide specific filter response amplitudes. When you provide <code>f</code> you must also provide <code>h</code> which contains the response values.

Argument	Description
h	Complex frequency response values.
n	Filter order for FIR filters and the numerator and denominator orders for IIR filters (when not specified by nb and na).
nb	Numerator order for IIR filters.
na	Denominator order for IIR filter designs.

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

## Specifying f and h

f and h are the input arguments you use to define the filter response desired. Each frequency value you specify in f must have a corresponding response value in h. This example creates a filter with two passbands (b = 4) and shows how f and h are related. This example is for illustration only. It is not an actual filter.

Define the frequency vector f as [0 0.1 0.2 0.4 0.5 0.6 0.9 1.0]

Define the response vector h as [0 0.5 0.5 0.1 0.1 0.8 0.8 0]

These specifications connect f and h as shown in the following table.

f (Normalized Frequency)	h (Response Desired at f)
0	0
0.1	0.5
0.2	0.5
0.4	0.1
0.5	0.1
0.6	0.8

# fdesign.arbmagnphase

<b>f (Normalized Frequency)</b>	<b>h (Response Desired at f)</b>
0.9	0.8
1.0	0.0

A response with two passbands—one roughly between 0.1 and 0.2 and the second between 0.6 and 0.9—results from the mapping between  $f$  and  $h$ . Plotting  $f$  and  $h$  yields the following figure that resembles a filter with two passbands.

The second example in Examples shows this plot in more detail with a complex filter response for  $h$ . In the example,  $h$  uses complex values for the response.

Different specification types often have different design methods available. Use `designmethods(d)` to get a list of design methods available for a given specification string and specifications object.

```
d =  
fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)  
initializes the filter specification object with specvalue1, specvalue2,  
and so on. Use get(d, 'description') for descriptions of the various  
specifications specvalue1, specvalue2, ...specn.
```

```
d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)  
uses the default specification string n,f,h, setting the filter order, filter  
frequency vector, and the complex frequency response vector to the  
values specvalue1, specvalue2, and specvalue3.
```

```
d = fdesign.arbmagnphase(...,fs) specifies the sampling frequency  
in Hz. All other frequency specifications are also assumed to be in Hz  
when you specify fs.
```

## Examples

Use `fdesign.arbmagnphase` to model a complex analog filter:

```
d=fdesign.arbmagnphase('n,f,h',100); % N=100, f and h set to defaults.  
design(d,'freqsamp');
```

For a more complex example, design a bandpass filter with low group delay by specifying the desired delay and using `f` and `h` to define the filter bands.

```
n = 50;      % Group delay of a linear phase filter would be 25.  
gd = 12;    % Set the desired group delay for the filter.  
f1=linspace(0,.25,30); % Define the first stopband frequencies.  
f2=linspace(.3,.56,40);% Define the passband frequencies.  
f3=linspace(.62,1,30); % Define the second stopband frequencies.  
h1 = zeros(size(f1)); % Specify the filter response at the freqs in f1.  
h2 = exp(-1j*pi*gd*f2); % Specify the filter response at the freqs in f2.  
h3 = zeros(size(f3)); % Specify the response at the freqs in f3.  
d=fdesign.arbmagnphase('n,b,f,h',50,3,f1,h1,f2,h2,f3,h3);  
D = design(d,'equiripple');  
fvtool(D,'Analysis','freq');
```

# fdesign.arbmagnphase

## Purpose

Audio weighting filter specification object

## Syntax

```
HAWf = fdesign.audioweighting  
HAWf = fdesign.audioweighting(spec)  
HAWf = fdesign.audioweighting(spec,specvalue1,specvalue2)  
HAWf = fdesign.audioweighting(specvalue1,specvalue2)  
HAWf = fdesign.audioweighting(...,Fs)
```

## Description

Supported audio weighting filter types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468–4 weighting.

*HAWf* = fdesign.audioweighting constructs an audio weighting filter specification object *HAWf* with a weighting type of A and a filter class of 1. Use the `design` method to instantiate a `dfilt` object based on the specifications in *HAWf*. Use `designmethods` to find valid filter design methods. Because the standards for audio weighting filters are in Hz, normalized frequency specifications are not supported for `fdesign.audioweighting` objects. The default sampling frequency for A weighting, C weighting, C-message, and ITU-T 0.41 filters is 48 kHz. The default sampling frequency for the ITU-R 468–4 filter is 80 kHz. If you invoke the `normalizefreq` method, a warning is issued when you instantiate the `dfilt` object and the default sampling frequencies in Hz are used.

*HAWf* = fdesign.audioweighting(*spec*) returns an audio weighting filter specification object using default values for the specification string in *spec*. The following are valid entries for *spec*. The entries are not case sensitive.

- 'WT,Class' (default *spec*)

The 'WT,Class' specification is valid for A weighting and C weighting filters of class 1 or 2.

The weighting type is specified by the string: 'A' or 'C'. The class is the scalar 1 or 2.

The default values for 'WT,Class' are 'A',1.

- 'WT'

The 'WT' specification is valid for C-message (default), ITU-T 0.41, and ITU-R 468–4 weighting filters.

The weighting type is specified by the string: 'Cmessage', 'ITUT041', or 'ITUR4684'.

*HAwf* = fdesign.audioweighting(*spec*,*specvalue1*,*specvalue2*) constructs an audio weighting filter specification object *HAwf* and sets its specifications at construction time.

*HAwf* = fdesign.audioweighting(*specvalue1*,*specvalue2*) constructs an audio weighting filter specification object *HAwf* with the specification 'WT,Class' using the values you provide. The valid weighting types are 'A' or 'C'.

*HAwf* = fdesign.audioweighting(...,*Fs*) specifies the sampling frequency in Hz. The sampling frequency is a scalar trailing all other input arguments.

## Input Arguments

### Parameter Name/Value Pairs

#### 'WT'

Weighting type

The weighting type defines the frequency response of the filter. The valid weighting types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468–4 weighting. The weighting types are described in “Definitions” on page 4-517.

#### 'Class'

Filter Class

Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards [1], [2]. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in *fvtool* for the analysis of the filter design.

Default: 1

## Definitions

### A weighting

The specifications for the A weighting filter are found in ANSI standard S1.42-2001. The A weighting filter is based on the 40-phon Fletcher-Munson equal loudness contour [3]. One phon is equal to one dB sound pressure level (SPL) at one kHz. The Fletcher-Munson equal loudness contours are designed to account for frequency and level dependent differences in the perceived loudness of tonal stimuli. The 40-phon contour reflects the fact that the human auditory system is more sensitive to frequencies around 1–2 kHz than lower and higher frequencies. The filter roll off is more pronounced at lower frequencies and more modest at higher frequencies. While A weighting is based on the equal loudness contour for low-level (40-phon) tonal stimuli, it is commonly used in the United States for assessing potential health risks associated with noise exposure to narrowband and broadband stimuli at high levels.

### C weighting

The specifications for the C weighting filter are found in ANSI standard S1.42-2001. The C weighting filter approximates the 100-phon Fletcher-Munson equal loudness contour for tonal stimuli. The C weighting magnitude response is essentially flat with 3-dB frequencies at 31.5 Hz and 8000 Hz. While C weighting is not as common as A weighting, sound level meters frequently have a C weighting filter option.

### C-message

The specifications for the C-message weighting filter are found in Bell System Technical Reference, PUB 41009. C-message weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [6]. C-message weighting filters are commonly used in North America, while the ITU-T 0.41 filter is more commonly used outside of North America.

## ITU-R 468-4

The specifications for the ITU-R 468-4 weighting filter are found in the International Telecommunication Union Recommendation ITU-R BS.468-4. ITU-R 468-4 is an equal loudness contour weighting filter. Unlike the A weighting filter, the ITU-R 468-4 filter describes subjective loudness judgements for broadband stimuli [4]. A common criticism of the A weighting filter is that it underestimates the loudness judgement of real-world stimuli particularly in the frequency band from about 1–9 kHz. A comparison of A weighting and ITU-R 468-4 weighting curves shows that the ITU-R 468-4 curve applies more gain between 1 and 10 kHz with a peak difference of approximately 12 dB around 6–7 kHz.

## ITU-T 0.41

The specifications for the ITU-T 0.41 filter are found in the ITU-T Recommendation 0.41. ITU-T 0.41 weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [5]. ITU-T 0.41 weighting filters are commonly used outside of North America, while the C-message weighting filter is more common in North America.

## Examples

Compare class 1 A weighting and ITU-R 468-4 filters between 0.1 and 12 kHz:

```
HawfA = fdesign.audioweighting('WT,Class','A',1,44.1e3);  
% Sampling frequency is 44.1 kHz  
HawfITUR = fdesign.audioweighting('WT','ITUR4684',44.1e3);  
Afilter = design(HawfA);  
ITURfilter = design(HawfITUR);  
hfvT = fvtool([Afilter ITURfilter]);  
axis([0.1 12 -80 20]);  
legend(hfvT,'A-weighting','ITU-R 468-4');
```

Compare C-message and ITU-T 0.41 filters:

```
hCmessage = fdesign.audioweighting('WT','Cmessage',24e3);
hITUT = fdesign.audioweighting('WT','ITUT041',24e3);
dCmessage = design(hCmessage);
dITUT = design(hITUT);
hfvtool = fvtool([dCmessage dITUT]);
legend(hfvtool,'C-Message Weighting','ITU-T 0.41 Weighting');
axis([0.1 10 -50 5]);
```

# fdesign.audioweighting

Construct an ITU-R 468–4 filter using all available design methods:

```
HAwf = fdesign.audioweighting('WT','ITUR4684');  
ValidDesigns = designmethods(HAwf);  
% returns iirlpnorm,equiripple,freqsamp in cell array  
D = design(HAwf,'all'); % returns all designs  
hfvf = fvtool(D);  
legend(hfvf,'Least P-norm IIR','FIR Equiripple',...  
'FIR Frequency Sampling')
```

## How To

- Audio Weighting Filters Example
- “Design a Filter in Fdesign — Process Overview”

**Purpose** Bandpass filter specification object

**Syntax**

```
D = fdesign.bandpass
D = fdesign.bandpass(SPEC)
D = fdesign.bandpass(spec,specvalue1,specvalue2,...)
D = fdesign.bandpass(specvalue1,specvalue2,specvalue3,
specvalue4,...specvalue4,specvalue5,specvalue6)
D = fdesign.bandpass(...,Fs)
D = fdesign.bandpass(...,MAGUNITS)
```

**Description** D = fdesign.bandpass constructs a bandpass filter specification object D, applying default values for the properties Fstop1, Fpass1, Fpass2, Fstop2, Astop1, Apass, and Astop2 — one possible set of values you use to specify a bandpass filter.

D = fdesign.bandpass(SPEC) constructs object D and sets its Specification property to SPEC. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC are shown below and used to define the bandpass filter. The strings are not case sensitive.

---

**Note** Specifications strings marked with an asterisk require the DSP System Toolbox software.

---

- 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default spec)
- 'N,F3dB1,F3dB2'
- "N,F3dB1,F3dB2,Ap" \*
- 'N,F3dB1,F3dB2,Ast' \*
- 'N,F3dB1,F3dB2,Ast1,Ap,Ast2' \*
- 'N,F3dB1,F3dB2,BWp' \*
- 'N,F3dB1,F3dB2,BWst' \*
- 'N,Fc1,Fc2'

- 'N,Fc1,Fc2,Ast1,Ap,Ast2'
- 'N,Fp1,Fp2,Ap'
- 'N,Fp1,Fp2,Ast1,Ap,Ast2'
- 'N,Fst1,Fp1,Fp2,Fst2'
- 'N,Fst1,Fp1,Fp2,Fst2,C' \*
- 'N,Fst1,Fp1,Fp2,Fst2,Ap' \*
- 'N,Fst1,Fst2,Ast'
- 'Nb,Na,Fst1,Fp1,Fp2,Fst2' \*

The string entries are defined as follows:

- **Ap** — amount of ripple allowed in the pass band. Also called **Apass**.
- **Ast1** — attenuation in the first stop band in decibels (the default units). Also called **Astop1**.
- **Ast2** — attenuation in the second stop band in decibels (the default units). Also called **Astop2**.
- **BWp** — bandwidth of the filter passband. Specified in normalized frequency units.
- **BWst** — bandwidth of the filter stopband. Specified in normalized frequency units.
- **C** — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

In the specification string 'N,Fst1,Fp1,Fp2,Fst2,C', you cannot specify constraints in both stopbands and the passband simultaneously. You can specify constraints in any one or two bands.

- **F3dB1** — cutoff frequency for the point 3 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (IIR filters)

- **F3dB2** — cutoff frequency for the point 3 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (IIR filters)
- **Fc1** — cutoff frequency for the point 6 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (FIR filters)
- **Fc2** — cutoff frequency for the point 6 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (FIR filters)
- **Fp1** — frequency at the edge of the start of the pass band. Specified in normalized frequency units. Also called **Fpass1**.
- **Fp2** — frequency at the edge of the end of the pass band. Specified in normalized frequency units. Also called **Fpass2**.
- **Fst1** — frequency at the edge of the start of the first stop band. Specified in normalized frequency units. Also called **Fstop1**.
- **Fst2** — frequency at the edge of the start of the second stop band. Specified in normalized frequency units. Also called **Fstop2**.
- **N** — filter order for FIR filters. Or both the numerator and denominator orders for IIR filters when **na** and **nb** are not provided.
- **Na** — denominator order for IIR filters
- **Nb** — numerator order for IIR filters

Graphically, the filter specifications look similar to those shown in the following figure.

# fdesign.bandpass

Regions between specification values like  $F_{st1}$  and  $F_{p1}$  are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandpass filter specification object change depending on the Specification string. Use `designmethods` to determine which design methods apply to an object and the Specification property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, METHOD.

`D = fdesign.bandpass(spec,specvalue1,specvalue2,...)`  
constructs an object D and sets its specifications at construction time.

`D = fdesign.bandpass(specvalue1,specvalue2,specvalue3,specvalue4,...specvalue4,specvalue5,specvalue6)`  
constructs D with the default Specification property string, using the values you provide as input arguments for `specvalue1,specvalue2,specvalue3,specvalue4,specvalue4,specvalue5,specvalue6` and `specvalue7`.

`D = fdesign.bandpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.bandpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

Filter a discrete-time signal with a bandpass filter. The signal is a sum of three discrete-time sinusoids,  $\pi/8$ ,  $\pi/2$ , and  $3\pi/4$  radians/sample.

```
n = 0:159;  
x = cos(pi/8*n)+cos(pi/2*n)+sin(3*pi/4*n);
```

Design an FIR equiripple bandpass filter to remove the lowest and highest discrete-time sinusoids.

```
d = fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2',1/4,3/8,5/8,6/8,  
Hd = design(d,'equiripple');
```

Apply the filter to the discrete-time signal.

```
y = filter(Hd,x);  
freq = 0:(2*pi)/length(x):pi;  
xdft = fft(x);  
ydft = fft(y);  
plot(freq,abs(xdft(1:length(x)/2+1)));  
hold on;  
plot(freq,abs(ydft(1:length(x)/2+1)),'r','linewidth',2);  
legend('Original Signal','Bandpass Signal');
```

## fdesign.bandpass

---

Design an IIR Butterworth filter of order 10 with 3-dB frequencies of 1 and 1.2 kHz. The sampling frequency is 10 kHz

```
d = fdesign.bandpass('N,F3dB1,F3dB2',10,1e3,1.2e3,1e4);  
Hd = design(d,'butter');  
fvtool(Hd)
```

---

This example requires the DSP System Toolbox software.

Design a constrained-band FIR equiripple filter of order 100 with a passband of [1, 1.4] kHz. Both stopband attenuation values are constrained to 60 dB. The sampling frequency is 10 kHz.

```
d = fdesign.bandpass('N,Fst1,Fp1,Fp2,Fst2,C',100,800,1e3,1.4e3,1.6e3,1e4);  
d.Stopband1Constrained = true; d.Astop1 = 60;  
d.Stopband2Constrained = true; d.Astop2 = 60;  
Hd = design(d,'equiripple');  
fvtool(Hd);  
measure(Hd)
```

The passband ripple is slightly over 2 dB. Because the design constrains both stopbands, you cannot constrain the passband ripple.

**Purpose** Bandstop filter specification object

**Syntax**

```
D = fdesign.bandstop
D = fdesign.bandstop(SPEC)
D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)
D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,...
specvalue5,specvalue6,specvalue7)
D = fdesign.bandstop(...,Fs)
D = fdesign.bandstop(...,MAGUNITS)
```

**Description** D = fdesign.bandstop constructs a bandstop filter specification object D, applying default values for the properties Fpass1, Fstop1, Fstop2, Fpass2, Apass1, Astop1 and Apass2.

D = fdesign.bandstop(SPEC) constructs object D and sets the Specification property to SPEC. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC are shown below. The strings are not case sensitive.

---

**Note** Specifications strings marked with an asterisk require the DSP System Toolbox software.

---

- 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default spec)
- 'N,F3dB1,F3dB2'
- 'N,F3dB1,F3dB2,Ap' \*
- 'N,F3dB1,F3dB2,Ap,Ast' \*
- 'N,F3dB1,F3dB2,Ast' \*
- 'N,F3dB1,F3dB2,BWp' \*
- 'N,F3dB1,F3dB2,BWst' \*
- 'N,Fc1,Fc2'

- 'N,Fc1,Fc2,Ap1,Ast,Ap2'
- 'N,Fp1,Fp2,Ap'
- 'N,Fp1,Fp2,Ap,Ast'
- 'N,Fp1,Fst1,Fst2,Fp2'
- 'N,Fp1,Fst1,Fst2,Fp2,C' \*
- 'N,Fp1,Fst1,Fst2,Fp2,Ap' \*
- 'N,Fst1,Fst2,Ast'
- 'Nb,Na,Fp1,Fst1,Fst2,Fp2' \*

The string entries are defined as follows:

- Ap — amount of ripple allowed in the passband in decibels (the default units). Also called Apass.
- Ap1 — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass1.
- Ap2 — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass2.
- Ast — attenuation in the first stopband in decibels (the default units). Also called Astop1.
- BWp — bandwidth of the filter passband. Specified in normalized frequency units.
- BWst — bandwidth of the filter stopband. Specified in normalized frequency units.
- C — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

In the specification string 'N,Fp1,Fst1,Fst2,Fp2,C', you cannot specify constraints simultaneously in both passbands and the stopband. You can specify constraints in any one or two bands.

- $F_{3dB1}$  — cutoff frequency for the point 3 dB point below the passband value for the first cutoff.
- $F_{3dB2}$  — cutoff frequency for the point 3 dB point below the passband value for the second cutoff.
- $F_{c1}$  — cutoff frequency for the point 6 dB point below the passband value for the first cutoff. (FIR filters)
- $F_{c2}$  — cutoff frequency for the point 6 dB point below the passband value for the second cutoff. (FIR filters)
- $F_{p1}$  — frequency at the start of the pass band. Also called  $F_{pass1}$ .
- $F_{p2}$  — frequency at the end of the pass band. Also called  $F_{pass2}$ .
- $F_{st1}$  — frequency at the end of the first stop band. Also called  $F_{stop1}$ .
- $F_{st2}$  — frequency at the start of the second stop band. Also called  $F_{stop2}$ .
- $N$  — filter order.
- $N_a$  — denominator order for IIR filters.
- $N_b$  — numerator order for IIR filters.

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like `Fp1` and `Fst1` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandstop filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design methods apply to an object and the `Specification` property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)`  
constructs an object `D` and sets its specifications at construction time.

`D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,...,specvalue5,specvalue6,specvalue7)` constructs an object `D` with the default `Specification` property string, using the values you provide in `specvalue1`, `specvalue2`, `specvalue3`, `specvalue4`, `specvalue5`, `specvalue6` and `specvalue7`.

`D = fdesign.bandstop(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency. If you specify the sampling frequency as a trailing scalar, all frequencies in the specifications are in Hz as well.

`D = fdesign.bandstop(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

Construct a bandstop filter to reject the discrete frequency band between  $3\pi/8$  and  $5\pi/8$  radians/sample. Apply the filter to a discrete-time signal consisting of the superposition of three discrete-time sinusoids.

Design an FIR equiripple filter and view the magnitude response.

```
d = fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2',2/8,3/8,5/8,6/8,1,1,1);
Hd = design(d,'equiripple');
fvtool(Hd)
```

Construct the discrete-time signal to filter.

```
n = 0:99;
x = cos(pi/5*n)+sin(pi/2*n)+cos(4*pi/5*n);
y = filter(Hd,x);
xdft = fft(x);
ydft = fft(y);
freq = 0:(2*pi)/length(x):pi;
plot(freq,abs(xdft(1:length(x)/2+1)));
hold on;
plot(freq,abs(ydft(1:length(y)/2+1)),'r','linewidth',2);
xlabel('Radians/Sample'); ylabel('Magnitude');
legend('Original Signal','Bandstop Signal');
```

---

Create a Butterworth bandstop filter for data sampled at 10 kHz. The stopband is [1,1.5] kHz. The order of the filter is 20.

```
d = fdesign.bandstop('N,F3dB1,F3dB2',20,1e3,1.5e3,1e4);
Hd = design(d,'butter');
fvtool(Hd);
```

Zoom in on the magnitude response plot to verify that the 3-dB down points are located at 1 and 1.5 kHz.

---

The following example requires the DSP System Toolbox license.

## fdesign.bandstop

---

Design a constrained-band FIR equiripple filter of order 100 for data sampled at 10 kHz. You can specify constraints on at most two of the three bands: two passbands and one stopband. In this example, you choose to constrain the passband ripple to be 0.5 dB in each passband. Design the filter, visualize the magnitude response and measure the filter's design.

```
d = fdesign.bandstop('N,Fp1,Fst1,Fst2,Fp2,C',100,800,1e3,1.5e3,1.7e3,1e4)
d.Passband1Constrained = true; d.Apass1 = 0.5;
d.Passband2Constrained = true; d.Apass2 = 0.5;
Hd = design(d,'equiripple');
fvtool(Hd);
measure(Hd)
```

With this order filter and passband ripple constraints, you achieve approximately 50 dB of stopband attenuation.

### See Also

fdesign, fdesign.bandpass, fdesign.highpass, fdesign.lowpass

**Purpose**

CIC compensator filter specification object

**Syntax**

```
d= fdesign.ciccomp
d= fdesign.ciccomp(d,nsections,rcic)
d= fdesign.ciccomp(...,spec)
h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)
```

**Description**

`d= fdesign.ciccomp` constructs a CIC compensator specifications object `d`, applying default values for the properties `Fpass`, `Fstop`, `Apass`, and `Astop`. In this syntax, the filter has two sections and the differential delay is 1.

Using `fdesign.ciccomp` with a design method creates a `dfilt` object, a single-rate discrete-time filter.

`d= fdesign.ciccomp(d,nsections,rcic)` constructs a CIC compensator specifications object with the filter differential delay set to `d`, the number of sections in the filter set to `nsections`, and the CIC rate change factor set to `rcic`. The default values of these parameters are: the differential delay equal to 1, the number of sections equal to 2, and the CIC rate change factor equal to 1.

If the CIC rate change factor is equal to 1, the filter passband response is an inverse sinc that is an approximation to the true inverse passband response of the CIC filter.

If you specify a CIC rate change factor not equal to 1, the filter passband response is an inverse Dirichlet sinc that matches exactly the true inverse passband response of the CIC filter.

`d= fdesign.ciccomp(...,spec)` constructs a CIC Compensator specifications object and sets its `Specification` property to `spec`. Entries in the `spec` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown in the list below. The strings are not case sensitive.

- 'fp,fst,ap,ast' (default spec)
- 'n,fc,ap,ast'
- 'n,fp,ap,ast'

- 'n,fp,fst'
- 'n,fst,ap,ast'

The string entries are defined as follows:

- ap — amount of ripple allowed in the pass band in decibels (the default units). Also called  $A_{\text{pass}}$ .
- ast — attenuation in the stop band in decibels (the default units). Also called  $A_{\text{stop}}$ .
- fc — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- fp — frequency at the end of the pass band. Specified in normalized frequency units. Also called  $F_{\text{pass}}$ .
- fst — frequency at the start of the stop band. Specified in normalized frequency units. Also called  $F_{\text{stop}}$ .
- n — filter order.

In graphic form, the filter specifications look like this:

Regions between specification values like  $f_p$  and  $f_{st}$  are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a CIC compensator specifications object change depending on the Specification string.

Use `designmethods` to determine which design method applies to an object and its specification string.

```
h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)
```

constructs an object and sets the specifications in the order they are specified in the `spec` input when you construct the object.

## Designing CIC Compensators

Typically, when they develop filters, designers want flat passbands and transition regions that are as narrow as possible. CIC filters present a  $(\sin x/x)$  profile in the passband and relatively wide transitions.

To compensate for this fall off in the passband, and to try to reduce the width of the transition region, you can use a CIC compensator filter that demonstrates an  $(x/\sin x)$  profile in the passband. `fdesign.ciccomp` is specifically tailored to designing CIC compensators.

Here is a plot of a CIC filter and a compensator for that filter. The example that produces these filters follows the plot.

Given a CIC filter, how do you design a compensator for that filter? CIC compensators share three defining properties with the CIC filter — differential delay,  $d$ ; number of sections, `numberofsections`; and the usable passband frequency,  $F_{\text{pass}}$ .

By taking the number of sections, passband, and differential delay from your CIC filter and using them in the definition of the CIC compensator, the resulting compensator filter effectively corrects for the passband droop of the CIC filter, and narrows the transition region.

As a demonstration of this concept, this example creates a CIC decimator and its compensator.

```
fs = 96e3; % Input sampling frequency.
fpass = 4e3; % Frequency band of interest.
m = 6; % Decimation factor.
hcic = design(fdesign.decimator(m,'cic',1,fpass,60,fs));
```

```
hd = cascade(dfilt.scalar(1/gain(hcic)),hcic);
hd(2) = design(fdesign.ciccomp(hcic.differentialdelay, ...
    hcic.numberofsections,fpass,4.5e3,.1,60,fs/m));
fvtool(hd(1),hd(2),...
cascade(hd(1),hd(2)), 'Fs', [96e3 96e3/m 96e3])
```

You see the results in the preceding plot.

## Examples

Designed to compensate for the rolloff inherent in CIC filters, CIC compensators can improve the performance of your CIC design. This example designs a compensator *d* with five sections and a differential delay equal to one. The plot displayed after the code shows the increasing gain in the passband that is characteristic of CIC compensators, to overcome the droop in the CIC filter passband. Ideally, cascading the CIC compensator with the CIC filter results in a lowpass filter with flat passband response and narrow transition region.

```
h = fdesign.ciccomp;
set(h, 'NumberOfSections', 5, 'DifferentialDelay', 1);
hd = equiripple(h);
fvtool(hd);
```

This compensator would work for a decimator or interpolator that had differential delay of 1 and 5 sections.

`fdesign.decimator` | `fdesign.interpolator`

**Purpose** IIR comb filter specification object

**Syntax**

```
d=fdesign.comb
d=fdesign.comb(combtype)
d=fdesign(combtype,specstring)
d=fdesign(combtype,specstring,specvalue1,specvalue2,...)
d=fdesign.comb(...,Fs)
```

**Description** `fdesign.comb` specifies a peaking or notching comb filter. Comb filters amplify or attenuate a set of harmonically related frequencies.

`d=fdesign.comb` creates a notching comb filter specification object and applies default values for the filter order (N=10) and quality factor (Q=16).

`d=fdesign.comb(combtype)` creates a comb filter specification object of the specified type and applies default values for the filter order and quality factor. The valid entries for `combtype` are shown in the following table. The entries are not case-sensitive.

Argument	Description
notch	creates a comb filter that attenuates a set of harmonically related frequencies.
peak	creates a comb filter that amplifies a set of harmonically related frequencies.

`d=fdesign(combtype,specstring)` creates a comb filter specification object of type `combtype` and sets its `Specification` property to `specstring` with default values. The entries in `specstring` determine the number of peaks or notches in the comb filter as well as their bandwidth and slope. Valid entries for `specstring` are shown below. The entries are not case-sensitive.

- 'N,Q' (default)
- ''N,BW'

- 'L,BW,GWB,Nsh'

The following table describes the arguments in *specstring*.

Argument	Description
BW	Bandwidth of the notch or peak. By default the bandwidth is calculated at the point $-3$ dB down from the center frequency of the peak or notch. For example, setting $BW=0.01$ specifies that the $-3$ dB point will be $\pm 0.005$ (in normalized frequency) from the center of the notch or peak.
GWB	Gain at which the bandwidth is measured. This allows the user to specify the bandwidth of the notch or peak at a gain different from the $-3$ dB default.
L	Upsampling factor for a shelving filter of order $Nsh$ . $L$ determines the number of peaks or notches, which are equally spaced over the normalized frequency interval $[-1,1]$ .
N	Filter order. Specifies a filter with $N+1$ numerator and denominator coefficients. The filter will have $N$ peaks or notches equally spaced over the interval $[-1,1]$ .

Argument	Description
Nsh	Shelving filter order. Nsh represents a positive integer that determines the sharpness of the peaks or notches. The greater the value of the shelving filter order, the steeper the slope of the peak or notch. This results in a filter of order $L * Nsh$ .
Q	Peak or notch quality factor. Q represents the ratio of the lowest center frequency peak or notch (not including DC) to the bandwidth calculated at the $-3$ dB point.

`d=fdesign(combtype,specstring,specvalue1,specvalue2,...)` creates an IIR comb filter specification object of type `combtype` and sets its `Specification` property to the values in `specvalue1,specvalue2,...`

`d=fdesign.comb(...,Fs)` creates an IIR comb filter specification object using the sampling frequency, `Fs`, of the signal to be filtered. The function assumes that `Fs` is in Hertz and must be specified as a scalar trailing all other provided values.

## Examples

These examples demonstrate how to create IIR comb filter specification objects. First, create a default specification object.

```
d=fdesign.comb;
```

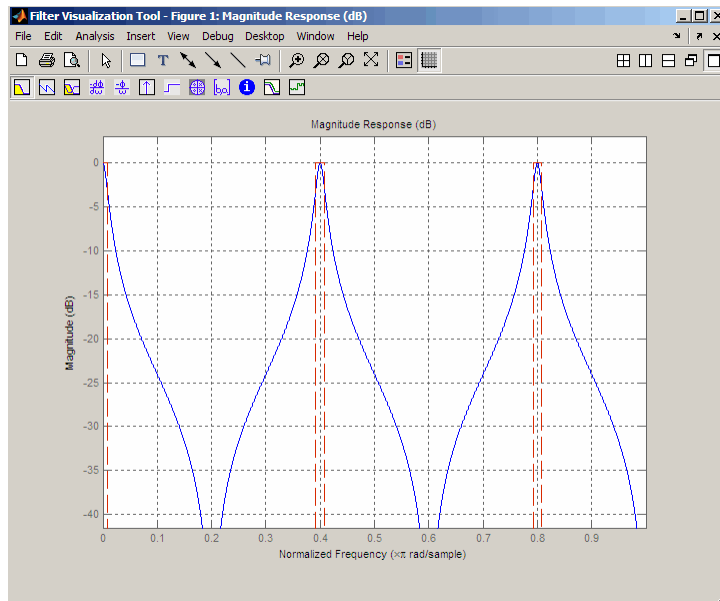

In the next example, create a notching filter of order 8 with a bandwidth of 0.02 (normalized frequency) referenced to the  $-3$  dB point.

```
d = fdesign.comb('notch','N,BW',8,0.02);
Hd = design(d);
fvtool(Hd)
```

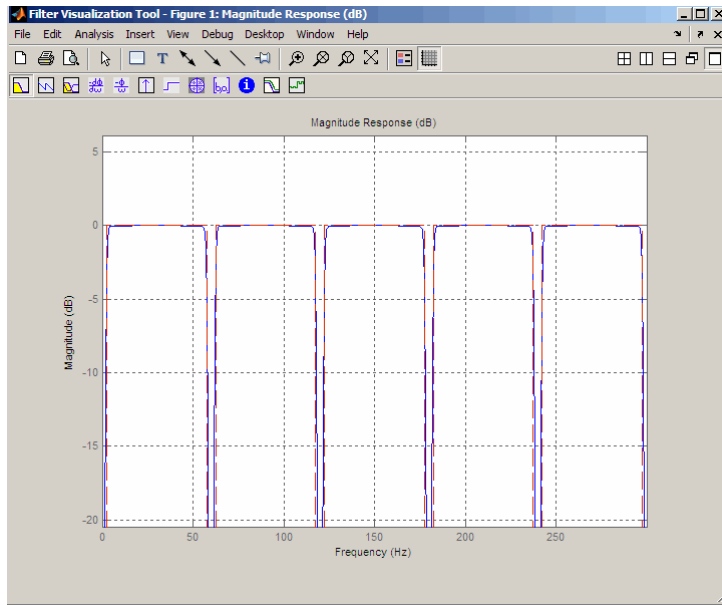

Next, create a peaking comb filter with 5 peaks and a quality factor of 25.

```
d = fdesign.comb('peak','N,Q',5,25);  
Hd = design(d);  
fvtool(Hd)
```

In the next example, create a notching filter to remove interference at 60 Hz and its harmonics. The following code creates a filter with 10 notches and a notch bandwidth of 5 Hz referenced to the -4dB level. The filter has a shelving filter order of 4 and a sampling frequency of 600 Hz. Because the notches are equidistantly spaced in the interval [-300, 300] Hz, they occur at multiples of 60 Hz.

```
d = fdesign.comb('notch','L,BW,GBW,Nsh',10,5,-4,4,600);
Hd=design(d);
fvtool(Hd)
```

## Purpose

Decimator filter specification object

## Syntax

```
D = fdesign.decimator(M)
D = fdesign.decimator(M,RESPONSE)
D = fdesign.decimator(M,PULSESHAPINGRESPONSE,SPS)
D = fdesign.decimator(M,CICRESPONSE,D)
D = fdesign.decimator(M,RESPONSE,SPEC)
D = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...)
D = fdesign.decimator(...,Fs)
D = fdesign.decimator(...,MAGUNITS)
```

## Description

`D = fdesign.decimator(M)` constructs a decimator filter specification object `D` with the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are  $0.1\pi$  radians/sample and 80 dB. If `M` is unspecified, `M` defaults to 2.

`D = fdesign.decimator(M,RESPONSE)` constructs a decimator specification object with the decimation factor `M` and the `'Response'` property.

`D = fdesign.decimator(M,PULSESHAPINGRESPONSE,SPS)` constructs a pulse-shaping decimator specification object with the decimation factor `M` and `'Response'` property equal to one of the supported pulse-shaping filters: `'Gaussian'`, `'Raised Cosine'`, or `'Square Root Raised Cosine'`. `SPS` is the samples per symbol. The samples per symbol, `SPS`, must precede any specification string.

`D = fdesign.decimator(M,CICRESPONSE,D)` constructs a CIC or CIC compensator decimator specification object with the decimation factor, `M`, `'Response'` property equal to `'CIC'` or `'CICCOMP'`, and `D` equal to the differential delay. The differential delay, `D`, must precede any specification string.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters. The decimation factor `M` is not included in the specification strings. Different filter responses support different specifications. The

# fdesign.decimator

following table lists the supported response types and specification strings. The strings are not case sensitive.

Design String	Valid Specification Strings
'Arbitrary Magnitude'	See <code>fdesign.arbmag</code> for a description of the specification string entries. <ul style="list-style-type: none"> <li>'N,F,A' (default string)</li> <li>'N,B,F,A'</li> </ul>
'Arbitrary Magnitude and Phase'	See <code>fdesign.arbmagnphase</code> for a description of the specification string entries. <ul style="list-style-type: none"> <li>'N,F,H' (default string)</li> <li>'N,B,F,H'</li> </ul>
'Bandpass'	See <code>fdesign.bandpass</code> for a description of the specification string entries. <ul style="list-style-type: none"> <li>'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default string)</li> <li>'N,Fc1,Fc2'</li> <li>'N,Fst1,Fp1,Fp2,Fst2'</li> </ul>
'Bandstop'	See <code>fdesign.bandstop</code> for a description of the specification string entries.
'CIC'	'Fp,Ast' — Only valid specification. Fp is the passband frequency and Ast is the stopband attenuation in decibels.  To specify a CIC decimator, include the differential delay after 'CIC' and before the filter specification string: 'Fp,Ast'. For example: d = <code>fdesign.decimator(2,'cic',4,'Fp,Ast',0.4,40);</code>

Design String	Valid Specification Strings
'CIC Compensator'	<p>See <code>fdesign.ciccomp</code> for a description of the specification string entries.</p> <ul style="list-style-type: none"> <li>'Fp,Fst,Ap,Ast' (default string)</li> <li>'N,Fc,Ap,Ast'</li> <li>'N,Fp,Ap,Ast'</li> <li>'N,Fp,Fst'</li> <li>'N,Fst,Ap,Ast'</li> </ul> <p>To specify a CIC compensator decimator, include the differential delay after 'CICCOMP' and before the filter specification string.. For example:  <code>d = fdesign.decimator(2,'ciccomp',4);</code></p>
'Differentiator'	'N' — filter order
'Gaussian'	<p>'Nsym,BT — Nsym is the filter order in symbols and BT is the bandwidth-symbol time product.</p> <p>The specification string must be preceded by an integer-valued <code>SamplesPerSymbol</code>.</p>

`D = fdesign.decimator(M,RESPONSE,SPEC)` constructs object `D` and sets the `Specification` property to `SPEC` for the response type, `RESPONSE`. Entries in the `SPEC` string represent various filter response features,

such as the filter order, that govern the filter design. Valid entries for SPEC depend on the RESPONSE type.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters with such response types as `fdesign.lowpass`. The strings are not case sensitive.

The decimation factor *M* is not in the specification strings.

`D = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...)` constructs an object *D* and sets its specifications at construction time.

`D = fdesign.decimator(...,Fs)` provides the sampling frequency of the signal to be filtered. *Fs* must be specified as a scalar trailing the other numerical values provided. *Fs* is assumed to be in Hz as are all other frequency values provided.

`D = fdesign.decimator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. *MAGUNITS* can be one of

- 'linear' — specify the magnitude in linear units.
- 'dB' — specify the magnitude in dB (decibels).
- 'squared' — specify the magnitude in power units.

When you omit the *MAGUNITS* argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

These examples show how to construct decimating filter specification objects. First, create a default specifications object without using input arguments except for the decimation factor *m*.

```
d = fdesign.decimator(2,'Nyquist',2,0.1,80) % Set tw=0.1, and ast=80.
```

Now create an object by passing a specification type string 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design — the resulting object uses default values for the filter specifications. You must provide

# fdesign.decimator

---

the design input argument, `bandpass` in this example, when you include a specification.

```
d=fdesign.decimator(8,'bandpass',...  
'fst1,fp1,fp2,fst2,ast1,ap,ast2');
```

Create another decimating filter specification object, passing the specification values to the object rather than accepting the default values for `fp`, `fst`, `ap`, `ast`.

```
d=fdesign.decimator(3,'lowpass',.45,0.55,.1,60);
```

Now pass the filter specifications that correspond to the specifications — `n`, `fc`, `ap`, `ast`.

```
d=fdesign.decimator(3,'ciccomp',1,2,'n,fc,ap,ast',...  
20,0.45,.05,50);
```

Now design a decimator using the `equiripple` design method.

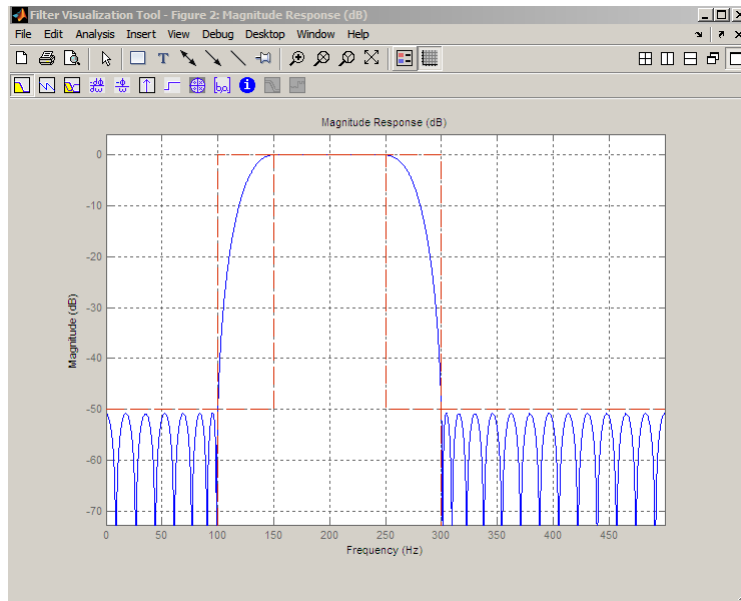

```
hm = equiripple(d);
```

Pass a new specification type for the filter, specifying the filter order. Note that the inputs must include the differential delay `dd` with the CIC input argument to design a CIC specification object.

```
m = 5;  
dd = 2;  
d = fdesign.decimator(m,'cic',dd,'fp,ast',0.55,55);
```

In this example, you specify a sampling frequency as the last input argument. Here is it 1000 Hz. Design an `equiripple` filter and plot the magnitude response:

```
d=fdesign.decimator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2',...  
100,150,250,300,50,.05,50,1000);  
fvtool(design(d,'equiripple'))
```

## See Also

[fdesign](#) | [fdesign.arbmag](#) | [fdesign.arbmagnphase](#) | [fdesign.interpolator](#) | [fdesign.rsrc](#)

# fdesign.differentiator

---

**Purpose** Differentiator filter specification object

**Syntax**

```
D = fdesign.differentiator
D = fdesign.differentiator(SPEC)
D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)
D = fdesign.differentiator(specvalue1)
D = fdesign.differentiator(...,Fs)
D = fdesign.differentiator(...,MAGUNITS)
```

**Description** `D = fdesign.differentiator` constructs a default differentiator filter designer `D` with the filter order set to 31.

`D = fdesign.differentiator(SPEC)` initializes the filter designer `Specification` property to `SPEC`. You provide one of the following strings as input to replace `SPEC`. The string you provide is not case sensitive.

---

**Note** Specifications strings marked with an asterisk require the DSP System Toolbox software.

---

- 'N' — Full band differentiator (default)
- 'N,Fp,Fst' — Partial band differentiator
- 'N,Fp,Fst,Ap' — Partial band differentiator \*
- 'N,Fp,Fst,Ast' — Partial band differentiator \*
- 'Ap' — Minimum order full band differentiator \*
- 'Fp,Fst,Ap,Ast' — Minimum order partial band differentiator \*

The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called `Apass`.
- `Ast` — attenuation in the stop band in decibels (the default units). Also called `Astop`.

- `Fp` — frequency at the start of the pass band. Specified in normalized frequency units. Also called `Fpass`.
- `Fst` — frequency at the end of the stop band. Specified in normalized frequency units. Also called `Fstop`.
- `N` — filter order.

By default, `fdesign.differentiator` assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)` initializes the filter designer specifications in `SPEC` with `specvalue1`, `specvalue2`, and so on. To get a description of the specifications `specvalue1`, `specvalue2`, and more, enter

```
get(d, 'description')
```

at the Command prompt.

`D = fdesign.differentiator(specvalue1)` assumes the default specification string `N`, setting the filter order to the value you provide.

`D = fdesign.differentiator(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.differentiator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

Use an FIR equiripple differentiator to transform frequency modulation into amplitude modulation, which can be detected using an envelope detector.

Modulate a message signal consisting of a 20-Hz sine wave with a 1 kHz carrier frequency. The sampling frequency is 10 kHz .

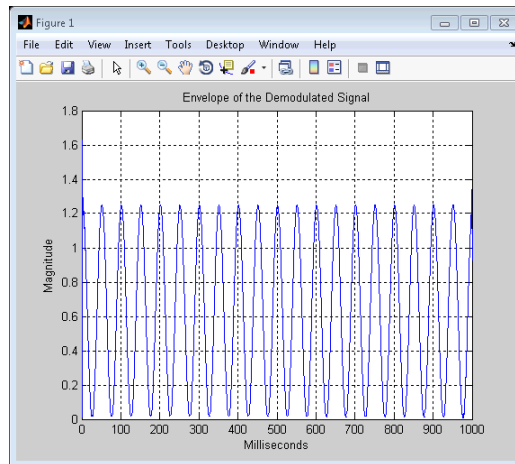

```
t = linspace(0,1,1e4);
x = cos(2*pi*20*t);
Fc = 1e3;
Fs = 1e4;
y = modulate(x,Fc,Fs,'fm');
```

Design the equiripple FIR differentiator of order 31.

```
d = fdesign.differentiator(31,1e4);
Hd = design(d,'equiripple');
```

Filter the modulated signal and take the Hilbert transform to obtain the envelope.

```
y1 = filter(Hd,y);
y1 = hilbert(y1);
% Plot the envelope
plot(t.*1000,abs(y1));
xlabel('Milliseconds'); ylabel('Magnitude');
grid on;
title('Envelope of the Demodulated Signal');
```

From the preceding figure, you see that the envelope completes two cycles every 100 milliseconds. The envelope is oscillating at 20 Hz, which corresponds to the frequency of the message signal.

Design an FIR differentiator using least squares and plot the zero phase response.

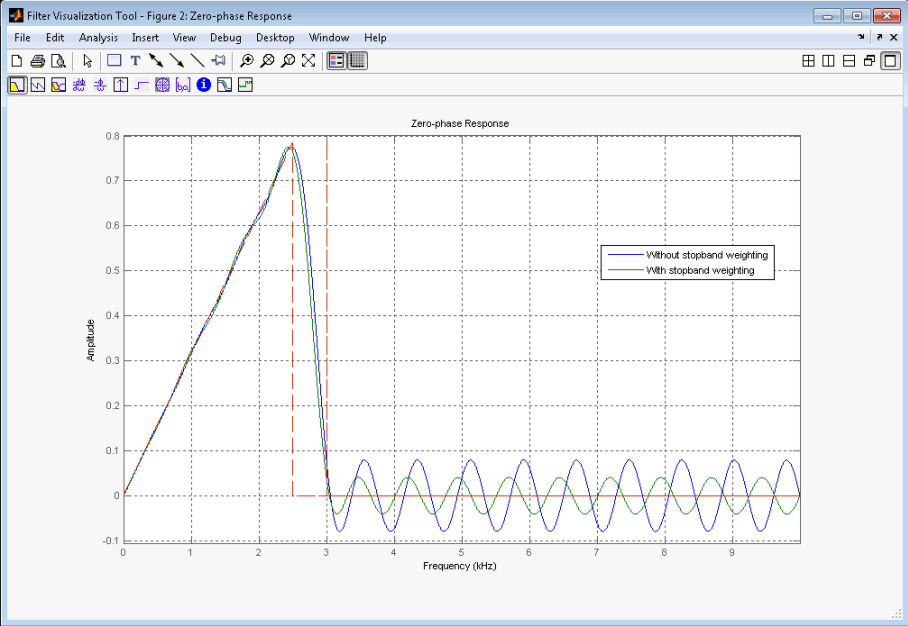

```
d = fdesign.differentiator(33); % Filter order is 33.
hd = design(d,'firls');
fvtool(hd,'magnitudedisplay','zero-phase',...
'frequencyrange','[-pi, pi]')
```

# fdesign.differentiator

Design a narrow band differentiator. Differentiate the first 25 percent of the frequencies in the Nyquist range and filter the higher frequencies.

```
Fs=20000; %sampling frequency
d = fdesign.differentiator('N,Fp,Fst',54,2500,3000,Fs);
Hd= design(d,'equiripple');
% Weight the stopband to increase attenuation
Hd1 = design(d,'equiripple','Wstop',4);
hfvt = fvtool(Hd,Hd1,'magnitudedisplay','zero-phase',...
'frequencyrange',[0, Fs/2]);
legend(hfvt,'Without stopband weighting',...
'With stopband weighting');
```

**See Also** design | fdesign

# fdesign.fracdelay

---

**Purpose** Fractional delay filter specification object

**Syntax**

```
d = fdesign.fracdelay(delta)
d = fdesign.fracdelay(delta, 'N')
d = fdesign.fracdelay(delta, 'N', n)
d = fdesign.fracdelay(delta, n)
d = fdesign.fracdelay(..., fs)
```

**Description**

`d = fdesign.fracdelay(delta)` constructs a default fractional delay filter designer `d` with the filter order set to 3 and the delay value set to `delta`. The fractional delay `delta` must be between 0 and 1 samples.

`d = fdesign.fracdelay(delta, 'N')` initializes the filter designer specification string to `N`, where `N` specifies the fractional delay filter order and defaults to filter order of 3.

Use `designmethods(d)` to get a list of the design methods available for a specification string.

`d = fdesign.fracdelay(delta, 'N', n)` initializes the filter designer to specification string `N` and sets the filter order to `n`.

`d = fdesign.fracdelay(delta, n)` assumes the default specification `N`, filter order, and sets the filter order to the value you provide in input `n`.

`d = fdesign.fracdelay(..., fs)` adds the argument `fs`, specified in units of Hertz (Hz) to define the sampling frequency. In this case, specify the fractional delay `delta` to be between 0 and  $1/fs$ .

**Examples**

Design a second-order fractional delay filter of 0.2 samples using the Lagrange method. Implement the filter using a Farrow fractional delay (`fd`) structure.

```
d = fdesign.fracdelay(0.2, 'N', 2);
hd = design(d, 'lagrange', 'filterstructure', 'farrowfd');
fvtool(hd, 'analysis', 'grpdelay')
```

Design a cubic fractional delay filter with a sampling frequency of 8 kHz and fractional delay of 50 microseconds using the Lagrange method.

```
d = fdesign.fracdelay(50e-6,'N',3,8000);  
Hd = design(d, 'lagrange', 'FilterStructure', 'farrowfd');
```

[design](#) | [designopts](#) | [fdesign](#) | [setspecs](#)

# fdesign.halfband

---

**Purpose** Halfband filter specification object

**Syntax**

```
d = fdesign.halfband
d = fdesign.halfband('type',type)
d = fdesign.halfband(spec)
d = fdesign.halfband(spec,specvalue1,specvalue2,...)
d = fdesign.halfband(specvalue1,specvalue2)
d = fdesign.halfband(...,fs)
d = fdesign.halfband(...,magunits)
```

**Description** `d = fdesign.halfband` constructs a halfband filter specification object `d`, applying default values for the properties `tw` and `ast`.

Using `fdesign.halfband` with a design method generates a `dfilt` object.

`d = fdesign.halfband('type',type)` initializes the filter designer 'Type' property with `type`. "type" must be either `lowpass` or `highpass` and is not case sensitive.

`d = fdesign.halfband(spec)` constructs object `d` and sets its 'Specification' to `spec`. Entries in the `spec` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown below. The strings are not case sensitive.

- `tw,ast` (default `spec`)
- `n,tw`
- `n`
- `n,ast`

The string entries are defined as follows:

- `ast` — attenuation in the stop band in decibels (the default units).
- `n` — filter order.
- `tw` — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

By default, all frequency specifications are assumed to be in normalized frequency units. Moreover, all magnitude specifications are assumed to be in dB. Different specification types may have different design methods available.

The filter design methods that apply to a halfband filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string. Different filter design methods also have options that you can specify. Use `designopts` with the design method string to see the available options. For example:

```
f=fdesign.halfband('N,TW');  
designmethods(f)
```

```
d = fdesign.halfband(spec,specvalue1,specvalue2,...)  
constructs an object d and sets its specifications at construction time.
```

```
d = fdesign.halfband(specvalue1,specvalue2) constructs an  
object d assuming the default Specification property string tw,ast,  
using the values you provide for the input arguments specvalue1 and  
specvalue2 for tw and ast.
```

```
d = fdesign.halfband(...,fs) adds the argument fs, specified in Hz  
to define the sampling frequency to use. In this case, all frequencies in  
the specifications are in Hz as well.
```

```
d = fdesign.halfband(...,magunits) specifies the units for any  
magnitude specification you provide in the input arguments. magunits  
can be one of
```

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

Create a default halfband filter specifications object:

```
d=fdesign.halfband;
```

Create another halfband filter object, passing the specification values to the object rather than accepting the default values for `n` and `ast`.

```
d = fdesign.halfband('n,ast', 42, 80);
```

For another example, pass the filter values that correspond to the default Specification — `n,ast`.

```
d = fdesign.halfband(.01, 80);
```

This example designs an equiripple FIR filter, starting by passing a new specification type and specification values to `fdesign.halfband`.

```
hs = fdesign.halfband('n,ast',80,70);  
hd =design(hs,'equiripple'); % Opens FVTool automatically.
```

In this example, pass the specifications for the filter, and then design a least-squares FIR filter from the object, using `firls` as the design method.

```
hs = fdesign.halfband('n,tw', 42, .04);  
% designmethods(hs)  
hd=design(hs,'firls');
```

Create two equiripple halfband filters with and without a nonnegative zero phase response:

```
f=fdesign.halfband('N,TW',12,0.2);  
% Equiripple halfband filter with nonnegative zero phase response  
Hd1=design(f,'equiripple','ZeroPhase',true);  
% Equiripple halfband filter with zero phase false  
% 'zerophase',false is the default  
Hd2=design(f,'equiripple','ZeroPhase',false);  
%Obtain real-valued amplitudes (not magnitudes)  
[Hr_zerophase,W]=zerophase(Hd1);
```

```
[Hr,W]=zerophase(Hd2);
% Plot and compare response
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
legend('with ''ZeroPhase'', true','with ''ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies.

The 'ZeroPhase' option is valid only for equiripple halfband designs with the 'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

# fdesign.highpass

---

**Purpose** Highpass filter specification object

**Syntax**

```
D = fdesign.highpass
D = fdesign.highpass(SPEC)
D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.highpass(specvalue1,specvalue2,specvalue3,
specvalue4)
D = fdesign.highpass(...,Fs)
D = fdesign.highpass(...,MAGUNITS)
```

**Description** D = fdesign.highpass constructs a highpass filter specification object D, applying default values for the specification string, 'Fst,Fp,Ast,Ap'.  
D = fdesign.highpass(SPEC) constructs object D and sets the Specification property to SPEC. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC are shown below. The strings are not case sensitive.

---

**Note** Specifications strings marked with an asterisk require the DSP System Toolbox software.

---

- 'Fst,Fp,Ast,Ap' (default spec)
- 'N,F3db'
- 'N,F3db,Ap' \*
- 'N,F3db,Ast' \*
- 'N,F3db,Ast,Ap' \*
- 'N,F3db,Fp' \*
- 'N,Fc'
- 'N,Fc,Ast,Ap'
- 'N,Fp,Ap'

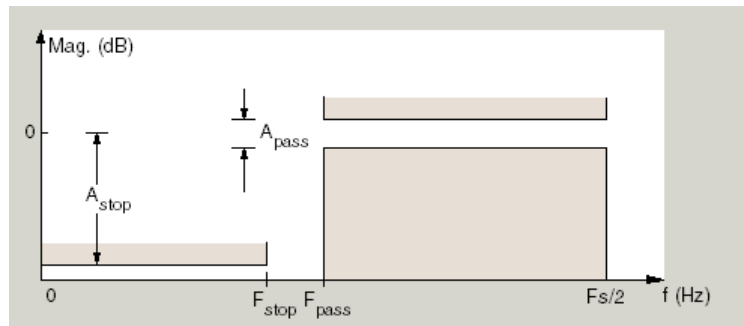

- 'N,Fp,Ast,Ap'
- 'N,Fst,Ast'
- 'N,Fst,Ast,Ap'
- 'N,Fst,F3db' \*
- 'N,Fst,Fp'
- 'N,Fst,Fp,Ap' \*
- 'N,Fst,Fp,Ast' \*
- 'Nb,Na,Fst,Fp' \*

The string entries are defined as follows:

- Ap — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.
- Ast — attenuation in the stop band in decibels (the default units). Also called Astop.
- F3db — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- Fc — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- Fp — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.
- Fst — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.
- N — filter order.
- Na and Nb are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.

# fdesign.highpass

Regions between specification values like  $F_{st}$  and  $F_p$  are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a highpass filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string.

Use `designopts` to determine which design options are valid for a given design method. For detailed information on design options for a given design method, `METHOD`, enter `help(D,METHOD)` at the MATLAB command line.

`D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)` constructs an object `d` and sets its specification values at construction time.

`D = fdesign.highpass(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` with the default `Specification` property and the values you enter for `specvalue1,specvalue2,...`

`D = fdesign.highpass(...,Fs)` provides the sampling frequency for the filter specification object. `Fs` is in Hz and must be specified as a scalar trailing the other numerical values provided. If you specify a sampling frequency, all other frequency specifications are in Hz.

`D = fdesign.highpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

Highpass filter a discrete-time signal consisting of two sine waves.

Create a highpass filter specification object. Specify the passband frequency to be  $0.25\pi$  radians/sample and the stopband frequency to be  $0.15\pi$  radians/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.highpass('Fst,Fp,Ast,Ap',0.15,0.25,60,1);
```

Query the valid design methods for your filter specification object, `d`.

```
designmethods(d)
```

Create an FIR equiripple filter and view the filter magnitude response with `fvtool`.

```
Hd = design(d,'equiripple');  
fvtool(Hd);
```

Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of  $\pi/8$  and  $\pi/4$  radians/sample and amplitudes of 1 and 0.25 respectively. Filter the discrete-time signal with the FIR equiripple filter object, `Hd`

```
n = 0:159;  
x = cos((pi/8)*n)+0.25*sin((pi/4)*n);  
y = filter(Hd,x);  
Omega = (2*pi)/160;  
freq = 0:(2*pi)/160:pi;
```

## fdesign.highpass

---

```
xdft = fft(x);
ydft = fft(y);
plot(freq,abs(xdft(1:length(x)/2+1)));
hold on;
plot(freq,abs(ydft(1:length(y)/2+1)),'r','linewidth',2);
legend('Original Signal','Lowpass Signal', ...
'Location','NorthEast');
ylabel('Magnitude'); xlabel('Radians/Sample');
```

---

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sampling frequency of 48 kHz.

```
d=fdesign.highpass('N,Fc',10,9600,48000);
designmethods(d)
% only valid design method is FIR window method
Hd = design(d);
% Display filter magnitude response
fvtool(Hd);
```

---

If you have the DSP System Toolbox software, you can specify the shape of the stopband and the rate at which the stopband decays.

Create two FIR equiripple filters with different linear stopband slopes. Specify the passband frequency to be  $0.3\pi$  radians/sample and the stopband frequency to be  $0.35\pi$  radians/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB. Design one filter with a 20 dB/rad/sample stopband slope and another filter with 40 dB/rad/sample.

```
D = fdesign.highpass('Fst,Fp,Ast,Ap',0.3,0.35,60,1);
Hd1 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',20);
Hd2 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',40);
hfvtool([Hd1 Hd2]);
legend(hfvtool,'20 dB/rad/sample','40 dB/rad/sample');
```

[design](#) | [designmethods](#) | [fdesign](#)

# fdesign.hilbert

---

**Purpose** Hilbert filter specification object

**Syntax**

```
d = fdesign.hilbert
d = fdesign.hilbert(specvalue1,specvalue2)
d = fdesign.hilbert(spec)
d = fdesign.hilbert(spec,specvalue1,specvalue2)
d = fdesign.hilbert(...,Fs)
d = fdesign.hilbert(...,MAGUNITS)
```

**Description**

`d = fdesign.hilbert` constructs a default Hilbert filter designer `d` with `N`, the filter order, set to 30 and `TW`, the transition width set to  $0.1\pi$  radians/sample.

`d = fdesign.hilbert(specvalue1,specvalue2)` constructs a Hilbert filter designer `d` assuming the default specification string `'N,TW'`. You input `specvalue1` and `specvalue2` for `N` and `TW`.

`d = fdesign.hilbert(spec)` initializes the filter designer `Specification` property to `spec`. You provide one of the following strings as input to replace `spec`. The specification strings are not case sensitive.

---

**Note** Specifications strings marked with an asterisk require the DSP System Toolbox software.

---

- `'N,TW'` default spec string.
- `'TW,Ap'` \*

The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called `Apass`.
- `N` — filter order.
- `TW` — width of the transition region between the pass and stop bands.

By default, `fdesign.hilbert` assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Different specification strings may have different design methods available. Use `designmethods(d)` to get a list of the design methods available for a given specification string.

`d = fdesign.hilbert(spec,specvalue1,specvalue2)` initializes the filter designer specifications in `spec` with `specvalue1`, `specvalue2`, and so on. To get a description of the specifications `specvalue1` and `specvalue2`, enter

```
get(d, 'description')
```

at the Command prompt.

`d = fdesign.hilbert(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.hilbert(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

Design a Hilbert transformer of order 30 with a transition width of  $0.2\pi$  radians/sample. Plot the zero phase response from  $[-\pi,\pi]$  radians/sample and the impulse response.

```
d = fdesign.hilbert('N,TW',30,0.2);
```

# fdesign.hilbert

```
% Show available design methods
designmethods(d)
% Use least square minimization to obtain linear-phase FIR filter
Hd = design(d,'equiripple');
% Display zero phase response from [-pi,pi)
fvtool(Hd,'magnitudedisplay','zero-phase',...
'frequencyrange','[-pi, pi)')
```

The impulse response of this even order filter is antisymmetric (type III).

```
fvtool(Hd,'analysis','impulse')
```

Apply the filter to a discrete-time sinusoid with a frequency of  $\pi/2$  radians/sample.

```
n = 0:99;
x = cos(pi/2*n);
y = filter(Hd,x);
% Correct for the filter delay
Delay = floor(length(Hd.Numerator)/2);
y = y(Delay+1:end);
```

# fdesign.hilbert

Plot the filter input and output and validate the approximate  $\pi/2$  phase shift obtained with the Hilbert transformer.

```
stem(x(1:end-Delay), 'markerfacecolor', [0 0 1]);  
hold on;  
stem(y, 'Color', [1 0 0], 'markerfacecolor', [1 0 0]);  
axis([10 20 -1.5 1.5]); grid on;  
xlabel('Samples'); ylabel('Amplitude');  
legend('Input', 'Output', 'Location', 'NorthWest')
```

Because the frequency of the discrete-time sinusoid is  $\pi/2$  radians/sample, a one sample shift corresponds to a phase shift of  $\pi/2$ .

Form the analytic signal and demonstrate that the frequency content of the analytic signal is zero for negative frequencies and approximately twice the spectrum of the input for positive frequencies.

```
x1 = x(1:end-Delay);  
% Form the analytic signal  
xa = x1+1j*y;  
freq = -pi:(2*pi)/length(x1):pi-(2*pi)/length(x);  
plot(freq,abs(fftshift(fft(x1))));  
hold on;  
plot(freq,abs(fftshift(fft(xa))), 'r'); grid on;  
xlabel('Radians/Sample'); ylabel('Magnitude');  
legend('Input DFT', 'Analytic Signal DFT', 'Location', 'NorthWest');
```

Design a minimum-order Hilbert transformer that has a sampling frequency of 1 kHz. Specify the passband ripple to be 1 dB.

```
d = fdesign.hilbert('TW,Ap',1,0.1,1e3);  
hd = design(d,'equiripple');  
fvtool(hd,'magnitudedisplay','zero-phase', ...  
    'frequencyrange','[-Fs/2, Fs/2)');
```

**See Also**      `design` | `fdesign` | `setspecs`

# fdesign.interpolator

---

**Purpose** Interpolator filter specification

**Syntax**

```
D = fdesign.interpolator(L)
D = fdesign.interpolator(L,RESPONSE)
D = fdesign.interpolator(L,PULSESHPINGRESPONSE,SPS)
D = fdesign.interpolator(L,CICRESPONSE,D)
D = fdesign.interpolator(L,RESPONSE,spec)
D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)
D = fdesign.interpolator(...,Fs)
d = fdesign.interpolator(...,MAGUNITS)
```

**Description**

`D = fdesign.interpolator(L)` constructs an interpolator filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are  $0.1\pi$  radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 2.

`D = fdesign.interpolator(L,RESPONSE)` constructs a interpolator specification object with the interpolation factor `L` and the `'Response'` property set to one of the supported types.

`D = fdesign.interpolator(L,PULSESHPINGRESPONSE,SPS)` constructs a pulse-shaping interpolator specification object with the interpolation factor `L` and `'Response'` property equal to one of the supported pulse-shaping filters: `'Gaussian'`, `'Raised Cosine'`, or `'Square Root Raised Cosine'`. `SPS` is the samples per symbol. The samples per symbol, `SPS`, must precede any specification string.

`D = fdesign.interpolator(L,CICRESPONSE,D)` constructs a `CIC` or `CIC` compensator interpolator specification object with the interpolation factor, `L`, and `'Response'` property equal to `'CIC'` or `'CICCOMP'`. `D` is the differential delay. The differential delay, `D`, must precede any specification string.

`D = fdesign.interpolator(L,RESPONSE,spec)` constructs object `D` and sets its `Specification` property to `spec`. Entries in the `spec` string represent various filter response features, such as the filter order, that

govern the filter design. Valid entries for `spec` depend on the design type of the specifications object.

When you add the `spec` input argument, you must also add the `RESPONSE` input argument.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters with design methods such as `fdesign.lowpass`. The strings are not case sensitive.

The interpolation factor `L` is not in the specification strings. The different filter responses support different specifications. The following table lists the supported response types and specification strings.

Design String	Valid Specification Strings
'Arbitrary Magnitude'	See <code>fdesign.arbmag</code> for a description of the specification string entries. <ul style="list-style-type: none"> <li>'N,F,A' (default string)</li> <li>'N,B,F,A'</li> </ul>

`D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)`  
constructs an object `D` and sets its specifications at construction time.

# fdesign.interpolator

---

`D = fdesign.interpolator(...,Fs)` adds the argument `Fs`, specified in Hz, to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.interpolator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units.
- 'dB' — specify the magnitude in dB (decibels).
- 'squared' — specify the magnitude in power units.

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

These examples show how to construct interpolating filter specification objects. First, create a default specifications object without using input arguments except for the interpolation factor `l`.

```
l = 2;  
d = fdesign.interpolator(2);
```

Now create an object by passing a specification string `'fst1,fp1,fp2,fst2,ast1,ap,ast2'` and a design — the resulting object uses default values for all of the filter specifications. You must provide the design input argument when you include a specification.

```
d=fdesign.interpolator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2');
```

Create another interpolating filter object, passing the specification values to the object rather than accepting the default values for, in this case, `fp,fst,ap,ast`.

```
d=fdesign.interpolator(3,'lowpass',.45,0.55,.1,60);
```

Now pass the filter specifications that correspond to the specifications — `n,fc,ap,ast`.

```
d=fdesign.interpolator(3,'ciccomp',1,2,'n,fc,ap,ast',...  
20,0.45,.05,50);
```

With the specifications object in your workspace, design an interpolator using the `equiripple` design method.

```
hm = design(d,'equiripple');
```

Pass a new specification type for the filter, specifying the filter order.

```
d = fdesign.interpolator(5,'CIC',1,'fp,ast',0.55,55);
```

With the specifications object in your workspace, design an interpolator using the `multisection` design method.

```
hm = design(d,'multisection');
```

In this example, you specify a sampling frequency as the right most input argument. Here, it is set to 1000 Hz.

```
d=fdesign.interpolator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2',...  
0.25,0.35,.55,.65,50,.05,1e3);
```

In this, the last example, use the `linear` option for the filter specification object and specify the stopband ripple attenuation in linear form.

```
d = fdesign.interpolator(4,'lowpass','n,fst,ap,ast',15,0.55,.05,...  
1e3,'linear'); % 1e3 = 60dB.
```

Now design a CIC interpolator for a signal sampled at 19200 Hz. Specify the differential delay of 2 and set the attenuation of information beyond 50 Hz to be at least 80 dB.

The filter object sampling frequency is  $(1 \times f_s)$  where `fs` is the sampling frequency of the input signal.

## fdesign.interpolator

---

```
dd = 2;      % Differential delay.
fp = 50;    % Passband of interest.
ast = 80;   % Minimum attenuation of alias components in passband.
fs = 600;   % Sampling frequency for input signal.
l = 32;     % Interpolation factor.
d = fdesign.interpolator(l,'cic',dd,'fp,ast',fp,ast,l*fs);
hm = design(d); %Use the default design method.
```

This next example results in a minimum-order CIC compensator that interpolates by 4 and compensates for the droop in the passband for the CIC filter `hm` from the previous example.

```
nsecs = hm.numberofsections;
d = fdesign.interpolator(4,'ciccomp',dd,nsecs,...
50,100,0.1,80,fs);
hmc = design(d,'equiripple');
hmc.arithmetic = 'fixed';
```

`hmc` is designed to compensate for `hm`. To see the effect of the compensating CIC filter, use FVTool to analyze both filters individually and include the compound filter response by cascading `hm` and `hmc`.

```
hfvtool = fvtool(hmc,hm,cascade(hmc,hm),'fs',[fs,l*fs,l*fs],...
'showreference','off');
legend(hfvtool,'CIC Compensator','CIC Interpolator',...
'Overall Response');
```

FVTool returns with this plot.

For the third example, use `fdesign.interpolator` to design a minimum-order Nyquist interpolator that uses a Kaiser window. For comparison, design a multistage interpolator as well and compare the responses.

```

l = 15; % Set the interpolation factor and the Nyquist band.
tw = 0.05; % Specify the normalized transition width.
ast = 40; % Set the minimum stopband attenuation in dB.
d = fdesign.interpolator(l,'nyquist',l,tw,ast);
hm = design(d,'kaiserwin');
hm2 = design(d,'multistage'); % Design the multistage interpolator.
hfv = fvtool(hm,hm2);
legend(hfv,'Kaiser Window','Multistage')
    
```

FVTool shows both responses.

Design a lowpass interpolator for an interpolation factor of 8. Compare the single-stage equiripple design to a multistage design with the same interpolation factor.

```
l = 8; % Interpolation factor.
d = fdesign.interpolator(l,'lowpass');
hm(1) = design(d,'equiripple');
% Use halfband filters whenever possible.
hm(2) = design(d,'multistage','usehalfbands',true);
hfvt = fvtool(hm);
legend(hfvt,'Single-Stage Equiripple','Multistage')
```

# fdesign.isinchnp

---

**Purpose** Inverse sinc highpass filter specification

**Syntax**

```
D = fdesign.isinchnp
D = fdesign.isinchnp(SPEC)
D = fdesign.isinchnp(SPEC,specvalue1,specvalue2,...)
D = fdesign.isinchnp(specvalue1,specvalue2,specvalue3,
    specvalue4)
D = fdesign.isinchnp(...,Fs)
D = fdesign.isinchnp(...,MAGUNITS)
```

**Description** `D = fdesign.isinchnp` constructs an inverse sinc highpass filter specification object `D`, applying default values for the default specification string `'Fst,Fp,Ast,Ap'`.

`D = fdesign.isinchnp(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The strings are not case sensitive.

- `'Fst,Fp,Ast,Ap'` (default spec)
- `'N,Fc,Ast,Ap'`
- `'N,Fst,Fp'`
- `'N,Fp,Ast,Ap'`
- `'N,Fst,Ast,Ap'`

The string entries are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called `Astop`.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called `Apass`.
- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called `Fpass`.

- `Fst` — frequency at the end of the stopband. Specified in normalized frequency units. Also called `Fstop`.
- `N` — filter order.

The filter design methods that apply to an inverse sinc highpass filter specification object change depending on the value of the `Specification` property. Use `designmethods` to determine which design method applies to a specific `Specification`.

Use `designopts` to see the available design options for a specific design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed information on the design options for a given design method, `METHOD`.

`D = fdesign.isinchnp(SPEC,specvalue1,specvalue2,...)`  
constructs an object `D` and sets the specifications at construction time.

`D = fdesign.isinchnp(specvalue1,specvalue2,specvalue3,specvalue4)`  
constructs an object `D` assuming the default `Specification` property string `'Fst,Fp,Ast,Ap'`, using the values you provide in `specvalue1,specvalue2, specvalue3, and specvalue4`.

`D = fdesign.isinchnp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.isinchnp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

# fdesign.isinchnp

---

The design method of `fdesign.isinchnp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = \text{sinc}(C(1 - \omega))^{-P}$$

You can control the values of the sinc frequency factor,  $C$ , and the sinc power,  $P$ , using the `'SincFrequencyFactor'` and `'SincPower'` options in the design method. `'SincFrequencyFactor'` and `'SincPower'` default to 0.5 and 1 respectively.

## Examples

Design a minimum order inverse sinc highpass filter and shape the stopband to have a slope of 20 dB/radian/sample.

```
d = fdesign.isinchnp('Fst,Fp,Ast,Ap',.4,.5,40,0.01);  
Hd = design(d);  
% Shape the stopband to have a linear slope of 20 dB/rad/sample  
Hd1 = design(d,'StopbandShape','linear','StopbandDecay',20);  
fvtool(Hd,Hd1);
```

Design a 50th order inverse sinc highpass filter. Set the sinc frequency factor to 0.25, and the sinc power to 16 to achieve a magnitude response in the passband of the form  $H(\omega) = \text{sinc}(0.25*(1-\omega))^{(-16)}$ .

```
d = fdesign.isinchnp('N,Fst,Fp',50,.4,.5);
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16);
fvtool(Hd);
```

**Purpose**

Inverse sinc lowpass filter specification

**Syntax**

```
d = fdesign.isinclp
d = fdesign.isinclp(spec)
d = fdesign.isinclp(spec,specvalue1,specvalue2,...)
d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,
    specvalue4)
d = fdesign.isinclp(...,Fs)
d = fdesign.isinclp(...,MAGUNITS)
```

**Description**

`d = fdesign.isinclp` constructs an inverse sinc lowpass filter specification object `d`, applying default values for the default specification string, 'Fp,Fst,Ap,Ast'.

`d = fdesign.isinclp(spec)` constructs object `d` and sets its 'Specification' to `spec`. Entries in the `spec` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown below. The strings are not case sensitive.

- 'Fp,Fst,Ap,Ast' (default spec)
- 'N,Fc,Ap,Ast'
- 'N,Fp,Ap,Ast'
- 'N,Fp,Fst'
- 'N,Fst,Ap,Ast'

The string entries are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called `Astop`.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called `Apass`.
- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called `Fpass`.

# fdesign.isinclp

---

- `Fst` — frequency at the end of the stopband. Specified in normalized frequency units. Also called `Fstop`.
- `N` — filter order.

The filter design methods that apply to an inverse sinc lowpass filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string.

`d = fdesign.isinclp(spec,specvalue1,specvalue2,...)`  
constructs an object `d` and sets its specifications at construction time.

`d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)`  
constructs an object `d` assuming the default `Specification` property string `'Fp,Fst,Ap,Ast'`, using the values you provide in `specvalue1,specvalue2,specvalue3,` and `specvalue4`.

`d = fdesign.isinclp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.isinclp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of `fdesign.isinclp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = \text{sinc}(C\omega)^{-P}$$

You can control the values of the sinc frequency factor,  $C$ , and the sinc power,  $P$ , using the 'SincFrequencyFactor' and 'SincPower' options in the design method. 'SincFrequencyFactor' and 'SincPower' default to 0.5 and 1 respectively.

## Examples

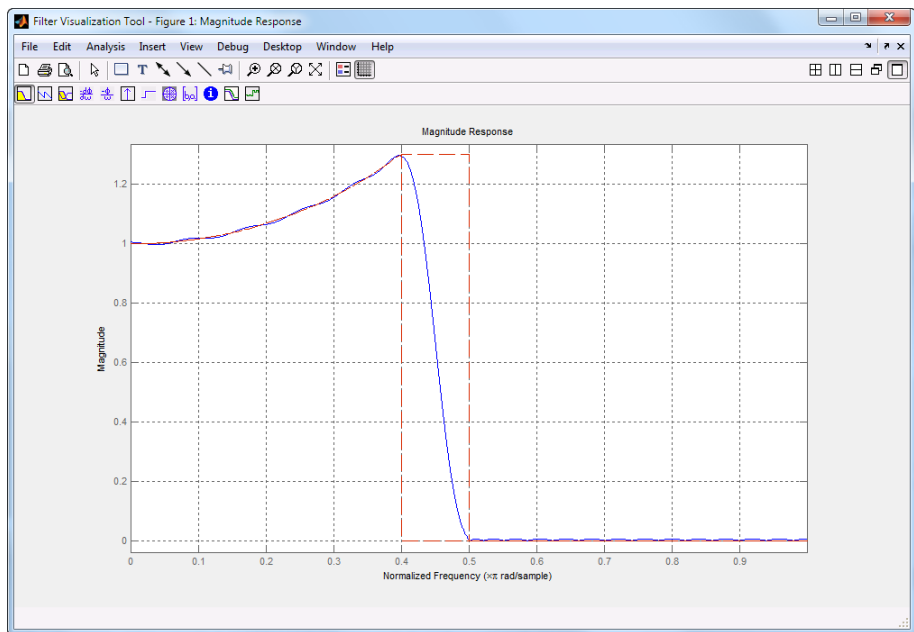

Pass the specifications for the default specification — 'Fp,Fst,Ap,Ast' — as input arguments to the specifications object.

```
d = fdesign.isinclp(.4,.5,.01,40);  
hd = design(d,'equiripple');  
fvtool(hd);
```

---

Design a 50th order inverse sinc lowpass filter. Set the sinc frequency factor to 0.25 and the sinc power to 16 to achieve a magnitude response in the passband of the form  $H(w) = \text{sinc}(0.25*w)^{-16}$ .

```
d = fdesign.isinclp('N,Fp,Fst',50,.4,.5);  
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16);  
fvtool(Hd, 'MagnitudeDisplay', 'Magnitude');
```

`fdesign.halfband` | `fdesign.highpass` | `fdesign.lowpass` |  
`fdesign.nyquist`

**Purpose** Lowpass filter specification

**Syntax**

```
D = fdesign.lowpass
D = fdesign.lowpass(SPEC)
D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,
    specvalue4)
D = fdesign.lowpass(...,Fs)
D = fdesign.lowpass(...,MAGUNITS)
```

**Description**

D = fdesign.lowpass constructs a lowpass filter specification object D, applying default values for the default specification string 'Fp,Fst,Ap,Ast'.

D = fdesign.lowpass(SPEC) constructs object D and sets the Specification property to the string in SPEC. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC are shown below. The strings are not case sensitive.

---

**Note** Specifications strings marked with an asterisk require the DSP System Toolbox software.

---

- 'Fp,Fst,Ap,Ast' (default spec)
- 'N,F3db'
- 'N,F3db,Ap' \*
- 'N,F3db,Ap,Ast' \*
- 'N,F3db,Ast' \*
- 'N,F3db,Fst' \*
- 'N,Fc'
- "N,Fc,Ap,Ast"

- 'N,Fp,Ap'
- 'N,Fp,Ap,Ast'
- 'N,Fp,Fst,Ap' \*
- 'N,Fp,F3db' \*
- 'N,Fp,Fst'
- 'N,Fp,Fst,Ast' \*
- 'N,Fst,Ap,Ast' \*
- 'N,Fst,Ast'
- 'Nb,Na,Fp,Fst' \*

The string entries are defined as follows:

- Ap — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.
- Ast — attenuation in the stop band in decibels (the default units). Also called Astop.
- F3db — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- Fc — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- Fp — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.
- Fst — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.
- N — filter order.
- Na and Nb are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like  $F_p$  and  $F_{st}$  are transition regions where the filter response is not explicitly defined.

`D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets the specification values at construction time using `specvalue1`, `specvalue2`, and so on for all of the specification variables in `SPEC`.

`D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` with values for the default Specification property string `'Fp,Fst,Ap,Ast'` using the specifications you provide as input arguments `specvalue1,specvalue2,specvalue3,specvalue4`.

`D = fdesign.lowpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.lowpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGNUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

Lowpass filter a discrete-time signal consisting of two sine waves.

Create a lowpass filter specification object. Specify the passband frequency to be  $0.15\pi$  radians/sample and the stopband frequency to be  $0.25\pi$  radians/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d=fdesign.lowpass('Fp,Fst,Ap,Ast',0.15,0.25,1,60);
```

Query the valid design methods for your filter specification object, `d`.

```
designmethods(d)
```

Create an FIR equiripple filter and view the filter magnitude response with `fvtool`.

```
Hd = design(d,'equiripple');  
fvtool(Hd);
```

Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of  $\pi/8$  and  $\pi/4$  radians/sample and amplitudes of 1 and 0.25 respectively. Filter the discrete-time signal with the FIR equiripple filter object, `Hd`.

```
n = 0:159;  
x = 0.25*cos((pi/8)*n)+sin((pi/4)*n);  
y = filter(Hd,x);  
Domega = (2*pi)/160;  
freq = 0:(2*pi)/160:pi;  
xdft = fft(x);  
ydft = fft(y);  
plot(freq,abs(xdft(1:length(x)/2+1)));  
hold on;  
plot(freq,abs(ydft(1:length(y)/2+1)),'r','linewidth',2);
```

```
legend('Original Signal','Highpass Signal', ...  
      'Location','NorthEast');  
ylabel('Magnitude'); xlabel('Radians/Sample');
```

---

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sampling frequency of 48 kHz.

```
d=fdesign.lowpass('N,Fc',10,9600,48000);  
designmethods(d)  
% only valid design method is FIR window method  
Hd = design(d);  
% Display filter magnitude response  
fvtool(Hd);
```

Zoom in on the magnitude response to verify that the -6 dB point is at 9.6 kHz.

---

If you have the DSP System Toolbox software, you can specify the shape of the stopband and the rate at which the stopband decays. The following example requires the DSP System Toolbox.

Create an FIR equiripple filter with a passband frequency of  $0.2\pi$  radians/sample, a stopband frequency of  $0.25\pi$  radians/sample, a passband ripple of 1 dB, and a stopband attenuation of 60 dB. Design the filter with a 20 dB/rad/sample linear stopband.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,1,60);  
Hd = design(D,'equiripple','StopBandShape','linear','StopBandDecay',20);  
fvtool(Hd);
```

## See Also

[design](#) | [designmethods](#) | [fdesign](#)

# fdesign.notch

---

**Purpose** Notch filter specification

**Syntax**

```
d = fdesign.notch(specstring, value1, value2, ...)  
d = fdesign.notch(n,f0,q)  
d = fdesign.notch(...,Fs)  
d = fdesign.notch(...,MAGUNITS)
```

**Description** `d = fdesign.notch(specstring, value1, value2, ...)` constructs a notch filter specification object `d`, with a specification string set to `specstring` and values provided for all members of the `specstring`. The possible specification strings, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth
- Ap - Passband Ripple (decibels)
- Ast - Stopband Attenuation (decibels)

Different specification strings, resulting in different specification objects, may have different design methods available. Use the function

`designmethods` to get a list of design methods available for a given specification. For example:

```
d = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
% designmethods(d) returns
% Design Methods for class fdesign.notch (N,F0,Q,Ap):
% cheby1
```

`d = fdesign.notch(n,f0,q)` constructs a notch filter specification object using the default specstring ('N,F0,Q') and setting the corresponding values to `n`, `f0`, and `q`.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

`d = fdesign.notch(...,Fs)` constructs a notch filter specification object while providing the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other values provided. If you specify an `Fs`, it is assumed to be in Hz, as are all the other frequency values provided.

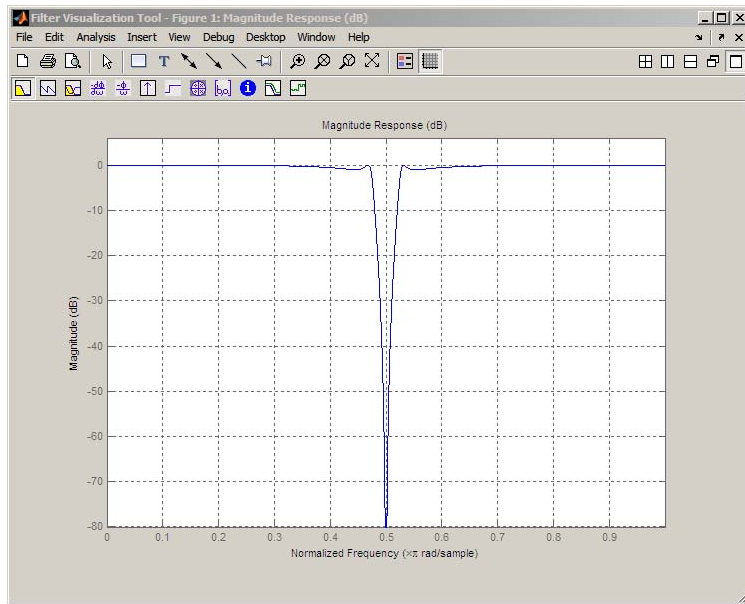

`d = fdesign.notch(...,MAGUNITS)` constructs a notch filter specification while providing the units for any magnitude specification given. `MAGUNITS` can be one of the following: 'linear', 'dB', or 'squared'. If this argument is omitted, 'dB' is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If `Fs` is provided, `MAGUNITS` must follow `Fs` in the input argument list.

## Examples

Design a notching filter with a passband ripple of 1 dB.

```
d = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
Hd = design(d);
fvtool(Hd)
```

# fdesign.notch

**See Also** [fdesign](#) | [fdesign.peak](#)

**Purpose**

Nyquist filter specification

**Syntax**

```
d = fdesign.nyquist
d = fdesign.nyquist(1,spec)
d = fdesign.nyquist(1,spec,specvalue1,specvalue2,...)
d = fdesign.nyquist(1,specvalue1,specvalue2)
d = fdesign.nyquist(...,fs)
d = fdesign.nyquist(...,magunits)
```

**Description**

`d = fdesign.nyquist` constructs a Nyquist or L-band filter specification object `d`, applying default values for the properties `tw` and `ast`. By default, the filter object designs a minimum-order half-band ( $L=2$ ) Nyquist filter.

Using `fdesign.nyquist` with a design method generates a `dfilt` object.

`d = fdesign.nyquist(1,spec)` constructs object `d` and sets its Specification property to `spec`. Use `1` to specify the desired value for `L`.  $L = 2$  designs a half-band FIR filter,  $L = 3$  a third-band FIR filter, and so on. When you use a Nyquist filter as an interpolator, `l` or `L` is the interpolation factor. The first input argument must be `l` when you are not using the default syntax `d = fdesign.nyquist`.

Entries in the `spec` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown below. The strings are not case sensitive.

- `tw,ast` (default `spec`)
- `n,tw`
- `n`
- `n,ast`

The string entries are defined as follows:

- `ast` — attenuation in the stop band in decibels (the default units).
- `n` — filter order.

- `tw` — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

The filter design methods that apply to a Nyquist filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string. Different filter design methods also have options that you can specify. Use `designopts` with the design method string to see the available options. For example:

```
f=fdesign.nyquist(4,'N,TW');  
designmethods(f)
```

```
d = fdesign.nyquist(1,spec,specvalue1,specvalue2,...)
```

constructs an object `d` and sets its specification to `spec`, and the specification values to `specvalue1`, `specvalue2`, and so on at construction time.

```
d = fdesign.nyquist(1,specvalue1,specvalue2)
```

constructs an object `d` with the values you provide in `1`, `specvalue1`, `specvalue2` as the values for `l`, `tw` and `ast`.

```
d = fdesign.nyquist(...,fs)
```

adds the argument `fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

```
d = fdesign.nyquist(...,magunits)
```

specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Limitations of the Nyquist fdesign Object

Using Nyquist filter specification objects with the `equiripple` design method imposes a few limitations on the resulting filter, caused by the `equiripple` design algorithm.

- When you request a minimum-order design from `equiripple` with your Nyquist object, the design algorithm might not converge and can fail with a filter convergence error.
- When you specify the order of your desired filter, and use the `equiripple` design method, the design might not converge.
- Generally, the following specifications, alone or in combination with one another, can cause filter convergence problems with Nyquist objects and the `equiripple` design method.
  - very high order
  - small transition width
  - very large stopband attenuation

Note that halfband filters (filters where  $\text{band} = 2$ ) do not exhibit convergence problems.

When convergence issues arise, either in the cases mentioned or in others, you might be able to design your filter with the `kaiserwin` method.

In addition, if you use Nyquist objects to design decimators or interpolators (where the interpolation or decimation factor is not a prime number), using multistage filter designs might be your best approach.

## Examples

These examples show how to construct a Nyquist filter specification object. First, create a default specifications object without using input arguments.

```
d=fdesign.nyquist
```

Now create an object by passing a specification type string 'n,ast' — the resulting object uses default values for n and ast.

```
d=fdesign.nyquist(2,'n,ast')
```

Create another Nyquist filter object, passing the specification values to the object rather than accepting the default values for n and ast.

```
d=fdesign.nyquist(3,'n,ast',42,80)
```

Finally, pass the filter specifications that correspond to the default Specification — tw,ast. When you pass only the values, fdesign.nyquist assumes the default Specification string.

```
d = fdesign.nyquist(4,.01,80)
```

Now design a Nyquist filter using the kaiserwin design method.

```
hd = design(d,'kaiserwin')
```

Create two equiripple Nyquist 4th-band filters with and without a nonnegative zero phase response:

```
f=fdesign.nyquist(4,'N,TW',12,0.2);  
% Equiripple Nyquist 4th-band filter with  
% nonnegative zero phase response  
Hd1=design(f,'equiripple','zerophase',true);  
% Equiripple Nyquist 4th-band filter with 'ZeroPhase' set to false  
% 'zerophase',false is the default  
Hd2=design(f,'equiripple','zerophase',false);  
%Obtain real-valued amplitudes (not magnitudes)  
[Hr_zerophase,W]=zerophase(Hd1);  
[Hr,W]=zerophase(Hd2);  
% Plot and compare response  
plot(W,Hr_zerophase,'k','linewidth',2);  
xlabel('Radians/sample'); ylabel('Amplitude');  
hold on;  
plot(W,Hr,'r');  
axis tight; grid on;
```

```
legend('with 'ZeroPhase'', true,'with 'ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies.

The 'ZeroPhase' option is valid only for equiripple Nyquist designs with the 'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

fdesign.interpolator | fdesign.rsrc | zerophase

# fdesign.octave

---

**Purpose** Octave filter specification

**Syntax**

```
d = fdesign.octave(1)
d = fdesign.octave(1, MASK)
d = fdesign.octave(1, MASK, spec)
d = fdesign.octave(..., Fs)
```

**Description** `d = fdesign.octave(1)` constructs an octave filter specification object `d`, with 1 bands per octave. The default value for 1 is 1.

`d = fdesign.octave(1, MASK)` constructs an octave filter specification object `d` with 1 bands per octave and `MASK` specification for the FVTool. The available values for `mask` are:

- 'class 0'
- 'class 1'
- 'class 2'

`d = fdesign.octave(1, MASK, spec)` constructs an octave filter specification object `d` with 1 bands per octave, `MASK` specification for the FVTool, and the `spec` specification string. The specification strings available are:

- 'N, F0'

(not case sensitive), where:

- N is the filter order
- F0 is the center frequency.

The center frequency is typically specified in normalized frequency units, unless a sampling frequency in Hz is included in the specification: `d = fdesign.octave(..., Fs)`. In this case, all frequencies must be specified in Hz, with the center frequency falling between 20 Hz and 20 kHz (the audio range).

**Examples** Design an sixth order, octave-band class 0 filter with a center frequency of 1000 Hz and, a sampling frequency of 44.1 kHz.

```
d = fdesign.octave(1, 'Class 0', 'N,F0', 6, 1000, 44100);  
Hd = design(d);  
fvtool(Hd)
```

The following figure shows the magnitude response plot of the filter. The logarithmic scale for frequency is automatically set by FVTool for the octave filters.

fdesign

# fdesign.parmeq

---

**Purpose** Parametric equalizer filter specification

**Syntax** `d = fdesign.parmeq(spec, specvalue1, specvalue2, ...)`  
`d = fdesign.parmeq(... fs)`

**Description** `d = fdesign.parmeq(spec, specvalue1, specvalue2, ...)` constructs a parametric equalizer filter design object, where `spec` is a non-case sensitive specification string. The choices for `spec` are as follows:

- 'FO, BW, BWp, Gref, GO, GBW, Gp' (minimum order default)
- 'FO, BW, BWst, Gref, GO, GBW, Gst'
- 'FO, BW, BWp, Gref, GO, GBW, Gp, Gst'
- 'N, FO, BW, Gref, GO, GBW'
- 'N, FO, BW, Gref, GO, GBW, Gp'
- 'N, FO, Fc, Qa, GO'
- 'N, FO, Fc, S, GO'
- 'N, FO, BW, Gref, GO, GBW, Gst'
- 'N, FO, BW, Gref, GO, GBW, Gp, Gst'
- 'N, Flow, Fhigh, Gref, GO, GBW'
- 'N, Flow, Fhigh, Gref, GO, GBW, Gp'
- 'N, Flow, Fhigh, Gref, GO, GBW, Gst'
- 'N, Flow, Fhigh, Gref, GO, GBW, Gp, Gst'

where the parameters are defined as follows:

- BW — Bandwidth
- BWp — Passband Bandwidth
- BWst — Stopband Bandwidth
- Gref — Reference Gain (decibels)

- $G_0$  — Center Frequency Gain (decibels)
- $GBW$  — Gain at which Bandwidth (BW) is measured (decibels)
- $G_p$  — Passband Gain (decibels)
- $G_{st}$  — Stopband Gain (decibels)
- $N$  — Filter Order
- $F_0$  — Center Frequency
- $F_c$  — Cutoff frequency
- $F_{high}$  - Higher Frequency at Gain  $GBW$
- $F_{low}$  - Lower Frequency at Gain  $GBW$
- $Q_a$ -Quality Factor
- $S$ -Slope Parameter for Shelving Filters

Regardless of the specification string chosen, there are some conditions that apply to the specification parameters. These are as follows:

- Specifications for parametric equalizers must be given in decibels
- To boost the input signal, set  $G_0 > G_{ref}$ ; to cut, set  $G_{ref} > G_0$
- For boost:  $G_0 > G_p > GBW > G_{st} > G_{ref}$ ; For cut:  $G_0 < G_p < GBW < G_{st} < G_{ref}$
- Bandwidth must satisfy:  $BW_{st} > BW > BW_p$

`d = fdesign.parmeq(... fs)` adds the input sampling frequency.  $F_s$  must be specified as a scalar trailing the other numerical values provided, and is assumed to be in Hz.

## Examples

Design a Chebyshev Type II parametric equalizer filter that cuts by 12 dB:

```
d = fdesign.parmeq('N,Flow,Fhigh,Gref,G0,GBW,Gst',...
    4,.3,.5,0,-12,-10,-1);
Hd = design(d,'cheby2');
fvtool(Hd)
```

Design a 4th order audio lowpass ( $F0 = 0$ ) shelving filter with cutoff frequency of  $Fc = 0.25$ , quality factor  $Qa = 10$ , and boost gain of  $G0 = 8$  dB:

```
d = fdesign.parameq('N,F0,Fc,Qa,G0',4,0,0.25,10,8);  
Hd = design(d);  
fvtool(Hd)
```

Design 4th-order highpass shelving filters with  $S=1.5$  and  $S=3$ :

```

N=4;
FO = 1;
Fc = .4; % Cutoff Frequency
GO = 10;
S = 1.5;
S2=3;
f = fdesign.parmeq('N,FO,Fc,S,GO',N,FO,Fc,S,GO);
h1 = design(f);
f.S=3;
h2=design(f);
hfvt=fvtool([h1 h2]);
set(hfvt,'Filters',[h1 h2]);
legend(hfvt,'S=1.5','S=3');
    
```

## See Also

fdesign

## How To

- Parametric Equalizer Design

**Purpose**

Peak filter specification

**Syntax**

```
d = fdesign.peak(specstring, value1, value2, ...)  
d = fdesign.peak(n,f0,q)  
d = fdesign.peak(...,Fs)  
d = fdesign.peak(...,MAGUNITS)
```

**Description**

`d = fdesign.peak(specstring, value1, value2, ...)` constructs a peaking filter specification object `d`, with a specification string set to `specstring` and values provided for all members of the `specstring`. The possible specification strings, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth
- Ap - Passband Ripple (decibels)
- Ast - Stopband Attenuation (decibels)

Different specification strings, resulting in different specification objects, may have different design methods available. Use the function

`designmethods` to get a list of design methods available for a given specification. For example:

```
>> d = fdesign.peak('N,F0,Q,Ap',6,0.5,10,1);  
>> designmethods(d)
```

Design Methods for class `fdesign.peak (N,F0,Q,Ap)`:

`cheby1`

`d = fdesign.peak(n,f0,q)` constructs a peaking filter specification object using the default `specstring ('N,F0,Q')` and setting the corresponding values to `n`, `f0`, and `q`.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

`d = fdesign.peak(...,Fs)` constructs a peak filter specification object while providing the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other values provided. If you specify an `Fs`, it is assumed to be in Hz, as all the other frequency values provided.

`d = fdesign.peak(...,MAGUNITS)` constructs a notch filter specification while providing the units for any magnitude specification given. `MAGUNITS` can be one of the following: `'linear'`, `'dB'`, or `'squared'`. If this argument is omitted, `'dB'` is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If `Fs` is provided, `MAGUNITS` must follow `Fs` in the input argument list.

## Examples

Design a Chebyshev Type II peaking filter with a stopband attenuation of 80 dB:

```
d = fdesign.peak('N,F0,BW,Ast',8,.65,.02,80);  
Hd = design(d,'cheby2');
```

```
fvtool(Hd)
```

This design produces a filter with the magnitude response shown in the following figure.

**See Also**

`fdesign` | `fdesign.notch` | `fdesign.parmreq`

# fdesign.polysrc

---

**Purpose** Construct polynomial sample-rate converter (POLYSRC) filter designer

**Syntax**

```
d = fdesign.polysrc(L,m)
d = fdesign.polysrc(L,m,'Fractional Delay','Np',Np)
d = fdesign.polysrc(...,Fs)
```

**Description**

`d = fdesign.polysrc(L,m)` constructs a polynomial sample-rate converter filter designer `D` with an interpolation factor `L` and a decimation factor `M`. `L` defaults to 3. `M` defaults to 2. `L` and `M` can be arbitrary positive numbers.

`d = fdesign.polysrc(L,m,'Fractional Delay','Np',Np)` initializes the filter designer specification with `Np` and sets the polynomial order to the value `Np`. If omitted `Np` defaults to 3.

`d = fdesign.polysrc(...,Fs)` specifies the sampling frequency (in Hz).

**Examples** This example shows how to design sample-rate converter that uses a 3rd order Lagrange interpolation filter to convert from 44.1kHz to 48kHz:

```
[L,M] = rat(48/44.1);
f = fdesign.polysrc(L,M,'Fractional Delay','Np',3);
Hm = design(f,'lagrange');
% Original sampling frequency
Fs = 44.1e3;
% 9408 samples, 0.213 seconds long
n = 0:9407;
% Original signal, sinusoid at 1kHz
x = sin(2*pi*1e3/Fs*n);
% 10241 samples, still 0.213 seconds
y = filter(Hm,x);
% Plot original sampled at 44.1kHz
stem(n(1:45)/Fs,x(1:45))
hold on
% Plot fractionally interpolated signal (48kHz) in red
stem((n(3:51)-2)/(Fs*L/M),y(3:51),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48 kHz sample rate')
```

This code generates the following figure.

For more information about Farrow SRCs, see the “Efficient Sample Rate Conversion between Arbitrary Factors” example, `efficientsrcdemo`.

## See Also

`fdesign`

# fdesign.pulseshaping

---

**Purpose** Pulse-shaping filter specification object

**Syntax**

```
D = fdesign.pulseshaping
D = fdesign.pulseshaping(sps)
D = fdesign.pulseshaping(sps,shape)
d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)
d = fdesign.pulseshaping(...,fs)
d = fdesign.pulseshaping(...,magunits)
```

**Description** `D = fdesign.pulseshaping` constructs a specification object `D`, which can be used to design a minimum-order raised cosine filter object with a default stop band attenuation of 60dB and a rolloff factor of 0.25.

`D = fdesign.pulseshaping(sps)` constructs a minimum-order raised cosine filter specification object `d` with a positive integer-valued oversampling factor, `SamplesPerSymbol`.

`D = fdesign.pulseshaping(sps,shape)` constructs `d` where `shape` specifies the `PulseShape` property. Valid entries for `shape` are:

- 'Raised Cosine'
- 'Square Root Raised Cosine'
- 'Gaussian'

`d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)` constructs `d` where `spec` defines the `Specification` properties. The string entries for `spec` specify various properties of the filter, including the order and frequency response. Valid entries for `spec` depend upon the `shape` property. For 'Raised Cosine' and 'Square Root Raised Cosine' filters, the valid entries for `spec` are:

- 'Ast,Beta' (minimum order; default)
- 'Nsym,Beta'
- 'N,Beta'

The string entries are defined as follows:

- **Ast** —stopband attenuation (in dB). The default stopband attenuation for a raised cosine filter is 60 dB. The default stopband attenuation for a square root raised cosine filter is 30 dB. If **Ast** is specified, the minimum-order filter is returned.
- **Beta** —rolloff factor expressed as a real-valued scalar ranging from 0 to 1. Smaller rolloff factors result in steeper transitions between the passband and stopband of the filter.
- **Nsym** —filter order in symbols. The length of the impulse response is given by  $Nsym * SamplesPerSymbol + 1$ . The product  $Nsym * SamplesPerSymbol$  must be even.
- **N** —filter order (must be even). The length of the impulse response is  $N + 1$ .

If the **shape** property is specified as 'Gaussian', the valid entries for **spec** are:

- 'Nsym,BT' (default)

The string entries are defined as follows:

- **Nsym**—filter order in symbols. **Nsym** defaults to 6. The length of the filter impulse response is  $Nsym * SamplesPerSymbol + 1$ . The product  $Nsym * SamplesPerSymbol$  must be even.
- **BT** —the 3-dB bandwidth-symbol time product. **BT** is a positive real-valued scalar, which defaults to 0.3. Larger values of **BT** produce a narrower pulse width in time with poorer concentration of energy in the frequency domain.

**d** = `fdesign.pulseshaping(...,fs)` specifies the sampling frequency of the signal to be filtered. **fs** must be specified as a scalar trailing the other numerical values provided. For this case, **fs** is assumed to be in Hz and is used for analysis and visualization.

**d** = `fdesign.pulseshaping(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. Valid entries for **magunits** are:

- **linear** — specify the magnitude in linear units

- dB — specify the magnitude in dB (decibels)
- squared — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

After creating the specification object `d`, you can use the `design` function to create a filter object such as `h` in the following example:

```
d = fdesign.pulseshaping(8,'Raised Cosine','Nsym,Beta',6,0.25);  
h = design(d);
```

Normally, the `Specification` property of the specification object also determines which design methods you can use when you create the filter object. Currently, regardless of the `Specification` property, the `design` function uses the window design method with all `fdesign.pulseshaping` specification objects. The window method creates an FIR filter with a windowed impulse response.

## Examples

Pulse-shaping can be used to change the waveform of transmitted pulses so the signal bandwidth matches that of the communication channel. This helps to reduce distortion and intersymbol interference (ISI).

This example shows how to design a minimum-order raised cosine filter that provides a stop band attenuation of 60 dB, rolloff factor of 0.50, and 8 samples per symbol.

```
h = fdesign.pulseshaping(8,'Raised Cosine','Ast,Beta',60,0.50);  
Hd = design(h);  
fvtool(Hd)
```

This code generates the following figure.

This example shows how to design a raised cosine filter that spans 8 symbol durations (i.e., of order 8 symbols), has a rolloff factor of 0.50, and oversampling factor of 10.

```
h = fdesign.pulseshaping(10,'Raised Cosine','Nsym,Beta',8,0.50);  
Hd = design(h);  
fvtool(Hd, 'impulse')
```

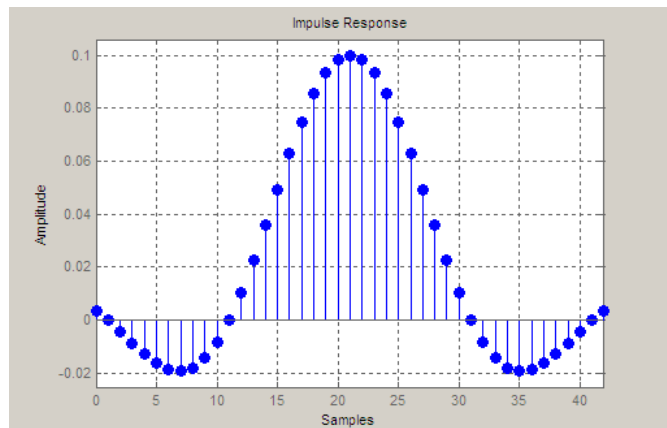

# fdesign.pulseshaping

---

This example shows how to design a square root raised cosine filter of order 42, rolloff factor of 0.25, and 10 samples per symbol.

```
h = fdesign.pulseshaping(10,'Square Root Raised Cosine','N,Beta',42);  
Hd = design(h);  
fvtool(Hd, 'impulse')
```

The following example demonstrates how to create a Gaussian pulse-shaping filter with an oversampling factor (sps) of 10, a bandwidth-time symbol product of 0.2, and 8 symbol periods. The sampling frequency is specified as 10 kHz.

## Purpose

Rational-factor sample-rate converter specification

## Syntax

```
D = fdesign.rsrc(L,M)
D = fdesign.rsrc(L,M,RESPONSE)
D = fdesign.rsrc(L,M,PULSESHAPINGRESPONSE,SPS)
D = fdesign.rsrc(L,M,CICRESPONSE,D)
D = fdesign.rsrc(L,M,RESPONSE,SPEC)
D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...)
D = fdesign.rsrc(...,Fs)
D = fdesign.rsrc(...,MAGUNITS)
```

## Description

`D = fdesign.rsrc(L,M)` constructs a rational-factor sample-rate filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L`, the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to 'Nyquist'. The default values for the transition width and stopband attenuation in the Nyquist design are  $0.1\pi$  radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 3. If `M` is unspecified, `M` defaults to 2.

`D = fdesign.rsrc(L,M,RESPONSE)` constructs an rational-factor sample-rate converter with the interpolation factor `L`, decimation factor `M`, and the response you specify in `RESPONSE`.

`D = fdesign.rsrc(L,M,PULSESHAPINGRESPONSE,SPS)` constructs a pulse-shaping rational-factor sample-rate convertor filter specification object with the 'RESPONSE' property equal to one of the supported pulseshaping filters: 'Gaussian', 'Raised Cosine', or 'Square Root Raised Cosine'. `SPS` is the samples per symbol. The samples per symbol, `SPS`, must precede any specification string.

`D = fdesign.rsrc(L,M,CICRESPONSE,D)` constructs a CIC or CIC compensator rational-factor sample-rate convertor filter specification object with the 'RESPONSE' property equal to 'CIC' or 'CICCOMP'. `D` is the differential delay. The differential delay, `D`, must precede any specification string.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters. The interpolation and decimation factors are not included in

the specification strings. Different filter responses support different specifications. The following table lists the supported response types and specification strings. The strings are not case sensitive.

<b>Design String</b>	<b>Valid Specification Strings</b>
'Arbitrary Magnitude'	See <code>fdesign.arbmag</code> for a description of the specification string entries. <ul style="list-style-type: none"> <li>• 'N,F,A' (default string)</li> <li>• 'N,B,F,A'</li> </ul>
'Arbitrary Magnitude and Phase'	See <code>fdesign.arbmagnphase</code> for a description of the specification string entries. <ul style="list-style-type: none"> <li>• 'N,F,H' (default string)</li> <li>• 'N,B,F,H'</li> </ul>
'Bandpass'	See <code>fdesign.bandpass</code> for a description of the specification string entries. <ul style="list-style-type: none"> <li>• 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default string)</li> <li>• 'N,Fc1,Fc2'</li> <li>• 'N,Fst1,Fp1,Fp2,Fst2'</li> </ul>
'Bandstop'	See <code>fdesign.bandstop</code> for a description of the specification string entries.
'CIC'	'Fp,Fst,Ap,Ast' — Only valid specification. Fp is the passband frequency, Fst is the stopband frequency, Ap is the passband ripple, and Ast is the stopband attenuation in decibels.  To specify a CIC rational-factor sample-rate convertor, include the differential delay after 'CIC' and before the filter specification string: 'Fp,Ast'. For example: <code>d = fdesign.rsrc(2,2,'cic',4);</code>

Design String	Valid Specification Strings

<b>Design String</b>	<b>Valid Specification Strings</b>
'Inverse-sinc Highpass'	See <code>fdesign.isinchnp</code> for a description of the specification string entries. <ul style="list-style-type: none"><li>• 'Fst,Fp,Ast,Ap' (default string)</li><li>• 'N,Fc,Ast,Ap'</li><li>• 'N,Fst,Fp'</li><li>• 'N,Fst,Ast,Ap'</li></ul>
'Lowpass'	See <code>fdesign.lowpass</code> for a description of the specification string entries. <ul style="list-style-type: none"><li>• 'Fp,Fst,Ap,Ast' (default string)</li><li>• 'N,F3dB'</li><li>• 'N,Fc'</li><li>• 'N,Fc,Ap,Ast'</li><li>• 'N,Fp,Ap,Ast'</li><li>• 'N,Fp,Fst'</li><li>• 'N,Fp,Fst,Ap'</li><li>• 'N,Fp,Fst,Ast'</li><li>• 'N,Fst,Ap,Ast'</li></ul>

Design String	Valid Specification Strings
'Nyquist'	<p>See <code>fdesign.nyquist</code> for a description of the specification string entries. For all Nyquist specifications, you must specify the <i>L</i>th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved.</p> <ul style="list-style-type: none"> <li>• 'TW,Ast' (default string)</li> <li>• 'N'</li> <li>• 'N,Ast'</li> <li>• 'N,Ast'</li> </ul>
'Raised Cosine'	<p>See <code>fdesign.pulseshaping</code> for a description of the specification string entries.</p> <ul style="list-style-type: none"> <li>• 'Ast,Beta' (default string)</li> <li>• 'Nsym,Beta'</li> <li>• 'N,Beta'</li> </ul> <p>The specification string must be preceded by an integer-valued <code>SamplesPerSymbol</code>.</p>
'Square Root Raised Cosine'	<p>See <code>fdesign.pulseshaping</code> for a description of the specification string entries.</p> <ul style="list-style-type: none"> <li>• 'Ast,Beta' (default string)</li> <li>• 'Nsym,Beta'</li> <li>• 'N,Beta'</li> </ul> <p>The specification string must be preceded by an integer-valued <code>SamplesPerSymbol</code>.</p>

`D = fdesign.rsrc(L,M,RESPONSE,SPEC)` constructs object `D` and sets its `Specification` property to `SPEC`. Entries in the `SPEC` string represent various filter response features, such as the filter order, that govern

the filter design. Valid entries for SPEC depend on the design type of the specifications object.

When you add the SPEC input argument, you must also add the RESPONSE input argument.

`D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...)`  
constructs an object D and sets its specifications at construction time.

`D = fdesign.rsrc(...,Fs)` provides the sampling frequency of the signal to be filtered. Fs must be specified as a scalar trailing the other numerical values provided. Fs is assumed to be in Hz as are all other frequency values provided.

`D = fdesign.rsrc(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units.
- 'dB' — specify the magnitude in dB (decibels).
- 'squared' — specify the magnitude in power units.

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use the default Nyquist design with a transition width of  $0.05\pi$  radians/sample and stopband attenuation of 40 dB. The *L*th band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,.05,40);  
hm = design(d,'kaiserwin'); %design with Kaiser window
```

---

Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use a Nyquist design with the 'N,TW'

specification string. Set the order equal to 12 and the transition width to  $0.1\pi$  radians/sample. The  $L$ th band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,'N,TW',12,0.1);
```

---

Design a rational-factor sample-rate converter. Assume the data are sampled at 10 kHz. Set the rational sample-rate change to  $3/2$ . Use a Nyquist design with the 'N,TW' specification string. Set the order equal to 12 and the transition width to 100 Hz. The  $L$ th band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(3,2,'nyquist',3,'N,TW',12,100,1e4);  
hd = design(d,'equiripple');
```

# fftcoeffs

---

**Purpose** Frequency-domain coefficients

**Syntax**  
`c = fftcoeffs(hd)`  
`c = fftcoeffs(ha)`

**Description** `c = fftcoeffs(hd)` return the frequency-domain coefficients used when filtering with the `dfilt.fftfilter` object. `c` contains the coefficients

`c = fftcoeffs(ha)` return the frequency-domain coefficients used when filtering with `adaptfilt` objects.

`fftcoeffs` applies to the following adaptive filter algorithms:

- `adaptfilt.fdaf`
- `adaptfilt.pbfdaf`
- `adaptfilt.pbufdaf`
- `adaptfilt.ufdaf`

**Examples** This example demonstrates returning the FFT coefficients from the discrete-time filter `hd`.

```
b = [0.05 0.9 0.05];  
len = 50;  
hd = dfilt.fftfilter(b,len);  
c=fftcoeffs(hd);
```

Similarly, you can use `fftcoeffs` with the adaptive filters algorithms listed above. Start by constructing an adaptive filter `ha`.

```
d = 16; % Number of samples of delay.  
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel.  
a = [1 -0.7]; % Denominator coefficients of channel.  
ntr= 1000; % Number of iterations.  
s = sign(randn(1,ntr+d)) +...  
1j*sign(randn(1,ntr+d)); % Baseband QPSK signal.  
n = 0.1*(randn(1,ntr+d) + 1j*randn(1,ntr+d)); % Noise signal.  
r = filter(b,a,s)+n; % Received signal.
```

```
x = r(1+d:ntr+d);           % Input signal (received signal).
s = s(1:ntr);               % Desired signal (delayed QPSK signal).
del = 1;                     % Initial FFT input powers.
mu = 0.1;                    % Step size.
lam = 0.9;                   % Averaging factor.
blocksize = 8;               % Block size.
ha = adaptfilt.pbufdaf(32,mu,1,del,lam,blocksize);
```

Here are the coefficients before you filter a signal.

```
c=fftcoeffs(ha);
% all coefficients are zero
NumNonzero =nnz(c);
```

Filtering a signal `y` produces complex nonzero coefficients that you use `fftcoeffs` to see.

```
[y,e] = filter(ha,x,s);
c=fftcoeffs(ha);
```

y = filter(hm,x,dim)
```

**Description** This reference page contains three sections that describe the syntaxes for the filter objects:

- “Fixed-Point Filter Syntaxes” on page 4-644
- “Adaptive Filter Syntaxes” on page 4-645
- “Multirate Filter Syntaxes” on page 4-646

**Fixed-Point Filter Syntaxes**

`y = filter(hd,x)` filters a vector of real or complex input data `x` through a fixed-point filter `hd`, producing filtered output data `y`. The vectors `x` and `y` have the same length. `filter` stores the final conditions for the filter in the `States` property of `hd` — `hd.States`.

When you set the property `PersistentMemory` to `false` (the default setting), the initial conditions for the filter are set to zero before filtering starts. To use nonzero initial conditions for `hd`, set `PersistentMemory` to `true`. Then set `hd.States` to a vector of `nstates(hd)` elements, one element for each state to set. If you specify a scalar for `hd.States`, `filter` expands the scalar to a vector of the proper length for the states. All elements of the expanded vector have the value of the scalar.

If `x` is a matrix, `y = filter(hd,x)` filters along each column of `x` to produce a matrix `y` of independent channels. If `x` is a multidimensional

array, `y = filter(hd,x)` filters `x` along the first nonsingleton dimension of `x`.

To use nonzero initial conditions when you are filtering a matrix `x`, set the filter states to a matrix of initial condition values. Set the initial conditions by setting the `States` property for the filter (`hd.states`) to a matrix of `nstates(hd)` rows and `size(x,2)` columns.

`y = filter(hd,x,dim)` applies the filter `hd` to the input data located along the specific dimension of `x` specified by `dim`.

When you are filtering multichannel data, `dim` lets you specify which dimension of the input matrix to filter along — whether a row represents a channel or a column represents a channel. When you provide the `dim` input argument, the filter operates along the dimension specified by `dim`. When your input data `x` is a vector or matrix and `dim` is 1, each column of `x` is treated as a one input channel. When `dim` is 2, the filter treats each row of the input `x` as a channel.

To filter multichannel data in a loop environment, you must use the `dim` input argument to set the proper processing dimension.

You specify the initial conditions for each channel individually, when needed, by setting `hm.states` to a matrix of `nstates(hd)` rows (one row containing the states for one channel of input data) and `size(x,2)` columns (one column containing the filter states for each channel).

### Adaptive Filter Syntaxes

`y = filter(ha,x,d)` filters a vector of real or complex input data `x` through an adaptive filter object `ha`, producing the estimated desired response data `y` from the process of adapting the filter. The vectors `x` and `y` have the same length. Use `d` for the desired signal. Note that `d` and `x` must be the same length signal chains.

`[y,e] = filter(ha,x,d)` produces the estimated desired response data `y` and the prediction error `e` (refer to previous syntax for more information).

## Multirate Filter Syntaxes

`y = filter(hd,x)` filters a vector of real or complex input data `x` through a fixed-point filter `hd`, producing filtered output data `y`. The vectors `x` and `y` have the same length. `filter` stores the final conditions for the filter in the `States` property of `hd` — `hd.states`.

`y = filter(hm,x,dim)` applies the filter `hd` to the input data located along the specific dimension of `x` specified by `dim`.

When you are filtering multichannel data, `dim` lets you specify which dimension of the input matrix to filter along — whether a row represents a channel or a column represents a channel. When you provide the `dim` input argument, the filter operates along the dimension specified by `dim`. When your input data `x` is a vector or matrix and `dim` is 1, each column of `x` is treated as a one input channel. When `dim` is 2, the filter treats each row of the input `x` as a channel.

To filter multichannel data in a loop environment, you must use the `dim` input argument to set the processing dimension.

You specify the initial conditions for each channel individually, when needed, by setting `hm.states` to a matrix of `nstates(hm)` rows (one row containing the states for one channel of input data) and `size(x,2)` columns (one column containing the filter states for each channel).

The number of data samples in your input data set `x` does not need to be a multiple of the rate change factor `r` for the object. When the rate change factor is not an even divisor of the number of input samples `x`, `filter` processes the samples as shown in the following figure, where the rate change factor is 3 and the number of input samples is 23. Decimators always take the first input sample to generate the first output sample. After that, the next output sample comes after each `r` number of input samples.

## Examples

Filter a signal using a filter with various initial conditions (IC) or no initial conditions.

```
x = randn(100,1); % Original signal.
b = fir1(50,.4); % 50th-order linear-phase FIR filter.
hd = dfilt.dffir(b); % Direct-form FIR implementation.
```

% Do not set specific initial conditions.

```
y1 = filter(hd,x); % 'PersistentMemory'='false' (default).
zf = hd.states; % Final conditions.
```

Now use nonzero initial conditions by setting ICs after before you filter.

```
hd.persistentmemory = true;
hd.states = 1; % Uses scalar expansion.
y2 = filter(hd,x);
stem([y1 y2]) % Different sequences at beginning.
```

Looking at the stem plot shows that the sequences are different at the beginning of the filter process.

# filter

Here is one way to use `filter` with streaming data.

```
reset(hd);           % Clear filter history.  
y3 = filter(hd,x);  % Filter entire signal in one block.
```

As an experiment, repeat the process, filtering the data as sections, rather than in streaming form.

```
reset(hd);           % Clear filter history.  
yloop = zeros(20,5); % Preallocate output array.  
xblock = reshape(x,[20 5]);  
for i=1:5,  
    yloop(:,i) = filter(hd,xblock(:,i));  
end
```

Use a stem plot to see the comparison between streaming and block-by-block filtering.

```
stem([y3 yloop(:)]);
```

Filtering the signal section-by-section is equivalent to filtering the entire signal at once.

To show the similarity between filtering with discrete-time and with multirate filters, this example demonstrates multirate filtering.

```
Fs = 44.1e3;           % Original sampling frequency: 44.1kHz.
n = [0:10239].';      % 10240 samples, 0.232 second long signal.
x = sin(2*pi*1e3/Fs*n); % Original signal, sinusoid at 1kHz.
m = 2;                % Decimation factor.
hm = mfilt.firdecim(m); % Use the default filter.
```

First, filter without setting initial conditions.

```
y1 = filter(hm,x);      % PersistentMemory is false (default).  
zf = hm.states;       % Final conditions.
```

This time, set nonzero initial conditions before filtering the data.

```
hm.persistentmemory = true;  
hm.states = 1;        % Uses scalar expansion to set ICs.  
y2 = filter(hm,x);  
stem([y1(1:60) y2(1:60)]) % Show the filtering results.
```

Note the different sequences at the start of filtering.

Finally, try filtering streaming data.

```
reset(hm);            % Clear the filter history.  
y3 = filter(hm,x);   % Filter entire signal in one block.
```

As with the discrete-time filter, filtering the signal section by section is equivalent to filtering the entire signal at once.

```
reset(hm);           % Clear filter history again.  
yloop = zeros(1024,5); % Preallocate output array.  
xblock = reshape(x,[2048 5]);  
for i=1:5,  
    yloop(:,i) = filter(hm,xblock(:,i));  
end  
stem([y3 yloop(:)]);
```

## Algorithms

### Quantized Filters

The `filter` command implements fixed- or floating-point arithmetic on the quantized filter structure you specify.

The algorithm applied by `filter` when you use a discrete-time filter object on an input signal depends on the response you chose for the filter, such as lowpass or Nyquist or bandstop. To learn more about each filter algorithm, refer to the literature reference provided on the appropriate discrete-time filter reference page.

---

**Note** `dfilt/filter` does not normalize the filter coefficients automatically. Function `filter` supplied by MATLAB does normalize the coefficients.

---

### Adaptive Filters

The algorithm used by `filter` when you apply an adaptive filter object to a signal depends on the algorithm you chose for your adaptive filter. To learn more about each adaptive filter algorithm, refer to the literature reference provided on the appropriate `adaptfilt.algorithm` reference page.

### Multirate Filters

The algorithm applied by `filter` when you apply a multirate filter objects to signals depends on the algorithm you chose for the filter — the form of the multirate filter, such as decimator or interpolator. To learn more about each filter algorithm, refer to the literature reference provided on the appropriate multirate filter reference page.

# filterbuilder

---

**Purpose** GUI-based filter design

**Syntax** `filterbuilder(h)`  
`filterbuilder('response')`

**Description** `filterbuilder` starts a GUI-based tool for building filters. It relies on the `fdesign` object-object oriented filter design paradigm, and is intended to reduce development time during the filter design process. `filterbuilder` uses a specification-centered approach to find the best algorithm for the desired response.

---

**Note** You must have the Signal Processing Toolbox installed to use `fdesign` and `filterbuilder`. Some of the features described below may be unavailable if your installation does not additionally include the DSP System Toolbox. You can verify the presence of both toolboxes by typing `ver` at the command prompt.

---

The `filterbuilder` GUI contains many features not available in `FDATool`. For more information on how to use `filterbuilder`, see “Filterbuilder Design Process”.

To use `filterbuilder`, enter `filterbuilder` at the MATLAB command line using one of three approaches:

- Simply enter `filterbuilder`. MATLAB opens a dialog for you to select a filter response type. After you select a filter response type, `filterbuilder` launches the appropriate filter design dialog box.
- Enter `filterbuilder(h)`, where `h` is an existing filter object. For example, if `h` is a bandpass filter, `filterbuilder(h)` opens the bandpass filter design dialog box. (The `h` object must have been created using `filterbuilder` or must be a `dfilt`, `mfilt`, or filter System object created using `fdesign`.)

**Note** You must have the DSP System Toolbox software to create and import filter System objects.

- Enter `filterbuilder('response')`, replacing *response* with a response string from the following table. MATLAB opens a filter design dialog that corresponds to the response string.

**Note** You must have the DSP System Toolbox software to implement a number of the filter designs listed in the following table. If you only have the Signal Processing Toolbox software, you can design a limited set of the following filter-response types.

Response String	Description of Resulting Filter Design	Filter Object
arbgrpdelay	Arbitrary group delay filter design	<code>fdesign.arbgrpdelay</code>
arbmag	Arbitrary magnitude filter design	<code>fdesign.arbmag</code>
arbmagnphase	Arbitrary response filter (magnitude and phase)	<code>fdesign.arbmagnphase</code>
audioweighting	Audio weighting filter	<code>fdesign.audioweighting</code>
bandpass or bp	Bandpass filter	<code>fdesign.bandpass</code>
bandstop or bs	Bandstop filter	<code>fdesign.bandstop</code>
cic	CIC filter	<code>fdesign.decimator(M,'cic',... or</code>
ciccomp	CIC compensator	<code>fdesign.ciccomp</code> <code>r(L,'cic',</code>
comb	Comb filter	<code>fdesign.comb</code>

and  
`fdesign.interpolator`

# filterbuilder

---

Response String	Description of Resulting Filter Design	Filter Object
diff	Differentiator filter	fdesign.differentiator
fracdelay	Fractional delay filter	fdesign.fracdelay
halfband or hb	Halfband filter	fdesign.halfband
highpass or hp	Highpass filter	fdesign.highpass
hilb	Hilbert filter	fdesign.hilbert
isinc, isinclp, or isinchp	Inverse sinc lowpass or highpass filter	fdesign.isinclp and fdesign.isinchp
lowpass or lp	Lowpass filter (default)	fdesign.lowpass
notch	Notch filter	fdesign.notch
nyquist	Nyquist filter	fdesign.nyquist
octave	Octave filter	fdesign.octave
parameq	Parametric equalizer filter	fdesign.parameq
peak	Peak filter	fdesign.peak
pulseshaping	Pulse-shaping filter	fdesign.pulseshaping

---

**Note** Because they do not change the filter structure, the magnitude specifications and design method are tunable when using `filterbuilder`.

---

## Filterbuilder Design Panes

### Main Design Pane

The main pane of filterbuilder varies depending on the filter response type, but the basic structure is the same. The following figure shows the basic layout of the dialog box.

As you choose the response for the filter, the available options and design parameters displayed in the dialog box change. This display allows you to focus only on parameters that make sense in the context of your filter design.

Every filter design dialog box includes the options displayed at the top of the dialog box, shown in the following figure.

- **Save variable as** — When you click **Apply** to apply your changes or **OK** to close this dialog box, `filterbuilder` saves the current filter to your MATLAB workspace as a filter object with the name you enter.
- **View Filter Response** — Displays the magnitude response for the current filter specifications and design method by opening the Filter Visualization Tool (`fvttool`).

---

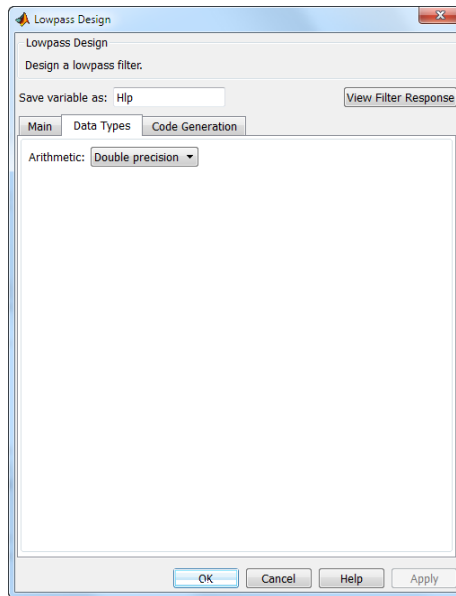

**Note** The `filterbuilder` dialog box includes an **Apply** option. Each time you click **Apply**, `filterbuilder` writes the modified filter to your MATLAB workspace. This modified filter has the variable name you assign in **Save variable as**. To apply changes without overwriting the variable in your workspace, change the variable name in **Save variable as** before you click **Apply**.

---

There are three tabs in the Filterbuilder dialog box, containing three panes: **Main**, **Data Types**, and **Code Generation**. The first pane changes according to the filter being designed. The last two panes are the same for all filters. These panes are discussed in the following sections.

### Data Types Pane

The second tab in the Filterbuilder dialog box is shown in the following figure.

The **Arithmetic** drop down box allows the choice of **Double precision**, **Single precision**, or **Fixed point**. Some of these options may be unavailable depending on the filter parameters. The following table describes these options.

<b>Arithmetic List Entry</b>	<b>Effect on the Filter</b>
Double precision	All filtering operations and coefficients use double-precision, floating-point representations and math. When you use filterbuilder to

Arithmetic List Entry	Effect on the Filter
	create a filter, double precision is the default value for the Arithmetic property.
Single precision	All filtering operations and coefficients use single-precision floating-point representations and math.
Fixed point	This string applies selected default values, typically used on many digital processors, for the properties in the fixed-point filter. These properties include coefficient word lengths, fraction lengths, and various operating modes. This setting allows signed fixed data types only. Fixed-point filter design with <code>filterbuilder</code> is available only when you install Fixed-Point Designer software along with DSP System Toolbox software.

The following figure shows the **Data Types** pane after you select **Fixed point** for **Arithmetic** and set **Filter internals** to **Specify precision**. This figure shows the **Data Types** pane for the case where the **Use a System object to implement filter** check box is not selected in the **Main** pane.

**Bandpass Design**

Bandpass Design

Design a bandpass filter.

Save variable as:

Main | Data Types | Code Generation

Arithmetic:

Fixed-point data types

	Mode	Signed	Word length	Fr
Input signal	Binary point scaling	yes	<input type="text" value="16"/>	<input type="text" value="15"/>
Coefficients	<input type="text" value="Specify word length"/>	<input checked="" type="checkbox"/>	<input type="text" value="16"/>	
Filter internals	<input type="text" value="Specify precision"/>			
Product	Binary point scaling	yes	<input type="text" value="32"/>	<input type="text" value="29"/>

Output	Binary point scaling	yes	<input type="text" value="16"/>	<input type="text" value="15"/>

Fixed-point operational parameters

Rounding mode:  Overflow mode:

## Input signal

Specify the format the filter applies to data to be filtered. For all cases, `filterbuilder` implements filters that use binary point scaling and signed input. You set the word length and fraction length as needed.

## Coefficients

Choose how you specify the word length and the fraction length of the filter numerator and denominator coefficients:

- `Specify word length` enables you to enter the word length of the coefficients in bits. In this mode, `filterbuilder` automatically sets the fraction length of the coefficients to the binary-point only scaling that provides the best possible precision for the value and word length of the coefficients.
- `Binary point scaling` enables you to enter the word length and the fraction length of the coefficients in bits. If applicable, enter separate fraction lengths for the numerator and denominator coefficients.
- The filter coefficients do not obey the **Rounding mode** and **Overflow mode** parameters that are available when you select `Specify precision` from the Filter internals list. Coefficients are always saturated and rounded to `Nearest`.

## Section Input

Choose how you specify the word length and the fraction length of the fixed-point data type going into each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- `Binary point scaling` enables you to enter the word and fraction lengths of the section input in bits.
- `Specify word length` enables you to enter the word lengths in bits.

## Section Output

Choose how you specify the word length and the fraction length of the fixed-point data type coming out of each section of an SOS

filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- **Binary point scaling** enables you to enter the word and fraction lengths of the section output in bits.
- **Specify word length** enables you to enter the output word lengths in bits.

## State

Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Use this parameter to specify how to designate the state word and fraction lengths. This parameter is not visible for direct form and direct form I filter structures because `filterbuilder` deduces the state directly from the input format. States always use signed representation:

- **Binary point scaling** enables you to enter the word length and the fraction length of the accumulator in bits.
- **Specify precision** enables you to enter the word length and fraction length in bits (if available).

## Product

Determines how the filter handles the output of product operations. Choose from the following options:

- **Full precision** — Maintain full precision in the result.
- **Keep LSB** — Keep the least significant bit in the result when you need to shorten the data words.
- **Specify Precision** — Enables you to set the precision (the fraction length) used by the output from the multiplies.

## Filter internals

Specify how the fixed-point filter performs arithmetic operations within the filter. The affected filter portions are filter products, sums, states, and output. Select one of these options:

- **Full precision** — Specifies that the filter maintains full precision in all calculations for products, output, and in the accumulator.
- **Specify precision** — Set the word and fraction lengths applied to the results of product operations, the filter output, and the accumulator. Selecting this option enables the word and fraction length controls.

## **Signed**

Selecting this option directs the filter to use signed representations for the filter coefficients.

## **Word length**

Sets the word length for the associated filter parameter in bits.

## **Fraction length**

Sets the fraction length for the associate filter parameter in bits.

## **Accum**

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

Determines how the accumulator outputs stored values. Choose from the following options:

- **Full precision** — Maintain full precision in the accumulator.
- **Keep MSB** — Keep the most significant bit in the accumulator.
- **Keep LSB** — Keep the least significant bit in the accumulator when you need to shorten the data words.
- **Specify Precision** — Enables you to set the precision (the fraction length) used by the accumulator.

## **Output**

Sets the mode the filter uses to scale the output data after filtering. You have the following choices:

- **Avoid Overflow** — Set the output data fraction length to avoid causing the data to overflow. **Avoid overflow** is considered

the conservative setting because it is independent of the input data values and range.

- **Best Precision** — Set the output data fraction length to maximize the precision in the output data.
- **Specify Precision** — Set the fraction length used by the filtered data.

## **Fixed-point operational parameters**

Parameters in this group control how the filter rounds fixed-point values and how it treats values that overflow.

### **Rounding mode**

Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).

- **ceil** - Round toward positive infinity.
- **convergent** - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.
- **zero/fix** - Round toward zero.
- **floor** - Round toward negative infinity.
- **nearest** - Round toward nearest. Ties round toward positive infinity.
- **round** - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

### **Overflow mode**

Sets the mode the filter uses to respond to overflow conditions in fixed-point arithmetic. Choose from the following options:

- **Saturate** — Limit the output to the largest positive or negative representable value.
- **Wrap** — Set overflowing values to the nearest representable value using modular arithmetic.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

### **Cast before sum**

Specifies whether to cast numeric data to the appropriate accumulator format before performing sum operations. Selecting **Cast before sum** ensures that the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

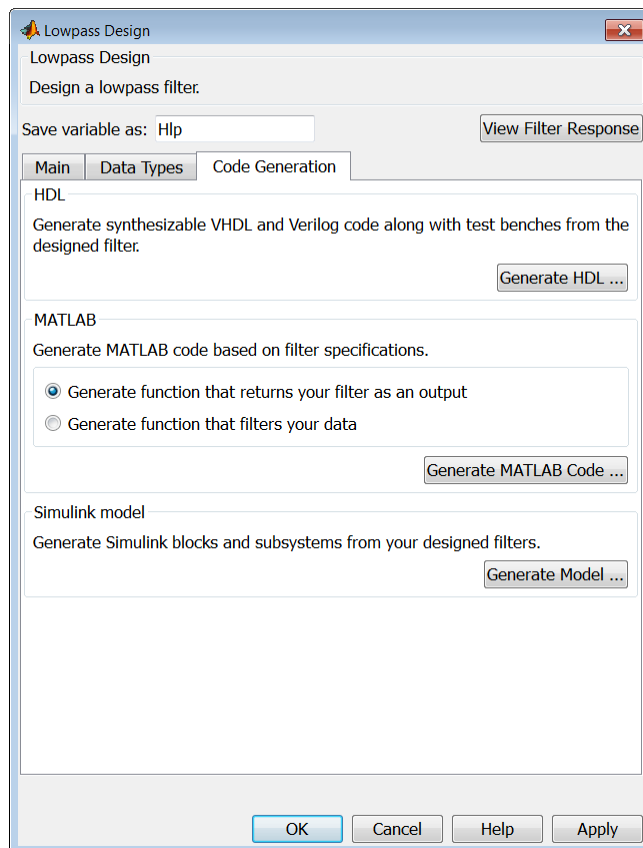

If you clear **Cast before sum**, the filter prevents the addends from being cast to the sum format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use. The input format referenced by **Cast before sum** depends on the filter structure you are using.

The effect of clearing or selecting **Cast before sum** is as follows:

- **Cleared** — Configures filter summation operations to retain the addends in the format carried from the previous operation.
- **Selected** — Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually, selecting **Cast before sum** generates results from the summation that more closely match those found from digital signal processors.

## Code Generation Pane

The code generation pane contains options for various implementations of the completed filter design. Depending on your installation, you can generate MATLAB, VHDL, and Verilog code from the designed filter. You can also choose to create or update a Simulink model from the designed filter. The following section explains these options.

## HDL

For more information on this option, see “Opening the Filter Design HDL Coder™ GUI From the filterbuilder GUI”.

## MATLAB

### Generate MATLAB code based on filter specifications

- **Generate function that returns your filter as an output**

Selecting this option generates a function that designs either a DFILT/MFILT object or a system object (depending on whether you have selected the **Use a System object to implement the filter** check box) using `fdesign`. The function call returns a filter object.

- **Generate function that filters your data**

Selecting this option generates a function that takes data as input, and outputs data filtered with the designed filter.

Clicking on the **Generate MATLAB code** button, brings up a Save File dialog. Specify the file name and location, and save. The filter is now contained in an editable file.

## Simulink Model

### Generate Simulink blocks and subsystems from your designed filters

When the **Use a System object to implement filter** check box is selected in the **Main** pane, you are able to generate Simulink models as long as the **Arithmetic** is not set to **Fixed point** in the **Data Types** pane. If the **Arithmetic** is set to **Fixed point**, the **Generate Model** button in the **Simulink model** panel will be disabled.

Clicking on the **Generate Model** button brings up the **Export to Simulink** dialog box, as shown in the following figure.

You can set the following parameters in this dialog box:

- **Block Name** — The name for the new subsystem block, set to **Filter** by default.
- **Destination** — **Current** saves the generated model to the current Simulink model; **New** creates a new model to contain the generated block; **User Defined** creates a new model or subsystem to the user-specified location enumerated in the **User Defined** text box.
- **Overwrite generated 'Filter' block** — When this check box is selected, DSP System Toolbox software overwrites an existing block with the name specified in **Block Name**; when cleared, creates a new block with the same name.
- **Build model using basic elements** — When this check box is selected, DSP System Toolbox software builds the model using only basic blocks.
- **Optimize for zero gains** — When this check box is selected, DSP System Toolbox software removes all zero gain blocks from the model.

- **Optimize for unity gains** — When this check box is selected, DSP System Toolbox software replaces all unity gains with direct connections.
  - **Optimize for negative gains** — When this check box is selected, DSP System Toolbox software removes all negative unity gain blocks, and changes sign at the nearest summation block.
  - **Optimize delay chains** — When this check box is selected, DSP System Toolbox software replaces delay chains made up of  $n$  unit delays with a single delay by  $n$ .
  - **Optimize for unity scale values** — When this check box is selected, DSP System Toolbox software removes all scale value multiplications by 1 from the filter structure.
  - **Input processing** — Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:
    - **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
    - **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.
- For more information about sample- and frame-based processing, see “Sample- and Frame-Based Concepts”.
- **Realize Model** — DSP System Toolbox software builds the model with the set parameters.

## Filter Responses

Select your filter response from the **filterbuilder Response Selection** main menu.

If you have the DSP System Toolbox software, the following **Response Selection** menu appears.

Select your desired filter response from the menu and design your filter. The following sections describe the options available for each response type.

## Arbitrary Response Filter Design Dialog Box – Main Pane

Arbitrary Response Design

Arbitrary Response Design

Design an arbitrary response filter. The constraint can be on the magnitude only, or on the magnitude and the phase.

▸ Design options

## Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

### Impulse response

This dialog only applies if you have the DSP System Toolbox software. Select either **FIR** or **IIR** from the drop down list, where **FIR** is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. Arbitrary group delay designs are only available if **Impulse response** is **IIR**. Without the DSP System Toolbox, the only available arbitrary response filter design is **FIR**.

### Order mode

This dialog only applies if you have the DSP System Toolbox software. Choose **Minimum** or **Specify**. Choosing **Specify** enables the **Order** dialog.

### Order

This dialog only applies when **Order mode** is **Specify**. For an **FIR** design, specify the filter order. For an **IIR** design, you can specify an equal order for the numerator and denominator, or you can specify different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box. Because the Signal Processing Toolbox only supports **FIR** arbitrary-magnitude filters, you do not have the option to specify a denominator order.

### Denominator order

Select the check box and enter the denominator order. This option is enabled only if **IIR** is selected for **Impulse response**.

### Filter type

This dialog only applies if you have the DSP System Toolbox software and is only available for **FIR** filters. Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods

and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### **Decimation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2 for `Decimator` and 3 for `Sample-rate converter`.

### **Interpolation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

## **Response Specification**

### **Number of Bands**

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

### **Specify response as:**

Specify the response as `Amplitudes`, `Magnitudes and phase`, `Frequency response`, or `Group delay`. `Amplitudes` is the only option if you do not have the DSP System Toolbox software. `Group delay` is only available for IIR designs.

### **Frequency units**

Specify frequency units as either `Normalized`, `Hz`, `kHz`, `MHz`, or `GHz`.

### Input Fs

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down box. This option is enabled when **Frequency units** is set to an option in hertz.

### Band Properties

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down box. Two or three columns are presented for input. The first column is always Frequencies. The other columns are either Amplitudes, Magnitudes, Phases, or Frequency Response. Enter the corresponding vectors of values for each column.

- **Frequencies and Amplitudes** — These columns are presented for input if you select Amplitudes in the **Specify response as** drop-down box.
- **Frequencies, Magnitudes, and Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is Magnitudes and phases.
- **Frequencies and Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is Frequency response.

### Algorithm

The options for each design are specific for each design method. In the arbitrary response design, the available options also depend on the **Response specifications**. This section does not present all of the available options for all designs and design methods.

### Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

## Design Options

- **Window** — Valid when the **Design method** is Frequency Sampling. Replace the square brackets with the name of a window function or function handle. For example, 'hamming' or @hamming. If the window function takes parameters other than the length, use a cell array. For example, {'kaiser',3.5} or {@chebwin,60}.
- **Density factor** — Valid when the **Design method** is equiripple. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

The default changes to 20 for an IIR arbitrary group delay design.

- **Phase constraint** — Valid when the **Design method** is equiripple, you have the DSP System Toolbox installed, and **Specify response as** is set to Amplitudes. Choose one of Linear, Minimum, or Maximum.
- **Weights** — Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple frequency bands, the **Weights** design option changes to **B1 Weights**, **B2 Weights** to designate the separate bands. Use **Bi Weights** to specify weights for the i-th band. The **Bi Weights** design option is only available when you specify the i-th band as an unconstrained.
- **Bi forced frequency point** — This option is only available in a multi-band constrained equiripple design when **Specify response as** is Amplitudes. **Bi forced frequency point** is

the frequency point in the  $i$ -th band at which the response is forced to be zero. The index  $i$  corresponds to the frequency bands in **Band properties**. For example, if you specify two bands in **Band properties**, you have **B1 forced frequency point** and **B2 forced frequency point**.

- **Norm** — Valid only for IIR arbitrary group delay designs. **Norm** is the norm used in the optimization. The default value is 128, which essentially equals the L-infinity norm. The norm must be even.
- **Max pole radius** — Valid only for IIR arbitrary group delay designs. Constrains the maximum pole radius. The default is 0.999999. Reducing the **Max pole radius** can produce a transfer function more resistant to quantization.
- **Init norm** — Valid only for IIR arbitrary group delay designs. The initial norm used in the optimization. The default initial norm is 2.
- **Init numerator** — Specifies an initial estimate of the filter numerator coefficients.
- **Init denominator** — Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems. In allpass filters, you only have to specify either the denominator or numerator coefficients. If you specify the denominator coefficients, you can obtain the numerator coefficients.

## Filter implementation

### Structure

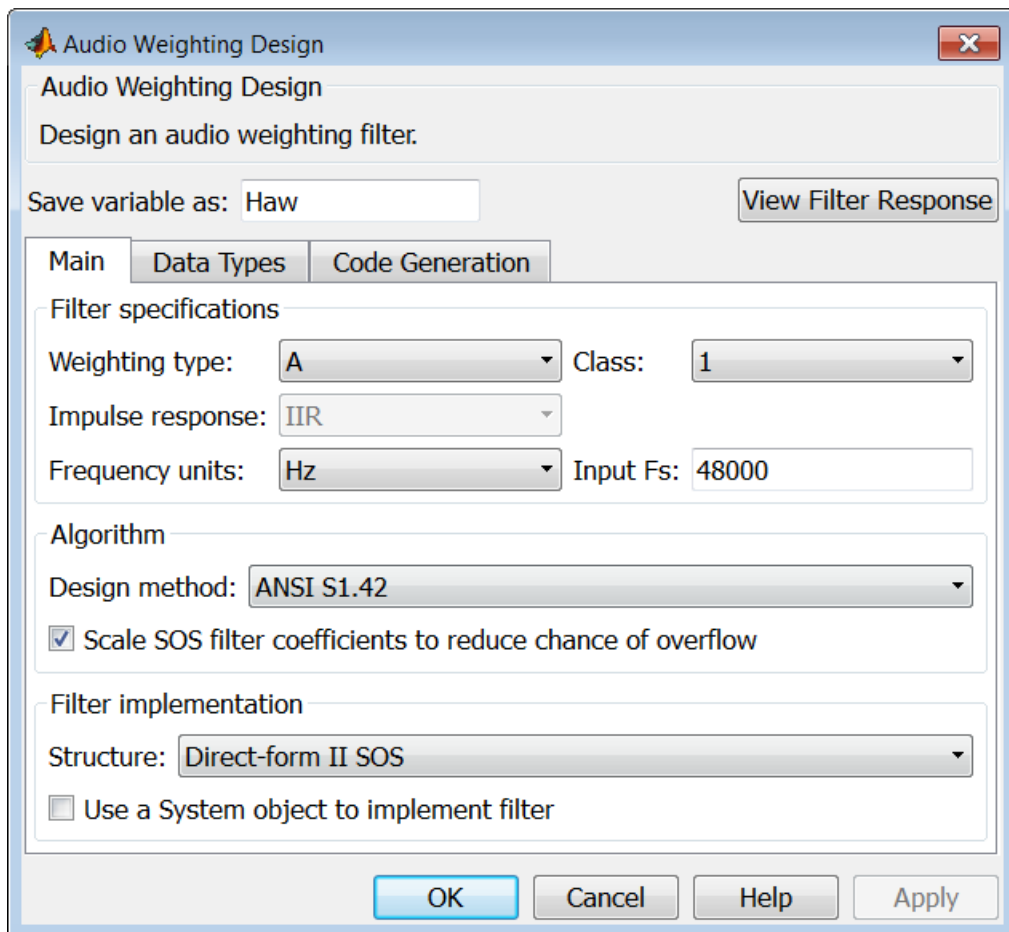

Select the structure for the filter. The available filter structures depend on the parameters you select for your filter.

### Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned

off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## Audio Weighting Filter Design Dialog Box – Main Pane

## Filter specifications

- **Weighting type** — The weighting type defines the frequency response of the filter. The valid weighting types are: A, C, C-message, ITU-T 0.41, and ITU-R 468–4 weighting. See `fdesign.audioweighting` for definitions of the weighting types.
- **Class** — Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design.
- **Impulse response** — Impulse response type as one of IIR or FIR. For A, C, C-message, and ITU-R 468–4 filter, IIR is the only option. For a ITU-T 0.41 weighting filter, FIR is the only option.
- **Frequency units** — Choose Hz, kHz, MHz, or GHz. Normalized frequency designs are not supported for audio weighting filters.
- **Input Fs** — The sampling frequency in **Frequency units**. For example, if **Frequency units** is set to kHz, setting **Input Fs** to 40 is equivalent to a 40 kHz sampling frequency.

## Algorithm

- **Design method** — Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is ANSI S1.42. This is an IIR design method that follows ANSI standard S1.42–2001. For a C message filter, the only valid design method is Bell 41009, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468–4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design, the design method is IIR least p-norm. If you choose an FIR design, the design method choices are: Equiripple or Frequency Sampling. For an ITU-T 0.41 weighting filter, the available FIR design methods are equiripple or Frequency Sampling

- **Scale SOS filter coefficients to reduce chance of overflow** — Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

## **Filter implementation**

- **Structure** — For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

For FIR designs, you can choose direct form, direct-form transposed, direct-form symmetric, direct-form asymmetric structures, or an overlap and add structure.

- **Use a System object to implement filter** — Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Filter implementation

## Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select Minimum (the default) or Specify from the drop-down box. Selecting Specify enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

**Filter type** — This dialog only applies if you have the DSP System Toolbox software.

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

## Order

Enter the filter order. This option is enabled only if you select Specify for **Order mode**.

## Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

## Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

## Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, regions between specification values such as  $F_{stop1}$  and  $F_{pass1}$  represent transition regions where the filter response is not explicitly defined.

## Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- **Passband and stopband edges** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband edges** — Define the filter by specifying frequencies for the edges of the passband.
- **Stopband edges** — Define the filter by specifying frequencies for the edges of the stopbands.
- **3dB points** — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3-dB point is the frequency for the point 3 dB below the passband value.
- **3dB points and passband width** — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the passband. (IIR filters)
- **3dB points and stopband widths** — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the stopband. (IIR filters)
- **6dB points** — Define the filter response by specifying the locations of the 6-dB points. The 6-dB point is the frequency for the point 6dB below the passband value. (FIR filters)

## Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in hertz, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

**Input Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

**Fstop1**

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Fpass1**

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Fpass2**

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Fstop2**

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

**Magnitude constraints**

Specify as **Unconstrained** or **Constrained** bands. You must have the DSP System Toolbox software to select **Constrained** bands. Selecting **Constrained** bands enables dialogs for both stopbands and the passband: **Astop1**, **Astop2**, and **Apass**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to **Constrained bands** enables the **Wstop** and **Wpass** options under **Design options**.

## Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in dB (decibels). This is the default setting.
- **Squared** — Specify the magnitude in squared units.

## Astop1

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**, either linear or decibels.

## Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

## Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

## Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

## Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

## Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

## Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Phase constraint

Valid when the **Design method** is equiripple and you have the DSP System Toolbox installed. Choose one of Linear, Minimum, or Maximum.

### Minimum order

This option only applies when you have the DSP System Toolbox software and **Order mode** is Minimum.

Select Any (default), Even, or Odd. Selecting Even or Odd forces the minimum-order design to be an even or odd order.

**Wstop1**

Weight for the first stopband.

**Wpass**

Passband weight.

**Wstop2**

Weight for the second stopband.

**Max pole radius**

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

**Init norm**

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

**Init numerator**

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

**Init denominator**

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

**Filter implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

**Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

### Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

## Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- **Passband and stopband edges** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband edges** — Define the filter by specifying frequencies for the edges of the passband.
- **Stopband edges** — Define the filter by specifying frequencies for the edges of the stopbands.
- **3dB points** — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3 dB point is the frequency for the point 3 dB point below the passband value.
- **3dB points and passband width** — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband (IIR filters).
- **3dB points and stopband widths** — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband (IIR filters).
- **6dB points** — Define the filter response by specifying the locations of the 6-dB points (FIR filters). The 6-dB point is the frequency for the point 6 dB point below the passband value.

## Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

## **Input Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

## **Output Fs**

When you design an interpolator, Fs represents the sampling frequency at the filter output rather than the filter input. This option is available only when you set **Filter type** is interpolator.

## **Fpass1**

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

## **Fstop1**

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Fstop2**

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Fpass2**

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

## Magnitude constraints

Specify as **Unconstrained** or **Constrained** bands. You must have the DSP System Toolbox software to select **Constrained** bands. Selecting **Constrained** bands enables dialogs for both passbands and the stopband: **Apass1**, **Apass2**, and **Astop**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to **Constrained** bands enables the **Wstop** and **Wpass** options under **Design options**.

## Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).
- **Squared** — Specify the magnitude in squared units.

## Apass1

Enter the filter ripple allowed in the first passband in the units you choose for **Magnitude units**, either linear or decibels.

## Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels

## Apass2

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**, either linear or decibels

## Algorithm

The parameters in this group allow you to specify the design method and structure that **filterbuilder** uses to implement your filter.

## Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the

specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### **Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### **Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### **Phase constraint**

Valid when the **Design method** is equiripple and you have the DSP System Toolbox installed. Choose one of Linear, Minimum, or Maximum.

**Minimum order**

This option only applies when you have the DSP System Toolbox software and **Order mode** is Minimum.

Select Any (default), Even, or Odd. Selecting Even or Odd forces the minimum-order design to be an even or odd order.

**Wpass1**

Weight for the first passband.

**Wstop**

Stopband weight.

**Wpass2**

Weight for the second passband.

**Match exactly**

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband .

**Max pole radius**

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

**Init norm**

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

**Init numerator**

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

**Init denominator**

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

## **Filter implementation**

### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## Filter specifications

Parameters in this group enable you to specify your CIC filter format, such as the filter type and the differential delay.

### Filter type

Select whether your filter will be a decimator or an interpolator. Your choice determines the type of filter and the design methods and structures that are available to implement your filter. Selecting decimator or interpolator activates the **Factor** option. When you design an interpolator, you enable the **Output Fs** parameter.

When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

### Differential Delay

Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

### Factor

Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

## Frequency specifications

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

## Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

## Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

## Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## Magnitude specifications

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

### Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

## **Filter implementation**

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## CIC Compensator Filter Design Dialog Box – Main Pane

The image shows a software dialog box titled "CIC Compensator Design". The main pane contains the following sections and controls:

## Filter specifications

Parameters in this group enable you to specify your filter format, such as the filter order mode and the filter type.

### Order mode

Select **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

## **Number of CIC sections**

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

## **Differential Delay**

Specify the differential delay of your target CIC filter. The default value is 1. Most CIC filters use 1 or 2.

## **Frequency specifications**

The parameters in this group allow you to specify your filter response curve.

## **Frequency specifications**

### **Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

### **Input Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### **Output Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

## **F<sub>pass</sub>**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **F<sub>stop</sub>**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

### **Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

## **A<sub>pass</sub>**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

## **Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

### **Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The

default IIR design method is usually Butterworth, and the default FIR method is equiripple.

## Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

### Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select Any, Even, or Odd from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

---

**Note** Generally, **Minimum order** designs are not available for IIR filters.

---

### **Match exactly**

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select **passband** or **stopband** or both from the drop-down list.

### **Stopband Shape**

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where **f** is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### **Stopband Decay**

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. **filterbuilder** applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay.

`filterbuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

## **Filter implementation**

### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## Filter specifications

Parameters in this group enable you to specify the type of comb filter and the number of peaks or notches.

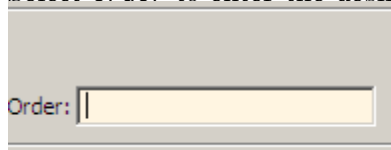

### Comb Type

Select Notch or Peak from the drop-down list. Notch creates a comb filter that attenuates a set of harmonically related frequencies. Peak creates a comb filter that amplifies a set of harmonically related frequencies.

### Order mode

Select Order or Number of Peaks/Notches from the drop-down menu.

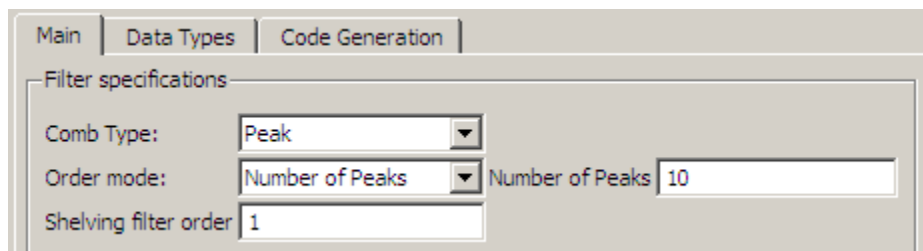

Select Order to enter the desired filter order in the

Order:

dialog box. The comb filter has notches or peaks at increments of  $2/Order$  in normalized frequency units.

Select Number of Peaks or Number of Notches to specify the number of peaks or notches and the Shelving filter order

Main | Data Types | Code Generation

Filter specifications

Comb Type:

Order mode:  Number of Peaks

Shelving filter order

**Shelving filter order**

The Shelving filter order is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

**Frequency specifications**

Parameters in this group enable you to specify the frequency constraints and frequency units.

**Frequency specifications**

Select Quality factor or Bandwidth.

Quality factor is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the  $-3$  dB point.

Bandwidth specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the  $-3$  dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

**Frequency Units**

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input Fs** dialog box.

**Magnitude specifications**

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Bandwidth gain** — Specify the gain at which the bandwidth is measured. The default is  $-3$  dB.

## **Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

## **Design Method**

The IIR Butterworth design is the only option for peaking or notching comb filters.

## **Filter implementation**

### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off.

## Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, regions between specification values such as **Fpass** ( $f_1$ ) and **Fstop** ( $f_3$ ) represent transition regions where the filter response is not explicitly defined.

### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### **Order**

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

### **Decimation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### **Interpolation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

## **Frequency specifications**

The parameters in this group allow you to specify your filter response curve.

### **Frequency constraints**

This option is only available when you specify the order of the filter design. Supported options are **Unconstrained** and **Passband edge and stopband edge**.

### **Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the

frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

## **Input Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

## **Fpass**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Fstop**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

## **Magnitude constraints**

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. If the value of **Frequency constraints** is Unconstrained, **Magnitude constraints** must be Unconstrained. If the value of **Frequency constraints** is Passband edge and stopband edge, **Magnitude constraints** can be Unconstrained, Passband ripple, or Stopband attenuation.

## Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

## Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

## Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

## Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

## Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

## Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

## Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

## Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

## Wpass

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

## Wstop

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

## Filter implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned

off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

### Fractional Delay Filter Design Dialog Box – Main Pane

#### Frequency specifications

Parameters in this group enable you to specify your filter format, such as the fractional delay and the filter order.

## **Order**

If you choose **Specify** for **Order mode**, enter your filter order in this field, or select the order from the drop-down list. `list.filterbuilder` designs a filter with the order you specify.

## **Fractional delay**

Specify a value between 0 and 1 samples for the filter fractional delay. The default value is 0.5 samples.

## **Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

## **Input Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

## Filter specifications

Parameters in this group enable you to specify your filter type and order.

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select Single-rate, Decimator, or Interpolator. By default, filterbuilder specifies single-rate filters.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that decimates or interpolates your input by a factor of two.

### Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

## Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.

In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

### Input Fs

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

## Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

## Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

## Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).

## Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

## Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

## Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are Equiripple and Kaiser window. For IIR halfband filters, the available design options are Butterworth, Elliptic, and IIR quasi-linear phase.

## Design Options

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

**Minimum phase**

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

**Stopband Shape**

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

**Stopband Decay**

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. **filterbuilder** applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. **filterbuilder** applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

## **Filter implementation**

### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Filter implementation

## Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option so you can enter the filter order.

If your **Impulse response** is IIR, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

### Filter type

This option is only available if you have the DSP System Toolbox software. Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a highpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the region between specification values  $F_{stop}$  and  $F_{pass}$  represents the transition region where the filter response is not explicitly defined.

## Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Stopband edge and passband edge** — Define the filter by specifying the frequencies for the edges for the stopband and passband.
- **Passband edge** — Define the filter by specifying the frequency for the edge of the passband.
- **Stopband edge** — Define the filter by specifying the frequency for the edges of the stopband.
- **Stopband edge and 3dB point** — Define the filter by specifying the stopband edge frequency and the 3-dB down point (IIR designs).
- **3dB point and passband edge** — Define the filter by specifying the 3-dB down point and passband edge frequency (IIR designs).
- **3dB point** — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- **6dB point** — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

## Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

## Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the

specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

**Fpass**

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Fstop**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Astop**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Apass**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

## Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

## Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

## Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

## Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

## Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a

reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

**Phase constraint**

This option only applies when you have the DSP System Toolbox software and when the **Design method** is `equiripple`. Select one of `Linear`, `Minimum`, or `Maximum`.

**Minimum order** — This option only applies when you have the DSP System Toolbox software and the **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

**Match Exactly**

Specifies that the resulting filter design matches either the passband or stopband when you select `Passband` or `Stopband`.

**Stopband Shape**

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

**Stopband Decay**

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.

- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.
- When you set **Stopband shape** to  $1/f$ , enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterbuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

## **Wpass**

Passband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

## **Wstop**

Stopband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

## **Filter implementation**

### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

## Order mode

This option is only available if you have the DSP System Toolbox software. Select either **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

## Filter type

This option is only available if you have the DSP System Toolbox software. Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, **filterbuilder** specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

## Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

**Decimation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

**Interpolation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

**Frequency specifications**

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the regions between 0 and  $f_1$  and between  $f_2$  and 1 represent the transition regions where the filter response is explicitly defined by the transition width.

## Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

## Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

## Transition width

Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

## Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

## Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default)
- **Squared** — Specify the magnitude in squared units.

## Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

## Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

## Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

## Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

## Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

## Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a

reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

## **FIR Type**

This option is only available in a minimum-order design. Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients
  - Type 4 — FIR filter with odd order antisymmetric coefficients
- Select 3 or 4 from the drop-down list.

## **Filter implementation**

### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

## **Order mode**

Select **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

## **Response type**

Select **Lowpass** or **Highpass** to design an inverse sinc lowpass or highpass filter.

## **Filter type**

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, **filterbuilder** specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

## **Order**

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

## **Decimation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

## **Interpolation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values such as  $F_{pass}$  and  $F_{stop}$  represent transition regions where the filter response is not explicitly defined.

### Frequency constraints

This option is only available when you specify the filter order. The following options are available:

- Passband and stopband edges — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- Passband edge — Define the filter by specifying frequencies for the edges of the passband.
- Stopband edge — Define the filter by specifying frequencies for the edges of the stopbands.

- **6dB point** — The 6-dB point is the frequency for the point 6 dB point below the passband value.

## **Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

## **Input Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

## **Fpass**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Fstop**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

## **Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.

- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

**Apass**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

**Astop**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

**Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

**Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

## Phase constraint

Available options are Linear, Minimum, and Maximum.

## Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

## Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.
- When you set **Stopband shape** to 1/f, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterbuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

## **Sinc frequency factor**

A frequency dilation factor. The sinc frequency factor,  $C$ , parameterizes the passband magnitude response for a lowpass design through  $H(\omega) = \text{sinc}(C\omega)^{-P}$  and for a highpass design through  $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$ .

## **Sinc power**

Negative power of passband magnitude response. The sinc power,  $P$ , parameterizes the passband magnitude response for a lowpass design through  $H(\omega) = \text{sinc}(C\omega)^{-P}$  and for a highpass design through  $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$ .

## **Filter implementation**

### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

If your **Impulse response** is IIR, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

### Filter type

This option is only available if you have the DSP System Toolbox. Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

## Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

## Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

## Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

## Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.

In the figure, regions between specification values such as  $F_{\text{pass}}$  and  $F_{\text{stop}}$  represent transition regions where the filter response is not explicitly defined.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Passband and stopband edge** — Define the filter by specifying the frequencies for the edge of the stopband and passband.
- **Passband edge** — Define the filter by specifying the frequency for the edge of the passband.
- **Stopband edge** — Define the filter by specifying the frequency for the edges of the stopband.
- **Passband edge and 3dB point** — Define the filter by specifying the passband edge frequency and the 3-dB down point (IIR designs).
- **3dB point and stopband edge** — Define the filter by specifying the 3-dB down point and stopband edge frequency (IIR designs).
- **3dB point** — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- **6dB point** — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

### Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is

available when you select one of the frequency options from the **Frequency units** list.

## **Fpass**

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Fstop**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

## **Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

## **Apass**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

## **Astop**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

## **Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

## Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

## Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

## Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

## Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

## Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is equiripple. Select one of Linear, Minimum, or Maximum.

**Minimum order** — This option only applies when you have the DSP System Toolbox software and the **Order mode** is Minimum.

Select Any (default), Even, or Odd. Selecting Even or Odd forces the minimum-order design to be an even or odd order.

## Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select Passband or Stopband.

## Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

## Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.

- When you set **Stopband shape** to  $1/f$ , enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. filterbuilder applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

**Wpass**

Passband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

**Wstop**

Stopband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

**Filter implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

**Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

**Notch**

See “Peak/Notch Filter Design Dialog Box — Main Pane” on page 4-771.

## Nyquist Filter Design Dialog Box – Main Pane

## Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

### Band

Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region,  $bw$ , is calculated using the value for Band:

$$bw = F_s/(2*Band).$$

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

## Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

## Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

## Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

## Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, BW is the width of the transition region and **Band** determines the location of the center of the region.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Passband and stopband edges** — Define the filter by specifying the frequencies for the edges for the stopbands and passbands.
- **Passband edges** — Define the filter by specifying frequencies for the edges of the passband.
- **Stopband edges** — Define the filter by specifying frequencies for the edges of the stopbands.
- **3 dB points** — Define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point 3 dB point below the passband value.
- **3 dB points and passband width** — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- **3 dB points and stopband widths** — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

## Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

## Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

## Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

### Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

## Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

## Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

## Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

## Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

## Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

## Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

## Minimum order

When you select this parameter, the design method determines and designs the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select Any, Even, or Odd from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

---

**Note** Generally, **Minimum order** designs are not available for IIR filters.

---

## Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband or both from the drop-down list.

## Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. filterbuilder applies that slope to the stopband.
- When you set **Stopband shape** to  $1/f$ , enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. filterbuilder applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

#### Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Specify frequency units as Hz or kHz.

### **Input Fs**

Specify the input sampling frequency in the frequency units specified previously.

### **Center Frequency**

Select from the drop-down list of available center frequency values.

## **Algorithm**

### **Design Method**

Butterworth is the design method used for this type of filter.

### **Scale SOS filter coefficients to reduce chance of overflow**

Select the check box to scale the filter coefficients.

## **Filter implementation**

### **Structure**

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

## **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default, the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## Filter specifications

### Order mode

Select **Minimum** to design a minimum order filter that meets the design specifications, or **Specify** to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a **Minimum** order filter, the available frequency constraints are:

- Center frequency, bandwidth, passband width
- Center frequency, bandwidth, stopband width

If you select **Specify**, the available frequency constraints are:

- Center frequency, bandwidth
- Center frequency, quality factor
- Shelf type, cutoff frequency, quality factor
- Shelf type, cutoff frequency, shelf slope parameter
- Low frequency, high frequency

### Order

This parameter is enabled only if the **Order mode** is set to **Specify**. Enter the filter order in this text box.

## Frequency specifications

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

### Frequency constraints

Select the specification to represent the frequency constraints. The following options are available:

- Center frequency, bandwidth, passband width (available for minimum order only)

- Center frequency, bandwidth, stopband width (available for minimum order only)
- Center frequency, bandwidth (available for a specified order only)
- Center frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, shelf slope parameter (available for a specified order only)
- Low frequency, high frequency (available for a specified order only)

### Frequency units

Select the frequency units from the available drop down list (Normalized, Hz, kHz, MHz, GHz). If Normalized is selected, then the **Input Fs** box is disabled for input.

### Input Fs

Enter the input sampling frequency. This input box is disabled for input if Normalized is selected in the **Frequency units** input box.

### Center frequency

Enter the center frequency in the units specified by the value in **Frequency units**.

### Bandwidth

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to  $\text{db}(\text{sqrt}(.5))$ , or  $-3$  dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency constraints** are: Center frequency, bandwidth, passband width, Center frequency, bandwidth, stopband width, or Center frequency, bandwidth.

## Passband width

The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, passband width.

## Stopband width

The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, stopband width.

## Low frequency

Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

## High frequency

Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

## Gain specifications

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

## Gain constraints

Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- Reference, center frequency, bandwidth, passband
- Reference, center frequency, bandwidth, stopband
- Reference, center frequency, bandwidth, passband, stopband
- Reference, center frequency, bandwidth

## Gain units

Specify the gain units either dB or squared. These units are used for all gain specifications in the dialog box.

## Reference gain

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

## Bandwidth gain

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a bandwidth parameter, or is Low frequency, high frequency.

## Center frequency gain

Specify the center frequency in **Gain units**

## Passband gain

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

## Stopband gain

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constraints** are Center frequency, bandwidth, stopband width.

## **Boost/cut gain**

The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the `Shelf` type parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

## **Algorithm**

### **Design method**

Select the design method from the drop-down list. Different IIR design methods are available depending on the filter constraints you specify.

### **Scale SOS filter coefficients to reduce chance of overflow**

Select the check box to scale the filter coefficients.

## **Filter implementation**

### **Structure**

Select filter structure. The possible choices are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## **Filter specifications**

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

### **Response**

Select Peak or Notch from the drop-down box.

### **Order**

Enter the filter order. The order must be even.

## **Frequency specifications**

This group of parameters allows you to specify frequency constraints and units.

### **Frequency Constraints**

Select the frequency constraints for filter specification. There are two choices as follows:

- Center frequency and quality factor
- Center frequency and bandwidth

### **Frequency units**

The frequency units are normalized by default. If you specify units other than normalized, `filterbuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz.

### **Input Fs**

This input box is enabled if **Frequency units** other than Normalized (0 to 1) are specified. Enter the input sampling frequency.

### **Center frequency**

Enter the center frequency in the units you specified in **Frequency units**.

## **Quality Factor**

This input box is enabled only when Center frequency and quality factor is chosen for the **Frequency Constraints**. Enter the quality factor.

## **Bandwidth**

This input box is enabled only when Center frequency and bandwidth is chosen for the **Frequency Constraints**. Enter the bandwidth.

## **Magnitude specifications**

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

### **Magnitude Constraints**

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- Unconstrained
- Passband ripple
- Stopband attenuation
- Passband ripple and stopband attenuation

### **Magnitude units**

Select the magnitude units: either dB or squared.

### **A<sub>pass</sub>**

This input box is enabled if the magnitude constraints selected are Passband ripple or Passband ripple and stopband attenuation. Enter the passband ripple.

### **A<sub>stop</sub>**

This input box is enabled if the magnitude constraints selected are Stopband attenuation or Passband ripple and stopband attenuation. Enter the stopband attenuation.

## Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

## Design Method

Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

## Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

## Filter implementation

### Structure

Lists all available filter structures for the filter specifications and design method you select. The typical options are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

### Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Filter implementation

Structure:

Use a System object to implement filter

## Filter specifications

Parameters in this group enable you to specify the shape and length of the filter.

### Pulse shape

Select the shape of the impulse response from the following options:

- Raised Cosine
- Square Root Raised Cosine
- Gaussian

### Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- **Minimum**— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.
- **Specify order**—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be  $\text{Order}+1$ .
- **Specify symbols**—This option enables the user to specify the length of the impulse response in an alternative manner. If **Specify symbols** is chosen, the **Order** input box changes to the **Number of symbols** input box.

### Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response. If **Order** is specified in **Number of symbols**, the filter length will be  $\text{Number of symbols} * \text{Samples per symbol} + 1$ . The product  $\text{Number of symbols} * \text{Samples per symbol}$  must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product **Number of symbols\*Samples per symbol** must be an even number. The filter length will be **Number of symbols\*Samples per symbol+1**.

## Filter Type

This option is only available if you have the DSP System Toolbox software. Choose **Single rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. If you select **Decimator** or **Interpolator**, the decimation and interpolation factors default to the value of the **Samples per symbol**. If you select **Sample-rate converter**, the interpolation factor defaults to **Samples per symbol** and the decimation factor defaults to 3.

## Frequency specifications

Parameters in this group enable you to specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

### Rolloff factor

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

### Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterbuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: **Normalized** (0 to 1), **Hz**, **kHz**, **MHz**, **GHz**

For a Gaussian pulse shape, the available frequency specifications are:

### Bandwidth-time product

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (BT) must be a positive real number.

Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

## Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterbuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz

## Magnitude specifications

If the **Order mode** is specified as Minimum, the **Magnitude units** may be selected from:

- dB—Specify the magnitude in decibels (default).
- Linear—Specify the magnitude in linear units.

## Algorithm

The only **Design method** available for FIR pulse-shaping filters is the Window method.

## Filter implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

### Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

**Purpose**

Store CIC filter states

**Description**

`filtstates.cic` objects hold the states information for CIC filters. Once you create a CIC filter, the states for the filter are stored in `filtstates.cic` objects, and you can access them and change them as you would any property of the filter. This arrangement parallels that of the `filtstates` object that IIR direct-form I filters use (refer to `filtstates` for more information).

Each `States` property in the CIC filter comprises two properties — `Numerator` and `Comb` — that hold `filtstates.cic` objects. Within the `filtstates.cic` objects are the numerator-related and comb-related filter states. The states are column vectors, where each column represents the states for one section of the filter. For example, a CIC filter with four decimator sections and four interpolator sections has `filtstates.cic` objects that contain four columns of states each.

**Examples**

To show you the `filtstates.cic` object, create a CIC decimator and filter a signal:

```
fs = 44.1e3;           % Original sampling frequency: 44.1kHz.  
n = 0:10239;         % 10240 samples, 0.232 second long signal.  
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1kHz.  
hm=mfilt.cicdecim(5,2,4);  
y=filter(hm,x);
```

`hm` has nonzero states now.

You can use `int` to see the states as 32-bit integers.

```
s=hm.states;  
int(s.Integrator)
```

**See Also**

`mfilt` | `mfilt.cicdecim` | `mfilt.cicinterp` | `filtstates`

# firband

---

**Purpose** Constrained-band equiripple FIR filter

**Syntax**

```
b = firband(n,f,a,w,c)
b = firband(n,f,a,s)
b = firband(...,'1')
b = firband(...,'minphase')
b = firband(...,'check')
b = firband(...,{lgrid})
[b,err] = firband(...)
[b,err,res] = firband(...)
```

**Description** `firband` is a minimax filter design algorithm that you use to design the following types of real FIR filters:

- Types 1-4 linear phase
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase
- Maximum phase
- Minimum order (even or odd), extra ripple
- Maximal ripple
- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain
- Arbitrary shape frequency response curve filters

`b = firband(n,f,a,w,c)` designs filters having constrained error magnitudes (ripples). `c` is a cell array of strings of the same length as `w`. The entries of `c` must be either 'c' to indicate that the corresponding element in `w` is a constraint (the ripple for that band cannot exceed that

value) or `'w'` indicating that the corresponding entry in `w` is a weight. There must be at least one unconstrained band — `c` must contain at least one `w` entry. For instance, Example 1 below uses a weight of one in the passband, and constrains the stopband ripple not to exceed 0.2 (about 14 dB).

A hint about using constrained values: if your constrained filter does not touch the constraints, increase the error weighting you apply to the unconstrained bands.

Notice that, when you work with constrained stopbands, you enter the stopband constraint according to the standard conversion formula for power — the resulting filter attenuation or constraint equals  $20 \cdot \log(\textit{constraint})$  where *constraint* is the value you enter in the function. For example, to set 20 dB of attenuation, use a value for the constraint equal to 0.1. This applies to constrained stopbands only.

`b = fircband(n,f,a,s)` is used to design filters with special properties at certain frequency points. `s` is a cell array of strings and must be the same length as `f` and `a`. Entries of `s` must be one of:

- `'n'` — normal frequency point.
- `'s'` — single-point band. The frequency band is given by a single point. You must specify the corresponding gain at this frequency point in `a`.
- `'f'` — forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- `'i'` — indeterminate frequency point. Use this argument when bands abut one another (no transition region).

`b = fircband(...,'1')` designs a type 1 filter (even-order symmetric). You could also specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), or type 4 (odd-order antisymmetric) filters. Note there are restrictions on `a` at `f = 0` or `f = 1` for types 2, 3, and 4.

`b = fircband(...,'minphase')` designs a minimum-phase FIR filter. There is also `'maxphase'`.

# fircband

---

`b = fircband(..., 'check')` produces a warning when there are potential transition-region anomalies in the filter response.

`b = fircband(..., {lgrid})`, where `{lgrid}` is a scalar cell array containing an integer, controls the density of the frequency grid.

`[b,err] = fircband(...)` returns the unweighted approximation error magnitudes. `err` has one element for each independent approximation error.

`[b,err,res] = fircband(...)` returns a structure `res` of optional results computed by `fircband`, and contains the following fields:

Structure Field	Contents
<code>res.fgrid</code>	Vector containing the frequency grid used in the filter design optimization
<code>res.des</code>	Desired response on <code>fgrid</code>
<code>res.wt</code>	Weights on <code>fgrid</code>
<code>res.h</code>	Actual frequency response on the frequency grid
<code>res.error</code>	Error at each point (desired response - actual response) on the frequency grid
<code>res.iextr</code>	Vector of indices into <code>fgrid</code> of external frequencies
<code>res.fextr</code>	Vector of extremely frequencies
<code>res.order</code>	Filter order
<code>res.edgecheck</code>	Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK , 0 = probable transition-region anomaly , -1 = edge not checked. Computed when you specify the 'check' input option in the function syntax.

Structure Field	Contents
res.iterations	Number of Remez iterations for the optimization
res.evals	Number of function evaluations for the optimization

## Examples

Two examples of designing filters with constrained bands.

### Example 1

design a 12th-order lowpass filter with a constraint on the filter response.

```
b = fircband(12,[0 0.4 0.5 1], [1 1 0 0], ...  
[1 0.2], {'w' 'c'});
```

Using `fvtool` to display the result `b` shows you the response of the filter you designed.

## Example 2

design two filters of different order with the stopband constrained to 60 dB. Use excess order (80) in the second filter to improve the passband ripple.

```
b1=firband(60,[0 .2 .25 1],[1 1 0 0],...  
[1 .001],{'w','c'});  
b2=firband(80,[0 .2 .25 1],[1 1 0 0],...  
[1 .001],{'w','c'});  
hfvt = fvtool(b1,1,b2,1);  
legend(hfvt,'Filter Order 60','Filter Order 80');
```

To set the stopband constraint to 60 dB, enter 0.001, since  $20 \cdot \log(0.001) = -60$ , or 60 dB of signal attenuation.

**See Also**

[firceqrip](#) | [firgr](#) | [firls](#) | [firpm](#)

# fireqint

---

## Purpose

Equiripple FIR interpolators

## Syntax

```
b = fireqint(n,1,alpha)
b = fireqint(n,1,alpha,w)
b = fireqint('minorder',1,alpha,r)
b = fireqint({'minorder',initord},1,alpha,r)
```

## Description

`b = fireqint(n,1,alpha)` designs an FIR equiripple filter useful for interpolating input signals. `n` is the filter order and it must be an integer. `1`, also an integer, is the interpolation factor. `alpha` is the bandlimitedness factor, identical to the same feature in `intfilt`.

`alpha` is inversely proportional to the transition bandwidth of the filter. It also affects the bandwidth of the don't-care regions in the stopband. Specifying `alpha` allows you to control how much of the Nyquist interval your input signal occupies. This can be beneficial for signals to be interpolated because it allows you to increase the transition bandwidth without affecting the interpolation, resulting in better stopband attenuation for a given `1`. If you set `alpha` to `1`, `fireqint` assumes that your signal occupies the entire Nyquist interval. Setting `alpha` to a value less than one allows for don't-care regions in the stopband. For example, if your input occupies half the Nyquist interval, you could set `alpha` to `0.5`.

The signal to be interpolated is assumed to have zero (or negligible) power in the frequency band between  $(\alpha \cdot \pi)$  and  $\pi$ . `alpha` must therefore be a positive scalar between `0` and `1`. `fireqint` treat such bands as don't-care regions for assessing filter design.

`b = fireqint(n,1,alpha,w)` allows you to specify a vector of weights in `w`. The number of weights required in `w` is given by `1 + floor(1/2)`. The weights in `w` are applied to the passband ripple and stopband attenuations. Using weights (values between `0` and `1`) enables you to specify different attenuations in different parts of the stopband, as well as providing the ability to adjust the compromise between passband ripple and stopband attenuation.

`b = fireqint('minorder',1,alpha,r)` allows you to design a minimum-order filter that meets the design specifications. `r` is a vector

of maximum deviations or ripples from the ideal filter magnitude response. When you use the input argument **minorder**, you must provide the vector **r**. The number of elements required in **r** is given by  $1 + \text{floor}(1/2)$ .

`b = fireqint({'minorder',initord},l,alpha,r)` adds the argument **initord** so you can provide an initial estimate of the filter order. Any positive integer is valid here. Again, you must provide **r**, the vector of maximum deviations or ripples, from the ideal filter magnitude response.

## Examples

Design a minimum order interpolation filter for  $l = 6$  and  $\alpha = 0.8$ . A vector of ripples must be supplied with the input argument **minorder**.

```
b = fireqint('minorder',6,.8,[0.01 .1 .05 .02]);  
hm = mfilt.firinterp(6,b); % Create a polyphase interpolator filter  
zerophase(hm);
```

Here is the resulting plot of the zerophase response for **hm**.

For `hm`, the minimum order filter with the requested design specifications, here is the filter information.

`hm =`

```
FilterStructure: 'Direct-Form FIR Polyphase Interpolator'  
Arithmetic: 'double'  
Numerator: [1x70 double]  
InterpolationFactor: 6  
PersistentMemory: false
```

## See Also

`firgr` | `firhalfband` | `firls` | `firnyquist` | `mfilt` | `intfilt`

**Purpose** Constrained equiripple FIR filter

**Syntax**

```
B = firceqrip(n,Fo,DEV)
B = firceqrip(...,'slope',r)
B = firceqrip(...,'passedge')
B = firceqrip(...,'stopedge')
B = firceqrip(...,'high')
B = firceqrip(...,'min')
B = firceqrip(...,'invsinc',C)
B = firceqrip(...,'invdiric',C)
```

**Description** `B = firceqrip(n,Fo,DEV)` designs an order  $n$  filter (filter length equal  $n + 1$ ) lowpass FIR filter with linear phase.

`firceqrip` produces the same equiripple lowpass filters that `firpm` produces using the Parks-McClellan algorithm. The difference is how you specify the filter characteristics for the function.

The input argument `Fo` specifies the frequency at the upper edge of the passband in normalized frequency ( $0 < Fo < 1$ ). The two-element vector `dev` specifies the peak or maximum error allowed in the passband and stopbands. Enter `[d1 d2]` for `dev` where `d1` sets the passband error and `d2` sets the stopband error.

`B = firceqrip(...,'slope',r)` uses the input keyword 'slope' and input argument `r` to design a filter with a nonequiripple stopband. `r` is specified as a positive constant and determines the slope of the stopband attenuation in dB/normalized frequency. Greater values of `r` result in increased stopband attenuation in dB/normalized frequency.

`B = firceqrip(...,'passedge')` designs a filter where `Fo` specifies the frequency at which the passband starts to rolloff.

`B = firceqrip(...,'stopedge')` designs a filter where `Fo` specifies the frequency at which the stopband begins.

`B = firceqrip(...,'high')` designs a high pass FIR filter instead of a lowpass filter.

`B = firceqrip(...,'min')` designs a minimum-phase filter.

`B = firceqrip(..., 'invsinc', C)` designs a lowpass filter whose magnitude response has the shape of an inverse sinc function. This may be used to compensate for sinc-like responses in the frequency domain such as the effect of the zero-order hold in a D/A converter. The amount of compensation in the passband is controlled by `C`, which is specified as a scalar or two-element vector. The elements of `C` are specified as follows:

- If `C` is supplied as a real-valued scalar or the first element of a two-element vector, `firceqrip` constructs a filter with a magnitude response of  $1/\text{sinc}(C*\pi*F)$  where `F` is the normalized frequency.
- If `C` is supplied as a two-element vector, the inverse-sinc shaped magnitude response is raised to the positive power `C(2)`. If we set `P=C(2)`, `firceqrip` constructs a filter with a magnitude response  $1/\text{sinc}(C*\pi*F)^P$ .

If this FIR filter is used with a cascaded integrator-comb (CIC) filter, setting `C(2)` equal to the number of stages compensates for the multiplicative effect of the successive sinc-like responses of the CIC filters.

---

**Note** Since the value of the inverse sinc function becomes unbounded at  $C=1/F$ , the value of `C` should be greater the reciprocal of the passband edge frequency. This can be expressed as  $F_0 < 1/C$ . For users familiar with CIC decimators, `C` is equal to 1/2 the product of the differential delay and decimation factor.

---

`B = firceqrip(..., 'invdiric', C)` designs a lowpass filter with a passband that has the shape of an inverse Dirichlet sinc function. The frequency response of the inverse Dirichlet sinc function is given by

$$\left\{ rC \frac{\sin(f/2r)}{\sin(Cf/2)} \right\}^p$$

where  $C$ ,  $r$ , and  $p$  are scalars. The input  $C$  can be a scalar or vector containing 2 or 3 elements. If  $C$  is a scalar,  $p$  and  $r$  equal 1. If  $C$  is a two-element vector, the first element is  $C$  and the second element is  $p$ ,  $[C \ p]$ . If  $C$  is a three-element vector, the third element is  $r$ ,  $[C \ p \ r]$ .

## Examples

To introduce a few of the variations on FIR filters that you design with `firceqrip`, these five examples cover both the default syntax `b = firceqrip(n,wo,del)` and some of the optional input arguments. For each example, the input arguments  $n$ ,  $wo$ , and  $del$  remain the same.

### Example 1

Design an order = 30 FIR filter.

```
b = firceqrip(30,0.4,[0.05 0.03]); fvtool(h)
```

When the plot appears in the Filter Visualization Tool window, select **Analysis > Overlay Analysis > Phase Response**. Then select **View > Full View**. This displays the following plot.

## Example 2

Design an order = 30 FIR filter with the `stopedge` keyword to define the response at the edge of the filter stopband.

```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge'); fvtool(h)
```

## Example 3

Design an order = 30 FIR filter with the `slope` keyword and `r = 20`.

```
b = firceqrip(30,0.4,[0.05 0.03],'slope',20,'stopedge'); fvtool(h)
```

## Example 4

Design an order = 30 FIR filter defining the stopband and specifying that the resulting filter is minimum phase with the `min` keyword.

```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge','min'); fvtool(h)
```

Comparing this filter to the filter in Example 1, the cutoff frequency  $\omega_0 = 0.4$  now applies to the edge of the stopband rather than the point at which the frequency response magnitude is 0.5.

Viewing the zero-pole plot shown here reveals this is a minimum phase FIR filter — the zeros lie on or inside the unit circle,  $z = 1$ .

### Example 5

Design an order = 30 FIR filter with the `invsinc` keyword to shape the filter passband with an inverse sinc function.

```
b = firceqrip(30,0.4,[0.05 0.03],'invsinc',[2 1.5]); fvtool(h)
```

With the inverse sinc function being applied defined as  $1/\text{sinc}(2*w)^{1.5}$ , the figure shows the reshaping of the passband that results from using the **invsinc** keyword option, and entering `c` as the two-element vector `[2 1.5]`.

## Inverse-Dirichlet-Sinc-Shaped Passband

Design two order 30 constrained equiripple FIR filters with inverse-Dirichlet-sinc-shaped passbands. The cutoff frequency in both designs is  $\pi/4$  radians/sample. Set  $C=1$  in one design  $C=2$  in the second design. The maximum passband and stopband ripple is 0.05. Set  $p=1$  in one design and  $p=2$  in the second design.

Design the filters.

```
b1 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[1 1]);  
b2 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[2 2]);
```

Obtain the filter frequency responses using `freqz`. Plot the magnitude responses.

```
[h1,~] = freqz(b1,1);  
[h2,w] = freqz(b2,1);  
plot(w,abs(h1)); hold on;  
plot(w,abs(h2),'r');  
axis([0 pi 0 1.5]);  
xlabel('Radians/sample');
```

```
ylabel('Magnitude');  
legend('C=1 p=1', 'C=2 p=2');
```

Inspect the stopband ripple in the design with  $C=1$  and  $p=1$ . The constrained design sets the maximum ripple to be 0.05. Zoom in on the stopband from the cutoff frequency of  $\pi/4$  radians/sample to  $3\pi/4$  radians/sample.

```
figure;  
plot(w,abs(h1));  
set(gca,'xlim',[pi/4 3*pi/4]);  
grid on;
```

```

**Purpose** FIR Constrained Least Squares filter

**Syntax**

```
hd = design(d, 'fircls')
hd = design(d, 'fircls', 'FilterStructure', value)
hd = design(d, 'fircls', 'PassbandOffset', value)
hd = design(d, 'fircls', 'zerophase', value)
```

**Description** `hd = design(d, 'fircls')` designs a FIR Constrained Least Squares (CLS) filter, `hd`, from a filter specifications object, `d`.

`hd = design(d, 'fircls', 'FilterStructure', value)` where `value` is one of the following filter structures:

- 'dffir', a discrete-time, direct-form FIR filter (the default value)
- 'dffirt', a discrete-time, direct-form FIR transposed filter
- 'dfsymfir', a discrete-time, direct-form symmetric FIR filter
- 'fftfir', a discrete-time, overlap-add, FIR filter

`hd = design(d, 'fircls', 'PassbandOffset', value)` where `value` sets the passband band gain in dB. The `PassbandOffset` and `Ap` values affect the upper and lower approximation bound in the passband as follows:

- Lower bound =  $(\text{PassbandOffset} - A_p/2)$
- Upper bound =  $(\text{PassbandOffset} + A_p/2)$

For bandstop filters, the `PassbandOffset` is a vector of length two that specifies the first and second passband gains. The `PassbandOffset` value defaults to 0 for lowpass, highpass and bandpass filters. The `PassbandOffset` value defaults to [0 0] for bandstop filters.

`hd = design(d, 'fircls', 'zerophase', value)` where `value` is either 'true' ('1') or 'false' ('0'). If `zerophase` is true, the lower approximation bound in the stopband is forced to zero (i.e., the filter has a zero phase response). `Zerophase` is false (0) by default.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'fircls')
```

For complete help about using `fircls`, refer to the command line help system. For example, to get specific information about using `fircls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'fircls')
```

## Examples

The following example designs a constrained least-squares FIR lowpass filter.

```
h = fdesign.lowpass('n,fc,ap,ast', 50, 0.3, 2, 30);
Hd = design(h, 'fircls');
fvtool(Hd)
```

The following example constructs a constrained least-squares FIR bandpass filter.

```
d = fdesign.bandpass('N,Fc1,Fc2,Ast1,Ap,Ast2', ...
```

# fircls

```
30,0.4,0.6,60,1,60);  
Hd = design(d, 'fircls');  
fvtool(Hd)
```

b = firgr(n,f,a,s)
b = firgr(n,f,a,s,w,e)
b = firgr(...,'1')
b = firgr(...,'minphase')
b = firgr(...,'check')
b = firgr(...,{lgrid}),
[b,err] = firgr(...)
[b,err,res] = firgr(...)
b = firgr(n,f,fresp,w)
b = firgr(n,f,{fresp,p1,p2,...},w)
b = firgr(n,f,a,w)
```

**Description**

`firgr` is a minimax filter design algorithm you use to design the following types of real FIR filters:

- Types 1-4 linear phase:
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase
- Maximum phase
- Minimum order (even or odd)
- Extra ripple
- Maximal ripple

- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain
- Arbitrary shape frequency response curve filters

`b = firgr(n,f,a,w)` returns a length  $n+1$  linear phase FIR filter which has the best approximation to the desired frequency response described by `f` and `a` in the minimax sense. `w` is a vector of weights, one per band. When you omit `w`, all bands are weighted equally. For more information on the input arguments, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(n,f,a,'hilbert')` and `b = firgr(n,f,a,'differentiator')` design FIR Hilbert transformers and differentiators. For more information on designing these filters, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(m,f,a,r)`, where `m` is one of 'minorder', 'mineven' or 'minodd', designs filters repeatedly until the minimum order filter, as specified in `m`, that meets the specifications is found. `r` is a vector containing the peak ripple per frequency band. You must specify `r`. When you specify 'mineven' or 'minodd', the minimum even or odd order filter is found.

`b = firgr({m,ni},f,a,r)` where `m` is one of 'minorder', 'mineven' or 'minodd', uses `ni` as the initial estimate of the filter order. `ni` is optional for common filter designs, but it must be specified for designs in which `firpmord` cannot be used, such as while designing differentiators or Hilbert transformers.

`b = firgr(n,f,a,w,e)` specifies independent approximation errors for different bands. Use this syntax to design extra ripple or maximal ripple filters. These filters have interesting properties such as having the minimum transition width. `e` is a cell array of strings specifying the approximation errors to use. Its length must equal the number of bands. Entries of `e` must be in the form 'e#' where # indicates which approximation error to use for the corresponding band. For example, when `e = {'e1', 'e2', 'e1'}`, the first and third bands use the same

approximation error 'e1' and the second band uses a different one 'e2'. Note that when all bands use the same approximation error, such as {'e1', 'e1', 'e1', ...}, it is equivalent to omitting e, as in `b = firgr(n,f,a,w)`.

`b = firgr(n,f,a,s)` is used to design filters with special properties at certain frequency points. `s` is a cell array of strings and must be the same length as `f` and `a`. Entries of `s` must be one of:

- 'n' — normal frequency point.
- 's' — single-point band. The frequency “band” is given by a single point. The corresponding gain at this frequency point must be specified in `a`.
- 'f' — forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- 'i' — indeterminate frequency point. Use this argument when adjacent bands abut one another (no transition region).

For example, the following command designs a bandstop filter with zero-valued single-point stop bands (notches) at 0.25 and 0.55.

```
b = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],...
[1 1 0 1 1 0 1 1],{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'})
```

`b = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...{'n' 'i' 'f' 'n' 'n' 'n'})` designs a highpass filter with the gain at 0.06 forced to be zero. The band edge at 0.055 is indeterminate since the first two bands actually touch. The other band edges are normal.

`b = firgr(n,f,a,s,w,e)` specifies weights and independent approximation errors for filters with special properties. The weights and properties are included in vectors `w` and `e`. Sometimes, you may need to use independent approximation errors to get designs with forced values to converge. For example,

```
b = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

`b = firgr(..., '1')` designs a type 1 filter (even-order symmetric). You can specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), and type 4 (odd-order antisymmetric) filters as well. Note that restrictions apply to `a` at `f = 0` or `f = 1` for FIR filter types 2, 3, and 4.

`b = firgr(..., 'minphase')` designs a minimum-phase FIR filter. You can use the argument `'maxphase'` to design a maximum phase FIR filter.

`b = firgr(..., 'check')` returns a warning when there are potential transition-region anomalies.

`b = firgr(..., {lgrid})`, where `{lgrid}` is a scalar cell array. The value of the scalar controls the density of the frequency grid by setting the number of samples used along the frequency axis.

`[b,err] = firgr(...)` returns the unweighted approximation error magnitudes. `err` contains one element for each independent approximation error returned by the function.

`[b,err,res] = firgr(...)` returns the structure `res` comprising optional results computed by `firgr`. `res` contains the following fields.

Structure Field	Contents
<code>res.fgrid</code>	Vector containing the frequency grid used in the filter design optimization
<code>res.des</code>	Desired response on <code>fgrid</code>
<code>res.wt</code>	Weights on <code>fgrid</code>
<code>res.h</code>	Actual frequency response on the frequency grid
<code>res.error</code>	Error at each point (desired response - actual response) on the frequency grid
<code>res.iextr</code>	Vector of indices into <code>fgrid</code> of external frequencies
<code>res.fextr</code>	Vector of external frequencies

Structure Field	Contents
res.order	Filter order
res.edgecheck	Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK, 0 = probable transition-region anomaly, -1 = edge not checked. Computed when you specify the 'check' input option in the function syntax.
res.iterations	Number of s iterations for the optimization
res.evals	Number of function evaluations for the optimization

`firgr` is also a “function function,” allowing you to write a function that defines the desired frequency response.

`b = firgr(n,f,fresp,w)` returns a length  $N + 1$  FIR filter which has the best approximation to the desired frequency response as returned by the user-defined function `fresp`. Use the following `firgr` syntax to call `fresp`:

```
[dh,dw] = fresp(n,f,gf,w)
```

where:

- `fresp` is the string variable that identifies the function that you use to define your desired filter frequency response.
- `n` is the filter order.
- `f` is the vector of frequency band edges which must appear monotonically between 0 and 1, where 1 is one-half of the sampling frequency. The frequency bands span  $f(k)$  to  $f(k+1)$  for  $k$  odd. The intervals  $f(k+1)$  to  $f(k+2)$  for  $k$  odd are “transition bands” or “don’t care” regions during optimization.

- *gf* is a vector of grid points that have been chosen over each specified frequency band by *firgr*, and determines the frequencies at which *firgr* evaluates the response function.
- *w* is a vector of real, positive weights, one per band, for use during optimization. *w* is optional in the call to *firgr*. If you do not specify *w*, it is set to unity weighting before being passed to *fresp*.
- *dh* and *dw* are the desired frequency response and optimization weight vectors, evaluated at each frequency in grid *gf*.

*firgr* includes a predefined frequency response function named 'firpmfrf2'. You can write your own based on the simpler 'firpmfrf'. See the help for `private/firpmfrf` for more information.

`b = firgr(n,f,{fresp,p1,p2,...},w)` specifies optional arguments *p1*, *p2*,..., *pn* to be passed to the response function *fresp*.

`b = firgr(n,f,a,w)` is a synonym for `b = firgr(n,f,{ 'firpmfrf2', a },w)`, where *a* is a vector containing your specified response amplitudes at each band edge in *f*. By default, *firgr* designs symmetric (even) FIR filters. 'firpmfrf2' is the predefined frequency response function. If you do not specify your own frequency response function (the *fresp* string variable), *firgr* uses 'firpmfrf2'.

`b = firgr(..., 'h')` and `b = firgr(..., 'd')` design antisymmetric (odd) filters. When you omit the 'h' or 'd' arguments from the *firgr* command syntax, each frequency response function *fresp* can tell *firgr* to design either an even or odd filter. Use the command syntax `sym = fresp('defaults',{n,f,[],w,p1,p2,...})`.

*firgr* expects *fresp* to return `sym = 'even'` or `sym = 'odd'`. If *fresp* does not support this call, *firgr* assumes even symmetry.

For more information about the input arguments to *firgr*, refer to *firpm*.

## Examples

These examples demonstrate some filters you might design using *firgr*.

### Example 1

design an FIR filter with two single-band notches at 0.25 and 0.55

```
b1 = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],[1 1 0 1 1 0 1 1],...  
{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'});
```

### Example 2

design a highpass filter whose gain at 0.06 is forced to be zero. The gain at 0.055 is indeterminate since it should about the band.

```
b2 = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...  
{'n' 'i' 'f' 'n' 'n' 'n'});
```

### Example 3

design a second highpass filter with forced values and independent approximation errors.

```
b3 = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1], ...  
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

Use the filter visualization tool to view the results of the filters created in these examples.

```
fvtool(b1,1,b2,1,b3,1)
```

Here is the figure from FVTool.

**Purpose**

Halfband FIR filter

**Syntax**

```
b = firhalfband(n,fp)
b = firhalfband(n,win)
b = firhalfband(n,dev,'dev')
b = firhalfband('minorder',fp,dev)
b = firhalfband('minorder',fp,dev,'kaiser')
b = firhalfband(...,'high')
b = firhalfband(...,'minphase')
```

**Description**

`b = firhalfband(n,fp)` designs a lowpass halfband FIR filter of order `n` with an equiripple characteristic. `n` must be an even integer. `fp` determines the passband edge frequency, and it must satisfy  $0 < fp < 1/2$ , where  $1/2$  corresponds to  $\pi/2$  rad/sample.

`b = firhalfband(n,win)` designs a lowpass Nth-order filter using the truncated, windowed-impulse response method instead of the equiripple method. `win` is an `n+1` length vector. The ideal impulse response is truncated to length `n + 1`, and then multiplied point-by-point with the window specified in `win`.

`b = firhalfband(n,dev,'dev')` designs an Nth-order lowpass halfband filter with an equiripple characteristic. Input argument `dev` sets the value for the maximum passband and stopband ripple allowed.

`b = firhalfband('minorder',fp,dev)` designs a lowpass minimum-order filter, with passband edge `fp`. The peak ripple is constrained by the scalar `dev`. This design uses the equiripple method.

`b = firhalfband('minorder',fp,dev,'kaiser')` designs a lowpass minimum-order filter, with passband edge `fp`. The peak ripple is constrained by the scalar `dev`. This design uses the Kaiser window method.

`b = firhalfband(...,'high')` returns a highpass halfband FIR filter.

`b = firhalfband(...,'minphase')` designs a minimum-phase FIR filter such that the filter is a spectral factor of a halfband filter (recall that `h = conv(b,flip1r(b))` is a halfband filter). This can be useful for designing perfect reconstruction, two-channel FIR filter

# firhalfband

banks. The **minphase** option for `firhalfband` is not available for the window-based halfband filter designs — `b = firhalfband(n,win)` and `b = firhalfband('minorder',fp,dev,'kaiser')`.

In the minimum phase cases, the filter order must be odd.

## Examples

This example designs a minimum order halfband filter with specified maximum ripple:

```
b = firhalfband('minorder',.45,0.0001);  
h = dfilt.dfsymfir(b);  
impz(b) % Impulse response is zero for every other sample
```

The next example designs a halfband filter with specified maximum ripple of 0.0001 dB in the pass and stop bands.

```
b = firhalfband(98,0.0001,'dev');  
h = mfilter.firdecim(2,b); % Create a polyphase decimator  
freqz(h); % 80 dB attenuation in the stopband
```

<b>Purpose</b>	Convert FIR Type I lowpass to FIR Type 1 lowpass with inverse bandwidth
<b>Syntax</b>	<code>g = firlp2lp(b)</code>
<b>Description</b>	<p><code>g = firlp2lp(b)</code> transforms the Type I lowpass FIR filter <code>b</code> with zero-phase response <math>H_r(w)</math> to a Type I lowpass FIR filter <code>g</code> with zero-phase response <math>[1 - H_r(\pi-w)]</math>.</p> <p>When <code>b</code> is a narrowband filter, <code>g</code> will be a wideband filter and vice versa. The passband and stopband ripples of <code>g</code> will be equal to the stopband and passband ripples of <code>b</code>.</p>
<b>Examples</b>	<p>Overlay the original narrowband lowpass and the resulting wideband lowpass</p> <pre>b = firgr(36,[0 .2 .25 1],[1 1 0 0],[1 5]); zerophase(b); hold on h = firlp2lp(b); zerophase(h);</pre>
<b>References</b>	Saramaki, T, Finite Impulse Response Filter Design, <i>Handbook for Digital Signal Processing</i> . S.K. Mitra and J.F. Kaiser Eds. Wiley-Interscience, N.Y., 1993, Chapter 4.
<b>See Also</b>	<code>firlp2hp</code>   <code>zerophase</code>

**Purpose**

Convert FIR lowpass filter to Type I FIR highpass filter

**Syntax**

```
g = fir1p2hp(b)
g = fir1p2hp(b, 'narrow')
g = fir1p2hp(b, 'wide')
```

**Description**

`g = fir1p2hp(b)` transforms the lowpass FIR filter `b` into a Type I highpass FIR filter `g` with zero-phase response  $H_r(\pi-w)$ . Filter `b` can be any FIR filter, including a nonlinear-phase filter.

The passband and stopband ripples of `g` will be equal to the passband and stopband ripples of `b`.

`g = fir1p2hp(b, 'narrow')` transforms the lowpass FIR filter `b` into a Type I narrow band highpass FIR filter `g` with zero-phase response  $H_r(\pi-w)$ . `b` can be any FIR filter, including a nonlinear-phase filter.

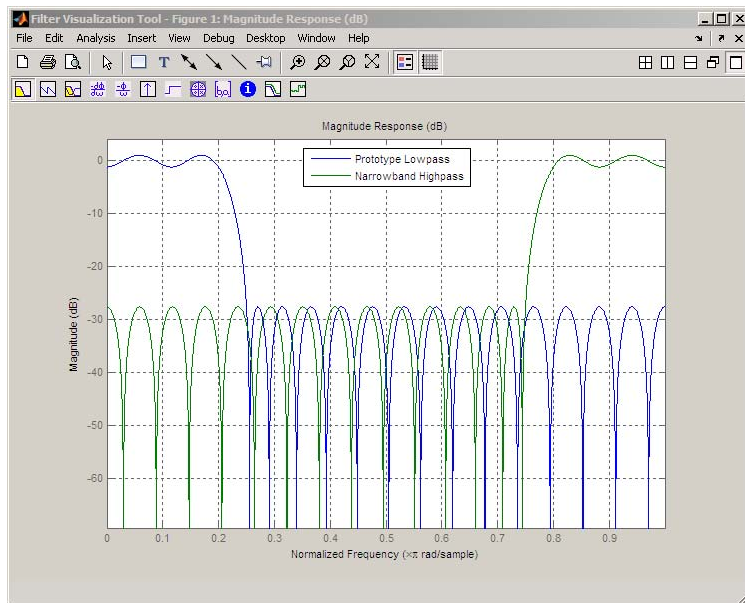

`g = fir1p2hp(b, 'wide')` transforms the Type I lowpass FIR filter `b` with zero-phase response  $H_r(w)$  into a Type I wide band highpass FIR filter `g` with zero-phase response  $1 - H_r(w)$ . Note the restriction that `b` must be a Type I linear-phase filter.

For this case, the passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.

**Examples**

Overlay the original narrowband lowpass (the prototype filter) and the post-conversion narrowband highpass and wideband highpass filters to compare and assess the conversion. The following plot shows the results.

```
b = firgr(36,[0 .2 .25 1],[1 1 0 0],[1 3]);
h = fir1p2hp(b);
hfvt = fvtool(b,1,h,1);
legend(hfvt,'Prototype Lowpass','Narrowband Highpass');
```

firlp2lp | zerophase

**Purpose** Least P-norm optimal FIR filter

**Syntax**

```
b = firlpnorm(n,f,edges,a)
b = firlpnorm(n,f,edges,a,w)
b = firlpnorm(n,f,edges,a,w,p)
b = firlpnorm(n,f,edges,a,w,p,dens)
b = firlpnorm(n,f,edges,a,w,p,dens,initnum)
b = firlpnorm(...,'minphase')
[b,err] = firlpnorm(...)
```

**Description** `b = firlpnorm(n,f,edges,a)` returns a filter of numerator order `n` which represents the best approximation to the frequency response described by `f` and `a` in the least-Pth norm sense. `P` is set to 128 by default, which essentially equivalent to the infinity norm. Vector `edges` specifies the band-edge frequencies for multiband designs. `firlpnorm` uses an unconstrained quasi-Newton algorithm to design the specified filter.

`f` and `a` must have the same number of elements, which can exceed the number of elements in `edges`. This lets you specify filters with any gain contour within each band. However, the frequencies in `edges` must also be in vector `f`. Always use `freqz` to check the resulting filter.

---

**Note** `firlpnorm` uses a nonlinear optimization routine that may not converge in some filter design cases. Furthermore the algorithm is not well-suited for certain large-order (order > 100) filter designs.

---

`b = firlpnorm(n,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `firlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. For example,

```
b = firlpnorm(20,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband, and with emphasis placed on minimizing the error in the stopband.

`b = firlpnorm(n,f,edges,a,w,p)` where `p` is a two-element vector [`pmin pmax`] lets you specify the minimum and maximum values of `p` used in the least- $p$ th algorithm. Default is [2 128] which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even numbers. The design algorithm starts optimizing the filter with `pmin` and moves toward an optimal filter in the `pmax` sense. When `p` is the string `'inspect'`, `firlpnorm` does not optimize the resulting filter. You might use this feature to inspect the initial zero placement.

`b = firlpnorm(n,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is [`dens*(n+1)`]. The default is 20. You can specify `dens` as a single-element cell array. The grid is equally spaced.

`b = firlpnorm(n,f,edges,a,w,p,dens,initnum)` lets you determine the initial estimate of the filter numerator coefficients in vector `initnum`. This can prove helpful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum`.

`b = firlpnorm(...,'minphase')` where string `'minphase'` is the last argument in the argument list generates a minimum-phase FIR filter. By default, `firlpnorm` design mixed-phase filters. Specifying input option `'minphase'` causes `firlpnorm` to use a different optimization method to design the minimum-phase filter. As a result of the different optimization used, the minimum-phase filter can yield slightly different results.

`[b,err] = firlpnorm(...)` returns the least- $p$ th approximation error `err`.

## Examples

To demonstrate `firlpnorm`, here are two examples — the first designs a lowpass filter and the second a highpass, minimum-phase filter.

```
% Lowpass filter with a peak of 1.4 in the passband.  
b = firlpnorm(22,[0 .15 .4 .5 1],[0 .4 .5 1],[1 1.4 1 0 0],...
```

```
[1 1 1 2 2]);
fvtool(b)
```

From the figure you see the resulting filter is lowpass, with the desired 1.4 peak in the passband (notice the 1.4 specified in vector a).

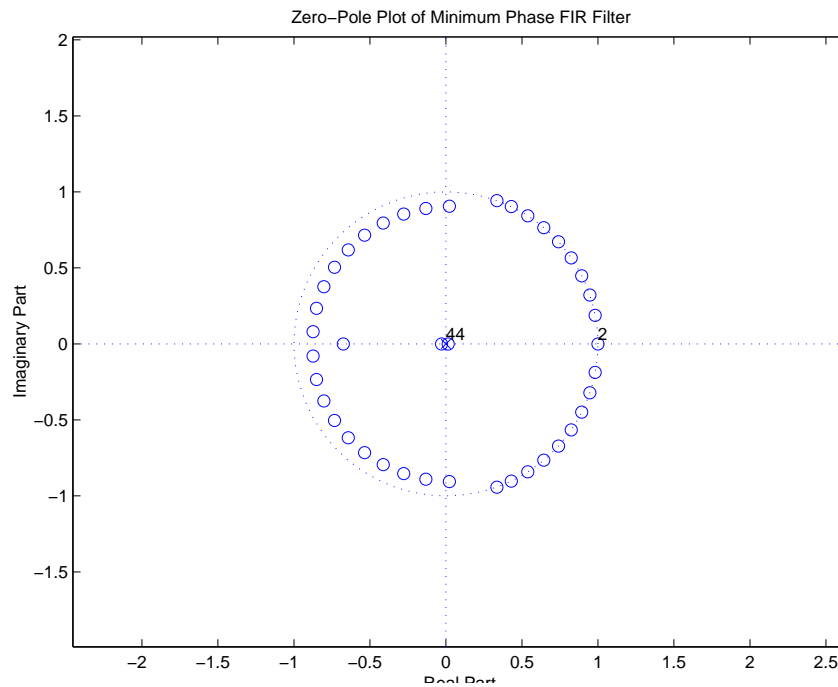

Now for the minimum-phase filter.

```
% Highpass minimum-phase filter optimized for the 4-norm.
b = firlpnorm(44,[0 .4 .45 1],[0 .4 .45 1],[0 0 1 1],[5 1 1 1],...
[2 4], 'minphase');
fvtool(b)
```

As shown in the next figure, this is a minimum-phase, highpass filter.

The next zero-pole plot shows the minimum phase nature more clearly.

This filter has frequency-amplitude characteristics approximately matching those given by vectors, <code>f</code> and <code>a</code>.</p> <p><code>b = firls(n,f,a,w)</code> uses the weights in vector <code>w</code>, to weigh the error.</p> <p><code>b = firls(n,f,a,ftype)</code> specifies a filter type where <code>ftype</code> is:</p> <ul style="list-style-type: none"><li>• 'hilbert'</li><li>• 'differentiator'</li></ul> <p><code>b = firls(n,f,a,w,ftype)</code> uses the weights in vector <code>w</code> to weigh the error. It also specifies a filter type where <code>ftype</code> is:</p> <ul style="list-style-type: none"><li>• 'hilbert'</li><li>• 'differentiator'</li></ul>
<b>Input Arguments</b>	<p><b>n - Filter order</b> (default)   integer scalar</p> <p>Order of the filter, specified as an integer scalar. For odd orders, the frequency response at the Nyquist frequency is necessarily 0. For this reason, <code>firls</code> always uses an even filter order for configurations with a passband at the Nyquist frequency. If you specify an odd-valued <code>n</code>, <code>firls</code> increments it by 1.</p> <p><b>Example:</b> 8</p>

## Data Types

int8 | int16 | int32 | int64

**Complex Number Support:** No

## **f** - Pairs of frequency points

vector of numeric values

Pairs of frequency points, specified as a vector of values ranging between 0 and 1, where 1 corresponds to the Nyquist frequency. The frequencies must be in increasing order, and duplicate frequency points are allowed. You can use duplicate frequency points to design filters exactly like those returned by the `fir1` and `fir2` functions with a rectangular (`rectwin`) window.

`f` and `a` are the same length. This length must be an even number.

**Example:** [0 0.3 0.4 1]

## Data Types

double | single

**Complex Number Support:** No

## **a** - Amplitude values

vector of numeric values

Amplitude values of the function at each frequency point, specified as a vector of the same length as `f`. This length must be an even number.

The desired amplitude at frequencies between pairs of points  $(f(k), f(k+1))$  for  $k$  odd, is the line segment connecting the points  $(f(k), a(k))$  and  $(f(k+1), a(k+1))$ .

The desired amplitude at frequencies between pairs of points  $(f(k), f(k+1))$  for  $k$  even is unspecified. These are transition or “don’t care” regions.

**Example:** [1 1 0 0]

## Data Types

double | single

**Complex Number Support:** No

**w - Weights**

vector of numeric values

Weights to weigh the fit for each frequency band, specified as a vector of length half the length of `f` and `a`, so there is exactly one weight per band. `w` indicates how much emphasis to put on minimizing the integral squared error in each band, relative to the other bands.

**Example:** `[0.5 1]`**Data Types**

double | single

**Complex Number Support:** No**ftype - Filter type**

'hilbert' and 'differentiator'

Filter type, specified as either 'hilbert' or 'differentiator'.

**Example:** 'hilbert'**Data Types**

char

**Output Arguments****b - Filter coefficients**

vector of numeric values

Filter coefficients, returned as a numeric vector of  $n+1$  values, where  $n$  is the filter order.

`b = firls(n,f,a)` designs a linear-phase filter of type I ( $n$  odd) and type II ( $n$ ). The output coefficients, or “taps,” in `b` obey the relation:

$$b(k) = b(n+2-k), k = 1, \dots, n + 1$$

`b = firls(n,f,a,'hilbert')` designs a linear-phase filter with odd symmetry (type III and type IV). The output coefficients, or “taps,” in `b` obey the relation:

$$b(k) = -b(n+2-k), k = 1, \dots, n + 1$$

`b = firls(n,f,a,'differentiator')` designs type III and type IV filters, using a special weighting technique. For nonzero amplitude bands, the integrated squared error has a weight of  $(1/f)^2$ . This weighting causes the error at low frequencies to be much smaller than at high frequencies. For FIR differentiators, which have an amplitude characteristic proportional to frequency, the filters minimize the relative integrated squared error. This value is the integral of the square of the ratio of the error to the desired amplitude.

## Examples

### Design a Lowpass Filter with Transition Band

The following illustrates how to design a lowpass filter of order 225 with transition band.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.25 0.3 1]
a = [1 1 0 0]
```

Use `firls` to obtain the  $n+1$  coefficients of the order  $n$  lowpass FIR filter.

```
b = firls(255,f,a);
```

### Design an Antisymmetric Filter with Piecewise Linear Passbands

The following shows how to design a 24<sup>th</sup>-order anti-symmetric filter with piecewise linear passbands, and plot the desired and actual amplitude responses.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.3 0.4 0.6 0.7 0.9];
a = [0 1 0 0 0.5 0.5];
```

Use `firls` to obtain the 25 coefficients of the filter.

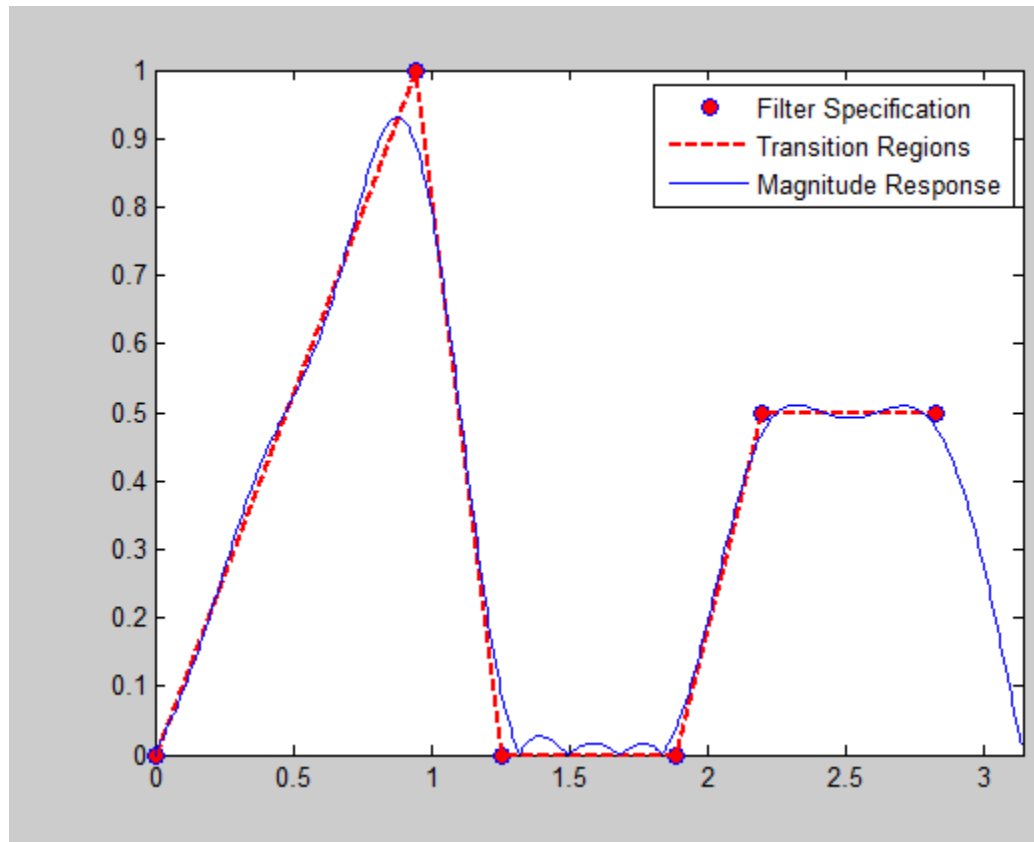

```
b = firls(24,f,a,'hilbert');
```

Plot the ideal amplitude response along with the transition regions.

```
plot(f.*pi,a,'o','markerfacecolor',[1 0 0]);  
hold on;  
plot(f.*pi,a,'r--','linewidth',2);
```

Use `freqz` to obtain the frequency response of the designed filter and plot the magnitude response of the filter.

```
[H,F] = freqz(b,1);  
plot(F,abs(H));  
set(gca,'xlim',[0 pi])  
legend('Filter Specification','Transition Regions','Magnitude Response')
```

## Algorithms

`firls` designs a linear-phase FIR filter. This filter minimizes the weighted, integrated squared error between an ideal piecewise linear function and the magnitude response of the filter over a set of desired frequency bands.

Reference [1] describes the theoretical approach behind `firls`. The function solves a system of linear equations involving an inner product matrix of size roughly  $n/2$  using the `MATLAB \` operator.

This function designs type I, II, III, and IV linear-phase filters. Type I and II are the defaults for  $n$  even and odd respectively. The 'hilbert' and 'differentiator' flags produce type III ( $n$  even) and IV ( $n$  odd) filters. The various filter types have different symmetries and constraints on their frequency responses (see [2] for details).

Linear Phase Filter Type	Filter Order	Symmetry of Coefficients	Response $H(f)$ , $f = 0$	Response $H(f)$ , $f = 1$ (Nyquist)
Type I	Even	$b(k) = b(n+2-k)$ , $k=1, \dots, n+1$	No restriction	No restriction
Type II	Even	$b(k) = b(n+2-k)$ , $k=1, \dots, n+1$	No restriction	$H(1) = 0$
Type III	Odd	$b(k) = -b(n+2-k)$ , $k=1, \dots, n+1$	$H(0) = 0$	$H(1) = 0$
Type IV	Odd	$b(k) = -b(n+2-k)$ , $k=1, \dots, n+1$	$H(0) = 0$	No restriction

## Definitions

## Diagnostics

Error and warning messages

One of the following diagnostic messages is displayed when an incorrect argument is used:

F must be even length.

F and A must be equal lengths.

Requires symmetry to be 'hilbert' or 'differentiator'.

Requires one weight per band.

Frequencies in F must be nondecreasing.

Frequencies in F must be in range [0,1].

A more serious warning message is

Warning: Matrix is close to singular or badly scaled.

This tends to happen when the product of the filter length and transition width grows large. In this case, the filter coefficients  $b$  might not represent the desired filter. You can check the filter by looking at its frequency response.

<b>Purpose</b>	Lowpass Nyquist (Lth-band) FIR filter
<b>Syntax</b>	<pre> b = firnyquist(n,l,r) b = firnyquist('minorder',l,r,dev) b = firnyquist(n,l,r,decay) b = firnyquist(n,l,r,'nonnegative') b = firnyquist(n,l,r,'minphase') </pre>
<b>Description</b>	<p><code>b = firnyquist(n,l,r)</code> designs an Nth order, Lth band, Nyquist FIR filter with a rolloff factor <math>r</math> and an equiripple characteristic.</p> <p>The rolloff factor <math>r</math> is related to the normalized transition width <math>tw</math> by <math>tw = 2\pi(r/l)</math> (rad/sample). The order, <math>n</math>, must be even. <math>l</math> must be an integer greater than one. If <math>l</math> is not specified, it defaults to 4. <math>r</math> must satisfy <math>0 &lt; r &lt; 1</math>. If <math>r</math> is not specified, it defaults to 0.5.</p> <p><code>b = firnyquist('minorder',l,r,dev)</code> designs a minimum-order, Lth band Nyquist FIR filter with a rolloff factor <math>r</math> using the Kaiser window. The peak ripple is constrained by the scalar <code>dev</code>.</p> <p><code>b = firnyquist(n,l,r,decay)</code> designs an Nth order (<math>n</math>), Lth band (<math>l</math>), Nyquist FIR filter where the scalar <code>decay</code>, specifies the rate of decay in the stopband. <code>decay</code> must be nonnegative. If you omit or leave it empty, <code>decay</code> defaults to 0 which yields an equiripple stopband. A nonequiripple stopband (<code>decay</code> <math>\neq</math> 0) may be desirable for decimation purposes.</p> <p><code>b = firnyquist(n,l,r,'nonnegative')</code> returns an FIR filter with nonnegative zero-phase response. This filter can be spectrally factored into minimum-phase and maximum-phase “square-root” filters. This allows you to use the spectral factors in applications such as matched-filtering.</p> <p><code>b = firnyquist(n,l,r,'minphase')</code> returns the minimum-phase spectral factor <code>bmin</code> of order <math>n</math>. <code>bmin</code> meets the condition <code>b=conv(bmin,bmax)</code> so that <code>b</code> is an Lth band FIR Nyquist filter of order <math>2n</math> with filter rolloff factor <math>r</math>. Obtain <code>bmax</code>, the maximum phase spectral factor by reversing the coefficients of <code>bmin</code>. For example, <code>bmax = bmin(end:-1:1)</code>.</p>

# firnyquist

---

## Examples

### Example 1

This example designs a minimum phase factor of a Nyquist filter.

```
bmin = firnyquist(47,10,.45,'minphase');  
b = firnyquist(2*47,10,.45,'nonnegative');  
[h,w,s] = freqz(b); hmin = freqz(bmin);  
fvtool(b,1,bmin,1);
```

### Example 2

This example compares filters with different decay rates.

```
b1 = firnyquist(72,8,.3,0); % Equiripple  
b2 = firnyquist(72,8,.3,15);  
b3 = firnyquist(72,8,.3,25);  
fvtool(b1,1,b2,1,b3,1);
```

**Purpose**

Two-channel FIR filter bank for perfect reconstruction

**Syntax**

```
[h0,h1,g0,g1] = firpr2chfb(n,fp)
[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')
[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)
```

**Description**

`[h0,h1,g0,g1] = firpr2chfb(n,fp)` designs four FIR filters for the analysis sections (`h0` and `h1`) and synthesis section is (`g0` and `g1`) of a two-channel perfect reconstruction filter bank. The design corresponds to the orthogonal filter banks also known as power-symmetric filter banks.

`n` is the order of all four filters. It must be an odd integer. `fp` is the passband-edge for the lowpass filters `h0` and `g0`. The passband-edge argument `fp` must be less than 0.5. `h1` and `g1` are highpass filters with the passband-edge given by  $(1-fp)$ .

`[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')` designs the four filters such that the maximum stopband ripple of `h0` is given by the scalar `dev`. Specify `dev` in linear units, not decibels. The stopband-ripple of `h1` is also be given by `dev`, while the maximum stopband-ripple for both `g0` and `g1` is  $(2*dev)$ .

`[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)` designs the four filters such that `h0` meets the passband-edge specification `fp` and the stopband-ripple `dev` using minimum order filters to meet the specification.

**Examples**

Design a filter bank with filters of order `n` equal to 99 and passband edges of 0.45 and 0.55.

```
n = 99;
[h0,h1,g0,g1] = firpr2chfb(n,.45);
fvtool(h0,1,h1,1,g0,1,g1,1);
```

Here are the filters, showing clearly the passband edges.

Use the following stem plots to verify perfect reconstruction using the filter bank created by `firpr2chfb`.

```
stem(1/2*conv(g0,h0)+1/2*conv(g1,h1))
n=0:n;
stem(1/2*conv((-1).^n.*h0,g0)+1/2*conv((-1).^n.*h1,g1))
stem(1/2*conv((-1).^n.*g0,h0)+1/2*conv((-1).^n.*g1,h1))
stem(1/2*conv((-1).^n.*g0,(-1).^n.*h0)+...
1/2*conv((-1).^n.*g1,(-1).^n.*h1))
stem(conv((-1).^n.*h1,h0)-conv((-1).^n.*h0,h1))
```

You must have the DSP System Toolbox software to use this syntax.</p> <p><code>t = firtype(hs)</code> determines the type of the FIR filter System object <code>hs</code>. The filter must be real and have linear phase. You must have the DSP System Toolbox software to use this syntax.</p>
<b>Input Arguments</b>	<p><b>b</b> vector Filter coefficients for the FIR filter, specified as a double- or single-precision real-valued row or column vector.</p> <p><b>hd</b> <code>dfilt</code> filter object.</p> <p><b>hm</b> Multirate <code>mfilt</code> filter object. Requires DSP System Toolbox.</p> <p><b>hs</b></p>

Filter System object. Requires DSP System Toolbox. The function supports the following filters .

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`
- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

## Output Arguments

**t**

Filter type. `t` is either 1, 2, 3, or 4. These types are defined as follows:

- Type 1 — Even-order symmetric coefficients
- Type 2 — Odd-order symmetric coefficients
- Type 3 — Even-order antisymmetric coefficients
- Type 4 — Odd-order antisymmetric coefficients

## Examples

Determine the filter type for an FIR filter designed using the window method. Plot the impulse response.

```
b1 = fir1(5,0.5);  
t = firtype(b1)  
stem(0:5,b1); set(gca,'xtick',0:5)
```

Determine the type of the default interpolator for  $L=4$ . Requires DSP System Toolbox .

```
l = 4;  
hm = mfilt.firinterp(l);  
t = firtype(hm)
```

# freqrespest

---

**Purpose** Frequency response estimate via filtering

**Syntax**

```
[h,w] = freqrespest(H,L)
[h,w] = freqrespest(H,L,param1,value1,param2,value2,...)
[h,w] = freqrespest(H,L,opts)
freqrespest(H,...)
```

**Description** `[h,w] = freqrespest(H,L)` estimates the frequency response of a `dfilt` object or a filter System object. A set of input data is filtered and then forming the ratio between output data and input data. The test input data comprises sinusoids with uniformly distributed random frequencies.

Use this technique for comparing the performance of fixed-point filters to that of another filter type. You can, for example, compare fixed—point frequency response estimate to that of a similar filter that uses quantized coefficients, but applies floating-point arithmetic internally. Such comparison determines whether the fixed-point filter performance closely matches the floating-point, quantized coefficients version of the filter.

`L` is the number of trials to use to compute the estimate. If you do not specify this value, `L` defaults to 10. More trials generates a more accurate estimate of the response, but require more time to compute the estimate.

`h` is the estimate of the complex frequency response. `w` contains the vector of frequencies at which `h` is estimated.

`[h,w] = freqrespest(H,L,param1,value1,param2,value2,...)` accepts `H` as either a `dfilt` object or a filter System object. This approach uses parameter value (PV) pairs as input arguments to specify optional parameters for the test. These parameters are the valid PV pairs. Enter the parameter names as string input arguments in single quotation marks. The following table provides valid parameters for `[h, w]`.

Parameter Name	Default Value	Description
NFFT	512	Number of FFT points to use.
NormalizedFrequency	true	Indicate whether to use normalized frequency or linear frequency. Values are true (use normalized frequency), or false (use linear frequency). When you specify false, you must supply the sampling frequency Fs.
Fs	normalized	Specify the sampling frequency when NormalizedFrequency is false. No default value. You must set NormalizedFrequency to false before setting a value for Fs.
SpectrumRange	half	Specify the spectrum range to be used as whole or half (default).
CenterDC	false	Specify whether to set the center of the spectrum to the DC value in the output plot. If you select true, both the negative and positive values appear in the plot. If you select false, DC appears at the origin of the axes.
Arithmetic (only for filter System objects)	ARITH	Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to double, single, or fixed. The analysis tool assumes a double-precision

# freqrespest

Parameter Name	Default Value	Description
		filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

If H is a filter System object, `freqrespest` requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the Arithmetic parameter, i.e., use the syntax `[h,w] = freqrespest(H)`, then the following rules apply for this method:

- The System object state is Unlocked — `freqrespest` performs double precision analysis.
- The System object state is Locked — `freqrespest` performs analysis based on the locked input data type.

When you do specify the Arithmetic parameter, i.e., use the syntax `[h,w] = freqrespest(H, 'Arithmetic', ARITH)`, review the following rules for this method. Which rule applies depends on the value you set for the Arithmetic parameter.

Value	System Object State	Rule
ARITH = 'double'	Unlocked	<code>freqrespest</code> performs double-precision analysis.
	Locked	<code>freqrespest</code> performs double-precision analysis.

Value	System Object State	Rule
ARITH = `single`	Unlocked	freqrespest performs single-precision analysis.
	Locked	freqrespest performs single-precision analysis.
ARITH = `fixed`	Unlocked	freqrespest produces an error because the fixed-point input data type is unknown.
	Locked	If the input data type is double or single, then freqrespest produces an error because the fixed-point input data type is unknown.
		When the input data is of fixed-point type, freqrespest performs analysis based on the locked input data type.

freqrespest supports only the following filter System objects:

- dsp.FIRFilter
- dsp.IIRFilter
- dsp.AllpoleFilter

- `dsp.BiquadFilter`

Regardless of whether `H` is a `dfilt` object or a filter System object, `[h,w] = freqrespest(H,L,opts)` uses an object, `opts`, to specify the optional input parameters. This specification is not done directly by specifying PV pairs as input arguments. Create `opts` with

```
opts = freqrespest(H);
```

Because `opts` is an object, you use `set` to change the parameter values in `opts` before you use it with `freqrespest`. For example, you could specify a new sample rate with

```
set(opts,'fs',48e3); % Same as opts.fs=48e3
```

Regardless of whether `H` is a `dfilt` object or a filter System object, `freqrespest(H,...)` with no output argument launches FVTool.

`freqrespest` can also compute the frequency response of double-precision floating filters. Such filters cannot be converted to transfer-function form without introducing significant round off errors which affect the `freqz` frequency response computation. Examples of these kinds of filters include state-space or lattice filters, especially if they are high-order filters.

## Examples

These examples demonstrate some uses for `freqrespest`.

### Example 1

Start by estimating the frequency response of a fixed-point FIR filter that has filter internals set to full precision.

```
hd = design(fdesign.lowpass(.4,.5,1,60),'equiripple');  
hd.arithmetic = 'fixed';  
[h,w] = freqrespest(hd); % This should be about the same as freqz.
```

Continuing with filter `hd`, change the value of the `filterinternals` property to `specifyprecision` and then specify the word lengths and precision (the fraction lengths) applied to the output from internal addition and multiplication operations. After you set the word and

fraction lengths, use `freqrespest` to compute the frequency response estimate for the fixed-point filter.

```
hd.filterinternals = 'specifyprecision';
hd.outputwordlength=16;
hd.outputfraclength=15;
hd.productwordlength=16;
hd.productfraclength=15;
hd.accumwordlength=16;
hd.accumfraclength=15;
[h,w] = freqrespest(hd,2);
[h2,w2] = freqz(hd,512);
plot(w/pi,20*log10(abs([h,h2])))
legend('Frequency response estimated by filtering',...
'Freq. response computed by quantizing coefficients only');
xlabel('Normalized Frequency (\times\pi rad/sample)')
ylabel('Magnitude (dB)')
```

# freqrespest

## Example 2

freqrespest works with state-space filters as well. This example estimates the frequency response of a state-space filter.

```
fs = 315000;  
wp = [320 3800]/(fs/2);  
ws = [50 19000]/(fs/2);  
rp=0.15; rs=60;  
[n,wn]=cheb1ord(wp,ws,rp,rs);  
[a,b,c,d] = cheby1(n,rp,wn);  
hd = dfilt.statespace(a,b,c,d);  
% Compare the following to freqz(hd,8192)  
freqrespest(hd,1,'nfft',8192);
```

**See Also**      `dfilt | freqrespopts | freqz | limitcycle | noise PSD | scale`

# freqrespopts

---

**Purpose** Options for filter frequency response analysis

**Syntax** `opts = freqrespopts(H)`

**Description** `opts = freqrespopts(H)` uses the settings in the `dfilt` object or the filter System object, `H`, to create an object, `opts`. This object contains parameters and values for estimating the filter frequency response. You pass `opts` as an input argument to `freqz` to specify values for the input parameters.

`freqrespopts` allows you to use the same settings for `freqz` with multiple filters without specifying all of the parameters as input arguments to `freqz`.

`freqrespopts` supports only the following filter System objects:

- `dsp.FIRFilter`
- `dsp.IIRFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`

**Examples** This example shows `freqrespopts` in use for setting options for `freqz`. `hd` and `hd2` are bandpass filters that use different design methods. The `opts` object makes it easier to set the same conditions for the frequency response estimate in `freqz`.

```
d=fdesign.bandpass('fst1,fp1,fp2,fst2,ast1,ap,ast2',...  
0.25,0.3,0.45,0.5,60,0.1,60);
```

```
hd=design(d,'butter');  
hd.arithmetic='fixed';  
hd2=design(d,'cheby2')  
hd2.arithmetic='fixed';  
opts=freqrespopts(hd)
```

```
opts =
```

```
                NFFT: 512
NormalizedFrequency: true
                Fs: 'Normalized'
SpectrumRange: 'Half'
                CenterDC: false

opts.NFFT=256; % Same as set(opts,'nfft',256).
opts.NormalizedFrequency=false;
opts.fs=1.5e3;
opts.CenterDC=true

opts =

                NFFT: 256
NormalizedFrequency: false
                Fs: 1500
SpectrumRange: 'Whole'
                CenterDC: true
```

With `opts` configured as needed, use it as an input argument for `freqrespest`.

```
[h2,w2]=freqrespest(hd2,20,opts);
[h1,w1]=freqrespest(hd,20,opts);
```

`freqrespest` | `noisepsd` | `noisepsdopts` | `norm` | `scale`

# freqsamp

---

**Purpose** Real or complex frequency-sampled FIR filter from specification object

**Syntax**

```
hd = design(d, 'freqsamp')
hd = design(..., 'filterstructure', structure)
hd = design(..., 'window', window)
```

**Description** `hd = design(d, 'freqsamp')` designs a frequency-sampled filter specified by the filter specifications object `d`.

`hd = design(..., 'filterstructure', structure)` returns a filter with the filter structure you specify by the `structure` input argument. `structure` is `dffir` by default and can be any one of the following filter structures.

Structure String	Description of Resulting Filter Structure
<code>dffir</code>	Direct-form FIR filter
<code>dffirt</code>	Transposed direct-form FIR filter
<code>dfsymfir</code>	Symmetrical direct-form FIR filter
<code>dfasymfir</code>	Asymmetrical direct-form FIR filter
<code>fftfir</code>	Fast Fourier transform FIR filter

`hd = design(..., 'window', window)` designs filters using the window specified by the string in `window`. Provide the input argument `window` as

- A string for the window type. For example, use `'bartlett'`, or `'hamming'`. See `window` for the full list of windows available or refer to `window` in the *Signal Processing Toolbox User's Guide*.
- A function handle that references the window function. When the window function requires more than one input, use a cell array to hold the required arguments. The first example shows a cell array input argument.
- The window vector itself.

## Examples

These examples design FIR filters that have arbitrary magnitude responses. In the first filter, the response has three distinct sections and the resulting filter is real.

The second example creates a complex filter.

```
b1 = 0:0.01:0.18;
b2 = [.2 .38 .4 .55 .562 .585 .6 .78];
b3 = [0.79:0.01:1];
a1 = .5+sin(2*pi*7.5*b1)/4; % Sinusoidal response section.
a2 = [.5 2.3 1 1 -.2 -.2 1 1]; % Piecewise linear response section.
a3 = .2+18*(1-b3).^2; % Quadratic response section.
f = [b1 b2 b3];
a = [a1 a2 a3];
n = 300;
d = fdesign.arbmag('n,f,a',n,f,a); % First specifications object.
hd = design(d,'freqsamp','window',{@kaiser,.5}); % Filter.
fvtool(hd)
```

The plot from FVTool shows the response for hd.

# freqsamp

Now design the arbitrary-magnitude complex FIR filter. Recall that vector  $f$  contains frequency locations and vector  $a$  contains the desired filter response values at the locations specified in  $f$ .

```
f = [-1 -.93443 -.86885 -.80328 -.7377 -.67213 -.60656 -.54098 ...  
-.47541,-.40984 -.34426 -.27869 -.21311 -.14754 -.081967 ...  
-.016393 .04918 .11475,.18033 .2459 .31148 .37705 .44262 ...  
.5082 .57377 .63934 .70492 .77049,.83607 .90164 1];  
a = [.0095848 .021972 .047249 .099869 .23119 .57569 .94032 ...  
.98084 .99707,.99565 .9958 .99899 .99402 .99978 .99995 .99733 ...  
.99731 .96979 .94936,.8196 .28502 .065469 .0044517 .018164 ...  
.023305 .02397 .023141 .021341,.019364 .017379 .016061];  
n = 48;  
d = fdesign.arbmag('n,f,a',n,f,a); % Second spec. object.  
hdc = design(d,'freqsamp','window','rectwin'); % Filter.  
fvtool(hdc)
```

FVTool shows you the response for `hdc` from -1 to 1 in normalized frequency. `design(d, ...)` returns a complex filter for `hdc` because the frequency vector includes negative frequency values.

# freqz

---

**Purpose** Frequency response of filter

**Syntax**

```
[h,w] = freqz(hfilt)
[h,w] = freqz(hfilt,n)
freqz(hfilt)
[h,w] = freqz(hs)
[h,w] = freqz(hs,n)
[h,w] = freqz(hs,Name,Value)
freqz(hs)
```

**Description** `freqz` returns the frequency response based on the current filter coefficients. This section describes common `freqz` operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to `freqz` in Signal Processing Toolbox documentation.

`[h,w] = freqz(hfilt)` returns the frequency response `h` and the corresponding frequencies `w` at which the filter response of `hfilt` is computed. The frequency response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[h,w] = freqz(hfilt,n)` returns the frequency response `h` and corresponding frequencies `w` for the filter or vector of filters `hfilt`. The frequency response is evaluated at `n` points equally spaced around the upper half of the unit circle. `freqz` uses the transfer function associated with the filter to calculate the frequency response of the filter with the current coefficient values.

`freqz(hfilt)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter `hfilt`. If `hfilt` is a vector of filters, `freqz` plots the magnitude response and phase for each filter in the vector.

`[h,w] = freqz(hs)` returns a frequency response for the filter System object `hs` using 8192 samples.

`[h,w] = freqz(hs,n)` returns a frequency response for the filter System object `hs` using `n` samples.

`[h,w] = freqz(hs,Name,Value)` returns a frequency response with additional options specified by one or more `Name,Value` pair arguments.

`freqz(hs)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `hs`.

## Input Arguments

### **hfiltr**

`hfiltr` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

### **hs**

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`
- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

### **n**

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

**Default:** 8192

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'Arithmetic'

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **h**

Complex, n-element frequency response vector. If `hfilt` is a vector of filters, `h` is a complex, `length(hfilt)`-by-`n` matrix of frequency response vectors corresponding to each filter in `hfilt`. If `n` is not specified, the function uses a default value of 8192.

For adaptive filters, `h` is the instantaneous frequency response.

### **w**

# freqz

---

Frequency vector of length  $n$ , in radians/sample.  $w$  consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

## Tips

There are several ways of analyzing the frequency response of filters. `freqz` accounts for quantization effects in the filter coefficients, but does not account for quantization effects in filtering arithmetic. To account for the quantization effects in filtering arithmetic, refer to function `noisepsd`.

## Algorithms

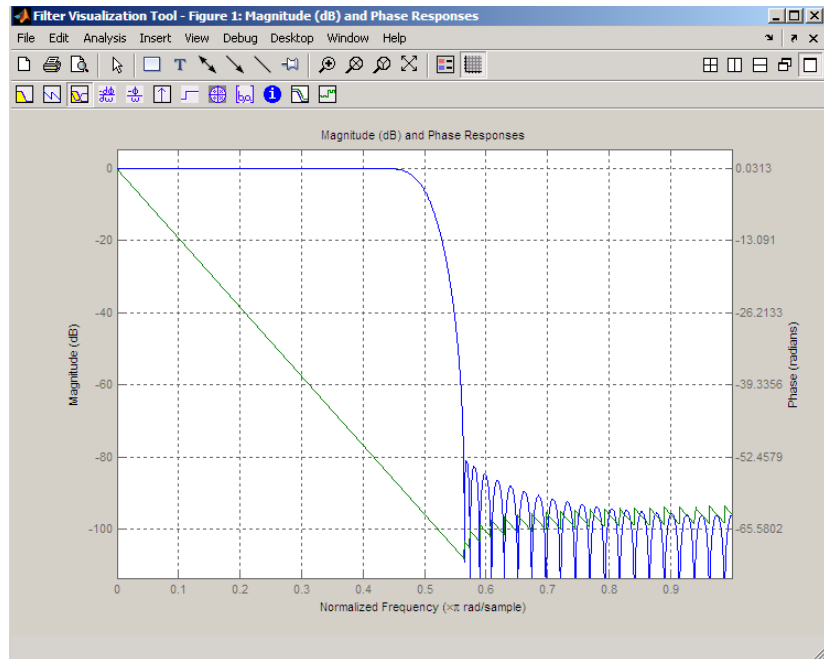

`freqz` calculates the frequency response for a filter from the filter transfer function  $Hq(z)$ . The complex-valued frequency response is calculated by evaluating  $Hq(e^{jw})$  at discrete values of  $w$  specified by the syntax you use. The integer input argument  $n$  determines the number of equally-spaced points around the upper half of the unit circle at which `freqz` evaluates the frequency response. The frequency ranges from 0 to  $\pi$  radians per sample when you do not supply a sampling frequency as an input argument. When you supply the scalar sampling frequency `fs` as an input argument to `freqz`, the frequency ranges from 0 to `fs/2` Hz.

## Examples

Plot the estimated frequency response of a filter. This example uses discrete-time filters, but `hd` can be any `adaptfilt` object, `dfilt` object, `mfilt` object, or filter `System` object. First plot the results for one filter.

```
b = fir1(80,0.5,kaiser(81,8));  
hd = dfilt.dffir(b);  
freqz(hd);
```

If you have more than one filter, you can plot them on the same figure using a vector of filters.

```
b = fir1(40,0.5,kaiser(41,6));
hd2 = dfilt.dffir(b);
h = [hd hd2];
freqz(h);
```

**See Also**

`adaptfilt` | `dfilt` | `mfilt` | `fvtool`

**Purpose** CIC filter gain

**Syntax** gain(hm)  
gain(hm, j)  
gain(hs)

**Description** gain(hm) returns the gain of hm, the CIC decimation or interpolation filter.

When hm is a decimator, gain returns the gain for the overall CIC decimator.

When hm is an interpolator, the CIC interpolator inserts zeros into the input data stream, reducing the filter overall gain by  $1/R$ , where  $R$  is the interpolation factor, to account for the added zero valued samples. Therefore, the gain of a CIC interpolator is  $(RM)^N/R$ , where  $N$  is the number of filter sections and  $M$  is the filter differential delay. gain(hm) returns this value. The next example presents this case.

gain(hm, j) returns the gain of the jth section of a CIC interpolation filter. When you omit j, gain assumes that j is  $2*N$ , where  $N$  is the number of sections, and returns the gain of the last section of the filter. This syntax does not apply when hm is a decimator.

gain(hs) returns the gain of the filter System object hs. The function supports the dsp.CICDecimator and dsp.CICInterpolator filter structures.

## Examples

To compare the performance of two interpolators, one a CIC filter and the other an FIR filter, use gain to adjust the CIC filter output amplitude to match the FIR filter output amplitude. Start by creating an input data set—a sinusoidal signal x.

```
fs = 1000;           % Input sampling frequency.  
t = 0:1/fs:1.5;     % Signal length = 1501 samples.  
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
```

```
l = 4; % Interpolation factor for FIR filter.  
d = fdesign.interpolator(l);
```

```
hm = design(d,'multistage');
ym = filter(hm,x);

r = 4; % Interpolation factor for the CIC filter.
d = fdesign.interpolator(r,'cic');
hcic = design(d,'multisection');
ycic = filter(hcic,x);
gaincic = gain(hcic);
subplot(211);
plot(1:length(ym),[ym; double(ycic)]);
subplot(212)
plot(1:length(ym),[ym; double(ycic)/gain(hcic)]);
```

After correcting for the gain induced by the CIC interpolator, the figure shows the filters provide nearly identical interpolation.

scale

**Purpose** Filter group delay

**Syntax**

```
[gd,w]=grpdelay(hfilt)
[gd,w]=grpdelay(hfilt,n)
grpdelay(hfilt)
[gd,w] = grpdelay(hs)
[gd,w] = grpdelay(hs,n)
[gd,w] = grpdelay(hs,Name,Value)
grpdelay(hs)
```

**Description** `grpdelay` returns the group delay based on the current filter coefficients. This section describes common `grpdelay` operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to `grpdelay` in Signal Processing Toolbox documentation.

`[gd,w]=grpdelay(hfilt)` returns the phase response  $\phi$  of the filter `hfilt` and the corresponding frequencies  $w$  at which the function evaluates the group delay. Group delay is

$$-\frac{d}{dw}(\text{angle}(w))$$

The group delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[gd,w]=grpdelay(hfilt,n)` returns the group delay  $\phi$  of the filter `hfilt` and the corresponding frequencies  $w$  at which the function evaluates the group delay. The group delay is evaluated at  $n$  points equally spaced around the upper half of the unit circle.

`grpdelay(hfilt)` displays the group delay of `hfilt` in the Filter Visualization Tool (FVTool).

`[gd,w] = grpdelay(hs)` returns the group delay for the filter System object `hs` using 8192 samples.

`[gd,w] = grpdelay(hs,n)` returns the group delay for the filter System object `hs` using  $n$  samples.

`[gd,w] = grpdelay(hs,Name,Value)` returns the group delay with additional options specified by one or more `Name,Value` pair arguments.

`grpdelay(hs)` uses FVTool to plot the group delay of the filter System object `hs`.

## Input Arguments

### **hfilt**

`hfilt` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

### **hs**

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`
- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

### **n**

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

**Default:** 8192

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

#### 'Arithmetic'

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

#### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **gd**

Complex, n-element group-delay vector. If `hfilt` is a vector of filters, `gd` is a complex, `length(hfilt)`-by-`n` matrix of group-delay vectors whose columns correspond to each filter in `hfilt`. If `n` is not specified, the function uses a default value of 8192.

For adaptive filters, `gd` is the instantaneous group delay.

### **w**

Frequency vector of length  $n$ , in radians/sample.  $w$  consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If `hfilt` is a vector of filters,  $w$  is a complex, `length(hfilt)`-by- $n$  matrix of group-delay vectors whose columns correspond to each filter in `hfilt`. If  $n$  is not specified, the function uses a default value of 8192.

**Purpose** Help for design method with filter specification

**Syntax** `help(d, 'designmethod')`

**Description** `help(d, 'designmethod')` displays help in the Command Window for the design algorithm `designmethod` for the current specifications of the filter specification object `d`. The string you enter for `designmethod` must be one of the strings returned by `designmethods` for `d`, the design object.

**Examples** Get specific help for designing lowpass Butterworth filters. The first lowpass filter uses the default specification string 'Fp,Fst,Ap,Ast' and returns help text specific to the specification string.

```
d = fdesign.lowpass;  
designmethods(d)
```

```
Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```
butter  
cheby1  
cheby2  
ellip  
equiripple  
ifir  
kaiserwin  
multistage
```

```
help(d, 'butter')
```

```
DESIGN Design a Butterworth IIR filter.
```

```
HD = DESIGN(D, 'butter') designs a Butterworth filter specified  
by the FDESIGN object D.
```

```
HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter  
with the structure STRUCTURE. STRUCTURE is 'df2sos' by default  
and can be any of the following.
```

```
'df1sos'
'df2sos'
'df1tsos'
'df2tsos'
```

HD = DESIGN(..., 'MatchExactly', MATCH) designs a Butterworth filter and matches the frequency and magnitude specification for the band MATCH exactly. The other band will exceed the specification. MATCH can be 'stopband' or 'passband' and is 'stopband' by default.

```
% Example #1 - Compare passband and stopband MatchExactly.
h      = fdesign.lowpass('Fp,Fst,Ap,Ast', .1, .3, 1, 60);
Hd     = design(h, 'butter', 'MatchExactly', 'passband');
Hd(2) = design(h, 'butter', 'MatchExactly', 'stopband');
```

```
% Compare the passband edges in FVTool.
fvtool(Hd);
axis([.09 .11 -2 0]);
```

Note the discussion of the MatchExactly input option. When you use a design object that uses a different specification string, such as 'N,F3dB', the help content for the butter design method changes.

In this case, the MatchExactly option does not appear in the help because it is not an available input argument for the specification string 'N,F3dB'.

```
d=fdesign.lowpass('N,F3dB')
```

```
d =
           Response: 'Lowpass'
      Specification: 'N,F3dB'
      Description: {'Filter Order';'3dB Frequency'}
NormalizedFrequency: true
           FilterOrder: 10
                   F3dB: 0.5
```

```
designmethods(d)
```

```
Design Methods for class fdesign.lowpass (N,F3dB):

```

**Purpose**

Interpolated FIR filter from filter specification

**Syntax**

```
hd = ifir(d)
hd = design(d, 'ifir', designoption, value, designoption, ...
value, ...)
```

**Description**

`hd = ifir(d)` designs an FIR filter from design object `d`, using the interpolated FIR method. `ifir` returns `hd` as a cascade of two filters that act together to meet the specifications in `d`. The resulting filter is particularly efficient, having a low number of multipliers. However, if `ifir` determines that a single-stage filter would be more efficient than the default two-stage design, it returns `hd` as a single-stage filter. `ifir` only creates linear phase filters. Generally, `ifir` uses an advanced optimization algorithm to create highly efficient FIR filters.

`ifir` returns `hd` as either a single-rate `dfilt` object or a multirate `mfilt` object (when you have DSP System Toolbox software installed), based on the specifications you provide in `d`, the filter specification object.

specifications supplied in the object `h`.

`hd = design(d, 'ifir', designoption, value, designoption, ... value, ...)` returns an interpolated FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d, 'method')
```

For complete help about using `ifir`, refer to the command line help system. For example, to get specific information about using `ifir` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d, 'ifir')
```

---

**Note** For help about how you use `ifir` to design filters without using design objects, enter

```
help ifir
```

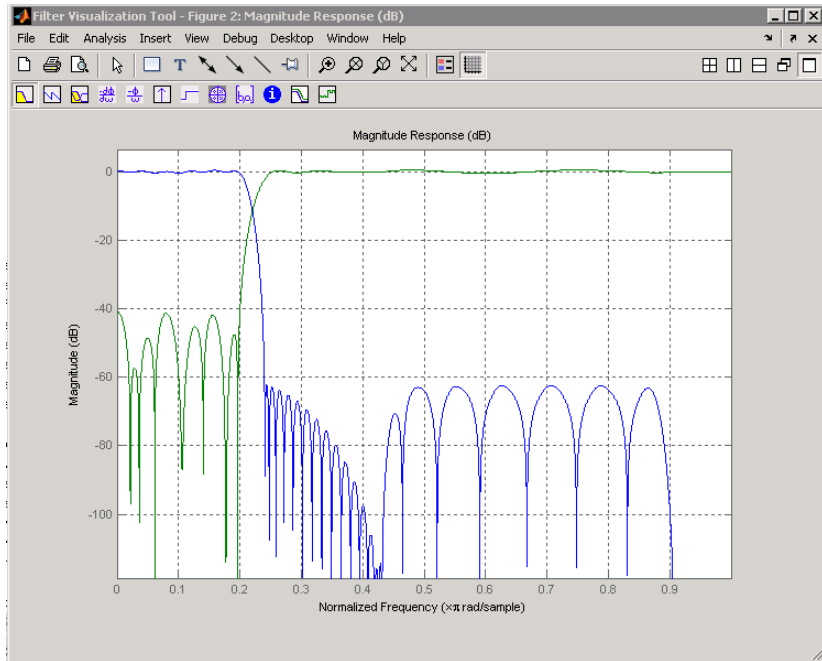

at the MATLAB prompt.

---

## Examples

Use `fdesign.lowpass` and `fdesign.highpass` to design a lowpass filter and a wideband highpass filter. After designing the filters, use `FVTool` to plot the response curves for both.

```
fpass = 0.2;  
fstop = 0.24;  
d1 = fdesign.lowpass(fpass, fstop);  
hd1 = design(d1, 'ifir');  
fstop = 0.2;  
fpass = 0.25;  
astop = 40;  
apass = 1;  
d2 = fdesign.highpass(fstop, fpass, astop, apass);  
hd2 = design(d2, 'ifir');  
fvtool(hd1, hd2)
```

# iirbpc2bpc

---

<b>Purpose</b>	Transform IIR complex bandpass filter to IIR complex bandpass filter with different characteristics
<b>Syntax</b>	<code>[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)</code>
<b>Description</b>	<p><code>[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)</code> returns the numerator and denominator vectors, Num and Den respectively, of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation.</p> <p>It also returns the numerator, AllpassNum, and the denominator, AllpassDen, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by B and the denominator specified by A.</p> <p>This transformation effectively places two features of an original filter, located at frequencies <math>W_{o1}</math> and <math>W_{o2}</math>, at the required target frequency locations, <math>W_{t1}</math>, and <math>W_{t2}</math> respectively. It is assumed that <math>W_{t2}</math> is greater than <math>W_{t1}</math>. In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.</p> <p>Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, <math>F_1</math> and <math>F_2</math>, with <math>F_1</math> preceding <math>F_2</math>. Feature <math>F_1</math> will still precede <math>F_2</math> after the transformation. However, the distance between <math>F_1</math> and <math>F_2</math> will not be the same before and after the transformation.</p> <p>This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle; e.g., in the adaptive system.</p>
<b>Examples</b>	<p>Design a prototype real IIR halfband filter using a standard elliptic approach:</p> <pre>[b, a] = ellip(3, 0.1, 30, 0.409);</pre>

Create a complex passband from 0.25 to 0.75:

```
[b, a] = iirlp2bpc(b, a, 0.5, [0.25,0.75]);  
[num, den] = iirbpc2bpc(b, a, [0.25, 0.75], [-0.5, 0.5]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Using FVTool to plot the filters shows you the comparison, presented in this figure.

# iirbpc2bpc

---

## Arguments

Variable	Description
<i>B</i>	Numerator of the prototype lowpass filter
<i>A</i>	Denominator of the prototype lowpass filter
<i>Wo</i>	Frequency values to be transformed from the prototype filter
<i>Wt</i>	Desired frequency locations in the transformed target filter
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## See Also

[iirftransf](#) | [allpassbpc2bpc](#) | [zpkbpc2bpc](#)

**Purpose** IIR comb notch or peak filter

**Syntax**

```
[num,den] = iircomb(n,bw)
[num,den] = iircomb(n,bw,ab)
[num,den] = iircomb(...,'type')
```

**Description** [num,den] = iircomb(n,bw) returns a digital notching filter with order  $n$  and with the width of the filter notch at -3 dB set to  $bw$ , the filter bandwidth. The filter order must be a positive integer.  $n$  also defines the number of notches in the filter across the frequency range from 0 to  $2\pi$  — the number of notches equals  $n+1$ .

For the notching filter, the transfer function takes the form

$$H(z) = b \frac{1 - z^{-n}}{1 - \alpha z^{-n}}$$

where  $\alpha$  and  $b$  are the positive scalars and  $n$  is the filter order or the number of notches in the filter minus 1.

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = \omega_0/bw$  where  $\omega_0$  is the frequency to remove from the signal.

[num,den] = iircomb(n,bw,ab) returns a digital notching filter whose bandwidth,  $bw$ , is specified at a level of  $-ab$  decibels. Including the optional input argument  $ab$  lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

[num,den] = iircomb(...,'type') returns a digital filter of the specified type. The input argument `type` can be either

- 'notch' to design an IIR notch filter. Notch filters attenuate the response at the specified frequencies. This is the default type. When you omit the `type` input argument, `iircomb` returns a notch filter.
- 'peak' to design an IIR peaking filter. Peaking filters boost the signal at the specified frequencies.

The transfer function for peaking filters is

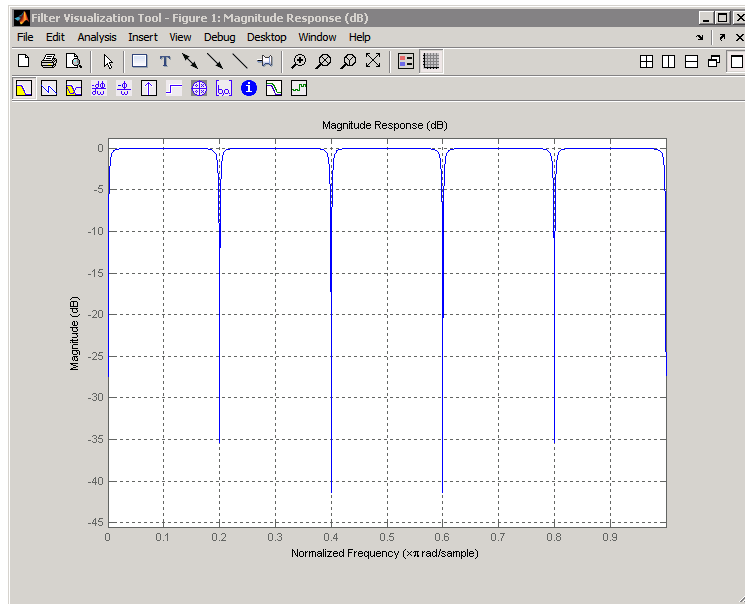

$$H(z) = b \frac{1 - z^{-n}}{1 + az^{-n}}$$

## Examples

Design and plot an IIR notch filter with 11 notches (equal to filter order plus 1) that removes a 60 Hz tone ( $f_0$ ) from a signal at 600 Hz ( $f_s$ ). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth.

```
fs = 600; fo = 60; q = 35; bw = (fo/(fs/2))/q;  
[b,a] = iircomb(fs/fo,bw,'notch'); % Note type flag 'notch'  
fvtool(b,a);
```

Using the Filter Visualization Tool (FVTool) generates the following plot showing the filter notches. Note the notches are evenly spaced and one falls at exactly 60 Hz.

# iirftransf

---

**Purpose** IIR frequency transformation of filter

**Syntax** `[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)`

**Description** `[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)` returns the numerator and denominator vectors, `OutNum` and `OutDen`, of the target filter, which is the result of transforming the prototype filter specified by the numerator, `OrigNum`, and denominator, `OrigDen`, with the mapping filter given by the numerator, `FTFNum`, and the denominator, `FTFDen`. If the allpass mapping filter is not specified, then the function returns an original filter.

**Examples** Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);  
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);  
[num, den] = iirftransf(b, a, AlpNum, AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Here's the comparison between the filters.

## Arguments

Variable	Description
<i>OrigNum</i>	Numerator of the prototype lowpass filter
<i>OrigDen</i>	Denominator of the prototype lowpass filter
<i>FTFNum</i>	Numerator of the mapping filter
<i>FTFDen</i>	Denominator of the mapping filter
<i>OutNum</i>	Numerator of the target filter
<i>OutDen</i>	Denominator of the target filter

# iirgrpdelay

---

## Purpose

Optimal IIR filter with prescribed group-delay

## Syntax

```
[num,den] = iirgrpdelay(n,f,edges,a)
[num,den] = iirgrpdelay(n,f,edges,a,w)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,
    tau)
[num,den,tau] = iirgrpdelay(n,f,edges,a,w)
```

## Description

`[num,den] = iirgrpdelay(n,f,edges,a)` returns an allpass IIR filter of order  $n$  ( $n$  must be even) which is the best approximation to the relative group-delay response described by  $f$  and  $a$  in the least- $p$ th sense.  $f$  is a vector of frequencies between 0 and 1 and  $a$  is specified in samples. The vector `edges` specifies the band-edge frequencies for multi-band designs. `iirgrpdelay` uses a constrained Newton-type algorithm. Always check your resulting filter using `grpdelay` or `freqz`.

`[num,den] = iirgrpdelay(n,f,edges,a,w)` uses the weights in  $w$  to weight the error.  $w$  has one entry per frequency point and must be the same length as  $f$  and  $a$ ). Entries in  $w$  tell `iirgrpdelay` how much emphasis to put on minimizing the error in the vicinity of each specified frequency point relative to the other points.

$f$  and  $a$  must have the same number of elements.  $f$  and  $a$  can contain more elements than the vector `edges` contains. This lets you use  $f$  and  $a$  to specify a filter that has any group-delay contour within each band.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius)` returns a filter having a maximum pole radius equal to `radius`, where  $0 < \text{radius} < 1$ . `radius` defaults to 0.999999. Filters whose pole radius you constrain to be less than 1.0 can better retain transfer function accuracy after quantization.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)`, where  $p$  is a two-element vector `[pmin pmax]`, lets you determine the minimum and maximum values of  $p$  used in the least- $p$ th algorithm.  $p$  defaults to `[2`

128] which yields filters very similar to the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If `p` is the string 'inspect', no optimization occurs. You might use this feature to inspect the initial pole/zero placement.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization process. The number of grid points is  $(dens*(n+1))$ . The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)` allows you to specify the initial estimate of the denominator coefficients in vector `initden`. This can be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initden`.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau)` allows the initial estimate of the group delay offset to be specified by the value of `tau`, in samples.

`[num,den,tau] = iirgrpdelay(n,f,edges,a,w)` returns the resulting group delay offset. In all cases, the resulting filter has a group delay that approximates  $[a + \tau]$ . Allpass filters can have only positive group delay and a non-zero value of `tau` accounts for any additional group delay that is needed to meet the shape of the contour specified by  $(f,a)$ . The default for `tau` is `max(a)`.

Hint: If the zeros or poles cluster together, your filter order may be too low or the pole radius may be too small (overly constrained). Try increasing `n` or `radius`.

For group-delay equalization of an IIR filter, compute `a` by subtracting the filter's group delay from its maximum group delay. For example,

```
[be,ae] = ellip(4,1,40,0.2);  
f = 0:0.001:0.2;  
g = grpdelay(be,ae,f,2); % Equalize only the passband.  
a = max(g)-g;
```

# iirgrpdelay

---

```
[num,den]=iirgrpdelay(8, f, [0 0.2], a);
```

**Purpose** Quasi-linear phase IIR filter from halfband filter specification

**Syntax**

```
hd = design(d,'iirlinphase')
hd = design(...,'filterstructure',structure)
```

**Description** `hd = design(d,'iirlinphase')` designs a quasi-linear phase filter `hd` specified by the filter specification object `d`.

`hd = design(...,'filterstructure',structure)` returns a filter with the structure specified by `structure`. By default, the filter structure is `df2sos` (direct-form II with second-order sections). You can substitute one of the following strings for `structure` to specify the structure of `hd`.

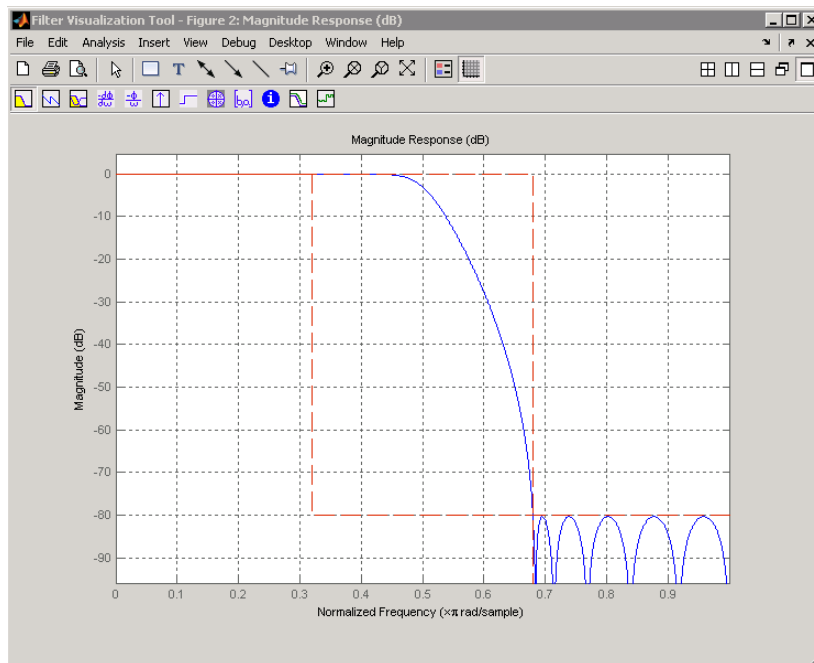

Structure String	Filter Structure
<code>df1sos</code>	Direct-form I IIR filter with second-order sections
<code>df2sos</code>	Direct-form II IIR filter with second-order sections
<code>df1tsos</code>	Transposed direct-form I IIR filter with second-order sections
<code>df2tsos</code>	Transposed direct-form II IIR filter with second-order sections

**Examples** Design a quasi-linear phase, minimum-order halfband IIR filter with transition width of 0.36 and stopband attenuation of at least 80 dB.

```
tw = 0.36;
ast = 80;
d = fdesign.halfband('tw,ast',tw,ast); % Transition width,
                                     % stopband attenuation.
hd = design(d,'iirlinphase');
fvtool(hd)
```

Notice the characteristic halfband nature of the ripple in the stopband. If you measure the resulting filter, you see it meets the specifications.

`measure(hd)`

`fdesign.halfband`

**Purpose**

Transform IIR lowpass filter to IIR bandpass filter

**Syntax**

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2bp(Hd,Wo,Wt)
```

where Hd is a `dfilt` object

**Description**

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)` returns the numerator and denominator vectors, Num and Den respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.

It also returns the numerator, AllpassNum, and the denominator AllpassDen, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by B and a denominator specified by A.

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the “DC Mobility,” meaning that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_t$ s.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature: the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies.

`[G,AllpassNum,AllpassDen] = iirlp2bp(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a real bandpass magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b,a] = ellip(3, 0.1, 30, 0.409);
```

Create the real bandpass filter by placing the cutoff frequencies of the prototype filter at the band edge frequencies  $W_{t1}=0.25$  and  $W_{t2}=0.75$ :

```
[num,den] = iirlp2bp(b,a,0.5,[0.25,0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b,a,num,den);
```

You can compare the results in this figure to verify the transformation.

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$W_o$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency locations in the transformed target filter
$Num$	Numerator of the target filter
$Den$	Denominator of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

**Purpose**

IIR lowpass to complex bandpass transformation

**Syntax**

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2bpc(Hd,Wo,Wt)
```

where Hd is a `dfilt` object

**Description**

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; for example real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

`[G,AllpassNum,AllpassDen] = iirlp2bpc(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a bandpass magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Move the cutoffs of the prototype filter to the new locations  $W_{t1}=0.25$  and  $W_{t2}=0.75$  creating a complex bandpass filter:

```
[num, den] = iirlp2bpc(b, a, 0.5, [0.25, 0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Plotting the prototype and target filters together in FVTool lets you compare the filters.

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$W_0$	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
$W_t$	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
$Num$	Numerator of the target filter

# iirlp2bpc

iirftransf | allpasslp2bpc | zpklp2bpc

**Purpose**

Transform IIR lowpass filter to IIR bandstop filter

**Syntax**

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2bs(Hd,Wo,Wt)
```

where Hd is a `dfilt` object

**Description**

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)` returns the numerator and denominator vectors, Num and Den respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandstop frequency mapping.

It also returns the numerator, AllpassNum, and the denominator, AllpassDen, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by B and a denominator specified by A.

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ s.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

`[G,AllpassNum,AllpassDen] = iirlp2bs(Hd,Wo,Wt)` returns transformed `dfilt` object G with a bandstop magnitude response. The coefficients AllpassNum and AllpassDen represent the allpass mapping

filter for mapping the prototype filter frequency  $\omega_0$  and the target frequencies vector  $\omega_t$ . Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Create the real bandstop filter by placing the cutoff frequencies of the prototype filter at the band edge frequencies  $\omega_{t1}=0.25$  and  $\omega_{t2}=0.75$ :

```
[num, den] = iirlp2bs(b, a, 0.5, [0.25, 0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

With both filters plotted in the figure, you see clearly the results of the transformation.

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$W_o$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency locations in the transformed target filter
$Num$	Numerator of the target filter
$Den$	Denominator of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

[iirftransf](#) | [allpasslp2bs](#) | [zpklp2bs](#)

**Purpose**

Transform IIR lowpass filter to IIR complex bandstop filter

**Syntax**

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bsc(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2bsc(Hd,Wo,Wt)
```

where Hd is a `dfilt` object

**Description**

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bsc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and the denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandstop filters for band

attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

`[G,AllpassNum,AllpassDen] = iirlp2bsc(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a bandstop magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Move the cutoffs of the prototype filter to the new locations  $W_{t1}=0.25$  and  $W_{t2}=0.75$  creating a complex bandstop filter:

```
[num, den] = iirlp2bsc(b, a, 0.5, [0.25, 0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

The last command in the example plots both filters in the same window so you can compare the results.

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$W_0$	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
$W_t$	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

# iirlp2bsc

---

<b>Variable</b>	<b>Description</b>
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## See Also

**Purpose**

Transform lowpass IIR filter to highpass filter

**Syntax**

```
[num,den] = iir1p2hp(b,a,wc,wd)
[G,AllpassNum,AllpassDen] = iir1p2hp(Hd,Wo,Wt)
```

where Hd is a `dfilt` object

**Description**

`[num,den] = iir1p2hp(b,a,wc,wd)` with input arguments `b` and `a`, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, `iir1p2hp` transforms the magnitude response from lowpass to highpass. `num` and `den` return the coefficients for the transformed highpass filter. For `wc`, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in `wd`. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select `wc` and designate `wd`, the transformation algorithm sets the magnitude response at the `wd` values of your bandstop filter to be the same as the magnitude response of your lowpass filter at `wc`. Filter performance between the values in `wd` is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as `wc`. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

`[G,AllpassNum,AllpassDen] = iirlp2hp(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a highpass magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

This example transforms an IIR filter from lowpass to high pass by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter. To generate a highpass filter whose passband flattens out at 0.4, select the frequency in the lowpass filter where the passband starts to rolloff (`wc = 0.0175`) and move it to the new location at `wd = 0.4`.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1],...  
[0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0],...  
[1 1 1 1 10 10]);  
wc = 0.0175;  
wd = 0.4;  
[num,den] = iirlp2hp(b,a,wc,wd);  
fvtool(b,a,num,den);
```

In the figure showing the magnitude responses for the two filters, the transition band for the highpass filter is essentially the mirror image of the transition for the lowpass filter from 0.0175 to 0.025, stretched out over a wider frequency range. In the passbands, the filter share common ripple characteristics and magnitude.

**Purpose** Transform lowpass IIR filter to different lowpass filter

**Syntax** `[num,den] = iirlp2hp(b,a,wc,wd)`  
`[G,AllpassNum,AllpassDen] = iirlp2lp(Hd,Wo,Wt)`  
where Hd is a `dfilt` object

**Description** `[num,den] = iirlp2hp(b,a,wc,wd)` with input arguments `b` and `a`, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, `iirlp2hp` transforms the magnitude response from lowpass to highpass. `num` and `den` return the coefficients for the transformed highpass filter. For `wc`, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in `wd`. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select `wc` and designate `wd`, the transformation algorithm sets the magnitude response at the `wd` values of your bandstop filter to be the same as the magnitude response of your lowpass filter at `wc`. Filter performance between the values in `wd` is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as `wc`. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

`[G,AllpassNum,AllpassDen] = iirlp2lp(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a lowpass magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

This example transforms an IIR filter from lowpass to high pass by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter. To generate a lowpass filter whose passband extends out to 0.2, select the frequency in the lowpass filter where the passband starts to rolloff (`wc = 0.0175`) and move it to the new location at `wd = 0.2`.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1],...  
[0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0],...  
[1 1 1 1 10 10]);  
wc = 0.0175;  
wd = 0.2;  
[num,den] = iirlp2lp(b,a,wc,wd);  
fvtool(b,a,num,den);
```

Moving the edge of the passband from 0.0175 to 0.2 results in a new lowpass filter whose peak response in-band is the same as the original filter: same ripple, same absolute magnitude.

The rolloff is slightly less steep and the stopband profiles are the same for both filters; the new filter stopband is a “stretched” version of the original, as is the passband of the new filter.

[iirlp2bp](#) | [iirlp2bs](#) | [iirlp2hp](#) | [firlp2lp](#) | [firlp2hp](#)

**Purpose**

Transform IIR lowpass filter to IIR M-band filter

**Syntax**

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)
[G,AllpassNum,AllpassDen] = iirlp2mb(Hd,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2mb(...,Pass)
```

**Description**

`[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an `M`th-order real lowpass to real multiple bandpass frequency mapping. By default the DC feature is kept at its original location.

`[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the “DC Mobility” and the “Nyquist Mobility.” In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter do not change in the target filter. It is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iirlp2mb(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with an IIR real M-band filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

`[G,AllpassNum,AllpassDen] = iirlp2mb(...,Pass)` returns transformed `dfilt` object `G` with an IIR real M-band filter frequency response. This syntax allows you to specify an additional parameter, `Pass`, which chooses between using the “DC Mobility” and the “Nyquist Mobility.” In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

### Example 1

Create the real multiband filter with two passbands:

```
[num1, den1] = iirlp2mb(b, a, 0.5, [2 4 6 8]/10);  
[num2, den2] = iirlp2mb(b, a, 0.5, [2 4 6 8]/10, 'pass');
```

The second code snippet uses the `pass` option to select the Nyquist mobility option. In this case the resulting filter is the same.

### **Example 2**

Create the real multiband filter with two stopbands:

```
[num3, den3] = iirlp2mb(b, a, 0.5, [2 4 6 8]/10, 'stop');
```

Verify the result by comparing the prototype filter with target filters:

```
fvtool(b, a, num1, den1, num2, den2, num3, den3);
```

Combining all of the filters, prototypes and targets, on one figure makes comparing them straightforward. Passbands for the filters in example 1 appear separately in the figure, although they overlap to a degree that makes them hard to identify — they have identical coefficients.

## Arguments

Variable	Description
<i>B</i>	Numerator of the prototype lowpass filter
<i>A</i>	Denominator of the prototype lowpass filter
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency locations in the transformed target filter
<i>Pass</i>	Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default
<i>Num</i>	Numerator of the target filter

Variable	Description
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

**Purpose** Transform IIR lowpass filter to IIR complex M-band filter

**Syntax**  $[Num, Den, AllpassNum, AllpassDen] = iirlp2mbc(B, A, Wo, Wc)$   
 $[G, AllpassNum, AllpassDen] = iirlp2mbc(Hd, Wo, Wt)$   
where Hd is a `dfilt` object

**Description**  $[Num, Den, AllpassNum, AllpassDen] = iirlp2mbc(B, A, Wo, Wc)$  returns the numerator and denominator vectors, Num and Den respectively, of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to complex multibandpass frequency transformation.

It also returns the numerator, AllpassNum, and the denominator, AllpassDen, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by B and a denominator specified by A.

This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iir1p2mbc(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with an IIR complex `M`-band filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Now create a complex multiband filter with two passbands:

```
[num1, den1] = iir1p2mbc(b, a, 0.5, [2 4 6 8]/10);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num1, den1);
```

You see in the figure that `iirlp2mbc` replicates the desired feature at 0.5 in the lowpass filter at four locations in the multiband filter.

## Arguments

Variable	Description
<i>B</i>	Numerator of the prototype lowpass filter.
<i>A</i>	Denominator of the prototype lowpass filter.
<i>Wo</i>	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Wc</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>Num</i>	Numerator of the target filter.

<b>Variable</b>	<b>Description</b>
<i>Den</i>	Denominator of the target filter.
<i>AllpassNum</i>	Numerator of the mapping filter.
<i>AllpassDen</i>	Denominator of the mapping filter.

`iirftransf` | `allpasslp2mbc` | `zpk1p2mbc`

**Purpose**

Transform IIR lowpass filter to IIR complex N-point filter

**Syntax**

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2xc(Hd,Wo,Wt)
```

where Hd is a `dfilt` object

**Description**

`[Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt)` returns the numerator and denominator vectors, Num and Den respectively, of the target filter transformed from the real lowpass prototype by applying an Nth-order real lowpass to complex multipoint frequency transformation.

It also returns the numerator, AllpassNum, and the denominator, AllpassDen, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by B and a denominator specified by A.

Parameter N also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places N features of an original filter, located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., a stopband edge, DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iirlp2xc(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with an IIR complex `N`-point filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Create the complex bandpass filter from the real lowpass filter:

```
[num, den] = iirlp2xc(b, a, [-0.5 0.5], [-0.25 0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Reviewing the coefficients and the figure produced by the example shows that the target filter has complex coefficients and is indeed a bandpass filter as expected.

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter.
$A$	Denominator of the prototype lowpass filter.
$W_o$	Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
$W_t$	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
$Num$	Numerator of the target filter.

Variable	Description
<i>Den</i>	Denominator of the target filter.
<i>AllpassNum</i>	Numerator of the mapping filter.
<i>AllpassDen</i>	Denominator of the mapping filter.

iirftransf | allpasslp2xc | zpklp2xc

## Purpose

Transform IIR lowpass filter to IIR real N-point filter

## Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt,Pass)
[G,AllpassNum,AllpassDen] = iirlp2bpc(Hd,Wo,Wt),
where Hd is a dfilt object
[G,AllpassNum,AllpassDen] = iirlp2bpc(...,Pass)
```

## Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an `N`th-order real lowpass to real multipoint frequency transformation, where `N` is the number of features being mapped. By default the DC feature is kept at its original location.

`[Num,Den,AllpassNum,AllpassDen]= iirlp2xn(B,A,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after

the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating  $N$  bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iirlp2xn(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with an IIR real  $N$ -point filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

`[G,AllpassNum,AllpassDen] = iirlp2xn(...,Pass)` returns transformed `dfilt` object `G` with an IIR real  $N$ -point filter frequency response. This syntax allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Move the cutoffs of the prototype filter to the new locations  $W_{t1}=0.25$  and  $W_{t2}=0.75$  creating a real bandpass filter:

```
[num, den] = iirlp2xn(b, a, [-0.5 0.5], [0.25 0.75], ...  
pass');
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

`iirlp2xn` has created the desired bandpass filter with the cutoff locations specified in the command.

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$W_0$	Frequency values to be transformed from the prototype filter
$W_t$	Desired frequency locations in the transformed target filter
$Pass$	Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default
$Num$	Numerator of the target filter

Variable	Description
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## See Also

`iirftransf` | `allpasslp2xn` | `zpklp2xn`

**Purpose**

Least P-norm optimal IIR filter

**Syntax**

```
[num,den] = iirlpnorm(n,d,f,edges,a)
[num,den] = iirlpnorm(n,d,f,edges,a,w)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)
```

**Description**

`[num,den] = iirlpnorm(n,d,f,edges,a)` returns a filter having a numerator order `n` and denominator order `d` which is the best approximation to the desired frequency response described by `f` and `a` in the least-`p`th sense. The vector `edges` specifies the band-edge frequencies for multi-band designs. An unconstrained quasi-Newton algorithm is employed and any poles or zeros that lie outside of the unit circle are reflected back inside. `n` and `d` should be chosen so that the zeros and poles are used effectively. See the “Hints” on page 4-922 section. Always use `freqz` to check the resulting filter.

`[num,den] = iirlpnorm(n,d,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `iirlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. `f` and `a` must have the same number of elements, which may exceed the number of elements in `edges`. This allows for the specification of filters having any gain contour within each band. The frequencies specified in `edges` must also appear in the vector `f`. For example,

```
[num,den] = iirlpnorm(5,12,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

is a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p)` where `p` is a two-element vector `[pmin pmax]` allows for the specification of the minimum and maximum values of `p` used in the least-`p`th algorithm. Default is `[2 128]` which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If `p` is the string `'inspect'`, no

# iirlpnorm

---

optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is  $(dens*(n+d+1))$ . The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

## Hints

- This is a weighted least-pth optimization.
- Check the radii and locations of the poles and zeros for your filter. If the zeros are on the unit circle and the poles are well inside the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.
- Similarly, if several poles have a large radii and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weighting in the passband.

## See Also

`iirlpnormc` | `filter` | `freqz` | `iigrpdelay` | `zplane`

**Purpose**

Constrained least Pth-norm optimal IIR filter

**Syntax**

```
[num,den] = iirlpnormc(n,d,f,edges,a)
[num,den] = iirlpnormc(n,d,f,edges,a,w)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens,...
initnum,initden)
[num,den,err] = iirlpnormc(...)
[num,den,err,sos,g] = iirlpnormc(...)
```

**Description**

`[num,den] = iirlpnormc(n,d,f,edges,a)` returns a filter having numerator order `n` and denominator order `d` which is the best approximation to the desired frequency response described by `f` and `a` in the least-`p`th sense. The vector `edges` specifies the band-edge frequencies for multi-band designs. A constrained Newton-type algorithm is employed. `n` and `d` should be chosen so that the zeros and poles are used effectively. See the Hints section. Always check the resulting filter using `fvtool`.

`[num,den] = iirlpnormc(n,d,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `iirlpnormc` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. `f` and `a` must have the same number of elements, which can exceed the number of elements in `edges`. This allows for the specification of filters having any gain contour within each band. The frequencies specified in `edges` must also appear in the vector `f`. For example,

```
[num,den] = iirlpnormc(5,5,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)` returns a filter having a maximum pole radius of `radius` where  $0 < \text{radius} < 1$ . `radius`

defaults to 0.999999. Filters that have a reduced pole radius may retain better transfer function accuracy after you quantize them.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)` where `p` is a two-element vector `[pmin pmax]` allows for the specification of the minimum and maximum values of `p` used in the least-pth algorithm. Default is `[2 128]` which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If `p` is the string `'inspect'`, no optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is `(dens*(n+d+1))`. The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens,...,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

`[num,den,err] = iirlpnormc(...)` returns the least-Pth approximation error `err`.

`[num,den,err,sos,g] = iirlpnormc(...)` returns the second-order section representation in the matrix `SOS` and gain `G`. For numerical reasons you may find `SOS` and `G` beneficial in some cases.

## Hints

- This is a weighted least-pth optimization.
- Check the radii and location of the resulting poles and zeros.
- If the zeros are all on the unit circle and the poles are well inside of the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.

- Similarly, if several poles have a large radius and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weight in the passband.
- If you reduce the pole radius, you might need to increase the order of the denominator.

The message

Poorly conditioned matrix. See the "help" file.

indicates that `iirlpnormc` cannot accurately compute the optimization because either:

- 1 The approximation error is extremely small (try reducing the number of poles or zeros — refer to the hints above).
- 2 The filter specifications have huge variation, such as `a=[1 1e9 0 0]`.

## Examples

This example returns a lowpass filter whose pole radius is constrained to 0.8

```
[b,a,err,s,g] = iirlpnormc(6,6,[0 .4 .5 1],[0 .4 .5 1],...
[1 1 0 0],[1 1 1 1],.8);
hd = dfilt.df1sos(s,g); % Construct second-order sections filter.
fvtool(hd); % View filter's magnitude response
```

From the magnitude response shown here you see the lowpass nature of the filter. The pole/zero plot following shows that the poles are constrained to 0.8 as specified in the command.

# iirls

---

<b>Purpose</b>	Least-squares IIR filter from specification object
<b>Syntax</b>	<pre>hd = design(d, 'iirls') hd = design(d, 'iirls', designoption, value, designoption, value, ...)</pre>
<b>Description</b>	hd = design(d, 'iirls') designs a least-squares filter specified by the filter specification object d.

---

**Note** The `iirls` algorithm might not be well behaved in all cases. Experience is your best guide to determining if the resulting filter meets your needs. When you use `iirls` to design a filter, review the filter carefully to ensure that it is appropriate for your use.

---

hd =  
design(d, 'iirls', designoption, value, designoption, value, ...) returns a least-squares IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d, 'method')
```

For complete help about using `iirls`, refer to the command line help system. For example, to get specific information about using `iirls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d, 'iirls')
```

**Examples** Starting from an arbitrary magnitude and phase design object `d`, generate a complex bandpass filter of order = 5. To make the example a little easier to do, use the default values for `F`, and `H`, the frequency vector and the complex desired frequency response.

```
d = fdesign.arbmagnphase('N,F,H',5);  
d =
```

```
    Response: 'Arbitrary Magnitude and Phase'  
    Specification: 'N,F,H'  
    Description: {'Filter Order';'Frequency Vector';'  
                Complex Desired Frequency Response'  
    NormalizedFrequency: true  
    FilterOrder: 5  
    Frequencies: [1x655 double]  
    FreqResponse: [1x655 double]
```

```
design(d,'iirls'); % Opens FVTool to show the filter.
```

Displaying both the phase and magnitude response in FVTool shows you the filter.

# iirls

fdesign.arbmag | fdesign.arbmagnphase | fir1s

**Purpose** Second-order IIR notch filter

**Syntax** `[num,den] = iirnotch(w0,bw)`  
`[num,den] = iirnotch(w0,bw,ab)`

**Description** `[num,den] = iirnotch(w0,bw)` turns a digital notching filter with the notch located at  $w_0$ , and with the bandwidth at the -3 dB point set to  $bw$ . To design the filter,  $w_0$  must meet the condition  $0.0 < w_0 < 1.0$ , where 1.0 corresponds to  $\pi$  radians per sample in the frequency range.

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = w_0/bw$  where  $\omega_0$  is  $w_0$ , the frequency to remove from the signal.

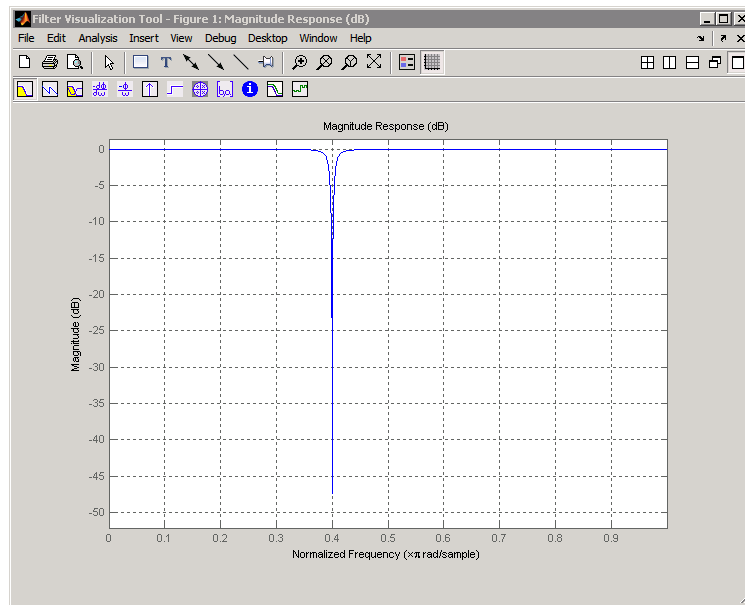

`[num,den] = iirnotch(w0,bw,ab)` returns a digital notching filter whose bandwidth,  $bw$ , is specified at a level of  $-ab$  decibels. Including the optional input argument  $ab$  lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

**Examples** Design and plot an IIR notch filter that removes a 60 Hz tone ( $f_0$ ) from a signal at 300 Hz ( $f_s$ ). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth:

```
wo = 60/(300/2);  bw = wo/35;  
[b,a] = iirnotch(wo,bw);  
fvtool(b,a);
```

Shown in the next plot, the notch filter has the desired bandwidth with the notch located at 60 Hz, or  $0.4\pi$  radians per sample. Compare this plot to the comb filter plot shown on the reference page for `iircomb`.

# iirnotch

**See Also** `firgr` | `iircomb` | `iirpeak`

**Purpose**

Second-order IIR peak or resonator filter

**Syntax**

```
[num,den] = iirpeak(w0,bw)
[num,den] = iirpeak(w0,bw,ab)
```

**Description**

`[num,den] = iirpeak(w0,bw)` turns a second-order digital peaking filter with the peak located at  $w_0$ , and with the bandwidth at the +3 dB point set to  $bw$ . To design the filter,  $w_0$  must meet the condition  $0.0 < w_0 < 1.0$ , where 1.0 corresponds to  $\pi$  radians per sample in the frequency range.

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = w_0/bw$  where  $\omega_0$  is  $w_0$  the signal frequency to boost.

`[num,den] = iirpeak(w0,bw,ab)` returns a digital peaking filter whose bandwidth,  $bw$ , is specified at a level of  $+ab$  decibels. Including the optional input argument  $ab$  lets you specify the magnitude response bandwidth at a level that is not the default +3 dB point, such as +6 dB or 0 dB.

**Examples**

Design and plot an IIR peaking filter that boosts the frequency at 1.75 Khz in a signal and has bandwidth of 500 Hz at the -3 dB point:

```
fs = 10000; wo = 1750/(fs/2); bw = 500/(fs/2);
[b,a] = iirpeak(wo,bw);
fvtool(b,a);
```

Shown in the next plot, the peak filter has the desired gain and bandwidth at 1.75 KHz.

**See Also** [firgr](#) | [iircomb](#) | [iirnotch](#)

**Purpose** Power complementary IIR filter

**Syntax**  
`[bp,ap] = iirpowcomp(b,a)`  
`[bp,ap,c] = iirpowcomp(b,a)`

**Description** `[bp,ap] = iirpowcomp(b,a)` returns the coefficients of the power complementary IIR filter  $g(z) = bp(z)/ap(z)$  in vectors `bp` and `ap`, given the coefficients of the IIR filter  $h(z) = b(z)/a(z)$  in vectors `b` and `a`. `b` must be symmetric (Hermitian) or antisymmetric (antihermitian) and of the same length as `a`. The two power complementary filters satisfy the relation

$$|H(w)|^2 + |G(w)|^2 = 1.$$

`[bp,ap,c] = iirpowcomp(b,a)` where `c` is a complex scalar of magnitude = 1, forces `bp` to satisfy the generalized hermitian property  $\text{conj}(bp(\text{end}:-1:1)) = c*bp$ .

When `c` is omitted, it is chosen as follows:

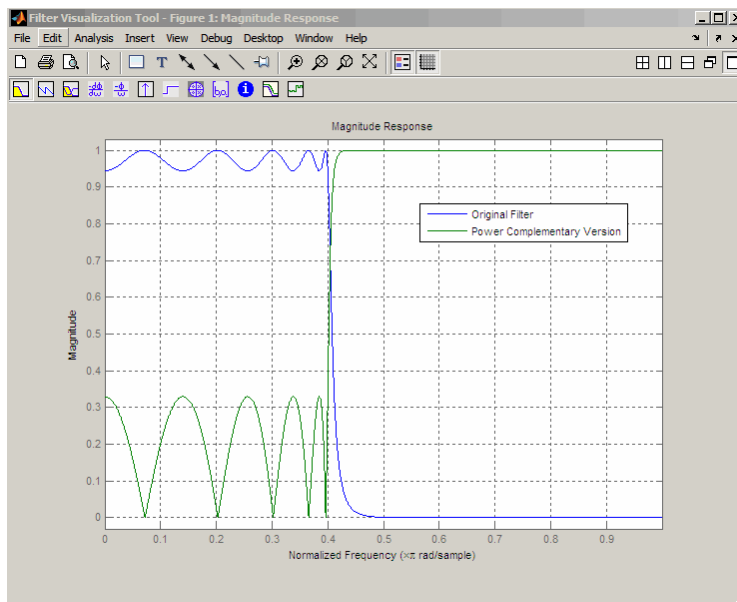

- When `b` is real, chooses `C` as 1 or -1, whichever yields `bp` real
- When `b` is complex, `C` defaults to 1

`ap` is always equal to `a`.

**Examples**

```
[b,a]=cheby1(10,.5,.4);
[bp,ap]=iirpowcomp(b,a);
Hd1 = dfilt.df2(b,a);
Hd2 = dfilt.df2(bp,ap);
hfvf = fvtool([Hd1,Hd2], 'MagnitudeDisplay', 'Magnitude');
legend(hfvf, 'Original Filter', 'Power Complementary Version');
```

The next figure presents the results of applying `iirpowcomp` to the Chebyshev filter — the power complementary version of the original filter.

**See Also**

`tf2ca` | `tf2c1` | `ca2tf` | `c12tf`

**Purpose**

Upsample IIR filter by integer factor

**Syntax**

```
[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)
```

**Description**

`[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter being transformed from any prototype by applying an  $N$ th-order rateup frequency transformation, where  $N$  is the upsample ratio. Transformation creates  $N$  equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

The relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

**Examples**

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);  
[num, den] = iirrateup(b, a, 4);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

As shown in the figure produced by FVTool, the transformed filter appears as expected.

## Arguments

Variable	Description
<i>B</i>	Numerator of the prototype lowpass filter
<i>A</i>	Denominator of the prototype lowpass filter
<i>N</i>	Frequency multiplication ratio
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

**See Also**      [iirftransf](#) | [allpassrateup](#) | [zpkrateup](#)

# iirshift

---

**Purpose** Shift frequency response of IIR filter

**Syntax** `[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)`

**Description** `[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)` returns the numerator and denominator vectors, Num and Den respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real shift frequency mapping.

It also returns the numerator, AllpassNum, and the denominator of the allpass mapping filter, AllpassDen. The prototype lowpass filter is given with the numerator specified by B and the denominator specified by A.

This transformation places one selected feature of an original filter located at frequency  $W_o$  to the required target frequency location,  $W_t$ . This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them from the beginning.

**Examples** Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Perform the real frequency shift by defining where the selected feature of the prototype filter, originally at  $W_o=0.5$ , should be placed in the target filter,  $W_t=0.75$ :

```
Wo = 0.5; Wt = 0.75;  
[num, den] = iirshift(b, a, Wo, Wt);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Shifting the specified feature from the prototype to the target generates the response shown in the figure.

# iirshift

---

## Arguments

Variable	Description
<i>B</i>	Numerator of the prototype lowpass filter
<i>A</i>	Denominator of the prototype lowpass filter
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## See Also

`iirftransf` | `allpassshift` | `zpkshift`

**Purpose**

Shift frequency response of IIR complex filter

**Syntax**

```
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)
```

**Description**

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at  $W_o$ , placed at  $W_t$  in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)` calculates the allpass filter for doing the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)` calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

**Examples**

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Rotate all features of the prototype filter in the frequency domain by the same amount by specifying where the selected feature of an original filter,  $W_o = 0.5$ , should appear in the target filter,  $W_t = 0.25$ :

# iirshiftc

```
[num, den] = iirshiftc(b, a, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

After applying the shift, the selected feature from the original filter is just where it should be, at  $W_t = 0.25$ .

## Arguments

Variable	Description
<i>B</i>	Numerator of the prototype lowpass filter
<i>A</i>	Denominator of the prototype lowpass filter

Variable	Description
$W_o$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency location in the transformed target filter
$Num$	Numerator of the target filter
$Den$	Denominator of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## Purpose

Filter impulse response

## Syntax

```
[h,t] = impz(hfilt)
[h,t] = impz(hfilt,n)
[h,t] = impz(hfilt,n,fs)
[h,t] = impz(hfilt,[],fs)
impz(hfilt)
[h,t] = impz(hs)
[h,t] = impz(hs,Name,Value)
impz(hs)
```

## Description

`impz` returns the impulse response based on the current filter coefficients. This section describes common `impz` operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to `impz` in Signal Processing Toolbox documentation.

`[h,t] = impz(hfilt)` returns the impulse response `h` and the corresponding time points `w` at which the impulse response of `hfilt` is computed. The impulse response is evaluated at 10 1-second intervals—`(0:9)'`.

`[h,t] = impz(hfilt,n)` returns the impulse response evaluated at `floor(n)` 1-second intervals—`(0:floor(n)-1)'`.

`[h,t] = impz(hfilt,n,fs)` returns the impulse response evaluated at `floor(n) 1/fs`-second intervals—`(0:floor(n)-1)'/fs`.

`[h,t] = impz(hfilt,[],fs)` returns the impulse response evaluated at 10 `1/fs`-second intervals—`(0:9)'/fs`.

`impz(hfilt)` uses `FVTool` to plot the impulse response of the filter. You can also provide the optional input arguments `n` and `fs` with this syntax.

`[h,t] = impz(hs)` returns the impulse response for the filter System object `hs`. The impulse response is evaluated at 10 1-second intervals—`(0:9)'`. You can also provide the optional input arguments `n` and `fs` with this syntax.

`[h,t] = impz(hs,Name,Value)` returns an impulse response with additional options specified by one or more `Name,Value` pair arguments.

`impz(hs)` uses FVTool to plot the impulse response of the filter System object `hs`.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

## Input Arguments

### `hfilter`

`hfilter` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter impulse response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `impz` assumes the filter is running at that rate.

For multistage cascades, `impz` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `impz` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `impz` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `impz`, the function interprets `fs` as the rate at which the equivalent filter is running.

## **hs**

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`
- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

## **n**

Number of samples.

**Default:** 10

## **fs**

Sampling frequency.

**Default:** 1

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'Arithmetic'**

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

**Output Arguments**

**h**

Complex, n-element impulse response vector. If `hfilt` is a vector of filters, `h` is a complex, `length(hfilt)`-by-`n` matrix of impulse response vectors corresponding to each filter in `hfilt`. If `n` is not specified, the function uses a default value of 8192.

For adaptive filters, `h` is the instantaneous impulse response.

**t**

Time vector of length  $n$ , in seconds.  $t$  consists of  $n$  points equally spaced from 0 to  $\text{floor}(n)/fs$ . If  $n$  is not specified, the function uses a default value of 10. If  $fs$  is not specified, the function uses a default value of 1.

## Examples

Create a discrete-time filter for a fourth-order, lowpass elliptic filter with a cutoff frequency of 0.4 times the Nyquist frequency. Use a second-order sections structure to resist quantization errors. Plot the first 50 samples of the impulse response, along with the reference impulse response.

```
d = fdesign.lowpass(.4,.5,1,80);  
% Create a design object for the prototype filter.
```

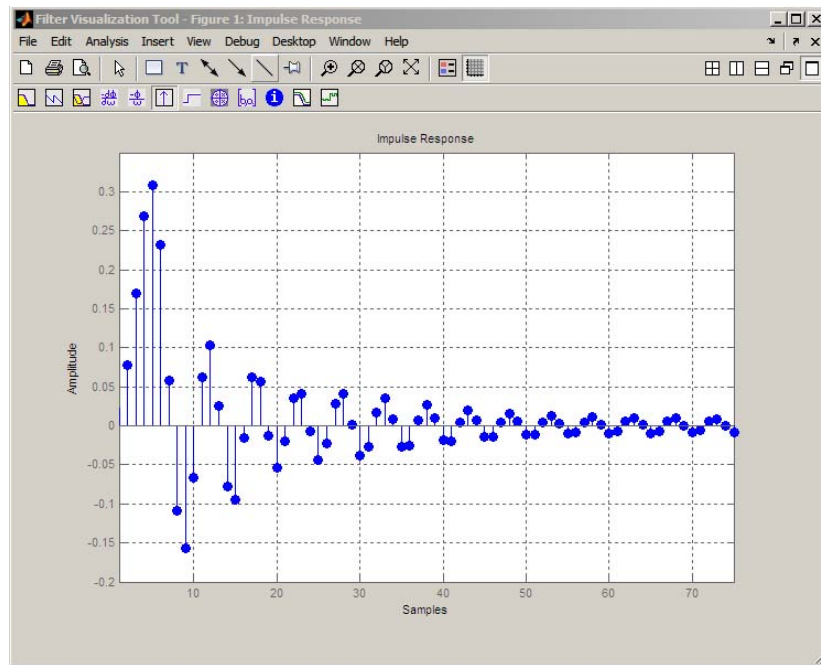

Use `ellip` to design a minimum order discrete-time filter in second-order section form.

```
hd=design(d,'ellip');
```

Convert `hd` to fixed-point, and plot the impulse response:

```
impz(hd);  
axis([1 75 -0.2 0.35])
```

# impz

**Purpose** States from CIC filter

**Syntax** `integerstates = int(hm.states)`

**Description** `integerstates = int(hm.states)` returns the states of a CIC filter in matrix form, rather than as the native `filtstates` object. An important point about `int` is that it quantizes the state values to the smallest number of bits possible while maintaining the values accurately.

**Examples** For many users, the states of multirate filters are most useful as a matrix, but the CIC filters store the states as objects. Here is how you get the states from you CIC filter as a matrix.

```
hm = mfilt.cicdecim;
hs = hm.states; % Returns a FILTSTATES.CIC object hs.
states = int(hs); % Convert object hs to a signed integer matrix.
```

After using `int` to convert the states object to a matrix, here is what you get.

Before converting:

```
hm.states

ans =

    Integrator: [2x1 States]
    Comb: [2x1 States]
```

After the conversion and assigning the states to `states`:

```
states

states =

     0     0
     0     0
```

# int

---

## **See Also**

`filtstates.cic` | `mfilt.cicdecim` | `mfilt.cicinterp`

**Purpose**

Determine whether filter is allpass

**Syntax**

```
flag = isallpass(b,a)
flag = isallpass(hd)
flag = isallpass(sos)
flag = islinphase(...,tol)
flag = isallpass(hs,...)
flag = isallpass(hs,'Arithmetic',arithtype)
```

**Description**

`flag = isallpass(b,a)` returns a logical output, `flag`, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is an allpass filter. If the filter is not an allpass filter, `flag` is equal to `false`.

`flag = isallpass(hd)` returns `true` if the filter object, `hd`, is an allpass filter.

`flag = isallpass(sos)` returns `true` if the filter specified by second order sections matrix, `SOS`, is an allpass filter. `SOS` is a `K`-by-6 matrix, where the number of sections, `K`, must be greater than or equal to 2. Each row of `SOS` corresponds to the coefficients of a second order (biquad) filter. The  $i$ -th row of the `SOS` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = islinphase(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to  $\text{eps}^{(2/3)}$ . Specifying a tolerance may be most helpful in fixed-point allpass filters.

`flag = isallpass(hs,...)` returns `true` if the filter System object `hs` is an allpass filter. You must have the DSP System Toolbox software to use this syntax.

`flag = isallpass(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified `arithtype`. `arithtype` can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System

object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

## Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on

System Object State	Coefficient Data Type	Rule
		the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

Create an allpass filter and verify that the frequency response is allpass.

```
b = [1/3 1/4 1/5 1];
a = flip1r(b);
flag = isallpass(b,a)
fvtool(b,a)
```

Create a lattice allpass filter and verify that the filter is allpass.

```
k = [1/2 1/3 1/4 1/5];
[b,a] = latc2tf(k,'allpass');
flag_isallpass = isallpass(b,a)
fvtool(b,a)
```

## See Also

islinphase | ismaxphase | isminphase | istable

# isfir

---

**Purpose** Determine whether filter is FIR

**Syntax** `isfir(h)`  
`isfir(hs)`

**Description** `isfir(h)` determines whether filter `h` is an FIR filter, returning 1 when the filter is an FIR filter, and 0 when it is IIR. `isfir` applies to `dfilt`, `mfilt`, and `adaptfilt` objects.

To determine whether `h` is an FIR filter, `isfir(h)` inspects filter `h` and determines whether the filter, in transfer function form, has a scalar denominator. If it does, it is an FIR filter.

`isfir(hs)` determines whether the filter System object `hs` is an FIR filter, returning 1 if true and 0 if false.

**Examples**

```
d = fdesign.lowpass;  
h = design(d);  
isfir(h)  
ans =
```

```
1
```

returns 1 for the status of filter `h`. The filter is an FIR structure with denominator reference coefficient equal to 1.

For multirate filters, `isfir` works the same way.

```
d = fdesign.interpolator(5); % Interpolate by 5.  
h = design(d); % Use the default design method.  
isfir(h)
```

```
ans =
```

```
1
```

Use `isfir` with adaptive filters as well.

**See Also**

issos | isstable

# islinphase

---

**Purpose** Determine whether filter has linear phase

**Syntax**

```
flag = islinphase(b,a)
flag = islinphase(sos)
flag = islinphase(h)
flag = islinphase(...,tol)
flag = islinphase(hs,...)
flag = islinphase(hs,'Arithmetic',arithtype)
```

**Description** `flag = islinphase(b,a)` returns a logical output, `flag`, equal to `true` if the filter coefficients in `b` and `a` define a linear phase filter. `flag` is equal to `false` if the filter does not have linear phase.

`flag = islinphase(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, is linear phase. `sos` is a K-by-6 matrix, where the number of sections, K, must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The i-th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = islinphase(h)` determines if the filter object `h` is linear phase. `islinphase` accepts an `adapfilt`, `dfilt`, or `mfilt` object. To create an `adapfilt` or `mfilt` object, you must have the DSP System Toolbox software.

`flag = islinphase(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to `eps^(2/3)`.

`flag = islinphase(hs,...)` determines whether the filter System object `hs` is linear phase. You must have the DSP System Toolbox to use `islinphase` with a System object.

`flag = islinphase(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified *arithtype*. *arithtype* can be one of `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System

object is locked or unlocked. You must have the DSP System Toolbox to use `islinphase` with a System object.

## Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on

# islinphase

System Object State	Coefficient Data Type	Rule
		the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

This FIR filter has linear phase.

```
d = fdesign.lowpass('n,fc',10,0.55);  
h = design(d,'window');  
flag = islinphase(h)
```

Using the specification `nb,na,fp,fst` results in an IIR filter that is not linear phase in this design.

```
nb=15  
na=10  
d=fdesign.lowpass('nb,na,fp,fst',nb,na,0.45,0.55)  
h=design(d);  
flag = islinphase(h)
```

## See Also

[isallpass](#) | [ismaxphase](#) | [isminphase](#) | [isstable](#)

**Purpose**

Determine whether filter is maximum phase

**Syntax**

```
flag = ismaxphase(b,a)
flag = ismaxphase(sos)
flag = ismaxphase(h)
flag = ismaxphase(...,tol)
flag = ismaxphase(hs,...)
flag = ismaxphase(hs,'Arithmetic',arithtype)
```

**Description**

`flag = ismaxphase(b,a)` returns a logical output, `flag`, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is a maximum phase filter.

`flag = ismaxphase(sos)` returns `true` if the filter specified by second order sections matrix, `SOS`, is a maximum phase filter. `SOS` is a `K`-by-`6` matrix, where the number of sections, `K`, must be greater than or equal to 2. Each row of `SOS` corresponds to the coefficients of a second order (biquad) filter. The `i`-th row of the `SOS` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = ismaxphase(h)` returns `true` if the `dfilt` filter object `h` is a maximum phase filter. If you have the DSP System Toolbox software, `ismaxphase` works with `adapfilt` and `mfilt` objects.

`flag = ismaxphase(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to `eps^(2/3)`.

`flag = ismaxphase(hs,...)` returns `true` if the filter System object `hs` is a maximum phase filter. You must have the DSP System Toolbox software to use this syntax.

`flag = ismaxphase(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified `arithtype`. `arithtype` can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System

object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

## Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on

System Object State	Coefficient Data Type	Rule
		the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

Design maximum-phase and minimum-phase lattice filters and verify their phase type.

```
k = [1/6 1/1.4];
bmax = latc2tf(k,'max');
bmin = latc2tf(k,'min');
max_flag = ismaxphase(bmax)
min_flag = isminphase(bmin)
```

For a filter defined with a set of single precision numerator and denominator coefficients, check if the filter is maximum phase for different tolerances.

```
b = single([1 -0.9999]);
a = single([1 0.45]);
max_flag1 = ismaxphase(b,a)
max_flag2 = ismaxphase(b,a,1e-3)
```

## See Also

isallpass | islinphase | isminphase | isstable

# isminphase

---

**Purpose** Determine whether filter is minimum phase

**Syntax**

```
flag = isminphase(b,a)
flag = isminphase(sos)
flag = isminphase(h)
flag = isminphase(...,tol)
flag = isminphase(hs,...)
isminphase(hs,'Arithmetic',arithtype)
```

**Description** `flag = isminphase(b,a)` returns a logical output, `flag`, equal to true if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is a minimum phase filter.

`flag = isminphase(sos)` returns true if the filter specified by second order sections matrix, `SOS`, is minimum phase. `SOS` is a `K`-by-6 matrix, where the number of sections, `K`, must be greater than or equal to 2. Each row of `SOS` corresponds to the coefficients of a second order (biquad) filter. The *i*-th row of the `SOS` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isminphase(h)` determines if the `dfilt` filter object `h` is minimum phase. If you have the DSP System Toolbox software, `isminphase` works with `adapfilt` and `mfilt` objects.

`flag = isminphase(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to `eps^(2/3)`.

A filter is *minimum phase* when all the zeros of its transfer function are on or inside the unit circle, or the numerator is a scalar. An equivalent definition for a minimum phase filter is a causal and stable system with a causal and stable inverse.

`flag = isminphase(hs,...)` determines whether the filter System object `hs` is minimum phase, returning 1 if true and 0 if false. You must have the DSP System Toolbox software to use this syntax.

`isminphase(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified *arithtype*. *arithtype* can be 'double', 'single', or 'fixed'. When you specify 'double' or

'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

## Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.

# isminphase

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

Design a lowpass Butterworth IIR filter using second order sections and check if the filter is minimum phase.

```
[z,p,k] = butter(6,0.15);  
SOS = zp2sos(z,p,k);  
min_flag = isminphase(SOS)
```

For a filter defined with a set of single precision numerator and denominator coefficients, check if the filter is minimum phase for different tolerances.

```
b = single([1 1.00001]);  
a = single([1 .45]);  
min_flag1 = isminphase(b,a)  
min_flag2 = isminphase(b,a,1e-3)
```

## See Also

[isallpass](#) | [islinphase](#) | [ismaxphase](#) | [isstable](#)

# isreal

---

**Purpose** Determine whether filter uses real coefficients

**Syntax** `isreal(hd)`  
`isreal(hs)`

**Description** `isreal(hd)` returns 1 (or true) if all filter coefficients for the filter `hd` are real, and returns 0 (or false) otherwise. Complex filters have one or more coefficients with nonzero imaginary parts.

`isreal(hs)` determines whether the filter coefficients of the filter System object `hs` are real, returning 1 if true and 0 if false.

---

**Note** Quantizing a filter cannot make a real filter into a complex filter.

---

**Examples** Create a double-precision filter and a fixed-point filter. Then, test the coefficients of the fixed-point filter to see if they are strictly real.

```
d=fdesign.lowpass('n,fp,ap,ast',5,0.4,0.5,20);  
hd=design(d,'ellip');  
hd.arithmetic='fixed';  
IsReal =isreal(hd);  
% Returns a 1
```

**See Also** `isfir` | `islinphase` | `ismaxphase` | `isminphase` | `issos` | `isstable` | `isallpass`

**Purpose**

Determine whether filter is SOS form

**Syntax**

```
issos(hd)
issoss(hs)
```

**Description**

`issos(hd)` determines whether quantized filter `hq` consists of second-order sections. Returns 1 if all sections of quantized filter `hq` have order less than or equal to two, and 0 otherwise.

`issoss(hs)` determines whether the filter System object `hs` consists of second-order sections, returning 1 if true and 0 if false.

**Examples**

By default, `fdesign` and `design` return SOS filters when possible. This example designs a lowpass SOS filter that uses fixed-point arithmetic.

```
d=fdesign.lowpass('n,fp,ap,ast',40,0.55,0.1,60);
hd=design(d,'ellip');
hd.arithmetic='fixed';
IsSOS=issos(hd);
```

The fixed-point filter `hd` is in second-order section form, as is the double-precision version.

**See Also**

```
isallpass | isfir | islinphase | ismaxphase | isminphase |
isreal | isstable
```

# isstable

---

**Purpose** Determine whether filter is stable

**Syntax**

```
flag = isstable(b,a)
flag = isstable(sos)
flag = isstable(h)
flag = isstable(hs)
flag = isstable(hs,'Arithmetic',arithtype)
```

**Description**

`flag = isstable(b,a)` returns a logical output, `flag`, equal to true if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is a stable filter. If the poles lie on or outside the circle, `isstable` returns false. If the poles are inside the circle, `isstable` returns true.

`flag = isstable(sos)` returns true if the filter specified by second order sections matrix, `sos`, is stable. `sos` is a K-by-6 matrix, where the number of sections, K, must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The i-th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isstable(h)` returns true if the filter object, `h`, is stable. If you have the DSP System Toolbox, you can use `isstable` with `adaptfilt` and `mfilt` objects.

`flag = isstable(hs)` returns true if the filter System object `hs` is stable. You must have the DSP System Toolbox software to use this syntax.

`flag = isstable(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified `arithtype`. `arithtype` can be 'double', 'single', or 'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

**Details for Fixed-Point Arithmetic**

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

# isstable

---

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

Design a Butterworth highpass IIR filter using second order sections and determine whether the filter is stable.

```
[z,p,k] = butter(6,0.7,'high');
SOS = zp2sos(z,p,k);
flag = isstable(SOS)
zplane(z,p)
```

Create a filter and determine the filter's stability for different coefficient data types and tolerances.

```
b = [1 -.5];
a = [1 -.999999999];
act_flag1 = isstable(b,a)
act_flag2 = isstable(single(b),single(a))
zplane(b,a)
```

<b>Purpose</b>	Kaiser window filter from specification object
<b>Syntax</b>	<pre>h = design(d,'kaiserwin') h = design(d,'kaiserwin',designoption,value,designoption,... value,...)</pre>
<b>Description</b>	<p><code>h = design(d,'kaiserwin')</code> designs a digital filter <code>hd</code>, or a multirate filter <code>hm</code> that uses a Kaiser window. For <code>kaiserwin</code> to work properly, the filter order in the specifications object must be even. In addition, higher order filters (filter order greater than 120) tend to be more accurate for smaller transition widths. <code>kaiserwin</code> returns a warning when your filter order may be too low to design your filter accurately.</p> <pre>h = design(d,'kaiserwin',designoption,value,designoption,... value,...)</pre> returns a filter where you specify design options as input arguments and the design process uses the Kaiser window technique.
	<p>To determine the available design options, use <code>designopts</code> with the specification object and the design method as input arguments as shown.</p> <pre>designopts(d,'method')</pre>
	<p>For complete help about using <code>kaiserwin</code>, refer to the command line help system. For example, to get specific information about using <code>kaiserwin</code> with <code>d</code>, the specification object, enter the following at the MATLAB prompt.</p> <pre>help(d,'kaiserwin')</pre>
<b>Examples</b>	<p>This example designs a direct form FIR filter from a halfband filter specification object.</p> <pre>d=fdesign.halfband('n,tw',200,0.01) hd= design(d,'kaiserwin','filterstructure','dffir')</pre>

# kaiserwin

---

In this example, `kaiserwin` uses an interpolating filter specification object:

```
d=fdesign.interpolator(4,'lowpass');  
h = design(d,'kaiserwin');
```

**Purpose** Fractional delay filter from `fdesign.fracdelay` specification object

**Syntax** `Hd = design(d, 'lagrange')`  
`hd = design(d, 'lagrange', FilterStructure, structure)`

**Description** `Hd = design(d, 'lagrange')` designs a fractional delay filter using the Lagrange method based on the specifications in `d`.

`hd = design(d, 'lagrange', FilterStructure, structure)` specifies the Lagrange design method and the `structure` filter structure for `hd`. The sole valid filter structure string for `structure` is `fd`, describing the fractional delay structure.

**Examples** This example uses a fractional delay of 0.30 samples. The `help` and `designopts` commands provide the details about designing fractional delay filters.

```
d=fdesign.fracdelay(.30)
```

```
d =
```

```
           Response: 'Fractional Delay'  
Specification: 'N'  
Description: {'Filter Order'}  
           FracDelay: 0.3  
NormalizedFrequency: true  
           FilterOrder: 3
```

```
designmethods(d)
```

```
Design Methods for class fdesign.fracdelay (N):
```

```
lagrange
```

```
help(d, 'lagrange')
```

DESIGN Design a Lagrange fractional delay filter.  
HD = DESIGN(D, 'lagrange') designs a Lagrange filter specified by the FDESIGN object D.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the structure STRUCTURE. STRUCTURE is 'fd' by default and can be any of the following:

'fd'

```
% Example #1 - Design a linear Lagrange fractional
% delay filter of 0.2 samples.
h = fdesign.fracdelay(0.2,'N',2);
Hd = design(h, 'lagrange', 'FilterStructure', 'fd')
```

```
% Example #2 - Design a cubic Lagrange fractional
% delay filter.
Fs = 8000;          % Sampling frequency of 8kHz
fdelay = 50e-6;    % Fractional delay of 50 microseconds.
h = fdesign.fracdelay(fdelay,'N',3,Fs);
Hd = design(h, 'lagrange', 'FilterStructure', 'fd');
```

This example designs a linear Lagrange fractional delay filter where you set the delay to 0.2 seconds and the filter order N to 2.

```
h = fdesign.fracdelay(0.2,'N',2);
hd = design(h,'lagrange','FilterStructure','fd')
```

Design a cubic Lagrange fractional delay filter with filter order equal to 3..

```
Fs = 8000;          % Sampling frequency of 8 kHz.
fdelay = 50e-6;    % Fractional delay of 50 microseconds.
h = fdesign.fracdelay(fdelay,'N',3,Fs);
hd = design(h,'lagrange','FilterStructure','fd');
```

# liblinks

---

**Purpose** Check model for blocks from specific DSP System Toolbox libraries

**Syntax**

```
liblinks(lib)
liblinks(lib,sys)
liblinks(lib,sys,c)
```

**Description** `liblinks(lib)` returns a cell array of strings that lists the blocks in the current model that are linked to the specified libraries. The input `lib` provides a cell array of strings with the library names. Use the library name visible in the title bar when you open a library model.

`liblinks(lib,sys)` acts on the named model `sys`.

`liblinks(lib,sys,c)` changes the foreground color of the returned blocks to the color `c`. Possible values of `c` are 'blue', 'green', 'red', 'cyan', 'magenta', 'yellow', or 'black'.

**Examples** Check for blocks from the Sources library in the specified model:

```
rlsdemo
liblinks('dspsrcs4',gcs)
```

**See Also** `dsp_links`

**Purpose** Response of single-rate, fixed-point IIR filter

**Syntax**  
`report = limitcycle(hd)`  
`report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)`

**Description** `report = limitcycle(hd)` returns the structure `report` that contains information about how filter `hd` responds to a zero-valued input vector. By default, the input vector has length equal to twice the impulse response length of the filter.

`limitcycle` returns a structure whose elements contain the details about the limit cycle testing. As shown in this table, the `report` includes the following details.

Output Object Property	Description
LimitCycleType	Contains one of the following results: <ul style="list-style-type: none"> <li>• <b>Granular</b> — indicates that a granular overflow occurred.</li> <li>• <b>Overflow</b> — indicates that an overflow limit cycle occurred.</li> <li>• <b>None</b> — indicates that the test did not find any limit cycles.</li> </ul>
Zi	Contains the initial condition value(s) that caused the detected limit cycle to occur.
Output	Contains the output of the filter in the steady state.
Trial	Returns the number of the Monte Carlo trial on which the limit cycle testing stopped. For example, <code>Trial = 10</code> indicates that testing stopped on the tenth Monte Carlo trial.

# limitcycle

---

Using an input vector longer than the filter impulse response ensures that the filter is in steady-state operation during the limit cycle testing. `limitcycle` ignores output that occurs before the filter reaches the steady state. For example, if the filter impulse length is 500 samples, `limitcycle` ignores the filter output from the first 500 input samples.

To perform limit cycle testing on your IIR filter, you must set the filter Arithmetic property to `fixed` and `hd` must be a fixed-point IIR filter of one of the following forms:

- `df1` — direct-form I
- `df1t` — direct-form I transposed
- `df1sos` — direct-form I with second-order sections
- `df1tsos` — direct-form I transposed with second-order sections
- `df2` — direct-form II
- `df2t` — direct-form II transposed
- `df2sos` — direct-form II with second-order sections
- `df2tsos` — direct-form II transposed with second-order sections

When you use `limitcycle` without optional input arguments, the default settings are

- Run 20 Monte Carlo trials
- Use an input vector twice the length of the filter impulse response
- Stop testing if the simulation process encounters either a granular or overflow limit cycle

To determine the length of the filter impulse response, use `impzlength`:

```
impzlength(hd)
```

During limit cycle testing, if the simulation runs reveal both overflow and granular limit cycles, the overflow limit cycle takes precedence and is the limit cycle that appears in the report.

Each time you run `limitcycle`, it uses a different sequence of random initial conditions, so the results can differ from run to run.

Each Monte Carlo trial uses a new set of randomly determined initial states for the filter. Test processing stops when `limitcycle` detects a zero-input limit cycle in filter `hd`. `report = limitcycle(hd, ntrials, inputlengthfactor, stopcriterion)` lets you set the following optional input arguments:

- `ntrials` — Number of Monte Carlo trials (default is 20).
- `inputlengthfactor` — integer factor used to calculate the length of the input vector. The length of the input vector comes from  $(\text{impzlength}(\text{hd}) * \text{inputlengthfactor})$ , where `inputlengthfactor = 2` is the default value.
- `stopcriterion` — the criterion for stopping the Monte Carlo trial processing. `stopcriterion` can be set to **either** (the default), **granular**, **overflow**. This table describes the results of each stop criterion.

<b>stopcriterion Setting</b>	<b>Description</b>
<b>either</b>	Stop the Monte Carlo trials when <code>limitcycle</code> detects either a granular or overflow limit cycle.
<b>granular</b>	Stop the Monte Carlo trials when <code>limitcycle</code> detects a granular limit cycle.
<b>overflow</b>	Stop the Monte Carlo trials when <code>limitcycle</code> detects an overflow limit cycle.

---

**Note** An important feature is that if you specify a specific limit cycle stop criterion, such as `overflow`, the Monte Carlo trials do not stop when testing encounters a granular limit cycle. You receive a warning that no `overflow` limit cycle occurred, but consider that a `granular` limit cycle might have occurred.

---

## Examples

In this example, there is a region of initial conditions in which no limit cycles occur and a region where they do. If no limit cycles are detected before the Monte Carlo trials are over, the state sequence converges to zero. When a limit cycle is found, the states do not end at zero. Each time you run this example, it uses a different sequence of random initial conditions, so the plot you get can differ from the one displayed in the following figure.

```
s = [1 0 0 1 0.9606 0.9849];
hd = dfilt.df2sos(s);
hd.arithmetic = 'fixed';
greport = limitcycle(hd,20,2,'granular')
oreport = limitcycle(hd,20,2,'overflow')
figure,
subplot(211),plot(greport.Output(1:20)), title('Granular Limit Cycle');
subplot(212),plot(oreport.Output(1:20)), title('Overflow Limit Cycle');
```

```
greport =

  LimitCycle: 'granular'
           Zi: [2x1 double]
           Output: [1303x1 embedded.fi]
           Trial: 1
```

```
oreport =

  LimitCycle: 'overflow'
           Zi: [2x1 double]
           Output: [1303x1 embedded.fi]
```

Trial: 2

The plots shown in this figure present both limit cycle types — the first displays the small amplitude granular limit cycle, the second the larger amplitude overflow limit cycle.

As you see from the plots, and as is generally true, overflow limit cycles are much greater magnitude than granular limit cycles. This is why `limitcycle` favors overflow limit cycle detection and reporting.

# maxflat

---

## Purpose

Maxflat FIR filter

## Syntax

```
hd = design(d, 'maxflat')  
hd = design(d, 'maxflat', 'FilterStructure', structure)
```

## Description

`hd = design(d, 'maxflat')` designs a maximally flat filter, `hd`, from a filter specification object, `d`.

`hd = design(d, 'maxflat', 'FilterStructure', structure)` designs a maximally flat filter where `structure` is one of the following:

- 'dffir', a discrete-time, direct-form FIR filter (the default value)
- 'dffirt', a discrete-time, direct-form FIR transposed filter
- 'dfsymfir', a discrete-time, direct-form symmetric FIR filter
- 'fftfir', a discrete-time, overlap-add, FIR filter

## Examples

Example 1: Design a lowpass filter with a maximally flat FIR structure.

```
d = fdesign.lowpass('N,F3dB', 50, 0.3);  
Hd = design(d, 'maxflat');
```

Example 2: Design a highpass filter with a maximally flat overlap-add FIR structure.

```
d = fdesign.highpass('N,F3dB', 50, 0.7);  
Hd=design(d, 'maxflat', 'FilterStructure', 'fftfir');
```

**Purpose** Maximize stopband attenuation of fixed-point filter

**Syntax**  
`Hq = maximizestopband(Hd,Wordlength)`  
`Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)`

**Description** `Hq = maximizestopband(Hd,Wordlength)` quantizes the single-stage or multistage FIR filter `Hd` and returns the fixed-point filter `Hq` with `wordlength wordlength` that maximizes the stopband attenuation. `Hd` must be generated using `fdesign` and `design`. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same `wordlength` is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `maximizestopband` uses a stochastic noise-shaping procedure by default to minimize the `wordlength`. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

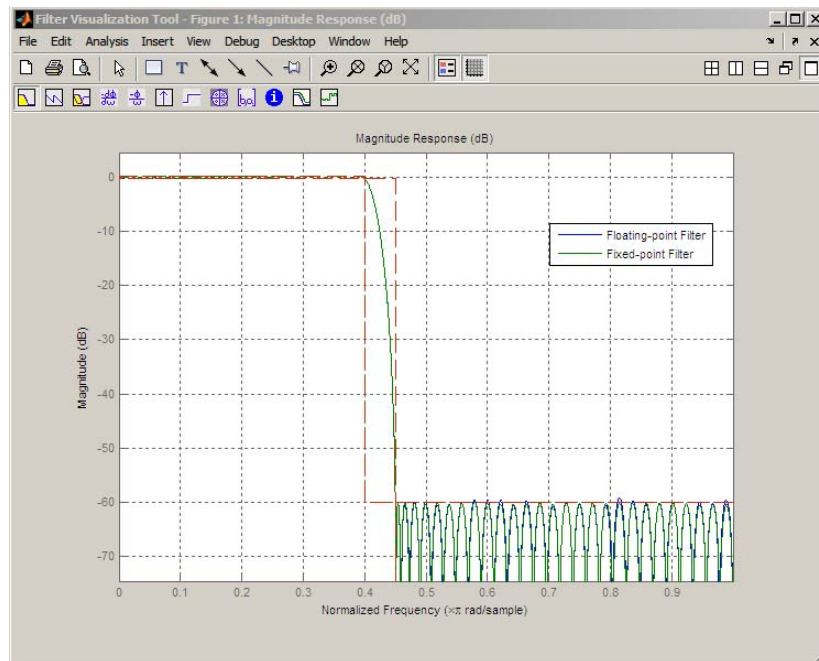

`Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use in the maximization. `Hq` is the fixed-point filter with the largest stopband attenuation among the trials. The number of Monte Carlo trials `N` defaults to 1.

You must have the Fixed-Point Designer software installed to use this function.

**Examples** Maximize stopband attenuation for 16-bit fixed-point filter.

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',0.4,0.45,0.5,60);  
Hd = design(Hf,'equiripple');  
WL = 16; % use 16 bits to represent coefficients  
Hq = maximizestopband(Hd,WL);  
% Compare stopband attenuation  
md = measure(Hd);  
mq = measure(Hq);  
hfvf=fvtool(Hd,Hq,'showreference','off');  
legend(hfvf,'Floating-point Filter','Fixed-point Filter');
```

# maximizestopband

## Tutorials

- “Fixed-Point Data Types”

**Purpose** Maximum step size for adaptive filter convergence

**Syntax** `mumax = maxstep(ha,x)`  
`[mumax,mumaxmse] = maxstep(ha,x)`

**Description** `mumax = maxstep(ha,x)` predicts a bound on the step size to provide convergence of the mean values of the adaptive filter coefficients. The columns of the matrix `x` contain individual input signal sequences. The signal set is assumed to have zero mean or nearly so.

`[mumax,mumaxmse] = maxstep(ha,x)` predicts a bound on the adaptive filter step size to provide convergence of the LMS adaptive filter coefficients in the mean-square sense. `maxstep` issues a warning when `ha.stepsize` is outside of the range  $0 < \text{ha.stepsize} < \text{mumaxmse}/2$ .

`maxstep` is available for the following adaptive filter objects:

- `adaptfilt.blms`
- `adaptfilt.blmsfft`
- `adaptfilt.lms`
- `adaptfilt.nlms` (uses a different syntax. Refer to the text below.)
- `adaptfilt.se`

---

**Note** With `adaptfilt.nlms` filter objects, `maxstep` uses the following slightly different syntax:

`mumax = maxstep(ha)`  
`[mumax,mumaxmse] = maxstep(ha)`

The maximum step size for convergence is fully defined by the filter object `ha`. Matrix `x` is not necessary. If you include an `x` input matrix, MATLAB returns an error.

---

## Examples

Analyze and simulate a 32-coefficient (31st-order) LMS adaptive filter object. To demonstrate the adaptation process, run 2000 iterations and 50 trials.

```
% Specify [numiterations,numexamples] = size(x);
x = zeros(2000,50);
d = x;
obj = fdesign.lowpass('n,fc',31,0.5);
hd = design(obj,'window'); % FIR filter to identified.
coef = cell2mat(hd.coefficients); % Convert cell array to matrix.

for k=1:size(x,2); % Create input and desired response signal
    % matrices.
% Set the (k)th input to the filter.
    x(:,k) = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x,1),1)));
    n = 0.1*randn(size(x,1),1); % (k)th observation noise signal.
    d(:,k) = filter(coef,1,x(:,k))+n; % (k)th desired signal end.
end
mu = 0.1; % LMS step size.
ha = adaptfilt.lms(32,mu);
[mumax,mumaxmse] = maxstep(ha,x);
```

```
Warning: Step size is not in the range 0 < mu < mumaxmse/2:
Erratic behavior might result.
```

```
mumax
mumax =
    0.0623
mumaxmse
mumaxmse =
    0.0530
```

**See Also**      msepred | msesim | filter

# measure

---

**Purpose** Measure filter magnitude response

**Syntax**  
`measure(hd)`  
`measure(hm)`  
`measure(hs)`  
`measure(hs)`

**Description** `measure(hd)` returns measured values for specific points in the magnitude response curve for filter object `hd`. When you use a design object `d` to create a filter (by using `fdesign.type` to create `d`), you specify one or more values that define your desired filter response. `measure(hd)` tests the filter to determine the actual values in the magnitude response of the filter, such as the stopband attenuation or the passband ripple. Comparing the results returned by `measure` to the specifications you provided in the design object helps you assess whether the filter meets your design criteria.

---

**Note** To use `measure`, `hd`, `hm`, or `hs` must result from using a filter design method with a filter specifications object. `measure` works with multirate filters and discrete-time filters. The function does not support adaptive filters because you cannot use `fdesign.type` to construct adaptive filter specifications objects.

---

`measure(hd)` returns measurements for the discrete-time filter `hd`. The function determines the relevant specifications based on the response type of the design object you use to create the filter. For example, for single-rate lowpass filters made from design objects, `measure(hd)` returns the following filter specifications.

Lowpass Filter Specification	Description
Sampling Frequency	Filter sampling frequency.
Passband Edge	Location of the edge of the passband as it enters transition.

<b>Lowpass Filter Specification</b>	<b>Description</b>
3-dB Point	Location of the $-3$ dB point on the response curve.
6-dB Point	Location of the $-6$ dB point on the response curve.
Stopband Edge	Location of the edge of the transition band as it enters the stopband.
Passband Ripple	Ripple in the passband.
Stopband Atten.	Attenuation in the stopband.
Transition Width	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between $F_{pass}$ and $F_{stop}$ .

In contrast, when you use a bandstop design object, `measure(hd)` returns these specifications for the resulting bandstop filter.

<b>Bandstop Filter Specification</b>	<b>Description</b>
Sampling Frequency	Filter sampling frequency.
First Passband Edge	Location of the edge of the first passband.
First 3-dB Point	Location of the edge of the $-3$ dB point in the first transition band.
First 6-dB Point	Location of the edge of the $-6$ dB point in the first transition band.
First Stopband Edge	Location of the start of the stopband.
Second Stopband Edge	Location of the end of the stopband.

## measure

---

<b>Bandstop Filter Specification</b>	<b>Description</b>
Second 6-dB Point	Location of the edge of the $-6$ dB point in the second transition band.
Second 3-dB Point	Location of the edge of the $-3$ dB point in the second transition band.
Second Passband Edge	Location of the start of the second passband.
First Passband Ripple	Ripple in the first passband.
Stopband Atten.	Attenuation in the stopband.
Second Passband Edge	Ripple in the second passband.
First Transition Width	Width of the first transition region. Measured between the $-3$ and $-6$ dB points.
Second Transition Width	Width of the second transition region. Measured between the $-6$ and $-3$ dB points.

`measure(hm)` returns measurements for the multirate filter `hm`. The set of filter specifications that `measure` returns for multirate filters might be different from those for discrete-time filters.

The set of response measurements that `measure` returns depends on the response you use to design the filter. For example, when `hm` is an FIR lowpass interpolator (whose response is lowpass), `measure(hm)` returns the following set of measurements.

<b>Interpolator Filter Specification</b>	<b>Description</b>
First Passband Edge	Location of the edge of the passband as it enters transition.
3-dB Point	Location of the $-3$ dB point on the response curve.

Interpolator Filter Specification	Description
6-dB Point	Location of the $-6$ dB point on the response curve.
Stopband Edge	Location of the edge of the transition band as it enters the stopband.
Passband Ripple	Ripple in the passband.
Stopband Atten.	Attenuation in the stopband.
Transition Width	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between $F_{pass}$ and $F_{stop}$ .

For reference, the specification object `d` created the interpolator specifications shown in the preceding table:

```
d=fdesign.interpolator(6,'lowpass')
```

```
d =
```

```

    MultirateType: 'Interpolator'
  InterpolationFactor: 6
           Response: 'Lowpass'
    Specification: 'Fp,Fst,Ap,Ast'
           Description: {4x1 cell}
  NormalizedFrequency: true
                Fpass: 0.133333333333333
                Fstop: 0.166666666666667
                Apass: 1
                Astop: 60

```

`measure(hs)` returns measurements for the filter System object `hs`. You must construct `hs` using `design` with the optional name-value pair argument `'SystemObject',true`.

# measure

---

`measure(hs)` returns measurements for the filter System object `hs` with additional options specified by one or more `Name, Value` pair arguments.

## Tips

For designs that do not specify some of the frequency constraints, the function may not be able to determine corresponding magnitude measurements. In these cases, a constraint can be passed in to `measure` to determine such measurements. For example:

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
H = design(f,'cheby2','SystemObject',true);
measure(H)
```

returns values of `Unknown` for the passband edge, passband ripple, and transition width measurements, but

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
H = design(f,'cheby2','SystemObject',true);
measure(H,'Fpass',0.4)
```

provides measurements for all returned values.

## Input Arguments

### **hd**

Discrete-time `dfilt` filter object.

### **hm**

Multirate `mfilt` filter object.

### **hs**

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`

- dsp.CICInterpolator
- dsp.FIRDecimator
- dsp.CICDecimator
- dsp.FIRRateConverter

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

### 'Arithmetic'

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the **CoefficientDataType** property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point

## measure

System Object State	Coefficient Data Type	Rule
		analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

For the first example, create a lowpass filter and check whether the actual filter meets the specifications. For this case, use normalized frequency for  $F_s$ , the default setting.

```
d2=fdesign.lowpass('Fp,Fst,Ap,Ast',0.45,0.55,0.1,80)
```

```
d2 =
```

```
           Response: 'Lowpass'  
    Specification: 'Fp,Fst,Ap,Ast'  
      Description: {4x1 cell}  
NormalizedFrequency: true  
           Fpass: 0.45  
           Fstop: 0.55  
           Apass: 0.1  
           Astop: 80
```

```
designmethods(d2)
```

```
Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```
butter  
cheby1  
cheby2  
ellip  
equiripple  
ifir  
kaiserwin  
multistage
```

```
hd2=design(d2) % Use the default equiripple design method.
```

```
hd2 =
```

```
FilterStructure: 'Direct-Form FIR'
```

## measure

---

```
Arithmetic: 'double'  
  Numerator: [1x68 double]  
PersistentMemory: false
```

```
measure(hd2)
```

```
ans =
```

```
Sampling Frequency : N/A (normalized frequency)  
Passband Edge      : 0.45  
3-dB Point         : 0.47794  
6-dB Point         : 0.48909  
Stopband Edge      : 0.55  
Passband Ripple    : 0.09615 dB  
Stopband Atten.   : 80.2907 dB  
Transition Width   : 0.1
```

Stopband Edge, Passband Edge, Passband Ripple, and Stopband Atten. all meet the specifications.

Now, using  $F_s$  in linear frequency, create a bandpass filter, and measure the magnitude response characteristics.

```
d=fdesign.bandpass
```

```
d =
```

```
Response: 'Bandpass'  
Specification: 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'  
Description: {7x1 cell}  
NormalizedFrequency: true  
  Fstop1: 0.35  
  Fpass1: 0.45  
  Fpass2: 0.55  
  Fstop2: 0.65  
  Astop1: 60  
  Apass: 1  
  Astop2: 60
```

```
normalizefreq(d,false,1.5e3) % Convert to linear freq.
```

```
hd=design(d,'cheby2');
```

```
measure(hd)
```

```
ans =
```

```
Sampling Frequency      : 1.5 kHz  
First Stopband Edge    : 0.2625 kHz  
First 6-dB Point       : 0.31996 kHz  
First 3-dB Point       : 0.32497 kHz  
First Passband Edge    : 0.3375 kHz  
Second Passband Edge   : 0.4125 kHz  
Second 3-dB Point      : 0.42503 kHz  
Second 6-dB Point      : 0.43004 kHz  
Second Stopband Edge   : 0.4875 kHz  
First Stopband Atten.  : 60 dB  
Passband Ripple        : 0.17985 dB  
Second Stopband Atten. : 60 dB  
First Transition Width  : 0.075 kHz  
Second Transition Width : 0.075 kHz
```

`measure(hd)` returns the actual response values, in the units you chose. In this example, all frequencies appear in kilohertz because the sampling frequency is in kilohertz.

# mfilt

---

**Purpose** Multirate filter

**Syntax** `hm = mfilt.structure(input1,input2,...)`

**Description** `hm = mfilt.structure(input1,input2,...)` returns the object `hm` of type *structure*. As with `dfilt` and `adaptfilt` objects, you must include the *structure* string to construct a multirate filter object. You can, however, construct a default multirate filter object of a given structure by not including input arguments in your calling syntax.

Multirate filters include decimators and interpolators, and fractional decimators and fractional interpolators where the resulting interpolation or decimation factor is not an integer.

## Structures

Each of the following multirate filter structures has a reference page of its own.

<b>Filter Structure String</b>	<b>Description of Resulting Multirate Filter</b>	<b>Coefficient Mapping Support in <code>realizemd1</code> and <code>block</code></b>
<code>mfilt.cascade</code>	Cascade multirate filters to form another filter	Supported
<code>mfilt.cicdecim</code>	Cascaded integrator-comb decimator	Not supported
<code>mfilt.cicinterp</code>	Cascaded integrator-comb interpolator	Not supported
<code>mfilt.farrowsrc</code>	Multirate Farrow filter	Supported.

<b>Filter Structure String</b>	<b>Description of Resulting Multirate Filter</b>	<b>Coefficient Mapping Support in <code>realizemdl</code> and <code>block</code></b>
<code>mfilt.fftfirinterp</code>	Overlap-add FIR polyphase interpolator	Not supported
<code>mfilt.firdecim</code>	Direct-form FIR polyphase decimator	Supported
<code>mfilt.firinterp</code>	Direct-form FIR polyphase interpolator	Supported
<code>mfilt.firsrc</code>	Direct-form FIR polyphase sample rate converter	Supported
<code>mfilt.firtdecim</code>	Direct-form transposed FIR polyphase decimator	Supported
<code>mfilt.holdinterp</code>	FIR hold interpolator	Not supported
<code>mfilt.iirdecim</code>	IIR decimator	Supported
<code>mfilt.iirinterp</code>	IIR interpolator	Supported
<code>mfilt.linearinterp</code>	FIR Linear interpolator	Supported
<code>mfilt.iirwdfdecim</code>	IIR wave digital filter decimator	Supported
<code>mfilt.iirwdfinterp</code>	IIR wave digital filter interpolator	Supported

### Copying `mfilt` Objects

To create a copy of an `mfilt` object, use the `copy` method.

```
h2 = copy(hd)
```

---

**Note** The syntax `hd2 = hd` copies only the object handle. It does not create a new object. `hd2` and `hd` are not independent. If you change the property value for one of the two, such as `hd2`, you are changing the property for both.

---

## Examples

Decimation by a factor of two. Convert input sampled at 48 kHz to 24 kHz:

```
Fs = 4.8e4;
t = 0:1/Fs:1-(1/Fs);
x = cos(2*pi*4000*t);
Hm=mfilt.firdecim(2);
% Note cutoff frequency of 1/2 normalized frequency
fvtool(Hm);
% Note the group delay of 34 samples
fvtool(Hm,'analysis','grpdelay');
y = filter(Hm,x);
% Note delay in output is consistent with 36/2
stem(y(1:48),'markerfacecolor',[0 0 1]);
```

Using existing coefficients to decimate a signal by a factor of two:

```
M = 2; % Decimation factor
b = firhalfband('minorder',.45,0.0001);
Hm = mfilt.firdecim(M,b);
% Decimate a signal which consists of the sum of 2 sinusoids.
N = 160;
x = sin(2*pi*.05*[0:N-1]+pi/3)+cos(2*pi*.03*[0:N-1]+pi/3);
y = filter(Hm,x);
```

---

**Note** Multirate filters can also have complex coefficients. For example, you can specify complex coefficients in the argument `num` passed to the filter structure. This works for all multirate filter structures.

```
m = 2;  
num = [0.5 0.5+1j*0.2];  
Hm = mfilt.firdecim(m, num);  
y = filter(Hm, [1:10]);
```

---

**See Also**

[mfilt.firinterp](#) | [mfilt.firsrc](#) | [mfilt.firtdecim](#)

# mfilt.cascade

---

**Purpose** Cascade filter objects

**Syntax** `hm = cascade(hm1, hm2, ..., hmn)`

**Description** `hm = cascade(hm1, hm2, ..., hmn)` creates filter object `hm` by cascading (connecting in series) the individual filter objects `hm1`, `hm2`, and so on to `hmn`.

In block diagram form, the cascade looks like this, with `x` as the input to the filter `hm` and `y` the output from the cascade filter `hm`:

`mfilt.cascade` accepts any combination of `mfilt` and `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

**Examples** Create a variety of `mfilt` objects and cascade them together.

```
hm(1) = mfilt.firdecim(12);  
hm(2) = mfilt.firdecim(4);  
h1 = mfilt.cascade(hm(1),hm(2));  
hm(3) = mfilt.firinterp(4);  
hm(4) = mfilt.firinterp(12);  
h2 = mfilt.cascade(hm(3),hm(4));  
% Cascade h1 and h2 together  
h3 = mfilt.cascade(h1,h2,9600);
```

**See Also** `dfilt.cascade`

**Purpose** Fixed-point CIC decimator

**Syntax** `hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)`

**Description** `hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)` returns a cascaded integrator-comb (CIC) decimation filter object.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

<b>Input Arguments</b>	<b>Description</b>
<code>r</code>	Decimation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. <code>r</code> must be an integer value greater than or equal to 1. The default value is 2.
<code>m</code>	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing <code>m</code> increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. <code>m</code> must be an integer value greater than or equal to 1. The default value is 1.
<code>n</code>	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. 2 is the default value.
<code>iwl</code>	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.

Input Arguments	Description
owl	Word length of the output signal. It can be any positive integer number of bits. By default, owl is 16 bits.
wlps	<p>Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter wlps as a scalar or vector of length 2*n, where n is the number of sections. When wlps is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.</p> <p>When you elect to specify wlps as an input argument, the FilterInternals property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.</p>

## Constraints and Word Length Considerations

CIC decimators have the following constraint — the word lengths of the filter section must be monotonically decreasing. The word length of each filter section must be the same size as, or smaller than, the word length of the previous filter section.

The formula for  $B_{max}$ , the most significant bit at the filter output, is given in the Hogenauer paper in the References below.

$$B_{max} = (N \log_2 RM + B_{in} - 1)$$

where  $B_{in}$  is the number of bits of the input.

The cast operations shown in the diagram in “Algorithms” on page 4-1026 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints above, the constructor returns an error.

When you specify the word lengths correctly, the most significant bit  $B_{max}$  stays the same throughout the filter, while the word length of each section either decreases or stays the same. This can cause the fraction length to change throughout the filter as least significant bits are truncated to decrease the word length, as shown in “Algorithms” on page 4-1026.

**Properties of the Object**

Objects have properties that control the way the object behaves. This table lists all the properties for the filter, with a description of each.

<b>Name</b>	<b>Values</b>	<b>Default</b>	<b>Description</b>
Arithmetic	fixed	fixed	Reports the kind of arithmetic the filter uses. CIC decimators are always fixed-point filters.
DecimationFactor	Any positive integer	2	Amount to reduce the input sampling rate.
DifferentialDelay	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
FilterStructure	mfilt structure string	None	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt objects.
FilterInternals	FullPrecision, MinWordLengths, SpecifyPrecision, SpecifyWordLengths	FullPrecision	Set the usage mode for the filter. Refer to “Usage Modes” on page 4-1018 below for details.

# mfilt.cicdecim

Name	Values	Default	Description
InputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the input data to the filter.
InputOffset	Integers in the range $0 \leq \text{InputOffset} \leq r-1$	0	Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples that have been processed so far and $m$ is the decimation factor.  The <code>InputOffset</code> property applies only when you set the <code>PersistentMemory</code> property to <code>true</code> . See “ <code>InputOffset</code> ” on page 5-125 for more information.
InputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.

<b>Name</b>	<b>Values</b>	<b>Default</b>	<b>Description</b>
NumberOfSections	Any positive integer	2	Number of sections used in the decimator. Generally called n. Reflects either the number of decimator or comb sections, not the total number of sections in the filter.
OutputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.
OutputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.
PersistentMemory	false or true	false	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States

# mfilt.cicdecim

Name	Values	Default	Description
			that the filter does not change are not affected. When <code>PersistentMemory</code> is <code>false</code> , you cannot access the filter states. Setting <code>PersistentMemory</code> to <code>true</code> reveals the <code>States</code> property so you can modify the filter states.

Name	Values	Default	Description
<code>SectionWordLengths</code>	Any integer or a vector of length $2*n$ .	16	Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter <code>SectionWordLengths</code> as a scalar or vector of length $2*n$ , where $n$ is the number of sections. When <code>SectionWordLengths</code> is a scalar, the scalar value is applied to each filter section. When <code>SectionWordLengths</code> is a vector of values,

Name	Values	Default	Description
			<p>the values apply to the sections in order. The default is 16 for each section in the decimator. Available when <code>FilterInternals</code> is 'SpecifyWordLengths'.</p>
States	filtstates.cic object	m+1-by-n matrix of zeros, after you call function <code>int</code> .	<p>Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. <code>m</code> is the differential delay of the comb section and <code>n</code> is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when <code>PersistentMemory</code> is true. Refer to the <code>filtstates</code> object in Signal Processing Toolbox documentation for more general information about the <code>filtstates</code> object.</p>

## Usage Modes

There are four modes of usage for this which are set using the `FilterInternals` property

- `FullPrecision` — All word and fraction lengths set to  $B_{max} + 1$ , called  $B_{accum}$  by Fred Harris in [3]. Full Precision is the default setting.
- `MinWordLengths` — Automatically set the sections for minimum word lengths.
- `SpecifyWordLengths` — Specify the word lengths for each section.
- `SpecifyPrecision` — Specify precision by providing values for the word and fraction lengths for each section.

### Full Precision

In full precision mode, the word lengths of all sections and the output are set to  $B_{accum}$  as defined by

$$B_{accum} = \text{ceil}(N_{secs}(\text{Log}_2(D \times M)) + \text{InputWordLength})$$

where  $N_{secs}$  is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false  
  
InputWordLength: 16  
InputFracLength: 15  
  
FilterInternals: 'FullPrecision'
```

### Minimum Wordlengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than  $B_{accum}$ , roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [1]) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than  $B_{accum}$  as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from  $B_{accum}$  to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output wordlength for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'MinWordLengths'
```

```
OutputWordLength: 16
```

Specify word lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length  $2 \times (\text{NumberOfSections})$ , where each vector element represents the word length for a section. If you specify a scalar, such as  $B_{accum}$ , the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;  
hcic.FilterInternals='minwordlengths';  
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display for the SpecifyWordLengths mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'SpecifyWordLengths'
```

```
SectionWordLengths: [19 18 18 17]
```

OutputWordLength: 16

### Specify precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the SpecifyPrecision mode, you must enter a vector of length  $2*(\text{NumberOfSections})$  with elements that represent the word length for each section. When you enter a scalar such as  $B_{\text{accum}}$ , `mfilt.cicdecim` expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length  $2*(\text{NumberOfSections})$  with elements that represent the fraction length for each section as well. When you enter a scalar such as  $B_{\text{accum}}$ , `mfilt.cicdecim` applies scalar expansion as done for the word lengths.

Here is the SpecifyPrecision display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'SpecifyPrecision'
```

```
SectionWordLengths: [19 18 18 17]  
SectionFracLengths: [14 13 13 12]
```

```
OutputWordLength: 16  
OutputFracLength: 11
```

## About the States of the Filter

In the `states` property you find the states for both the integrator and comb portions of the filter. `states` is a matrix of dimensions  $m + 1$ -by- $n$ , with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix..

To review the states of a CIC filter, use `int` to assign the states to a variable in MATLAB. As an example, here are the states for a CIC decimator `hm` before and after filtering a data set.

```
x = fi(ones(1,10),true,16,0); % Fixed-point input data.
hm = mfilt.cicdecim(2,1,2,16,16,16);
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified.
y=filter(hm,x);
sts=int(hm.states)
```

STS is an integer matrix that `int` returns from the contents of the `filtstates.cic` object in `hm`.

## Design Considerations

When you design your CIC decimation filter, remember the following general points:

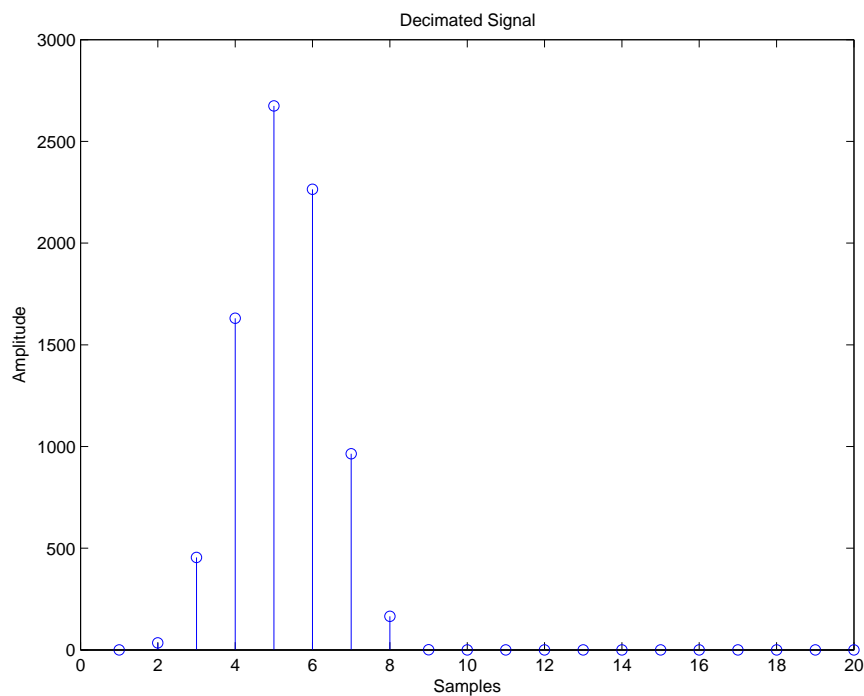

- The filter output spectrum has nulls at  $\omega = k * 2\pi/rm$  radians,  $k = 1,2,3\dots$
- Aliasing and imaging occur in the vicinity of the nulls.
- $n$ , the number of sections in the filter, determines the passband attenuation. Increasing  $n$  improves the filter ability to reject aliasing and imaging, but it also increases the droop (or rolloff) in the filter passband. Using an appropriate FIR filter in series after the CIC decimation filter can help you compensate for the induced droop.

- The DC gain for the filter is a function of the decimation factor. Raising the decimation factor increases the DC gain.

## Examples

This example applies a decimation factor  $r$  equal to 8 to a 160-point impulse signal. The signal output from the filter has  $160/r$ , or 20, points or samples. Choosing 10 bits for the word length represents a fairly common setting for analog to digital converters. The plot shown after the code presents the stem plot of the decimated signal, with 20 samples remaining after decimation:

```
m = 2; % Differential delays in the filter.
n = 4; % Filter sections
r = 8; % Decimation factor
x = int16(zeros(160,1)); x(1) = 1; % Create a 160-point
                                   % impulse signal.
hm = mfilt.cicdecim(r,m,n); % Expects 16-bit input
                              % by default.
y = filter(hm,x);
stem(double(y)); % Plot output as a stem plot.
xlabel('Samples'); ylabel('Amplitude');
title('Decimated Signal');
```

The next example demonstrates one way to compute the filter frequency response, using a 4-section decimation filter with the decimation factor set to 7:

```
hm = mfilt.cicdecim(7,1,4);  
fvtool(hm)
```

FVTool provides ways for you to change the title and x labels to match the figure shown. Here's the frequency response plot for the filter. For details about the transfer function used to produce the frequency response, refer to [1] in the References section.

This final example demonstrates the decimator for converting from 44.1 kHz audio to 22.05 kHz — decimation by two. To overlay the before and after signals, scale the output and plot the signals on a stem plot.

```
r = 2; % Decimation factor.
hm = mfilt.cicdecim(r); % Use default NumberOfSections &
% DifferentialDelay property values.
fs = 44.1e3; % Original sampling frequency: 44.1kHz.
n = 0:10239; % 10240 samples, 0.232 second long signal.
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay the stem plots.
x = double(x);
y = double(y_fi);
```

```
y = y/max(abs(y));  
stem(n(1:44)/fs,x(2:45)); hold on; % Plot original signal  
% sampled at 44.1kHz.  
stem(n(1:22)/(fs/r),y(3:24),'r','filled'); % Plot decimated  
% signal (22.05kHz)  
% in red.  
xlabel('Time (seconds)');ylabel('Signal Value');
```

## Algorithms

To show how the CIC decimation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC decimation filter ( $n = 2$ ).  $f_s$  is the high sampling rate, the input to the decimation process.

For details about the bits that are removed in the Comb section, refer to [1] in References.

mfilt.cicdecim calculates the fraction length at each section of the decimator to avoid overflows at the output of the filter.

mfilt | mfilt.cicinterp

# mfilt.cicinterp

---

**Purpose** Fixed-point CIC interpolator

**Syntax**  
`hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)`  
`hm = mfilt.cicinterp`  
`hm = mfilt.cicinterp(R,...)`

**Description** `hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)` constructs a cascaded integrator-comb (CIC) interpolation filter object that uses fixed-point arithmetic.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

Input Arguments	Description
R	Interpolation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. R must be an integer value greater than or equal to 1. The default value is 2.
M	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing M increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. M must be an integer value greater than or equal to 1. The default value is 1.
N	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. By default, the filter has two sections.

Input Arguments	Description
IWL	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.
OWL	Word length of the output signal. It can be any positive integer number of bits. By default, OWL is 16 bits.
WLPS	<p>Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter WLPS as a scalar or vector of length 2*N, where N is the number of sections. When WLPS is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the integrator.</p> <p>When you elect to specify <code>wlps</code> as an input argument, the <code>FilterInternals</code> property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.</p>

`hm = mfilt.cicinterp` constructs the CIC interpolator using the default values for the optional input arguments.

`hm = mfilt.cicinterp(R, ...)` constructs the CIC interpolator applying the values you provide for `R` and any other values you specify as input arguments.

### Constraints and Conversions

In Hogenauer [1], the author describes the constraints on CIC interpolator filters. `mfilt.cicinterp` enforces a constraint—the word lengths of the filter sections must be non-decreasing. That is, the word length of each filter section must be the same size as, or greater than, the word length of the previous filter section.

The formula for  $W_j$ , the minimum register width, is derived in [1]. The formula for  $W_j$  is given by

$$W_j = \text{ceil}(B_{in} + \log_2 G_j)$$

where  $G_j$ , the maximum register growth up to the  $j$ th section, is given by

$$G_j = \begin{cases} 2^j, & j = 1, 2, \dots, N \\ \frac{2^{2N-j}(RM)^{j-N}}{R}, & j = N + 1, \dots, 2N \end{cases}$$

When the differential delay,  $M$ , is 1, there is also a special condition for the register width of the last comb,  $W_N$ , that is given by

$$W_N = B_{in} + N - 1 \text{ if } M = 1$$

The conversions denoted by the cast blocks in the integrator diagrams in “Algorithms” on page 4-1038 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints described in this section, `mfilt.cicinterp` returns an error.

The fraction lengths and scalings of the filter sections do not change. At each section the word length is either staying the same or increasing. The signal scaling can change at the output after the final filter section if you choose the output word length to be less than the word length of the final filter section.

**Properties of the Object**

The following table lists the properties for the filter with a description of each.

<b>Name</b>	<b>Values</b>	<b>Default</b>	<b>Description</b>
Arithmetic	fixed	fixed	Reports the kind of arithmetic the filter uses. CIC interpolators are always fixed-point filters.
InterpolationFactor	Any positive integer	2	Amount to increase the input sampling rate.
DifferentialDelay	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
FilterStructure	mfilt structure string	None	Reports the type of filter object, such as a interpolator or fractional integrator. You cannot set this property — it is always read only and results from your choice of mfilt objects.
FilterInternals	FullPrecision, MinWordLengths, SpecifyWordLengths, SpecifyPrecision	FullPrecision	Set the usage mode for the filter. Refer to “Usage Modes” on page 4-1034 below for details.
InputFracLength	Any positive integer	16	The number of bits applied as the fraction length to interpret the input data to the filter.

## mfilt.cicinterp

Name	Values	Default	Description
InputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.
NumberOfSections	Any positive integer	2	Number of sections used in the interpolator. Generally called n. Reflects either the number of interpolator or comb sections, not the total number of sections in the filter.
OutputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.
OutputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.
PersistentMemory	false or true	false	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing.

Name	Values	Default	Description
			States that the filter does not change are not affected. When <code>PersistentMemory</code> is <code>false</code> , you cannot access the filter states. Setting <code>PersistentMemory</code> to <code>true</code> reveals the <code>States</code> property so you can modify the filter states.
SectionWordLengths	Any integer or a vector of length $2^N$ , where $N$ is a positive integer.  This property only applies when the <code>FilterInternals</code> is <code>SpecifyWordLengths</code> .	16	Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter <code>SectionWordLengths</code> as a scalar or vector of length $2*n$ , where $n$ is the number of sections. When <code>SectionWordLengths</code> is a scalar, the scalar value is applied to each filter section. When <code>SectionWordLengths</code> is a vector of values, the values apply to the sections in order. The default is 16 for each section in the interpolator. Available

# mfilt.cicinterp

Name	Values	Default	Description
			when <code>FilterInternals</code> is 'SpecifyWordLengths'.
States	<code>filtstates.cic</code> object	$m+1$ -by- $n$ matrix of zeros, after you call function <code>int</code> .	Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. $m$ is the differential delay of the comb section and $n$ is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when <code>PersistentMemory</code> is true. Refer to the <code>filtstates</code> object in Signal Processing Toolbox documentation for more general information about the <code>filtstates</code> object.

## Usage Modes

There are usage modes which are set using the `FilterInternals` property:

- **FullPrecision** — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths are set to:

$$\text{wordlength} = \text{ceil}(\log_2((RM)^N / R)) + I,$$

where  $R$  is the interpolation factor,  $M$  is the differential delay,  $N$  is the number of filter sections, and  $I$  denotes the input word length.

- **MinWordLengths** — In this mode, you specify the word length of the filter output in the `OutputWordLength` property. The word lengths of the filter sections are automatically set in the same way as in the `FullPrecision` mode. The section fraction lengths are set to the input fraction length. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.
- **SpecifyWordLengths** — In this mode, you specify the word lengths of the filter sections and output in the `SectionWordLengths` and `OutputWordLength` properties. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.
- **SpecifyPrecision** — In this mode, you specify the word and fraction lengths of the filter sections and output in the `SectionWordLengths`, `SectionFracLengths`, `OutputWordLength`, and `OutputFracLength` properties.

### About the States of the Filter

In the `states` property you find the states for both the integrator and comb portions of the filter. `states` is a matrix of dimensions  $m+1$ -by- $n$ , with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

To review the states of a CIC filter, use the `int` method to assign the states. As an example, here are the states for a CIC interpolator `hm` before and after filtering data:

```
x = fi(cos(pi/4*[0:99]),true,16,0); % Fixed-point input data
```

```
hm = mfilt.cicinterp(2,1,2,16,16,16);
% get initial states-all zero
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified
y=filter(hm,x);
sts=int(hm.states)
%sts =
%
%      -1      -1
%      -1      -1
```

## Design Considerations

When you design your CIC interpolation filter, remember the following general points:

- The filter output spectrum has nulls at  $\omega = k * 2\pi/rm$  radians,  $k = 1,2,3,\dots$
- Aliasing and imaging occur in the vicinity of the nulls.
- $n$ , the number of sections in the filter, determines the passband attenuation. Increasing  $n$  improves the filter ability to reject aliasing and imaging, but it also increases the droop or rolloff in the filter passband. Using an appropriate FIR filter in series after the CIC interpolation filter can help you compensate for the induced droop.
- The DC gain for the filter is a function of the interpolation factor. Raising the interpolation factor increases the DC gain.

## Examples

Demonstrate interpolation by a factor of two, in this case from 22.05 kHz to 44.1 kHz. Note the scaling required to see the results in the stem plot and to use the full range of the int16 data type.

```
R = 2; % Interpolation factor.
hm = mfilt.cicinterp(R); % Use default NumberOfSections and
% DifferentialDelay property values.
fs = 22.05e3; % Original sample frequency:22.05 kHz.
n = 0:5119; % 5120 samples, .232 second long signal.
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz.
```

```

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay stem plots correctly.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:22)/fs,x(1:22),'filled'); % Plot original signal sampled
                                     % at 22.05 kHz.

hold on;
stem(n(1:44)/(fs*R),y(4:47),'r'); % Plot interpolated signal
                                     % (44.1 kHz) in red.

xlabel('Time (sec)');ylabel('Signal Value');

```

As you expect, the plot shows that the interpolated signal matches the input sine shape, with additional samples between each original sample.

Use the filter visualization tool (FVTool) to plot the response of the interpolator object. For example, to plot the response of an interpolator with an interpolation factor of 7, 4 sections, and 1 differential delay, do something like the following:

```
hm = mfilt.cicinterp(7,1,4)
fvtool(hm)
```

## Algorithms

To show how the CIC interpolation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC interpolation filter ( $n = 2$ ).  $f_s$  is the high sampling rate, the output from the interpolation process.

For details about the bits that are removed in the integrator section, refer to [1] in References.

When you select `MinWordLengths`, the filter section word lengths are automatically set to the minimum number of bits possible in a valid CIC interpolator. `mfilt.cicinterp` computes the wordlength for each section so the roundoff noise introduced by all sections is less than the roundoff noise introduced by the quantization at the output.

# mfilt.farrowsrc

---

**Purpose** Sample rate converter with arbitrary conversion factor

**Syntax**

```
hm = mfilt.farrowsrc(L,M,C)
hm = mfilt.farrowsrc
hm = mfilt.farrowsrc(1,...)
```

**Description** `hm = mfilt.farrowsrc(L,M,C)` returns a filter object that is a natural extension of `dfilt.farrowfd` with a time-varying fractional delay. It provides a economical implementation of a sample rate converter with an arbitrary conversion factor. This filter works well in the interpolation case, but may exhibit poor anti-aliasing properties in the decimation case.

---

**Note** You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.farrowsrc`.

---

## Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. The default value of l is 3.
m	Decimation factor for the filter. m specifies the amount to decrease the input sampling rate. The default value for m is 2.
c	Coefficients for the filter. When no input arguments are specified, the default coefficients are [-1 1; 1, 0]

`hm = mfilt.farrowsrc` constructs the filter using the default values for l, m, and c.

`hm = mfilt.farrowsrc(1, ...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

### **mfilt.farrowsrc Object Properties**

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.farrowsrc` objects. The next table describes each property for an `mfilt.farrowsrc` filter object.

<b>Name</b>	<b>Values</b>	<b>Description</b>
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
Arithmetic	String	Reports the arithmetic precision used by the filter.
Coefficients	Vector	Vector containing the coefficients of the FIR lowpass filter
InterpolationFactor	Integer	Interpolation factor for the filter. It specifies the amount to increase the input sampling rate.

Name	Values	Description
DecimationFactor	Integer	Decimation factor for the filter. It specifies the amount to increase the input sampling rate.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

## Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```
[L,M] = rat(48/44.1);
Hm = mfilt.farrowsrc(L,M);           % We use the default filter
Fs = 44.1e3;                         % Original sampling frequency
n = 0:9407;                          % 9408 samples, 0.213 seconds long
x = sin(2*pi*1e3/Fs*n);              % Original signal, sinusoid at 1kHz
y = filter(Hm,x);                   % 10241 samples, still 0.213 seconds
stem(n(1:45)/Fs,x(1:45))            % Plot original sampled at 44.1kHz
hold on
% Plot fractionally interpolated signal (48kHz) in red
stem((n(2:50)-1)/(Fs*L/M),y(2:50),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48kHz sample rate')
```

The results of the example are shown in the following figure:

# mfilt.fftfirinterp

---

**Purpose** Overlap-add FIR polyphase interpolator

**Syntax**  
`hm = mfilt.fftfirinterp(1,num,b1)`  
`hm = mfilt.fftfirinterp`  
`hm = mfilt.fftfirinterp(1,...)`

**Description** `hm = mfilt.fftfirinterp(1,num,b1)` returns a discrete-time FIR filter object that uses the overlap-add method for filtering input data.

The input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The number of FFT points is given by  $[b1 + \text{ceil}(\text{length}(\text{num})/1) - 1]$ . It is to your advantage to choose `b1` such that the number of FFT points is a power of two—using powers of two can improve the efficiency of the FFT and the associated interpolation process.

## Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
<code>1</code>	Interpolation factor for the filter. <code>1</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>1</code> it defaults to <code>2</code> .
<code>num</code>	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When <code>num</code> is not provided as an input, <code>fftfirinterp</code> uses a lowpass Nyquist filter with gain equal to <code>1</code> and cutoff frequency equal to $\pi/1$ by default.
<code>b1</code>	Length of each block of input data used in the filtering. <code>b1</code> must be an integer. When you omit input <code>b1</code> , it defaults to <code>100</code> .

`hm = mfilt.fffirinterp` constructs the filter using the default values for `l`, `num`, and `bl`.

`hm = mfilt.fffirinterp(l,...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

## **mfilt.fffirinterp Object Properties**

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.fffirinterp` objects. The next table describes each property for an `mfilt.fffirinterp` filter object.

<b>Name</b>	<b>Values</b>	<b>Description</b>
FilterStructure		Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
Numerator		Vector containing the coefficients of the FIR lowpass filter used for interpolation.
InterpolationFactor		Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer.
BlockLength		Length of each block of input data used in the filtering.

Name	Values	Description
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.
States		Stored conditions for the filter, including values for the interpolator states.

## Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```

l = 8; % Interpolation factor
hm = mfilt.fftfirinterp(l); % We use the default filter
n = 8192; % Number of points
hm.blocklength = n; % Set block length to number of points
fs = 44.1e3; % Original sample freq: 44.1 kHz.
n = 0:n-1; % 0.1858 secs of data
x = sin(2*pi*n*22e3/fs); % Original signal, sinusoid at 22 kHz
y = filter(hm,x); % Interpolated sinusoid
xu = 1*upsample(x,8); % Upsample to compare--the spectrum
% does not change
[px,f]=periodogram(xu,[],65536,1*fs); % Power spectrum of original
% signal
[py,f]=periodogram(y,[],65536,1*fs); % Power spectrum of
% interpolated signal

```

```

plot(f,10*log10([fs*px,1*fs*py]))
legend('22 kHz sinusoid sampled at 44.1 kHz',...
'22 kHz sinusoid sampled at 352.8 kHz')
xlabel('Frequency (Hz)'); ylabel('Power Spectrum');

```

To see the results of the example, look at this figure.

# mfilt.firdecim

---

**Purpose** Direct-form FIR polyphase decimator

**Syntax**  
`hm = mfilt.firdecim(m)`  
`hm = mfilt.firdecim(m,num)`

**Description** `hm = mfilt.firdecim(m)` returns a direct-form FIR polyphase decimator object `hm` with a decimation factor of  $m$ . A lowpass Nyquist filter of gain 1 and cutoff frequency of  $\pi/m$  is designed by default. This filter allows some aliasing in the transition band but it very efficient because the first polyphase component is a pure delay.

`hm = mfilt.firdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. This lets you specify more completely the FIR filter to use for the decimator.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input arguments for creating `hm`.

<b>Input Argument</b>	<b>Description</b>
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 2.
num	Vector containing the coefficients of the FIR lowpass filter used for decimation. When num is not provided as an input, mfilt.firdecim constructs a lowpass Nyquist filter with gain of 1 and cutoff frequency equal to $\pi/m$ by default. The default length for the Nyquist filter is $24*m$ . Therefore, each polyphase filter component has length 24.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firdecim objects. The next table describes each property for an mfilt.firdecim filter object.

<b>Name</b>	<b>Values</b>	<b>Description</b>
Arithmetic	Double, single, fixed	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operation mode for your filter.
DecimationFactor	Integer	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of

## **mfilt.firdecim**

---

<b>Name</b>	<b>Values</b>	<b>Description</b>
		the input signal. It must be an integer.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples that have been processed so far and $m$ is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	false, true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to

Name	Values	Description
		true allows you to modify the States, InputOffset, and PolyphaseAccum properties.
PolyphaseAccum	0 in double, single, or fixed for the different filter arithmetic settings.	Differentiates between the adders in the filter that work in full precision at all times (PolyphaseAccum) and the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision.
States	Double, single, or fi matching the filter arithmetic setting.	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Double is the default setting for floating-point filters in double arithmetic.

**Fixed-Point Filter Properties**

This table shows the properties associated with the fixed-point implementation of the filter. You see one or more of these properties when you set Arithmetic to fixed. Some of the properties have different default values when they refer fixed point filters. One example is the property PolyphaseAccum which stores data as doubles when you use your filter in double-precision mode, but stores a fi object in fixed-point mode.

---

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use `info(hm)` where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 5-115.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
AccumWordLength	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

<b>Name</b>	<b>Values</b>	<b>Description</b>
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits[16]	Specifies the word length applied to interpret input data.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

# mfilt.firdecim

Name	Values	Description
OverflowMode	saturate, [wrap]	<p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.</p>
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul>

Name	Values	Description
		The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

**Filter Structure**

To provide decimation, `mfilt.firdecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firdecim`.

# mfilt.firdecim

Notice the order of the states in the filter flow diagram. States 1 through 9 appear in the diagram above each delay element. State 1 applies to the first delay element in phase 2. State 2 applies to the first delay element in phase 1. State 3 applies to the first delay element in phase 0. State 4 applies to the second delay in phase 2, and so on. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

In property value form, the states for a filter `hm` are

```
hm.states=[1:9];
```

## Examples

Convert an input signal from 44.1 kHz to 22.05 kHz using decimation by a factor of 2. In the figure that appears after the example code, you see the results of the decimation.

```
m = 2; % Decimation factor.
hm = mfilter.firdecim(m); % Use the default filter.
fs = 44.1e3; % Original sample freq: 44.1kHz.
n = 0:10239; % 10240 samples, 0.232 second long
% signal.
x = sin(2*pi*1e3/fs*n); % Original signal--sinusoid at 1kHz.
```

```

y = filter(hm,x);           % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44))   % Plot original sampled at 44.1 kHz.
hold on                    % Plot decimated signal (22.05 kHz)
                           % in red.
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')

```

[mfilt.firtdecim](#) | [mfilt.firsrc](#) | [mfilt.cicdecim](#)

# **mfilt.firfracdecim (Obsolete)**

---

**Purpose** Direct-form FIR polyphase fractional decimator

**Syntax** `hm = mfilt.firfracdecim(l,m,num)`

**Description** `mfilt.firfracdecim` will be removed in a future release. Use `mfilt.firsrc` instead.

`hm = mfilt.firfracdecim(l,m,num)` returns a direct-form FIR polyphase fractional decimator. Input argument `l` is the interpolation factor. `l` must be an integer. When you omit `l` in the calling syntax, it defaults to 2. `m` is the decimation factor. It must be an integer. If not specified, it defaults to `l+1`.

`num` is a vector containing the coefficients of the FIR lowpass filter used for decimation. If you omit `num`, a lowpass Nyquist filter of gain 1 and cutoff frequency of  $n/\max(l, m)$  is used by default.

By specifying both a decimation factor and an interpolation factor, you can decimate your input signal by noninteger amounts. The fractional decimator first interpolates the input, then decimates to result in an output signal whose sample rate is  $1/m$  of the input rate. By default, the resulting decimation factor is  $2/3$  when you do not provide `l` and `m` in the calling syntax. Specify `l` smaller than `m` for proper decimation.

## **Input Arguments**

The following table describes the input arguments for creating `hm`.

<b>Input Argument</b>	<b>Description</b>
<code>l</code>	Interpolation factor for the filter. It must be an integer. When you do not specify a value for <code>l</code> it defaults to 2.
<code>num</code>	Vector containing the coefficients of the FIR lowpass filter used for decimation. When <code>num</code> is not provided as an input, <code>firfracdecim</code> uses a lowpass Nyquist

Input Argument	Description
	filter with gain equal to 1 and cutoff frequency equal to $\pi/\max(1,m)$ by default.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 1 + 1.

## mfilt.firfracdecim Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firfracdecim` objects. The next table describes each property for an `mfilt.firfracdecim` filter object.

Name	Values	Description
FilterStructure	String	Reports the type of filter object, such as a decimator or fractional decimator. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
InputOffset	Integers	Contains the number of input data samples processed without generating an output sample. The default value is 0.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for interpolation.

## **mfilt.firfracdecim (Obsolete)**

<b>Name</b>	<b>Values</b>	<b>Description</b>
RateChangeFactors	[1,m]	Reports the decimation (m) and interpolation (1) factors for the filter object. Combining these factors results in the final rate change for the signal.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.
States	Matrix	Stored conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter.  The number of states is $(1h-1)*m+(l-1)*(1o+mo)$ where 1h is the length of each subfilter, and l and m are the interpolation and decimation factors. 1o and mo, the input and output delays between each interpolation phase, are integers from Euclid's theorem such that $1o*1-mo*m = -1$ (refer to the reference for more details). Use euclidfactors to get 1o and mo for an mfilt.firfracdecim object

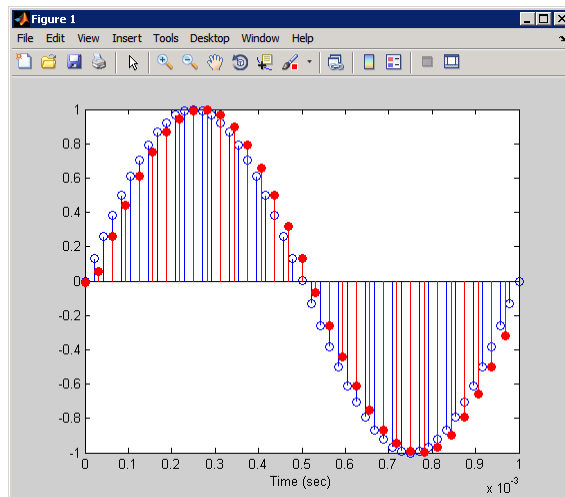

## Examples

To demonstrate `firfracdecim`, perform a fractional decimation by a factor of  $2/3$ . This is one way to downsample a 48 kHz signal to 32 kHz, commonly done in audio processing.

```
l = 2; m = 3; % Interpolation/decimation factors.
hm = mfilter.firfracdecim(l,m); % We use the default
fs = 48e3; % Original sample freq: 48 kHz.
n = 0:10239; % 10240 samples, 0.213 second long
% signal
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz
y = filter(hm,x); % 9408 samples, still 0.213 seconds
stem(n(1:49)/fs,x(1:49)); hold on; % Plot original signal sampled
% at 48 kHz
stem(n(1:32)/(fs*l/m),y(13:44),'r','filled') % Plot decimated
% signal at 32 kHz
xlabel('Time (sec)');
```

As shown, the plot clearly demonstrates the reduced sampling frequency of 32 kHz.

## **See Also**

`mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

**Purpose**

Direct-form FIR polyphase fractional interpolator

**Syntax**

```
hm = mfilt.firfracinterp(1,m,num)
```

**Description**

`mfilt.firfracinterp` will be removed in a future release. Use `mfilt.firsrc` instead.

`hm = mfilt.firfracinterp(1,m,num)` returns a direct-form FIR polyphase fractional interpolator `mfilt` object. `1` is the interpolation factor. It must be an integer. If not specified, `1` defaults to `3`.

`m` is the decimation factor. Like `1`, it must be an integer. If you do not specify `m` in the calling syntax, it defaults to `1`. If you also do not specify a value for `1`, `m` defaults to `2`.

`num` is a vector containing the coefficients of the FIR lowpass filter used for interpolation. If omitted, a lowpass Nyquist filter of gain `1` and cutoff frequency of  $\pi/\max(1,m)$  is used by default.

By specifying both a decimation factor and an interpolation factor, you can interpolate your input signal by noninteger amounts. The fractional interpolator first interpolates the input, then decimates to result in an output signal whose sample rate is  $1/m$  of the input rate. For proper interpolation, you specify `1` to be greater than `m`. By default, the resulting interpolation factor is  $3/2$  when you do not provide `1` and `m` in the calling syntax.

**Input Arguments**

The following table describes the input arguments for creating `hm`.

## **mfilt.firfracinterp (Obsolete)**

---

<b>Input Argument</b>	<b>Description</b>
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l it defaults to 3.
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, firfracinterp uses a lowpass Nyquist filter with gain equal to 1 and cutoff frequency equal to $\pi/\max(1,m)$ by default.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 1. When you do not specify l as well, m defaults to 2.

### **mfilt.firfracinterp Object Properties**

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firfracinterp` objects. The next table describes each property for an `mfilt.firfracinterp` filter object.

<b>Name</b>	<b>Values</b>	<b>Description</b>
FilterStructure		Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
Numerator		Vector containing the coefficients of the FIR lowpass filter used for interpolation.

Name	Values	Description
RateChangeFactors	[l,m]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to the default values any state that the filter changes during processing. States that the filter does not change are not affected.
States	Matrix	Stored conditions for the filter, including values for the interpolator and comb states.

## Examples

To convert a signal from 32 kHz to 48 kHz requires fractional interpolation. This example uses the `mfilt.firfracinterp` object to upsample an input signal. Setting `l = 3` and `m = 2` returns the same `mfilt` object as the default `mfilt.firfracinterp` object.

```

l = 3; m = 2;                % Interpolation/decimation factors.
hm = mfilt.firfracinterp(l,m); % We use the default filter
fs = 32e3;                  % Original sample freq: 32 kHz.
n = 0:6799;                 % 6800 samples, 0.212 second long signal
x = sin(2*pi*1e3/fs*n);     % Original signal, sinusoid at 1 kHz

```

# mfilt.firfracinterp (Obsolete)

```
y = filter(hm,x);           % 10200 samples, still 0.212 seconds
stem(n(1:32)/fs,x(1:32),'filled') % Plot original sampled at
                                % 32 kHz

hold on;
% Plot fractionally interpolated signal (48 kHz) in red
stem(n(1:48)/(fs*1/m),y(20:67),'r')
xlabel('Time (sec)');ylabel('Signal Value')
```

The ability to interpolate by fractional amounts lets you raise the sampling rate from 32 to 48 kHz, something you cannot do with integral interpolators. Both signals appear in the following figure.

[mfilt.firsrc](#) | [mfilt.firinterp](#) | [mfilt.firdecim](#)

**Purpose**                    FIR filter-based interpolator

**Syntax**                    `Hm = mfilt.firinterp(L)`  
                               `Hm = mfilt.firinterp(L,num)`

**Description**              `Hm = mfilt.firinterp(L)` returns a FIR polyphase interpolator object `Hm` with an interpolation factor of `L` and gain equal to `L`. `L` defaults to 2 if unspecified.

`Hm = mfilt.firinterp(L,num)` uses the values in the vector `num` as the coefficients of the interpolation filter.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter `Hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

### Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
1	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for 1 it defaults to 2.
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When <code>num</code> is not provided as an input, <code>firinterp</code> uses a lowpass Nyquist filter with gain equal to 1 and cutoff frequency equal to $\pi/1$ by default. The default length for the Nyquist filter is $24 \times 1$ . Therefore, each polyphase filter component has length 24.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firinterp` objects. The next table describes each property for an `mfilt.firinterp` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operation mode for your filter.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Describes the signal flow for the filter object.
InterpolationFactor	Integer	Interpolation factor for the filter. 1 specifies the amount to increase the sampling rate of the input signal. It must be an integer.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.

Name	Values	Description
PersistentMemory	[false], true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to <code>true</code> allows you to modify the <code>States</code> property.
States	Double, single, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

### Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firinterp` filter.

---

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

`info(hm)`

where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 5-115.

## mfilt.firinterp

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any integer number of bits[39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

<b>Name</b>	<b>Values</b>	<b>Description</b>
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

# mfilt.firinterp

Name	Values	Description
OverflowMode	saturate, [wrap]	<p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.</p>
RoundMode	[convergent], <code>ceil</code> , <code>fix</code> , <code>floor</code> , <code>nearest</code> , <code>round</code>	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul>

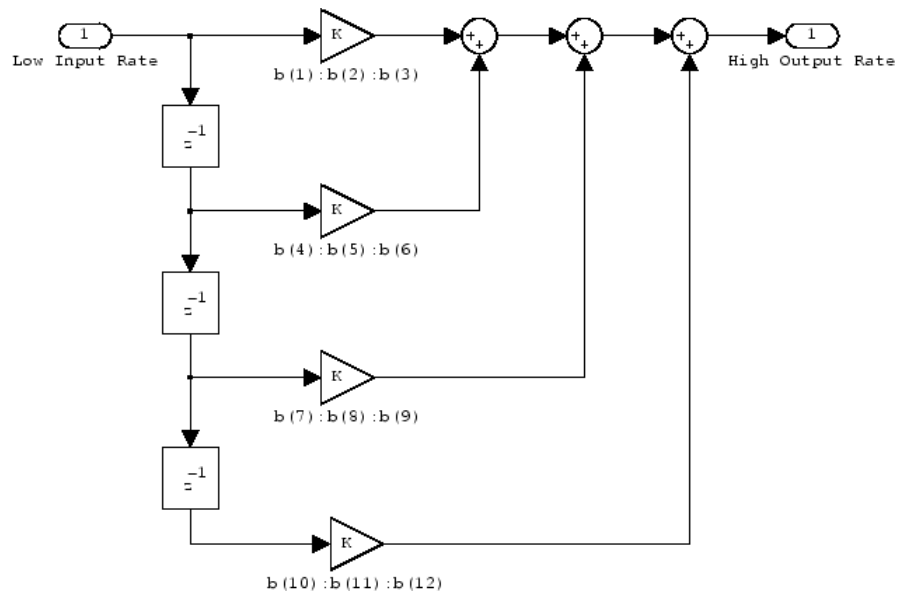

Name	Values	Description
		The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

**Filter Structure**

To provide interpolation, `mfilt.firinterp` uses the following structure.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firinterp`. In the figure, the delay line updates happen at the lower input rate. The remainder of the filter — the sums and coefficients — operate at the higher output rate.

# mfilt.firinterp

## Examples

This example uses `mfilt.firinterp` to double the sample rate of a 22.05 kHz input signal. The output signal ends up at 44.1 kHz. Although `l` is set explicitly to 2, this represents the default interpolation value for `mfilt.firinterp` objects.

```
L = 2; % Interpolation factor.
Hm = mfilt.firinterp(L); % Use the default filter.
fs = 22.05e3; % Original sample freq: 22.05 kHz.
n = 0:5119; % 5120 samples, 0.232s long signal.
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz.
y = filter(Hm,x); % 10240 samples, still 0.232s.
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
% 22.05 kHz.

hold on;

% Plot interpolated signal (44.1 kHz) in red
stem(n(1:44)/(fs*L),y(25:68),'r')
xlabel('Time (sec)');ylabel('Signal Value')
```

```
legend('Original Signal','Interpolated Signal');
```

With interpolation by 2, the resulting signal perfectly matches the original, but with twice as many samples — one between each original sample, as shown in the following figure.

## See Also

[mfilt.holdinterp](#) | [mfilt.linearinterp](#) | [mfilt.fftfirinterp](#) | [mfilt.firsrc](#) | [mfilt.cicinterp](#)

**Purpose** Direct-form FIR polyphase sample rate converter

**Syntax** `hm = mfilt.firsrc(1,m,num)`

**Description** `hm = mfilt.firsrc(1,m,num)` returns a direct-form FIR polyphase sample rate converter. `l` specifies the interpolation factor. It must be an integer and when omitted in the calling syntax, it defaults to 2.

`m` is the decimation factor. It must be an integer. If not specified, `m` defaults to 1. If `l` is also not specified, `m` defaults to 3 and the overall rate change factor is  $2/3$ .

You specify the coefficients of the FIR lowpass filter used for sample rate conversion in `num`. If omitted, a lowpass Nyquist filter with gain 1 and cutoff frequency of  $\pi/\max(1,m)$  is the default.

Combining an interpolation factor and a decimation factor lets you use `mfilt.firsrc` to perform fractional interpolation or decimation on an input signal. Using an `mfilt.firsrc` object applies a rate change factor defined by  $1/m$  to the input signal. For proper rate changing to occur, `l` and `m` must be relatively prime — meaning the ratio  $1/m$  cannot be reduced to a ratio of smaller integers.

When you are doing sample-rate conversion with large values of `l` or `m`, such as `l` or `m` greater than 20, using the `mfilt.firsrc` structure is the most effective approach.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

---

**Note** You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.firsrc`.

---

### Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
1	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for 1, it defaults to 2.
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, <code>mfilt.firsrc</code> uses a lowpass Nyquist filter with gain equal to 1 and cutoff frequency equal to $\pi/\max(1,m)$ by default. The default length for the Nyquist filter is $24*m$ . Therefore, each polyphase filter component has length 24.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m, it defaults to 1. When 1 is unspecified as well, m defaults to 3.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also

## **mfilt.firsrc**

input arguments for creating `mfilt.firsrc` objects. The next table describes each property for an `mfilt.firsrc` filter object.

<b>Name</b>	<b>Values</b>	<b>Description</b>
Arithmetic	[Double], single, fixed	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operation mode for your filter.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples and $m$ is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	false, true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to <code>true</code> allows you to modify the <code>States</code> , <code>InputOffset</code> , and <code>PolyphaseAccum</code> properties.

<b>Name</b>	<b>Values</b>	<b>Description</b>
RateChangeFactors	Positive integers. [2 3]	Specifies the interpolation and decimation factors [1 m] (the rate change factors ) for changing the input sample rate by nonintegral amounts.
States	Double, single, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

### **Fixed-Point Filter Properties**

This table shows the properties associated with the fixed-point implementation of the `mfilt.firsrc` filter.

---

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

`info(hm)`

where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 5-115.

<b>Name</b>	<b>Values</b>	<b>Description</b>
AccumFracLength	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
AccumWordLength	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.

Name	Values	Description
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.

Name	Values	Description
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
RateChangeFactors	Positive integers [2 3]	Specifies the interpolation and decimation factors [1 m] (the rate change factors) for changing the input sample rate by nonintegral amounts.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>

Name	Values	Description
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

## Examples

This is an example of a common audio rate change process — changing the sample rate of a high end audio (48 kHz) signal to the compact disc sample rate (44.1 kHz). This conversion requires a rate change factor of 0.91875, or  $l = 147$  and  $m = 160$ .

```

l = 147; m = 160;           % Interpolation/decimation factors.
hm = mfilt.firsrc(l,m);   % Use the default FIR filter.
fs = 48e3;                % Original sample freq: 48 kHz.
n = 0:10239;              % 10240 samples, 0.213 seconds long.
x = sin(2*pi*1e3/fs*n);   % Original signal, sinusoid at 1 kHz.
y = filter(hm,x);         % 9408 samples, still 0.213 seconds.
stem(n(1:49)/fs,x(1:49))  % Plot original sampled at 48 kHz.
hold on

% Plot fractionally decimated signal (44.1 kHz) in red
stem(n(1:45)/(fs*l/m),y(13:57),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')

```

Fractional decimation provides you the flexibility to pick and choose the sample rates you want by carefully selecting  $l$  and  $m$ , the interpolation and decimation factors, that result in the final fractional decimation.

The following figure shows the signal after applying the rate change filter `hm` to the original signal.

## See Also

`mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

**Purpose** Direct-form transposed FIR filter

**Syntax**  
`hm = mfilt.firtdecim(m)`  
`hm = mfilt.firtdecim(m,num)`

**Description** `hm = mfilt.firtdecim(m)` returns a polyphase decimator `mfilt` object `hm` based on a direct-form transposed FIR structure with a decimation factor of  $m$ . A lowpass Nyquist filter of gain 1 and cutoff frequency of  $\pi/m$  is the default.

`hm = mfilt.firtdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. `num` is a vector containing the coefficients of the transposed FIR lowpass filter used for decimation. If omitted, a lowpass Nyquist filter with gain of 1 and cutoff frequency of  $\pi/m$  is the default.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input arguments for creating `hm`.

# mfilt.firtdecim

Input Argument	Description
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, <code>firtdecim</code> uses a lowpass Nyquist filter with gain equal to 1 and cutoff frequency equal to $\pi/m$ by default. The default length for the Nyquist filter is $24*m$ . Therefore, each polyphase filter component has length 24.
m	Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for <code>m</code> it defaults to 2.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firtdecim` objects. The next table describes each property for an `mfilt.firtdecim` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
DecimationFactor	Integer	Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer.

Name	Values	Description
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object. Also describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples that have been processed so far and $m$ is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	[false], true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory set to false returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to true allows you to modify the States, InputOffset, and PolyphaseAccum properties.

# mfilt.firtdecim

---

Name	Values	Description
PolyphaseAccum	Double, single [0]	The idea behind having both PolyphaseAccum and Accum is to differentiate between the adders in the filter that work in full precision at all times (PolyphaseAccum) from the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision.
States	Double, single matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

## Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firtdecim` filter.

---

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

`info(hm)`

where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 5-115.

<b>Name</b>	<b>Values</b>	<b>Description</b>
AccumFracLength	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

## mfilt.firtdecim

Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
PolyphaseAccum	fi object with zeros to start	Differentiates between the adders in the filter that work in full precision at all times ( <code>PolyphaseAccum</code> ) and the adders in the filter that the user controls and that may introduce quantization effects when <code>FilterInternals</code> is set to <code>SpecifyPrecision</code> .
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> </ul>

# mfilt.firtdecim

Name	Values	Description
		<ul style="list-style-type: none"><li>• round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

## Filter Structure

To provide sample rate changes, `mfilt.firtdecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter. To keep track of the position of the commutator, the `mfilt` object uses the property `InputOffset` which reports the current position of the commutator in the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firtdecim`.

Notice the order of the states in the filter flow diagram. States 1 through 3 appear in the following diagram at each delay element. State 1 applies to the third delay element in phase 2. State 2 applies to the second delay element in phase 2. State 3 applies to the first delay element in phase 2. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

In property value form, the states for a filter `hm` are

```
hm.states=[1:3];
```

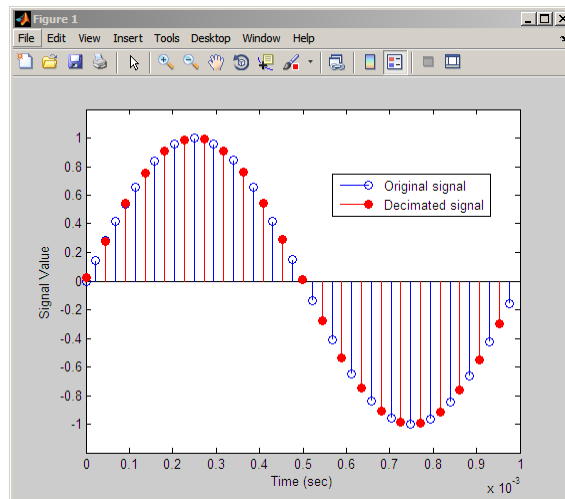

## Examples

Demonstrate decimating an input signal by a factor of 2, in this case converting from 44.1 kHz down to 22.05 kHz. In the figure shown following the code, you see the results of decimating the signal.

```
m = 2; % Decimation factor.
hm = mfilter.firtdecim(m); % Use the default filter coeffs.
fs = 44.1e3; % Original sample freq: 44.1 kHz.
n = 0:10239; % 10240 samples, 0.232 second long signal
x = sin(2*pi*1e3/fs*n); % Original signal--sinusoid at 1 kHz.
y = filter(hm,x); % 5120 samples, 0.232 seconds.
```

# mfilt.firtdecim

```
stem(n(1:44)/fs,x(1:44)) % Plot original sampled at 44.1 kHz.  
axis([0 0.001 -1.2 1.2]);  
hold on % Plot decimated signal (22.05 kHz) in red  
stem(n(1:22)/(fs/m),y(13:34),'r','filled')  
xlabel('Time (sec)');ylabel('Signal Value');  
legend('Original signal','Decimated signal','location','best');
```

## See Also

[mfilt.firdecim](#) | [mfilt.firsrc](#) | [mfilt.cicdecim](#)

**Purpose** FIR hold interpolator

**Syntax** `hm = mfilt.holdinterp(1)`

**Description** `hm = mfilt.holdinterp(1)` returns the object `hm` that represents a hold interpolator with the interpolation factor 1. To work, 1 must be an integer. When you do not include 1 in the calling syntax, it defaults to 2. To perform interpolation by noninteger amounts, use one of the fractional interpolator objects, such as `mfilt.firsrc`.

When you use this hold interpolator, each sample added to the input signal between existing samples has the value of the most recent sample from the original signal. Thus you see something like a staircase profile where the interpolated samples form a plateau between the previous and next original samples. The example demonstrates this profile clearly. Compare this to the interpolation process for other interpolators in the toolbox, such as `mfilt.linearinterp`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
1	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for 1 it defaults to 2.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.holdinterp` objects. The next table describes each property for an `mfilt.interp` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
Interpolation-Factor	Integer	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate. It must be an integer.

Name	Values	Description
PersistentMemory	'false' or 'true'	Determines whether the filter states are restored to zero for each filtering operation.
States	Double or single array	Filter states. <code>states</code> defaults to a vector of zeros that has length equal to <code>nstates</code> ( <code>hm</code> ). Always available, but visible in the display only when <code>PersistentMemory</code> is true.

### Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.holdinterp` filter.

---

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

`info(hm)`

where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 5-115.

## mfilt.holdinterp

---

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
Interpolation-Factor	Integer	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate. It must be an integer.
PersistentMemory	'false' or 'true'	Determine whether the filter states get restored to zero for each filtering operation
States	fi object	Contains the filter states before, during, and after filter operations. For hold interpolators, the states are always empty — hold interpolators do not have states. The states use <code>fi</code> objects, with the

Name	Values	Description
		associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

## Filter Structure

Hold interpolators do not have filter coefficients and their filter structure is trivial.

## Examples

To see the effects of hold-based interpolation, interpolate an input sine wave from 22.05 to 44.1 kHz. Note that each added sample retains the value of the most recent original sample.

```

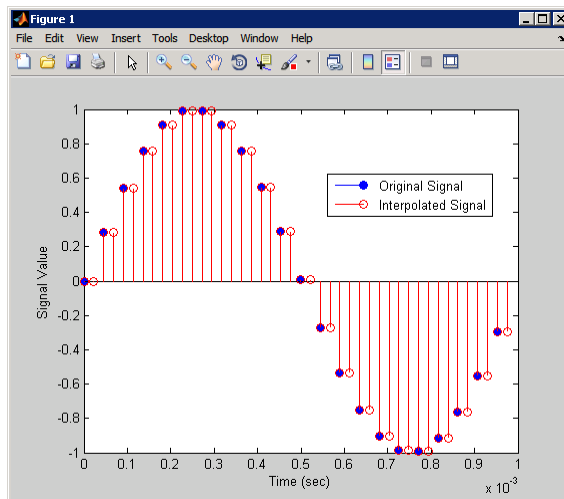

l = 2; % Interpolation factor
hm = mfilt.holdinterp(l);
fs = 22.05e3; % Original sample freq: 22.05 kHz.
n = 0:5119; % 5120 samples, 0.232 second long signal
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz
y = filter(hm,x); % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
% 22.05 kHz

hold on % Plot interpolated signal (44.1 kHz)
stem(n(1:44)/(fs*l),y(1:44),'r')
legend('Original Signal','Interpolated Signal','Location','best');
xlabel('Time (sec)');ylabel('Signal Value')

```

The following figure shows clearly the step nature of the signal that comes from interpolating the signal using the hold algorithm approach. Compare the output to the linear interpolation used in `mfilt.linearinterp`.

# mfilt.holdinterp

## See Also

`mfilt.linearinterp` | `mfilt.firinterp` | `mfilt.firsrc` |  
`mfilt.cicinterp`

**Purpose** IIR decimator

**Syntax** `hm = mfilt.iirdecim(c1,c2,...)`

**Description** `hm = mfilt.iirdecim(c1,c2,...)` constructs an IIR decimator filter given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The resulting IIR decimator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR decimators.

Although the first example shows how to construct an IIR decimators explicitly, one usually constructs an IIR decimators filter as a result of designing an decimators, as shown in the subsequent examples.

**Examples** When the coefficients are known, you can construct the IIR decimator directly using `mfilt.iirdecim`. For example, if the filter's coefficients are [0.6 0.5] for the first phase in the first stage, 0.7 for the second phase in the first stage and 0.8 for the third phase in the first stage; as well as 0.5 for the first phase in the second stage and 0.4 for the second phase in the second stage, construct the filter as shown here.

```
Hm = mfilt.iirdecim({[0.6 0.5] 0.7 0.8},{0.5 0.4})
```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of the “IIR Polyphase Filter Design” example, `iirallpassdemo` example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband decimator with a decimation factor of 2. The example specifies the optional sampling frequency argument.

```
tw = 100;    % Transition width of filter.
ast = 80;   % Stopband attenuation of filter.
fs = 2000;  % Sampling frequency of signal to filter.
m = 2;      % Decimation factor.
hm = fdesign.decimator(m, 'halfband', 'tw,ast', tw, ast, fs);
```

`hm` contains the specifications for a decimator defined by `tw`, `ast`, `m`, and `fs`.

Use the specification object `hm` to design a `mfilt.iirdecim` filter object.

```
d = design(hm, 'ellip', 'filterstructure', 'iirdecim');
% Note that realizemdl requires Simulink
realizemdl(d)    % Build model of the filter.
```

Designing a linear phase decimator is similar to the previous example. In this case, design a halfband linear phase decimator with decimation factor of 2.

```
tw = 100;    % Transition width of filter.
ast = 60;   % Stopband attenuation of filter.
fs = 2000;  % Sampling frequency of signal to filter.
m = 2;      % Decimation factor.
```

Create a specification object for the decimator.

```
hm = fdesign.decimator(m, 'halfband', 'tw,ast', tw, ast, fs);
```

Finally, design the filter `d`.

```
d = design(hm, 'iirlinphase', 'filterstructure', 'iirdecim');
```

```
% Note that realizemdl requires Simulink  
realizemdl(d) % Build model of the filter.
```

The filter implementation appears in this model, generated by realizemdl and Simulink.

Given the design specifications shown here

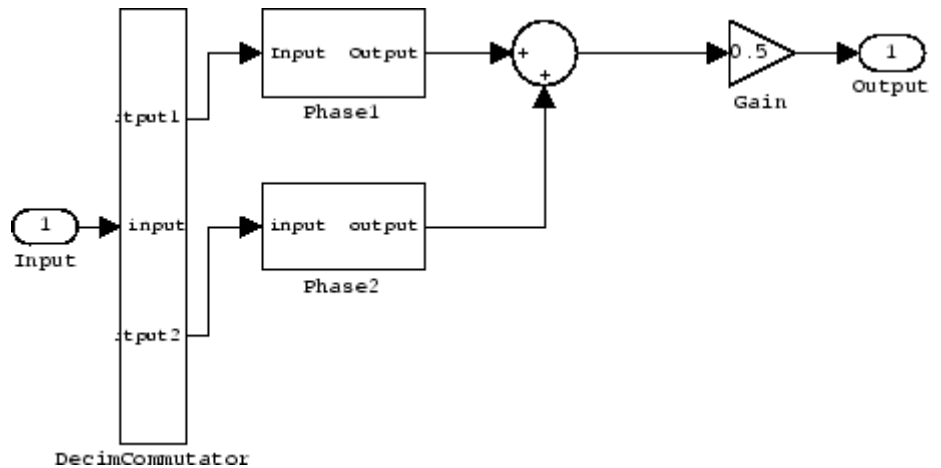

the first phase is a delay section with 0s and a 1 for coefficients and the second phase is a linear phase decimator, shown in the next models.

**Phase 1 model**

Phase 2 model

### Overall model

### See Also

`dfilt.cascadeallpass` | `mfilt` | `mfilt.iirinterp` | `mfilt.iirwdfdecim`

# mfilt.iirinterp

---

**Purpose** IIR interpolator

**Syntax** `hm = mfilt.iirinterp(c1,c2,...)`

**Description** `hm = mfilt.iirinterp(c1,c2,...)` constructs an IIR interpolator filter given the coefficients specified in the cell arrays `C1`, `C2`, etc.

The IIR interpolator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array—if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and a unique element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR interpolators.

Although the first example shows how to construct an IIR interpolator explicitly, one usually constructs an IIR interpolator filter as a result of designing an interpolator, as shown in the subsequent examples.

## Examples

When the coefficients are known, you can construct the IIR interpolator directly using `mfilt.iirinterp`. In the following example, a cascaded polyphase IIR interpolator filter is constructed using 2 phases for each of three stages. The coefficients are given below:

```
Phase1Sect1=0.0603;Phase1Sect2=0.4126; Phase1Sect3=0.7727;  
Phase2Sect1=0.2160; Phase2Sect2=0.6044; Phase2Sect3=0.9239;
```

Next the filter is implemented by passing the above coefficients to `mfilt.iirinterp` as cell arrays, where each cell array represents a different phase.

```
Hm = mfilt.iirinterp({Phase1Sect1,Phase1Sect2,Phase1Sect3},...
{Phase2Sect1,Phase2Sect2,Phase2Sect3})
```

Hm =

```

    FilterStructure: 'IIR Polyphase Interpolator'
      Polyphase: Phase1: Section1: 0.0603
                  Section2: 0.4126
                  Section3: 0.7727
                Phase2: Section1: 0.216
                  Section2: 0.6044
                  Section3: 0.9239
  InterpolationFactor: 2
    PersistentMemory: false
```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of the “IIR Polyphase Filter Design” example, `iirallpassdemo` example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband interpolator with a interpolation factor of 2.

```
tw = 100; % Transition width of filter.
ast = 80; % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Specification object `d` stores the interpolator design specifics. With the details in `d`, design the filter, returning `hm`, an `mfilt.iirinterp` object. Use `hm` to realize the filter if you have Simulink installed.

```
hm = design(d,'ellip','filterstructure','iirinterp');
```

# mfilt.iirinterp

---

```
% Note that realizedml requires Simulink
realizedml(hm)    % Build model of the filter.
```

Designing a linear phase halfband interpolator follows the same pattern.

```
tw = 100; % Transition width of filter.
ast= 60;  % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

fdesign.interpolator returns a specification object that stores the design features for an interpolator.

Now perform the actual design that results in an mfilt.iirinterp filter, hm.

```
hm = design(d,'iirlinphase','filterstructure','iirinterp');
% Note that realizedml requires Simulink
realizedml(hm)    % Build model of the filter.
```

The toolbox creates a Simulink model for hm, shown here. Phase1, Phase2, and InterpCommutator are all subsystem blocks.

For more information about Multirate Filter Constructors see the “Getting Started with Multirate Filter (MFILT) Objects” example, `mfiltgettingstarteddemo`.

# **mfilt.iirwdfdecim**

---

**Purpose** IIR wave digital filter decimator

**Syntax** `hm = mfilter.iirwdfdecim(c1,c2,...)`

**Description** `hm = mfilter.iirwdfdecim(c1,c2,...)` constructs an IIR wave digital decimator given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The IIR decimator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilter.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilter.iirwdfdecim` interprets them same way as `mfilter.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilter.delay` section with latency equal to the number of zeros, rather than a `dfilter.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR decimators.

Usually you do not construct IIR wave digital filter decimators explicitly. Instead, you obtain an IIR wave digital filter decimator as a result of designing a halfband decimator. The first example in the following section illustrates this case.

## **Examples**

Design an elliptic halfband decimator with a decimation factor equal to 2. Both examples use the `iirwdfdecim` filter structure (an input argument to the `design` method) to design the final decimator.

The first portion of this example generates a filter specification object `d` that stores the specifications for the decimator.

```
tw = 100; % Transition width of filter to design, 100 Hz.  
ast = 80; % Stopband attenuation of filter 80 dB.  
fs = 2000; % Sampling frequency of the input signal.  
m = 2; % Decimation factor.
```

```
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design using d. Filter object hm is an `mfilt.iirwdfdecim` filter.

```
Hm = design(d,'ellip','FilterStructure','iirwdfdecim');  
% Note that realizemdl requires Simulink  
realizemdl(hm) % Build model of the filter.
```

Design a linear phase halfband decimator for decimating a signal by a factor of 2.

```
tw = 100; % Transition width of filter, 100 Hz.  
ast = 60; % Filter stopband attenuation = 80 dB  
fs = 2000; % Input signal sampling frequency.  
m = 2; % Decimation factor.  
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Use d to design the final filter hm, an `mfilt.iirwdfdecim` object.

```
hm = design(d,'iirlinphase','filterstructure',...  
'iirwdfdecim');  
% Note that realizemdl requires Simulink  
realizemdl(hm) % Build model of the filter.
```

# mfilt.iirwdfdecim

The models that `realizemdl` returns for each example appear below. At this level, the realizations of the filters are identical. The differences appear in the subsystem blocks Phase1 and Phase2.

This is the Phase1 subsystem from the halfband model.

# mfilt.iirwdfdecim

---

Phase1 subsystem from the linear phase model is less revealing—an allpass filter.

## See Also

`dfilt.cascadewdfallpass` | `mfilt` | `mfilt.iirdecim` |  
`mfilt.iirwdfinterp`

## Purpose

IIR wave digital filter interpolator

## Syntax

```
hm = mfilter.iirwdfinterp(c1,c2,...)
```

## Description

`hm = mfilter.iirwdfinterp(c1,c2,...)` constructs an IIR wave digital interpolator given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The IIR interpolator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilter.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilter.iirwdfinterp` interprets them same way as `mfilter.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilter.delay` section with latency equal to the number of zeros, rather than a `dfilter.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR interpolators.

Usually you do not construct IIR wave digital filter interpolators explicitly. Rather, you obtain an IIR wave digital interpolator as a result of designing a halfband interpolator. The first example in the following section illustrates this case.

## Examples

Design an elliptic halfband interpolator with interpolation factor equal to 2. At the end of the design process, `hm` is an IIR wave digital filter interpolator.

```
tw = 100; % Transition width of filter, 100 Hz.  
ast = 80; % Stopband attenuation of filter, 80 dB.  
fs = 2000; % Sampling frequency after interpolation.  
l = 2; % Interpolation factor.  
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

# mfilt.iirwdfinterp

---

The specification object `d` stores the interpolator design requirements. Now use `d` to design the actual filter `hm`.

```
hm = design(d,'ellip','filterstructure','iirwdfinterp');
```

If you have Simulink installed, you can realize your filter as a model built from DSP System Toolbox blocks.

```
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

For variety, design a linear phase halfband interpolator with an interpolation factor of 2.

```
tw = 100; % Transition width of filter, 100 Hz.
ast = 80; % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency after interpolation.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design process with `d`. Filter `hm` is an IIR wave digital filter interpolator. As in the previous example, `realizemdl` returns a Simulink model of the filter if you have Simulink installed.

```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfinterp');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

## See Also

[dfilt.cascadewdfallpass](#) | [mfilt.iirinterp](#) | [mfilt.iirwdfdecim](#)

**Purpose** Linear interpolator

**Syntax** `hm = mfilt.linearinterp(1)`

**Description** `hm = mfilt.linearinterp(1)` returns an FIR linear interpolator `hm` with an integer interpolation factor `1`. Provide `1` as a positive integer. The default value for the interpolation factor is `2` when you do not include the input argument `1`.

When you use this linear interpolator, the samples added to the input signal have values between the values of adjacent samples in the original signal. Thus you see something like a smooth profile where the interpolated samples continue a line between the previous and next original samples. The example demonstrates this smooth profile clearly. Compare this to the interpolation process for `mfilt.holdinterp`, which creates a stairstep profile.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input argument for `mfilt.linearinterp`.

Input Argument	Description
1	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for 1 it defaults to 2.

# mfilt.linearinterp

---

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.linearinterp` objects. The next table describes each property for an `mfilt.linearinterp` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
InterpolationFactor	Integer	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate. It must be an integer.
PersistentMemory	'false' or 'true'	Determine whether the filter states get restored to zero for each filtering operation
States	Double or single array	Filter states. <code>states</code> defaults to a vector of zeros that has length equal to <code>nstates(hm)</code> . Always available, but visible in the display only when <code>PersistentMemory</code> is true.

## Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.holdinterp` filter.

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 5-115.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits. Depends on L. [29 when L=2]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits [33]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.

## mfilt.linearinterp

Name	Values	Description
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.

Name	Values	Description
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

# mfilt.linearinterp

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <b>ceil</b> - Round toward positive infinity.</li><li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <b>fix</b> - Round toward zero.</li><li>• <b>floor</b> - Round toward negative infinity.</li><li>• <b>nearest</b> - Round toward nearest. Ties round toward positive infinity.</li><li>• <b>round</b> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>

Name	Values	Description
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure in the following section.

# mfilt.linearinterp

## Filter Structure

Linear interpolator structures depend on the FIR filter you use to implement the filter. By default, the structure is direct-form FIR.

## Examples

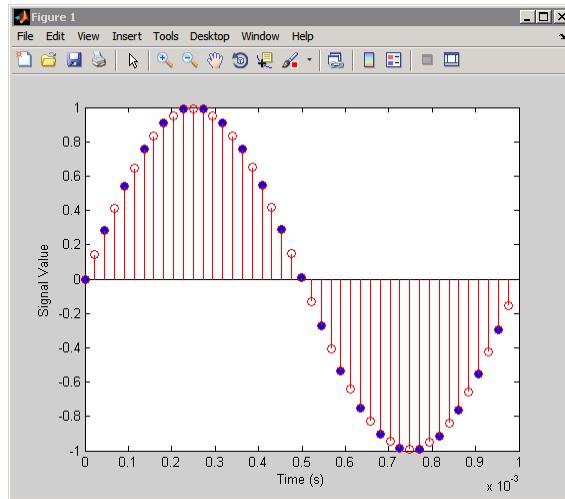

Interpolation by a factor of 2 (used to convert the input signal sampling rate from 22.05 kHz to 44.1 kHz).

```
l = 2; % Interpolation factor
hm = mfilt.linearinterp(l);
fs = 22.05e3; % Original sample freq: 22.05 kHz.
n = 0:5119; % 5120 samples, 0.232 second long signal
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz
y = filter(hm,x); % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
% 22.05 kHz
hold on % Plot interpolated signal (44.1
% kHz) in red
```

```
stem(n(1:44)/(fs*1),y(2:45),'r')  
xlabel('Time (s)');ylabel('Signal Value')
```

Using linear interpolation, as compared to the hold approach of `mfilt.holdinterp`, provides greater fidelity to the original signal.

`mfilt.cicinterp`

# minimizecoeffwl

---

**Purpose** Minimum wordlength fixed-point filter

**Syntax**

```
Hq = minimizecoeffwl(Hd)
Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)
Hq = minimizecoeffwl(Hd,...,'NTrials',N)
Hq = minimizecoeffwl(Hd,...,'Apasstol',Apasstol)
Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)
Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)
```

**Description**

Hq = minimizecoeffwl(Hd) returns the minimum wordlength fixed-point filter object Hq that meets the design specifications of the single-stage or multistage FIR filter object Hd. Hd must be generated using fdesign and design. If Hd is a multistage filter object, the procedure minimizes the wordlength for each stage separately. minimizecoeffwl uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator rand.

Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag) enables or disables the stochastic noise-shaping procedure in the minimization of the wordlength. By default NSFlag is true. Setting NSFlag to false minimizes the wordlength without using noise-shaping.

Hq = minimizecoeffwl(Hd,...,'NTrials',N) specifies the number of Monte Carlo trials to use in the minimization. Hq is the filter with the minimum wordlength among the N trials that meets the specifications in Hd. 'NTrials' defaults to one.

Hq = minimizecoeffwl(Hd,...,'Apasstol',Apasstol) specifies the passband ripple tolerance in dB. 'Apasstol' defaults to 1e-4.

Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol) specifies the stopband tolerance in dB. 'Astoptol' defaults to 1e-2.

Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag) determines whether the fixed-point filter matches the filter order and transition width of the floating-point design. Setting 'MatchRefFilter' to true returns a fixed-point filter with the same order and transition width as Hd. The 'MatchRefFilter' property defaults to false and the

resulting fixed-point filter may have a different order and transition width than the floating-point design Hd.

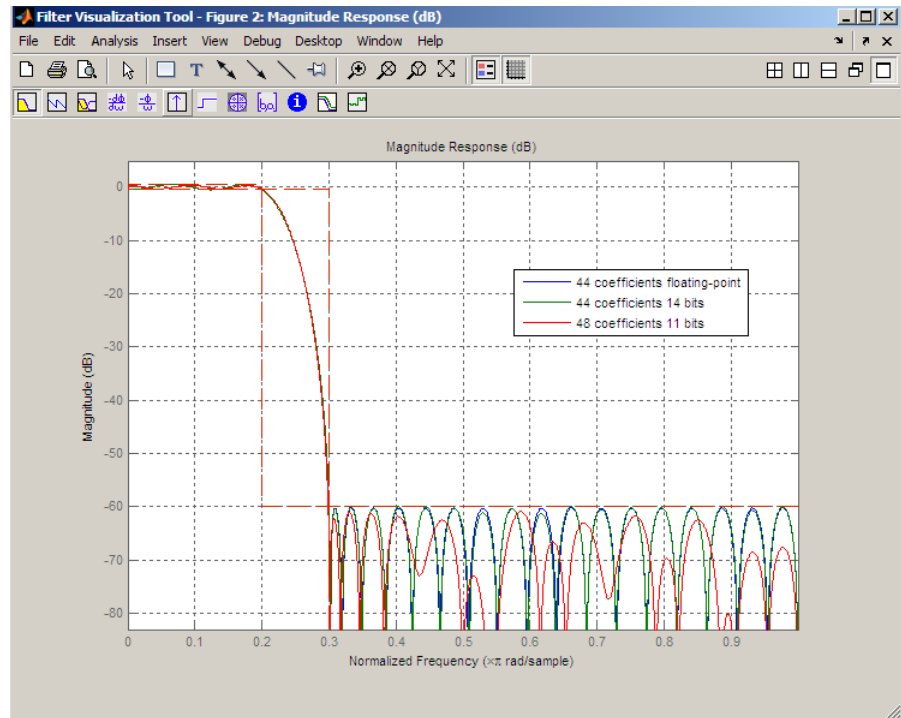

You must have the Fixed-Point Designer software installed to use this function.

## Examples

Minimize wordlength for lowpass FIR equiripple filter:

```
f=fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.3,1,60);
% Design filter with double-precision floating point
Hd=design(f,'equiripple');
% Find minimum wordlength fixed-point filter
% with 0.15 dB stopband tolerance
Hq=minimizecoeffwl(Hd,'MatchRefFilter',true,'Astoptol',0.15);
Hq1=minimizecoeffwl(Hd,'Astoptol',0.15);
% Hq.coeffwordlength is 14 bits.
% Hq1.coeffwordlength is 11 bits
hfvtool(Hd,Hq,Hq1,'showreference','off');
legend(hfvtool,'44 coefficients floating-point',...
'44 coefficients 14 bits','48 coefficients 11 bits');
```

# minimizecoeffwl

## Tutorials

- “Fixed-Point Data Types”

**Purpose**

Predicted mean-squared error for adaptive filter

**Syntax**

```
[mmse,emse] = msepred(ha,x,d)
[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d)
[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d,m)
```

**Description**

`[mmse,emse] = msepred(ha,x,d)` predicts the steady-state values at convergence of the minimum mean-squared error (`mmse`) and the excess mean-squared error (`emse`) given the input and desired response signal sequences in `x` and `d` and the property values in the `adaptfilt` object `ha`.

`[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d)` calculates three sequences corresponding to the analytical behavior of the LMS adaptive filter defined by `ha`:

- `meanw` — contains the sequence of coefficient vector means. The columns of matrix `meanw` contain predictions of the mean values of the LMS adaptive filter coefficients at each time instant. The dimensions of `meanw` are `(size(x,1))-by-(ha.length)`.
- `mse` — contains the sequence of mean-square errors. This column vector contains predictions of the mean-square error of the LMS adaptive filter at each time instant. The length of `mse` is equal to `size(x,1)`.
- `tracek` — contains the sequence of total coefficient error powers. This column vector contains predictions of the total coefficient error power of the LMS adaptive filter at each time instant. The length of `tracek` is equal to `size(x,1)`.

`[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d,m)` specifies an optional input argument `m` that is the decimation factor for computing `meanw`, `mse`, and `tracek`. When `m > 1`, `msepred` saves every `m`th predicted value of each of these sequences. When you omit the optional argument `m`, it defaults to one.

---

**Note** msepred is available for the following adaptive filters only:  
— adaptfilt.blms — adaptfilt.blmsfft — adaptfilt.lms —  
adaptfilt.nlms — adaptfilt.se Using msepred is the same for any  
adaptfilt object constructed by the supported filters.

---

## Examples

Analyze and simulate a 32-coefficient adaptive filter using 25 trials of 2000 iterations each.

```
x = zeros(2000,25); d = x;      % Initialize variables
ha = fir1(31,0.5);             % FIR system to be identified
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));        % observation noise signal
d = filter(ha,1,x)+n;          % desired signal
l = 32;                         % Filter length
mu = 0.008;                     % LMS step size.
m = 5;                           % Decimation factor for analysis
                                % and simulation results

ha = adaptfilt.lms(l,mu);
[mmse,emse,meanW,mse,traceK] = msepred(ha,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
(emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse]);
title('Mean-Square Error Performance');
axis([0 size(x,1) 0.001 10]);
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE');
```

```

xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim,nn,traceK,'r');
title('Sum-of-Squared Coefficient Errors'); axis([0 size(x,1)...
0.0001 1]);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Squared Error Value');

```

Viewing the plots in this figure you see the various error values plotted in both simulation and theory. Each subplot reveals more information about the results as the simulation converges with the theoretical performance.

[filter](#) | [maxstep](#) | [msesim](#)

**Purpose** Measured mean-squared error for adaptive filter

**Syntax**

```
mse = msesim(ha,x,d)
[mse,meanw,w,tracek] = msesim(ha,x,d)
[mse,meanw,w,tracek] = msesim(ha,x,d,m)
```

**Description** `mse = msesim(ha,x,d)` returns the sequence of mean-square errors in column vector `mse`. The vector contains estimates of the mean-square error of the adaptive filter at each time instant during adaptation. The length of `mse` is equal to `size(x,1)`. The columns of matrix `x` contain individual input signal sequences, and the columns of the matrix `d` contain corresponding desired response signal sequences.

`[mse,meanw,w,tracek] = msesim(ha,x,d)` calculates three parameters that correspond to the simulated behavior of the adaptive filter defined by `ha`:

- `meanw` — sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the LMS adaptive filter coefficients at each time instant. The dimensions of `meanw` are `(size(x,1))-by-(ha.length)`.
- `w` — estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `ha`.
- `tracek` — sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the LMS adaptive filter at each time instant. The length of `tracek` is equal to `size(X,1)`.

`[mse,meanw,w,tracek] = msesim(ha,x,d,m)` specifies an optional input argument `m` that is the decimation factor for computing `meanw`, `mse`, and `tracek`. When `m > 1`, `msepsim` saves every `m`th predicted value of each of these sequences. When you omit the optional argument `m`, it defaults to one.

**Examples** Simulation of a 32-coefficient FIR filter using 25 trials, each trial having 2000 iterations of the adaptation process.

```

x = zeros(2000,25); d = x;           % Initialize variables
ha = fir1(31,0.5);                   % FIR system to be identified
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));              % Observation noise signal
d = filter(ha,1,x)+n;               % Desired signal
l = 32;                               % Filter length
mu = 0.008;                          % LMS Step size.
m = 5;                                % Decimation factor for analysis
                                     % and simulation results

ha = adaptfilt.lms(l,mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanWsim(:,13:15),'b');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse);
title('Mean-Square Error Performance'); axis([0 size(x,1) 0.001...
10]);
legend('Measured MSE');
xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim);
title('Sum-of-Squared Coefficient Errors'); axis([0 size(x,1)...
0.0001 1]);
xlabel('Time Index'); ylabel('Squared Error Value');

```

Calculating the mean squared error for an adaptive filter is one measure of the performance of the adapting algorithm. In this figure, you see a variety of measures of the filter, including the error values.

**See Also** `filter` | `msepred`

**Purpose** Multistage filter from specification object

**Syntax**

```
hd = design(d, 'multistage')
hd = design(..., 'filterstructure', structure)
hd = design(..., 'nstages', nstages)
hd = design(..., 'usehalfbands', hb)
```

**Description**

hd = design(d, 'multistage') designs a multistage filter whose response you specified by the filter specification object d.

hd = design(..., 'filterstructure', structure) returns a filter with the structure specified by structure. Input argument structure is dffir by default and can also be one of the following strings.

structure String	Valid with These Responses
firdecim	Lowpass or Nyquist response
firtdecim	Lowpass or Nyquist response
firinterp	Lowpass or Nyquist response
lowpass	Default lowpass only

Multistage design applies to the default lowpass filter specification object and to decimators and interpolators that use either lowpass or Nyquist responses.

hd = design(..., 'nstages', nstages) specifies nstages, the number of stages to be used in the design. nstages must be an integer or the string auto. To allow the design algorithm to use the optimal number of stages while minimizing the cost of using the resulting filter, nstages is auto by default. When you specify an integer for nstages, the design algorithm minimizes the cost for the number of stages you specify.

hd = design(..., 'usehalfbands', hb) uses halfband filters when you set hb to true. The default value for hb is false.

---

**Note** To see a list of the design methods available for your filter, use `designmethods(hd)`.

---

## Examples

Design a minimum-order, multistage Nyquist interpolator.

```
l = 15; % Interpolation factor. Also the Nyquist band.  
tw = 0.05; % Normalized transition width  
ast = 40; % Minimum stopband attenuation in dB  
d = fdesign.interpolator(1,'nyquist',1,'tw,ast',tw,ast);  
hm = design(d,'multistage');  
fvtool(hm);
```

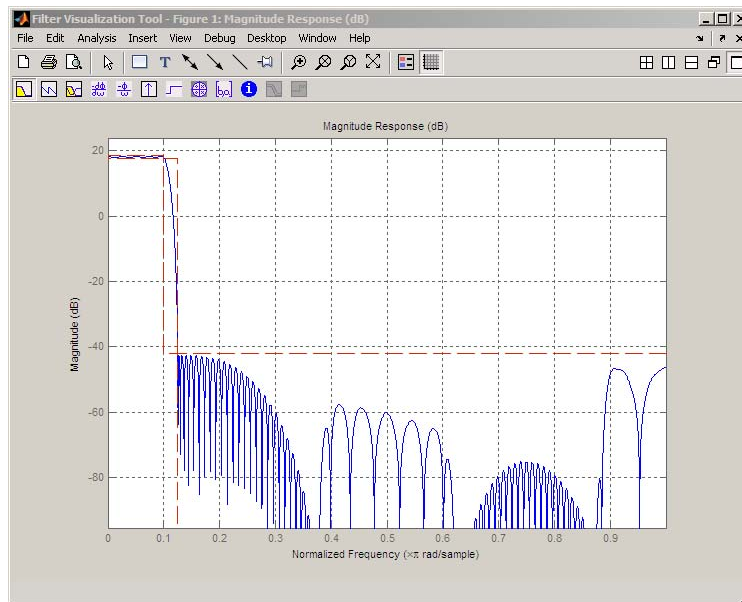

Design a multistage lowpass interpolator with an interpolation factor of 8.

```
m = 8; % Interpolation factor;
```

```
d = fdesign.interpolator(m,'lowpass');  
% Use halfband filters if possible.  
hm = design(d,'multistage','Usehalfbands',true);  
fvtool(hm);
```

This figure shows the response for hm.

---

**Purpose** Power spectral density of filter output due to roundoff noise

**Syntax**

```
hpsd = noisepsd(H,L)
hpsd = noisepsd(H,L,param1,value1,param2,value2,...)
hpsd = noisepsd(H,L,opts)
noisepsd(H,...)
```

**Description** `hpsd = noisepsd(H,L)` computes the power spectral density (PSD) at the output of `dfilt` object or filter System object, `H`, occurring because of roundoff noise. This noise is produced by quantization errors within the filter. `L` is the number of trials used to compute the average. The PSD is computed from the average over the `L` trials. The more trials you specify, the better the estimate, but at the expense of longer computation time. When you do not explicitly specify `L`, the default is 10 trials.

`hpsd` is a psd data object. To extract the PSD vector (the data from the PSD) from `hpsd`, enter

```
get(hpsd, 'data')
```

at the prompt. Plot the PSD data with `plot(hpsd)`. The average power of the output noise (the integral of the PSD) can be computed with `avgpower`, a method of `dspdata` objects:

```
avgpwr = avgpower(hpsd).
```

`hpsd = noisepsd(H,L,param1,value1,param2,value2,...)` where `H` can be either a `dfilt` object or a filter System object, specifies optional parameters via `propertyname/propertyvalue` pairs. Valid psd object property values are:

Property Name	Default Value	Description and Valid Entries
Nfft	512	Specify the number of FFT points to use to calculate the PSD.
NormalizedFrequency	true	Determine whether to use normalized frequency. Enter a logical value of true or false. Because this property is a logical value, and not a string, do not enclose the single quotation marks.
Fs	normalized	Specify the sampling frequency to use when you set NormalizedFrequency to false. Use any integer value greater than 1. Enter the value in Hz.
SpectrumType	onesided	<p>Specify how noisepsd should generate the PSD. Options are onesided or twosided. If you choose a two-sided computation, you can also choose CenterDC = true. Otherwise, CenterDC must be false.</p> <ul style="list-style-type: none"> <li>onesided converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li> <li>twosided converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li> </ul>

Property Name	Default Value	Description and Valid Entries
CenterDC	false	<p>Shift the zero-frequency component to the center of a two-sided spectrum.</p> <ul style="list-style-type: none"><li>• When you set <code>SpectrumType</code> to <code>onesided</code>, it is changed to <code>twosided</code> and the data is converted to a two-sided spectrum.</li><li>• Setting <code>CenterDC</code> to <code>false</code> shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not affect the <code>SpectrumType</code> property setting.</li></ul>
Arithmetic (only for filter System objects)	ARITH	<p>Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to <code>double</code>, <code>single</code>, or <code>fixed</code>. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.</p>

---

**Note** If the spectrum data you specify is calculated over half the Nyquist interval and you do not specify a corresponding frequency vector, the default frequency vector assumes that the number of points in the whole FFT was even. Also, the plot option to convert to a whole or two-sided spectrum assumes the original whole FFT length is even.

---

#### System object

If `H` is a filter System object, `noisepsd` requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the `Arithmetic` parameter, i.e., use the

syntax `[h,w] = noisepsd(H)` , then the following rules apply to this method:

- The System object state is **Unlocked** — `noisepsd` performs double-precision analysis.
- The System object state is **Locked** — `noisepsd` performs analysis based on the locked input data type.

If you do specify the **Arithmetic** parameter, i.e., use the syntax `[h,w] = noisepsd(H, 'Arithmetic', ARITH)`, review the following rules for this method. Which rule applies depends on the value you set for the **Arithmetic** parameter.

<b>Value</b>	<b>System Object State</b>	<b>Rule</b>
ARITH = 'double'	Unlocked	<code>noisepsd</code> performs double-precision analysis.
	Locked	<code>noisepsd</code> performs double-precision analysis.
ARITH = 'single'	Unlocked	<code>noisepsd</code> performs single-precision analysis.
	Locked	<code>noisepsd</code> performs single-precision analysis.

# noisepsd

Value	System Object State	Rule
ARITH = `fixed`	Unlocked	noisepsd produces an error because the fixed-point input data type is unknown.
	Locked	When the input data type is double or single, then noisepsd produces an error because since the fixed-point input data type is unknown.
		When the input data is of fixed-point type, noisepsd performs analysis based on the locked input data type.

noisepsd supports only the following filter System objects:

- dsp.FIRFilter
- dsp.IIRFilter
- dsp.AllpoleFilter
- dsp.BiquadFilter

Regardless of whether H is a `dfilt` object or a filter System object, `hpsd = noisepsd(H,L,opts)` uses an options object, `opts`, to specify the optional input arguments. This specification is not made using property-value pairs in the command. Use `opts = noisepsopts(H)` to create the object. `opts` then has the `noisepsd` settings from H. After creating `opts`, you change the property values before calling `noisepsd`:

```
set(opts,'fs',48e3); % Set Fs to 48 kHz.
```

Regardless of whether  $H$  is a `dfilt` object or a filter System object, `noisepsd(H, ...)` with no output argument launches FVTool.

## Examples

Compute the PSD of the output noise caused by the quantization processes in a fixed-point, direct form FIR filter.

```
b = firgr(27,[0 .4 .6 1],[1 1 0 0]);
h = dfilt.dffir(b); % Create the filter object.
% Quantize the filter to fixed-point.
h.arithmetic = 'fixed';
hpsd = noisepsd(h);
plot(hpsd)
```

`hpsd` looks similar to the following figure—the data resulting from the noise PSD calculation. You can review the data in `hpsd.data`.

`filter` | `noisepsopts` | `norm` | `reorder` | `scale`

**Purpose** Options for running filter output noise PSD

**Syntax** `opts = noisepsdopts(H)`

**Description** `opts = noisepsdopts(H)` uses the current settings in the `dfilt` object or the filter System object, `H`, to create an options object, `opts`, that contains specified options for computing the output noise PSD. You can pass `opts` to the `scale` method as an input argument to apply scaling settings to a second-order filter.

`noisepsdopts` returns the options object, `opts`, with which you can set the following properties for `noisepsd`:

Property Name	Default Value	Description and Valid Entries
Nfft	512	Specify the number of FFT points to use to calculate the PSD.
NormalizedFrequency	true	Determine whether to use normalized frequency. Enter a logical value of the logical true or false. Because this property is a logical value, and not a string, do not enclose with single quotation marks.
Fs	normalized	Specify the sampling frequency to use when you set <code>NormalizedFrequency</code> to false. Use any integer value greater than 1. Enter the value in Hz.

# noisepsdopts

Property Name	Default Value	Description and Valid Entries
SpectrumType	onesided	<p>Specify how noisepsd should generate the PSD. Options are onesided or twosided. If you choose a two-sided computation, you can also choose centerdc = true. Otherwise, centerdc must be false.</p> <ul style="list-style-type: none"><li>• onesided converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li><li>• twosided converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li></ul>
CenterDC	false	<p>Shift the zero-frequency component to the center of a two-sided spectrum.</p> <ul style="list-style-type: none"><li>• When you set SpectrumType to onesided, it is changed to twosided and the data is converted to a two-sided spectrum.</li><li>• Setting CenterDC to false shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum.</li></ul>

Property Name	Default Value	Description and Valid Entries
		This operation does not effect the SpectrumType property setting.
Arithmetic (only for filter System objects)	ARITH	Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to double, single, or fixed. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

# norm

---

**Purpose** P-norm of filter

**Syntax**

```
l = norm(ha)
l = norm(ha, pnorm)
l = norm(hd)
l = norm(hd, pnorm)
l = norm(hm)
l = norm(hm, pnorm)
```

**Description** All of the variants of `norm` return the filter p-norm for the object in the syntax, either an adaptive filter, a digital filter, or a multirate filter. When you omit the `pnorm` argument, `norm` returns the L2-norm for the object.

Note that by Parseval's theorem, the L2-norm of a filter is equal to the l2 norm. This equality is not true for the other norm variants.

## For `adaptfilt` Objects

`l = norm(ha)` returns the L2-norm of an adaptive filter. `l = norm(ha, pnorm)` adds the input argument `pnorm` to let you specify the norm returned. `pnorm` can be either

- Frequency-domain norms specified by one of `L1`, `L2`, or `Linf`
- Discrete-time domain norms specified by one of `l1`, `l2`, or `linf`

## For `dfilt` Objects

`l = norm(hd)` returns the L2-norm of a discrete-time filter.

`l = norm(hd, pnorm)` includes input argument `pnorm` that lets you specify the norm returned. `pnorm` can be either

- Frequency-domain norms specified by one of `L1`, `L2`, or `Linf`
- Discrete-time domain norms specified by one of `l1`, `l2`, or `linf`

By Parseval's theorem, the L2-norm of a filter is equal to the l2 norm. This equality is not true for the other norm variants.

IIR filters respond slightly differently to `norm`. When you compute the l2, linf, L1, and L2 norms for an IIR filter, `norm(..., L2, tol)` lets you

specify the tolerance for the accuracy in the computation. For `l1`, `l2`, `L2`, and `linf`, `norm` uses the tolerance to truncate the infinite impulse response that it uses to calculate the norm. For `L1`, `norm` passes the tolerance to the numerical integration algorithm. Refer to Examples to see this in use. You cannot specify `Linf` for the norm and include the `tol` option.

### For `mfilt` Objects

`l = norm(hm)` returns the L2-norm of a multirate filter.

`l = norm(hm, pnorm)` includes argument `pnorm` to let you specify the norm returned. `pnorm` can be either

- Frequency-domain norms specified by one of `L1`, `L2`, or `Linf`
- Discrete-time domain norms specified by one of `l1`, `l2`, or `linf`

Note that, by Parseval's theorem, the L2-norm of a filter is equal to the `l2` norm. This equality is not true for the other norm variants.

## Examples

### Adaptfilt Objects

For the adaptive filter example, compute the 2-norm of an `adaptfilt` object, here an LMS-based adaptive filter.

```
Ha = adaptfilt.lms; % norm(ha) is zero because all coeffs are zero
% Create some data to filter to generate filter coeffs
x = randn(100,1);
d = x + randn(100,1);
[y,e] = filter(Ha,x,d);
L2 = norm(Ha); % Now norm(ha) is nonzero
```

### Dfilt Objects

To demonstrate the tolerance option used with an IIR filter (`dfilt` object), compute the 2-norm of filter `hd` with a tolerance of `1e-10`.

```
H = fdesign.lowpass('n,fc',5,0.4);
Hd = butter(H);
L2=norm(Hd,'l2',1e-10);
```

## Mfilt Objects

In this example, compute the infinity norm of an FIR polyphase interpolator, which is an `mfilt` object.

```
Hm = mfilt.firinterp;  
Linf = norm(Hm, 'linf');
```

## See Also

[reorder](#) | [scale](#) | [scalecheck](#)

**Purpose**

Normalize filter numerator or feed-forward coefficients

**Syntax**

```
normalize(hq)
g = normalize(hd)
```

**Description**

`normalize(hq)` normalizes the filter numerator coefficients for a quantized filter to have values between -1 and 1. The coefficients of `hq` change — `normalize` does not copy `hq` and return the copy. To restore the coefficients of `hq` to the original values, use `denormalize`.

Note that for lattice filters, the feed-forward coefficients stored in the property `lattice` are normalized.

`g = normalize(hd)` normalizes the numerator coefficients for the filter `hq` to between -1 and 1 and returns the gain `g` due to the normalization operation. Calling `normalize` again does not change the coefficients. `g` always returns the gain returned by the first call to `normalize` the filter.

**Examples**

Create a direct form II quantized filter that uses second-order sections. Then use `normalize` to maximize the use of the range of representable coefficients.

```
d=fdesign.lowpass('n,fp,ap,ast',8,.5,2,40);
hd=design(d,'ellip');
hd.arithmetic='fixed';
```

Check the filter coefficients. Note that `InitialSOSMatrix(3,2)>1`

```
InitialSOSMatrix = hd.sosMatrix;
```

Use `normalize` to modify the coefficients into the range between -1 and 1. The output `g` contains the gains applied to each section of the SOS filter.

```
g = normalize(hd);
```

None of the numerator coefficients exceed -1 or 1.

# normalize

---

## **See Also**

denormalize

**Purpose** Switch filter specification between normalized frequency and absolute frequency

**Syntax**  
`normalizefreq(d)`  
`normalizefreq(d, flag)`  
`normalizefreq(d, false, fs)`

**Description** `normalizefreq(d)` normalizes the frequency specifications in filter specifications object `d`. By default, the `NormalizedFrequency` property is set to `true` when you create a design object. You provide the design specifications in normalized frequency units. `normalizefreq` does not affect filters that already use normalized frequency.

If you use this syntax when `d` does not use normalized frequency specifications, all of the frequency specifications are normalized by  $fs/2$  so they lie between 0 and 1, where `fs` is specified in the object. Included in the normalization are the filter properties that define the filter pass and stopband edge locations by frequency:

- `F3 dB` — Used by IIR filter specifications objects to describe the passband cutoff frequency
- `Fcutoff` — Used by FIR filter specifications objects to describe the passband cutoff frequency
- `Fpass` — Describes the passband edges
- `Fstop` — Describes the stopband edges

In this syntax, `normalizefreq(d)` assumes you specified `fs` when you created `d` or changed `d` to use absolute frequency specifications.

`normalizefreq(d, flag)` where `flag` is either **true** or **false**, specifies whether the `NormalizedFrequency` property value is `true` or `false` and therefore whether the filter normalizes the sampling frequency `fs` and other related frequency specifications. `fs` defaults to 1 for this syntax.

When you do not provide the input argument `flag`, it defaults to `true`. If you set `flag` to `false`, affected frequency specifications are multiplied by  $fs/2$  to remove the normalization. Use this syntax to switch your

# normalizefreq

---

filter between using normalized frequency specifications and not using normalized frequency specifications.

`normalizefreq(d, false, fs)` lets you specify a new sampling frequency `fs` when you set the `NormalizedFrequency` property to `false`.

## Examples

These examples demonstrate using `normalizefreq` in both of the major syntax applications—setting the design object frequency specifications to use absolute frequency (`normalizefreq(hd, false, fs)`) and resetting a design object to using normalized frequencies (`normalizefreq(d)`).

Construct a highpass filter specifications object by specifying the passband and stopband edges and the desired attenuations in the bands. By default, provide the frequency specifications in normalized values between 0 and 1.

```
d=fdesign.highpass(0.35, 0.45, 60, 40);
```

`Fstop` and `Fpass` are in normalized form, and the property `NormalizedFrequency` is `true`.

Now use `normalizedfreq` to convert to absolute frequency specifications, with a sampling frequency of 1000 Hz.

```
normalizefreq(d, false, 1e3);
```

Both of the attenuation specifications remain the same. The passband and stopband edge definitions now appear in Hz, where the new value represents the normalized values multiplied by  $F_s/2$ , or 500 Hz.

Converting to using normalized frequencies consists of using `normalizefreq` with the design object `d`.

```
normalizefreq(d)
```

For bandstop, bandpass, and multiple band filter specifications objects, `normalizefreq` works the same way for all band edge definitions. When you do not provide the sampling frequency `Fs` as an input argument and you are converting to absolute frequency specifications, `normalizefreq` sets `Fs` to 1, as shown in this example.

```
d=fdesign.bandstop(0.25,0.35,0.55,0.65,50,60);  
normalizefreq(d,false)
```

# nstates

---

**Purpose**            Number of filter states

**Syntax**            `n = nstates(hd)`  
                      `n = nstates(hm)`

**Description**      **Discrete-Time Filters**

`n = nstates(hd)` returns the number of states `n` in the discrete-time filter `hd`. The number of states depends on the filter structure and the coefficients.

**Multirate Filters**

`n = nstates(hm)` returns the number of states `n` in the multirate filter `hm`. The number of states depends on the filter structure and the coefficients.

**Examples**

Check the number of states for two different filters, one a direct form FIR filter, the other a multirate filter.

```
h = fir1s(30,[0 .1 .2 .5]*2,[1 1 0 0]);  
hd = dfilt.dffir(h);  
NstateDF = nstates(hd);  
hm = mfilt.firsrc(2,3);  
NstateMR = nstates(hm);
```

<b>Purpose</b>	Order of fixed-point filter
<b>Syntax</b>	<code>n = order(hq)</code> <code>n = order(hs)</code>
<b>Description</b>	<p><code>n = order(hq)</code> returns the order <code>n</code> of the quantized filter <code>hq</code>. When <code>hq</code> is a single-section filter, <code>n</code> is the number of delays required for a minimum realization of the filter.</p> <p>When <code>hq</code> has more than one section, <code>n</code> is the number of delays required for a minimum realization of the overall filter.</p> <p><code>n = order(hs)</code> returns the order <code>n</code> of the filter System object <code>hs</code>. The order depends on the filter structure and the reference double-precision floating-point coefficients. <code>hs</code> can be one of the following filter structures:</p> <ul style="list-style-type: none"><li>• <code>dsp.FIRFilter</code></li><li>• <code>dsp.BiquadFilter</code></li><li>• <code>dsp.FIRInterpolator</code></li><li>• <code>dsp.CICInterpolator</code></li><li>• <code>dsp.FIRDecimator</code></li><li>• <code>dsp.CICDecimator</code></li><li>• <code>dsp.FIRRateConverter</code></li></ul>
<b>Examples</b>	<p>Create a discrete-time filter, quantize it, and convert it to second-order section form. Then, use <code>order</code> to check the order of the filter.</p> <pre>[b,a] = ellip(4,3,20,.6); % Create the reference filter. hq = dfilt.df2(b,a); % Quantize the filter and convert to second-order sections. set(hq,'arithmetic','fixed');  n=order(hq); % Check the order of the overall filter.</pre>

# parallel

---

**Purpose** Multirate parallel filter structure

**Syntax** `hmp = parallel(hm1, hm2, ..., hmn)`

**Description** `hmp = parallel(hm1, hm2, ..., hmn)` returns a multirate filter `hmp` that is two or more `mfilt` objects `hm1`, `hm2`, and so on connected in a parallel structure. Each filter in the structure is one stage and all stages must have the same rate change factor.

Access the individual filters in the parallel structure by

**See Also** `dfilt.parallel` | `mfilt`

## Purpose

Phase delay of filter

## Syntax

```
[phi,w]=phasedelay(hfilt)
[phi,w]=phasedelay(hfilt,n)
phasedelay(hfilt)
[phi,w] = phasedelay(hs)
[phi,w] = phasedelay(hs,n)
[phi,w] = phasedelay(hs,Name,Value)
phasedelay(hs)
```

## Description

`phasedelay` returns the phase delay based on the current filter coefficients. This section describes `phasedelay` operation for discrete-time filters and multirate filters. For more information about optional input arguments for `phasedelay`, refer to `phasedelay` in Signal Processing Toolbox documentation.

`[phi,w]=phasedelay(hfilt)` returns the phase response `phi` of the filter `hfilt` and the corresponding frequencies `w` at which the function evaluates the phase delay.

The phase delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[phi,w]=phasedelay(hfilt,n)` returns the phase delay `phi` of the filter `hfilt` and the corresponding frequencies `w` at which the function evaluates the phase delay. The phase delay is evaluated at `n` points equally spaced around the upper half of the unit circle.

`phasedelay(hfilt)` displays the phase delay of `hfilt` in the Filter Visualization Tool (FVTool).

`[phi,w] = phasedelay(hs)` returns the phase delay for the filter System object `hs` using 8192 samples.

`[phi,w] = phasedelay(hs,n)` returns the phase delay for the filter System object `hs` using `n` samples.

`[phi,w] = phasedelay(hs,Name,Value)` returns the phase delay with additional options specified by one or more `Name,Value` pair arguments.

`phasedelay(hs)` uses FVTool to plot the phase delay of the filter System object `hs`.

## Input Arguments

### **hfilter**

`hfilter` is either:

- A discrete-time `dfilter`, or multirate `mfilt` filter object
- A vector of discrete-time, or multirate filter objects

The multirate filter delay response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `phasedelay` assumes the filter is running at that rate.

For multistage cascades, `phasedelay` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `phasedelay` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `phasedelay` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `phasedelay`, the function interprets `fs` as the rate at which the equivalent filter is running.

### **hs**

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`

- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

**n**

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

**Default:** 8192

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'Arithmetic'**

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

## Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **phi**

Complex, n-element phase-delay vector. If `hfilt` is a vector of filters, `phi` is a complex, `length(hfilt)`-by-`n` matrix of phase-delay vectors whose columns correspond to each filter in `hfilt`. If `n` is not specified, the function uses a default value of 8192.

For adaptive filters, `phi` is the instantaneous phase delay.

### **w**

Frequency vector of length `n`, in radians/sample. `w` consists of `n` points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If `hfilt` is a vector of filters, `w` is a complex, `length(hfilt)`-by-`n` matrix of phase-delay vectors whose columns correspond to each filter in `hfilt`. If `n` is not specified, the function uses a default value of 8192.

## Algorithms

You can provide `fs`, the sampling frequency, as an input as well. `phasedelay` uses `fs` to calculate the delay response and plots the response to `fs/2`.

## See Also

`freqz` | `grpdelay` | `phasez` | `zerophase` | `zplane` | `freqz` | `fvtool` | `phasez` | `zerophase`

**Purpose** Unwrapped phase response for filter

**Syntax**

```
[phi,w]=phasez(hfilt)
[phi,w]=phasez(hfilt,n)
phasez(hfilt)
[phi,w] = phasez(hs)
[phi,w] = phasez(hs,n)
[phi,w] = phasez(hs,Name,Value)
phasez(hs)
```

**Description** `phasez` returns the unwrapped phase response based on the current filter coefficients. This section describes `phasez` operation for adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more information about optional input arguments for `phasez`, refer to `phasez` in Signal Processing Toolbox documentation.

`[phi,w]=phasez(hfilt)` returns the phase response `phi` of the filter `hfilt` and the corresponding frequencies `w` at which the function evaluates the phase response. The phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[phi,w]=phasez(hfilt,n)` returns the phase response `phi` of the filter `hfilt` and the corresponding frequencies `w` at which the function evaluates the phase response. The phase response is evaluated at `n` points equally spaced around the upper half of the unit circle.

`phasez(hfilt)` displays the phase response of `hfilt` in the Filter Visualization Tool (FVTool).

`[phi,w] = phasez(hs)` returns a phase response for the filter System object `hs` using 8192 samples.

`[phi,w] = phasez(hs,n)` returns a phase response for the filter System object `hs` using `n` samples.

`[phi,w] = phasez(hs,Name,Value)` returns a phase response with additional options specified by one or more `Name,Value` pair arguments.

`phasez(hs)` uses FVTool to plot the phase response of the filter System object `hs`.

## Input Arguments

### **hfilt**

`hfiltr` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `phasez` assumes the filter is running at that rate.

For multistage cascades, `phasez` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `phasez` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `phasez` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `phasez`, the function interprets `fs` as the rate at which the equivalent filter is running.

### **hs**

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`

- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

## **n**

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

**Default:** 8192

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **'Arithmetic'**

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **phi**

Complex,  $n$ -element phase response vector. If `hfilt` is a vector of filters, `phi` is a complex, `length(hfilt)`-by- $n$  matrix of phase response vectors whose columns correspond to each filter in `hfilt`. If  $n$  is not specified, the function uses a default value of 8192.

For adaptive filters, `phi` is the instantaneous phase response.

### **w**

Frequency vector of length  $n$ , in radians/sample. `w` consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If `hfilt` is a vector of filters, `w` is a complex, `length(hfilt)`-by- $n$  matrix of phase response vectors whose columns correspond to each filter in `hfilt`. If  $n$  is not specified, the function uses a default value of 8192.

- dsp.FIRRateConverter

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

### 'Arithmetic'

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the **CoefficientDataType** property and whether the System object is locked or unlocked.

## Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the

System Object State	Coefficient Data Type	Rule
		CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### p

Polyphase matrix  $p$  of the multirate filter. Each row in the matrix represents one subfilter of the multirate filter. The first row of matrix  $p$  represents the first subfilter, the second row the second subfilter, and so on to the last subfilter.

## Examples

When you create a multirate filter that uses polyphase decomposition, `polyphase` lets you analyze the component filters individually by returning the components as rows in a matrix.

First, create an interpolate-by-eight filter.

```
hm=mfilt.firinterp(8)
```

```
hm =
```

```
          FilterStructure: 'Direct-Form FIR Polyphase Interpolator'  
          Numerator: [1x192 double]  
InterpolationFactor: 8  
 PersistentMemory: false  
          States: [23x1 double]
```

In this syntax, the matrix `p` contains all of the subfilters for `hm`, one filter per matrix row.

```
p=polyphase(hm)
```

```
p =
```

```
Columns 1 through 8
```

```
          0          0          0          0          0          0          0          0

```

Finally, using `polyphase` without an output argument opens the Filter Visualization Tool, ready for you to use the analysis capabilities of the tool to investigate the interpolator `hm`.

`polyphase(hm)`

In the following figure, FVTool shows the magnitude responses for the subfilters.

# polyphase

**See Also**

`mfilt`

**Purpose** Most recent fixed-point filtering operation report

**Syntax** `rlog = qreport(h)`

**Description** `rlog = qreport(h)` returns the logging report stored in the filter object `h` in the object `rlog`. The ability to log features of the filtering operation is integrated in the fixed-point filter object and the `filter` method.

Each time you filter a signal with `h`, new log data overwrites the results in the filter from the previous filtering operation. To save the log from a filtering simulation, change the name of the output argument for the operation before subsequent filtering runs.

---

**Note** `qreport` requires Fixed-Point Designer software and that filter `h` is a fixed-point filter. Data logging for `fi` operations is a preference you set for each MATLAB session. To learn more about logging, `LoggingMode`, and `fi` object preferences, refer to `fipref` in the Fixed-Point Designer documentation.

Also, you cannot use `qreport` to log the filtering operations from a fixed-point Farrow filter.

---

Enable logging during filtering by setting `LoggingMode` to `on` for `fi` objects for your MATLAB session. Trigger logging by setting the `Arithmetic` property for `h` to `fixed`, making `h` a fixed-point filter and filtering an input signal.

### Using Fixed-Point Filtering Logging

Filter operation logging with `qreport` requires some preparation in MATLAB. Complete these steps before you use `qreport`.

- 1 Set the fixed-point object preference for `LoggingMode` to `on` for your MATLAB session. This setting enables data logging.

```
fipref('LoggingMode', 'on')
```

- 2 Create your fixed-point filter.
- 3 Filter a signal with the filter.
- 4 Use `qreport` to return the filtering information stored in the filter object.

`qreport` provides a way to instrument your fixed-point filters and the resulting data log offers insight into how the filter responds to a particular input data signal.

Report object `rlog` contains a filter-structure-specific list of internal signals for the filter. Each signal contains

- Minimum and maximum values that were recorded during the last simulation. Minimum and maximum values correspond to values before quantization.
- Representable numerical range of the word length and fraction length format
- Number of overflows during filtering for that signal.

## Examples

`qreport` depends on the `LoggingMode` preference for fixed-point objects. This example demonstrates the process for enabling and using `qreport` to log the results of filtering with a fixed-point filter. `hd` is a fixed-point direct-form FIR filter.

```
f = fipref('loggingmode','on');
hd = design(fdesign.lowpass,'equiripple');
hd.arithmetic = 'fixed';
fs = 1000;           % Input sampling frequency.
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
y = filter(hd,x);
rlog = qreport(hd)
```

View the logging report of a direct-form II, second-order sections IIR filter the same way. While this example sets `loggingmode` to on, you

do that only once for a MATLAB session, unless you reset the mode to off during the session.

```
fipref('loggingmode','on');  
hd = design(fdesign.lowpass,'ellip');  
hd.arithmetic = 'fixed';  
y = filter(hd,rand(100,1));  
rlog = qreport(hd)
```

**See Also**

[dfilt](#) | [mfilt](#)

# realizemdl

---

**Purpose** Simulink subsystem block for filter

**Syntax** `realizemdl(hq)`  
`realizemdl(hq,Name,Value)`

**Description** `realizemdl(hq)` generates a model of filter `hq` in a Simulink subsystem block using sum, gain, and delay blocks from Simulink. The properties and values of `hq` define the resulting subsystem block parameters.

`realizemdl` requires Simulink. To accurately realize models of quantized filters, use Simulink Fixed-Point.

`realizemdl(hq,Name,Value)` generates the model for `hq` with additional options specified by one or more `Name,Value` pair arguments. Using name-value pair arguments lets you control more fully the way the block subsystem model gets built. You can specify such details as where the block goes, what the name is, or how to optimize the block structure.

---

**Note** Subsystem filter blocks that you use `realizemdl` to create support sample-based input and output only. You cannot input or output frame-based signals with the block.

---

## Input Arguments

### `hq`

One of the following types of filter object or filter System object:

- Discrete-time filter (`dfilt`) object
- Multirate filter (`mfilt`) object.
- Filter System object. The function supports the following structures:
  - `dsp.FIRFilter`
  - `dsp.BiquadFilter`
  - `dsp.FIRInterpolator`

- dsp.CICInterpolator
- dsp.FIRDecimator
- dsp.CICDecimator
- dsp.FIRRateConverter

## Name-Value Pair Arguments

### 'Destination'

'current' (default) | 'new' | subsystemname

Specify whether to add the block to your current Simulink model or create a new model to contain the block. If you provide the name of a current subsystem in *subsystemname*, *realizemdl* adds the new block to the specified subsystem.

### 'Blockname'

'filter' (default)

Provide the name for the new subsystem block. By default the block is named Filter.

### 'MapCoeffstoPorts'

'off' (default) | 'on'

Specify whether to map the coefficients of the filter to the ports of the block.

### 'MapStates'

'off' (default) | 'on'

Specify whether to apply the current filter states to the realized model. Such specification allows you to save states from a filter object you may have used or configured in a specific way. The default setting of 'off' means the states are not transferred to the model. Setting the property to 'on' preserves the current filter states in the realized model.

### 'OverwriteBlock'

'off' (default) | 'on'

Specify whether to overwrite an existing block with the same name or create a new block.

### **'OptimizeZeros'**

'off' (default) | 'on'

Specify whether to remove zero-gain blocks.

### **'OptimizeOnes'**

'off' (default) | 'on'

Specify whether to replace unity-gain blocks with direct connections.

### **'OptimizeNegOnes'**

'off' (default) | 'on'

Specify whether to replace negative unity-gain blocks with a sign change at the nearest sum block.

### **'OptimizeDelayChains'**

'off' (default) | 'on'

Specify whether to replace delay chains made up of  $n$  unit delays with a single delay by  $n$ .

### **'CoeffNames'**

{ 'Num' } (default FIR) | { 'Num', 'Den' } (default direct form IIR) |  
{ 'Num', 'Den', 'g' } (default IIR SOS) | { 'Num\_1', 'Num\_2', 'Num\_3' ... }  
(default multistage) | { 'K' } (default form lattice)

Specify the coefficient variable names as string variables in a cell array. `MapCoeffsToPorts` must be set to 'on' for this property to apply.

### **'InputProcessing'**

'columns as channels' (default) | 'elements as channels' |  
'inherited'

Specify sample-based ('elements as channels') or frame-based ('columns as channels') processing.

---

**Note** The `inherited` option will be removed in a future release.

---

### 'RateOption'

'enforce single rate' (default) | 'allow multirate'

Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when InputProcessing is 'columns as channels'.

### 'Arithmetic'

`double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the

System Object State	Coefficient Data Type	Rule
		CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

Realize Simulink model of lowpass Butterworth filter:

```
d = fdesign.lowpass('N,F3dB',4,0.25);
Hd = design(d,'butter');
realizemdl(Hd);
```

The realized model is shown in the figure:

# rebuffer\_delay

---

**Purpose** Number of samples of delay introduced by buffering and unbuffering operations

**Syntax** `d = rebuffer_delay(f,n,v)`  
`d = rebuffer_delay(f,n,v,'mode')`

**Description** `d = rebuffer_delay(f,n,v)` returns the delay, in samples, introduced by the Buffer or Unbuffer block in multitasking operations.

`d = rebuffer_delay(f,n,v,'mode')` returns the delay, in samples, introduced by the Buffer or Unbuffer block in the specified tasking mode.

## Input Arguments

**f**

Frame size of the input to the Buffer or Unbuffer block.

**n**

Size of the output buffer. Specify one of the following:

- The value of the **Output buffer size** parameter, if you are computing the delay introduced by a Buffer block.
- 1, if you are computing the delay introduced by an Unbuffer block.

**v**

Amount of buffer overlap. Specify one of the following:

- The value of the **Buffer overlap** parameter, if you are computing the delay introduced by a Buffer block.
- 0, if you are computing the delay introduced by an Unbuffer block.

**'mode'**

The tasking mode of the model. Specify one of the following options:

- 'singletasking'
- 'multitasking'

**Default:** 'multitasking'

## Definitions

### Multitasking

When you run a model in `MultiTasking` mode, Simulink processes groups of blocks with the same execution priority through each stage of simulation based on task priority. Multitasking mode helps to create valid models of real-world multitasking systems, where sections of your model represent concurrent tasks. The **Tasking mode for periodic sample times** parameter on the Solver pane of the Configuration Parameters dialog box controls this setting.

### SingleTasking

When you run a model in `SingleTasking` mode, Simulink processes all blocks through each stage of simulation together. The **Tasking mode for periodic sample times** parameter on the Solver pane of the Configuration Parameters dialog box controls this setting.

## Examples

Compute the delay introduced by a Buffer block in a multitasking model:

- 1 Open a model containing a Buffer block. For this example, open the `ex_buffer_tut4` model by typing `ex_buffer_tut4` at the MATLAB command line.
- 2 Double-click the Buffer block to open the block mask. Verify that you have the following settings:
  - **Output buffer size** = 3
  - **Buffer overlap** = 1
  - **Initial conditions** = 0

Based on these settings, two of the required inputs to the `rebuffer_delay` function are as follows:

- `n` = 3
- `v` = 1

## rebuffer\_delay

---

**3** To determine the frame size of the input signal to the Buffer block, open the Signal From Workspace block mask. Verify that you have the following settings:

- **Signal** = sp\_examples\_src
- **Sample time** = 1
- **Samples per frame** = 4

Because **Samples per frame** = 4, you know the *f* input to the `rebuffer_delay` function is 4.

**4** After you verify the values of all the inputs to the `rebuffer_delay` function, determine the delay that the Buffer block introduces in this multitasking model. To do so, type the following at the MATLAB command line:

```
d = rebuffer_delay(4,3,1)

d =

     8
```

---

Compute the delay introduced by an Unbuffer block in a multitasking model:

- 1** Open a model containing an Unbuffer block. For this example, open the `ex_unbuffer_ref1` model by typing `ex_unbuffer_ref1` at the MATLAB command line.
- 2** To determine the frame size of the input to the Buffer block, open the Signal From Workspace block mask by double-clicking the block in your model. Verify that you have the following settings:
  - **Signal** = sp\_examples\_src
  - **Sample time** = 1
  - **Samples per frame** = 3

Because **Samples per frame** = 3, you know the  $f$  input to the `rebuffer_delay` function is 3.

- 3 Use the `rebuffer_delay` function to determine the amount of delay that the Unbuffer block introduces in this multitasking model. To compute the delay introduced by the Unbuffer block, use  $f = 3$ ,  $n = 1$  and  $v = 0$ .

```
d = rebuffer_delay(3,1,0)
```

```
d =  
    3
```

## See Also

Buffer | Unbuffer

## How To

- “Buffer Delay and Initial Conditions”

# reffilter

---

**Purpose** Reference filter for fixed-point or single-precision filter

**Syntax** href = reffilter(hd)

**Description** href = reffilter(hd) returns a new filter href that has the same structure as hd, but uses the reference coefficients and has its arithmetic property set to double. Note that hd can be either a fixed-point filter (arithmetic property set to 'fixed', or a single-precision floating-point filter whose arithmetic property is 'single').

reffilter(hd) differs from double(hd) in that

- the filter href returned by reffilter has the reference coefficients of hd.
- double(hd) returns the quantized coefficients of hd represented in double-precision.

To check the performance of your fixed-point filter, use href = reffilter(hd) to quickly have the floating-point, double-precision version of hd available for comparison.

## Examples

Compare several fixed-point quantizations of a filter with the same double-precision floating-point version of the filter.

```
h = dfilt.dffir(firceqrip(87,.5,[1e-3,1e-6])); % Lowpass filter.
h1 = copy(h); h2 = copy(h); % Create copies of h.
h.arithmetic = 'fixed'; % Set h to filter using fixed-point...
% arithmetic.
h1.arithmetic = 'fixed'; % Same for h1.
h2.arithmetic = 'fixed'; % Same for h2.
h.CoeffWordLength = 16; % Use 16 bits to represent the...
% coefficients.
h1.CoeffWordLength = 12; % Use 12 bits to represent the...
% coefficients.
h2.CoeffWordLength = 8; % Use 8 bits to represent the...
% coefficients.

href = reffilter(h);
hfvt = fvtool(href,h,h1,h2);
```

```

set(hfvt,'ShowReference','off'); % Reference displayed once
                                % already.
legend(hfvt,'Reference filter','16-bits','12-bits','8-bits');

```

The following plot, taken from FVTool, shows `href`, the reference filter, and the effects of using three different word lengths to represent the coefficients.

As expected, the fidelity of the fixed-point filters suffers as you change the representation of the coefficients. With `href` available, it is easy to see just how the fixed-point filter compares to the ideal.

## See Also

`double`

# reorder

---

**Purpose** Rearrange sections in SOS filter

**Syntax**

```
reorder(hd,order)
reorder(hd,numorder,denorder)
reorder(hd,numorder,denorder,svorder)
reorder(hd,filter_type)
reorder(hd,dir_flag)
reorder(hd,dir_flag,sv)
reorder(hs,...)
reorder(hs,...,Name,Value)
```

**Description** `reorder(hd,order)` rearranges the sections of filter `hd` using the vector of indices provided in `order`.

`reorder(hd,numorder,denorder)` reorders the numerator and denominator separately using the vectors of indices in `numorder` and `denorder`.

`reorder(hd,numorder,denorder,svorder)` specifies that the scale values can be independently reordered.

`reorder(hd,filter_type)` reorders `hd` in a way suitable for the specified filter type. This reordering mode can be especially helpful for fixed-point implementations where the order of the filter sections can significantly affect your filter performance.

`reorder(hd,dir_flag)` specifies rearranges the sections according to proximity to the origin of the poles of the sections.

`reorder(hd,dir_flag,sv)` reorders scale values in addition to rearranging sections according to pole-origin proximity.

`reorder(hs,...)` rearranges the sections of the filter System object `hs` according to any of the preceding input arguments.

`reorder(hs,...,Name,Value)` rearranges the sections of the filter System object `hs` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **hd**

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsosfilter` object.

### **hs**

`dsp.BiquadFilter` filter System object.

### **order**

Vector of indices used to reorder the filter sections. `order` does not need to contain all of the indices of the filter. Omitting one or more filter section indices removes the omitted sections from the filter. You can use a logical array to remove sections from the filter, but not to reorder it.

### **numorder**

Vector of indices used to reorder the numerator. `numorder` and `denorder` must be the same length.

### **denorder**

Vector of indices used to reorder the denominator. `numorder` and `denorder` must be the same length.

### **svorder**

Independent reordering of scale values. When `svorder` is not specified, the scale values are reordered with the numerator. The output scale value always remains on the end when you use the argument `numorder` to reorder the scale values.

### **filter\_type**

'auto' | 'bandpass' | 'bandstop' | 'highpass' | 'lowpass'

Filter type. The 'auto' option and automatic ordering only apply to filters that you used `fdesign` to create. With the 'auto' option as an input argument, `reorder` automatically rearranges the filter sections depending on the specification response type of the design.

**dir\_flag**

'down' | 'up'

Pole direction flag. When `dir_flag` is 'up', the first filter section contains the poles closest to the origin, and the last section contains the poles closest to the unit circle. When `ir_flag` is 'down', the sections are ordered in the opposite direction. `reorder` always pairs zeros with the poles closest to them.

**sv**

'poles' | 'zeros'

Reorder scale values according to poles or zeros. By default the scale values are not reordered when you use the `dir_flag` input argument.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'Arithmetic'**

'double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Examples

Being able to rearrange the order of the sections in a filter can be a powerful tool for controlling the filter process. This example uses `reorder` to change the sections of a `df2sos` filter. Let `reorder` do the reordering automatically in the first example. In the second, use `reorder` to specify the new order for the sections.

First use the automatic reordering option on a lowpass filter.

```
d = fdesign.lowpass('n,f3db',15,0.75);
hd = design(d,'butter');
hdreorder=reorder(hd,'auto');
```

For another example of using `reorder`, create an SOS filter in the direct form II implementation.

```
[z,p,k] = butter(15,.5);
[sos, g] = zp2sos(z,p,k);
hd = dfilt.df2sos(sos,g);
reorder(hd, [1 3:7 2 8]);
hfvt = fvtool(hd, 'analysis', 'coefficients');
```

Reorder the sections by moving the second section to be between the seventh and eighth sections.

```
reorder(hd, [1 3:7 2 8]);
hfvt = fvtool(hd, 'analysis', 'coefficients');
```

Remove the third, fourth, and seventh sections.

```
hd1 = copy(hd);
reorder(hd1, logical([1 1 0 0 1 1 0 1]));
setfilter(hfvt, hd1);
```

Move the first filter to the end, and remove the eighth section

```
hd2 = copy(hd);  
reorder(hd2, [2:7 1]);  
setfilter(hfvt, hd2);
```

Move the numerator and denominator independently.

```
hd3 = copy(hd);  
reorder(hd3, [1 3:8 2], [1:8]);  
setfilter(hfvt, hd3);
```

[cumsec](#) | [scale](#) | [scaleopts](#)

# reset

---

**Purpose** Reset filter properties to initial conditions

**Syntax** `reset(ha)`  
`reset(hd)`  
`reset(hm)`

**Description** `reset(ha)` resets all the properties of the adaptive filter `ha` that are updated when filtering to the value specified at construction. If you do not specify a value for any particular property when you construct an adaptive filter, the property value for that property is reset to the default value for the property.

`reset(hd)` resets all the properties of the discrete-time filter `hd` to their factory values that are modified when you run the filter. In particular, the `States` property is reset to zero.

`reset(hm)` resets all the properties of the multirate filter `hm` to their factory value that are modified when the filter is run. In particular, the `States` property is reset to zero when `hm` is a decimator. Additionally, the filter internal properties are also reset to their factory values.

**Examples** Denoise a sinusoid and reset the filter after filtering with it.

```
h = adaptfilt.lms(5,.05,1,[0.5,0.5,0.5,0.5,0.5]);
n = filter(1,[1 1/2 1/3],.2*randn(1,2000));
d = sin((0:1999)*2*pi*0.005) + n; % Noisy sinusoid
x = n;
[y,e]= filter(h,x,d);           % e has denoised signal
disp(h)
reset(h); % Reset the coefficients and states.
disp(h)
```

**See Also** `set`

**Purpose**

Scale sections of SOS filter

**Syntax**

```
scale(hd)
scale(hd,pnorm)
scale(hd,pnorm,Name,Value)
scale(hd,pnorm,opts)
scale(hs)
```

**Description**

`scale(hd)` scales the second-order section filter `hd` using peak magnitude response scaling (L-infinity, 'Linf'). This scaling reduces the possibility of overflows when your filter `hd` operates in fixed-point arithmetic mode.

`scale(hd,pnorm)` specifies the norm used to scale the filter.

`scale(hd,pnorm,Name,Value)` scales the SOS filter with additional options specified by one or more `Name,Value` pair arguments.

`scale(hd,pnorm,opts)` uses an input scale options object `opts` to specify the optional scaling parameters instead of specifying parameter-value pairs.

`scale(hs)` scales the filter System object `hs`. You can also use `pnorm`, name-value pair arguments, or scale option objects with this syntax.

**Input Arguments****hd**

Discrete-time `dfilt` filter object.

With the `Arithmetic` property of `hd` set to `double` or `single`, the filter uses the default values for all options that you do not specify explicitly. When you set `Arithmetic` to `fixed`, the values used for the scaling options are set according to the settings in filter `hd`. However, if you specify a scaling option different from the settings in `hd`, the filter uses your explicit option selection for scaling purposes, but does not change the property setting in `hd`.

**hs**

`dsp.BiquadFilter` filter System object.

## **pnorm**

'l1' | 'l2' | 'linf' | 'L1' | 'L2' | 'Linf' (default)

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for `pnorm` are 'l1', 'l2', and 'linf'. Valid frequency-domain norm values are 'L1', 'L2', and 'Linf'. The 'L2' norm is equal to the 'l2' norm (by Parseval's theorem), but this equivalency does not hold for other norms — 'l1' is not the same as 'L1' and 'Linf' is not the same as 'linf'.

Filter norms can be ordered in terms of how stringent they are, as follows from most stringent to least: 'l1', 'Linf', 'l2' ('L2'), 'linf'. Using 'l1', the most stringent scaling, produces a filter that is least likely to overflow, but has the worst signal-to-noise ratio performance. The default scaling 'Linf' is the most commonly used scaling norm.

## **opts**

Scale options object. You can create the `opts` object using the `scalects` function.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'Arithmetic'**

`double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## **'MaxNumerator'**

Maximum allowed value for numerator coefficients.

**Default:** 2

## **'MaxScaleValue'**

Maximum allowed scale values. The filter applies the MaxScaleValue limit only when you set ScaleValueConstraint to a value other than unit (the default setting). Setting MaxScaleValue to any numerical value automatically changes the ScaleValueConstraint setting to none.

**Default:** 'Not Used'

## **'NumeratorConstraint'**

'none' (default) | 'normalize' | 'po2' | 'unit'

Specifies whether and how to constrain numerator coefficient values.

## **'OverflowMode'**

satall | saturate | wrap (default)

Sets the way the filter handles arithmetic overflow situations during scaling. If your device does not have guard bits available, and you are using saturation arithmetic for filtering, use 'satall' instead of 'saturate'.

## **'ScaleValueConstraint'**

'none' | 'po2' | 'unit' (default)

Specify whether to constrain the filter scale values, and how to constrain them. Choosing 'unit' for the constraint disables the MaxScaleValue

property setting. 'po2' constrains the scale values to be powers of 2, while 'none' removes any constraint on the scale values.

### 'sosReorder'

auto (default) | down | none | up

Reorder filter sections prior to applying scaling.

## Examples

Demonstrate the Linf-norm scaling of a lowpass elliptic filter with second-order sections. Start by creating a lowpass elliptical filter in zero, pole, gain (z,p,k) form.

```
[z,p,k] = ellip(5,1,50,.3);  
[sos,g] = zp2sos(z,p,k);  
hd = dfilt.df2sos(sos,g);  
scale(hd,'linf','scalevalueconstraint','none','maxscalevalue',2)
```

# scalecheck

---

## Purpose

Check scaling of SOS filter

## Syntax

```
s = scalecheck(hd,pnorm)
s = scalecheck(hs,pnorm)
s = scalecheck(hs,pnorm,Name,Value)
```

## Description

`s = scalecheck(hd,pnorm)` checks the scaling second-order section (SOS) `dfilt` filter object `hd`.

`s = scalecheck(hs,pnorm)` checks the scaling of the filter System object `hs`.

`s = scalecheck(hs,pnorm,Name,Value)` checks the scaling of the filter System object `hs` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **hd**

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsosfilter` object.

### **hs**

`dsp.BiquadFilter` filter System object.

### **pnorm**

```
'l1' | 'l2' | 'linf' | 'L1' | 'L2' | 'Linf'
```

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for `pnorm` are `'l1'`, `'l2'`, and `'linf'`. Valid frequency-domain norm values are `'L1'`, `'L2'`, and `'Linf'`. The `'L2'` norm is equal to the `'l2'` norm (by Parseval's theorem), but this equivalency does not hold for other norms — `'l1'` is not the same as `'L1'` and `'Linf'` is not the same as `'linf'`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding

value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**'Arithmetic'**

'double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Output Arguments

**s**

Filter scaling for a given p-norm. An optimally scaled filter has partial norms equal to one. In such cases, **s** contains all ones.

For direct-form I (`dfilt.df1sos`) and direct-form II transposed (`dfilt.df2tsos`) filters, the function returns the p-norm of the filter computed from the filter input to the output of each second-order section. Therefore, the number of elements in **s** is one less than the number of sections in the filter. This p-norm computation does not include the trailing scale value of the filter, which you can find by entering `hd.scalevalue(end)` at the MATLAB prompt.

For direct-form II (`dfilt.df2sos`) and direct-form I transposed (`dfilt.df1tsos`) filters, the function returns a row vector whose elements contain the p-norm from the filter input to the input of the recursive part of each second-order section. This computation of the p-norm corresponds to the input to the multipliers in these filter structures. These inputs correspond to the locations in the signal flow where overflow should be avoided.

When `hd` has nontrivial scale values, that is, if any scale values are not equal to one, `s` is a two-row matrix, rather than a vector. The first row elements of `s` report the p-norm of the filter computed from the filter input to the output of each second-order section. The elements of the second row of `s` contain the p-norm computed from the input of the filter to the input of each scale value between the sections. For `df2sos` and `df1tsos` filter structures, the last numerator and the trailing scale value for the filter are not included when `scalecheck` checks the scaling.

## Examples

Check the Linf-norm scaling of a filter.

```
% Create filter design specifications
hs = fdesign.lowpass;
object.
hd = ellip(hs);          % Design an elliptic sos filter
scale(hd,'Linf');
s = scalecheck(hd,'Linf')
```

In another form:

```
[b,a]=ellip(10,.5,20,0.5);
[s,g]=tf2sos(b,a);
hd=dfilt.df1sos(s,g)
```

hd =

```
FilterStructure: 'Direct-Form I, Second-Order Sections'
Arithmetic: 'double'
sosMatrix: [5x6 double]
ScaleValues: [6x1 double]
```

# scalecheck

---

```
PersistentMemory: false  
States: [1x1 filtstates.dfiir]
```

```
1x1 struct array with no fields.
```

```
scalecheck(hd, 'Linf')
```

```
ans =
```

```
0.7631    0.9627    0.9952    0.9994    1.0000
```

[norm](#) | [reorder](#) | [scale](#) | [scaleopts](#)

**Purpose** Options for scaling SOS filter

**Syntax**

```
opts = scaleopts(hd)
opts = scaleopts(hs)
opts = scaleopts(hs,Name,Value)
```

**Description** `opts = scaleopts(hd)` uses the current settings in the `dfilt` filter `hd` to create an options object `opts` that contains specified scaling options for second-order section scaling. You can pass `opts` as an input to `scale` to apply scaling settings to a second-order filter.

`opts = scaleopts(hs)` creates an options object based on the current settings of the filter System object `hs`.

`opts = scaleopts(hs,Name,Value)` creates an options object with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **hd**

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsosfilter` object.

### **hs**

`dsp.BiquadFilter` filter System object.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Arithmetic'**

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function

performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

## Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis

System Object State	Coefficient Data Type	Rule
		based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Output Arguments

### opts

Scaling object. The following table lists the properties of opts.

Parameter	Default	Description and Valid Value
MaxNumerator	2	Maximum allowed value for numerator coefficients.
MaxScaleValue	No default value	Maximum allowed scale values. The filter applies the MaxScaleValue limit only when you set ScaleValueConstraint to a value other than unit. Setting MaxScaleValue to a numerical value automatically changes the ScaleValueConstraint setting to none.

# scaleopts

Parameter	Default	Description and Valid Value
NumeratorConstraint	none	Specifies whether and how to constrain numerator coefficient values. Options are none, normalize, po2, and unit.
OverflowMode	wrap	Sets the way the filter handles arithmetic overflow situations during scaling. Choose one of wrap or saturate or satall.
ScaleValueConstraint	unit	Specify whether to constrain the filter scale values, and how to constrain them. Valid options are none, po2, and unit.

## Examples

From a filter `hd`, you can create an options scaling object that contains the scaling options settings you require.

```
[b,a]=ellip(10,.5,20,0.5);  
[s,g]=tf2sos(b,a);  
hd=dfilt.df1sos(s,g)  
opts=scaleopts(hd)
```

```
opts =
```

```
    MaxNumerator: 2  
    NumeratorConstraint: 'none'  
    OverflowMode: 'wrap'  
    ScaleValueConstraint: 'unit'
```

MaxScaleValue: 'Not used'

# set2int

---

**Purpose** Configure filter for integer filtering

**Syntax**

```
set2int(h)
set2int(h,coeffw1)
set2int(...,inw1)
g = set2int(...)
```

**Description** These sections apply to both discrete-time (dfilt) and multirate (mfilt) filters.

`set2int(h)` scales the filter coefficients to integer values and sets the filter coefficient and input fraction lengths to zero.

`set2int(h,coeffw1)` uses the number of bits specified by `coeffw1` as the word length it uses to represent the filter coefficients.

`set2int(...,inw1)` uses the number of bits specified by `coeffw1` as the word length it uses to represent the filter coefficients and the number of bits specified by `inw1` as the word length to represent the input data.

`g = set2int(...)` returns the gain `g` introduced into the filter by scaling the filter coefficients to integers. `g` is always calculated to be a power of 2.

---

**Note** `set2int` does not work with CIC decimators or interpolators because they do not have coefficients.

---

**Examples** These examples demonstrate some uses and ideas behind `set2int`.

The second parts of both examples depend on the following — after you filter a set of data, the input data and output data cover the same range of values, unless the filter process introduces gain in the output. Converting your filter object to integer form, and then filtering a set of data, does introduce gain into the system. When the examples refer to resetting the output to the same range as the input, the examples are accounting for this added gain feature.

## Discrete-Time Filter Example

Two parts comprise this example. Part 1 compares the step response of an FIR filter in both the fractional and integer filter modes. Fractional mode filtering is essentially the opposite of integer mode. Integer mode uses a filter which has coefficients represented by integers. Fractional mode filters have coefficients represented in fractional form (nonzero fraction length).

```
b = firrcos(100,.25,.25,2,'rolloff','sqrt');
hd = dfilt.dffir(b);
hd.Arithmetic = 'fixed';
hd.InputFracLength = 0; % Integer inputs.
x = ones(100,1);
yfrac = filter(hd,x); % Fractional mode output.
g = set2int(hd); % Convert to integer coefficients.
yint = filter(hd,x); % Integer mode output.
```

Note that `yint` and `yfrac` are `fi` objects. Later in this example, you use the `fi` object properties `WordLength` and `FractionLength` to work with the output data.

Now use the gain `g` to rescale the output from the integer mode filter operation. Verify that the scaled integer output is equal to the fractional output.

```
yints = double(yint)/g;
MaxDiff=max(abs(yints-double(yfrac)));
```

Verify that the scaled integer output is equal to the fractional output.

```
max(abs(yints-double(yfrac)))
```

In part two, the example reinterprets the output binary data, putting the input and the output on the same scale by weighting the most significant bits in the input and output data equally.

```
WL = yint.WordLength;
FL = yint.Fractionlength + log2(g);
```

```
yints2 = fi(zeros(size(yint)),true,WL,FL);
yints2.bin = yint.bin;
MaxDiff=max(abs(double(yints2)-double(yfrac)));
```

## Multirate Filter Example

This two-part example starts by comparing the step response of a multirate filter in both fractional and integer modes. Fractional mode filtering is essentially the opposite of integer mode. Integer mode uses a filter which has coefficients represented by integers. Fractional mode filters have coefficients in fractional form with nonzero fraction lengths.

```
hm = mfilt.firinterp;
hm.Arithmetic = 'fixed';
hm.InputFracLength = 0; % Integer inputs.
x = ones(100,1);
yfrac = filter(hm,x); % Fractional mode output.
g = set2int(hm); %Convert to integer coefficients.
yint = filter(hm,x); % Integer mode output.
```

Note that `yint` and `yfrac` are `fi` objects. In part 2 of this example, you use the `fi` object properties `WordLength` and `FractionLength` to work with the output data.

Now use the gain `g` to rescale the output from the integer mode filter operation.

```
yints = double(yint)/g;
```

Verify that the scaled integer output is equal to the fractional output.

```
max(abs(yints-double(yfrac)))
```

Part 2 demonstrates reinterpreting the output binary data by using the properties of `yint` to create a scaled version of `yint` named `yints2`. This process puts `yint` and `yints2` on the same scale by weighing the most significant bits of each object equally.

```
wl = yint.wordlength;
fl = yint.fractionlength + log2(g);
```

```
yints2 = fi(zeros(size(yint)),true,wl,f1);  
yints2.bin = yint.bin;  
max(abs(double(yints2)-double(yfrac)))
```

`mfilt`

# setspecs

---

**Purpose** Specifications for filter specification object

**Syntax**

```
setspecs(D,specvalue1,specvalue2,...)
setspecs(D,Specification,specvalue1,specvalue2,...)
setspecs(...Fs)
setspecs(...,MAGUNITS)
```

**Description**

`setspecs(D,specvalue1,specvalue2,...)` sets the specifications in filter specification object, `D`, in the same order they appear in the `Specification` property.

`setspecs(D,Specification,specvalue1,specvalue2,...)` changes the specifications for an existing filter specification object and sets values for the new `Specification` property.

`setspecs(...Fs)` specifies the sampling frequency, `Fs`, in Hz. The sampling frequency must be a scalar trailing all other specifications. Entering a sampling frequency causes all other frequency specifications to be in Hz.

`setspecs(...,MAGUNITS)` specifies the units for any magnitude specifications. `MAGUNITS` can be one of the following: 'linear', 'dB', or 'squared'. The default is 'dB'. The magnitude specifications are always converted and stored in dB regardless of how the units are specified.

Use `SET(D,'SPECIFICATION')` to get the list of all available specification types for the filter specification object, `D`.

**Examples**

Construct a lowpass filter with specifications for the filter order and cutoff frequency (-6 dB). Use `setspecs` after construction to set the values of the filter order and cutoff frequency. Display the values in the MATLAB command window.

```
D = fdesign.lowpass('N,Fc');
setspecs(D,10,0.2);
D.FilterOrder
D.Fcutoff
```

---

Construct a highpass filter with specifications for the numerator order, denominator order, and 3-dB frequency. Assume the sampling frequency is 1 kHz. Use `setspecs` to set the numerator and denominator orders to 6. Set the 3-dB frequency to 250 Hz. In order to use frequency specifications in Hz, specify the sampling frequency as a trailing scalar.

```
D = fdesign.highpass('Nb,Na,F3dB');  
setspecs(D,6,6,250,1000);
```

**See Also**

[design](#) | [designmethods](#) | [designopts](#) | [fdesign](#)

**Purpose** Convert quantized filter to second-order sections (SOS) form

**Syntax**

```
Hq2 = sos(Hq)
Hq2 = sos(Hq, order)
Hq2 = sos(Hq, order, scale)
```

**Description** `Hq2 = sos(Hq)` returns a quantized filter `Hq2` that has second-order sections and the `dft2` structure. Use the same optional arguments used in `tf2sos`.

`Hq2 = sos(Hq, order)` specifies the order of the sections in `Hq2`, where `order` is either of the following strings:

- 'down' — to order the sections so the first section of `Hq2` contains the poles closest to the unit circle ( $L_\infty$  norm scaling)
- 'up' — to order the sections so the first section of `Hq2` contains the poles farthest from the unit circle ( $L_2$  norm scaling and the default)

`Hq2 = sos(Hq, order, scale)` also specifies the desired scaling of the gain and numerator coefficients of all second-order sections, where `scale` is one of the following strings:

- 'none' — to apply no scaling (default)
- 'inf' — to apply infinity-norm scaling
- 'two' — to apply 2-norm scaling

Use infinity-norm scaling in conjunction with up-ordering to minimize the probability of overflow in the filter realization. Consider using 2-norm scaling in conjunction with down-ordering to minimize the peak round-off noise.

When `Hq` is a fixed-point filter, the filter coefficients are normalized so that the magnitude of the maximum coefficient in each section is 1. The gain of the filter is applied to the first scale value of `Hq2`.

`sos` uses the direct form II transposed (`dft2`) structure to implement second-order section filters.

## Examples

```
[b,a]=butter(8,.5);
Hq = dfilt.df2t(b,a);
Hq.arithmetic = 'fixed';
Hq1 = sos(Hq)

Hq1 =

    FilterStructure: 'Direct-Form II Transposed, Second-Order Sections'
    Arithmetic: 'double'
    sosMatrix: [4x6 double]
    ScaleValues: [0.00927734375;1;1;1;1]
    OptimizeScaleValues: true
    PersistentMemory: false
```

[convert](#) | [dfilt](#) | [tf2sos](#)

# specifyall

---

**Purpose** Fixed-point scaling modes in direct-form FIR filter

**Syntax**  
`specifyall(hd)`  
`specifyall(hd,false)`  
`specifyall(hd,true)`  
`specifyall(hs)`  
`specifyall(hs,false)`

**Description** `specifyall` sets all of the `autoscale` property values of direct-form FIR filters to `false` and all `*modes` of the filters to `SpecifyPrecision`. In this table, you see the results of using `specifyall` with direct-form FIR filters.

Property Name	Default	Setting After Applying <code>specifyall</code>
<code>CoeffAutoScale</code>	<code>true</code>	<code>false</code>
<code>OutputMode</code>	<code>AvoidOverflow</code>	<code>SpecifyPrecision</code>
<code>ProductMode</code>	<code>FullPrecision</code>	<code>SpecifyPrecision</code>
<code>AccumMode</code>	<code>KeepMSB</code>	<code>SpecifyPrecision</code>
<code>RoundMode</code>	<code>convergent</code>	<code>convergent</code>
<code>OverflowMode</code>	<code>wrap</code>	<code>wrap</code>

`specifyall(hd)` gives you maximum control over all settings in a filter `hd` by setting all of the `autoscale` options that are `true` to `false`, turning off all autoscaling and resetting all modes — `OutputMode`, `ProductMode`, and `AccumMode` — to `SpecifyPrecision`. After you use `specifyall`, you must supply the property values for the mode- and scaling related properties.

`specifyall` provides an alternative to changing all these properties individually. Using `specifyall` changes all of the settings. To set some but not all of the modes, set each property as you require.

`specifyall(hd,false)` performs the opposite operation of `specifyall(hd)` by setting all of the `autoscale` options to `true`; all

of the modes to their default values; and hiding the fraction length properties in the display, meaning you cannot access them to set them or view them.

`specifyall(hd,true)` is equivalent to `specifyall(hd)`.

`specifyall(hs)` sets all the data type fixed-point properties of the filter System object `hs` to 'Custom' so that you can easily specify all the fixed-point settings. If the object has a `FullPrecisionOverride` property, its value is set to `false`. `specifyall` is intended as a shortcut to changing all the fixed-point properties one by one.

`specifyall(hs,false)` sets all fixed-point properties of the filter System object `hs` to their default values and sets the filter to full-precision mode, if possible.

## Examples

This example demonstrates using `specifyall` to provide access to all of the fixed-point settings of an FIR filter implemented with the direct-form structure. Using `specifyall` disables all of the automatic filter scaling and reset the mode values.

```
b = fircband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],{'w' 'c'});
hd = dfilt.dffir(b);
hd.arithmetic = 'fixed'
specifyall(hd)
```

The mode properties `InputMode`, `ProductMode`, and `AccumMode` have the value `SpecifyPrecision` and the fraction length properties appear in the display. Now you use the properties (`InputFracLength`, `ProdFracLength`, `AccumFracLength`) to set the precision the filter applies to the input, product, and accumulator operations. `CoeffAutoScale` switches to `false`, which means that the filter coefficients will not be scaled automatically to prevent overflows. None of the other filter properties change when you apply `specifyall`.

`double` | `reffilter`

# stepz

---

**Purpose** Step response for filter

**Syntax**

```
[h,t] = stepz(hfilt)
[h,t] = stepz(hfilt,n)
[h,t] = stepz(hfilt,n,fs)
[h,t] = stepz(hfilt,[],fs)
stepz(hfilt)
[h,t] = stepz(hs)
[h,t] = stepz(hs,Name,Value)
stepz(hs)
```

**Description** `stepz` returns the step response based on the current filter coefficients. This section describes common `stepz` operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to `stepz` in Signal Processing Toolbox documentation.

`[h,t] = stepz(hfilt)` returns the impulse response `h` and the corresponding time points `w` at which the step response of `hfilt` is computed. The step response is evaluated at 10 1-second intervals—`(0:9)'`.

`[h,t] = stepz(hfilt,n)` returns the step response evaluated at `floor(n)` 1-second intervals—`(0:floor(n)-1)'`.

`[h,t] = stepz(hfilt,n,fs)` returns the step response evaluated at `floor(n) 1/fs`-second intervals—`(0:floor(n)-1)'/fs`.

`[h,t] = stepz(hfilt,[],fs)` returns the step response evaluated at 10 `1/fs`-second intervals—`(0:9)'/fs`.

`stepz(hfilt)` uses FVTool to plot the step response of the filter. You can also provide the optional input arguments `n` and `fs` with this syntax.

`[h,t] = stepz(hs)` returns the step response for the filter System object `hs`. The impulse response is evaluated at 10 1-second intervals—`(0:9)'`. You can also provide the optional input arguments `n` and `fs` with this syntax.

`[h,t] = stepz(hs,Name,Value)` returns a step response with additional options specified by one or more `Name,Value` pair arguments.

`stepz(hs)` uses FVTool to plot the step response of the filter System object `hs`.

---

**Note** `stepz` works for both real and complex filters. When you omit the output arguments, `stepz` plots only the real part of the step response.

---

## Input Arguments

### `hfiltr`

`hfiltr` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter step response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `stepz` assumes the filter is running at that rate.

For multistage cascades, `stepz` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `stepz` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `stepz` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `stepz`, the function interprets `fs` as the rate at which the equivalent filter is running.

### `hs`

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`
- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

**n**

Number of samples.

**Default:** 10

**fs**

Sampling frequency.

**Default:** 1

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**'Arithmetic'**

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify

'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point

System Object State	Coefficient Data Type	Rule
		analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **h**

Complex, n-element step response vector. If `hfilt` is a vector of filters, `h` is a complex, `length(hfilt)`-by-`n` matrix of step response vectors corresponding to each filter in `hfilt`. If `n` is not specified, the function uses a default value of 8192.

For adaptive filters, `h` is the instantaneous step response.

### **t**

Time vector of length `n`, in seconds. `t` consists of `n` points equally spaced from 0 to `floor(n) / fs`. If `n` is not specified, the function uses a default value of 10. If `fs` is not specified, the function uses a default value of 1.

Direct-form FIR ( <code>dfilt.dffir</code> )	<code>dsp.FIRFilter</code>
Direct-form FIR transposed ( <code>dfilt.dffirt</code> )	<code>dsp.FIRFilter</code>
Direct-form symmetric FIR ( <code>dfilt.dfsymfir</code> )	<code>dsp.FIRFilter</code>
Direct-form antisymmetric FIR ( <code>dfilt.dfasymfir</code> )	<code>dsp.FIRFilter</code>
Discrete-time, lattice, moving-average ( <code>dfilt.latticemamin</code> )	<code>dsp.FIRFilter</code>
Discrete-time, second-order section, direct-form I ( <code>dfilt.df1sos</code> )	<code>dsp.BiquadFilter</code>

Single-rate or multirate filter	Filter System object
Discrete-time, second-order section, direct-form I transposed (dfilt.df1tsos)	dsp.BiquadFilter
Discrete-time, second-order section, direct-form II (dfilt.df2sos)	dsp.BiquadFilter
Discrete-time, second-order section, direct-form II transposed (dfilt.df2tsos)	dsp.BiquadFilter
Direct-form FIR polyphase decimator (mfilt.firdecim)	dsp.FIRDecimator
Direct-form transposed FIR polyphase decimator (mfilt.firtdecim)	dsp.FIRDecimator
Fixed-point CIC decimator (mfilt.cicdecim)	dsp.CICDecimator
FIR polyphase interpolator (mfilt.firinterp)	dsp.FIRInterpolator
FIR linear interpolator (mfilt.linearinterp)	dsp.FIRInterpolator
Fixed-point CIC interpolator (mfilt.cicinterp)	dsp.CICInterpolator
Direct-form FIR polyphase sample rate converter (mfilt.firsrc)	dsp.FIRRateConverter

## Input Arguments

### hfilt

Discrete-time filter (dfilt) or multirate filter (mfilt) object. The preceding table lists supported filter structures.

The function interprets the `PersistentMemory` property differently for discrete-time and multirate filters:

- If `hfilt` is a discrete-time filter with the `PersistentMemory` property set to `true`, then the filter states are copied into the initial conditions properties of `hs`. Otherwise, initial conditions are ignored.
- Multirate-filter System objects do not have initial conditions. If `hfilt` is a multirate filter with the `PersistentMemory` property set to `true`, the initial conditions are not copied into `hs`, and the function issues a warning.

The function does not support some properties for SOS filter structures:

- If the `CastBeforeSum` property is set to `false`, the function issues a warning. `dsp.BiquadFilter` System objects always have a cast before a sum.
- If the `Signed` property is `false`, the function issues an error. `dsp.BiquadFilter` System objects do not support unsigned arithmetic.

## Output Arguments

### `hs`

Filter System object. The function maps almost all properties of `hfilt` into the filter System object. However, some properties are not mapped exactly:

- Filter System objects do not have a `CoeffAutoScale` property. The function specifies a word length and a fraction length regardless of whether the `CoeffAutoScale` property of `hfilt` is `true` or `false`.
- `dsp.BiquadFilter` System objects do not have a `FullPrecisionOverride` property. Full-precision values in `hfilt` are mapped to word and fraction lengths in `hs`. These settings correspond to the full-precision setting of the input data type.

## Examples

Convert a discrete-time filter object to a System object:

```
hfilt = dfilt.df1sos; %Direct-form I SOS
hs = sysobj(hfilt); %Biquadratic IIR filter
```

**See Also** `block`

**Purpose** Transfer function to coupled allpass

**Syntax**  
 $[d1, d2] = \text{tf2ca}(b, a)$   
 $[d1, d2] = \text{tf2ca}(b, a)$

**Description**  $[d1, d2] = \text{tf2ca}(b, a)$  where  $b$  is a real, symmetric vector of numerator coefficients and  $a$  is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors  $d1$  and  $d2$  containing the denominator coefficients of the allpass filters  $H1(z)$  and  $H2(z)$  such that

$$H(z) = \frac{B(z)}{A(z)} = \frac{1}{2[H1(z) + H2(z)]}$$

representing a coupled allpass decomposition.

$[d1, d2] = \text{tf2ca}(b, a)$  where  $b$  is a real, antisymmetric vector of numerator coefficients and  $a$  is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors  $d1$  and  $d2$  containing the denominator coefficients of the allpass filters  $H1(z)$  and  $H2(z)$  such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) - H2(z)]$$

In some cases, the decomposition is not possible with real  $H1(z)$  and  $H2(z)$ . In those cases a generalized coupled allpass decomposition may be possible, whose syntax is

$[d1, d2, \beta] = \text{tf2ca}(b, a)$

to return complex vectors  $d1$  and  $d2$  containing the denominator coefficients of the allpass filters  $H1(z)$  and  $H2(z)$ , and a complex scalar  $\beta$ , satisfying  $|\beta| = 1$ , such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[\bar{\beta} \cdot H1(z) + \beta \cdot H2(z)]$$

representing the generalized allpass decomposition.

In the above equations,  $H1(z)$  and  $H2(z)$  are real or complex allpass IIR filters given by

$$H1(z) = \frac{\text{fliplr}(\overline{D1(z)})}{D1(z)}, H2(z) = \frac{\text{fliplr}(\overline{D2(z)})}{D2(z)}$$

where  $D1(z)$  and  $D2(z)$  are polynomials whose coefficients are given by  $d1$  and  $d2$ .

---

**Note** A coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

---

## Examples

```
[b,a]=cheby1(9,.5,.4);
[d1,d2]=tf2ca(b,a); % TF2CA returns denominators of the allpass.
num = 0.5*conv(fliplr(d1),d2)+0.5*conv(fliplr(d2),d1);
den = conv(d1,d2); % Reconstruct numerator and denominator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
% numerator and denominators.
```

## Purpose

Structures for specification object with design method

## Syntax

```
filtstruct = validstructures(D)  
C = validstructures(D,METHOD)  
Cs = validstructures(D,...,'SystemObject',sysobjflag)
```

## Description

`filtstruct = validstructures(D)` returns a structure array containing all valid filter structures for the filter specification object, `D`, organized by design method. Each design method is a field in the structure array, `filtstruct`. The fields contain a cell array of strings.

`C = validstructures(D,METHOD)` returns the valid structures for the filter specification object, `D`, and the design method, `METHOD`, in a cell array of strings.

`Cs = validstructures(D,...,'SystemObject',sysobjflag)` returns the valid structures for designing a filter System object when *sysobjflag* is true. To use System objects, you must have the DSP System Toolbox product installed. When *sysobjflag* is false, the function returns valid structures for designing `dfilt` and `mfilt` objects, as described previously. Design methods and design options for filter System objects are not necessarily the same as those for `dfilt` and `mfilt` objects.

## Examples

Design a default lowpass filter specification object. Return all valid design methods and structures in a structure array. Display the fieldnames to see all valid design methods. Display the valid filter structures for the `equiripple` field.

```
D = fdesign.lowpass;  
filtstruct = validstructures(D);  
fieldnames(filtstruct)  
filtstruct.equiripple
```

---

Create a highpass filter of order 50 with a 3-dB frequency of 0.2. Obtain the available structures for a Butterworth design.

# validstructures

---

```
D = fdesign.highpass('N,F3dB',50,0.2);  
C = validstructures(D,'butter');
```

If you have DSP System Toolbox software installed, use the 'SystemObject', *sysobjflag* syntax to return valid structures for a filter System object:

```
Cs = validstructures(D,'butter','SystemObject',true);
```

[design](#) | [designmethods](#) | [designopts](#) | [fdesign](#)

**Purpose** FIR filter using windowed impulse response

**Syntax** `h = window(d,fcnhd1,fcarg)`  
`h = window(d,win)`

**description** `h = window(d,fcnhd1,fcarg)` designs an FIR filter using the specifications in filter specification object `d`. Depending on the specification type of `d`, the returned filter is either a single-rate digital filter — a `dfilt`, or a multirate digital filter — an `mfilt`.

`fcnhd1` is a handle to a filter design function that returns a window vector, such as the `hamming` or `blackman` functions. `fcarg` is an optional argument that returns a window. You pass the function to `window`. Refer to example 1 in the following section to see the function argument used to design the filter.

`h = window(d,win)` designs a filter using the vector you supply in `win`. The length of vector `win` must be the same as the impulse response of the filter, which is equal to the filter order plus one. Example 2 shows this being done.

**Examples** These examples design filters using the two design techniques of specifying a function handle or passing a window vector as an input argument.

### Example 1

Use a function handle and optional input arguments to design a multirate filter. We use a function handle to `hamming` to provide the window. Since this example creates a decimator filter specifications object, `window` returns a multirate filter.

```
d = fdesign.decimator(4,'lowpass','N,Fc',30,1000,10000);  
% Lowpass decimator with a 6-dB down frequency of 1 kHz  
% Order equal to 30 and sampling frequency 10 kHz  
Hd =window(d,'window',@hamming);  
fvtool(Hd)
```

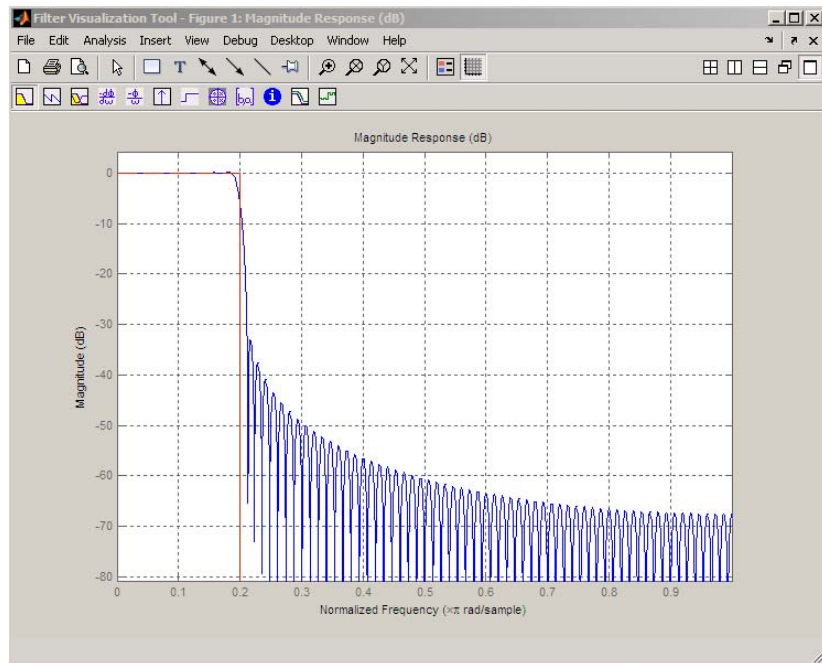

# window

## Example 2

Use a window vector provided by the kaiser window function to design a Nyquist filter. The window length must be the filter order plus one. .

```
d = fdesign.nyquist(5,'n',150);  
% Kaiser window with beta parameter 2.5  
Hd = window(d,'window',kaiser(151,2.5));  
fvtool(Hd)
```

**See Also**      `firls` | `kaiserwin`

# zerophase

---

**Purpose** Zero-phase response for filter

**Syntax**

```
[hr,w] = zerophase(hfilt)
[hr,w] = zerophase(hfilt,n)
zerophase(hfilt)
[hr,w] = zerophase(hs)
[hr,w] = zerophase(hs,n)
[hr,w] = zerophase(hs,Name,Value)
zerophase(hs)
```

**Description** zerophase returns the zero-phase response based on the current filter coefficients. This section describes common zerophase operation with adaptive, discrete-time, and multirate filters. For more input options, refer to zerophase in Signal Processing Toolbox documentation.

`[hr,w] = zerophase(hfilt)` returns the instantaneous zero-phase response `hr` and the frequencies `w` in radians at which zerophase evaluated the response. The zero-phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[hr,w] = zerophase(hfilt,n)` returns the instantaneous zero-phase response `hr` and the frequencies `w` in radians at which zerophase evaluated the response. The zero-phase response is evaluated at `n` points equally spaced around the upper half of the unit circle.

`zerophase(hfilt)` displays the zero-phase response of `ha` in the Filter Visualization Tool (FVTool).

`[hr,w] = zerophase(hs)` returns a zero-phase response for the filter System object `hs` using 8192 samples.

`[hr,w] = zerophase(hs,n)` returns a zero-phase response for the filter System object `hs` using `n` samples.

`[hr,w] = zerophase(hs,Name,Value)` returns a zero-phase response with additional options specified by one or more `NAME,VALUE` pair arguments.

`zerophase(hs)` uses FVTool to plot the zero-phase response of the filter System object `hs`.

## Input Arguments

### **hfilt**

hfiltr is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter zero-phase response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `zerophase` assumes the filter is running at that rate.

For multistage cascades, `zerophase` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `zerophase` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `zerophase` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `zerophase`, the function interprets `fs` as the rate at which the equivalent filter is running.

### **hs**

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`
- `dsp.FIRDecimator`

- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

## **n**

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

**Default:** 8192

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'Arithmetic'**

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **hr**

Complex,  $n$ -element zero-phase response vector. If `hfilt` is a vector of filters, `hr` is a complex, `length(hfilt)`-by- $n$  matrix of phase response vectors whose columns correspond to each filter in `hfilt`. If  $n$  is not specified, the function uses a default value of 8192.

For adaptive filters, `hr` is the instantaneous zero-phase response.

### **w**

Frequency vector of length  $n$ , in radians/sample. `w` consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If `hfilt` is a vector of filters, `w` is a complex, `length(hfilt)`-by- $n$  matrix of phase response vectors whose columns correspond to each filter in `hfilt`. If  $n$  is not specified, the function uses a default value of 8192.

<b>Purpose</b>	Zero-pole-gain complex bandpass frequency transformation
<b>Syntax</b>	<code>[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)</code>
<b>Description</b>	<p><code>[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)</code> returns zeros, <math>Z_2</math>, poles, <math>P_2</math>, and gain factor, <math>K_2</math>, of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation.</p> <p>It also returns the numerator, <code>AllpassNum</code>, and the denominator, <code>AllpassDen</code>, of the allpass mapping filter. The original lowpass filter is given with zeros, <math>Z</math>, poles, <math>P</math>, and gain factor, <math>K</math>.</p> <p>This transformation effectively places two features of an original filter, located at frequencies <math>W_{o1}</math> and <math>W_{o2}</math>, at the required target frequency locations, <math>W_{t1}</math>, and <math>W_{t2}</math> respectively. It is assumed that <math>W_{t2}</math> is greater than <math>W_{t1}</math>. In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.</p> <p>Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, <math>F_1</math> and <math>F_2</math>, with <math>F_1</math> preceding <math>F_2</math>. Feature <math>F_1</math> will still precede <math>F_2</math> after the transformation. However, the distance between <math>F_1</math> and <math>F_2</math> will not be the same before and after the transformation.</p> <p>This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle; e.g., in the adaptive system.</p>
<b>Examples</b>	<p>Design a prototype real IIR halfband filter using a standard elliptic approach:</p> <pre>[b, a] = ellip(3,0.1,30,0.409);</pre> <p>Create a complex passband from 0.25 to 0.75:</p>

# zpkbpc2bpc

```
[b, a] = iirlp2bpc(b,a,0.5,[0.25,0.75]);  
z = roots(b);  
p = roots(a);  
k = b(1);  
[z2,p2,k2] = zpkbpc2bpc(z,p,k,[0.25, 0.75],[-0.75, -0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Comparing the filters in FVTool shows the example results. Use the features in FVTool to check the filter coefficients, or other filter analyses.

**Arguments**

<b>Variable</b>	<b>Description</b>
<i>Z</i>	Zeros of the prototype lowpass filter
<i>P</i>	Poles of the prototype lowpass filter
<i>K</i>	Gain factor of the prototype lowpass filter
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

# zpkftransf

---

**Purpose** Zero-pole-gain frequency transformation

**Syntax** `[Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen)`

**Description** `[Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the transformed lowpass digital filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ . If `AllpassDen` is not specified it will default to 1. If neither `AllpassNum` nor `AllpassDen` is specified, then the function returns the input filter.

**Examples** Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);  
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);  
[z2, p2, k2] = zpkftransf(roots(b),roots(a),b(1),AlpNum,AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

After transforming the filter, you get the response shown in the figure, where the passband has been shifted towards zero.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$FTFNum$	Numerator of the mapping filter
$FTFDen$	Denominator of the mapping filter
$Z2$	Zeros of the target filter
$P2$	Poles of the target filter
$K2$	Gain factor of the target filter

<b>Purpose</b>	Zero-pole-gain lowpass to bandpass frequency transformation
<b>Syntax</b>	<code>[Z2,P2,K2,AllpassNum,AllpassDen] = zpk1p2bp(Z,P,K,Wo,Wt)</code>
<b>Description</b>	<p><code>[Z2,P2,K2,AllpassNum,AllpassDen] = zpk1p2bp(Z,P,K,Wo,Wt)</code> returns zeros, <math>Z_2</math>, poles, <math>P_2</math>, and gain factor, <math>K_2</math>, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.</p> <p>It also returns the numerator, <code>AllpassNum</code>, and the denominator <code>AllpassDen</code>, of the allpass mapping filter. The prototype lowpass filter is given with zeros, <math>Z</math>, poles, <math>P</math>, and gain factor, <math>K</math>.</p> <p>This transformation effectively places one feature of an original filter, located at frequency <math>-W_o</math>, at the required target frequency location, <math>W_{t1}</math>, and the second feature, originally at <math>+W_o</math>, at the new location, <math>W_{t2}</math>. It is assumed that <math>W_{t2}</math> is greater than <math>W_{t1}</math>. This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of <math>W_t</math>.</p> <p>Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, <math>F_1</math> and <math>F_2</math>, with <math>F_1</math> preceding <math>F_2</math>. Feature <math>F_1</math> will still precede <math>F_2</math> after the transformation. However, the distance between <math>F_1</math> and <math>F_2</math> will not be the same before and after the transformation.</p> <p>Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.</p> <p>Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be easily doubled and positioned at two distinct, desired frequencies.</p>
<b>Examples</b>	Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[B,A] = ellip(3,0.1,30,0.409);
Z = roots(B);
P = roots(A);
K = B(1);
[Z2,P2,K2] = zpk1p2bp(Z,P,K, 0.5, [0.2 0.3]);
hfvf = fvtool(B,A,K2*poly(Z2),poly(P2));
legend(hfvf,'Prototype Lowpass Filter', 'Bandpass Filter');
axis([0 1 -70 10]);
```

## Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter

Variable	Description
$W_0$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency location in the transformed target filter
$Z_2$	Zeros of the target filter
$P_2$	Poles of the target filter
$K_2$	Gain factor of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`zpkftransf` | `allpass1p2bs` | `iir1p2bs`

**Purpose** Zero-pole-gain lowpass to complex bandstop frequency transformation

**Syntax** `[Z2,P2,K2,AllpassNum,AllpassDen] = zpk1p2bsc(Z,P,K,Wo,Wt)`

**Description** `[Z2,P2,K2,AllpassNum,AllpassDen] = zpk1p2bsc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators.

**Examples** Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
```

```

z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpk1p2bsc(z, p, k, 0.5, [0.2, 0.3]);

```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

Variable	Description
<i>Z</i>	Zeros of the prototype lowpass filter
<i>P</i>	Poles of the prototype lowpass filter
<i>K</i>	Gain factor of the prototype lowpass filter
<i>W0</i>	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter

<i>AllpassDen</i>	Denominator of the mapping filter

## See Also

zpkftransf | allpass1p2bsc | iir1p2bsc

**Purpose** Zero-pole-gain lowpass to highpass frequency transformation

**Syntax** `[Z2,P2,K2,AllpassNum,AllpassDen] = zpk1p2hp(Z,P,K,Wo,Wt)`

**Description** `[Z2,P2,K2,AllpassNum,AllpassDen] = zpk1p2hp(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real highpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ , at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and the gain factor,  $K$ .

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, or the deep minimum in the stopband, or other ones.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.

**Examples** Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);  
z = roots(b);  
p = roots(a);
```

```
k = b(1);
[z2,p2,k2] = zpk1p2hp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

Variable	Description
<i>Z</i>	Zeros of the prototype lowpass filter
<i>P</i>	Poles of the prototype lowpass filter
<i>K</i>	Gain factor of the prototype lowpass filter
<i>W<sub>0</sub></i>	Frequency value to be transformed from the prototype filter
<i>W<sub>t</sub></i>	Desired frequency location in the transformed target filter
<i>Z<sub>2</sub></i>	Zeros of the target filter
<i>P<sub>2</sub></i>	Poles of the target filter
<i>K<sub>2</sub></i>	Gain factor of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

<b>Purpose</b>	Zero-pole-gain lowpass to lowpass frequency transformation
<b>Syntax</b>	<code>[Z2,P2,K2,AllpassNum,AllpassDen] = zpk1p2lp(Z,P,K,Wo,Wt)</code>
<b>Description</b>	<p><code>[Z2,P2,K2,AllpassNum,AllpassDen] = zpk1p2lp(Z,P,K,Wo,Wt)</code> returns zeros, <math>Z_2</math>, poles, <math>P_2</math>, and gain factor, <math>K_2</math>, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real lowpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency <math>W_o</math>, at the required target frequency location, <math>W_t</math>.</p> <p>It also returns the numerator, <code>AllpassNum</code>, and the denominator, <code>AllpassDen</code>, of the allpass mapping filter. The prototype lowpass filter is given with zeros, <math>Z</math>, poles, <math>P</math>, and gain factor, <math>K</math>.</p> <p>Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, <math>F_1</math> and <math>F_2</math>, with <math>F_1</math> preceding <math>F_2</math>. Feature <math>F_1</math> will still precede <math>F_2</math> after the transformation. However, the distance between <math>F_1</math> and <math>F_2</math> will not be the same before and after the transformation.</p> <p>Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.</p> <p>Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.</p>
<b>Examples</b>	<p>Design a prototype real IIR halfband filter using a standard elliptic approach:</p> <pre>[b, a] = ellip(3, 0.1, 30, 0.409); z = roots(b); p = roots(a); k = b(1); [z2,p2,k2] = zpk1p2lp(z, p, k, 0.5, 0.25);</pre>

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Using `zpk1p2lp` creates the desired half band IIR filter with the transformed features that you specify in the transformation function. This figure shows the results.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter

Variable	Description
$W_0$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency location in the transformed target filter
$Z_2$	Zeros of the target filter
$P_2$	Poles of the target filter
$K_2$	Gain factor of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

<b>Purpose</b>	Zero-pole-gain lowpass to M-band frequency transformation
<b>Syntax</b>	$[Z_2, P_2, K_2, \text{AllpassNum}, \text{AllpassDen}] = \text{zpk1p2mb}(Z, P, K, W_o, W_t)$ $[Z_2, P_2, K_2, \text{AllpassNum}, \text{AllpassDen}] = \text{zpk1p2mb}(Z, P, K, W_o, W_t, \text{Pass})$
<b>Description</b>	<p><math>[Z_2, P_2, K_2, \text{AllpassNum}, \text{AllpassDen}] = \text{zpk1p2mb}(Z, P, K, W_o, W_t)</math> returns zeros, <math>Z_2</math>, poles, <math>P_2</math>, and gain factor, <math>K_2</math>, of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to real multibandpass frequency mapping. By default the DC feature is kept at its original location.</p> <p><math>[Z_2, P_2, K_2, \text{AllpassNum}, \text{AllpassDen}] = \text{zpk1p2mb}(Z, P, K, W_o, W_t, \text{Pass})</math> allows you to specify an additional parameter, <b>Pass</b>, which chooses between using the "DC Mobility" and the "Nyquist Mobility". In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.</p> <p>It also returns the numerator, <b>AllpassNum</b>, and the denominator, <b>AllpassDen</b>, of the allpass mapping filter. The prototype lowpass filter is given with zeros, <math>Z</math>, poles, <math>P</math>, and gain factor, <math>K</math>.</p> <p>This transformation effectively places one feature of an original filter, located at frequency <math>W_o</math>, at the required target frequency locations, <math>W_{t1}, \dots, W_{tM}</math>.</p> <p>Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, <math>F_1</math> and <math>F_2</math>, with <math>F_1</math> preceding <math>F_2</math>. Feature <math>F_1</math> will still precede <math>F_2</math> after the transformation. However, the distance between <math>F_1</math> and <math>F_2</math> will not be the same before and after the transformation.</p> <p>Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.</p> <p>This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a</p>

number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);  
z = roots(b);  
p = roots(a);  
k = b(1);  
[z1,p1,k1] = zpk1p2mb(z, p, k, 0.5, [2 4 6 8]/10, 'pass');  
[z2,p2,k2] = zpk1p2mb(z, p, k, 0.5, [2 4 6 8]/10, 'stop');
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

The resulting multiband filter that replicates features from the prototype appears in the figure shown. Note the accuracy of the replication process.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$W_0$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency location in the transformed target filter
$Pass$	Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default
$Z_2$	Zeros of the target filter

Variable	Description
$P2$	Poles of the target filter
$K2$	Gain factor of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

# zpklp2mbc

---

**Purpose** Zero-pole-gain lowpass to complex M-band frequency transformation

**Syntax** `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)`

**Description** `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to complex multibandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature, for example, the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., to replicate notch filters and resonators at any required location.

**Examples** Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);  
z = roots(b);  
p = roots(a);  
k = b(1);
```

```
[z1,p1,k1] = zpk1p2mbc(z, p, k, 0.5, [2 4 6 8]/10);  
[z2,p2,k2] = zpk1p2mbc(z, p, k, 0.5, [2 4 6 8]/10);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

You could review the coefficients to compare the filters, but the graphical comparison shown here is quicker and easier.

However, looking at the coefficients in FVTool shows the complex nature desired.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating  $N$  bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpk1p2xn(z, p, k, [-0.5 0.5], [0 0.25], 'pass');
hfvf = fvtool(b, a, k2*poly(z2), poly(p2));
legend(hfvf,'Original Filter','Half-band Filter');
```

As demonstrated by the figure, the target filter has the desired response shape and values replicated from the prototype.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$\omega_0$	Frequency value to be transformed from the prototype filter

Variable	Description
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>Pass</i>	Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter
<i>AllpassDen</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

**Purpose** Zero-pole-gain complex bandpass frequency transformation

**Syntax** `[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)`

**Description** `[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter being transformed from any prototype by applying an Nth-order rateup frequency transformation, where N is the upsample ratio. Transformation creates N equal replicas of the prototype filter frequency response.

It also returns the numerator, AllpassNum, and the denominator, AllpassDen, of the allpass mapping filter. The original lowpass filter is given with zeros, Z, poles, P, and gain factor, K.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

**Examples** Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
% Upsample the prototype filter 4 times
[z2,p2,k2] = zpkrateup(z, p, k, 4);
% Compare prototype filter with target filter
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter

# zpkrateup

---

Variable	Description
<i>K</i>	Gain factor of the prototype lowpass filter
<i>N</i>	Integer upsampling ratio
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

[zpkftnsf](#) | [allpassshift](#) | [iirshift](#)

**Purpose**

Zero-pole-gain complex shift frequency transformation

**Syntax**

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,-0.5)
```

**Description**

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at  $W_o$ , placed at  $W_t$  in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and the gain factor,  $K$ .

`[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,0.5)` performs the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,-0.5)` performs the inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

**Examples**

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
```

**Rotation by  $\pi/4$  Radians/Sample**

Rotation by -0.25:

```
[z2,p2,k2] = zpkshifc(z, p, k, 0.5, 0.25);
```

```
hfvt = fvtool(b,a,k2*poly(z2),poly(p2));
```

## Rotation by $\pi/2$ Radians/Sample

```
[z3,p3,k3] = zpkshiftc(z, p, k, 0, 0.5);  
addfilter(hfvt,k3*poly(z3),poly(p3));  
legend(hfvt,'Original Filter','Rotation by  $-\pi/4$  radians/sample',...  
        'Rotation by  $\pi/2$  radians/sample');
```

## Rotation by $-\pi/2$ Radians/Sample

```
[z2,p2,k2] = zpkshiftc(z, p, k, 0.5, -0.5);  
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Result of Example 1

After performing the rotation, the resulting filter shows the features desired.

## Result of Example 2

Similar to the first example, performing the Hilbert transformation generates the desired target filter, shown here.

## Result of Example 3

Finally, using the inverse Hilbert transformation creates yet a third filter, as the figure shows.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$W_0$	Frequency value to be transformed from the prototype filter

Variable	Description
$Wt$	Desired frequency location in the transformed target filter
$Z2$	Zeros of the target filter
$P2$	Poles of the target filter
$K2$	Gain factor of the target filter
$AllpassDen$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

# zplane

---

**Purpose** Zero-poles plots for filters

**Syntax**

```
zplane(Hq)
zplane(Hq,plotoption)
zplane(Hq,plotoption,plotoption2)
zplane(Hq,Name,Value)
[zq,pq,kq] = zplane(Hq)
[zq,pq,kq,zr,pr,kr] = zplane(Hq)
```

**Description** `zplane(Hq)` plots the zeros and poles of a quantized filter `Hq` in the current figure window. The poles and zeros of the quantized and unquantized filters are plotted by default. The symbol `o` represents a zero of the unquantized reference filter, and the symbol `x` represents a pole of that filter. The symbols `□` and `+` are used to plot the zeros and poles of the quantized filter `Hq`. The plot includes the unit circle for reference.

`zplane(Hq,plotoption)` plots the poles and zeros associated with the quantized filter `Hq` according to one specified plot option. The string `plotoption` can be either of the following reference filter display options:

- **'on'** to display the poles and zeros of both the quantized filter and the associated reference filter (default)
- **'off'** to display the poles and zeros of only the quantized filter

`zplane(Hq,plotoption,plotoption2)` plots the poles and zeros associated with the quantized filter `Hq` according to two specified plot options. The string `plotoption` can be selected from the reference filter display options listed in the previous syntax. The string `plotoption2` can be selected from the section-by-section plotting style options described in the following list:

- **'individual'** to display the poles and zeros of each section of the filter in a separate figure window
- **'overlay'** to display the poles and zeros of all sections of the filter on the same plot

- **'tile'** to display the poles and zeros of each section of the filter in a separate plot in the same figure window

`zplane(Hq,Name,Value)` returns a phase response with additional options specified by one or more **Name,Value** pair arguments. Name-value pair arguments are only available if **Hq** is a filter System object.

`[zq,pq,kq] = zplane(Hq)` returns the vectors of zeros **zq**, poles **pq**, and gains **kq**. If **Hq** has  $n$  sections, **zq**, **pq**, and **kq** are returned as 1-by- $n$  cell arrays. If there are no zeros (or no poles), **zq** (or **pq**) is set to the empty matrix `[]`.

`[zq,pq,kq,zr,pr,kr] = zplane(Hq)` returns the vectors of zeros **zr**, poles **pr**, and gains **kr** of the reference filter associated with the quantized filter **Hq**. It also returns the vectors of zeros **zq**, poles **pq**, and gains **kq** for the quantized filter **Hq**.

## Input Arguments

### **Hq**

**hfilter** is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A filter System object. The function supports the following filter structures
  - `dsp.FIRFilter`
  - `dsp.BiquadFilter`
  - `dsp.FIRInterpolator`
  - `dsp.CICInterpolator`
  - `dsp.FIRDecimator`
  - `dsp.CICDecimator`
  - `dsp.FIRRateConverter`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

### 'Arithmetic'

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the **CoefficientDataType** property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <b>CustomCoefficientsDataType</b> property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### zq

Zeros of quantized filter.

### pq

Poles of quantized filter.

### kq

Gains of quantized filter.

**zr**

Zeros of reference filter.

**pr**

Poles of reference filter.

**kr**

Gains of reference filter.

## Examples

Create a quantized filter  $H_q$  from a fourth-order digital filter with cutoff frequency of 0.6. Plot the quantized and unquantized poles and zeros associated with this quantized filter.

```
[b,a] = ellip(4,.5,20,.6);  
Hq = dfilt.df2(b, a);  
Hq.arithmetic = 'fixed';  
zplane(Hq);
```

## Fixed-Point Filter Properties

In this section...
“Overview of Fixed-Point Filters” on page 5-2
“Fixed-Point Objects and Filters” on page 5-2
“Summary — Fixed-Point Filter Properties” on page 5-5
“Property Details for Fixed-Point Filters” on page 5-18

### Overview of Fixed-Point Filters

There is a distinction between fixed-point filters and quantized filters — quantized filters represent a superset that includes fixed-point filters.

When `dfilt` objects have their `Arithmetic` property set to `single` or `fixed`, they are quantized filters. However, after you set the `Arithmetic` property to `fixed`, the resulting filter is both quantized and fixed-point. Fixed-point filters perform arithmetic operations without allowing the binary point to move in response to the calculation — hence the name fixed-point. You can find out more about fixed-point arithmetic in your Fixed-Point Designer documentation or from the Help system.

With the `Arithmetic` property set to `single`, meaning the filter uses single-precision floating-point arithmetic, the filter allows the binary point to move during mathematical operations, such as sums or products. Therefore these filters cannot be considered fixed-point filters. But they are quantized filters.

The following sections present the properties for fixed-point filters, which includes all the properties for double-precision and single-precision floating-point filters as well.

### Fixed-Point Objects and Filters

Fixed-point filters depend in part on fixed-point objects from Fixed-Point Designer software. You can see this when you display a fixed-point filter at the command prompt.

```
hd=dfilt.df2t
```

```
hd =  
  
    FilterStructure: 'Direct-Form II Transposed'  
      Arithmetic: 'double'  
      Numerator: 1  
      Denominator: 1  
    PersistentMemory: false  
      States: [0x1 double]  
  
set(hd,'arithmetic','fixed')  
hd  
  
hd =  
  
    FilterStructure: 'Direct-Form II Transposed'  
      Arithmetic: 'fixed'  
      Numerator: 1  
      Denominator: 1  
    PersistentMemory: false  
      States: [1x1 embedded.fi]  
  
    CoeffWordLength: 16  
      CoeffAutoScale: true  
      Signed: true  
  
    InputWordLength: 16  
    InputFracLength: 15  
  
    OutputWordLength: 16  
    OutputFracLength: 15  
  
    StateWordLength: 16  
      StateAutoScale: true  
  
      ProductMode: 'FullPrecision'  
  
    AccumWordLength: 40  
      CastBeforeSum: true
```

```
RoundMode: 'convergent'  
OverflowMode: 'wrap'
```

Look at the States property, shown here

```
States: [1x1 embedded.fi]
```

The notation `embedded.fi` indicates that the states are being represented by fixed-point objects, usually called `fi` objects. If you take a closer look at the property `States`, you see how the properties of the `fi` object represent the values for the filter states.

```
hd.states
```

```
ans =
```

```
[]
```

```
DataType: Fixed  
Scaling: BinaryPoint  
Signed: true  
WordLength: 16  
FractionLength: 15
```

```
RoundMode: round  
OverflowMode: saturate  
ProductMode: FullPrecision  
MaxProductWordLength: 128  
SumMode: FullPrecision  
MaxSumWordLength: 128  
CastBeforeSum: true
```

To learn more about `fi` objects (fixed-point objects) in general, refer to your Fixed-Point Designer documentation.

As inputs (data to be filtered), fixed-point filters accept both regular double-precision values and `fi` objects. Which you use depends on your needs. How your filter responds to the input data is determined by the settings of the filter properties, discussed in the next few sections.

## Summary – Fixed-Point Filter Properties

Discrete-time filters in this toolbox use objects that perform the filtering and configuration of the filter. As objects, they include properties and methods that are often referred to as functions — not strictly the same as MATLAB functions but mostly so) to provide filtering capability. In discrete-time filters, or `dfilt` objects, many of the properties are dynamic, meaning they become available depending on the settings of other properties in the `dfilt` object or filter.

### Dynamic Properties

When you use a `dfilt.structure` function to create a filter, MATLAB displays the filter properties in the command window in return (unless you end the command with a semicolon which suppresses the output display). Generally you see six or seven properties, ranging from the property `FilterStructure` to `PersistentMemory`. These first properties are always present in the filter. One of the most important properties is `Arithmetic`. The `Arithmetic` property controls all of the dynamic properties for a filter.

Dynamic properties become available when you change another property in the filter. For example, when you change the `Arithmetic` property value to `fixed`, the display now shows many more properties for the filter, all of them considered dynamic. Here is an example that uses a direct form II filter. First create the default filter:

```
hd=dfilt.df2
```

```
hd =
```

```

    FilterStructure: 'Direct-Form II'
      Arithmetic: 'double'
      Numerator: 1
      Denominator: 1
 PersistentMemory: false
           States: [0x1 double]
```

With the filter `hd` in the workspace, convert the arithmetic to fixed-point. Do this by setting the property `Arithmetic` to `fixed`. Notice the display. Instead of a few properties, the filter now has many more, each one related

to a particular part of the filter and its operation. Each of the now-visible properties is dynamic.

```
hd.arithmetic='fixed'
```

```
hd =
```

```
    FilterStructure: 'Direct-Form II'  
      Arithmetic: 'fixed'  
      Numerator: 1  
      Denominator: 1  
    PersistentMemory: false  
      States: [1x1 embedded.fi]  
  
    CoeffWordLength: 16  
      CoeffAutoScale: true  
      Signed: true  
  
    InputWordLength: 16  
    InputFracLength: 15  
  
    OutputWordLength: 16  
      OutputMode: 'AvoidOverflow'  
  
    StateWordLength: 16  
    StateFracLength: 15  
  
      ProductMode: 'FullPrecision'  
  
    AccumWordLength: 40  
      CastBeforeSum: true  
  
      RoundMode: 'convergent'  
      OverflowMode: 'wrap'
```

Even this list of properties is not yet complete. Changing the value of other properties such as the `ProductMode` or `CoeffAutoScale` properties may reveal even more properties that control how the filter works. Remember this feature about `dfilt` objects and dynamic properties as you review the rest of this section about properties of fixed-point filters.

An important distinction is you cannot change the value of a property unless you see the property listed in the default display for the filter. Entering the filter name at the MATLAB prompt generates the default property display for the named filter. Using `get(filtername)` does not generate the default display — it lists all of the filter properties, both those that you can change and those that are not available yet.

The following table summarizes the properties, static and dynamic, of fixed-point filters and provides a brief description of each. Full descriptions of each property, in alphabetical order, follow the table.

Property Name	Valid Values [Default Value]	Brief Description
AccumFracLength	Any positive or negative integer number of bits [29]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any positive integer number of bits [40]	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	[Double], single, fixed	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	[True] or false	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
CoeffAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffFracLength	Any positive or negative integer number of bits [14]	Set the fraction length the filter uses to interpret coefficients. <code>CoeffFracLength</code> is not available until you set <code>CoeffAutoScale</code> to <code>false</code> . Scalar filters include this property.
CoeffWordLength	Any positive integer number of bits [16]	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving denominator coefficients.
DenFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
Denominator	Any filter coefficient value [1]	Holds the denominator coefficients for IIR filters.
DenProdFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value after you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
DenStateFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FracDelay	Any decimal value between 0 and 1 samples	Specifies the fractional delay provided by the filter, in decimal fractions of a sample.
FDAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper scaling to represent the fractional delay value without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>FDWordLength</code> and <code>FDFracLength</code> properties to specify the data format applied.
FDFracLength	Any positive or negative integer number of bits [5]	Specifies the fraction length to represent the fractional delay.
FDProdFracLength	Any positive or negative integer number of bits [34]	Specifies the fraction length to represent the result of multiplying the coefficients with the fractional delay.
FDProdWordLength	Any positive or negative integer number of bits [39]	Specifies the word length to represent result of multiplying the coefficients with the fractional delay.
FDWordLength	Any positive or negative integer number of bits [6]	Specifies the word length to represent the fractional delay.
DenStateWordLength	Any positive integer number of bits [16]	Specifies the word length used to represent the states associated with denominator coefficients in the filter.

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.
FilterStructure	Not applicable.	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret data to be processed by the filter.
InputWordLength	Any positive integer number of bits [16]	Specifies the word length applied to represent input data.
Ladder	Any ladder coefficients in double-precision data type [1]	latticearma filters include this property to store the ladder coefficients.
LadderAccumFracLength	Any positive or negative integer number of bits [29]	latticearma filters use this to define the fraction length applied to values output by the accumulator that stores the results of ladder computations.
LadderFracLength	Any positive or negative integer number of bits [14]	latticearma filters use ladder coefficients in the signal flow. This property determines the fraction length used to interpret the coefficients.

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
Lattice	Any lattice structure coefficients. No default value.	Stores the lattice coefficients for lattice-based filters.
LatticeAccumFracLength	Any positive or negative integer number of bits [29]	Specifies how the accumulator outputs the results of operations on the lattice coefficients.
LatticeFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length applied to the lattice coefficients.
MultiplicandFracLength	Any positive or negative integer number of bits [15]	Sets the fraction length for values used in product operations in the filter. Direct-form I transposed (df1t) filter structures include this property.
MultiplicandWordLength	Any positive integer number of bits [16]	Sets the word length applied to the values input to a multiply operation (the multiplicands). The filter structure df1t includes this property.
NumAccumFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients.
Numerator	Any double-precision filter coefficients [1]	Holds the numerator coefficient values for the filter.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
NumProdFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. You can change the property value after you set ProductMode to SpecifyPrecision.

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
NumStateFracLength	Any positive or negative integer number of bits [15]	For IIR filters, this defines the fraction length applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficients in the filter.
NumStateWordLength	Any positive integer number of bits [16]	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficients in the filter.
OutputFracLength	Any positive or negative integer number of bits — [15] or [12] bits depending on the filter structure	Determines how the filter interprets the filtered data. You can change the value of OutputFracLength after you set OutputMode to SpecifyPrecision.
OutputMode	[AvoidOverflow], BestPrecision, SpecifyPrecision	<p>Sets the mode the filter uses to scale the filtered input data. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the fraction length used by the filtered data.</li> </ul>
OutputWordLength	Any positive integer number of bits [16]	Determines the word length used for the filtered data.

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
OverflowMode	Saturate or [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — hey maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [29]	For the output from a product operation, this sets the fraction length used to interpret the numeric data. This property becomes writable (you can change the value) after you set <b>ProductMode</b> to <b>SpecifyPrecision</b> .
ProductMode	[FullPrecision], KeepLSB, KeepMSB, SpecifyPrecision	Determines how the filter handles the output of product operations. Choose from full precision ( <b>FullPrecision</b> ), or whether to keep the most significant bit ( <b>KeepMSB</b> ) or least significant bit ( <b>KeepLSB</b> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <b>ProductMode</b> to <b>SpecifyPrecision</b> .

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
ProductWordLength	Any positive number of bits. Default is 16 or 32 depending on the filter structure	Specifies the word length to use for the results of multiplication operations. This property becomes writable (you can change the value) after you set ProductMode to SpecifyPrecision.
PersistentMemory	True or [false]	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. True is the default setting.
RoundMode	[Convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <b>ceil</b> - Round toward positive infinity.</li> <li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <b>fix</b> - Round toward zero.</li> <li>• <b>floor</b> - Round toward negative infinity.</li> <li>• <b>nearest</b> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <b>round</b> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul>

Property Name	Valid Values [Default Value]	Brief Description
		The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Any positive or negative integer number of bits [29]	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Available only when you disable <code>CoeffAutoScale</code> by setting it to <code>false</code> .
ScaleValues	[2 x 1 double] array with values of 1	Stores the scaling values for sections in SOS filters.
Signed	[True] or false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
sosMatrix	[1 0 0 1 0 0]	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type <code>double</code> to represent the coefficients.

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
SectionInputAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data entering a section of an SOS filter. Setting this property to <b>false</b> enables you to change the SectionInputFracLength property to specify the precision used. Available only for SOS filters.
SectionInputFracLength	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data entering a section. Compare to SectionOutputFracLength. Available only when you disable SectionInputAutoScale by setting it to <b>false</b> .
SectionInputWordLength	Any positive or negative integer number of bits [29]	Sets the word length used to represent the data moving into a section of an SOS filter.
SectionOutputAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data leaving a section of an SOS filter. Setting this property to <b>false</b> enables you to change the SectionOutputFracLength property to specify the precision used.

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
SectionOutputFracLength	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data leaving a section. Compare to SectionInputFracLength. Available after you disable SectionOutputAutoScale by setting it to false.
SectionOutputWordLength	Any positive or negative integer number of bits [32]	Sets the word length used to represent the data moving out of one section of an SOS filter.
StateFracLength	Any positive or negative integer number of bits [15]	Lets you set the fraction length applied to interpret the filter states.
States	[1x1 embedded fi]	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Notice that the states use fi objects, with the associated properties from those objects. For details, refer to filtstates in your Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Any positive integer number of bits [16]	Sets the word length used to represent the filter states.
TapSumFracLength	Any positive or negative integer number of bits [15]	Sets the fraction length used to represent the filter tap values in addition operations. This is available after you set TapSumMode to false. Symmetric and antisymmetric FIR filters include this property.

Property Name	Valid Values [Default Value]	Brief Description
TapSumMode	FullPrecision, KeepLSB, [KeepMSB], SpecifyPrecision	<p>Determines how the accumulator outputs stored that involve filter tap weights. Choose from full precision (FullPrecision) to prevent overflows, or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when outputting results from the accumulator. To let you set the precision (the fraction length) used by the output from the accumulator, set FilterInternals to SpecifyPrecision.</p> <p>Symmetric and antisymmetric FIR filters include this property.</p>
TapSumWordLength	Any positive number of bits [17]	<p>Sets the word length used to represent the filter tap weights during addition. Symmetric and antisymmetric FIR filters include this property.</p>

### Property Details for Fixed-Point Filters

When you create a fixed-point filter, you are creating a filter object (a `dfilt` object). In this manual, the terms filter, `dfilt` object, and filter object are used interchangeably. To filter data, you apply the filter object to your data set. The output of the operation is the data filtered by the filter and the filter property values.

Filter objects have properties to which you assign property values. You use these property values to assign various characteristics to the filters you create, including

- The type of arithmetic to use in filtering operations
- The structure of the filter used to implement the filter (not a property you can set or change — you select it by the `dfilt.structure` function you choose)

- The locations of quantizations and cast operations in the filter
- The data formats used in quantizing, casting, and filtering operations

Details of the properties associated with fixed-point filters are described in alphabetical order on the following pages.

### **AccumFracLength**

Except for state-space filters, all `dfilt` objects that use fixed arithmetic have this property that defines the fraction length applied to data in the accumulator. Combined with `AccumWordLength`, `AccumFracLength` helps fully specify how the accumulator outputs data after processing addition operations. As with all fraction length properties, `AccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

### **AccumWordLength**

You use `AccumWordLength` to define the data word length used in the accumulator. Set this property to a value that matches your intended hardware. For example, many digital signal processors use 40-bit accumulators, so set `AccumWordLength` to 40 in your fixed-point filter:

```
set(hq,'arithmetic','fixed');  
set(hq,'AccumWordLength',40);
```

Note that `AccumWordLength` only applies to filters whose `Arithmetic` property value is `fixed`.

### **Arithmetic**

Perhaps the most important property when you are working with `dfilt` objects, `Arithmetic` determines the type of arithmetic the filter uses, and the properties or quantizers that compose the fixed-point or quantized filter. You use strings to set the `Arithmetic` property value.

The next table shows the valid strings for the `Arithmetic` property. Following the table, each property string appears with more detailed information about what happens when you select the string as the value for `Arithmetic` in your `dfilt`.

<b>Arithmetic Property String</b>	<b>Brief Description of Effect on the Filter</b>
double	All filtering operations and coefficients use double-precision floating-point representations and math. When you use <code>dfilt.structure</code> to create a filter object, <code>double</code> is the default value for the Arithmetic property.
single	All filtering operations and coefficients use single-precision floating-point representations and math.
fixed	This string applies selected default values for the properties in the fixed-point filter object, including such properties as coefficient word lengths, fraction lengths, and various operating modes. Generally, the default values match those you use on many digital signal processors. Allows signed fixed data types only. Fixed-point arithmetic filters are available only when you install Fixed-Point Designer software with this toolbox.

**double.** When you use one of the `dfilt.structure` methods to create a filter, the Arithmetic property value is `double` by default. Your filter is identical to the same filter without the Arithmetic property, as you would create if you used Signal Processing Toolbox software.

Double means that the filter uses double-precision floating-point arithmetic in all operations while filtering:

- All input to the filter must be double data type. Any other data type returns an error.
- The states and output are doubles as well.
- All internal calculations are done in double math.

When you use `double` data type filter coefficients, the reference and quantized (fixed-point) filter coefficients are identical. The filter stores the reference coefficients as double data type.

**single.** When your filter should use single-precision floating-point arithmetic, set the `Arithmetic` property to `single` so all arithmetic in the filter processing gets restricted to single-precision data type.

- Input data must be single data type. Other data types return errors.
- The filter states and filter output use single data type.

When you choose `single`, you can provide the filter coefficients in either of two ways:

- Double data type coefficients. With `Arithmetic` set to `single`, the filter casts the double data type coefficients to single data type representation.
- Single data type. These remain unchanged by the filter.

Depending on whether you specified single or double data type coefficients, the reference coefficients for the filter are stored in the data type you provided. If you provide coefficients in double data type, the reference coefficients are double as well. Providing single data type coefficients generates single data type reference coefficients. Note that the arithmetic used by the reference filter is always double.

When you use `refilter` to create a reference filter from the reference coefficients, the resulting filter uses double-precision versions of the reference filter coefficients.

To set the `Arithmetic` property value, create your filter, then use `set` to change the `Arithmetic` setting, as shown in this example using a direct form FIR filter.

```
b=fir1(7,0.45);
```

```
hd=dfilt.dffir(b)
```

```
hd =
```

```
    FilterStructure: 'Direct-Form FIR'  
      Arithmetic: 'double'  
      Numerator: [1x8 double]  
 PersistentMemory: false
```

```
States: [7x1 double]

set(hd,'arithmetic','single')
hd

hd =

    FilterStructure: 'Direct-Form FIR'
    Arithmetic: 'single'
    Numerator: [1x8 double]
    PersistentMemory: false
    States: [7x1 single]
```

**fixed.** Converting your `dfilt` object to use fixed arithmetic results in a filter structure that uses properties and property values to match how the filter would behave on digital signal processing hardware.

---

**Note** The `fixed` option for the property `Arithmetic` is available only when you install Fixed-Point Designer software as well as DSP System Toolbox software.

---

After you set `Arithmetic` to `fixed`, you are free to change any property value from the default value to a value that more closely matches your needs. You cannot, however, mix floating-point and fixed-point arithmetic in your filter when you select `fixed` as the `Arithmetic` property value. Choosing `fixed` restricts you to using either fixed-point or floating point throughout the filter (the data type must be homogenous). Also, all data types must be signed. `fixed` does not support unsigned data types except for unsigned coefficients when you set the property `Signed` to `false`. Mixing word and fraction lengths within the fixed object is acceptable. In short, using fixed arithmetic assumes

- fixed word length.
- fixed size and dedicated accumulator and product registers.
- the ability to do either saturation or wrap arithmetic.
- that multiple rounding modes are available.

Making these assumptions simplifies your job of creating fixed-point filters by reducing repetition in the filter construction process, such as only requiring you to enter the accumulator word size once, rather than for each step that uses the accumulator.

Default property values are a starting point in tailoring your filter to common hardware, such as choosing 40-bit word length for the accumulator, or 16-bit words for data and coefficients.

In this `dfilt` object example, `get` returns the default values for `dfilt.df1t` structures.

```
[b,a]=butter(6,0.45);
hd=dfilt.df1(b,a)
```

```

AccumWordLength: 40
    CastBeforeSum: true

    RoundMode: 'convergent'
    OverflowMode: 'wrap'
```

Unlike the `single` or `double` options for `Arithmetic`, `fixed` uses properties to define the word and fraction lengths for each portion of your filter. By changing the property value of any of the properties, you control your filter performance. Every word length and fraction length property is independent — set the one you need and the others remain unchanged, such as setting the input word length with `InputWordLength`, while leaving the fraction length the same.

```
d=fdesign.lowpass('n,fc',6,0.45)

```

Notice that the properties for the lattice filter `hdlat` and direct-form II filter `hd` are different, as befits their differing filter structures. Also, some properties are common to both objects, such as `RoundMode` and `PersistentMemory` and behave the same way in both objects.

**Notes About Fraction Length, Word Length, and Precision.** Word length and fraction length combine to make the format for a fixed-point number, where word length is the number of bits used to represent the value and fraction length specifies, in bits, the location of the binary point in the fixed-point representation. Therein lies a problem — fraction length, which you specify in bits, can be larger than the word length, or a negative number of bits. This section explains how that idea works and how you might use it.

Unfortunately fraction length is somewhat misnamed (although it continues to be used in this User's Guide and elsewhere for historical reasons).

Fraction length defined as the number of fractional bits (bits to the right of the binary point) is true only when the fraction length is positive and less than or equal to the word length. In MATLAB format notation you can use `[word length fraction length]`. For example, for the format `[16 16]`, the second 16 (the fraction length) is the number of fractional bits or bits to the right of the binary point. In this example, all 16 bits are to the right of the binary point.

But it is also possible to have fixed-point formats of `[16 18]` or `[16 -45]`. In these cases the fraction length can no longer be the number of bits to the right of the binary point since the format says the word length is 16 — there cannot be 18 fraction length bits on the right. And how can there be a negative number of bits for the fraction length, such as `[16 -45]`?

A better way to think about fixed-point format [word length fraction length] and what it means is that the representation of a fixed-point number is a weighted sum of powers of two driven by the fraction length, or the two's complement representation of the fixed-point number.

Consider the format [B L], where the fraction length L can be positive, negative, 0, greater than B (the word length) or less than B. (B and L are always integers and B is always positive.)

Given a binary string  $b(1) b(2) b(3) \dots b(B)$ , to determine the two's-complement value of the string in the format described by [B L], use the value of the individual bits in the binary string in the following formula, where  $b(1)$  is the first binary bit (and most significant bit, MSB),  $b(2)$  is the second, and on up to  $b(B)$ .

The decimal numeric value that those bits represent is given by

$$\text{value} = -b(1) * 2^{(B-L-1)} + b(2) * 2^{(B-L-2)} + b(3) * 2^{(B-L-3)} + \dots + b(B) * 2^{(-L)}$$

L, the fraction length, represents the negative of the weight of the last, or least significant bit (LSB). L is also the step size or the precision provided by a given fraction length.

**Precision.** Here is how precision works.

When all of the bits of a binary string are zero except for the LSB (which is therefore equal to one), the value represented by the bit string is given by  $2^{(-L)}$ . If L is negative, for example  $L=-16$ , the value is  $2^{16}$ . The smallest step between numbers that can be represented in a format where  $L=-16$  is given by  $1 \times 2^{16}$  (the rightmost term in the formula above), which is 65536. Note the precision does not depend on the word length.

Take a look at another example. When the word length set to 8 bits, the decimal value 12 is represented in binary by 00001100. That 12 is the decimal equivalent of 00001100 tells you that you are using [8 0] data format representation — the word length is 8 bits and fraction length 0 bits, and the step size or precision (the smallest difference between two adjacent values in the format [8,0], is  $2^0=1$ .

Suppose you plan to keep only the upper 5 bits and discard the other three. The resulting precision after removing the right-most three bits comes from the weight of the lowest remaining bit, the fifth bit from the left, which is  $2^3=8$ , so the format would be [5,-3].

Note that in this format the step size is 8, I cannot represent numbers that are between multiples of 8.

In MATLAB, with Fixed-Point Designer software installed:

```
x=8;
q=quantizer([8,0]); % Word length = 8, fraction length = 0
xq=quantize(q,x);
binxq=num2bin(q,xq);
q1=quantizer([5 -3]); % Word length = 5, fraction length = -3
xq1 = quantize(q1,xq);
binxq1=num2bin(q1,xq1);
binxq
```

```
binxq =
```

```
00001000
```

```
binxq1
```

```
binxq1 =
```

```
00001
```

But notice that in [5,-3] format, 00001 is the two's complement representation for 8, not for 1;  $q = \text{quantizer}([8 \ 0])$  and  $q1 = \text{quantizer}([5 \ -3])$  are not the same. They cover the about the same range —  $\text{range}(q) > \text{range}(q1)$  — but their quantization step is different —  $\text{eps}(q)=8$ , and  $\text{eps}(q1)=1$ .

Look at one more example. When you construct a quantizer  $q$

```
q = quantizer([a,b])
```

the first element in  $[a,b]$  is  $a$ , the word length used for quantization. The second element in the expression,  $b$ , is related to the quantization step — the numerical difference between the two closest values that the quantizer

can represent. This is also related to the weight given to the LSB. Note that  $2^{-b} = \text{eps}(q)$ .

Now construct two quantizers, `q1` and `q2`. Let `q1` use the format `[32,0]` and let `q2` use the format `[16, -16]`.

```
q1 = quantizer([32,0])
q2 = quantizer([16, -16])
```

Quantizers `q1` and `q2` cover the same range, but `q2` has less precision. It covers the range in steps of  $2^{16}$ , while `q1` covers the range in steps of 1.

This lost precision is due to (or can be used to model) throwing out 16 least-significant bits.

An important point to understand is that in `dfilt` objects and filtering you control which bits are carried from the sum and product operations in the filter to the filter output by setting the format for the output from the sum or product operation.

For instance, if you use `[16 0]` as the output format for a 32-bit result from a sum operation when the original format is `[32 0]`, you take the lower 16 bits from the result. If you use `[16 -16]`, you take the higher 16 bits of the original 32 bits. You could even take 16 bits somewhere in between the 32 bits by choosing something like `[16 -8]`, but you probably do not want to do that.

Filter scaling is directly implicated in the format and precision for a filter. When you know the filter input and output formats, as well as the filter internal formats, you can scale the inputs or outputs to stay within the format ranges. For more information about scaling filters, refer to “Floating-Point to Fixed-Point Filter Conversion”.

Notice that overflows or saturation might occur at the filter input, filter output, or within the filter itself, such as during add or multiply or accumulate operations. Improper scaling at any point in the filter can result in numerical errors that dramatically change the performance of your fixed-point filter implementation.

## CastBeforeSum

Setting the `CastBeforeSum` property determines how the filter handles the input values to sum operations in the filter. After you set your filter `Arithmetic` property value to `fixed`, you have the option of using `CastBeforeSum` to control the data type of some inputs (addends) to summations in your filter. To determine which addends reflect the `CastBeforeSum` property setting, refer to the reference page for the signal flow diagram for the filter structure.

`CastBeforeSum` specifies whether to cast selected addends to summations in the filter to the output format from the addition operation before performing the addition. When you specify `true` for the property value, the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

Specifying `CastBeforeSum` to be `false` prevents the addends from being cast to the output format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use.

Notice that the output format for every sum operation reflects the value of the output property specified in the filter structure diagram. Which input property is referenced by `CastBeforeSum` depends on the structure.

Property Value	Description
<code>false</code>	Configures filter summation operations to retain the addends in the format carried from the previous operation.
<code>true</code>	Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually this generates results from the summation that more closely match those found from digital signal processors

Another point — with `CastBeforeSum` set to `false`, the filter realization process inserts an intermediate data type format to hold temporarily the full precision sum of the inputs. A separate Convert block performs the process of casting the addition result to the accumulator format. This intermediate data format occurs because the Sum block in Simulink always casts input (addends) to the output data type.

**Diagrams of `CastBeforeSum` Settings.** When `CastBeforeSum` is `false`, sum elements in filter signal flow diagrams look like this:

showing that the input data to the sum operations (the addends) retain their format word length and fraction length from previous operations. The addition process uses the existing input formats and then casts the output to the format defined by `AccumFormat`. Thus the output data has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

When `CastBeforeSum` is `true`, sum elements in filter signal flow diagrams look like this:

showing that the input data gets recast to the accumulator format word length and fraction length (`AccumFormat`) before the sum operation occurs. The data output by the addition operation has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

## **CoeffAutoScale**

How the filter represents the filter coefficients depends on the property value of `CoeffAutoScale`. When you create a `dfilt` object, you use coefficients in double-precision format. Converting the `dfilt` object to fixed-point arithmetic forces the coefficients into a fixed-point representation. The representation the filter uses depends on whether the value of `CoeffAutoScale` is `true` or `false`.

- `CoeffAutoScale = true` means the filter chooses the fraction length to maintain the value of the coefficients as close to the double-precision values as possible. When you change the word length applied to the coefficients, the filter object changes the fraction length to try to accommodate the change. `true` is the default setting.
- `CoeffAutoScale = false` removes the automatic scaling of the fraction length for the coefficients and exposes the property that controls the coefficient fraction length so you can change it. For example, if the filter is a direct form FIR filter, setting `CoeffAutoScale = false` exposes the `NumFracLength` property that specifies the fraction length applied to numerator coefficients. If the filter is an IIR filter, setting `CoeffAutoScale = false` exposes both the `NumFracLength` and `DenFracLength` properties.

Here is an example of using `CoeffAutoScale` with a direct form filter.

```
hd2=dfilt.dffir([0.3 0.6 0.3])
```

```
hd2 =
```

```

    FilterStructure: 'Direct-Form FIR'
      Arithmetic: 'double'
      Numerator: [0.3000 0.6000 0.3000]
 PersistentMemory: false
      States: [2x1 double]
```

```
hd2.arithmetic='fixed'

hd2 =

    FilterStructure: 'Direct-Form FIR'
      Arithmetic: 'fixed'
      Numerator: [0.3000 0.6000 0.3000]
    PersistentMemory: false
      States: [1x1 embedded.fi]

    CoeffWordLength: 16
      CoeffAutoScale: true
      Signed: true

    InputWordLength: 16
    InputFracLength: 15

    OutputWordLength: 16
      OutputMode: 'AvoidOverflow'

      ProductMode: 'FullPrecision'

    AccumWordLength: 40
      CastBeforeSum: true

      RoundMode: 'convergent'
      OverflowMode: 'wrap'
```

To this point, the filter coefficients retain the original values from when you created the filter as shown in the Numerator property. Now change the CoeffAutoScale property value from true to false.

```
hd2.coeffautoScale=false

hd2 =

    FilterStructure: 'Direct-Form FIR'
      Arithmetic: 'fixed'
      Numerator: [0.3000 0.6000 0.3000]
    PersistentMemory: false
```

```

        States: [1x1 embedded.fi]

    CoeffWordLength: 16
    CoeffAutoScale: false
    NumFracLength: 15
    Signed: true

    InputWordLength: 16
    InputFracLength: 15

    OutputWordLength: 16
    OutputMode: 'AvoidOverflow'

    ProductMode: 'FullPrecision'

    AccumWordLength: 40
    CastBeforeSum: true

    RoundMode: 'convergent'
    OverflowMode: 'wrap'

```

With the NumFracLength property now available, change the word length to 5 bits.

Notice the coefficient values. Setting CoeffAutoScale to false removes the automatic fraction length adjustment and the filter coefficients cannot be represented by the current format of [5 15] — a word length of 5 bits, fraction length of 15 bits.

```
hd2.coeffwordlength=5
```

```
hd2 =
```

```

    FilterStructure: 'Direct-Form FIR'
    Arithmetic: 'fixed'
    Numerator: [4.5776e-004 4.5776e-004 4.5776e-004]
    PersistentMemory: false
    States: [1x1 embedded.fi]

    CoeffWordLength: 5

```

```
CoeffAutoScale: false
  NumFracLength: 15
    Signed: true

InputWordLength: 16
InputFracLength: 15

OutputWordLength: 16
  OutputMode: 'AvoidOverflow'

  ProductMode: 'FullPrecision'

AccumWordLength: 40
  CastBeforeSum: true

  RoundMode: 'convergent'
  OverflowMode: 'wrap'
```

Restoring `CoeffAutoScale` to `true` goes some way to fixing the coefficient values. Automatically scaling the coefficient fraction length results in setting the fraction length to 4 bits. You can check this with `get(hd2)` as shown below.

```
hd2.coeffautoScale=true
```

```
hd2 =
```

```
FilterStructure: 'Direct-Form FIR'

```

Clearly five bits is not enough to represent the coefficients accurately.

### **CoeffFracLength**

Fixed-point scalar filters that you create using `dfilt.scalar` use this property to define the fraction length applied to the scalar filter coefficients. Like the coefficient-fraction-length-related properties for the FIR, lattice, and IIR filters, `CoeffFracLength` is not displayed for scalar filters until you set `CoeffAutoScale` to `false`. Once you change the automatic scaling you can set the fraction length for the coefficients to any value you require.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 14 bits, with the `CoeffWordLength` of 16 bits.

### **CoeffWordLength**

One primary consideration in developing filters for hardware is the length of a data word. `CoeffWordLength` defines the word length for these data storage and arithmetic locations:

- Numerator and denominator filter coefficients
- Tap sum in `dfilt.dfsymfir` and `dfilt.dfasymfir` filter objects
- Section input, multiplicand, and state values in direct-form SOS filter objects such as `dfilt.df1t` and `dfilt.df2`
- Scale values in second-order filters
- Lattice and ladder coefficients in lattice filter objects, such as `dfilt.latticearma` and `dfilt.latticemamax`
- Gain in `dfilt.scalar`

Setting this property value controls the word length for the data listed. In most cases, the data words in this list have separate fraction length properties to define the associated fraction lengths.

Any positive, integer word length works here, limited by the machine you use to develop your filter and the hardware you use to deploy your filter.

## DenAccumFracLength

Filter structures `df1`, `df1t`, `df2`, and `df2t` that use fixed arithmetic have this property that defines the fraction length applied to denominator coefficients in the accumulator. In combination with `AccumWordLength`, the properties fully specify how the accumulator outputs data stored there.

As with all fraction length properties, `DenAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. To be able to change the property value for this property, you set `FilterInternals` to `SpecifyPrecision`.

## DenFracLength

Property `DenFracLength` contains the value that specifies the fraction length for the denominator coefficients for your filter. `DenFracLength` specifies the fraction length used to interpret the data stored in `C`. Used in combination with `CoeffWordLength`, these two properties define the interpretation of the coefficients stored in the vector that contains the denominator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `CoeffWordLength` of 16 bits.

## Denominator

The denominator coefficients for your IIR filter, taken from the prototype you start with, are stored in this property. Generally this is a 1-by-`N` array of data in double format, where `N` is the length of the filter.

All IIR filter objects include `Denominator`, except the lattice-based filters which store their coefficients in the `Lattice` property, and second-order section filters, such as `dfilt.df1tsos`, which use the `SosMatrix` property to hold the coefficients for the sections.

## DenProdFracLength

A property of all of the direct form IIR `dfilt` objects, except the ones that implement second-order sections, `DenProdFracLength` specifies the fraction

length applied to data output from product operations that the filter performs on denominator coefficients.

Looking at the signal flow diagram for the `dfilt.df1t` filter, for example, you see that denominators and numerators are handled separately. When you set `ProductMode` to `SpecifyPrecision`, you can change the `DenProdFracLength` setting manually. Otherwise, for multiplication operations that use the denominator coefficients, the filter sets the fraction length as defined by the `ProductMode` setting.

### **DenStateFracLength**

When you look at the flow diagram for the `dfilt.df1sos` filter object, the states associated with denominator coefficient operations take the fraction length from this property. In combination with the `DenStateWordLength` property, these properties fully specify how the filter interprets the states.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `DenStateWordLength` of 16 bits.

### **DenStateWordLength**

When you look at the flow diagram for the `dfilt.df1sos` filter object, the states associated with the denominator coefficient operations take the data format from this property and the `DenStateFracLength` property. In combination, these properties fully specify how the filter interprets the state it uses.

By default, the value is 16 bits, with the `DenStateFracLength` of 15 bits.

### **FilterInternals**

Similar to the `FilterInternals` pane in `FDATool`, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. Setting `FilterInternals` to `SpecifyPrecision` exposes the output

and accumulator related properties so you can set your own word and fraction lengths for them. Note that

## FilterStructure

Every `dfilt` object has a `FilterStructure` property. This is a read-only property containing a string that declares the structure of the filter object you created.

When you construct filter objects, the `FilterStructure` property value is returned containing one of the strings shown in the following table. Property `FilterStructure` indicates the filter architecture and comes from the constructor you use to create the filter.

After you create a filter object, you cannot change the `FilterStructure` property value. To make filters that use different structures, you construct new filters using the appropriate methods, or use `convert` to switch to a new structure.

**Default value.** Since this depends on the constructor you use and the constructor includes the filter structure definition, there is no default value. When you try to create a filter without specifying a structure, MATLAB returns an error.

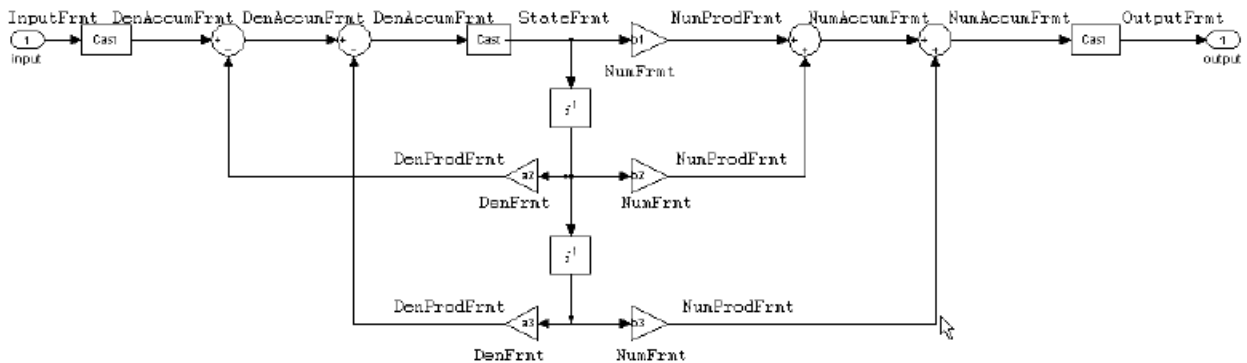

Filter Constructor Name	FilterStructure Property String and Filter Type
' <code>dfilt.df1</code> '	Direct form I
' <code>dfilt.df1sos</code> '	Direct form I filter implemented using second-order sections
' <code>dfilt.df1t</code> '	Direct form I transposed
' <code>dfilt.df2</code> '	Direct form II
' <code>dfilt.df2sos</code> '	Direct form II filter implemented using second order sections
' <code>dfilt.df2t</code> '	Direct form II transposed
' <code>dfilt.dfasymfir</code> '	Antisymmetric finite impulse response (FIR). Even and odd forms.

Filter Constructor Name	FilterStructure Property String and Filter Type
'dfilt.dffir'	Direct form FIR
'dfilt.dffirt'	Direct form FIR transposed
'dfilt.latticeallpass'	Lattice allpass
'dfilt.latticear'	Lattice autoregressive (AR)
'dfilt.latticemamin'	Lattice moving average (MA) minimum phase
'dfilt.latticemamax'	Lattice moving average (MA) maximum phase
'dfilt.latticearma'	Lattice ARMA
'dfilt.dfsymfir'	Symmetric FIR. Even and odd forms
'dfilt.scalar'	Scalar

**Filter Structures with Quantizations Shown in Place.** To help you understand how and where the quantizations occur in filter structures in this toolbox, the figure below shows the structure for a Direct Form II filter, including the quantizations (fixed-point formats) that compose part of the fixed-point filter. You see that one or more quantization processes, specified by the \*format label, accompany each filter element, such as a delay, product, or summation element. The input to or output from each element reflects the result of applying the associated quantization as defined by the word length and fraction length format. Wherever a particular filter element appears in a filter structure, recall the quantization process that accompanies the element as it appears in this figure. Each filter reference page, such as the `dfilt.df2` reference page, includes the signal flow diagram showing the formatting elements that define the quantizations that occur throughout the filter flow.

For example, a product quantization, either numerator or denominator, follows every product (gain) element and a sum quantization, also either numerator or denominator, follows each sum element. The figure shows the Arithmetic property value set to `fixed`.

df2 IIR Filter Structure Including the Formatting Objects, with Arithmetic Property Value fixed

When your `df2` filter uses the Arithmetic property set to fixed, the filter structure contains the formatting features shown in the diagram. The formats included in the structure are fixed-point objects that include properties to set various word and fraction length formats. For example, the `NumFormat` or `DenFormat` in the fixed-point arithmetic filter set the properties for quantizing numerator or denominator coefficients according to word and fraction length settings.

When the leading denominator coefficient `a(1)` in your filter is not 1, choose it to be a power of two so that a shift replaces the multiply that would otherwise be used.

**Fixed-Point Arithmetic Filter Structures.** You choose among several filter structures when you create fixed-point filters. You can also specify filters with single or multiple cascaded sections of the same type. Because quantization is a nonlinear process, different fixed-point filter structures produce different results.

To specify the filter structure, you select the appropriate `dfilt.structure` method to construct your filter. Refer to the function reference information for `dfilt` and `set` for details on setting property values for quantized filters.

The figures in the following subsections of this section serve as aids to help you determine how to enter your filter coefficients for each filter structure. Each subsection contains an example for constructing a filter of the given structure.

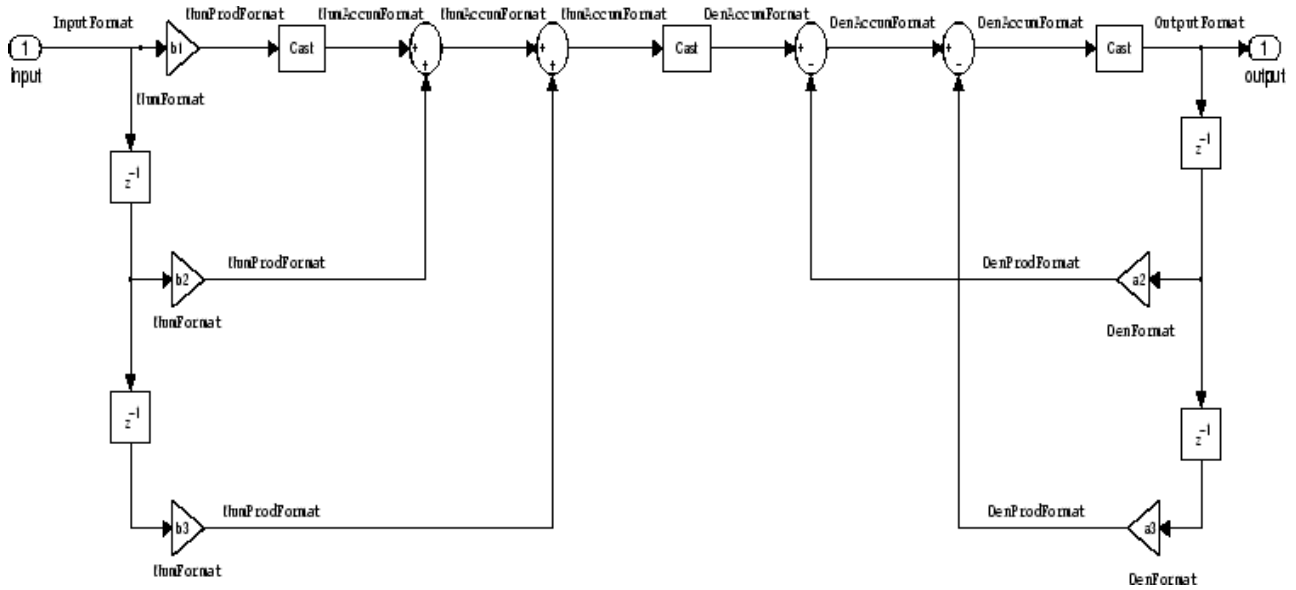

Scale factors for the input and output for the filters do not appear in the block diagrams. The default filter structures do not include, nor assume, the scale factors. For filter scaling information, refer to `scale` in the Help system.

**About the Filter Structure Diagrams.** In the diagrams that accompany the following filter structure descriptions, you see the active operators that define the filter, such as sums and gains, and the formatting features that control the processing in the filter. Notice also that the coefficients are labeled in the figure. This tells you the order in which the filter processes the coefficients.

While the meaning of the block elements is straightforward, the labels for the formats that form part of the filter are less clear. Each figure includes text in the form *labelFormat* that represents the existence of a formatting feature at that point in the structure. The *Format* stands for formatting object and the *label* specifies the data that the formatting object affects.

For example, in the `dfilt.df2` filter shown above, the entries `InputFormat` and `OutputFormat` are the formats applied, that is the word length and fraction length, to the filter input and output data. For example, filter properties like `OutputWordLength` and `InputWordLength` specify values that control filter operations at the input and output points in the structure and are represented by the formatting objects `InputFormat` and `OutputFormat` shown in the filter structure diagrams.

**Direct Form I Filter Structure.** The following figure depicts the *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are numbered  $b(i)$ ,  $i = 1, 2, 3$ ; the denominator coefficients are numbered  $a(i)$ ,  $i = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are labeled  $z(i)$ . In the figure, the Arithmetic property is set to `fixed`.

**Example – Specifying a Direct Form I Filter.** You can specify a second-order direct form I structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1(b,a);
```

To create the fixed-point filter, set the Arithmetic property to `fixed` as shown here.

```
set(hq,'arithmetic','fixed');
```

**Direct Form I Filter Structure With Second-Order Sections.** The following figure depicts a *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator and second-order sections. The numerator coefficients are numbered  $b(i)$ ,  $i = 1, 2, 3$ ; the denominator coefficients are numbered  $a(i)$ ,  $i = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are labeled  $z(i)$ . In the figure, the Arithmetic property is set to `fixed` to place the filter in fixed-point mode.

**Example – Specifying a Direct Form I Filter with Second-Order Sections.** You can specify an eighth-order direct form I structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1sos(b,a);
```

To create the fixed-point filter, set the `Arithmetic` property to `fixed`, as shown here.

```
set(hq,'arithmetic','fixed');
```

**Direct Form I Transposed Filter Structure.** The next signal flow diagram depicts a *direct form I transposed* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are  $b(i)$ ,  $i = 1, 2, 3$ ; the denominator coefficients are  $a(i)$ ,  $i = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are labeled  $z(i)$ . With the `Arithmetic` property value set to `fixed`, the figure shows the filter with the properties indicated.

**Example – Specifying a Direct Form I Transposed Filter.** You can specify a second-order direct form I transposed filter structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1t(b,a);
set(hq,'arithmetic','fixed');
```

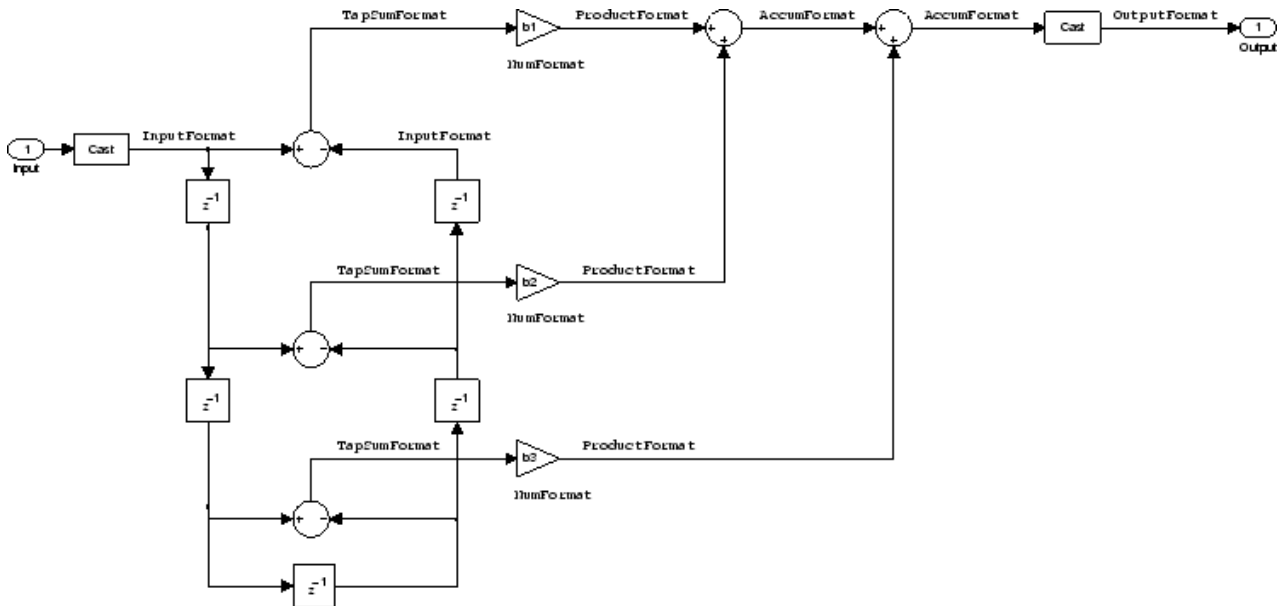

**Direct Form II Filter Structure.** The following graphic depicts a *direct form II* filter structure that directly realizes a transfer function with a second-order numerator and denominator. In the figure, the Arithmetic property value is fixed. Numerator coefficients are named  $b(i)$ ; denominator coefficients are named  $a(i)$ ,  $i = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are named  $z(i)$ .

**Direct Form Antisymmetric FIR Filter Structure (Any Order).** The following figure depicts a *direct form antisymmetric FIR* filter structure that directly realizes a second-order antisymmetric FIR filter. The filter coefficients are labeled  $b(i)$ , and the initial and final state values in filtering are labeled  $z(i)$ . This structure reflects the Arithmetic property set to fixed.

Use the method `dfilt.dfasymfir` to construct the filter, and then set the Arithmetic property to fixed to convert to a fixed-point filter with this structure.

**Example – Specifying an Odd-Order Direct Form Antisymmetric FIR Filter.** Specify a fifth-order direct form antisymmetric FIR filter structure for a fixed-point filter `hq` with the following code.

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];
hq = dfilt.dfasymfir(b);
set(hq,'arithmetic','fixed')
```

```
hq
```

```
hq =  
  
    FilterStructure: 'Direct-Form Antisymmetric FIR'

    ProductMode: 'FullPrecision'  
  
  AccumWordLength: 40  
  
    CastBeforeSum: true  
      RoundMode: 'convergent'  
        OverflowMode: 'wrap'  
  
  InheritSettings: false
```

**Direct Form Finite Impulse Response (FIR) Filter Structure.** In the next figure, you see the signal flow graph for a *direct form finite impulse response (FIR)* filter structure that directly realizes a second-order FIR filter. The filter coefficients are  $b(i)$ ,  $i = 1, 2, 3$ , and the states (used for initial and final state values in filtering) are  $z(i)$ . To generate the figure, set the `Arithmetic` property to `fixed` after you create your prototype filter in double-precision arithmetic.

Use the `dfilt.dffir` method to generate a filter that uses this structure.

**Example — Specifying a Direct Form FIR Filter.** You can specify a second-order direct form FIR filter structure for a fixed-point filter `hq` with the following code.

```
b = [0.05 0.9 0.05];
hd = dfilt.dffir(b);
hq = set(hd,'arithmetic','fixed');
```

**Direct Form FIR Transposed Filter Structure.** This figure uses the filter coefficients labeled  $b(i)$ ,  $i = 1, 2, 3$ , and states (used for initial and final state values in filtering) are labeled  $z(i)$ . These depict a *direct form finite impulse response (FIR) transposed* filter structure that directly realizes a second-order FIR filter.

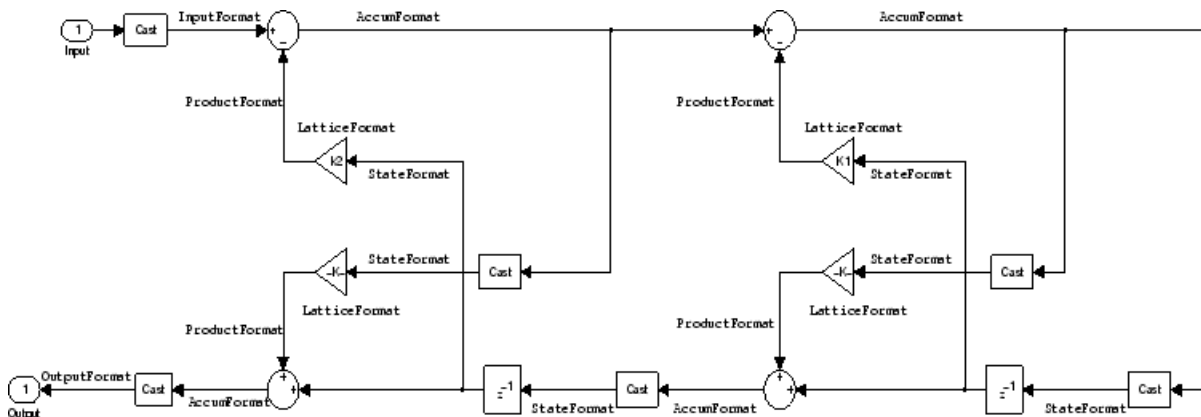

With the Arithmetic property set to fixed, your filter matches the figure. Using the method `dfilt.dffirt` returns a double-precision filter that you convert to a fixed-point filter.

**Example – Specifying a Direct Form FIR Transposed Filter.** You can specify a second-order direct form FIR transposed filter structure for a fixed-point filter `hq` with the following code.

```
b = [0.05 0.9 0.05];
hd=dfilt.dffirt(b);
hq = copy(hd);
hq.arithmetic = 'fixed';
```

**Lattice Allpass Filter Structure.** The following figure depicts the *lattice allpass* filter structure. The pictured structure directly realizes third-order lattice allpass filters using fixed-point arithmetic. The filter reflection coefficients are labeled  $k1(i)$ ,  $i = 1, 2, 3$ . The states (used for initial and final state values in filtering) are labeled  $z(i)$ .

To create a quantized filter that uses the lattice allpass structure shown in the figure, use the `dfilt.latticeallpass` method and set the `Arithmetic` property to `fixed`.

**Example – Specifying a Lattice Allpass Filter.** You can create a third-order lattice allpass filter structure for a quantized filter `hq` with the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
set(hq,'arithmetic','fixed');
```

**Lattice Moving Average Maximum Phase Filter Structure.** In the next figure you see a *lattice moving average maximum phase* filter structure. This signal flow diagram directly realizes a third-order lattice moving average (MA) filter with the following phase form depending on the initial transfer function:

- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a maximum phase filter.
- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average maximum phase structure will not be maximum phase.
- When you start with a maximum phase filter, the resulting lattice filter is maximum phase also.

The filter reflection coefficients are labeled  $k(i)$ ,  $i = 1, 2, 3$ . The states (used for initial and final state values in filtering) are labeled  $z(i)$ . In the figure, we set the Arithmetic property to fixed to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.

**Example — Constructing a Lattice Moving Average Maximum Phase Filter.** Constructing a fourth-order lattice MA maximum phase filter structure for a quantized filter `hq` begins with the following code.

```
k = [.66 .7 .44 .33];
hd=dfilt.latticemamax(k);
```

**Lattice Autoregressive (AR) Filter Structure.** The method `dfilt.latticear` directly realizes lattice autoregressive filters in the toolbox. The following figure depicts the third-order *lattice autoregressive (AR)* filter structure — with the Arithmetic property equal to `fixed`. The filter reflection coefficients are labeled  $k(i)$ ,  $i = 1, 2, 3$ , and the states (used for initial and final state values in filtering) are labeled  $z(i)$ .

**Example — Specifying a Lattice AR Filter.** You can specify a third-order lattice AR filter structure for a quantized filter `hq` with the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticear(k);
hq.arithmetic = 'custom';
```

**Lattice Moving Average (MA) Filter Structure for Minimum Phase.**

The following figures depict *lattice moving average (MA)* filter structures that directly realize third-order lattice MA filters for minimum phase. The filter reflection coefficients are labeled  $k(i)$ ,  $(i) = 1, 2, 3$ , and the states (used for initial and final state values in filtering) are labeled  $z(i)$ . Setting the Arithmetic property of the filter to `fixed` results in a fixed-point filter that matches the figure.

This signal flow diagram directly realizes a third-order lattice moving average (MA) filter with the following phase form depending on the initial transfer function:

- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a minimum phase filter.
- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average minimum phase structure will not be minimum phase.
- When you start with a minimum phase filter, the resulting lattice filter is minimum phase also.

The filter reflection coefficients are labeled  $k(i)$ ,  $i = 1, 2, 3$ . The states (used for initial and final state values in filtering) are labeled  $z(i)$ . This figure shows the filter structure when the Arithmetic property is set to fixed to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.

**Example — Specifying a Minimum Phase Lattice MA Filter.** You can specify a third-order lattice MA filter structure for minimum phase applications using variations of the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticemamin(k);
set(hq,'arithmetic','fixed');
```

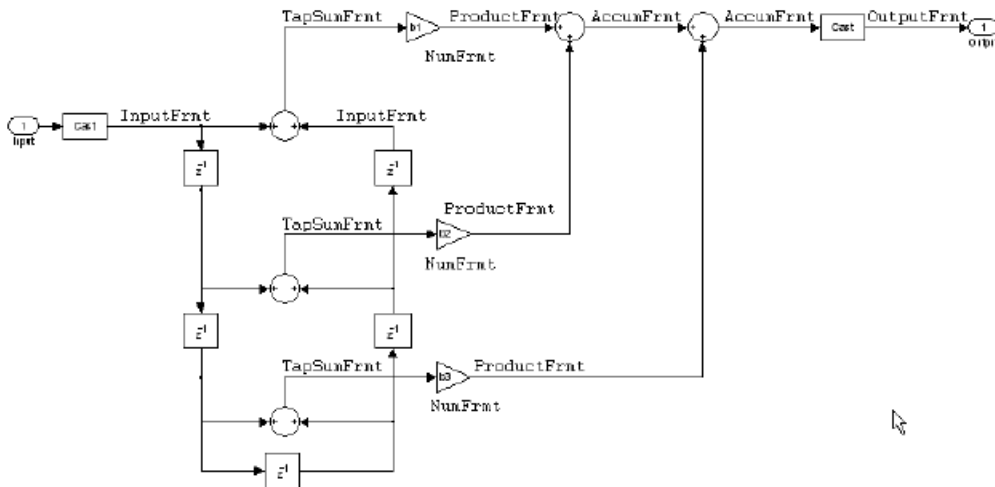

**Lattice Autoregressive Moving Average (ARMA) Filter Structure.** The figure below depicts a *lattice autoregressive moving average (ARMA)* filter structure that directly realizes a fourth-order lattice ARMA filter. The filter reflection coefficients are labeled  $k(i)$ ,  $(i) = 1, \dots, 4$ ; the ladder coefficients are labeled  $v(i)$ ,  $(i) = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are labeled  $z(i)$ .

**Example – Specifying an Lattice ARMA Filter.** The following code specifies a fourth-order lattice ARMA filter structure for a quantized filter `hq`, starting from `hd`, a floating-point version of the filter.

```
k = [.66 .7 .44 .66];
v = [1 0 0];
hd=dfilt.latticearma(k,v);
hq.arithmetic = 'fixed';
```

**Direct Form Symmetric FIR Filter Structure (Any Order).** Shown in the next figure, you see signal flow that depicts a *direct form symmetric FIR* filter structure that directly realizes a fifth-order direct form symmetric FIR filter. Filter coefficients are labeled  $b(i)$ ,  $i = 1, \dots, n$ , and states (used for initial and final state values in filtering) are labeled  $z(i)$ . Showing the filter structure used when you select fixed for the Arithmetic property value, the first figure details the properties in the filter object.

**Example — Specifying an Odd-Order Direct Form Symmetric FIR Filter.** By using the following code in MATLAB, you can specify a fifth-order direct form symmetric FIR filter for a fixed-point filter `hq`:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd=dfilt.dfsymfir(b);
set(hq,'arithmetic','fixed');
```

**Assigning Filter Coefficients.** The syntax you use to assign filter coefficients for your floating-point or fixed-point filter depends on the structure you select for your filter.

**Converting Filters Between Representations.** Filter conversion functions in this toolbox and in Signal Processing Toolbox software let you convert filter transfer functions to other filter forms, and from other filter forms to transfer function form. Relevant conversion functions include the following functions.

<b>Conversion Function</b>	<b>Description</b>
ca2tf	Converts from a coupled allpass filter to a transfer function.
cl2tf	Converts from a lattice coupled allpass filter to a transfer function.
convert	Convert a discrete-time filter from one filter structure to another.
sos	Converts quantized filters to create second-order sections. We recommend this method for converting quantized filters to second-order sections.
tf2ca	Converts from a transfer function to a coupled allpass filter.
tf2cl	Converts from a transfer function to a lattice coupled allpass filter.
tf2latc	Converts from a transfer function to a lattice filter.
tf2sos	Converts from a transfer function to a second-order section form.
tf2ss	Converts from a transfer function to state-space form.
tf2zp	Converts from a rational transfer function to its factored (single section) form (zero-pole-gain form).
zp2sos	Converts a zero-pole-gain form to a second-order section form.
zp2ss	Conversion of zero-pole-gain form to a state-space form.
zp2tf	Conversion of zero-pole-gain form to transfer functions of multiple order sections.

Note that these conversion routines do not apply to `dfilt` objects.

The function `convert` is a special case — when you use `convert` to change the filter structure of a fixed-point filter, you lose all of the filter states and settings. Your new filter has default values for all properties, and it is not fixed-point.

To demonstrate the changes that occur, convert a fixed-point direct form I transposed filter to direct form II structure.

```
hd=dfilt.df1t

hd =

    FilterStructure: 'Direct-Form I Transposed'
      Arithmetic: 'double'
      Numerator: 1
      Denominator: 1
 PersistentMemory: false
           States: Numerator: [0x0 double]
                  Denominator:[0x0 double]

hd.arithmetic='fixed'
hd =

    FilterStructure: 'Direct-Form I Transposed'
      Arithmetic: 'fixed'
      Numerator: 1
      Denominator: 1
 PersistentMemory: false
           States: Numerator: [0x0 fi]
                  Denominator:[0x0 fi]

convert(hd,'df2')
```

Warning: Using reference filter for structure conversion.  
Fixed-point attributes will not be converted.

```
ans =
```

```
FilterStructure: 'Direct-Form II'  
Arithmetic: 'double'  
Numerator: 1  
Denominator: 1  
PersistentMemory: false  
States: [0x1 double]
```

You can specify a filter with  $L$  sections of arbitrary order by

- 1 Factoring your entire transfer function with `tf2zp`. This converts your transfer function to zero-pole-gain form.
- 2 Using `zp2tf` to compose the transfer function for each section from the selected first-order factors obtained in step 1.

---

**Note** You are not required to normalize the leading coefficients of each section's denominator polynomial when you specify second-order sections, though `tf2sos` does.

---

### Gain

`dfilt.scalar` filters have a gain value stored in the `gain` property. By default the gain value is one — the filter acts as a wire.

### InputFracLength

`InputFracLength` defines the fraction length assigned to the input data for your filter. Used in tandem with `InputWordLength`, the pair defines the data format for input data you provide for filtering.

As with all fraction length properties in `dfilt` objects, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, in this case `InputWordLength`, as well.

### InputWordLength

Specifies the number of bits your filter uses to represent your input data. Your word length option is limited by the arithmetic you choose — up to 32 bits for

double, float, and fixed. Setting Arithmetic to single (single-precision floating-point) limits word length to 16 bits. The default value is 16 bits.

### Ladder

Included as a property in `dfilt.latticearma` filter objects, Ladder contains the denominator coefficients that form an IIR lattice filter object. For instance, the following code creates a high pass filter object that uses the lattice ARMA structure.

```
[b,a]=cheby1(5,.5,.5,'high')

b =

    0.0282   -0.1409    0.2817   -0.2817    0.1409   -0.0282

a =

    1.0000    0.9437    1.4400    0.9629    0.5301    0.1620

hd=dfilt.latticearma(b,a)

hd =

    FilterStructure: [1x44 char]
      Arithmetic: 'double'
      Lattice: [1x6 double]
      Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
 PersistentMemory: false
      States: [6x1 double]

hd.arithmetic='fixed'

hd =

    FilterStructure: [1x44 char]
      Arithmetic: 'fixed'
      Lattice: [1x6 double]
      Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
```

```
PersistentMemory: false
    States: [1x1 embedded.fi]

    CoeffWordLength: 16
    CoeffAutoScale: true
    Signed: true

    InputWordLength: 16
    InputFracLength: 15

    OutputWordLength: 16
    OutputMode: 'AvoidOverflow'

    StateWordLength: 16
    StateFracLength: 15

    ProductMode: 'FullPrecision'

    AccumWordLength: 40
    CastBeforeSum: true

    RoundMode: 'convergent'
    OverflowMode: 'wrap'
```

### **LadderAccumFracLength**

Autoregressive, moving average lattice filter objects (`latticearma`) use ladder coefficients to define the filter. In combination with `LadderFracLength` and `CoeffWordLength`, these three properties specify or reflect how the accumulator outputs data stored there. As with all fraction length properties, `LadderAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. The default value is 29 bits.

### **LadderFracLength**

To let you control the way your `latticearma` filter interprets the denominator coefficients, `LadderFracLength` sets the fraction length applied to the ladder coefficients for your filter. The default value is 14 bits.

As with all fraction length properties, `LadderFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

## **Lattice**

When you create a lattice-based IIR filter, your numerator coefficients (from your IIR prototype filter or the default `dfilt` lattice filter function) get stored in the `Lattice` property of the `dfilt` object. The properties `CoeffWordLength` and `LatticeFracLength` define the data format the object uses to represent the lattice coefficients. By default, lattice coefficients are in double-precision format.

## **LatticeAccumFracLength**

Lattice filter objects (`latticeallpass`, `latticearma`, `latticeamax`, and `latticeamin`) use lattice coefficients to define the filter. In combination with `LatticeFracLength` and `CoeffWordLength`, these three properties specify how the accumulator outputs lattice coefficient-related data stored there. As with all fraction length properties, `LatticeAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. By default, the property is set to 31 bits.

## **LatticeFracLength**

To let you control the way your filter interprets the denominator coefficients, `LatticeFracLength` sets the fraction length applied to the lattice coefficients for your lattice filter. When you create the default lattice filter, `LatticeFracLength` is 16 bits.

As with all fraction length properties, `LatticeFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers.

## **MultiplicandFracLength**

Each input data element for a multiply operation has both word length and fraction length to define its representation. `MultiplicandFracLength` sets the fraction length to use when the filter object performs any multiply operation during filtering. For default filters, this is set to 15 bits.

As with all word and fraction length properties, `MultiplicandFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers.

### **MultiplicandWordLength**

Each input data element for a multiply operation has both word length and fraction length to define its representation. `MultiplicandWordLength` sets the word length to use when the filter performs any multiply operation during filtering. For default filters, this is set to 16 bits. Only the `df1t` and `df1tsos` filter objects include the `MultiplicandFracLength` property.

Only the `df1t` and `df1tsos` filter objects include the `MultiplicandWordLength` property.

### **NumAccumFracLength**

Filter structures `df1`, `df1t`, `df2`, and `df2t` that use fixed arithmetic have this property that defines the fraction length applied to numerator coefficients in output from the accumulator. In combination with `AccumWordLength`, the `NumAccumFracLength` property fully specifies how the accumulator outputs numerator-related data stored there.

As with all fraction length properties, `NumAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. 30 bits is the default value when you create the filter object. To be able to change the value for this property, set `FilterInternals` for the filter to `SpecifyPrecision`.

### **Numerator**

The numerator coefficients for your filter, taken from the prototype you start with or from the default filter, are stored in this property. Generally this is a 1-by-N array of data in double format, where N is the length of the filter.

All of the filter objects include `Numerator`, except the lattice-based and second-order section filters, such as `dfilt.latticema` and `dfilt.df1tsos`.

## NumFracLength

Property `NumFracLength` contains the value that specifies the fraction length for the numerator coefficients for your filter. `NumFracLength` specifies the fraction length used to interpret the numerator coefficients. Used in combination with `CoeffWordLength`, these two properties define the interpretation of the coefficients stored in the vector that contains the numerator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `CoeffWordLength` of 16 bits.

## NumProdFracLength

A property of all of the direct form IIR `dfilt` objects, except the ones that implement second-order sections, `NumProdFracLength` specifies the fraction length applied to data output from product operations the filter performs on numerator coefficients.

Looking at the signal flow diagram for the `dfilt.df1t` filter, for example, you see that denominators and numerators are handled separately. When you set `ProductMode` to `SpecifyPrecision`, you can change the `NumProdFracLength` setting manually. Otherwise, for multiplication operations that use the numerator coefficients, the filter sets the word length as defined by the `ProductMode` setting.

## NumStateFracLength

All the variants of the direct form I structure include the property `NumStateFracLength` to store the fraction length applied to the numerator states for your filter object. By default, this property has the value 15 bits, with the `CoeffWordLength` of 16 bits, which you can change after you create the filter object.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well.

### **NumStateWordLength**

When you look at the flow diagram for the `df1sos` filter object, the states associated with the numerator coefficient operations take the data format from this property and the `NumStateFracLength` property. In combination, these properties fully specify how the filter interprets the state it uses.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 16 bits, with the `NumStateFracLength` of 11 bits.

### **OutputFracLength**

To define the output from your filter object, you need both the word and fraction lengths. `OutputFracLength` determines the fraction length applied to interpret the output data. Combining this with `OutputWordLength` fully specifies the format of the output.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

### **OutputMode**

Sets the mode the filter uses to scale the filtered (output) data. You have the following choices:

- **AvoidOverflow** — directs the filter to set the property that controls the output data fraction length to avoid causing the data to overflow. In a `df2` filter, this would be the `OutputFracLength` property.
- **BestPrecision** — directs the filter to set the property that controls the output data fraction length to maximize the precision in the output data. For `df1t` filters, this is the `OutputFracLength` property. When you change the word length (`OutputWordLength`), the filter adjusts the fraction length to maintain the best precision for the new word size.
- **SpecifyPrecision** — lets you set the fraction length used by the filtered data. When you select this choice, you can set the output fraction length using the `OutputFracLength` property to define the output precision.

All filters include this property except the direct form I filter which takes the output format from the filter states.

Here is an example that changes the mode setting to `bestprecision`, and then adjusts the word length for the output.

```
hd=dfilt.df2
```

```
hd =
```

```
    FilterStructure: 'Direct-Form II'

    AccumWordLength: 40  
        CastBeforeSum: true  
  
        RoundMode: 'convergent'  
        OverflowMode: 'wrap'  
  
hd.outputWordLength=8;  
  
get(hd)  
    PersistentMemory: false  
    FilterStructure: 'Direct-Form II'  
        States: [1x1 embedded.fi]  
        Numerator: 1  
        Denominator: 1  
        Arithmetic: 'fixed'
```

```
    CoeffWordLength: 16
    CoeffAutoScale: 1
        Signed: 1
        RoundMode: 'convergent'
    OverflowMode: 'wrap'
    InputWordLength: 16
    InputFracLength: 15
    OutputWordLength: 8
        OutputMode: 'BestPrecision'
        ProductMode: 'FullPrecision'
    StateWordLength: 16
    StateFracLength: 15
        NumFracLength: 14
        DenFracLength: 14
    OutputFracLength: 5
    ProductWordLength: 32
    NumProdFracLength: 29
    DenProdFracLength: 29
        AccumWordLength: 40
    NumAccumFracLength: 29
    DenAccumFracLength: 29
    CastBeforeSum: 1
```

Changing the `OutputWordLength` to 8 bits caused the filter to change the `OutputFracLength` to 5 bits to keep the best precision for the output data.

### OutputWordLength

Use the property `OutputWordLength` to set the word length used by the output from your filter. Set this property to a value that matches your intended hardware. For example, some digital signal processors use 32-bit output so you would set `OutputWordLength` to 32.

```
[b,a] = butter(6,.5);
hd=dfilt.df1t(b,a);

set(hd,'arithmetic','fixed')

hd

hd =
```

```
FilterStructure: 'Direct-Form I Transposed'
  Arithmetic: 'fixed'
  Numerator: [1x7 double]
  Denominator: [1 0 0.7777 0 0.1142 0 0.0018]
PersistentMemory: false
  States: Numerator: [6x1 fi]
         Denominator:[6x1 fi]

  CoeffWordLength: 16
  CoeffAutoScale: true
  Signed: true

  InputWordLength: 16
  InputFracLength: 15

  OutputWordLength: 16
  OutputMode: 'AvoidOverflow'

MultiplicandWordLength: 16
MultiplicandFracLength: 15

  StateWordLength: 16
  StateAutoScale: true

  ProductMode: 'FullPrecision'

  AccumWordLength: 40
  CastBeforeSum: true

  RoundMode: 'convergent'
  OverflowMode: 'wrap'

hd.outputwordLength=32

hd =

  FilterStructure: 'Direct-Form I Transposed'
  Arithmetic: 'fixed'
```

```
        Numerator: [1x7 double]
        Denominator: [1 0 0.7777 0 0.1142 0 0.0018]
PersistentMemory: false
        States: Numerator: [6x1 fi]
               Denominator:[6x1 fi]

        CoeffWordLength: 16
        CoeffAutoScale: true
        Signed: true

        InputWordLength: 16
        InputFracLength: 15

        OutputWordLength: 32
        OutputMode: 'AvoidOverflow'

MultiplicandWordLength: 16
MultiplicandFracLength: 15

        StateWordLength: 16
        StateAutoScale: true

        ProductMode: 'FullPrecision'

        AccumWordLength: 40
        CastBeforeSum: true

        RoundMode: 'convergent'
        OverflowMode: 'wrap'
```

When you create a filter object, this property starts with the value 16.

### **OverflowMode**

The `OverflowMode` property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- `'saturate'` — saturate overflows.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest. `saturate` is the default value for `OverflowMode`.

- 'wrap' — wrap all overflows to the range of representable values.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Designer documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.
- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

---

**Note** Numbers in floating-point filters that extend beyond the dynamic range overflow to  $\pm\text{inf}$ .

---

## ProductFracLength

After you set `ProductMode` for a fixed-point filter to `SpecifyPrecision`, this property becomes available for you to change. `ProductFracLength` sets the fraction length the filter uses for the results of multiplication operations. Only the FIR filters such as asymmetric FIRs or lattice autoregressive filters include this dynamic property.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

## **ProductMode**

This property, available when your filter is in fixed-point arithmetic mode, specifies how the filter outputs the results of multiplication operations. All `dfilt` objects include this property when they use fixed-point arithmetic.

When available, you select from one of the following values for `ProductMode`:

- `FullPrecision` — means the filter automatically chooses the word length and fraction length it uses to represent the results of multiplication operations. The setting allow the product to retain the precision provided by the inputs (multiplicands) to the operation.
- `KeepMSB` — means you specify the word length for representing product operation results. The filter sets the fraction length to discard the LSBs, keep the higher order bits in the data, and maintain the precision.
- `KeepLSB` — means you specify the word length for representing the product operation results. The filter sets the fraction length to discard the MSBs, keep the lower order bits, and maintain the precision. Compare to the `KeepMSB` option.
- `SpecifyPrecision` — means you specify the word length and the fraction length to apply to data output from product operations.

When you switch to fixed-point filtering from floating-point, you are most likely going to throw away some data bits after product operations in your filter, perhaps because you have limited resources. When you have to discard some bits, you might choose to discard the least significant bits (LSB) from a result since the resulting quantization error would be small as the LSBs carry less weight. Or you might choose to keep the LSBs because the results have MSBs that are mostly zero, such as when your values are small relative to the range of the format in which they are represented. So the options for `ProductMode` let you choose how to maintain the information you need from the accumulator.

For more information about data formats, word length, and fraction length in fixed-point arithmetic, refer to “Notes About Fraction Length, Word Length, and Precision” on page 5-29.

## ProductWordLength

You use `ProductWordLength` to define the data word length used by the output from multiplication operations. Set this property to a value that matches your intended application. For example, the default value is 32 bits, but you can set any word length.

```
set(hq,'arithmetic','fixed');
set(hq,'ProductWordLength',64);
```

Note that `ProductWordLength` applies only to filters whose `Arithmetic` property value is `fixed`.

## PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false` — the filter does not retain memory about filtering operations from one to the next. Maintaining memory (setting `PersistentMemory` to `true`) lets you filter large data sets as collections of smaller subsets and get the same result.

In this example, filter `hd` first filters data `xtot` in one pass. Then you can use `hd` to filter `x` as two separate data sets. The results `ytot` and `ysec` are the same in both cases.

```
xtot=[x,x];
ytot=filter(hd,xtot)
ytot =

           0  -0.0003   0.0005  -0.0014   0.0028  -0.0054   0.0092
reset(hm1); % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hd,x) filter(hd,x)]

ysec =

           0  -0.0003   0.0005  -0.0014   0.0028  -0.0054   0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

### **RoundMode**

The `RoundMode` property value specifies the rounding method used for quantizing numerical values. Specify the `RoundMode` property values as one of the following five strings.

<b>RoundMode String</b>	<b>Description of Rounding Algorithm</b>
Ceiling	Round toward positive infinity.
Floor	Round toward negative infinity.
Nearest	Round toward nearest. Ties round toward positive infinity.
Nearest (Convergent)	Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.
Round	Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.
Zero	Round toward zero.

The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

### **ScaleValueFracLength**

Filter structures `df1sos`, `df1tsos`, `df2sos`, and `df2tsos` that use fixed arithmetic have this property that defines the fraction length applied to the scale values the filter uses between sections. In combination with `CoeffWordLength`, these two properties fully specify how the filter interprets and uses the scale values stored in the property `ScaleValues`. As with fraction length properties, `ScaleValueFracLength` can be any integer,

including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter.

## ScaleValues

The `ScaleValues` property values are specified as a scalar (or vector) that introduces scaling for inputs (and the outputs from cascaded sections in the vector case) during filtering:

- When you only have a single section in your filter:
  - Specify the `ScaleValues` property value as a scalar if you only want to scale the input to your filter.
  - Specify the `ScaleValues` property as a vector of length 2 if you want to specify scaling to the input (scaled with the first entry in the vector) and the output (scaled with the last entry in the vector).
- When you have  $L$  cascaded sections in your filter:
  - Specify the `ScaleValues` property value as a scalar if you only want to scale the input to your filter.
  - Specify the value for the `ScaleValues` property as a vector of length  $L+1$  if you want to scale the inputs to every section in your filter, along with the output:

The first entry of your vector specifies the input scaling

Each successive entry specifies the scaling at the output of the next section

The final entry specifies the scaling for the filter output.

The default value for `ScaleValues` is 0.

The interpretation of this property is described as follows with diagrams in “Interpreting the `ScaleValues` Property” on page 5-84.

---

**Note** The value of the `ScaleValues` property is not quantized. Data affected by the presence of a scaling factor in the filter is quantized according to the appropriate data format.

---

When you apply `normalize` to a fixed-point filter, the value for the `ScaleValues` property is changed accordingly.

It is good practice to choose values for this property that are either positive or negative powers of two.

**Interpreting the `ScaleValues` Property.** When you specify the values of the `ScaleValues` property of a quantized filter, the values are entered as a vector, the length of which is determined by the number of cascaded sections in your filter:

- When you have only one section, the value of the `ScaleValues` property can be a scalar or a two-element vector.
- When you have  $L$  cascaded sections in your filter, the value of the `ScaleValues` property can be a scalar or an  $L+1$ -element vector.

The following diagram shows how the `ScaleValues` property values are applied to a quantized filter with only one section.

### Application of `ScaleValues` to a Single Section

The following diagram shows how the `ScaleValues` property values are applied to a quantized filter with two sections.

### Application of ScaleValues to Multiple Sections

### Signed

When you create a `dfilt` object for fixed-point filtering (you set the property `Arithmetic` to `fixed`, the property `Signed` specifies whether the filter interprets coefficients as signed or unsigned. This setting applies only to the coefficients. While the default setting is `true`, meaning that all coefficients are assumed to be signed, you can change the setting to `false` after you create the fixed-point filter.

For example, create a fixed-point direct-form II transposed filter with both negative and positive coefficients, and then change the property value for `Signed` from `true` to `false` to see what happens to the negative coefficient values.

```
hd=dfilt.df2t(-5:5)
```

```
hd =
```

```

    FilterStructure: 'Direct-Form II Transposed'
    Arithmetic: 'double'
    Numerator: [-5 -4 -3 -2 -1 0 1 2 3 4 5]
    Denominator: 1
    PersistentMemory: false
    States: [10x1 double]
```

```
set(hd,'arithmetic','fixed')
```

```
hd.numerator
```

```
ans =
```

```

-5    -4    -3    -2    -1     0
```

```
          1      2      3      4      5

set(hd,'signed',false)
hd.numerator

ans =

          0      0      0      0      0      0
          1      2      3      4      5
```

Using unsigned coefficients limits you to using only positive coefficients in your filter. `Signed` is a dynamic property — you cannot set or change it until you switch the setting for the `Arithmetic` property to `fixed`.

### **SosMatrix**

When you convert a `dfilt` object to second-order section form, or create a second-order section filter, `sosMatrix` holds the filter coefficients as property values. Using the `double` data type by default, the matrix is in [sections coefficients per section] form, displayed as [15-x-6] for filters with 6 coefficients per section and 15 sections, [15 6].

To demonstrate, the following code creates an order 30 filter using second-order sections in the direct-form II transposed configuration. Notice the `sosMatrix` property contains the coefficients for all the sections.

```
d = fdesign.lowpass('n,fc',30,0.5);
hd = butter(d);

hd =

    FilterStructure: 'Direct-Form II, Second-Order Sections'
      Arithmetic: 'double'
      sosMatrix: [15x6 double]
    ScaleValues: [16x1 double]
PersistentMemory: false
      States: [2x15 double]

hd.arithmetic='fixed'

hd =
```

```

FilterStructure: 'Direct-Form II, Second-Order Sections'
  Arithmetic: 'fixed'
    sosMatrix: [15x6 double]
    ScaleValues: [16x1 double]
PersistentMemory: false
  States: [1x1 embedded.fi]

```

```

CoeffWordLength: 16
  CoeffAutoScale: true
    Signed: true

```

```

1.0000	2.0000	1.0000	1.0000	0	0.0173
1.0000	2.0000	1.0000	1.0000	0	0.0062
1.0000	2.0000	1.0000	1.0000	0	0.0007

The SOS matrix is an M-by-6 matrix, where M is the number of sections in the second-order section filter. Filter `hd` has M equal to 15 as shown above (15 rows). Each row of the SOS matrix contains the numerator and denominator coefficients (b's and a's) and the scale factors of the corresponding section in the filter.

### **SectionInputAutoScale**

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of `SectionInputAutoScale`. The representation the filter uses between the filter sections depends on whether the value of `SectionInputAutoScale` is `true` or `false`.

- `SectionInputAutoScale = true` means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. `true` is the default setting.
- `SectionInputAutoScale = false` removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (`SectionInputFracLength`) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting `SectionInputAutoScale` to `false` exposes the

`SectionInputFracLength` property that specifies the fraction length applied to data between the sections.

### **SectionInputFracLength**

Second-order section filters use quantizers at the input to each section of the filter. The quantizers apply to the input data entering each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the input values, use the property value in `SectionInputFracLength`.

In combination with `CoeffWordLength`, `SectionInputFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`. As with all word and fraction length properties, `SectionInputFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

### **SectionInputWordLength**

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. `SectionInputWordLength` specifies the word length applied to data as it enters one filter section from the previous section. Only second-order implementations of direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier =1, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.

`SectionInputWordLength` defaults to 16 bits.

### **SectionOutputAutoScale**

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of `SectionOutputAutoScale`. The representation the filter uses between the filter sections depends on whether the value of `SectionOutputAutoScale` is `true` or `false`.

- `SectionOutputAutoScale = true` means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. `true` is the default setting.
- `SectionOutputAutoScale = false` removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (`SectionOutputFracLength`) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting `SectionOutputAutoScale = false` exposes the `SectionOutputFracLength` property that specifies the fraction length applied to data between the sections.

### **SectionOutputFracLength**

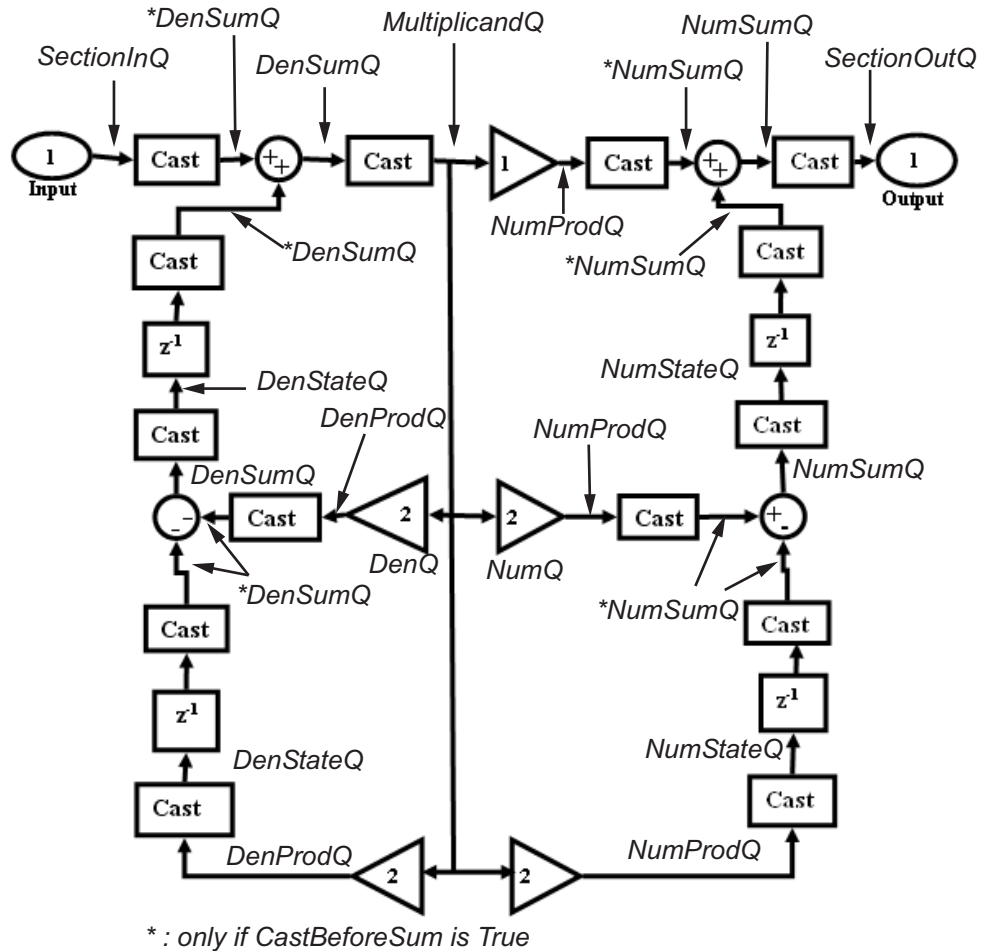

Second-order section filters use quantizers at the output from each section of the filter. The quantizers apply to the output data leaving each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the output values, use the property value in `SectionOutputFracLength`.

In combination with `CoeffWordLength`, `SectionOutputFracLength` determines how the filter interprets and uses the state values stored in the property `States`. As with all fraction length properties, `SectionOutputFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

### **SectionOutputWordLength**

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. `SectionOutputWordLength` specifies the word length applied to data as it leaves one filter section to go to the next. Only second-order implementations direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier =1, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.

SectionOutputWordLength defaults to 16 bits.

### **StateAutoScale**

Although all filters use states, some do not allow you to choose whether the filter automatically scales the state values to prevent overruns or bad arithmetic errors. You select either of the following settings:

- `StateAutoScale = true` means the filter chooses the fraction length to maintain the value of the states as close to the double-precision values as possible. When you change the word length applied to the states (where allowed by the filter structure), the filter object changes the fraction length to try to accommodate the change. `true` is the default setting.
- `StateAutoScale = false` removes the automatic scaling of the fraction length for the states and exposes the property that controls the coefficient fraction length so you can change it. For example, in a direct form I transposed SOS FIR filter, setting `StateAutoScale = false` exposes the `NumStateFracLength` and `DenStateFracLength` properties that specify the fraction length applied to states.

Each of the following filter structures provides the `StateAutoScale` property:

- `df1t`
- `df1tsos`
- `df2t`
- `df2tsos`
- `dffirt`

Other filter structures do not include this property.

### **StateFracLength**

Filter states stored in the property `States` have both word length and fraction length. To set the fraction length for interpreting the stored filter object state values, use the property value in `StateFracLength`.

In combination with `CoeffWordLength`, `StateFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`.

As with all fraction length properties, `StateFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

## States

Digital filters are dynamic systems. The behavior of dynamic systems (their response) depends on the input (stimulus) to the system and the current or previous *state* of the system. You can say the system has memory or inertia. All fixed- or floating-point digital filters (as well as analog filters) have states.

Filters use the states to compute the filter output for each input sample, as well using them while filtering in loops to maintain the filter state between loop iterations. This toolbox assumes zero-valued initial conditions (the dynamic system is at rest) by default when you filter the first input sample. Assuming the states are zero initially does not mean the states are not used; they are, but arithmetically they do not have any effect.

Filter objects store the state values in the property `States`. The number of stored states depends on the filter implementation, since the states represent the delays in the filter implementation.

When you review the display for a filter object with fixed arithmetic, notice that the states return an embedded `fi` object, as you see here.

```
b = ellip(6,3,50,300/500);
hd=dfilt.dffir(b)

hd =

    FilterStructure: 'Direct-Form FIR'
      Arithmetic: 'double'
      Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
 PersistentMemory: false
           States: [6x1 double]
```

```
hd.arithmetic='fixed'

hd =

    FilterStructure: 'Direct-Form FIR'
      Arithmetic: 'fixed'
      Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
    PersistentMemory: false
      States: [1x1 embedded.fi]

    CoeffWordLength: 16
      CoeffAutoScale: 'on'
      Signed: 'on'

    InputWordLength: 16
    InputFracLength: 15

    OutputWordLength: 16
      OutputMode: 'AvoidOverflow'

      ProductMode: 'FullPrecision'

    AccumWordLength: 40
      CastBeforeSum: 'on'

      RoundMode: 'convergent'
      OverflowMode: 'wrap'

    InheritSettings: 'off'
```

`fi` objects provide fixed-point support for the filters. To learn more about the details about `fi` objects, refer to your Fixed-Point Designer documentation.

The property `States` lets you use a `fi` object to define how the filter interprets the filter states. For example, you can create a `fi` object in MATLAB, then assign the object to `States`, as follows:

```
statefi=fi([],16,12)
```

```
statefi =

[]
    DataTypeMode = Fixed-point: binary point scaling
        Signed = true
        Wordlength = 16
    Fractionlength = 12
```

This `fi` object does not have a value associated (notice the `[]` input argument to `fi` for the value), and it has word length of 16 bits and fraction length of 12 bit. Now you can apply `statefi` to the `States` property of the filter `hd`.

```
set(hd,'States',statefi);
Warning: The 'States' property will be reset to the value
specified at construction before filtering.
Set the 'PersistentMemory' flag to 'True'
to avoid changing this property value.
hd
```

```
hd =

    FilterStructure: 'Direct-Form FIR'
    Arithmetic: 'fixed'
    Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858
               0.2938 0.0773]
    PersistentMemory: false
    States: [1x1 embedded.fi]

    CoeffWordLength: 16
    CoeffAutoScale: 'on'
    Signed: 'on'

    InputWordLength: 16
    InputFracLength: 15

    OutputWordLength: 16
    OutputMode: 'AvoidOverflow'

    ProductMode: 'FullPrecision'
    AccumWordLength: 40
```

```
CastBeforeSum: 'on'  
  
    RoundMode: 'convergent'  
    OverflowMode: 'wrap'
```

### StateWordLength

While all filters use states, some do not allow you to directly change the state representation — the word length and fraction lengths — independently. For the others, `StateWordLength` specifies the word length, in bits, the filter uses to represent the states. Filters that do not provide direct state word length control include:

- `df1`
- `dfasymfir`
- `dffir`
- `dfsymfir`

For these structures, the filter derives the state format from the input format you choose for the filter — except for the `df1` IIR filter. In this case, the numerator state format comes from the input format and the denominator state format comes from the output format. All other filter structures provide control of the state format directly.

### TapSumFracLength

Direct-form FIR filter objects, both symmetric and antisymmetric, use this property. To set the fraction length for output from the sum operations that involve the filter tap weights, use the property value in `TapSumFracLength`. To enable this property, set the `TapSumMode` to `SpecifyPrecision` in your filter.

As you can see in this code example that creates a fixed-point asymmetric FIR filter, the `TapSumFracLength` property becomes available after you change the `TapSumMode` property value.

```
hd=dfilt.dfasymfir  
  
hd =
```

```
        FilterStructure: 'Direct-Form Antisymmetric FIR'
          Arithmetic: 'double'
            Numerator: 1
    PersistentMemory: false
          States: [0x1 double]

set(hd,'arithmetic','fixed');
hd

hd =

        FilterStructure: 'Direct-Form Antisymmetric FIR'
          Arithmetic: 'fixed'
            Numerator: 1
    PersistentMemory: false
          States: [1x1 embedded.fi]

        CoeffWordLength: 16
          CoeffAutoScale: true
            Signed: true

        InputWordLength: 16
          InputFracLength: 15

    OutputWordLength: 16
          OutputMode: 'AvoidOverflow'

          TapSumMode: 'KeepMSB'
    TapSumWordLength: 17

          ProductMode: 'FullPrecision'

    AccumWordLength: 40

        CastBeforeSum: true
          RoundMode: 'convergent'
        OverflowMode: 'wrap'
```

With the filter now in fixed-point mode, you can change the `TapSumMode` property value to `SpecifyPrecision`, which gives you access to the `TapSumFracLength` property.

```
set(hd, 'TapSumMode', 'SpecifyPrecision');  
hd
```

```
hd =  
  
    FilterStructure: 'Direct-Form Antisymmetric FIR'  
    Arithmetic: 'fixed'  
    Numerator: 1  
    PersistentMemory: false  
    States: [1x1 embedded.fi]  
  
    CoeffWordLength: 16  
    CoeffAutoScale: true  
    Signed: true  
  
    InputWordLength: 16  
    InputFracLength: 15  
  
    OutputWordLength: 16  
    OutputMode: 'AvoidOverflow'  
  
    TapSumMode: 'SpecifyPrecision'  
    TapSumWordLength: 17  
    TapSumFracLength: 15  
  
    ProductMode: 'FullPrecision'  
  
    AccumWordLength: 40  
  
    CastBeforeSum: true  
    RoundMode: 'convergent'  
    OverflowMode: 'wrap'
```

In combination with `TapSumWordLength`, `TapSumFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`.

As with all fraction length properties, `TapSumFracLength` can be any integer, including integers larger than `TapSumWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

### **TapSumMode**

This property, available only after your filter is in fixed-point mode, specifies how the filter outputs the results of summation operations that involve the filter tap weights. Only symmetric (`dfilt.dfsymfir`) and antisymmetric (`dfilt.dfasymfir`) FIR filters use this property.

When available, you select from one of the following values:

- **FullPrecision** — means the filter automatically chooses the word length and fraction length to represent the results of the sum operation so they retain all of the precision provided by the inputs (addends).
- **KeepMSB** — means you specify the word length for representing tap sum summation results to keep the higher order bits in the data. The filter sets the fraction length to discard the LSBs from the sum operation. This is the default property value.
- **KeepLSB** — means you specify the word length for representing tap sum summation results to keep the lower order bits in the data. The filter sets the fraction length to discard the MSBs from the sum operation. Compare to the **KeepMSB** option.
- **SpecifyPrecision** — means you specify the word and fraction lengths to apply to data output from the tap sum operations.

### **TapSumWordLength**

Specifies the word length the filter uses to represent the output from tap sum operations. The default value is 17 bits. Only `dfasymfir` and `dfsymfir` filters include this property.

## Adaptive Filter Properties

In this section...
“Property Summaries” on page 5-102
“Property Details for Adaptive Filter Properties” on page 5-107
“References for Adaptive Filters” on page 5-114

### Property Summaries

The following table summarizes the adaptive filter properties and provides a brief description of each. Full descriptions of each property, in alphabetical order, are given in the subsequent section.

Property	Description
Algorithm	Reports the algorithm the object uses for adaptation. When you construct your adaptive filter object, this property is set automatically by the constructor, such as <code>adaptfilt.nlms</code> creating an adaptive filter that uses the normalized LMS algorithm. You cannot change the value — it is read only.
AvgFactor	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor should lie between zero and one. For default filter objects, AvgFactor equals $(1 - \text{step}) \cdot \text{lambda}$ . lambda is the input argument that represents AvgFactor
BkwdPredErrorPower	Returns the minimum mean-squared prediction error. Refer to [3] in the bibliography for details about linear prediction.
BkwdPrediction	Returns the predicted samples generated during adaptation. Refer to [3] in the bibliography for details about linear prediction.

Property	Description
Blocklength	Block length for the coefficient updates. This must be a positive integer such that $(1/\text{blocklength})$ is also an integer. For faster execution, <code>blocklength</code> should be a power of two. <code>blocklength</code> defaults to two.
Coefficients	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input.
ConversionFactor	Conversion factor defaults to the matrix $[1 \ -1]$ that specifies soft-constrained initialization. This is the <code>gamma</code> input argument for some of the fast transversal algorithms.
Delay	Update delay given in time samples. This scalar should be a positive integer—negative delays do not work. <code>delay</code> defaults to 1 for most algorithms.
DesiredSignalStates	Desired signal states of the adaptive filter. <code>dstates</code> defaults to a zero vector with length equal to $(\text{blocklen} - 1)$ or $(\text{swblocklen} - 1)$ depending on the algorithm.
EpsilonStates	Vector of the epsilon values of the adaptive filter. <code>EpsilonStates</code> defaults to a vector of zeros with $(\text{projectord} - 1)$ elements.
ErrorStates	Vector of the adaptive filter error states. <code>ErrorStates</code> defaults to a zero vector with length equal to $(\text{projectord} - 1)$ .
FFTCoefficients	Stores the discrete Fourier transform of the filter coefficients in <code>coeffs</code> .
FFTStates	Stores the states of the FFT of the filter coefficients during adaptation.
FilteredInputStates	Vector of filtered input states with length equal to $l - 1$ .

<b>Property</b>	<b>Description</b>
FilterLength	Contains the length of the filter. Note that this is not the filter order. Filter length is 1 greater than filter order. Thus a filter with length equal to 10 has filter order equal to 9.
ForgettingFactor	Determines how the RLS adaptive filter uses past data in each iteration. You use the forgetting factor to specify whether old data carries the same weight in the algorithm as more recent data.
FwdPredErrorPower	Returns the minimum mean-squared prediction error in the forward direction. Refer to [3] in the bibliography for details about linear prediction.
FwdPrediction	Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. Called <code>delta</code> as an input argument, this defaults to one.
InvCov	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix. Dimensions are 1-by-1, where 1 is the filter length.
KalmanGain	Empty when you construct the object, this gets populated after you run the filter.
KalmanGainStates	Contains the states of the Kalman gain updates during adaptation.

<b>Property</b>	<b>Description</b>
Leakage	Contains the setting for leakage in the adaptive filter algorithm. Using a leakage factor that is not 1 forces the weights to adapt even when they have found the minimum error solution. Forcing the adaptation can improve the numerical performance of the LMS algorithm.
OffsetCov	Contains the offset covariance matrix.
Offset	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors.
Power	A vector of 2*1 elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
ProjectionOrder	Projection order of the affine projection algorithm. <code>projectord</code> defines the size of the input signal covariance matrix and defaults to two.
ReflectionCoeffs	Coefficients determined for the reflection portion of the filter during adaptation.
ReflectionCoeffsStep	Size of the steps used to determine the reflection coefficients.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states and coefficients from previous filtering runs.
SecondaryPathCoeffs	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.
SecondaryPathEstimate	An estimate of the secondary path filter model.

<b>Property</b>	<b>Description</b>
SecondaryPathStates	The states of the secondary path filter, the unknown system.
SqrtCov	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
SqrtInvCov	Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
States	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros whose length depends on the chosen algorithm. Usually the length is a function of the filter length <code>l</code> and another input argument to the filter object, such as <code>projectord</code> .
StepSize	Reports the size of the step taken between iterations of the adaptive filter process. Each <code>adaptfilt</code> object has a default value that best meets the needs of the algorithm.
SwBlockLength	Block length of the sliding window. This integer must be at least as large as the filter length. <code>swblocklen</code> defaults to 16.

Like `dfilt` objects, `adaptfilt` objects have properties that govern their behavior and store some of the results of filtering operations. The following pages list, in alphabetical order, the name of every property associated with `adaptfilt` objects. Note that not all `adaptfilt` objects have all of these properties. To view the properties of a particular adaptive filter, such as an `adaptfilt.bap` filter, use `get` with the object handle, like this:

```

ha = adaptfilt.bap(32,0.5,4,1.0);
get(ha)
    PersistentMemory: false
        Algorithm: 'Block Affine Projection FIR Adaptive Filter'
        FilterLength: 32
        Coefficients: [1x32 double]

```

```
States: [35x1 double]
StepSize: 0.5000
ProjectionOrder: 4
OffsetCov: [4x4 double]
```

`get` shows you the properties for `ha` and the values for the properties. Entering the object handle returns the same values and properties without the formatting of the list and the more familiar property names.

## Property Details for Adaptive Filter Properties

### Algorithm

Reports the algorithm the object uses for adaptation. When you construct you adaptive filter object, this property is set automatically. You cannot change the value—it is read only.

### AvgFactor

Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. `AvgFactor` should lie between zero and one. For default filter objects, `AvgFactor` equals  $(1 - \text{step})$ . `lambda` is the input argument that represent `AvgFactor`

### BkwdPredErrorPower

Returns the minimum mean-squared prediction error in the backward direction. Refer to [3] in the bibliography for details about linear prediction.

### BkwdPrediction

When you use an adaptive filter that does backward prediction, such as `adaptfilt.ftf`, one property of the filter contains the backward prediction coefficients for the adapted filter. With these coefficient, the forward coefficients, and the system under test, you have the full set of knowledge of how the adaptation occurred. Two values stored in properties compose the `BkwdPrediction` property:

- `Coefficients`, which contains the coefficients of the system under test, as determined using backward predictions process.

- Error, which is the difference between the filter coefficients determined by backward prediction and the actual coefficients of the sample filter. In this example, `adaptfilt.ftf` identifies the coefficients of an unknown FIR system.

```

x = randn(1,500);    % Input to the filter
b = fir1(31,0.5);    % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n; % Desired signal
N = 31;              % Adaptive filter order
lam = 0.99;          % RLS forgetting factor
del = 0.1;           % Soft-constrained initialization factor
ha = adaptfilt.ftf(32,lam,del);
[y,e] = filter(ha,x,d);

ha

ha =

        Algorithm: 'Fast Transversal Least-Squares Adaptive Filter'
        FilterLength: 32
        Coefficients: [1x32 double]
           States: [31x1 double]

### **Blocklength**

Block length for the coefficient updates. This must be a positive integer such that  $(1/\text{blocklen})$  is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.

### **Coefficients**

Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.

### **ConversionFactor**

Conversion factor defaults to the matrix  $[1 \ -1]$  that specifies soft-constrained initialization. This is the `gamma` input argument for some of the fast transversal algorithms.

### **Delay**

Update delay given in time samples. This scalar should be a positive integer — negative delays do not work. `delay` defaults to 1 for most algorithms.

### **DesiredSignalStates**

Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to  $(\text{blocklen} - 1)$  or  $(\text{swblocklen} - 1)$  depending on the algorithm.

### **EpsilonStates**

Vector of the epsilon values of the adaptive filter. `EpsilonStates` defaults to a vector of zeros with  $(\text{projectord} - 1)$  elements.

### **ErrorStates**

Vector of the adaptive filter error states. `ErrorStates` defaults to a zero vector with length equal to  $(\text{projectord} - 1)$ .

### **FFTCoefficients**

Stores the discrete Fourier transform of the filter coefficients in `coeffs`.

**FFTStates**

Stores the states of the FFT of the filter coefficients during adaptation.

**FilteredInputStates**

Vector of filtered input states with length equal to  $1 - 1$ .

**FilterLength**

Contains the length of the filter. Note that this is not the filter order. Filter length is 1 greater than filter order. Thus a filter with length equal to 10 has filter order equal to 9.

**ForgettingFactor**

Determines how the RLS adaptive filter uses past data in each iteration. You use the forgetting factor to specify whether old data carries the same weight in the algorithm as more recent data.

This is a scalar and should lie in the range  $(0, 1]$ . It defaults to 1. Setting `forgetting factor = 1` denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.

**FwdPredErrorPower**

Returns the minimum mean-squared prediction error in the forward direction. Refer to [3] in the bibliography for details about linear prediction.

**FwdPrediction**

Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.

**InitFactor**

Returns the soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.

### **InvCov**

Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix. Dimensions are 1-by-1, where 1 is the filter length.

### **KalmanGain**

Empty when you construct the object, this gets populated after you run the filter.

### **KalmanGainStates**

Contains the states of the Kalman gain updates during adaptation.

### **Leakage**

Contains the setting for leakage in the adaptive filter algorithm. Using a leakage factor that is not 1 forces the weights to adapt even when they have found the minimum error solution. Forcing the adaptation can improve the numerical performance of the LMS algorithm.

### **OffsetCov**

Contains the offset covariance matrix.

### **Offset**

Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors.

Use this to avoid dividing by zero or by very small numbers when input signal amplitude becomes very small, or dividing by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to one.

### **Power**

A vector of 2\*1 elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.

**ProjectionOrder**

Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.

**ReflectionCoeffs**

For adaptive filters that use reflection coefficients, this property stores them.

**ReflectionCoeffsStep**

As the adaptive filter changes coefficient values during adaptation, the step size used between runs is stored here.

**PersistentMemory**

Determines whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter.

`PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.

**SecondaryPathCoeffs**

A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.

**SecondaryPathEstimate**

An estimate of the secondary path filter model.

**SecondaryPathStates**

The states of the secondary path filter, the unknown system.

**SqrtCov**

Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.

### **SqrtInvCov**

Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.

### **States**

Vector of the adaptive filter states. `states` defaults to a vector of zeros whose length depends on the chosen algorithm. Usually the length is a function of the filter length `l` and another input argument to the filter object, such as `projectord`.

### **StepSize**

Reports the size of the step taken between iterations of the adaptive filter process. Each `adaptfilt` object has a default value that best meets the needs of the algorithm.

### **SwBlockLength**

Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklength` defaults to 16.

## Multirate Filter Properties

### In this section...

“Property Summaries” on page 5-115

“Property Details for Multirate Filter Properties” on page 5-120

“References for Multirate Filters” on page 5-130

### Property Summaries

The following table summarizes the multirate filter properties and provides a brief description of each. Full descriptions of each property are given in the subsequent section.

Name	Values	Default	Description
BlockLength	Positive integers	100	Length of each block of data input to the FFT used in the filtering. <code>fftfirinterp</code> multirate filters include this property.
DecimationFactor	Any positive integer	2	Amount to reduce the input sampling rate.
DifferentialDelay	Any integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.

<b>Name</b>	<b>Values</b>	<b>Default</b>	<b>Description</b>
FilterInternals	FullPrecision, MinWordlengths, SpecifyWordLengths, SpecifyPrecision	FullPrecision	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.
FilterStructure	mfilt structure string	None	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.

Name	Values	Default	Description
InputOffset	Integers	0	Contains the number of input data samples processed without generating an output sample. $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples that have been processed so far and $m$ is the decimation factor.
InterpolationFactor	Positive integers	2	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate.
NumberOfSections	Any positive integer	2	Number of sections used in the decimator, or in the comb and integrator portions of CIC filters.
Numerator	Array of double values	No default values	Vector containing the coefficients of the FIR lowpass filter used for interpolation.
OverflowMode	saturate, [wrap]	wrap	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic. The choice you make affects only the accumulator and output

Name	Values	Default	Description
			<p>arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.</p>
PolyphaseAccum	<p>Values depend on filter type. Either double, single, or fixed-point object</p>	0	<p>Stores the value remaining in the accumulator after the filter processes the last input sample. The stored value for PolyphaseAccum affects the next output when PersistentMemory is true and InputOffset is not equal to 0. Always provides full precision values. Compare the AccumWordLength and AccumFracLength.</p>
PersistentMemory	false or true	false	<p>Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.</p>

Name	Values	Default	Description
RateChangeFactors	[1,m]	[2,3] or [3,2]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal. The default changes depending on whether the filter decimates or interpolates.
States	Any m+1-by-n matrix of double values	2-by-2 matrix, int32	Stored conditions for the filter, including values for the integrator and comb sections. n is the number of filter sections and m is the differential delay. Stored in a <code>filtstates</code> object.
SpecifyWordLengths	Vector of integers	[16 16 16 16] bits	
WordLengthPerSection	Any integer or a vector of length 2*n	16	Defines the word length used in each section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter <code>WordLengthPerSection</code> as a scalar or vector of length 2*n, where n is the number of sections. When <code>WordLengthPerSection</code> is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

The following sections provide details about the properties that govern the way multirate filter work. Creating any multirate filter object puts in place a number of these properties. The following pages list the `mfilt` object properties in alphabetical order.

## Property Details for Multirate Filter Properties

### **BitsPerSection**

Any integer or a vector of length  $2*n$ .

Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using `wrap` arithmetic). Enter `bps` as a scalar or vector of length  $2*n$ , where  $n$  is the number of sections. When `bps` is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

### **BlockLength**

Length of each block of input data used in the filtering.

`mfilt.fftfirinterp` objects process data in blocks whose length is determined by the value you set for the `BlockLength` property. By default the property value is 100. When you set the `BlockLength` value, try choosing a value so that  $[\text{BlockLength} + \text{length}(\text{filter order})]$  is a power of two.

Larger block lengths generally reduce the computation time.

### **DecimationFactor**

Decimation factor for the filter. `m` specifies the amount to reduce the sampling rate of the input signal. It must be an integer. You can enter any integer value. The default value is 2.

### **DifferentialDelay**

Sets the differential delay for the filter. Usually a value of one or two is appropriate. While you can set any value, the default is one and the maximum is usually two.

## FilterInternals

Similar to the FilterInternals pane in FDATool, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. Setting FilterInternals to SpecifyPrecision exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.

**About FilterInternals Mode.** There are four usage modes for this that you set using the FilterInternals property in multirate filters.

- FullPrecision — All word and fraction lengths set to  $B_{max} + 1$ , called  $B_{accum}$  by Fred Harris in [2]. Full precision is the default setting.
- MinWordLengths — Minimum Word Lengths
- SpecifyWordLengths — Specify Word Lengths
- SpecifyPrecision — Specify Precision

### Full Precision

In full precision mode, the word lengths of all sections and the output are set to  $B_{accum}$  as defined by

$$B_{accum} = \text{ceil}(N_{secs}(\text{Log}_2(D \times M)) + \text{InputWordLength})$$

where  $N_{secs}$  is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display looks for this mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'FullPrecision'
```

### **Minimum Word Lengths**

In minimum word length mode, you control the output word length explicitly. When the output word length is less than  $B_{accum}$ , roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [3] in the following References section) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than  $B_{accum}$  as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from  $B_{accum}$  to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output word length for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'MinWordLengths'
```

```
OutputWordLength: 16
```

### Specify Word Lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length  $2 \times (\text{NumberOfSections})$ , where each vector element represents the word length for a section. If you specify a scalar, such as  $B_{accum}$ , the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display looks like for the SpecifyWordLengths mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
```

```
InputFracLength: 15
```

```
FilterInternals: 'SpecifyWordLengths'
```

```
SectionWordLengths: [19 18 18 17]
```

```
OutputWordLength: 16
```

### **Specify Precision**

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the `SpecifyPrecision` mode, you must enter a vector of length  $2*(\text{NumberOfSections})$  with elements that represent the word length for each section. When you enter a scalar such as  $B_{accum}$ , the CIC algorithm expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length  $2*(\text{NumberOfSections})$  with elements that represent the fraction length for each section as well. When you enter a calar such as  $B_{accum}$ , the design applies scalar expansion as done for the word lengths.

Here is the `SpecifyPrecision` display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
```

```
Arithmetic: 'fixed'
```

```
DifferentialDelay: 1
```

```
NumberOfSections: 2
```

```
DecimationFactor: 4
```

```
PersistentMemory: false
```

```
InputWordLength: 16
```

```
InputFracLength: 15
```

```
FilterInternals: 'SpecifyPrecision'
```

```
SectionWordLengths: [19 18 18 17]
```

```
SectionFracLengths: [14 13 13 12]
```

```
OutputWordLength: 16
OutputFracLength: 11
```

### FilterStructure

Reports the type of filter object, such as a decimator or fractional integrator. You cannot set this property — it is always read only and results from your choice of `mfilt` object. Because of the length of the names of multirate filters, `FilterStructure` often returns a vector specification for the string. For example, when you use `mfilt.firfracinterp` to design a filter, `FilterStructure` returns as [1x49 char].

```
hm=mfilt.firfracinterp
```

```
hm =
```

```
    FilterStructure: [1x49 char]
           Numerator: [1x72 double]
RateChangeFactors: [3 2]
 PersistentMemory: false
           States: [24x1 double]
```

### InputOffset

When you decimate signals whose length is not a multiple of the decimation factor  $M$ , the last samples —  $(nM + 1)$  to  $[(n+1)(M) - 1]$ , where  $n$  is an integer — are processed and used to track where the filter stopped processing input data and when to expect the next output sample. If you think of the filtering process as generating an output for a block of input data, `InputOffset` contains a count of the number of samples in the last incomplete block of input data.

---

**Note** `InputOffset` applies only when you set `PersistentMemory` to true. Otherwise, `InputOffset` is not available for you to use.

---

Two different cases can arise when you decimate a signal:

- 1 The input signal is a multiple of the filter decimation factor. In this case, the filter processes the input samples and generates output samples for all inputs as determined by the decimation factor. For example, processing 99 input samples with a filter that decimates by three returns 33 output samples.
- 2 The input signal is not a multiple of the decimation factor. When this occurs, the filter processes all of the input samples, generates output samples as determined by the decimation factor, and has one or more input samples that were processed but did not generate an output sample.

For example, when you filter 100 input samples with a filter which has decimation factor of 3, you get 33 output samples, and 1 sample that did not generate an output. In this case, `InputOffset` stores the value 1 after the filter run.

`InputOffset` equal to 1 indicates that, if you divide your input signal into blocks of data with length equal to your filter decimation factor, the filter processed one sample from a new (incomplete) block of data. Subsequent inputs to the filter are concatenated with this single sample to form the next block of length `m`.

One way to define the value stored in `InputOffset` is

```
InputOffset = mod(length(nx),m)
```

where `nx` is the number of input samples in the data set and `m` is the decimation factor.

Storing `InputOffset` in the filter allows you to stop filtering a signal at any point and start over from there, provided that the `PersistentMemory` property is set to `true`. Being able to resume filtering after stopping a signal lets you break large data sets in to smaller pieces for filtering. With `PersistentMemory` set to `true` and the `InputOffset` property in the filter, breaking a signal into sections of arbitrary length and filtering the sections is equivalent to filtering the entire signal at once.

```
xtot=[x,x];  
ytot=filter(hm1,xtot)  
ytot =
```

```

        0   -0.0003   0.0005  -0.0014   0.0028  -0.0054   0.0092
reset(hm1); % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

        0   -0.0003   0.0005  -0.0014   0.0028  -0.0054   0.0092

```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

### InterpolationFactor

Amount to increase the sampling rate. Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer. Two is the default value. You may use any positive value.

### NumberOfSections

Number of sections used in the multirate filter. By default multirate filters use two sections, but any positive integer works.

### OverflowMode

The `OverflowMode` property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- 'saturate' — saturate overflows.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest.

- 'wrap' — wrap all overflows to the range of representable values.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular

arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Designer documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.
- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

**Default value:** 'saturate'

---

**Note** Numbers in floating-point filters that extend beyond the dynamic range overflow to  $\pm\text{inf}$ .

---

### **PolyphaseAccum**

The idea behind `PolyphaseAccum` and `AccumWordLength/AccumFracLength` is to distinguish between the adders that always work in full precision (`PolyphaseAccum`) from the others [the adders that are controlled by the user (through `AccumWordLength` and `AccumFracLength`) and that may introduce quantization effects when you set property `FilterInternals` to `SpecifyPrecision`].

Given a product format determined by the input word and fraction lengths, and the coefficients word and fraction lengths, doing full precision accumulation means allowing enough guard bits to avoid overflows and underflows.

Property `PolyphaseAccum` stores the value that was in the accumulator the last time your filter ran out of input samples to process. The default value for `PolyphaseAccum` affects the next output only if `PersistentMemory` is true and `InputOffset` is not equal to 0.

`PolyphaseAccum` stores data in the format for the filter arithmetic. Double-precision filters store doubles in `PolyphaseAccum`. Single-precision

filter store singles in `PolyphaseAccum`. Fixed-point filters store `fi` objects in `PolyphaseAccum`.

### PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true` — the filter retains memory about filtering operations from one to the next. Maintaining memory lets you filter large data sets as collections of smaller subsets and get the same result.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =

    0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1); % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

    0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

### RateChangeFactors

Reports the decimation (`m`) and interpolation (`l`) factors for the filter object when you create fractional integrators and decimators, although `m` and `l` are used as arguments to both decimators and integrators, applying the

same meaning. Combining these factors as input arguments to the fractional decimator or integrator results in the final rate change for the signal.

For decimating filters, the default is [2,3]. For integrators, [3,2].

### States

Stored conditions for the filter, including values for the integrator and comb sections.  $m$  is the differential delay and  $n$  is the number of sections in the filter.

**About the States of Multirate Filters.** In the `states` property you find the states for both the integrator and comb portions of the filter, stored in a `filtstates` object. `states` is a matrix of dimensions  $m+1$ -by- $n$ , with the states in CIC filters apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

In the state matrix, state values are specified and stored in `double` format.

States stores conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter, including values for the interpolator and comb states.

The number of states is  $(l_h-1)*m+(l-1)*(l_0+m_0)$  where  $l_h$  is the length of each subfilter, and  $l$  and  $m$  are the interpolation and decimation factors.  $l_0$  and  $m_0$ , the input and output delays between each interpolation phase, are integers from Euclid's theorem such that  $l_0*l-m_0*m = -1$  (refer to the reference for more details). Use `euclidfactors` to get  $l_0$  and  $m_0$  for an `mfilt.firfracdecim` object.

States defaults to a vector of zeros that has length equal to `nstates(hm)`

This glossary defines terms related to fixed-point data types and numbers. These terms may appear in some or all of the documents that describe MathWorks® products that have fixed-point support.

## **arithmetic shift**

Shift of the bits of a binary word for which the sign bit is recycled for each bit shift to the right. A zero is incorporated into the least significant bit of the word for each bit shift to the left. In the absence of overflows, each arithmetic shift to the right is equivalent to a division by 2, and each arithmetic shift to the left is equivalent to a multiplication by 2.

*See also* binary point, binary word, bit, logical shift, most significant bit

## **bias**

Part of the numerical representation used to interpret a fixed-point number. Along with the slope, the bias forms the scaling of the number. Fixed-point numbers can be represented as

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$$

*See also* fixed-point representation, fractional slope, integer, scaling, slope, [Slope Bias]

## **binary number**

Value represented in a system of numbers that has two as its base and that uses 1's and 0's (bits) for its notation.

*See also* bit

**binary point**

Symbol in the shape of a period that separates the integer and fractional parts of a binary number. Bits to the left of the binary point are integer bits and/or sign bits, and bits to the right of the binary point are fractional bits.

*See also* binary number, bit, fraction, integer, radix point

**binary point-only scaling**

Scaling of a binary number that results from shifting the binary point of the number right or left, and which therefore can only occur by powers of two.

*See also* binary number, binary point, scaling

**binary word**

Fixed-length sequence of bits (1's and 0's). In digital hardware, numbers are stored in binary words. The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.

*See also* bit, data type, word

**bit**

Smallest unit of information in computer software or hardware. A bit can have the value 0 or 1.

**ceiling (round toward)**

Rounding mode that rounds to the closest representable number in the direction of positive infinity. This is equivalent to the `ceil` mode in Fixed-Point Designer software.

*See also* convergent rounding, floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)

**contiguous binary point**

Binary point that occurs within the word length of a data type. For example, if a data type has four bits, its contiguous binary point must be understood to occur at one of the following five positions:

.0000

0.000

00.00

000.0

0000.

*See also* data type, noncontiguous binary point, word length

**convergent rounding**

Rounding mode that rounds to the nearest allowable quantized value. Numbers that are exactly halfway between the two nearest allowable quantized values are rounded up only if the least significant bit (after rounding) would be set to 0.

*See also* ceiling (round toward), floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)

**data type**

Set of characteristics that define a group of values. A fixed-point data type is defined by its word length, its fraction length, and whether it is signed or unsigned. A floating-point data type is defined by its word length and whether it is signed or unsigned.

*See also* fixed-point representation, floating-point representation, fraction length, signedness, word length

**data type override**

Parameter in the Fixed-Point Tool that allows you to set the output data type and scaling of fixed-point blocks on a system or subsystem level.

*See also* data type, scaling

**exponent**

Part of the numerical representation used to express a floating-point or fixed-point number.

1. Floating-point numbers are typically represented as

$$\textit{real-world value} = \textit{mantissa} \times 2^{\textit{exponent}}$$

2. Fixed-point numbers can be represented as

$$\textit{real-world value} = (\textit{slope} \times \textit{stored integer}) + \textit{bias}$$

where the slope can be expressed as

$$\textit{slope} = \textit{fractional slope} \times 2^{\textit{exponent}}$$

The exponent of a fixed-point number is equal to the negative of the fraction length:

$$\textit{exponent} = -1 \times \textit{fraction length}$$

*See also* bias, fixed-point representation, floating-point representation, fraction length, fractional slope, integer, mantissa, slope

### **fixed-point representation**

Method for representing numerical values and data types that have a set range and precision.

1. Fixed-point numbers can be represented as

$$\textit{real-world value} = (\textit{slope} \times \textit{stored integer}) + \textit{bias}$$

where the slope can be expressed as

$$\textit{slope} = \textit{fractional slope} \times 2^{\textit{exponent}}$$

The slope and the bias together represent the scaling of the fixed-point number.

2. Fixed-point data types can be defined by their word length, their fraction length, and whether they are signed or unsigned.

*See also* bias, data type, exponent, fraction length, fractional slope, integer, precision, range, scaling, slope, word length

**floating-point representation**

Method for representing numerical values and data types that can have changing range and precision.

1. Floating-point numbers can be represented as

$$\text{real-world value} = \text{mantissa} \times 2^{\text{exponent}}$$

2. Floating-point data types are defined by their word length.

*See also* data type, exponent, mantissa, precision, range, word length

**floor (round toward)**

Rounding mode that rounds to the closest representable number in the direction of negative infinity.

*See also* ceiling (round toward), convergent rounding, nearest (round toward), rounding, truncation, zero (round toward)

**fraction**

Part of a fixed-point number represented by the bits to the right of the binary point. The fraction represents numbers that are less than one.

*See also* binary point, bit, fixed-point representation

**fraction length**

Number of bits to the right of the binary point in a fixed-point representation of a number.

*See also* binary point, bit, fixed-point representation, fraction

**fractional slope**

Part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$$

The term *slope adjustment* is sometimes used as a synonym for fractional slope.

*See also* bias, exponent, fixed-point representation, integer, slope

**full range**

The broadest range available for a data type. From  $-\infty$  to  $\infty$  for floating-point types. For integer types, the representable range is the range from the smallest to largest integer value (finite) the type can represent. For example, from -128 to 127 for a signed 8-bit integer. Also known as representable range.

**guard bits**

Extra bits in either a hardware register or software simulation that are added to the high end of a binary word to ensure that no information is lost in case of overflow.

*See also* binary word, bit, overflow

**incorrect range**

A range that is too restrictive and does not include values that can actually occur in the model element. A range that is too broad is not considered incorrect because it will not lead to overflow.

*See also* range analysis

**integer**

1. Part of a fixed-point number represented by the bits to the left of the binary point. The integer represents numbers that are greater than or equal to one.

2. Also called the "stored integer." The raw binary number, in which the binary point is assumed to be at the far right of the word. The integer is part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as

$$\text{real-world value} = 2^{-\text{fraction length}} \times \text{stored integer}$$

or

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$$

*See also* bias, fixed-point representation, fractional slope, integer, real-world value, slope

### **integer length**

Number of bits to the left of the binary point in a fixed-point representation of a number.

*See also* binary point, bit, fixed-point representation, fraction length, integer

### **least significant bit (LSB)**

Bit in a binary word that can represent the smallest value. The LSB is the rightmost bit in a big-endian-ordered binary word. The weight of the LSB is related to the fraction length according to

$$\text{weight of LSB} = 2^{-\text{fraction length}}$$

*See also* big-endian, binary word, bit, most significant bit

**logical shift**

Shift of the bits of a binary word, for which a zero is incorporated into the most significant bit for each bit shift to the right and into the least significant bit for each bit shift to the left.

*See also* arithmetic shift, binary point, binary word, bit, most significant bit

**mantissa**

Part of the numerical representation used to express a floating-point number. Floating-point numbers are typically represented as

$$\text{real - world value} = \text{mantissa} \times 2^{\text{exponent}}$$

*See also* exponent, floating-point representation

**model element**

Entities in a model that range analysis software tracks, for example, blocks, signals, parameters, block internal data (such as accumulators, products).

*See also* range analysis

**most significant bit (MSB)**

Bit in a binary word that can represent the largest value. The MSB is the leftmost bit in a big-endian-ordered binary word.

*See also* binary word, bit, least significant bit

**nearest (round toward)**

Rounding mode that rounds to the closest representable number, with the exact midpoint rounded to the closest representable number in the direction of positive infinity. This is equivalent to the nearest mode in Fixed-Point Designer software.

*See also* ceiling (round toward), convergent rounding, floor (round toward), rounding, truncation, zero (round toward)

**noncontiguous binary point**

Binary point that is understood to fall outside the word length of a data type. For example, the binary point for the following 4-bit word is understood to occur two bits to the right of the word length,

$$0000\_.$$

thereby giving the bits of the word the following potential values:

$$2^5 2^4 2^3 2^2 \_.$$

*See also* binary point, data type, word length

**one's complement representation**

Representation of signed fixed-point numbers. Negating a binary number in one's complement requires a bitwise complement. That is, all 0's are flipped to 1's and all 1's are flipped to 0's. In one's complement notation there are two ways to represent zero. A binary word of all 0's represents "positive" zero, while a binary word of all 1's represents "negative" zero.

*See also* binary number, binary word, sign/magnitude representation, signed fixed-point, two's complement representation

**overflow**

Situation that occurs when the magnitude of a calculation result is too large for the range of the data type being used. In many cases you can choose to either saturate or wrap overflows.

*See also* saturation, wrapping

**padding**

Extending the least significant bit of a binary word with one or more zeros.

*See also* least significant bit

**precision**

1. Measure of the smallest numerical interval that a fixed-point data type and scaling can represent, determined by the value of the number's least significant bit. The precision is given by the slope, or the number

of fractional bits. The term *resolution* is sometimes used as a synonym for this definition.

2. Measure of the difference between a real-world numerical value and the value of its quantized representation. This is sometimes called quantization error or quantization noise.

*See also* data type, fraction, least significant bit, quantization, quantization error, range, slope

### **Q format**

Representation used by Texas Instruments™ to encode signed two's complement fixed-point data types. This fixed-point notation takes the form

$Qm.n$

where

- $Q$  indicates that the number is in Q format.
- $m$  is the number of bits used to designate the two's complement integer part of the number.
- $n$  is the number of bits used to designate the two's complement fractional part of the number, or the number of bits to the right of the binary point.

In Q format notation, the most significant bit is assumed to be the sign bit.

*See also* binary point, bit, data type, fixed-point representation, fraction, integer, two's complement

### **quantization**

Representation of a value by a data type that has too few bits to represent it exactly.

*See also* bit, data type, quantization error

### **quantization error**

Error introduced when a value is represented by a data type that has too few bits to represent it exactly, or when a value is converted from

one data type to a shorter data type. Quantization error is also called quantization noise.

*See also* bit, data type, quantization

**radix point**

Symbol in the shape of a period that separates the integer and fractional parts of a number in any base system. Bits to the left of the radix point are integer and/or sign bits, and bits to the right of the radix point are fraction bits.

*See also* binary point, bit, fraction, integer, sign bit

**range**

Span of numbers that a certain data type can represent.

*See also* data type, full range, precision, representable range

**range analysis**

Static analysis of model to derive minimum and maximum range values for elements in the model. The software statically analyzes the ranges of the individual computations in the model based on specified design ranges, inputs, and the semantics of the calculation.

**real-world value**

Stored integer value with fixed-point scaling applied. Fixed-point numbers can be represented as

$$\text{real-world value} = 2^{-\text{fraction length}} \times \text{stored integer}$$

or

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$$

*See also* integer

**representable range**

The broadest range available for a data type. From  $-\infty$  to  $\infty$  for floating-point types. For integer types, the representable range is the range from the smallest to largest integer value (finite) the type can represent. For example, from -128 to 127 for a signed 8-bit integer. Also known as full range.

**resolution**

*See* **precision**

**rounding**

Limiting the number of bits required to express a number. One or more least significant bits are dropped, resulting in a loss of precision. Rounding is necessary when a value cannot be expressed exactly by the number of bits designated to represent it.

*See also* bit, ceiling (round toward), convergent rounding, floor (round toward), least significant bit, nearest (round toward), precision, truncation, zero (round toward)

**saturation**

Method of handling numeric overflow that represents positive overflows as the largest positive number in the range of the data type being used, and negative overflows as the largest negative number in the range.

*See also* overflow, wrapping

**scaled double**

A double data type that retains fixed-point scaling information. For example, in Simulink and Fixed-Point Designer software you can use data type override to convert your fixed-point data types to scaled doubles. You can then simulate to determine the ideal floating-point behavior of your system. After you gather that information you can turn data type override off to return to fixed-point data types, and your quantities still have their original scaling information because it was held in the scaled double data types.

**scaling**

1. Format used for a fixed-point number of a given word length and signedness. The slope and bias together form the scaling of a fixed-point number.
2. Changing the slope and/or bias of a fixed-point number without changing the stored integer.

*See also* bias, fixed-point representation, integer, slope

**shift**

Movement of the bits of a binary word either toward the most significant bit ("to the left") or toward the least significant bit ("to the right"). Shifts to the right can be either logical, where the spaces emptied at the front of the word with each shift are filled in with zeros, or arithmetic, where the word is sign extended as it is shifted to the right.

*See also* arithmetic shift, logical shift, sign extension

**sign bit**

Bit (or bits) in a signed binary number that indicates whether the number is positive or negative.

*See also* binary number, bit

**sign extension**

Addition of bits that have the value of the most significant bit to the high end of a two's complement number. Sign extension does not change the value of the binary number.

*See also* binary number, guard bits, most significant bit, two's complement representation, word

**sign/magnitude representation**

Representation of signed fixed-point or floating-point numbers. In sign/magnitude representation, one bit of a binary word is always the dedicated sign bit, while the remaining bits of the word encode the magnitude of the number. Negation using sign/magnitude representation consists of flipping the sign bit from 0 (positive) to 1 (negative), or from 1 to 0.

*See also* binary word, bit, fixed-point representation, floating-point representation, one's complement representation, sign bit, signed fixed-point, signedness, two's complement representation

**signed fixed-point**

Fixed-point number or data type that can represent both positive and negative numbers.

*See also* data type, fixed-point representation, signedness, unsigned fixed-point

**signedness**

The signedness of a number or data type can be signed or unsigned. Signed numbers and data types can represent both positive and negative values, whereas unsigned numbers and data types can only represent values that are greater than or equal to zero.

*See also* data type, sign bit, sign/magnitude representation, signed fixed-point, unsigned fixed-point

**slope**

Part of the numerical representation used to express a fixed-point number. Along with the bias, the slope forms the scaling of a fixed-point number. Fixed-point numbers can be represented as

$$\textit{real-world value} = (\textit{slope} \times \textit{stored integer}) + \textit{bias}$$

where the slope can be expressed as

$$\textit{slope} = \textit{fractional slope} \times 2^{\textit{exponent}}$$

*See also* bias, fixed-point representation, fractional slope, integer, scaling, [Slope Bias]

**slope adjustment**

*See fractional slope*

**[Slope Bias]**

Representation used to define the scaling of a fixed-point number.

*See also* bias, scaling, slope

**stored integer**

*See integer*

**trivial scaling**

Scaling that results in the real-world value of a number being simply equal to its stored integer value:

$$\textit{real - world value} = \textit{stored integer}$$

In [Slope Bias] representation, fixed-point numbers can be represented as

$$\textit{real-world value} = (\textit{slope} \times \textit{stored integer}) + \textit{bias}$$

In the trivial case, slope = 1 and bias = 0.

In terms of binary point-only scaling, the binary point is to the right of the least significant bit for trivial scaling, meaning that the fraction length is zero:

$$\textit{real - world value} = \textit{stored integer} \times 2^{-\textit{fraction length}} = \textit{stored integer} \times 2^0$$

Scaling is always trivial for pure integers, such as `int8`, and also for the true floating-point types `single` and `double`.

*See also* bias, binary point, binary point-only scaling, fixed-point representation, fraction length, integer, least significant bit, scaling, slope, [Slope Bias]

**truncation**

Rounding mode that drops one or more least significant bits from a number.

*See also* ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, zero (round toward)

**two's complement representation**

Common representation of signed fixed-point numbers. Negation using signed two's complement representation consists of a translation into one's complement followed by the binary addition of a one.

*See also* binary word, one's complement representation, sign/magnitude representation, signed fixed-point

**unsigned fixed-point**

Fixed-point number or data type that can only represent numbers greater than or equal to zero.

*See also* data type, fixed-point representation, signed fixed-point, signedness

**word**

Fixed-length sequence of binary digits (1's and 0's). In digital hardware, numbers are stored in words. The way hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.

*See also* binary word, data type

**word length**

Number of bits in a binary word or data type.

*See also* binary word, bit, data type

**wrapping**

Method of handling overflow. Wrapping uses modulo arithmetic to cast a number that falls outside of the representable range the data type being used back into the representable range.

*See also* data type, overflow, range, saturation

**zero (round toward)**

Rounding mode that rounds to the closest representable number in the direction of zero. This is equivalent to the `fix` mode in Fixed-Point Designer software.

*See also* ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, truncation

- triangular windows 1-1882
- Triggered Delay Line block 1-1645
- Triggered Shift Register block
  - initial state of 1-1646
- Triggered Signal From Workspace block 1-1649
- Triggered To Workspace block 1-1653
- triggering, for
  - N-Sample Enable block 1-1098
  - N-Sample Switch block 1-1102
  - Sample and Hold block 1-1311
  - Triggered Shift Register block 1-1645
  - Triggered Signal From Workspace block 1-1649
  - Triggered Signal To Workspace block 1-1653
- Two-Channel Analysis Subband Filter block 1-1658
- Two-Channel Synthesis Subband Filter block 1-1674

**U**

- UDP Receive block 1-1690
- UDP Send block 1-1695
- Unbuffer block 1-1698
  - initial state of 1-1699
- unbuffering
  - with the Buffer block 1-168
- Uniform Decoder block 1-1703
- Uniform Encoder block 1-1707
- Unwrap block 1-1712
- unwrapping radian phase angles 1-1712
- Upsample block 1-1720
- upsampling
  - by inserting zeros 1-1720
  - FIR Interpolation block 1-631
  - FIR Rate Conversion block 1-653
  - Repeat block 1-1285

**V**

- Variable Fractional Delay block 1-1726
  - initial conditions for 1-1727
- Variable Integer Delay block 1-1748
  - initial conditions for 1-1751
- Variable Selector block 1-1760
- variance 1-1766
  - tracking 1-1766
- Variance block 1-1766
- Vector Quantizer Decoder block 1-1785
- Vector Quantizer Design 1-1791
- Vector Quantizer Encoder block 1-1802
- Vector Scope block 1-1813
- vectors
  - converting to scalars 1-1698
  - creating from scalars 1-1645
  - exporting 1-1653
  - importing 1-713
  - importing from the workspace 1-1356

**W**

- Waterfall block 1-1839
- Window Function block 1-1879
- windows
  - applying 1-1879
  - Bartlett 1-1881
  - Blackman 1-1881
  - Chebyshev 1-1881
  - Hamming 1-1881
  - Hann 1-1881
  - Kaiser 1-1881
  - rectangular 1-1881
  - Taylor 1-1882
  - triangular 1-1882
- word length
  - about 5-29

**Y**

- Yule-Walker AR Estimator block 1-1897
- Yule-Walker Method block 1-1903

**Z**

- Zero Crossing block 1-1908
- zero-padding
  - Pad block 1-1188
- zero-pole plots 4-1288
- zerophase method 4-256
- zeros
  - Discrete Impulse block 1-519
  - inserting 1-631
  - N-Sample Enable block 1-1098
  - Signal From Workspace block 1-1356
  - Triggered Signal From Workspace
    - block 1-1650
- zpk method 4-256
- zplane 4-1288
  - plotting options 4-1288
- zplane method 4-256
