The data is displayed in a three-dimensional axis in the Waterfall window. By default, the *x*-axis represents amplitude, the *y*-axis represents samples, and the *z*-axis represents time. You can adjust the number of sample vectors that the block displays, move and resize the Waterfall window, and modify block parameter values during the simulation. The Waterfall window has toolbar buttons that enable you to zoom in on displayed data, suspend data capture, freeze the scope's display, save the scope position, and export data to the workspace. The toolbar buttons are labeled in the following figure, which shows the Waterfall window as it appears when you double-click a Waterfall block.

# Waterfall

## Sections of This Reference Page

## **Waterfall Parameters**

You can control the display and behavior of the Waterfall window using the Parameters dialog box.

---

**Note** You can alter the Waterfall parameters while the simulation is running. However, when you make changes to values in text boxes, you must click **Enter** or click outside the text box before the block accepts your changes.

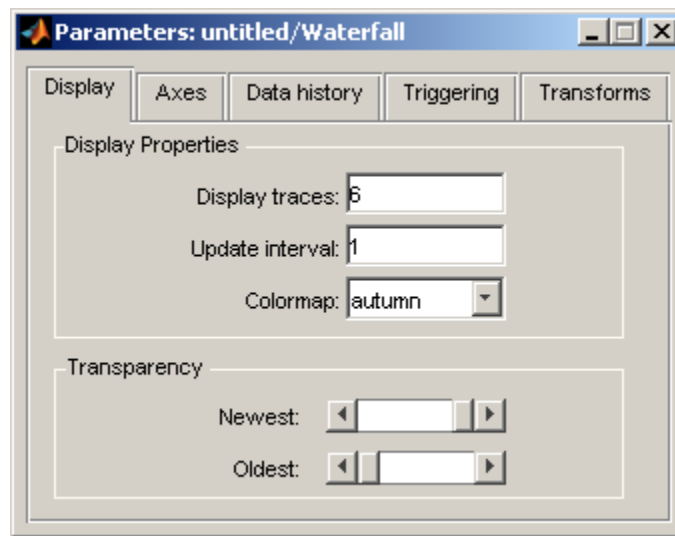

---

- 1** To open the Parameters dialog box, click the **Scope parameters** button.

# Waterfall

The Parameters dialog box appears.

**2** Click on the different panes to enter parameter settings.

## **Display Parameters**

The following parameters control the Waterfall window's display.

# Waterfall

---

## Display traces

Enter the number of vectors of data to be displayed in the Waterfall window.

## Update interval

Enter the number of vectors the block should store before it displays them to the window.

## Colormap

Choose a colormap for the displayed data.

## Transparency

Specify the transparency of the newest and oldest data vectors. Placing the slider in the left-most position tells the block to make the data vector transparent. Placing the slider in the right-most position tells the block to make the data vector opaque. The intermediate data vectors transition between the two chosen transparency values.

## Axes Parameters

The following parameters control the axes in the Waterfall window.

**Y Min**

Enter the minimum value of the *y*-axis.

**Y Max**

Enter the maximum value of the *y*-axis.

**Axis color**

Enter a background color for the axes. Specify the color using a character string. For example, to specify black, enter 'k'.

**X Axis**

Enter the *x*-axis label.

**Y Axis**

Enter the *y*-axis label.

**Z Axis**

Enter the *z*-axis label.

## Data History Parameters

The following parameters control how many input data vectors the Waterfall block stores. They also control how the data is exported to the MATLAB workspace or SPTool.

### History traces

Enter the number of vectors (traces) that you want the block to store.

### When the buffer is full

Use this parameter to control the behavior of the block when the buffer is filled:

- **Overwrite** — The old data is replaced with the new data.
- **Suspend** — The block stops storing data in the buffer; however, the simulation continues to run.
- **Extend** — The block extends the buffer so that it can continue to store all the input data.

## Data logging

Use this parameter to control which data is exported from the block:

- **Selected** — The selected data vector is exported.
- **All visible** — All of the data vectors displayed in the Waterfall window are exported.
- **All history** — All of the data vectors stored in the block's history buffer are exported.

## Export variable

Enter the name of the variable that represents your data in the MATLAB workspace or SPTool. The default variable name is ExportData.

## Export at end of simulation

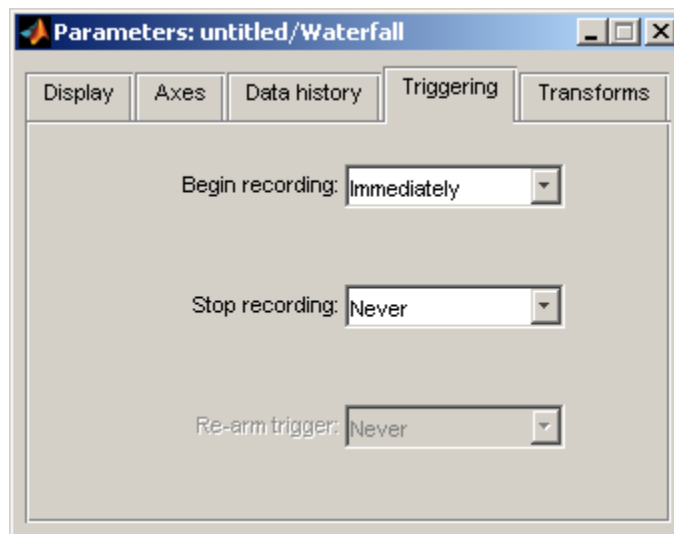

Select this check box to automatically export the data to the MATLAB workspace when the simulation stops.

## Triggering Parameters

The following parameters control when the Waterfall block starts and stops capturing data.

# Waterfall

---

## Begin recording

This parameter controls when the Waterfall block starts capturing data:

- **Immediately** — The Waterfall window captures the input data as soon as the simulation starts.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins capturing data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins capturing data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin capturing data. For more information about how you define this function, see “Scope Trigger Function” on page 1-1851.

## Stop recording

This parameter controls when the Waterfall block stops capturing data:

- **Never** — The block captures the input data as long as the simulation is running.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it stops capturing data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it stops capturing data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should stop capturing data. For more information about how you define this function, see “Scope Trigger Function” on page 1-1851.

## Re-arm trigger

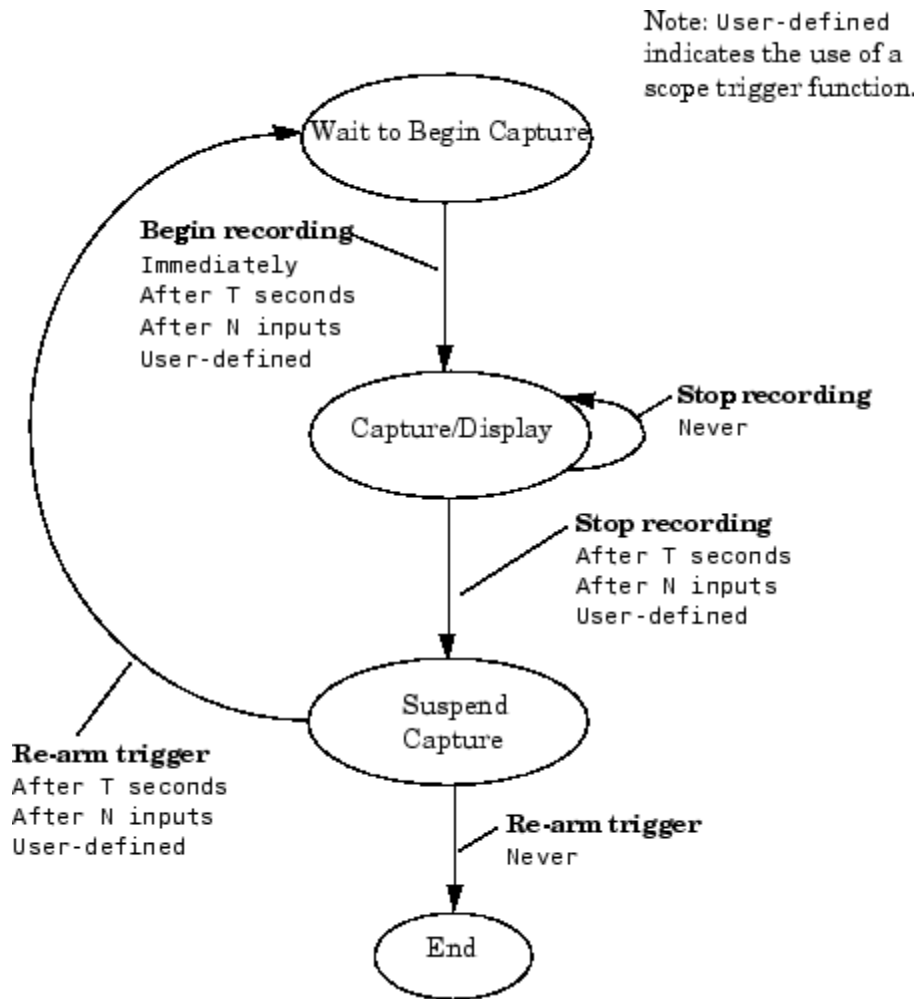

This parameter controls when the Waterfall block begins waiting to capture data. It is available only when you select **After T seconds**, **After N inputs**, or **User-defined** for the **Stop recording** parameter:

- **Never** — The Waterfall Scope block starts and stops capturing data as defined by the **Begin recording** and **Stop recording** parameters.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins waiting to capture data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins waiting to capture data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that

# Waterfall

defines when the block should begin waiting to capture data. For more information about how you define this function, see “Scope Trigger Function” on page 1-1851.

The triggering process is illustrated in the state diagram below.

## Scope Trigger Function

You can create custom scope trigger functions to control when the scope starts, stops, or begins waiting to capture data.

These functions must be valid MATLAB functions and be located either in the current folder or on the MATLAB path.

Each scope trigger function must have the following form

```
y = functionname(blk,t,u),
```

where `functionname` refers to the name you give your scope trigger function. The variable `blk` is the Simulink block handle. When the scope trigger function is called by the block, Simulink automatically populates this variable with the handle of the Waterfall block. The variable `t` is the current simulation time, represented by a real, double-precision, scalar value. The variable `u` is the vector input to the block. The output of the scope trigger function, `y`, is interpreted as a logical signal. It is either true or false:

# Waterfall

---

- Begin recording scope trigger function
  - When the output of this scope trigger function is true, the Waterfall block starts capturing data.
  - When the output is false, the block remains in its current state.
- Stop recording scope trigger function
  - When the output of this scope trigger function is true, the block stops capturing data.
  - When the output is false, the block remains in its current state.
- Re-arm trigger scope trigger function
  - When the output of this scope trigger function is true, the block waits for a begin recording event.
  - When the output is false, the block remains in its current state.

---

**Note** The Waterfall block passes its input data directly to the scope trigger functions. These functions do not use the transformed data defined by the Transform parameters.

---

The following is an example of a scope trigger function. This function, called `trigPower` detects when the energy in `u` exceeds a certain threshold.

```
function y = trigPower(blk, t, u)
```

```
y = (u'*u > 2300);
```

The following is another example of a scope trigger function. This function, called `count3`, triggers the scope once three vectors with positive means are input to the block. Then, the function resets itself and begins searching for the next three input vectors with positive means. This scope trigger function is valid only when one Waterfall block is present in your model.

```
function y = count3(blk, t, u)

persistent state;
if isempty(state); state = 0; end
if mean(u)>0; state = state+1; end
y = (state>=3);
if y; state = 0; end
```

## Transform Parameters

The following parameters transform the input data to the Waterfall block. The result of the transform is displayed in the Waterfall window.

---

**Note** The block assumes that the input to the block corresponds to the **Transform** parameter you select. For example, when you choose **Complex-> Angle**, the block assumes that the input is complex. The block does not produce an error when the input is not complex. Therefore, you must verify the format of your input data to guarantee that a meaningful result is displayed in the Waterfall window.

---

## Transform

Choose a transform that you would like to apply to the input of the Waterfall block:

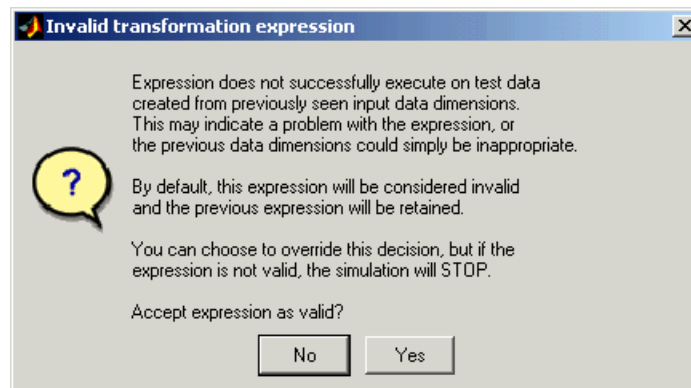

- **None** — The input is displayed as it is received by the block.
- **Amplitude-> dB** — The block converts the input amplitude into decibels.
- **Complex-> Mag Lin** — The block converts the complex input into linear magnitude.
- **Complex-> Mag dB** — The block converts the complex input into magnitude in decibels.
- **Complex-> Angle** — The block converts the complex input into phase.
- **FFT-> Mag Lin Fs/2** — The block takes the linear magnitude of the FFT input and plots it from 0 to the Nyquist frequency.
- **FFT-> Mag dB Fs/2** — The block takes the magnitude of the FFT input, converts it to decibels, and plots it from 0 to the Nyquist frequency.
- **FFT-> Angle Fs/2** — The block converts the FFT input into phase and plots it from 0 to the Nyquist frequency.
- **Power-> dB** — The block converts the input power into decibels.

## Function

This parameter is only available when you select User-defined fcn for the **Transform** parameter. Enter a function that you would like to apply to the input of the Waterfall block. For more information about how you define this function, see “Scope Transform Function” on page 1-1855.

## Expression

This parameter is only available when you select User-defined expr for the **Transform** parameter. Enter an expression that you would like to apply to the input of the Waterfall block. The result of this expression must be real-valued. When you write the expression, be sure to include only one unknown variable. The block assumes this unknown variable represents the input to the block. When the block believes your expression is invalid, the following window appears.

When you click **No**, your expression is not applied to the input. When you click **Yes** and your expression is invalid, your simulation stops and Simulink displays an error.

## Scope Transform Function

You can create a scope transform function to control how the Waterfall block transforms your input data. This function must have a valid

MATLAB function name and be located either in the current folder or on the MATLAB path.

Your scope transform function must have the following form

```
y = functionname(u),
```

where `functionname` refers to the name you give your function. The variable `u` is the real or complex vector input to the block. The output of the scope transform function, `y`, must be a double-precision, real-valued vector. When it is not, the simulation stops and Simulink displays an error. Note that the output vector does not need to be the same size as the input vector.

## Examples

The following examples illustrate some capabilities of the Waterfall block.

- “Exporting Data” on page 1-1856
- “Capturing Data” on page 1-1857
- “Linking Scopes” on page 1-1858
- “Selecting Data” on page 1-1859
- “Zooming” on page 1-1862
- “Rotating the Display” on page 1-1862
- “Scaling the Axes” on page 1-1862
- “Saving Scope Settings” on page 1-1863

### Exporting Data

You can use the Waterfall block to export data to the MATLAB workspace or to SPTool:

- 1 Open and run the `dspanc` example.
- 2 While the simulation is running, click the **Export to Workspace** button.

- 3 Type `whos` at the MATLAB command line.

The variable `ExportData` appears in your MATLAB workspace. `ExportData` is a 40-by-6 matrix. This matrix represents the six data vectors that were present in the Waterfall window at the time you clicked the **Export to Workspace** button. Each column of this matrix contains 40 filter coefficients. The columns of data were captured at six consecutive instants in time.

You can control what data is exported using the **Data logging** parameter in **Data history** pane of the Parameters dialog box. For more information, see “Data History Parameters” on page 1-1846.

- 4 While the simulation is running, click the **Export to SPTool** button.

The SPTool GUI opens and the variable `ExportData` is displayed in the **Signals** list.

For more information about SPTool, see the Signal Processing Toolbox documentation.

## Capturing Data

You can use the Waterfall block to interact with your data while it is being captured:

- 1 Open and run the `dspnc` example.
- 2 While the simulation is running, click the **Suspend data capture** button.  
  
The Waterfall block no longer captures or displays the data coming from the Downsample block.
- 3 To continue capturing data, click the **Resume data capture** button.
- 4 To freeze the data display while continuing to capture data, click the **Snapshot display** button.

# Waterfall

- 5 To view the Waterfall block that the data is coming from, click the **Go to scope block** button.

In the Simulink model window, the Waterfall block that corresponds to the active Waterfall window flashes. This feature is helpful when you have more than one Waterfall block in a model and you want to clarify which data is being displayed.

## Linking Scopes

You can link several Waterfall blocks together in order to capture the effect of a model event in all of the Waterfall windows in the model:

- 1 Open the dspanc example.
- 2 Drag a second Waterfall block into the example model.
- 3 Connect this block to the Output port of the LMS Filter block as shown in the figure below.

**4** Run the model and view the model behavior in both Waterfall windows.

**5** In the dspnc/Waterfall window, click the **Link scopes** button.

**6** In the same window, click the **Suspend data capture** button.

The data capture is suspended in both scope windows.

**7** Click the **Resume data capture** button.

The data capture resumes in both scope windows.

**8** In the dspnc/Waterfall window, click the **Snapshot display** button.

In both scope windows, the data display freezes while the block continues to capture data.

**9** To continue displaying the captured data, click the **Resume display** button.

## Selecting Data

The following figure shows the Waterfall window displaying the output of the dspnc example:

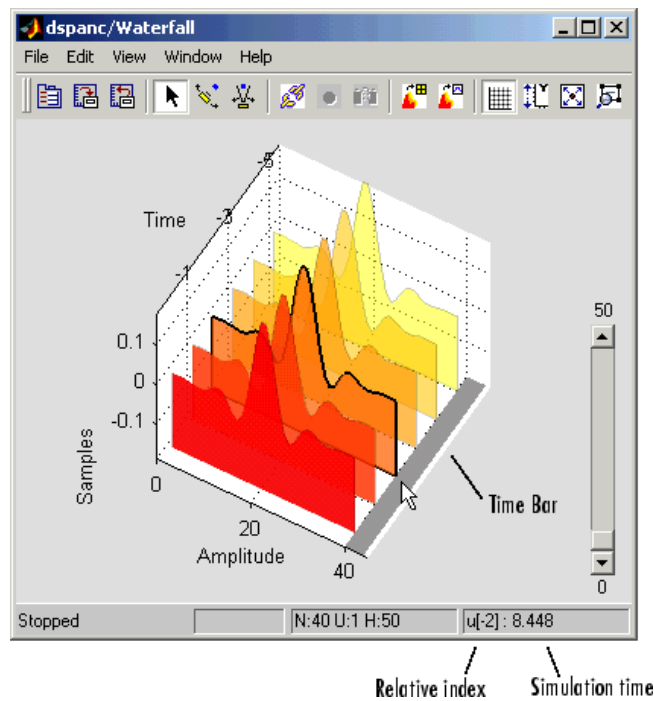

# Waterfall

- 1 To select a particular set of data, click the **Select** button.
- 2 Click on the Time Bar at the bottom right of the axes to select a vector of data.

The Waterfall block highlights the selected trace.

While the simulation is running, in the bottom right corner, the Waterfall window displays the relative index of the selected trace. For example, in the previous figure, the selected vector is two sample times away from the most current data vector. When the simulation is stopped, the Waterfall window displays both the relative index and the simulation time associated with the selected trace.

**3** To deselect the data vector, click it again.

**4** Click-and-drag along the Time Bar.

Your selection follows the movement of the pointer.

# Waterfall

---

You can use this feature to choose a particular vector to export to the MATLAB workspace or SPTool. For more information, see “Data History Parameters” on page 1-1846.

## Zooming

You can use the Waterfall window to zoom in on data:

- 1 Click the **Zoom camera** button.
- 2 In the Waterfall window, click and hold down the left mouse button.
- 3 Move the mouse up and down and side-to-side to move closer and farther away from the axes.
- 4 To resize the axes to fit the Waterfall window, click the **Fit to view** button.

## Rotating the Display

You can rotate the data displayed in the Waterfall window:

- 1 Click on the **Orbit camera** button.
- 2 In the Waterfall window, click and hold down the left mouse button.
- 3 Move the mouse in a circular motion to rotate the axes.
- 4 To return to the position of the original axes, click the **Restore scope position and view** button.

## Scaling the Axes

You can use the Waterfall window to rescale the  $y$ -axis values:

- 1 Open and run the `dspanc` example.
- 2 Click the **Rescale amplitude** button.

The  $y$ -axis changes so that its minimum value is zero. The maximum value is scaled to fit the data displayed.

Alternatively, you can scale the  $y$ -axis using the **Y Min** and **Y Max** parameters in the **Axes** pane of the Parameters dialog box. This is helpful when you want to undo the effects of rescaling the amplitude. For more information, see “Axes Parameters” on page 1-1844.

## Saving Scope Settings

The Waterfall block can save the screen position and viewpoint of the Waterfall window:

- 1 Click the **Save scope position and view** button.
- 2 Close the Waterfall window.
- 3 Reopen the Waterfall window.

It reopens at the same place on your screen. The viewpoint of the axes also remains the same.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>

The Waterfall block accepts any of these data types as input. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

# Wavelet Analysis (Obsolete)

## Purpose

Decompose signal into components of logarithmically decreasing frequency intervals and sample rates (requires the Wavelet Toolbox product)

## Library

dspobslib

## Description

**Note** The Wavelet Analysis block will be removed from the product in a future release. We strongly recommend replacing this block with the DWT block.

The Wavelet Analysis block uses the Wavelet Toolbox `wfilters` function to construct a dyadic analysis filter bank that decomposes a broadband signal into a collection of successively more bandlimited components. An  $n$ -level filter bank structure is shown below, where  $n$  is specified by the **Number of levels** parameter.

Wavelet Analysis Filter Bank,  $n$  Levels

At each level, the low-frequency output of the previous level is decomposed into adjacent high- and low-frequency subbands by a highpass (HP) and lowpass (LP) filter pair. Each of the two output subbands is half the bandwidth of the input to that level. The

# Wavelet Analysis (Obsolete)

---

bandlimited output of each filter is maximally decimated by a factor of 2 to preserve the bit rate of the original signal.

## Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	<code>wfilters('haar')</code>
Daubechies	<code>wfilters('db4')</code>
Symlets	<code>wfilters('sym3')</code>
Coiflets	<code>wfilters('coif1')</code>
Biorthogonal	<code>wfilters('bior3.1')</code>
Reverse Biorthogonal	<code>wfilters('rbio3.1')</code>
Discrete Meyer	<code>wfilters('dmey')</code>

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a **Daubechies** wavelet with **Wavelet order** equal to 6, the Wavelet Analysis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to `[2 / 6]`, the Wavelet Analysis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the analysis filter bank, use the Dyadic Analysis Filter Bank block.

## Tree Structure

The wavelet tree structure has  $n+1$  outputs, where  $n$  is the number of levels. The sample rate and bandwidth of the top output are half the input sample rate and bandwidth. The sample rate and bandwidth of each additional output (except the last) are half that of the output from the previous level. In general, for an input with sample period  $T_{si} = T_s$ , and bandwidth  $BW$ , output  $y_k$  has sample period  $T_{so,k}$  and bandwidth  $BW_k$ .

$$T_{so,k} = \begin{cases} (2^k) T_s & (1 \leq k \leq n) \\ (2^n) T_s & (k = n + 1) \end{cases}$$

$$BW_k = \begin{cases} \frac{BW}{2^k} & (1 \leq k \leq n) \\ \frac{BW}{2^n} & (k = n + 1) \end{cases}$$

Note that in frame-based mode, the change in the sample period of output  $y_k$  is reflected by its frame size  $M_{o,k}$ , rather than by its frame rate.

$$M_{o,k} = \begin{cases} \frac{M_i}{2^k} & (1 \leq k \leq n) \\ \frac{M_i}{2^n} & (k = n + 1) \end{cases}$$

The bottom two outputs ( $y_n$  and  $y_{n+1}$ ) share the same sample period, bandwidth, and frame size because they originate at the same tree level.

# Wavelet Analysis (Obsolete)

## Sample-Based Operation

An  $M$ -by- $N$  sample-based matrix input is treated as  $M \cdot N$  independent channels, and the block filters each channel independently over time. The output at each port is the same size as the input, one output channel for each input channel. As described earlier, each output port has a different sample period.

The figure below shows the input and output sample periods for a 64-channel sample-based input to a three-level filter bank. The input has a period of 1, so the fastest output has a period of 2.

## Frame-Based Operation

An  $M_i$ -by- $N$  frame-based matrix input is treated as  $N$  independent channels, and the block filters each channel independently over time. The input frame size  $M_i$  must be a multiple of  $2^n$ , and  $n$  is the number of filter bank levels. For example, a frame size of 8 would be appropriate for a three-level tree ( $2^3=8$ ). The number of columns in each output is the same as the number of columns in the input.

Each output port has the same frame period as the input. The reduction in the output sample rates results from the smaller output frame sizes, as shown in the example below for a four-channel input to a three-level filter bank.

## Zero Latency

The Wavelet Analysis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore analyzes the first input sample (received at  $t=0$ ) to produce the first output sample at each port.

## Nonzero Latency

For sample-based operation, the Wavelet Analysis block is multirate and has  $2^{n-1}$  samples of latency in both Simulink tasking modes. As a result, the block repeats a zero initial condition in each channel for the first  $2^{n-1}$  output samples, before propagating the first analyzed input sample (computed from the input received at  $t=0$ ).

---

**Note** For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and the topic on models with multiple sample rates in the Simulink Coder documentation.

---

# Wavelet Analysis (Obsolete)

---

## Dialog Box

The parameters displayed in the dialog box vary for different wavelet types. Only some of the parameters listed below are visible in the dialog box at any one time.

### Wavelet name

The wavelet used in the analysis.

### Wavelet order

The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

### Filter order [synthesis / analysis]

The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, [2 / 6] selects a second-order synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

### Number of levels

The number of filter bank levels. An  $n$ -level structure has  $n+1$  outputs.

# Wavelet Synthesis (Obsolete)

## Purpose

Reconstruct signal from its multirate bandlimited components (requires the Wavelet Toolbox product)

## Library

dspobslib

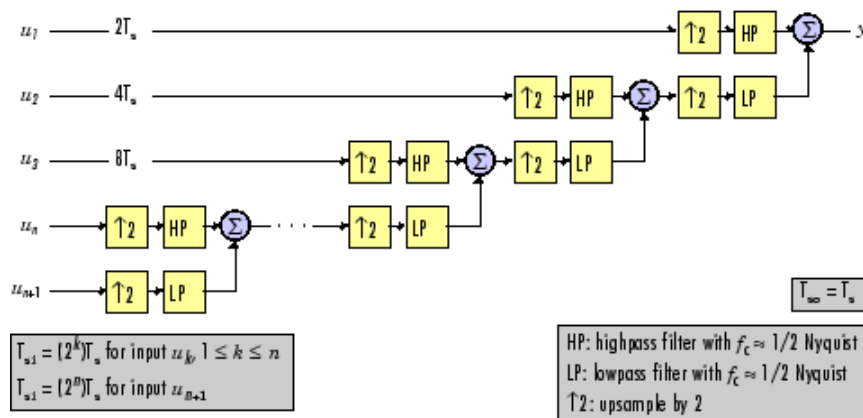

## Description

**Note** The Wavelet Synthesis block will be removed from the product in a future release. We strongly recommend replacing this block with the IDWT block.

The Wavelet Synthesis block uses the Wavelet Toolbox `wfilters` function to reconstruct a signal that was decomposed by the Wavelet Analysis (Obsolete) block. The reconstruction or synthesis process is the inverse of the analysis process, and restores the original signal by upsampling, filtering, and summing the bandlimited inputs in stages corresponding to the analysis process. An  $n$ -level synthesis filter bank structure is shown below, where  $n$  is specified by the **Number of levels** parameter.

**Wavelet Synthesis Filter Bank,  $n$  Levels**

At each level, the two bandlimited inputs (one low-frequency, one high-frequency, both with the same sample rate) are upsampled by

a factor of 2 to match the sample rate of the input to the next stage. They are then filtered by a highpass (HP) and lowpass (LP) filter pair with coefficients calculated to cancel (in the subsequent summation) the aliasing introduced in the corresponding analysis filter stage. The output from each (upsample-filter-sum) level has twice the bandwidth and twice the sample rate of the input to that level.

For perfect reconstruction, the Wavelet Synthesis and Wavelet Analysis blocks must have the same parameter settings.

## Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	<code>wfilters('haar')</code>
Daubechies	<code>wfilters('db4')</code>
Symlets	<code>wfilters('sym3')</code>
Coiflets	<code>wfilters('coif1')</code>
Biorthogonal	<code>wfilters('bior3.1')</code>
Reverse Biorthogonal	<code>wfilters('rbio3.1')</code>
Discrete Meyer	<code>wfilters('dmey')</code>

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a **Daubechies** wavelet with **Wavelet order** equal to 6, the Wavelet Synthesis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows

# Wavelet Synthesis (Obsolete)

---

you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to [2 / 6], the Wavelet Synthesis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the synthesis filter bank, use the Dyadic Synthesis Filter Bank block.

## Tree Structure

The wavelet tree structure has  $n+1$  inputs, where  $n$  is the number of levels. The sample rate and bandwidth of the output are twice the sample rate and bandwidth of the top input. The sample rate and bandwidth of each additional input (except the last) are half that of the input to the previous level.

$$T_{si,k+1} = 2T_{si,k} \quad 1 \leq k < n$$

$$BW_{k+1} = \frac{BW_k}{2} \quad 1 \leq k < n$$

The bottom two inputs ( $u_n$  and  $u_{n+1}$ ) should have the same sample rate and bandwidth since they are processed by the same level.

$$T_{si,n+1} = T_{si,n}$$

$$BW_{n+1} = BW_n$$

Note that in frame-based mode, the sample period of input  $u_k$  is reflected by its frame size  $M_{i,k}$ , rather than by its frame rate.

$$M_{i,k+1} = \frac{M_{i,k}}{2} \quad 1 \leq k < n$$

$$M_{i,n+1} = M_{i,n}$$

## Sample-Based Operation

An  $M$ -by- $N$  sample-based matrix input is treated as  $M \cdot N$  independent channels, and the block filters each channel independently over time. The output is the same size as the input at each port, one output channel for each input channel. As described earlier, each input port has a different sample period.

The figure below shows the input and output sample periods for the four 64-channel sample-based inputs to a three-level filter bank. The fastest input has a period of 2, so the output period is 1.

## Frame-Based Operation

An  $M_f$ -by- $N$  frame-based matrix input is treated as  $N$  independent channels, and the block filters each channel independently over time. The number of columns in the output is the same as the number of columns in the input.

All inputs must have the same frame period, which is also the output frame period. The different input sample rates should be represented by the input frame sizes: If the input to the top port has frame size  $M_f$ , the input to the second-from-top port should have frame size  $M_f/2$ , the input to the third-from-top port should have frame size  $M_f/4$ , and so on. The input to the bottom port should have the same frame size

# Wavelet Synthesis (Obsolete)

as the second-from-bottom port. The increase in the sample rate of the output is also represented by its frame size, which is twice the largest input frame size.

The relationship between sample periods, frame periods, and frame sizes is shown below for a four-channel frame-based input to a 3-level filter bank.

## Zero Latency

The Wavelet Synthesis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore uses the first input samples (received at  $t=0$ ) to synthesize the first output sample.

## Nonzero Latency

For sample-based operation, the Wavelet Synthesis block is multirate and has the following tasking latencies:

- $2^n - 2$  samples in Simulink's single-tasking mode
- $2^n$  samples in Simulink's multitasking mode

In the above cases, the block repeats a zero initial condition in each channel for the first  $D$  output samples, where  $D$  is the latency shown above. For example, in single-tasking mode the block generates  $2^n - 2$  zero-valued output samples in each channel before propagating the first synthesized output sample (computed from the inputs received at  $t=0$ ).

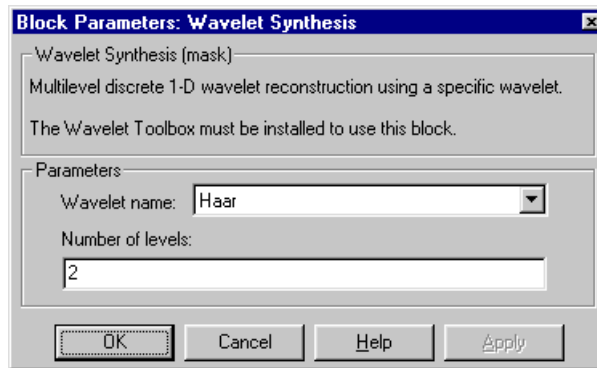

---

**Note** For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and the topic on models with multiple sample rates in the Simulink Coder documentation.

---

## Dialog Box

The parameters displayed in the dialog box vary for different wavelet types. Only some of the parameters listed below are visible in the dialog box at any one time.

### Wavelet name

The wavelet used in the synthesis.

### Wavelet order

The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

### Filter order [synthesis / analysis]

The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, [2 / 6] selects a second-order synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

# Wavelet Synthesis (Obsolete)

---

## Number of levels

The number of filter bank levels. An  $n$ -level structure has  $n+1$  outputs.

## Purpose

Compute and/or apply window to input signal

## Library

Signal Operations

dspsigops

## Description

The Window Function block computes a window and/or applies a window to an input signal. The input signal can be a matrix or an N-D array.

## Operation Modes

The Window Function block has three modes of operation that you can select via the **Operation** parameter. In each mode, the block first creates a window vector  $w$  by sampling the window specified in the **Window type** parameter at  $M$  discrete points. The operation modes are:

- Apply window to input

In this mode, the block computes an  $M$ -by-1 window vector  $w$  and applies it to the input. The output  $y$  always has the same dimension as the input.

When the input is an  $M$ -by- $N$  matrix  $u$ , the window is multiplied element-wise with each of the  $N$  channels in the input matrix  $u$ . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u           % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \dots, k) = w(i) * u(i, j, \dots, k) \quad i = 1, \dots, M, \quad j = 1, \dots, N, \quad \dots, \quad k = 1, \dots, P$$

A length- $M$  unoriented vector input is treated as an  $M$ -by-1 matrix.

- Generate window

# Window Function

---

In this mode, the block generates an unoriented window vector  $w$  with length  $M$  specified by the **Window length** parameter. The In port is disabled for this mode.

- **Generate and apply window**

In this mode, the block generates an  $M$ -by-1 window vector  $w$  and applies it to the input. The block produces two outputs:

- At the Out port, the block produces the result of the multiplication  $y$ , which has the same dimension as the input.
- At the Win port, the block produces the  $M$ -by-1 window vector  $w$ .

When the input is an  $M$ -by- $N$  matrix  $u$ , the window is multiplied element-wise with each of the  $N$  channels in the input matrix  $u$ . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u      % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i,j,\dots,k) = w(i) * u(i,j,\dots,k) \quad i = 1,\dots,M, \quad j = 1,\dots,N, \quad \dots, \quad k = 1,\dots,P$$

A length- $M$  1-D vector input is treated as an  $M$ -by-1 matrix.

## Window Type

The following table lists the available window types. For complete information about the window functions, consult the Signal Processing Toolbox documentation.

Window Type	Description
Bartlett	Computes a Bartlett window. $w = \text{bartlett}(M)$
Blackman	Computes a Blackman window. $w = \text{blackman}(M)$
Boxcar	Computes a rectangular window. $w = \text{rectwin}(M)$
Chebyshev	Computes a Chebyshev window with stopband ripple $R$ . $w = \text{chebwin}(M, R)$
Hamming	Computes a Hamming window. $w = \text{hamming}(M)$
Hann	Computes a Hann window (also known as a Hanning window). $w = \text{hann}(M)$
Hanning	Obsolete. This window type is included only for compatibility with older models. Use the Hann <b>Window type</b> instead of Hanning whenever possible.
Kaiser	Computes a Kaiser window with the Kaiser parameter $\beta$ . $w = \text{kaiser}(M, \beta)$

# Window Function

---

Window Type	Description
Taylor	Computes a Taylor window.  <code>w = taylorwin(M)</code>
Triang	Computes a triangular window.  <code>w = triang(M)</code>
User Defined	Computes the user-defined window function specified by the entry in the <b>Window function name</b> parameter, <code>usrwin</code> .  <code>w = usrwin(M) % Window takes no extra parameters</code> <code>w = usrwin(M,x<sub>1</sub>,...,x<sub>n</sub>) % Window takes extra parameters {x<sub>1</sub> ... x<sub>n</sub>}</code>

## Window Sampling

For the generalized-cosine windows (Blackman, Hamming, Hann, and Hanning), the **Sampling** parameter determines whether the window samples are computed in a periodic or a symmetric manner. For example, when **Sampling** is set to `Symmetric`, a Hamming window of length  $M$  is computed as

```
w = hamming(M) % Symmetric (aperiodic) window
```

When **Sampling** is set to `Periodic`, the same window is computed as

```
w = hamming(M+1) % Periodic (asymmetric) window  
w = w(1:M)
```

## **Fixed-Point Data Types**

The following diagram shows the data types used within the Window Function block for fixed-point signals for each of the three operating modes.

# Window Function

## Apply window to input

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is not output from the block.

## Generate window

In this mode, the block acts as a source. The window vector is output in the window data type you specify in the block dialog.

## Generate and apply window

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is output from the block.

You can set the window, product output, and output data types in the block dialog box. For more information see the “Dialog Box” on page 1-1886 section.

## Examples

The following model uses the Window Function block to generate and apply a Hamming window to a 3-dimensional input array.

In this example, set the **Operation** mode of the Window Function block to **Generate and apply window**, so the block provides two outputs: the window vector  $w$  at the Win port, and the result of the multiplication  $y$  at the Out port.

Open the model by typing `ex_windowfunction_ref` at the MATLAB command line, and run it.

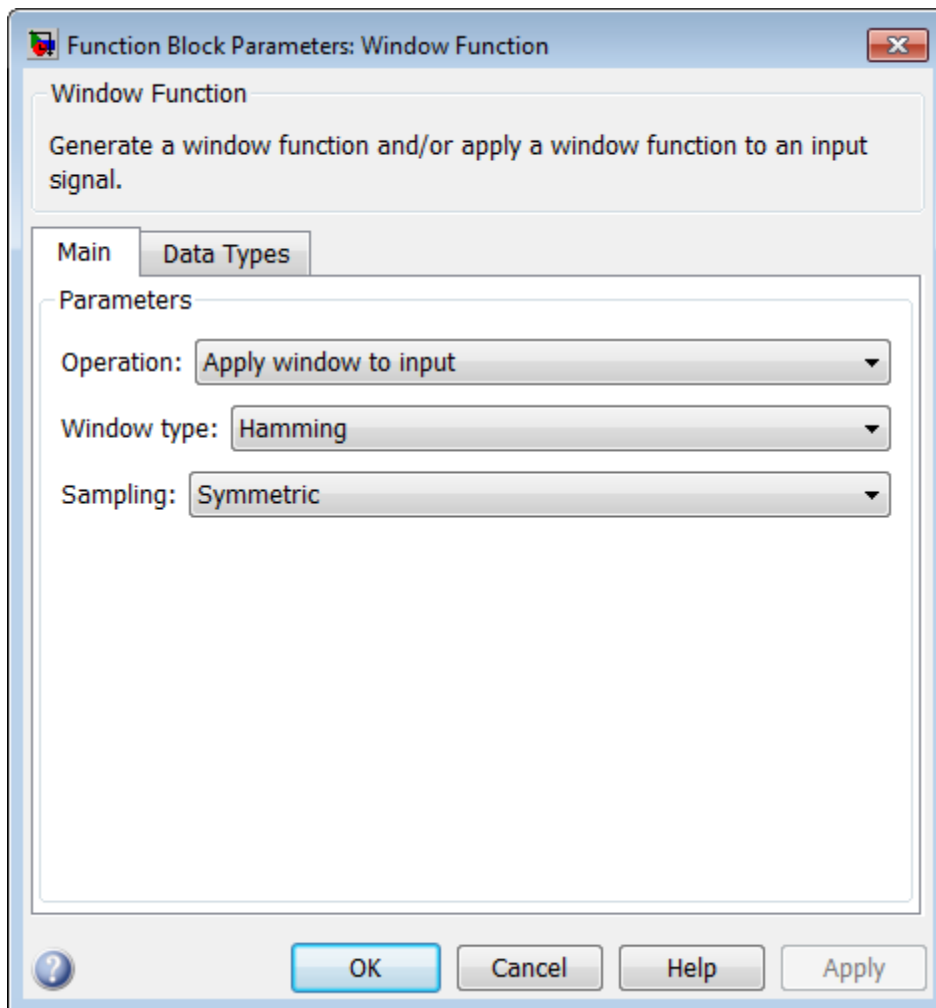

- The length of the first dimension of the input array is 10, so the Window Function block generates and outputs a Hamming window vector of length 10. To see the window vector generated by the Window Function block, type `w` at the MATLAB command line.
- To see the result of the multiplication, type `y` at the MATLAB command line.

# Window Function

## Dialog Box

The **Main** pane of the Window Function block dialog appears as follows.

## Operation

Specify the block's operation, as discussed in "Operation Modes" on page 1-1879. The port configuration of the block is updated to match the setting of this parameter.

## Window type

Specify the window type to apply, as listed in "Window Type" on page 1-1880. Tunable in simulation only.

## Sampling

Specify the window sampling for generalized-cosine windows. This parameter is only visible when you select **Blackman**, **Hamming**, **Hann**, or **Hanning** for the **Window type** parameter. Tunable in simulation only.

## Sample Mode

Specify the sample mode for the block, **Continuous** or **Discrete**, when it is in **Generate Window** mode. In the **Apply window to output** and **Generate and apply window** modes, the block inherits the sample time from its driving block. Therefore, this parameter is only visible when you select **Generate window** for the **Operation** parameter.

## Sample time

Specify the sample time for the block when it is in **Generate window** and **Discrete** modes. In **Apply window to output** and **Generate and apply window** modes, the block inherits the sample time from its driving block. This parameter is only visible when you select **Discrete** for the **Sample Mode** parameter.

## Window length

Specify the length of the window to apply. This parameter is only visible when you select **Generate window** for the **Operation** parameter. Otherwise, the window vector length is computed to match the length of the first dimension of the input.

## Stopband attenuation in dB

Specify the level of stopband attenuation,  $R_s$ , in decibels. This parameter is only visible when you select **Chebyshev** for the **Window type** parameter. Tunable in simulation only.

# Window Function

---

## **Beta**

Specify the Kaiser window  $\beta$  parameter. Increasing  $\beta$  widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This parameter is only visible when you select **Kaiser** for the **Window type** parameter. Tunable in simulation only.

## **Number of sidelobes**

Specify the number of sidelobes as a scalar integer value greater than zero. This parameter is only visible when you select **Taylor** for the **Window type** parameter.

## **Maximum sidelobe level relative to mainlobe (dB)**

Specify, in decibels, the maximum sidelobe level relative to the mainlobe. This parameter must be a scalar less than or equal to zero. The default value of  $-30$  produces sidelobes with peaks 30 dB down from the mainlobe peak. This parameter is only visible when you select **Taylor** for the **Window type** parameter.

## **Window function name**

Specify the name of the user-defined window function to be calculated by the block. This parameter is only visible when you select **User defined** for the **Window type** parameter.

## **Specify additional arguments to the hamming function**

Select to enable the **Cell array of additional arguments** parameter, when the user-defined window requires parameters other than the window length. This parameter is only visible when you select **User defined** for the **Window type** parameter.

## **Cell array of additional arguments**

Specify the extra parameters required by the user-defined window function, besides the window length. This parameter is only available when you select the **Specify additional arguments to the hamming function** parameter. The entry must be a cell array.

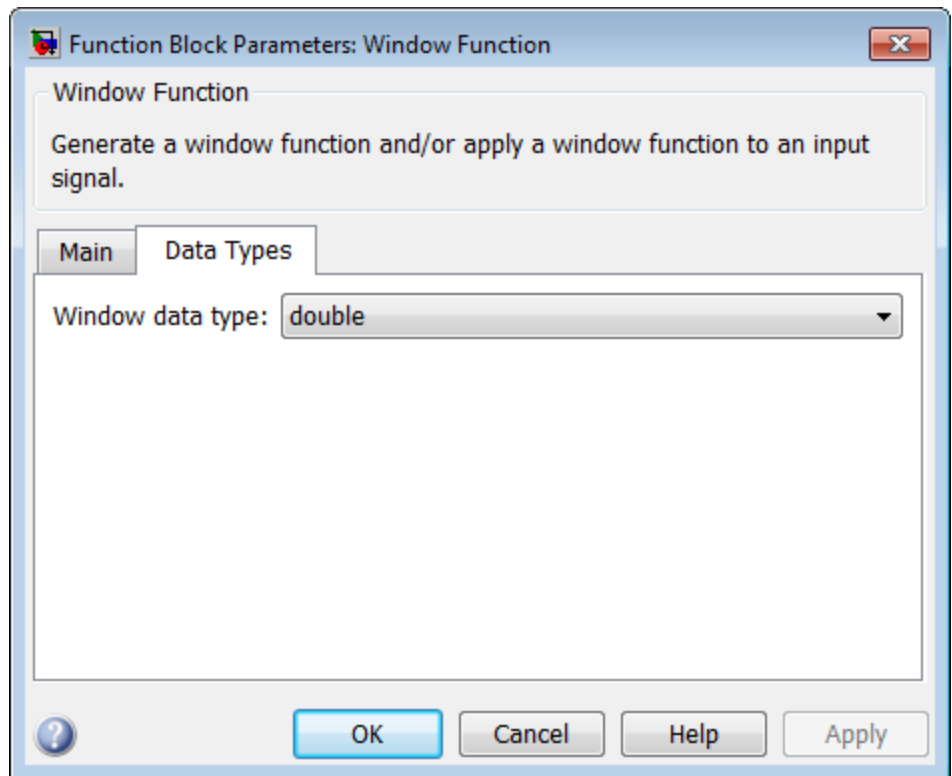

The **Data Types** pane of the Window Function block dialog is discussed in the following sections:

“Parameters for Generate Window Only Mode” on page 1-1889

“Parameters for Apply Window Modes” on page 1-1891

## Parameters for Generate Window Only Mode

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to Generate window.

### Window data type

Specify the window data type in one of the following ways:

- Choose double or single from the list.

# Window Function

---

- Choose **Fixed-point** to specify the window data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose **User-defined** to specify the window data type and scaling in the **User-defined data type**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose **Inherit via back propagation** to set the window data type and scaling to match the following block.

## **Signed**

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned.

## **Word length**

Specify the word length, in bits, of the fixed-point window data type. This parameter is only visible when you select **Fixed-point** for the **Window data type** parameter.

## **User-defined data type**

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the Fixed-Point Designer functions `sfix`, `ufix`, `sint`, `uint`, `sfrac`, and `ufrac`. This parameter is only visible when you select **User-defined** for the **Window data type** parameter.

## **Set fraction length in output to**

Specify the scaling of the fixed-point window data type by either of the following two methods:

- Choose **Best precision** to have the window data type scaling automatically set such that the output signal has the best possible precision.
- Choose **User-defined** to specify the window data type scaling in the **Fraction length** parameter.

This parameter is only visible when you select **Fixed-point** or **User-defined** for the **Window data type** parameter, and when the specified window data type is a fixed-point data type.

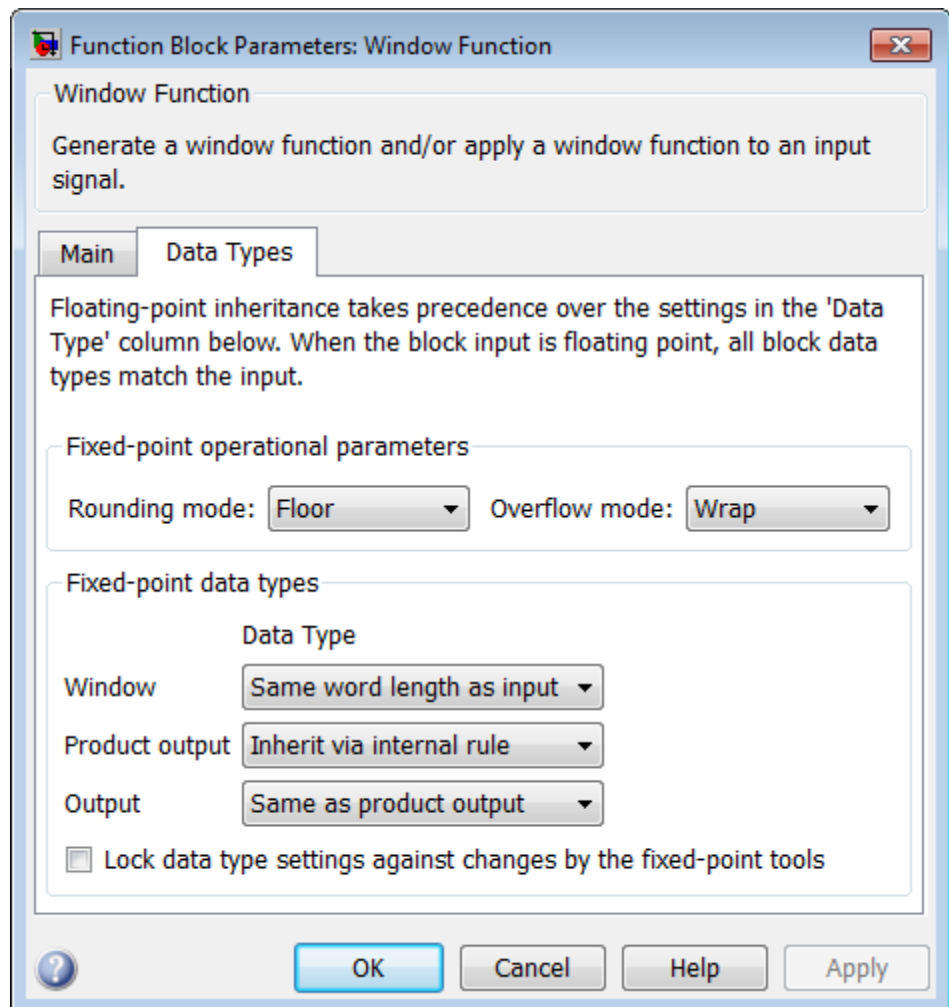

## **Fraction length**

Specify the fraction length, in bits, of the fixed-point window data type. This parameter is only visible when you select **Fixed-point** or **User-defined** for the **Window data type** parameter and **User-defined** for the **Set fraction length in output to** parameter.

## **Parameters for Apply Window Modes**

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to either **Apply window to input** or **Generate and apply window**.

# Window Function

## Rounding mode

Select the rounding mode for fixed-point operations.

The window vector  $w$  does not obey this parameter; it always rounds to Nearest.

---

**Note** The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of the following conditions exist:

- **Product output data type** is Inherit via internal rule
- **Output data type** is Same as product output

With these data type settings, the block is effectively operating in full precision mode.

---

## Overflow mode

Select the overflow mode for fixed-point operations.

The window vector  $w$  does not obey this parameter; it is always saturated.

## Window

Choose how you specify the word length and fraction length of the window vector  $w$ .

When you select **Same word length as input**, the word length of the window vector elements is the same as the word length of the input. The fraction length is automatically set to the best precision possible.

When you select **Specify word length**, you can enter the word length of the window vector elements in bits. The fraction length is automatically set to the best precision possible.

When you select **Binary point scaling**, you can enter the word length and the fraction length of the window vector elements in bits.

# Window Function

---

When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the window vector elements. This block requires power-of-two slope and a bias of zero.

The window vector does not obey the **Rounding mode** and **Overflow mode** parameters; it is always saturated and rounded to Nearest.

## Product output

Use this parameter to specify how you want to designate the product output word and fraction lengths. See “Fixed-Point Data Types” on page 1-1773 for illustrations depicting the use of the product output data type in this block:

- When you select **Inherit via internal rule**, the product output word length and fraction length are calculated automatically. For information about how the product output word and fraction lengths are calculated when an internal rule is used, see “Inherit via Internal Rule”.
- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Binary point scaling**, you can enter the word length and the fraction length of the product output, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

## Output

Choose how you specify the word length and fraction length of the output of the block:

- When you select **Same as product output**, these characteristics match those of the product output.
- When you select **Same as input**, these characteristics match those of the input to the block.

- When you select **Binary point scaling**, you can enter the word length and the fraction length of the output, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

### Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul>
Win	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point</li> <li>• 8-, 16-, and 32-bit integers</li> </ul>

# Yule-Walker AR Estimator

## Purpose

Compute estimate of autoregressive (AR) model parameters using Yule-Walker method

## Library

Estimation / Parametric Estimation  
dspparest3

## Description

The Yule-Walker AR Estimator block uses the Yule-Walker AR method, also called the autocorrelation method, to fit an autoregressive (AR) model to the windowed input data by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which are solved by the Levinson-Durbin recursion. Block outputs are always nonsingular.

The Yule-Walker AR Estimator block can output the AR model coefficients as polynomial coefficients, reflection coefficients, or both. Each channel of the input is a sample-based vector (row, column, or 1-D) or frame-based vector (column only) representing a frame of consecutive time samples from a signal that is assumed to be the output of an AR system driven by white noise. The block computes the normalized estimate of the AR system parameters,  $A(z)$ , independently for each successive input frame.

$$H(z) = \frac{\sqrt{G}}{A(z)} = \frac{\sqrt{G}}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

When you select **Inherit estimation order from input dimensions**, the order  $p$  of the all-pole model is one less than the length of each input channel. Otherwise, the order is the value specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be a scalar less than or equal to half the input channel length. The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

When **Output(s)** is set to A, port A is enabled. For each channel, port A outputs a column of length  $p+1$  that contains the normalized estimate of the AR model coefficients in descending powers of  $z$

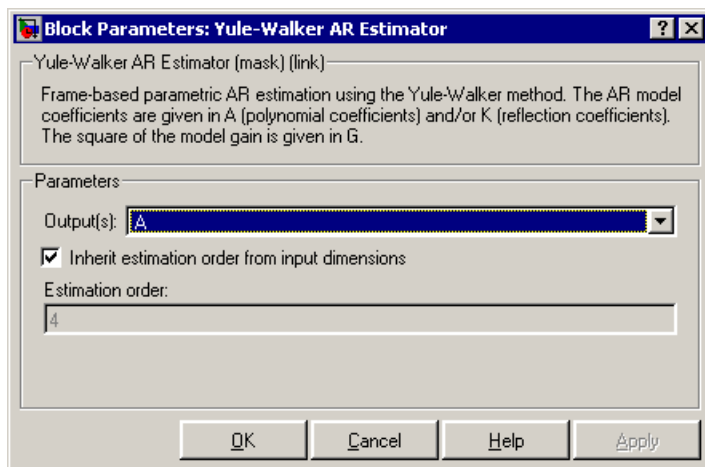

# Yule-Walker AR Estimator

[1 a(2) ... a(p+1)]

When **Output(s)** is set to K, port K is enabled. For each channel, port K outputs a length- $p$  column whose elements are the AR model reflection coefficients. When **Output(s)** is set to A and K, both port A and K are enabled, and each port outputs the respective AR model coefficients for each channel.

The square of the model gain,  $G$ , is provided at port G.  $G$  is a scalar for each channel.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

## Dialog Box

### Output(s)

The type of AR model coefficients output by the block. The block can output polynomial coefficients (A), reflection coefficients (K), or both (A and K).

### Inherit estimation order from input dimensions

When selected, sets the estimation order  $p$  to one less than the length of each input channel.

## Estimation order

The order of the AR model,  $p$ . This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

# Yule-Walker IIR Filter Design (Obsolete)

---

**Purpose** Design and apply IIR filter

**Library** dspobslib

## Description

---

**Note** The Yule-Walker IIR Filter Design block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Digital Filter block.

---

The Yule-Walker IIR Filter Design block designs a recursive (ARMA) digital filter with arbitrary multiband magnitude response, and applies it to a discrete-time input using the Direct-Form II Transpose Filter block. The filter design, which uses the Signal Processing Toolbox `yulewalk` function, performs a least-squares fit to the specified frequency response.

An  $M$ -by- $N$  sample-based matrix input is treated as  $M*N$  independent channels, and an  $M$ -by- $N$  frame-based matrix input is treated as  $N$  independent channels. In both cases, the block filters each channel independently over time, and the output has the same size and frame status as the input.

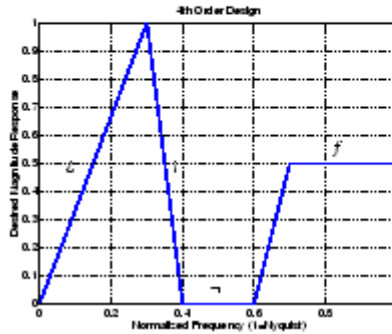

The **Band-edge frequency vector** parameter is a vector of frequency points in the range 0 to 1, where 1 corresponds to half the sample frequency. The first element of this vector must be 0 and the last element 1, and intermediate points must appear in ascending order. The **Magnitudes at these frequencies** parameter is a vector containing the desired magnitude response at the points specified in the **Band-edge frequency vector**.

Note that, unlike the Remez FIR Filter Design block, each frequency-magnitude pair specifies the junction of two adjacent frequency bands, so there are no “don’t care” regions.

# Yule-Walker IIR Filter Design (Obsolete)

Band edge frequency = [0.0 0.3 0.4 0.6 0.7 1.0]  
Magnitudes [0.0 1.0 0.0 0.0 0.5 0.5]  
Band:  $\underbrace{\quad\quad\quad}_L \underbrace{\quad\quad}_I \underbrace{\quad\quad}_T \underbrace{\quad\quad}_F$

When specifying the **Band-edge frequency vector** and **Magnitudes at these frequencies** vectors, avoid excessively sharp transitions from passband to stopband. You may need to experiment with the slope of the transition region to get the best filter design.

For more details on the Yule-Walker filter design algorithm, see the description of the `yulewalk` function in the Signal Processing Toolbox documentation.

# Yule-Walker IIR Filter Design (Obsolete)

---

## Dialog Box

### Filter order

The order of the filter.

### Band-edge frequency vector

A vector of frequency points. The value 1 corresponds to half the sample frequency. The first element of this vector must be 0 and the last element 1. Tunable.

### Magnitudes at these frequencies

A vector of frequency response magnitudes corresponding to the points in the **Band-edge frequency vector**. This vector must be the same length as the **Band-edge frequency vector**. Tunable.

## Purpose

Power spectral density estimate using Yule-Walker method

## Library

Estimation / Power Spectrum Estimation

dspsect3

## Description

The Yule-Walker Method block estimates the power spectral density (PSD) of the input using the Yule-Walker AR method. This method, also called the *autocorrelation method*, fits an autoregressive (AR) model to the windowed input data. It does so by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which the Levinson-Durbin recursion solves. Block outputs are always nonsingular.

The input is a sample-based vector (row, column, or 1-D) or frame-based vector (column only). This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at  $N_{fft}$  equally spaced frequency points. The frequency points are in the range  $[0, F_s)$ , where  $F_s$  is the sampling frequency of the signal.

When you select **Inherit estimation order from input dimensions**, the order of the all-pole model is one less than the input frame size. Otherwise, the **Estimation order** parameter value specifies the order. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that  $N_{fft}$  is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** check box allows you to use the **FFT length** parameter to specify  $N_{fft}$  as a power of 2. The block zero-pads or wraps the input to  $N_{fft}$  before computing the FFT. The output is always sample based.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

# Yule-Walker Method

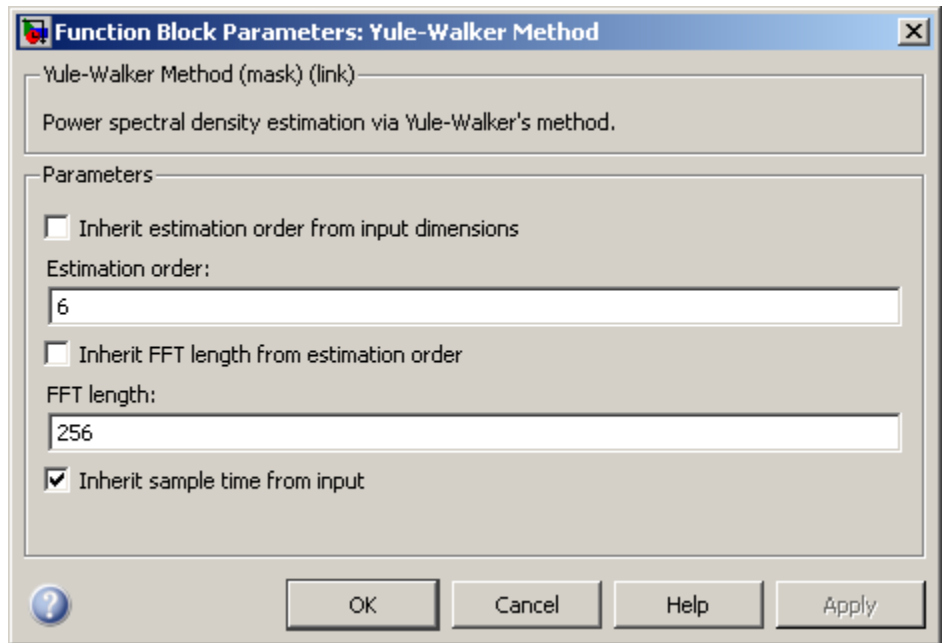

---

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker AR Estimator blocks. The Yule-Walker AR Estimator and Burg Method blocks return similar results for large buffer lengths.

## Dialog Box

### **Inherit estimation order from input dimensions**

When you select this option, it sets the estimation order to one less than the length of the input vector.

### **Estimation order**

Specify the order of the AR model. This parameter is only visible when you clear the **Inherit estimation order from input dimensions** check box.

### **Inherit FFT length from estimation order**

When you select the **Inherit FFT length from estimation order** check box, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

# Yule-Walker Method

---

## FFT length

Enter the number of data points on which to perform the FFT,  $N_{fft}$ . When  $N_{fft}$  is larger than the input frame size, the block zero-pads each frame as needed. When  $N_{fft}$  is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

## Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

## Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

# Zero Crossing

## Purpose

Count number of times signal crosses zero in single time step

## Library

Signal Operations

dspsigops

## Description

The Zero Crossing block concludes that a signal in a given channel has passed through zero if it meets any of the following criteria, where  $x_i$  is the current signal value,  $x_{i-1}$  is the previous signal value, and so on:

- $x_i < 0$  and  $x_{i-1} > 0$
- $x_i > 0$  and  $x_{i-1} < 0$
- For some positive integer  $L$ ,  $x_i < 0$ ,  $x_{i-l} = 0$ , and  $x_{i-L-1} > 0$ , where  $0 \leq l \leq L$ .
- For some positive integer  $L$ ,  $x_i > 0$ ,  $x_{i-l} = 0$ , and  $x_{i-L-1} < 0$ , where  $0 \leq l \leq L$ .

For the first input value,  $x_{i-1}$  and  $x_{i-2}$  are zero. The block outputs the number of times the signal crosses zero in a single time step at the Cnt port.

The input to this block must be a real-valued fixed-point or floating-point signal. If you set the **Input processing** parameter to **Elements as channels (sample based)**, the block treats each element of the input as a time-varying channel. If you set the **Input processing** parameter to **Columns as channels (frame based)**, the block treats each column of the input as an independent channel.

## Examples

The following example, `ex_zero_crossing` illustrates the behavior of the Zero Crossing block.

To run the model for one time step, the **Stop time** is set to 0.

1

Run the model.

Because the signal passes through zero once during the first time step, the Zero Crossing block finds one zero crossing. The number of detected zero crossings in the first time step is shown in the Display block in the following figure.

## 2

To run the model for two time steps, change the simulation **Stop time** to 1. To do so, open the Configuration Parameters dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. In the **Solver** pane, set **Stop time** to 1.

## 3

Run the model.

The Zero Crossing block remembers that the last value of the last frame was 3. Therefore, the signal passes through zero twice during the second time step. It passes through zero while going from 3 to -3, and it passes through zero again while going from -3 to 3. The Zero Crossing block finds two zero crossings in the second time step as shown in the Display block in the following figure.

# Zero Crossing

---

## Dialog Box

### Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The Inherited (this choice will be removed - see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

# dsp.AffineProjectionFilter

---

**Purpose** Compute output, error and coefficients using Affine Projection (AP) Algorithm

**Description** The `AffineProjectionFilter` object filters each channel of the input using AP filter implementations.

To filter each channel of the input:

- 1 Define and set up your AP filter. See “Construction” on page 3-2.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.AffineProjectionFilter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.AffineProjectionFilter` returns an adaptive FIR filter System object, `H`. This System object computes the filtered output and the filter error for a given input and desired signal using the Affine Projection (AP) algorithm.

`H = dsp.AffineProjectionFilter('PropertyName',PropertyValue, ...)` returns an `AffineProjectionFilter` System object, `H`, with each specified property set to the specified value.

`H = dsp.AffineProjectionFilter(LEN, 'PropertyName', PropertyValue, ...)` returns an RLS filter System object, `H`. This System object has the Length property set to `LEN`, and other specified properties set to the specified values.

## Properties

### Method

Method to calculate the filter coefficients

Specify the method used to calculate filter coefficients as one of | `Direct Matrix Inversion` | `Recursive Matrix Update` | `Block Direct Matrix Inversion`. The default value is `Direct Matrix Inversion`. This property is nontunable.

### Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a scalar positive integer value. The default value is 32. This property is nontunable.

## **ProjectionOrder**

Projection order of the affine projection algorithm

Specify the projection order of the affine projection algorithm as a scalar positive integer value greater than or equal to 2. This property defines the size of the input signal covariance matrix.. The default value is 2. This property is nontunable.

## **StepSize**

Affine projection step size

Specify the affine projection step size factor as a scalar non-negative numeric value between 0 and 1, both inclusive. Setting step equal to one provides the fastest convergence during adaptation. The default value is 1. This property is tunable.

## **InitialCoefficients**

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the Length property value. The default value is 0. This property is tunable.

## **InitialOffsetCovariance**

Initial values of the offset input covariance matrix

Specify the initial values for the offset input covariance matrix. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the ProjectionOrder property value. If it is a scalar value, the OffsetCovariance property is initialized to a diagonal matrix with the diagonal elements equal to that scalar value. If it is a square matrix, the OffsetCovariance property is initialized to

# dsp.AffineProjectionFilter

---

the value of that square matrix. This property is applicable only if the `Method` property is set to `Direct Matrix Inversion` or `Block Direct Matrix Inversion`. The default value is 1. This property is tunable.

## **InitialInverseOffsetCovariance**

Initial values of the offset input covariance matrix inverse

Specify the initial values for the offset input covariance matrix inverse. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `InverseOffsetCovariance` property is initialized to a diagonal matrix with each diagonal element equal to that scalar value. If it is a square matrix, the `InverseOffsetCovariance` property is initialized to the values of that square matrix.

This property is applicable only if the `Method` property is set to `Recursive Matrix Update`. The default value is 20. This property is tunable.

## **InitialCorrelationCoefficients**

Initial correlation coefficients

Specify the initial values of the correlation coefficients of the FIR filter as a scalar or a vector of length equal to `ProjectionOrder - 1`. This property is applicable only if the `Method` property is set to `Recursive Matrix Update`. The default value is 0. This property is tunable.

## **LockCoefficients**

Lock coefficient updates

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients are continuously updated). This property is tunable.

## Methods

clone	Create System object with same property values
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of a System object
step	Process inputs using object algorithm

## Examples

QPSK Adaptive Equalization Using a 32-Coefficient FIR Filter (1000 Iterations)

```
D = 16; % Number of samples of delay
b = exp(j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr = 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + j*sign(randn(1,ntr+D)); % Baseband signal
n = 0.1*(randn(1,ntr+D) + j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
mu = 0.1; % Step size
po = 4; % Projection order
offset = 0.05; % Offset for covariance matrix
h = dsp.AffineProjectionFilter('Length', 32, ...
    'StepSize', mu, 'ProjectionOrder', po, ...
    'InitialOffsetCovariance',offset);
[y,e] = step(h,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');

subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

## Algorithms

The affine projection algorithm (APA), is an adaptive scheme that estimates an unknown system based on multiple input vectors [1]. It is designed to improve the performance of other adaptive algorithms, mainly those that are LMS-based. The affine projection algorithm reuses old data resulting in fast convergence when the input signal is highly correlated, leading to a family of algorithms that can make trade-offs between computation complexity with convergence speed [2].

The following equations describe the conceptual algorithm used in designing AP filters:

$$\mathbf{U}_{ap}(n) = \begin{pmatrix} u(n) & \dots & u(n-L) \\ \vdots & \ddots & \vdots \\ u(n-N) & \dots & u(n-L-N) \end{pmatrix} = (\mathbf{u}(n) \quad \mathbf{u}(n-1) \quad \dots \quad \mathbf{u}(n-L))$$

$$\mathbf{y}_{ap}(n) = \mathbf{U}_{ap}^T(n) \mathbf{w}(n) = \begin{pmatrix} y(n) \\ \bullet \\ \bullet \\ \bullet \\ y(n-L) \end{pmatrix}$$

$$\mathbf{d}_{ap}(n) = \begin{pmatrix} d(n) \\ \bullet \\ \bullet \\ \bullet \\ d(n-L) \end{pmatrix}$$

$$\mathbf{e}_{ap}(n) = \mathbf{d}_{ap}(n) - \mathbf{y}_{ap}(n) = \begin{pmatrix} e(n) \\ \bullet \\ \bullet \\ \bullet \\ e(n-L) \end{pmatrix}$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mu \mathbf{U}_{ap}(n) (\mathbf{U}_{ap}^H(n) \mathbf{U}_{ap}(n) + \mathbf{C})^{-1} \mathbf{e}_{ap}$$

where  $\mathbf{C}$  is either  $\varepsilon \mathbf{I}$  if the initial offset covariance is a scalar  $\varepsilon$ , or  $\mathbf{R}$  if the initial offset covariance is a matrix  $\mathbf{R}$ . The variables are as follows:

Variable	Description
$n$	The current time index
$u(n)$	The input sample at step $n$

# dsp.AffineProjectionFilter

---

Variable	Description
$U_{ap}(n)$	The matrix of the last $L+1$ input signal vectors
$w(n)$	The adaptive filter coefficients vector
$y(n)$	The adaptive filter output
$d(n)$	The desired signal
$e(n)$	The error at step $n$
$L$	The projection order
$N$	The filter order (i.e., filter length = $N+1$ )
$\mu$	The step size

`dsp.AffineProjectionFilter.isLocked` |  
`dsp.AffineProjectionFilter.reset`

# **dsp.AffineProjectionFilter.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** L = isLocked(OBJ)

**Description** L = isLocked(OBJ) returns a logical value, L, which indicates whether input attributes and nontunable properties are locked for the System object, OBJ. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. Once this occurs, the isLocked method returns a true value.

**See Also** dsp.AffineProjectionFilter.step |  
dsp.AffineProjectionFilter.release

<b>Purpose</b>	Allow property value and input characteristics changes
<b>Syntax</b>	<code>release(Obj)</code>
<b>Description</b>	<p><code>release(Obj)</code> releases system resources, such as memory, file handles, and hardware connections of the System object, <code>Obj</code>, and allows all its properties and input characteristics to be changed.</p> <p>Once you call the <code>release</code> method on a System object, subsequent calls to <code>setup</code>, <code>step</code>, <code>reset</code>, or <code>release</code> are not supported for code generation.</p>
<b>See Also</b>	<code>dsp.AffineProjectionFilter.isLocked</code>   <code>dsp.AffineProjectionFilter.step</code>

# **dsp.AffineProjectionFilter.reset**

---

**Purpose**            Reset the internal states of a System object

**Syntax**            reset(Obj)

**Description**       reset(Obj) resets the internal states of the System object, Obj, to their initial values.

For many System objects, this method is nonoperational. Objects that have internal states describe in their **help** what the reset method does for that object. The reset method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

**Purpose** Process inputs using object algorithm

**Syntax**  $Y = \text{step}(\text{OBJ}, x)$   
 $[Y1, \dots, YN] = \text{step}(\text{OBJ}, x)$

**Description**  $Y = \text{step}(\text{OBJ}, x)$  processes the input data,  $x$ , to produce the output,  $Y$ , for the System object,  $\text{OBJ}$ .  $[Y1, \dots, YN] = \text{step}(\text{OBJ}, x)$  produces  $N$  outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

# dsp.AllpassFilter

---

**Purpose** Single section or cascaded allpass filter

**Description** The AllpassFilter object filters each channel of the input using Allpass filter implementations.

To filter each channel of the input:

- 1 Define and set up your Allpass filter. See “Construction” on page 3-14.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.AllpassFilter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.AllpassFilter` returns an Allpass filter System object, `H`, that filters each channel of the input signal independently using an allpass filter, with the default structure and coefficients.

`H = dsp.AllpassFilter('PropertyName',PropertyValue, ...)` returns an Allpass filter System object, `H`, with each property set to the specified value.

## Properties

### Structure

Internal allpass filter structure

You can specify the internal allpass filter implementation structure as one of | Minimum multiplier | Wave Digital Filter | Lattice. The default is Minimum multiplier. Each structure uses a different set of coefficients, independently stored in the corresponding object property.

### AllpassCoefficients

Allpass polynomial coefficients

Specify the real allpass polynomial filter coefficients. This property is applicable only when the Structure property is set to Minimum multiplier. The value of this property can be either a row vector (single-section configuration), or a cell array with as many cells as filter sections. The default value of this property is

[ 0.7071, 0.5000]. They define a stable second-order allpass filter with poles and zeros located at  $\pm\pi/3$  in the Z plane. This property is tunable.

## **WDFCoefficients**

Wave Digital Filter allpass coefficients

Specify the real allpass coefficients in the Wave Digital Filter form. This property is only applicable when the **Structure** property is set to **Wave Digital Filter**. The value of this property can be either a row vector (single-section configuration) or a cell array with as many cells as there are filter sections. Acceptable section orders are 1, 2 and 4. If the order is 4, then the second and fourth coefficients must be zeros. All elements must have absolute value  $\leq 1$ . The default value for this property is [0.5, -1.1547]. These are the transformed versions of the default value of **AllpassCoefficients**, so they define the same stable second-order allpass filter with **Structure** set to 'Wave Digital Filter'. This property is tunable.

## **LatticeCoefficients**

Lattice allpass coefficients

Specify the real or complex allpass coefficients as lattice reflection coefficients. This property is applicable only if the **Structure** property is set to **Lattice**. The value of this property can be either a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value for this property is [-1.1547, 0.5]. These are the transformed versions of the default value of **AllpassCoefficients**, so they define the same stable second-order allpass filter when **Structure** is set to 'Lattice'. This property is tunable.

## **InitialConditions**

Initial values of filter states

Specify the initial values of the internal filter states. The default value of this property is 0. Acceptable values include numeric

# dsp.AllpassFilter

---

scalar, numeric 1-D or 2-D array, and cell array with as many cells as filter sections. The numeric scalar is used for all filter states, and the numeric 1-D or 2-D array is single-section only. The inner dimensions must match exactly those of the internal filter states.

## Methods

clone	Create System object with same property values
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of a System object
step	Process inputs using object algorithm

More “Analysis Methods for Filter System Objects” on page 2-2.

## Examples

Use a Regalia shelving structure with a first-order allpass filter to boost frequency components of a random signal. This signal is below 10 kHz by 6 dB.

```
Fs = 48000;    % in Hz
wc = 2*pi*10000;
Vo = 2;       % 6 dB
c = -(2*wc/Fs)/(2+wc/Fs);
hAP = dsp.AllpassFilter('AllpassCoefficients', c);
hSR = dsp.SignalSource(randn(4096, 1), 128);
hLOG = dsp.SignalSink;
while ~isDone(hSR)
    in = step(hSR);
    shelvedOut = -(1-Vo)/2 * step(hAP, in) + (1+Vo)/2 * in;
    step(hLOG, [in, shelvedOut]);
end
```

```
signalTraces = hLOG.Buffer;  
figure  
tfestimate(signalTraces(:,1), signalTraces(:,2),[],[],[],Fs)
```

## Algorithms

The transfer function of an allpass filter is defined by:

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + z^{-n}}$$

given the nontrivial polynomial coefficients in  $c$ . The order  $n$  of the transfer function is given by the length of the vector  $c$ .

`dsp.AllpassFilter` realizes an allpass filter using three different implementation structures: Minimum multiplier, Wave Digital Filter, and Lattice. These structures differ from generic IIR filters such as `df1`, `df1t`, `df2`, `df2t`, in that they are computationally more economical and structurally more stable [1]. For all structures, a single instance of `dsp.AllpassFilter` can handle either a single-section or a multiple-section (cascaded) allpass filter. The different sections can have different orders but they are all implemented according to the same structure.

### Minimum multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order  $n$ . It also uses  $2n$  delay units and  $2n$  adders. The coefficients used by the multipliers are the same as `AllpassCoefficients`, which are equal to the polynomial vector  $c$  in the allpass transfer function. The following code shows an example of a second-order section as a Simulink diagram using basic building blocks. You need a Simulink license to generate the actual diagram using `realizemdl`.

```
hap = dsp.AllpassFilter('AllpassCoefficients', [0.1, -0.7]);  
realizemdl(hap)
```

# dsp.AllpassFilter

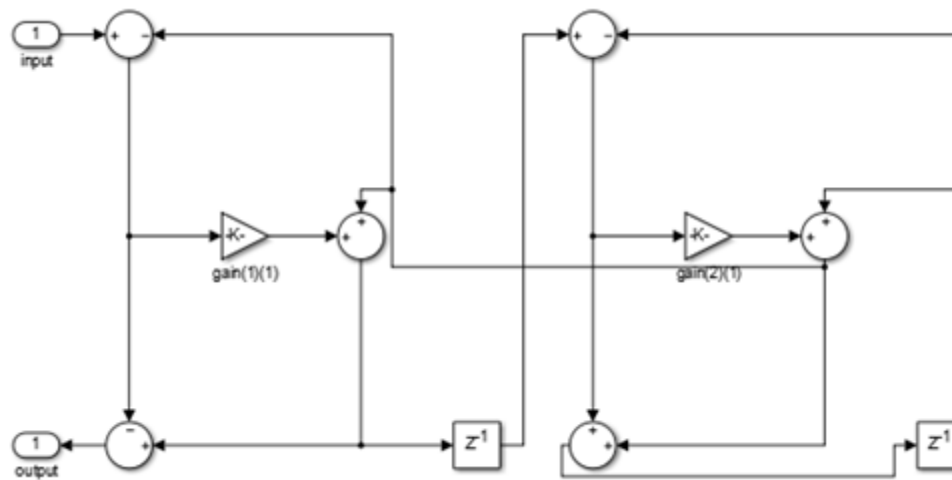

## Wave Digital Filter

This structure uses  $n$  multipliers, but only  $n$  delay units at the expense of requiring  $3n$  adders. To use this structure, you must specify the coefficients as `WDFCoefficients` in Wave Digital Filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients such as those in vector `c` in the preceding equation, by using the static method `dsp.AllpassFilter.poly2wdf`. You can also use a similar method, `dsp.AllpassFilter.wdf2poly` to convert given WDF-form coefficients into their equivalent allpass polynomial form. The following code shows an example of a second-order section as a Simulink diagram using basic

operation blocks. You need a Simulink license to generate the actual diagram using `realizemdl`. Use these coefficients for a functionally equivalent filter to the previous Minimum multiplier example.

```
c = [0.1, -0.7];  
w = dsp.AllpassFilter.poly2wdf(c);  
hap = dsp.AllpassFilter('Structure', 'Wave Digital Filter', 'WDFCoeff',  
realizemdl(hap))
```

The multipliers used in the filter implementation are a transformation of the WDF coefficients previously provided. The implementation structure around each multiplier depends on the actual value of the multiplier and can vary for different filtering stages among five different options. For example notice how in the preceding diagram, the first and the second stages are realized with two different inner structures. For more details refer to [2].

## Lattice

This lattice structure uses  $2n$  multipliers,  $n$  delay units, and  $2n$  adders. To use this structure, you must specify the coefficients

## dsp.AllpassFilter

---

as `LatticeCoefficients` in `Lattice` form. Obtain these from the conventional polynomial form of the allpass coefficients by using an appropriate conversion function, such as `tf2latc`. The following code shows an example of a second-order section as a Simulink diagram using basic operation blocks. You need a Simulink license to generate the actual diagram using `realizemdl`. Use these coefficients for a functionally equivalent filter to the Minimum multiplier structure.

```
c = [0.1 -0.7];  
k = tf2latc([1 c]);  
hap = dsp.AllpassFilter('Structure', 'Lattice', 'LatticeCoefficients', k)  
realizemdl(hap)
```

## **See Also**

`dsp.BiquadFilter` | `dsp.IIRFilter`

**Purpose** Create System object with same property values

**Syntax** `C = clone(OBJ)`

**Description** `C = clone(OBJ)` creates another instance of the System object, `OBJ`, with the same property values. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.AllpassFilter.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** L = isLocked(OBJ)

**Description** L = isLocked(OBJ) returns a logical value, L, which indicates whether input attributes and nontunable properties are locked for the System object, OBJ. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. Once this occurs, the isLocked method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(Obj)`

**Description** `release(Obj)` releases system resources, such as memory, file handles, and hardware connections of the System object, `Obj`, and allows all its properties and input characteristics to be changed.

Once you call the `release` method on a System object, subsequent calls to `setup`, `step`, `reset`, or `release` are not supported for code generation.

# **dsp.AllpassFilter.reset**

---

**Purpose**                 Reset internal states of a System object

**Syntax**                 reset(Obj)

**Description**           reset(Obj) resets the internal states of the System object, Obj, to their initial values.

For many System objects, this method is equivalent to no operation being executed. The reset method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

**Purpose** Process inputs using object algorithm

**Syntax**  $Y = \text{step}(\text{OBJ}, x)$   
 $[Y1, \dots, YN] = \text{step}(\text{OBJ}, x)$

**Description**  $Y = \text{step}(\text{OBJ}, x)$  processes the input data,  $x$ , to produce the output,  $Y$ , for the System object,  $\text{OBJ}$ .  $[Y1, \dots, YN] = \text{step}(\text{OBJ}, x)$  produces  $N$  outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

# dsp.AllpoleFilter

---

**Purpose** IIR Filter with no zeros

**Description** The `AllpoleFilter` object filters each channel of the input using Allpole filter implementations.

To filter each channel of the input:

- 1 Define and set up your Allpole filter. See “Construction” on page 3-28.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.AllpoleFilter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `HAllpole = dsp.AllpoleFilter` returns an Allpole filter System object, `HAllpole`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified Allpole filter implementation.

`HAllpole = dsp.AllpoleFilter('PropertyName',PropertyValue, ...)` returns an Allpole filter System object, `HAllpole`, with each property set to the specified value.

## Properties

### Structure

Filter structure

Specify the filter structure.

You can specify the filter structure as one of `Direct form` | `Direct form transposed` | `Lattice AR`. The default is `Direct form`. Analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`. This property is nontunable.

### Denominator

Filter denominator coefficients

Specify the denominator coefficients as a real or complex numeric row vector. This property is applicable when the Structure

property is set to one of `Direct form` | `Direct form transposed`. The default value of this property is `[1 0.1]`. This property is tunable.

## ReflectionCoefficients

Lattice filter coefficients

Specify the lattice filter coefficients as a real or complex numeric row vector. This property is applicable when the `Structure` property is set to `Lattice AR`. The default value of this property is `[0.2 0.4]`. This property is tunable.

## InitialConditions

Initial conditions for the filter states

Specify the initial conditions of the filter states. The default value is `0`.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property is tunable.

## FrameBasedProcessing

Process input as frames or as samples

Set this property to `true` to enable frame-based processing. When this property is `true`, the Allpole filter treats each column as an independent channel. Set this property to `false` to enable

sample-based processing. When this property is `false`, the Allpole filter treats each element of the input as an individual channel. The default is `true`. This property is nontunable.

## **CoefficientsDataType**

Denominator coefficients word- and fraction-length designations

Specify the denominator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

## **ReflectionCoefficientsDataType**

Reflection coefficients word- and fraction-length designations

Specify the reflection coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

## **Fixed-Point Properties**

### **ProductDataType**

Product word- and fraction-length designations

Specify the product fixed-point data type as one of `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`. This property is nontunable.

### **AccumulatorDataType**

Accumulator word- and fraction-length designations

Specify the accumulator fixed-point data type to one of `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`. This property is nontunable.

### **OutputDataType**

Output word- and fraction-length designations

Specify the output fixed-point data type as one of | Same as accumulator | Same as input | Custom |. The default is Same as input. This property is nontunable.

## **StateDataType**

State word- and fraction-length designations

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom. The default is Same as accumulator. This property is nontunable.

## **CustomCoefficientsDataType**

Custom denominator word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numeric type object. This property is applicable when the `CoefficientsDataType` property is `Custom`. The default value of this property is `numericType([],16,15)`. This property is nontunable.

## **CustomReflectionCoefficientsDataType**

Custom reflection coefficients word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numeric type object. This property is applicable when the `ReflectionCoefficientsDataType` property is `Custom`. The default value of this property is `numericType([],16,15)`. This property is nontunable.

## **CustomProductDataType**

Custom Product word- and fraction-lengths

Specify the product fixed-point type as an autosigned scaled numeric type object. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`. This property is nontunable.

## **CustomAccumulatorDataType**

Custom accumulator word- and fraction-lengths

# dsp.AllpoleFilter

---

Specify the accumulator fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`. This property is nontunable.

## **CustomStateDataType**

Custom state word- and fraction-lengths

Specify the state fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `StateDataType` property to `Custom`. The default is `numericType([],16,15)`. This property is nontunable.

## **CustomOutputDataType**

Custom output word- and fraction-lengths

Specify the output fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`. This property is nontunable.

## **Methods**

<code>clone</code>	Create Allpole filter with same property values
<code>freqz</code>	Frequency response
<code>fvtool</code>	Open filter visualization tool
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>impz</code>	Impulse response
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>phasez</code>	Unwrapped phase response

release	Allow property value and input characteristics changes
reset	Reset internal states of Allpole filter
step	Filter input with Allpole filter object

More “Analysis Methods for Filter System Objects” on page 2-2.

---

**Note** In AllpoleFilter, analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`.

---

## Examples

Use an Allpole filter to apply a lowpass filter to a waveform with two sinusoidal frequencies.

```
t = [0:1000]./8e3;
xin = sin(2*pi*1e3*t)+sin(2*pi*3e3*t);

hSR = dsp.SignalSource(xin', 4);
hLog = dsp.SignalSink;
hallpole = dsp.AllpoleFilter;
tt = (-25:25)';
xsinc = 0.4*sinc(0.4*tt);
asinc = lpc(xsinc,51);
hallpole.Denominator = asinc;

h = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'TwoSidedSpectrum',false,...
    'PowerUnits','dBW',...
    'YLimits', [-150 50]);

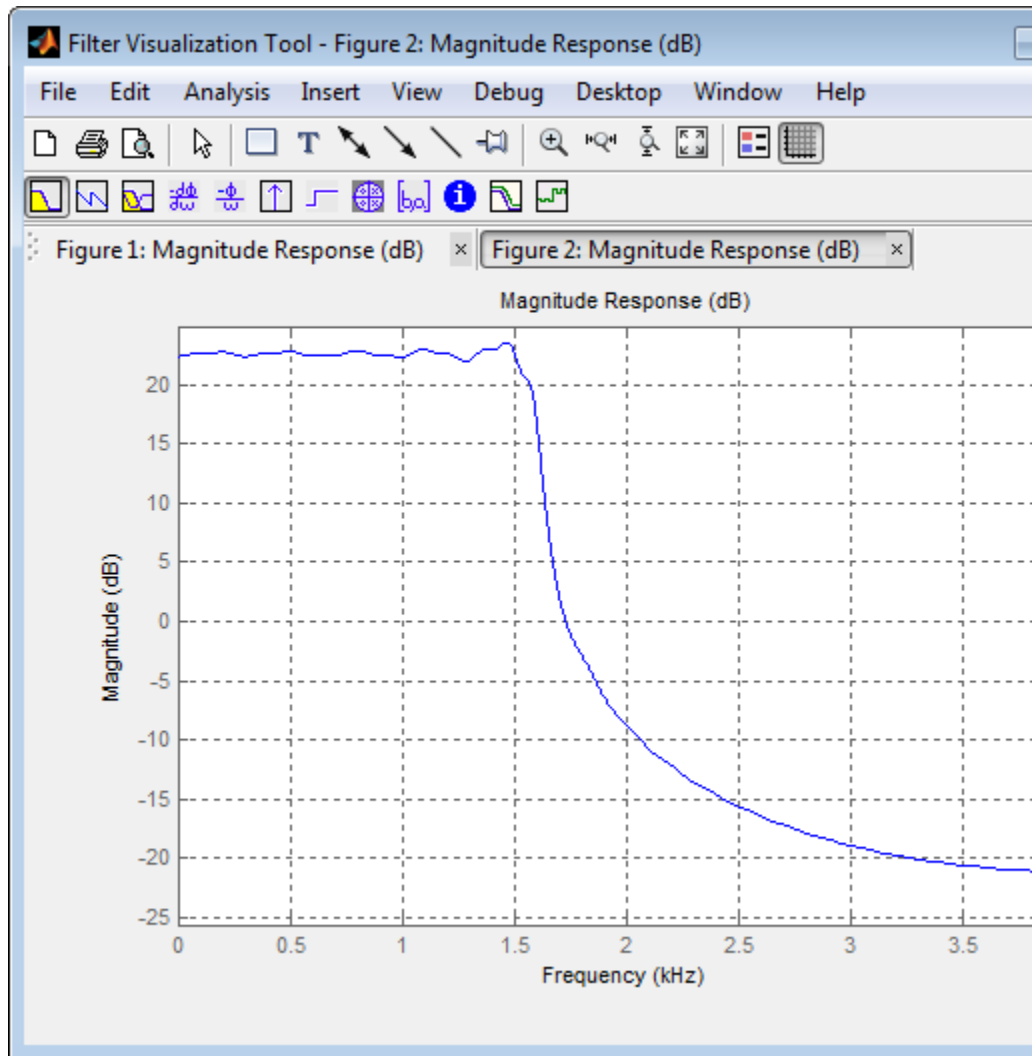

while ~isDone(hSR)
    input = step(hSR);
```

## **dsp.AllpoleFilter**

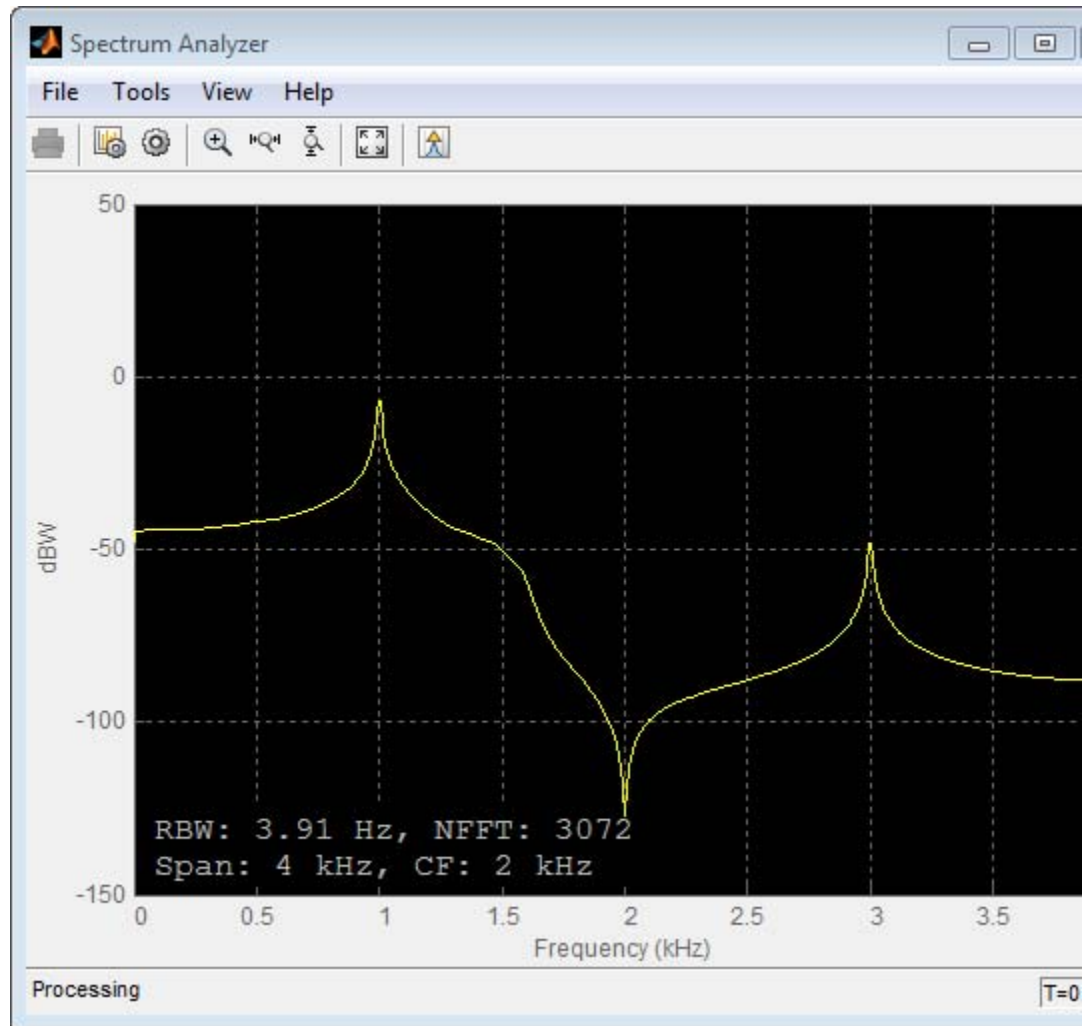

---

```
        filteredOutput = step(hallpole,input);
        step(hLog,filteredOutput);
        step(h,filteredOutput)
    end

    filteredResult = hLog.Buffer;
    fvtool(hallpole,'Fs',8000)
```

# dsp.AllpoleFilter

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Allpole Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

### See Also

`dsp.BiquadFilter` | `dsp.FIRFilter` | `dsp.IIRFilter`

## **dsp.AllpoleFilter.clone**

---

**Purpose** Create Allpole filter with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a Allpole filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

**Purpose**

Frequency response

**Syntax**

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

**Description**

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(H)` uses `FVTool` to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

# dsp.AllpoleFilter.fvtool

---

**Purpose** Open filter visualization tool

**Syntax** `fvtool(H)`  
`fvtool(H, 'Arithmetic', ARITH, ...)`

**Description** `fvtool(H)` performs an analysis and computes the magnitude response of the filter System object H.

`fvtool(H, 'Arithmetic', ARITH, ...)` analyzes the filter System object H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.AllpoleFilter.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Impulse response

**Syntax** `[h,t] = impz(H)`  
`[h,t] = impz(H,Name,Value)`  
`impz(H)`

**Description** `[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(H)` uses `FVTool` to plot the impulse response of the filter System object `H`.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

# **dsp.AllpoleFilter.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the Allpole filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Unwrapped phase response

**Syntax**

```
[phi,w] = phasez(H)  
[phi,w] = phasez(H,n)  
[phi,w] = phasez(H,Name,Value)  
phasez(H)
```

**Description**

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

# dsp.AllpoleFilter.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset internal states of Allpole filter

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the Allpole filter object, H, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the step method applies the Allpole filter object to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

For example:

```
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
H = dsp.AllpoleFilter;
a = lpc(x,20);
H.Denominator = a;
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

# dsp.AllpoleFilter.step

---

**Purpose** Filter input with Allpole filter object

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  filters the real or complex input signal  $X$  using the Allpole filter,  $H$ , to produce the output  $Y$ . When the input data is of a fixed-point type, it must be signed. The Allpole filter object operates on each channel of the input signal independently over successive calls to step method.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Purpose

Analytic signals of discrete-time inputs

## Description

The `AnalyticSignal` object computes analytic signals of discrete-time inputs. The real part of the analytic signal in each channel is a replica of the real input in that channel, and the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component. The object computes the Hilbert transform using an equiripple FIR filter.

To compute the analytic signal of a discrete-time input:

- 1 Define and set up your analytic signal calculation. See “Construction” on page 3-49.
- 2 Call `step` to compute the analytic signal according to the properties of `dsp.AnalyticSignal`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.AnalyticSignal` returns an analytic signal object, `H`, that computes the complex analytic signal corresponding to each channel of a real  $M$ -by- $N$  input matrix.

`H = dsp.AnalyticSignal('PropertyName',PropertyValue,...)` returns an analytic signal object, `H`, with each specified property set to the specified value.

`H = dsp.AnalyticSignal(order,'PropertyName',PropertyValue,...)` returns an analytic signal object, `H`, with the `FilterOrder` property set to `order` and other specified properties set to the specified values.

## Properties

### FilterOrder

Filter order used to compute Hilbert transform

Specify the order of the equiripple FIR filter used in computing the Hilbert transform as an even integer scalar. The default is 100.

# dsp.AnalyticSignal

---

## FrameBasedProcessing

Process input as frames or samples

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

## Methods

<code>clone</code>	Create analytic signal object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of analytic signal object
<code>step</code>	Analytic signal

## Examples

Compute the analytic signal of a sinusoidal input.

```
t = (-1:0.01:1)';
x = sin(4*pi*t);
hanlytc = dsp.AnalyticSignal(200);
y = step(hanlytc,x);

subplot(2,1,1), plot(t, x);
title('Original Signal');
subplot(2,1,2), plot(t, [real(y) imag(y)]);
title('Analytic signal of the input')
legend('Real signal','Imaginary signal',...
       'Location','best');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Analytic Signal block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

## See Also

`dsp.FFT` | `dsp.IFFT`

## **dsp.AnalyticSignal.clone**

---

**Purpose** Create analytic signal object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an `AnalyticSignal` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.AnalyticSignal.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `AnalyticSignal` object `H`.  
The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.AnalyticSignal.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset internal states of analytic signal object

**Syntax** reset(H)

**Description** reset(H) sets the internal states of the AnalyticSignal object H to their initial values.

# dsp.AnalyticSignal.step

---

**Purpose** Analytic signal

**Syntax**  $Y = \text{step}(H, X)$

**Description**  $Y = \text{step}(H, X)$  computes the analytic signal,  $Y$ , of the  $M$ -by- $N$  input matrix  $X$ , according to the equation

$$\mathbf{Y} = \mathbf{X} + jH\{\mathbf{X}\}$$

where  $j$  is the imaginary unit and  $H\{\mathbf{X}\}$  denotes the Hilbert transform.

When you set the `FrameBasedProcessing` property to `false`, each of the  $M$ -by- $N$  matrix elements is an independent channel. Thus, the method computes the analytic signal for each element of  $X$ . When you set the `FrameBasedProcessing` property to `true`, each of the  $N$  columns in  $X$  contains  $M$  sequential time samples from an independent channel. The method computes the analytic signal for each channel.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Purpose**

Display vectors or arrays

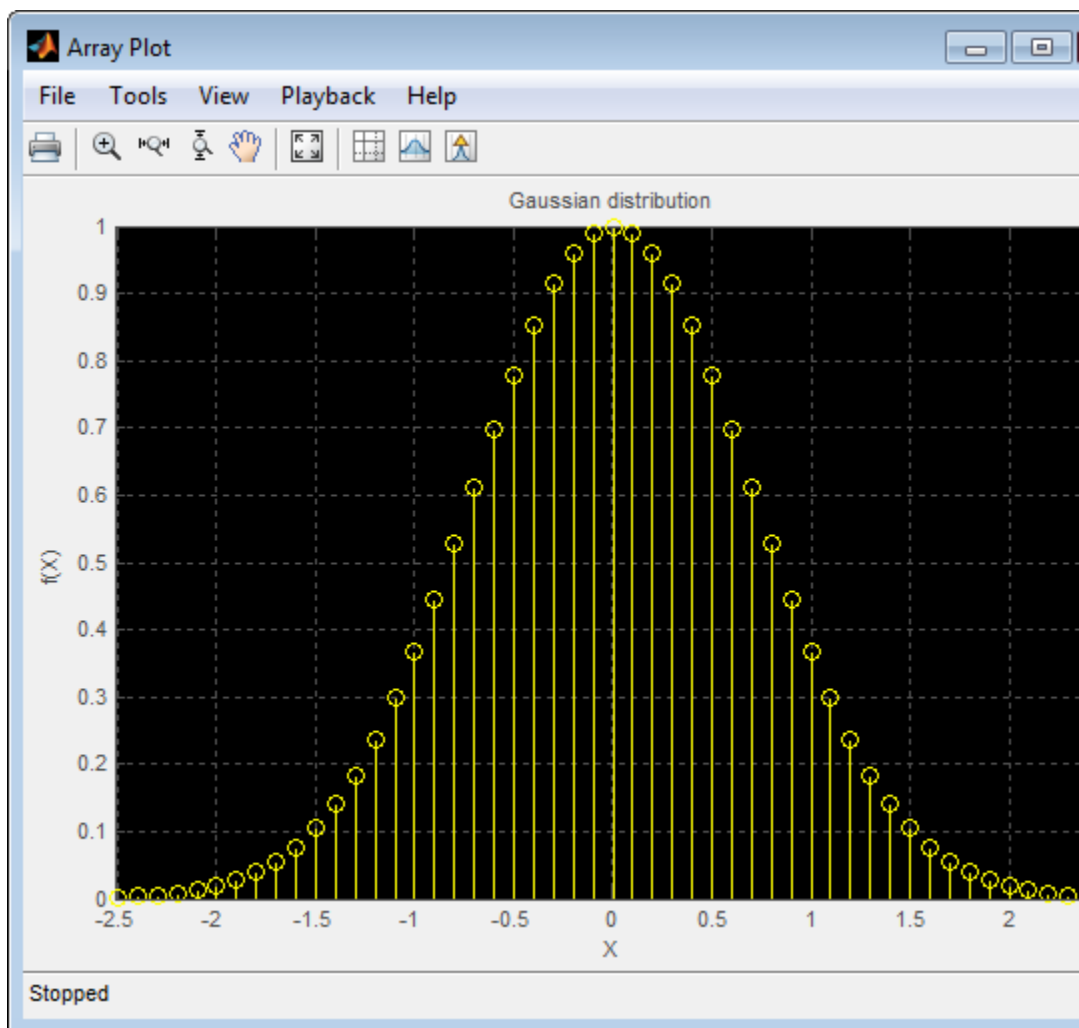

**Description**

The ArrayPlot object displays vectors or arrays.

To display vectors or array in Array Plot:

- 1** Define and set up your Array Plot. See “Construction” on page 3-61.
- 2** Call `step` to display the vectors or arrays in the Array Plot figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Array Plot figure window and clear its associated data. Use the `hide` method to hide the ArrayPlot window and the `show` method to make it visible.

See the following sections for more information on the Array Plot Graphical User Interface:

- “Signal Display” on page 3-69

- “Toolbar” on page 3-73
- “Measurements Panels” on page 3-76
- “Visuals — Array Plot Properties” on page 3-86
- “Style Dialog Box” on page 3-90
- “Tools — Plot Navigation Properties” on page 3-94

## Construction

H = dsp.ArrayPlot creates an Array PlotSystem object, H. This object displays vectors or arrays.

H = dsp.ArrayPlot('Name', Value, ...) creates an Array Plot System object, H, with each specified property *Name* set to the specified value. You can specify *Name-Value* arguments in any order.

## Properties

### MaximizeAxes

Maximize axes control

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in the display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- Auto — In this mode, the axes appear maximized only if the Title and YLabel properties are empty. If you enter any value for either of these properties, the axes are not maximized.
- On — In this mode, the axes appear maximized. Any values entered into the Title and YLabel properties are hidden.
- Off — In this mode, none of the axes appear maximized.

This property is Tunable.

**Default:** 'Auto'

### Name

Caption to display on Scope window

Specify as a string the caption to display on the scope window. This property is Tunable.

**Default:** 'Array Plot'

## **NumInputPorts**

Number of input signals

Specify the number of input signals to display on the scope as a positive integer. You must invoke the `step` method with the same number of inputs as the value of this property.

**Default:** 1

## **PlotAsMagnitudePhase**

Plot signal as Magnitude-and-Phase

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes. This property is particularly useful for complex-valued input signals. When the input signal is real-valued and you select this check box, the phase will be 0 degrees when the amplitude of the input signal is nonnegative and 180 degrees when the input signal is negative. This property is Tunable.

**Default:** false

## **PlotType**

Option to control the type of plot

Specify the type of plot to use for all the input signals displayed in the scope window.

- When you set this property to 'Stem' , the scope displays the input signal as circles with vertical lines extending down to the *x*-axis at each of the sampled values . This approach is similar to the functionality of the MATLAB `stem` function.
- When you set this property to 'Line' , the scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.
- When you set this property to 'Stairs' , the scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable.

**Default:** 'Stem'

## Position

Scope window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, [`left bottom width height`]. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is Tunable.

**Default:** The default depends on your screen resolution. By default, the Scope window appears in the center of your screen with a width of 410 pixels and height of 300 pixels.

## ReduceUpdates

Reduce updates to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time the `step` method is called. The simulation speed is faster when this property is set to `true`. This property is Tunable.

You can also modify this property from the scope window. Opening the **Playback** menu and clearing the **Reduce Updates to Improve Performance** check box is the same as setting this property to `false`.

**Default:** `true`

## ShowGrid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable.

**Default:** `true`

## ShowLegend

Source of legend

When you set this property to `true`, the scope displays a legend with automatic string labels for each input channel. When you set this property to `false`, the scope does not display a legend. See `FrameBasedProcessing` for information on input channels. This property is Tunable.

**Default:** `false`

## SampleIncrement

Sample increment of input

Specify the spacing between samples along the  $x$ -axis as a finite numeric scalar.

**Default:** 1

## **Title**

Display title

Specify the display title as a string. This property is Tunable.

**Default:** ''

## **XLabel**

The label for the  $x$ -axis

Specify as a string the text for the scope to display below the  $x$ -axis. This property is Tunable.

**Default:** ''

## **XOffset**

$x$ -axis display offset

Specify the offset to apply to the  $x$ -axis. This property is a numeric scalar. This property is Tunable.

**Default:** 0

## **YLabel**

The label for the  $y$ -axis

Specify as a string the text for the scope to display to the left of the  $y$ -axis. This property is Tunable.

**Default:** 'Amplitude'

## **YLimits**

# dsp.ArrayPlot

---

The limits for the  $y$ -axis

Specify the  $y$ -axis limits as a 2-element numeric vector, [ymin ymax]. This property is Tunable.

**Default:** [-10, 10]

## Methods

clone	Create scope object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
hide	Hide scope window
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of scope object
show	Make scope window visible
step	Display signal in scope figure

## Examples

The following examples illustrate how to use the Array Plot object to view a variety of input signals.

### Example: Plot a Gaussian Distribution

View a *Gaussian*, or normal, distribution on the Array Plot figure.

Create a new Array Plot object.

```
h=dsp.ArrayPlot;
```

Configure the properties of the Array Plot object for a Gaussian distribution.

```
h.YLimits = [0 1];  
h.XOffset = -2.5;  
h.SampleIncrement = 0.1;  
h.Title = 'Gaussian distribution';  
h.XLabel = 'X'  
h.YLabel = 'f(X)'
```

Call the `step` method to plot a Gaussian distribution.

```
step(h, exp(-[-2.5:.1:2.5].*[-2.5:.1:2.5]'));
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h);
```

Run the MATLAB `clear` function to close the scope window.

```
clear('h');
```

## **Example: Plot Changing Filter Weights**

View Least Mean Squares (LMS) adaptive filter weights on the Array Plot figure. Watch the filter weights change as they adapt to filter a noisy input signal.

Create an LMS adaptive filter System object.

```
hlms = dsp.LMSFilter(40,'Method', 'Normalized LMS', 'StepSize', .002);
```

Create and configure an audio file reader System object to read the input signal from the specified audio file.

```
hsigsource = dsp.AudioFileReader('dspafx_8000.wav', ...  
    'SamplesPerFrame', 40, ...  
    'PlayCount', Inf,...  
    'OutputDataType', 'double');
```

## dsp.ArrayPlot

---

Create and configure a fixed-point Finite Impulse Response (FIR) digital filter System object to filter random white noise, creating colored noise.

```
hfilt = dsp.FIRFilter('Numerator', fir1(39, .25));
```

Create and configure an Array Plot System object to display the adaptive filter weights.

```
harrayplot = dsp.ArrayPlot('XLabel', 'Filter Tap', ...  
    'YLabel', 'Filter Weight', ...  
    'YLimits', [-.05 .2]');
```

Plot the LMS filter weights as they adapt to a desired signal. Read from the audio file, produce random data, and filter the random data. Call the `step` method to update the filter weights and plot the filter weights after each step.

```
numplays = 0;  
while numplays < 3  
    [y, eof] = step(hsigsource);  
    noise = rand(40,1);  
    noisefilt = step(hfilt, noise);  
    desired = y + noisefilt;  
    [~, ~, wts] = step(hlms, noise, desired);  
    step(harrayplot, wts);  
    numplays = numplays + eof;  
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(harrayplot);
```

Run the MATLAB `clear` function to close the scope window.

```
clear('harrayplot');
```

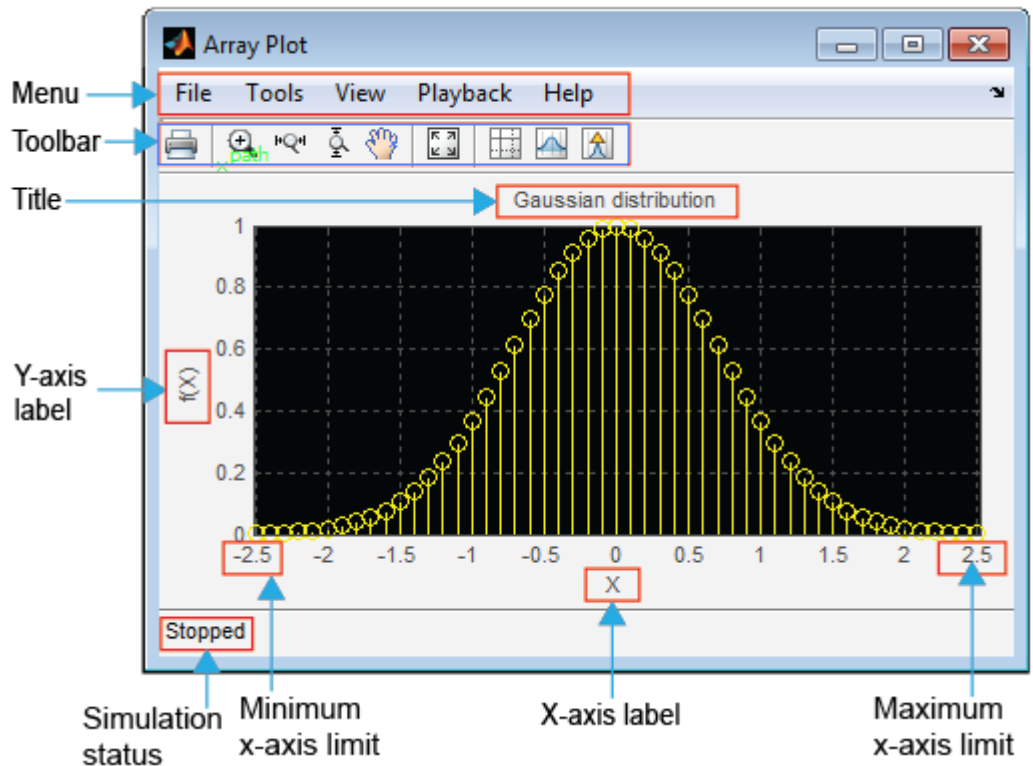

## Signal Display

Array Plot uses the `XOffset` and `SampleIncrement` properties to determine the time range. To change the **X-offset** setting in the Array Plot figure, select **View > Configuration Properties**. The Visuals — Array Plot Properties dialog box appears. Go to the **Main** tab, and modify the value for the **X-offset**.

The span of the  $x$ -axis data is related to the `SampleIncrement` property by the equation  $x_{span} = \text{SampleIncrement} \times (\text{length}(x) - 1)$ . Suppose you set `SampleIncrement` to 0.1 and the input signal data has 51 samples. The scope displays values on the  $x$ -axis from 0 to 5. If you also set the **X-offset** to 2.5, the scope displays values on the  $x$ -axis from 2.5 to 2.5. The values on the  $x$ -axis of the scope display remain the same throughout simulation.

The following figure highlights the important aspects of the Array Plot window.

# dsp.ArrayPlot

## Indicators

- **Minimum  $x$ -axis limit** — Array Plot sets the minimum  $x$ -axis limit using the value of the **X-offset** parameter on the **Main** tab of the Visuals—Array Plot Properties dialog box.
- **Maximum  $x$ -axis limit** — Array Plot sets the maximum  $x$ -axis limit by summing the value of **X-offset** parameter with the span of  $x$ -axis values. The equation  $x_{span} = \text{SampleIncrement} \times (\text{length}(x) - 1)$  defines the relationship of the span of the  $x$ -axis data to the `SampleIncrement` property.

- **Simulation status** — Provides the current status of the model simulation. The status can be either of the following conditions:
  - **Processing** — Occurs after you run the `step` method and before you run the `release` method.
  - **Stopped** — Occurs after you construct the scope object and before you first run the `step` method. This status also occurs after you run the `release` method.

The **Simulation status** is part of the **Status Bar** in the scope window. You can choose to hide or display the entire **Status Bar**. From the scope menu, select **View > Status Bar**.

### Multiple Signal Names

By default, if the input signal has multiple channels, the scope uses an index number to identify each channel of that signal. For example, a 2-channel signal would have the following default names in the channel legend: Channel 1, Channel 2. To show the legend, select **View > Configuration Properties**, click the **Display** tab, and select the **Show Legend** check box. If there are a total of 6 input channels, the following legend appears in the display.

### Multiple Signal Colors

By default, the scope has a black axes background and chooses line colors for each channel in a manner similar to the Simulink Scope block. When the scope axes background is black, it assigns each channel of each input signal a line color in the following order:

- 1 Yellow

# dsp.ArrayPlot

---

**2** Magenta

**3** Cyan

**4** Red

**5** Green

**6** Gray

If there are more than 6 channels, then the scope repeats this order to assign line colors to the remaining channels. To choose line colors for each channel in a manner similar to the MATLAB `plot` function, change the axes background color to any color except black. To change the axes background color to white, select **View > Style**, click the Axes

background color button () , and select white from the color palette. Run the simulation again. The following legend appears in the display.

When the scope axes background is not black, it assigns each channel of each input signal a line color in the following order:

**1** Blue

**2** Dark Green

**3** Red

**4** Cyan

5 Purple

6 Dark Yellow

7 Black

If there are more than 7 channels, then the scope repeats this order to assign line colors to the remaining channels. To manually modify any line color, select **View > Style** to open the Style dialog box. Next to **Properties for line**, select the signal name whose color you want to

change. Then, next to **Line**, click the Line color button () and select any color from the palette.

## Toolbar

The Array Plot toolbar contains the following buttons.

### Print, Settings, and Properties Buttons

Button	Menu Location	Shortcut Keys	Description
	<b>File &gt; Print</b>	<b>Ctrl+P</b>	Print the current scope window.  To print the current scope window to a figure rather than sending it to your printer, select <b>File &gt; Print to figure</b> .

### Axes Control Buttons

	<b>Tools &gt; Zoom In</b>	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw
---	---------------------------	-----	--

# dsp.ArrayPlot

			a rectangular area of interest inside the scope window.
	<b>Tools &gt; Zoom X</b>	N/A	When this tool is active, you can zoom in on the <i>x</i> -axis. To do so, click inside the scope window, or click and drag your cursor along the <i>x</i> -axis over your area of interest.
	<b>Tools &gt; Zoom Y</b>	N/A	When this tool is active, you can zoom in on the <i>y</i> -axis. To do so, click inside the scope window, or click and drag your cursor along the <i>y</i> -axis over your area of interest.
	<b>Tools &gt; Pan</b>	N/A	When this tool is active, you can pan on the scope window. To do so, click in the center of your area of interest and drag your cursor to the left, right, up, or down, to move the position of the display.
	<b>Tools &gt; Scale Axes Limits</b>	<b>Ctrl+A</b>	Click this button to scale the axes in the active scope window.  Alternatively, you can enable automatic axes scaling by selecting

			<p>one of the following options from the <b>Tools</b> menu:</p> <ul style="list-style-type: none"> <li>• <b>Automatically Scale Axes Limits</b> — When you select this option, the scope scales the axes as needed during simulation.</li> <li>• <b>Scale Axes Limits after 10 Updates</b> — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation.</li> <li>• <b>Scale Axes Limits at Stop</b> — When you select this option, the scope scales the axes each time the simulation is stopped.</li> </ul>
--	--	--	---

### Measurements Buttons

	<b>Tools &gt; Measurements &gt; Cursor Measurements</b>	N/A	<p>Open or close the <b>Cursor Measurements</b> panel. This panel puts screen cursors on the display.</p> <p>See the “Cursor Measurements Panel” on page 3-78 section for more information.</p>
	<b>Tools &gt; Measurements &gt; Signal Statistics</b>	N/A	<p>Open or close the <b>Signal Statistics</b> panel. This panel displays the maximum, minimum, peak-to-peak difference, mean, median, RMS values of a selected signal, and the times at which the maximum and minimum occur.</p>

			See the “Signal Statistics Panel” on page 3-80 section for more information.
	<b>Tools &gt; Measurements &gt; Peak Finder</b>	<b>None</b>	Click <b>Close</b> to close the <b>Peak Finder</b> panel. This panel displays maxima and the frequencies at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified.  See the “Peak Finder Panel” on page 3-1333 section for more information.

---

**Note** The zoom buttons do not change the settings related to span for the scope. These buttons are purely graphical.

---

You can control whether this toolbar appears in the Array Plot window. From the menu, select **View > Toolbar**.

**Measurements Panels** The Measurements panels are the panels that appear to the right side of the Array Plot figure. These panels are labeled **Trace selection**, **Cursor Measurements**, **Signal Statistics**, and **Peak Finder**.

### Measurements Panel Buttons

Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

Button	Description
	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button  .
	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button  again.
	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button  in the new window.
	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button  again.
	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button  to show each pane that is hidden in the current panel. Click the pane collapse button  to hide each pane that is shown in the current panel.

## Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. The Measurements

panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.

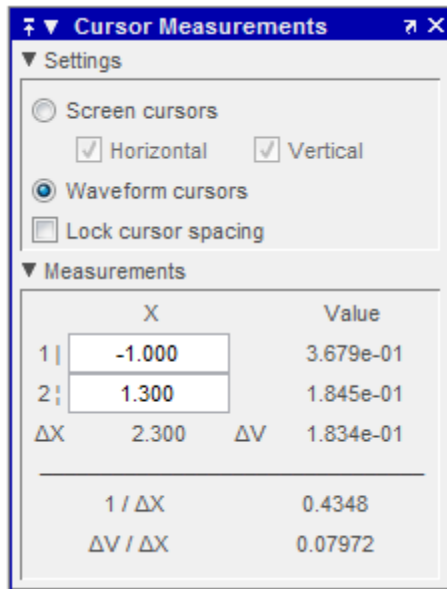

You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools > Measurements > Trace Selection**.

## Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. You can choose to hide or display the **Cursor Measurements** panel. In the scope menu, select **Tools > Measurements > Cursor Measurements**.

Alternatively, in the scope toolbar, click the Cursor Measurements  button.

### Settings Pane

The **Settings** pane enables you to modify the type of screen cursors used to calculate  $x$ -axis and  $y$ -axis value measurements.

- **Screen Cursors**— Shows screen cursors.
- **Horizontal**— Shows horizontal screen cursors.
- **Vertical**— Shows vertical screen cursors.
- **Waveform Cursors**— Shows cursors that attach to the input signals.
- **Lock Cursor Spacing**— Locks the time difference between the two cursors.

### Measurements Pane

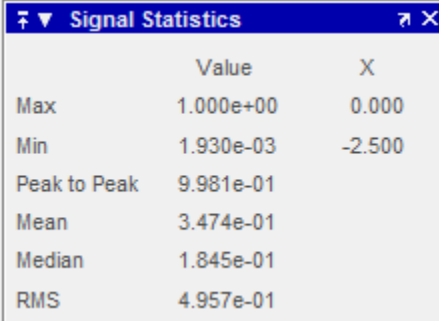

The **Measurements** pane shows the time and value measurements.

- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.
- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.
- **$\Delta X$** — Shows the absolute value of the difference in the  $x$ -axis values between cursor number one and cursor number two.
- **$\Delta V$** — Shows the absolute value of the difference in the  $y$ -axis values, or signal amplitudes, between cursor number one and cursor number two.
- **$1/\Delta X$** — Shows the rate, the reciprocal of the absolute value of the difference in the  $x$ -axis values between cursor number one and cursor number two.
- **$\Delta V/\Delta X$** — Shows the slope, the ratio of the absolute value of the difference in the  $y$ -axis values between cursors to the absolute value of the difference in the  $x$ -axis values between cursors.

## Signal Statistics Panel

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the  $x$ -axis indices at which the maximum and minimum values occur. You can choose to hide or display the **Signal Statistics** panel. In the scope menu, select **Tools > Measurements > Signal Statistics**. Alternatively, in the scope toolbar, click the Signal Statistics  button.

	Value	X
Max	1.000e+00	0.000
Min	1.930e-03	-2.500
Peak to Peak	9.981e-01	
Mean	3.474e-01	
Median	1.845e-01	
RMS	4.957e-01	

### Signal Statistics Measurements

The **Signal Statistics** panel shows statistics about the portion of the input signal within the  $x$ -axis and  $y$ -axis limits of the active display. The statistics shown are:

- **Max** — Shows the maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.
- **Min** — Shows the minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.
- **Peak to Peak** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.
- **Mean** — Shows the average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.
- **Median** — Shows the median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.

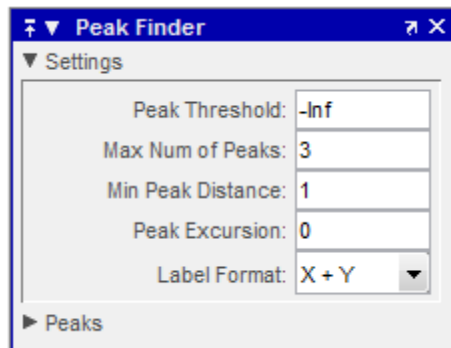

- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the  $x$ -axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal.

## Peak Finder Panel

The **Peak Finder** panel displays maxima and the  $x$ -axis values at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools > Measurements > Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder  button.

The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

### Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer between 1 and 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.

The *peak threshold* is a minimum value necessary for a sample value to be a peak. The *peak excursion* is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the THRESHOLD parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
  - X+Y — Display both *x*-axis and *y*-axis values.

- X — Display only  $x$ -axis values.
- Y — Display only  $y$ -axis values.

### Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.

The numerical values displayed in the **Value** column are equivalent to the `pk`s output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button (▼) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (▲). A filled sort button indicates that the peak values are currently sorted by this category. If the sort button is not filled (◻), then the peak values are sorted by the other category. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peaks are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peaks. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

## Visuals – Array Plot Properties

The Visuals—Array Plot Properties dialog box controls various properties about the Array Plot display. From the Array Plot menu, select **View > Configuration Properties** to open this dialog box.

### Main Pane

The **Main** pane of the Visuals—Array Plot Properties dialog box appears as follows.

## **X-offset**

Specify the offset to apply to the *x*-axis. This property is a numeric scalar. This property is Tunable.

## **Maximize axes**

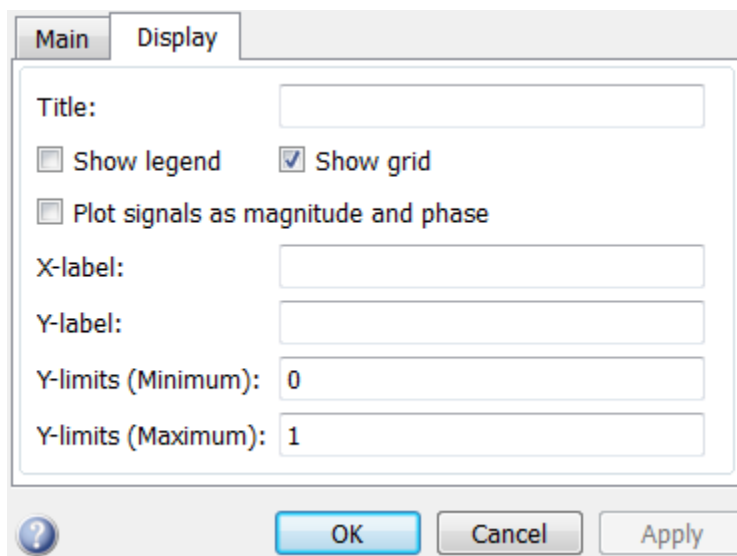

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in the display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- **Auto** — In this mode, the axes appear maximized only if the `Title` and `YLabel` properties are empty. If you enter any value for either of these properties, the axes are not maximized.
- **On** — In this mode, the axes appear maximized. Any values entered into the `Title` and `YLabel` properties are hidden.
- **Off** — In this mode, none of the axes appear maximized.

This property is Tunable.

## **Display Pane**

The **Display** pane of the Visuals—Array Plot Properties dialog box appears as follows.

## Title

Specify the display title as a string. This property is Tunable.

## Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. Tunable.

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View > Style**.

## Show grid

When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable.

### Plot signals as magnitude and phase

When you select this check box, the scope splits the display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal is complex valued, the scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes, as shown in the following figure.

Selecting this check box and clicking the **Apply** or **OK** button changes the display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.

This feature is particularly useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box always produces the same behavior. The phase is 0 for nonnegative input and 180 degrees for negative input. Tunable.

### **X-label**

Specify as a string the text for the scope to display below the  $x$ -axis. This property is Tunable.

### **Y-label**

Specify as a string the text for the scope to display to the left of the  $y$ -axis. This property is Tunable.

### **Y-limits (Minimum)**

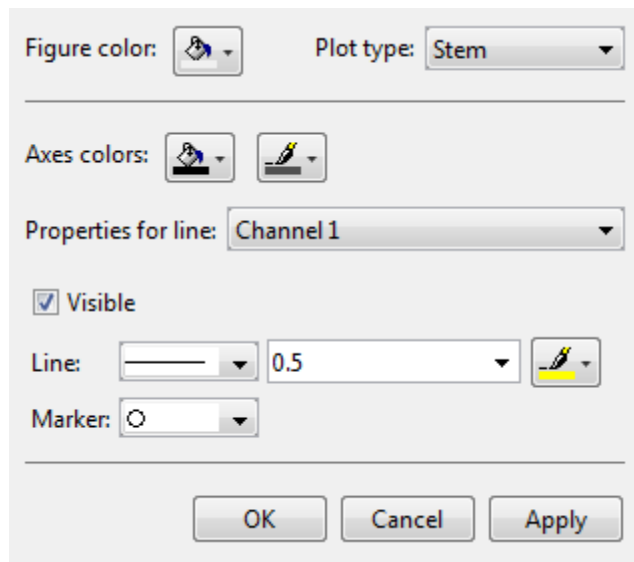

Specify the minimum value of the  $y$ -axis. Tunable.

### **Y-limits (Maximum)**

Specify the maximum value of the  $y$ -axis. Tunable.

## **Style Dialog Box**

In the **Style** dialog box, you can customize the style of displays. You are able to change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. From the scope menu, select **View > Style** to open this dialog box.

### Properties

The **Style** dialog box allows you to modify the following properties of the scope figure:

#### Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

#### Plot type

Specify the type of plot to use for all the input signals displayed in the scope window.

- When you set this property to 'Stem' , the scope displays the input signal as circles with vertical lines extending down to the  $x$ -axis at each of the sampled values . This approach is similar to the functionality of the MATLAB `stem` function.
- When you set this property to 'Line' , the scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.

- When you set this property to 'Stairs', the scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable.

The default setting is `Stem`.

### **Axes colors**

Specify the color that you want to apply to the background of the axes.

### **Properties for line**

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

### **Visible**

Specify whether the selected channel should be visible. If you clear this check box, the line disappears.

### **Line**

Specify the line style, line width, and line color for the selected channel.

### **Marker**

Specify marks for the selected channel to show at its data points. This parameter is similar to the `Marker` property for the MATLAB Handle Graphics plot objects. You can choose any of the marker symbols from the following table.

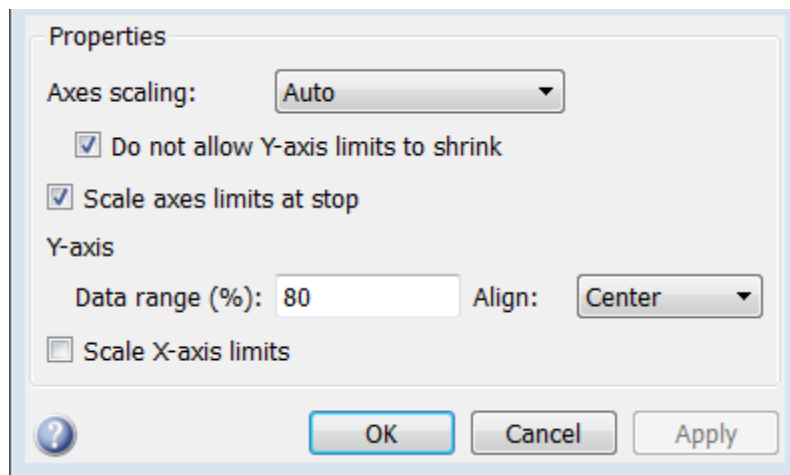

Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
•	Point
+	Plus sign
*	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle
☆	Five-pointed star (pentagram)
☆☆	Six-pointed star (hexagram)

## Tools — Plot Navigation Properties

The Tools—Plot Navigation Properties dialog box allows you to automatically zoom in on and zoom out of your data. You can also scale the axes of the scope. In the scope menu, select **Tools > Axes Scaling Properties** to open this dialog box.

### Properties

The Tools—Plot Navigation Properties dialog box appears as follows.

### Axes Scaling

Specify when the scope should automatically scale the axes. You can select one of the following options:

- **Manual** — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools > Scale axes limits**.
  - Press the **Scale Axes Limits** toolbar button.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.

- **Auto** — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- **After N Updates** — Selecting this option causes the scope to scale the axes after a specified number of updates. Selecting this option shows the **Number of updates** edit box.

This parameter is Tunable.

By default, this parameter is set to **Manual**.

#### **Do not allow Y-axis limits to shrink**

When you select this parameter, the *y*-axis limits are only allowed to grow during axes scaling operations. If you clear this check box, the *y*-axis limits may shrink during axes scaling operations.

This parameter appears only when you select **Auto** for the **Axis Scaling** parameter. When you set the **Axes Scaling** parameter to **Manual** or **After N Updates**, the *y*-axis limits are allowed to shrink. Tunable.

#### **Number of updates**

Specify as a positive integer the number of updates after which to scale the axes. This parameter appears only when you select **After N Updates** for the **Axes Scaling** parameter. Tunable.

#### **Scale axes limits at stop**

Select this check box to scale the axes limits when the simulation stops. The *y*-axis are always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

#### **Y-axis Data range (%)**

Set the percentage of the *y*-axis that the scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this parameter to 100, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this parameter to 30, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable.

# dsp.ArrayPlot

---

## **Y-axis Align**

Specify where the scope should align your data with respect to the *y*-axis when it scales the axes. You can select **Top**, **Center**, or **Bottom**. Tunable.

## **Scale X-axis limits**

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. Tunable.

## **X-axis Align**

Specify how the Scope should align your data with respect to the *x*-axis: **Left**, **Center**, or **Right**. This parameter appears only when you select the **Scale X-axis limits** check box. Tunable.

## **See Also**

`dsp.TimeScope` | `dsp.SpectrumAnalyzer` | `dsp.LogicAnalyzer`

**Purpose**

Create scope object with same property values

**Syntax**

```
C = clone(H)
```

**Description**

`C = clone(H)` creates a scope object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.ArrayPlot.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the step method. `N` equals the value of the `NumInputPorts` property.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the step method. The scope is a sink object, so `N` equals 0.

# dsp.ArrayPlot.hide

---

**Purpose** Hide scope window

**Syntax** `hide(H)`

**Description** `hide(H)` hides the scope window associated with System object, H.

**See Also** `dsp.ArrayPlot.show`

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the scope object H.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.ArrayPlot.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

You should call the `release` method after calling the `step` method when there is no new data for the simulation. When you call the `release` method, the axes will automatically scale in the scope figure window. After calling the `release` method, any non-tunable properties can be set once again.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Algorithms** In operation, the `release` method is similar to the `mdlTerminate` function.

**See Also** `dsp.ArrayPlot.reset`

**Purpose** Reset internal states of scope object

**Syntax** `reset(H)`

**Description** `reset(H)` sets the internal states of the scope object `H` to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the scope figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

**Algorithms** In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

**See Also** `dsp.ArrayPlot` | `dsp.ArrayPlot.release`

# dsp.ArrayPlot.show

---

**Purpose**            Make scope window visible

**Syntax**            show(H)

**Description**        show(H) makes the scope window associated with System object, H, visible.

**See Also**            dsp.ArrayPlot.hide

**Purpose** Display signal in scope figure

**Syntax** `step(H,X)`  
`step(H,X1,X2,...,XN)`

**Description** `step(H,X)` displays the signal, X, in the scope figure.  
`step(H,X1,X2,...,XN)` displays the signals X1, X2,...,XN in the scope figure when you set the NumInputPorts property to N. In this case, X1, X2,...,XN can have different data types.

# dsp.ArrayVectorAdder

---

**Purpose** Add array to vector along specified dimension

**Description** The ArrayVectorAdder object adds an N-D array to a vector along a specified dimension. The length of the vector must equal the size of the N-D array along the specified dimension.

To add an N-D array to a vector along a specified dimension:

- 1 Define and set up your array-vector addition object. See “Construction” on page 3-106.
- 2 Call `step` to add the N-D array according to the properties of `dsp.ArrayVectorAdder`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.ArrayVectorAdder` returns an array-vector addition object, `H`, that adds a vector to an N-D array along the first dimension.

`H = dsp.ArrayVectorAdder('PropertyName',PropertyValue, ...)` returns an array-vector addition object, `H`, with each property set to the specified value.

## Properties

### Dimension

Dimension along which to add vector elements to input

Specify the dimension along which to add the input array to the elements of the vector as a positive integer. The length of the vector must match the size of the N-D array along the specified dimension. The default is 1.

### VectorSource

Source of vector

Specify the source of the vector values as `|Input port | Property |`. The default is `Input port`.

### Vector

Vector values

Specify the vector values. This property applies only when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

## Fixed-Point Properties

### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

### VectorDataType

# dsp.ArrayVectorAdder

---

Vector word and fraction lengths

Specify the vector fixed-point data type as | Same word length as input | Custom |. This property applies when you set the VectorSource property to Property. The default is Same word length as input.

## **CustomVectorDataType**

Vector word and fraction lengths

Specify the vector fixed-point type as a numeric type object with a Signedness of Auto. This property applies when you set the VectorSource property to Property and the VectorDataType property to Custom. The default is numeric type ([ ], 16, 15).

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as | Full precision | Same as first input | Custom |. The default is Full precision.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when the AccumulatorDataType property is Custom. The default is numeric type ([ ], 32, 30).

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as | Same as accumulator | Same as first input | Custom |.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numericType([],16,15)`.

## Methods

<code>clone</code>	Create array-vector adder object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Add vector to N-D array

## Examples

Add 2-by-1 vector to 2-by-2 matrix along the first dimension of the array.

```
hava = dsp.ArrayVectorAdder;  
a = ones(2);  
x = [1 2]';  
y = step(hava, a, x);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Add block reference page. The object properties correspond to the block parameters, except:

The array-vector addition object does not have **Minimum** or **Maximum** options for data output.

## See Also

`dsp.ArrayVectorMultiplier` | `dsp.ArrayVectorDivider` | `dsp.ArrayVectorSubtractor`

## **dsp.ArrayVectorAdder.clone**

---

<b>Purpose</b>	Create array-vector adder object with same property values
<b>Syntax</b>	<code>C = clone(H)</code>
<b>Description</b>	<code>C = clone(H)</code> creates an array-vector adder object, <code>C</code> , with the same property values as <code>H</code> . The clone method creates a new unlocked object.

# dsp.ArrayVectorAdder.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.ArrayVectorAdder.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the array-vector adder.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.ArrayVectorAdder.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Add vector to N-D array

**Syntax**  
 $Y = \text{step}(H,A)$   
 $Y = \text{step}(H,A,V)$

**Description**  $Y = \text{step}(H,A)$  returns  $Y$ , the result of adding the input array  $A$  to the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of  $A$ .

$Y = \text{step}(H,A,V)$  returns  $Y$ , the result of adding the input array  $A$  to the elements of the input vector  $V$  along the specified dimension when the `VectorSource` property is `Input port`. The length of the input  $V$  must equal the length of the specified dimension of  $A$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the `System` object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.ArrayVectorDivider

---

**Purpose** Divide array by vector along specified dimension

**Description** The `ArrayVectorDivider` object divides an array by a vector along a specified dimension.

To divide an array by a vector along a specified dimension:

- 1 Define and set up your array-vector division object. See “Construction” on page 3-116.
- 2 Call `step` to divide the array according to the properties of `dsp.ArrayVectorDivider`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.ArrayVectorDivider` returns an array-vector division object, `H`, that divides an input array by the elements of a vector along the first dimension of the array.

`H = dsp.ArrayVectorDivider('PropertyName',PropertyValue,...)` returns an array-vector division object, `H`, with each property set to the specified value.

## Properties

### Dimension

Dimension along which to divide input by vector elements

Specify the dimension along which to divide the input array by the elements of a vector as a positive integer. The default is 1.

### VectorSource

Source of vector

Specify the source of the vector values as `| Input port | Property |`. The default is `Input port`.

### Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

## Fixed-Point Properties

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`.

### VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point mode as `| Same word length as input | Custom |`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

### CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([],16,15)`.

### OutputDataType

Output word and fraction lengths

# dsp.ArrayVectorDivider

---

Specify the output fixed-point data type as | Same as first input | Custom |. The default is Same as first input.

## CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## Methods

<code>clone</code>	Create array-vector division object with same property values
<code>getNumInputs</code>	Number of expected inputs to <code>step</code> method
<code>getNumOutputs</code>	Number of outputs of <code>step</code> method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Divide array by vector

## Examples

Divide a matrix by a vector.

```
havd = dsp.ArrayVectorDivider;  
a = ones(2);  
x = [2 3]';  
y = step(havd, a, x);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Divide block reference page. The object properties correspond to the block parameters, except:

The array-vector division object does not have **Minimum** or **Maximum** options for data output.

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.ArrayVectorMultiplier

---

**Purpose** Multiply array by vector along specified dimension

**Description** The `ArrayVectorMultiplier` object multiplies an array by a vector along a specified dimension.

To multiply an array by a vector along a specified:

- 1 Define and set up your array-vector multiplication object. See “Construction” on page 3-126.
- 2 Call `step` to multiply the array according to the properties of `dsp.ArrayVectorMultiplier`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.ArrayVectorMultiplier` returns an array-vector multiplication object, `H`, that multiplies an input N-D array by the elements of a vector along the second dimension.

`H = dsp.ArrayVectorMultiplier('PropertyName',PropertyValue,...)` returns an array-vector multiplication object, `H`, with each property set to the specified value.

## Properties

### Dimension

Dimension along which to multiply input by vector elements

Specify the dimension along which to multiply the input array by the elements of vector as a positive integer. The default is 2.

### VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

### Vector

Vector to multiply array

Specify the vector by which to multiply the array. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

## Fixed-Point Properties

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, `Zero`. The default is `floor`.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

### VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input`, `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

### CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([],16,15)`.

### ProductDataType

Product word and fraction lengths

# dsp.ArrayVectorMultiplier

---

Specify the product fixed-point data type as Full precision, Same as first input, or Custom. The default is Full precision.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies when you set the ProductDataType property to Custom. The default is numeric type([],32,30).

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as Full precision, Same as product, Same as first input, or Custom. The default is Full precision.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies when you set the AccumulatorDataType property to Custom. The default is numeric type([],32,30).

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as Same as product, Same as first input, or Custom. The default is Same as product.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies when

you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

## Methods

<code>clone</code>	Create array-vector multiplication object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Multiply array by vector

## Examples

Multiply a matrix by a vector:

```
havm = dsp.ArrayVectorMultiplier;  
a = ones(2);  
x = [2 3]';  
y = step(havm, a, x);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Multiply block reference page. The object properties correspond to the block parameters, except:

- The array-vector multiplication object does not have **Minimum** or **Maximum** options for data output.

## See Also

`dsp.ArrayVectorAdder` | `dsp.ArrayVectorDivider` | `dsp.ArrayVectorSubtractor`

# **dsp.ArrayVectorMultiplier.clone**

---

**Purpose** Create array-vector multiplication object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an array-vector multiplication object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.ArrayVectorMultiplier.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.ArrayVectorMultiplier.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of output arguments from the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the array-vector multiplication object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.ArrayVectorMultiplier.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Multiply array by vector

**Syntax**  
 $Y = \text{step}(H,A,V)$   
 $Y = \text{step}(H,A)$

**Description**  $Y = \text{step}(H,A,V)$  returns  $Y$ , the result of multiplying the input array  $A$  by the elements of input vector  $V$  along the specified dimension when the `VectorSource` property is `Input port`. The length of the input  $V$  must equal the length of the specified dimension of  $A$ .

$Y = \text{step}(H,A)$  returns  $Y$ , the result of multiplying the input array  $A$  by the elements of vector specified in `Vector` property along the specified dimension when the `VectorSource` property is set to `Property`. The length of the vector specified in `Vector` property must equal the length of the specified dimension of  $A$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.ArrayVectorSubtractor

---

**Purpose** Subtract vector from array along specified dimension

**Description** The ArrayVectorSubtractor object subtracts a vector from an N-D array along a specified dimension.

To subtract a vector from an N-D array along a specified dimension:

- 1** Define and set up your array-vector subtraction object. See “Construction” on page 3-136.
- 2** Call `step` to subtract the vector according to the properties of `dsp.ArrayVectorSubtractor`. The behavior of `step` is specified to each object in the toolbox.

**Construction** `H = dsp.ArrayVectorSubtractor` returns an array-vector subtraction object, `H`, that subtracts the elements of a vector from an N-D input array along the first dimension.

`H = dsp.ArrayVectorSubtractor('PropertyName',PropertyValue,...)` returns an array-vector subtraction object, `H`, with each property set to the specified value.

## Properties

### Dimension

Dimension along which to subtract vector elements from input

Specify the dimension along which to subtract the elements of the vector from the input array as an integer-valued scalar greater than 0. The default is 1.

### VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

### Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

## Fixed-Point Properties

### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only if the object is not in full precision mode.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

### VectorDataType

Vector word and fraction lengths

# dsp.ArrayVectorSubtractor

---

Specify the vector fixed-point data type as `Same word length as input` or `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

## **CustomVectorDataType**

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([],16,15)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## Methods

<code>clone</code>	Create array-vector subtractor with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Subtract vector from array along specified dimension

## Examples

Subtract a vector from a matrix:

```
havs = dsp.ArrayVectorSubtractor;  
a = ones(2);  
x = [1 2]';  
y = step(havs, a, x);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Subtract block reference page. The object properties correspond to the block parameters, except:

The array-vector subtraction object does not have **Minimum** or **Maximum** options for data output.

## See Also

`dsp.ArrayVectorMultiplier` | `dsp.ArrayVectorDivider` | `dsp.ArrayVectorAdder`

## **dsp.ArrayVectorSubtractor.clone**

---

**Purpose** Create array-vector subtractor with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an array-vector subtractor object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.ArrayVectorSubtractor.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.ArrayVectorSubtractor.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the array-vector subtractor object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.ArrayVectorSubtractor.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Subtract vector from array along specified dimension

**Syntax**  
 $Y = \text{step}(H,A,V)$   
 $Y = \text{step}(H,A)$

**Description**  $Y = \text{step}(H,A,V)$  returns  $Y$ . The value of  $Y$  results from subtracting the elements of input vector  $V$  from the input array  $A$  along the specified dimension when the `VectorSource` property is `Input port`. The length of the input  $V$  must equal the length of the specified dimension of  $A$ .

$Y = \text{step}(H,A)$  returns  $Y$ . The value of  $Y$  results from subtracting the elements of the vector specified in the `Vector` property from the input array  $A$  along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of  $A$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.AudioFileReader

---

**Purpose** Read audio samples from audio file

**Description** The `AudioFileReader` object reads audio samples from an audio file.  
To read audio samples from an audio file:

- 1 Define and set up your audio file reader object. See “Construction” on page 3-146.
- 2 Call `step` to read audio samples according to the properties of `dsp.AudioFileReader`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.AudioFileReader` returns an audio file reader System object, `H` that reads audio from an audio file. This audio file can be of the following formats on all platforms:

- MP3
- M4a
- MP4
- WAV
- FLAC
- OGG

`H = dsp.AudioFileReader('PropertyName',PropertyValue,...)` returns an audio file reader System object, `H`, with each specified property set to the specified value.

`H = dsp.AudioFileReader(FileName,'PropertyName',PropertyValue,...)` returns an audio file reader object, `H`, with `FileName` property set to `FILENAME` and other specified properties set to the specified values.

**Properties** **Filename**

Name of audio file from which to read

Specify the name of an audio file as a string. Specify the full path for the file only if the file is not on the MATLAB path. The default is `speech_dft.mp3`.

## **PlayCount**

Number of times to play file

Specify a positive integer or `inf` as the number of times to play the file. If you enter `inf`, the file plays repeatedly. The default is `inf`.

## **SampleRate**

Sampling rate of the audio file

This read-only property displays the sampling rate, in hertz, of the audio file.

## **SamplesPerFrame**

Number of samples in audio frame

Specify the number of samples in an audio frame as a positive, scalar integer value. The default value is `1024`.

## **OutputDataType**

Data type of output

Set the data type of the audio data output from the audio file reader object. Specify the data type as `|double| single | int16 | uint8|`. The default is `int16`.

## **Methods**

<code>clone</code>	Create audio file reader object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>info</code>	Information about specific audio file

# dsp.AudioFileReader

---

isDone	End-of-file status (logical)
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of audio file reader to read from beginning of file
step	Read audio samples from audio file

## Examples

Read and play back an audio file using the standard audio output device.

```
hmfr = dsp.AudioFileReader('speech_dft.mp3');
hap = dsp.AudioPlayer('SampleRate', hmfr.SampleRate);

while ~isDone(hmfr)
    audio = step(hmfr);
    step(hap, audio);
end

release(hmfr); % release the input file
release(hap); % release the audio output device
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs EOF as the last output.

- The object has no corresponding property for the **Multimedia Outputs** parameter because audio is the only supported output.
- The object has no corresponding property for the **Image signal** block parameter.
- The object has no corresponding property for the **Output color format** parameter.
- The object has no corresponding property for the **Video output data type** parameter.

## See Also

`dsp.AudioFileWriter`

# dsp.AudioFileReader.clone

---

**Purpose** Create audio file reader object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an `AudioFileReader` System object, `C`, with the same property values as `H`.

The clone method creates a new unlocked object with uninitialized states.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.AudioFileReader.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Information about specific audio file

**Syntax** `S = info(H)`

**Description** `S = info(H)` returns a MATLAB structure, `S`, with information about the audio file specified in the `Filename` property. The number of fields in `S` varies depending on the audio content of the file. For possible fields and values for the structure `S`, see the following table.

Field	Value
SampleRate	Audio sampling rate of the audio file in Hz.
NumBits	Number of bits used to encode the audio stream.
NumChannels	Number of audio channels.

# **dsp.AudioFileReader.isDone**

---

**Purpose**            End-of-file status (logical)

**Syntax**            STATUS = isDone(H)

**Description**        STATUS = isDone(H) returns a logical value, STATUS , when the AudioFileReader object, H , reaches the end of the audio file. If you set the PlayCount property to a value greater than 1 , STATUS is true each time the object reaches the end of the file. STATUS is the same as the EOF output value in the step method syntax.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `y = isLocked(H)`

**Description** `y = isLocked(H)` returns the locked state, Y, of the AudioFileReader object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# **dsp.AudioFileReader.reset**

---

<b>Purpose</b>	Reset internal states of audio file reader to read from beginning of file
<b>Syntax</b>	<code>reset(H)</code>
<b>Description</b>	<code>reset(H)</code> resets the <code>AudioFileReader</code> object to read from the beginning of the file.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

# dsp.AudioFileReader.step

---

**Purpose** Read audio samples from audio file

**Syntax** AUDIO = step(H)  
[AUDIO,EOF] = step(H)

**Description** AUDIO = step(H) outputs one frame of audio samples, AUDIO. You can specify the number of times to play the file using the PlayCount property. After playing the file for the number of times you specify, AUDIO contains silence.

[AUDIO,EOF] = step(H) returns an end-of-file indicator, EOF. EOF is true each time the output AUDIO contains the last audio sample in the file.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

**Purpose** Write audio samples to audio file

**Description** The AudioFileWriter object writes audio samples to an audio file.  
To write audio samples to an audio file:

- 1 Define and set up your audio file writer object. See “Construction” on page 3-159.
- 2 Call `step` to write audio samples according to the properties of `dsp.AudioFileWriter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.AudioFileWriter` returns an audio file writer System object, `H`. This object writes audio samples to an audio file. This audio file can be of the following formats on all platforms:

- WAV
- FLAC
- OGG

In addition, this System object supports MPEG-4 AAC audio files on Windows 7, and Mac OS X. You can use both M4A and MP4 extensions. The following platform specific restrictions apply when writing these files:

Windows 7	Mac OS X
<ul style="list-style-type: none"><li>• Only sample rates of 44100 and 48000 Hz are supported.</li></ul>	<ul style="list-style-type: none"><li>• Only mono or stereo outputs are allowed.</li></ul>
<ul style="list-style-type: none"><li>• Only mono or stereo outputs are allowed.</li></ul>	

# dsp.AudioFileWriter

Windows 7	Mac OS X
<ul style="list-style-type: none"><li>The output data is padded on both the front and back of the signal, with extra samples of silence.</li></ul> <p>Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.</p>	<ul style="list-style-type: none"><li>Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.</li></ul>
<ul style="list-style-type: none"><li>A minimum of 1025 samples must be written to the MPEG-4 AAC file.</li></ul>	

`H = dsp.AudioFileWriter('PropertyName',PropertyValue,...)`  
returns an audio file writer System object, H, with each specified property set to the specified value.

`H = dsp.AudioFileWriter(FILENAME,'PropertyName',PropertyValue,...)`  
returns an audio file writer System object, H. This object has the `Filename` property set to `FILENAME` and other specified properties set to the specified values.

## Properties

### Filename

Name of audio file to which to write

Specify the name of the audio file as a string. The default is `output.wav`.

### FileFormat

Audio file format

Specify which audio file format the object writes. On Microsoft platforms, select one of `AVI | WAV | FLAC | OGG | M4A | WMA`. On Linux platforms, select one of `AVI | WAV | FLAC | OGG`. On Mac OS

X platforms, select one of AVI | WAV | FLAC | OGG | M4A. These abbreviations correspond to the following file formats:

- AVI: Audio-Video Interleave
- WAV: Microsoft WAVE Files
- WMA: Windows Media Audio
- FLAC: Free Lossless Audio Codec
- OGG: Ogg/Vorbis Compressed Audio File
- M4A: MPEG-4 AAC File

The default is WAV.

## **SampleRate**

Sampling rate of audio data stream

Specify the sampling rate of the input audio data as a positive, numeric scalar value. The default is 44100 .

## **Compressor**

Algorithm that compresses audio data

Specify the type of compression algorithm the audio file writer uses to compress the audio data. Compression reduces the size of the audio file. Select `None` (uncompressed) to save uncompressed audio data to the file. The other options available reflect the audio compression algorithms installed on your system. You can use tab completion to query valid `Compressor` options for your computer by typing `H.Compressor = '` and then pressing the tab key. This property applies when writing WAV or AVI files on Windows platforms.

## **DataType**

Data type of the uncompressed audio

Specify the type of uncompressed audio data written to the file as one of `inherit`, `int16`, `int24`, `single`, or `uint8`. This property

# dsp.AudioFileWriter

---

only applies when writing uncompressed WAV files. The default value of this property is `int16`.

## Methods

<code>clone</code>	Create audio file writer object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Write one frame of audio output samples

## Examples

Decimate an audio signal, and write it to disk as an AVI file.

```
hmfr = dsp.AudioFileReader('OutputDataType',...
    'double');
hfirdec = dsp.FIRDecimator; % decimate by 2
hmfw = dsp.AudioFileWriter...
    ('speech_dft.wav', ...
    'SampleRate', hmfr.SampleRate/2);

while ~isDone(hmfr)
    audio = step(hmfr);
    audiod = step(hfirdec, audio);
    step(hmfw, audiod);
end

release(hmfr);
release(hmfw);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the [To Multimedia File](#) block reference page. The object properties correspond to the block parameters, except:

- The object `FileFormat` property does not support video-only file formats.
- The object has no corresponding property for the **Write** parameter. The object writes only audio content to files.
- The object has no corresponding property for the **Video compressor** parameter.
- The object has no corresponding property for the **File color format** parameter.
- The object has no corresponding property for the **Image signal** parameter.

## See Also

`dsp.AudioFileReader`

## **dsp.AudioFileWriter.clone**

---

**Purpose** Create audio file writer object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an `AudioFileWriter` System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

# dsp.AudioFileWriter.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, of the step method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.AudioFileWriter.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, of step method `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose**

Locked status for input attributes and nontunable properties

**Syntax**

isLocked(H)

**Description**

isLocked(H) returns the locked state of the AudioFileWriter System object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

# dsp.AudioFileWriter.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Write one frame of audio output samples

**Syntax** `step(H,AUDIO)`

**Description** `step(H,AUDIO)` writes one frame of audio samples, `AUDIO`, to the output file. `AUDIO` is either a vector or an M-by-N matrix for mono or N-channel audio inputs respectively.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.AudioPlayer

---

**Purpose** Play audio data using computer's audio device

**Description** The AudioPlayer object plays audio data using the computer's audio device.

To play audio data using the computer's audio device:

- 1 Define and set up your audio player object. See "Construction" on page 3-170.
- 2 Call step to play audio data according to the properties of dsp.AudioPlayer. The behavior of step is specific to each object in the toolbox.

This System object buffers the data from the audio device using the process illustrated by the following figure.

**Construction** `H = dsp.AudioPlayer` returns an audio player object, H, that plays audio samples using an audio output device in real-time.

`H = dsp.AudioPlayer('PropertyName',PropertyValue, ...)` returns an audio player object, H, with each property set to the specified value.

`H = dsp.AudioPlayer(SAMPLERATE, 'PropertyName', PropertyValue,`

...) returns an audio player object, H, with the `SampleRate` property set to `SAMPLERATE` and other specified properties set to the specified values. This System object supports variable-size input. If you use variable-size signals with this System object, you may experience sound dropouts when the size of the input frame increases. To avoid this behavior, use a signal of maximum expected size when you first call `step` to start running through this System object.

## Properties

### DeviceName

Device to which to send audio data

Specify the device to which to send the audio data. The default is `Default`, which is the computer's standard output device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key.

### SampleRate

Number of samples per second sent to audio device

Specify the number of samples per second in the signal as an integer. The default is 44100. This property is tunable.

### DeviceDataType

Data type used by device

Specify the data type used by the audio device to acquire audio data as `Determine from input data type`, 8-bit integer, 16-bit integer, 24-bit integer, or 32-bit float. The default is `Determine from input data type`.

### BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, an appropriate buffer size based on the `SampleRate` gets computed.

### BufferSize

## Buffer size

Specify the size of the buffer that the audio player object uses to communicate with the audio device as an integer. `BufferSize` is half the size of the sound card buffer. A frame of data cannot be passed to the queue until the device empties the buffer, which introduces *latency*. Latency is the time it takes the device to empty the queue and the buffer. `BufferSize` has to be smaller than the effective queue duration. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun). This property applies when you set the `BufferSizeSource` property to `Property`. The default is 4096. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to `'Property'`. You can select `BufferSize` in the list of properties.

## QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is 1.0. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:

$$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}$$
. To minimize latency, lower the `QueueDuration` or set it to 0.

However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer underrun occurs. To correct the underrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer overrun occurs, causing the System object to wait before writing data to the queue. To minimize the chance of dropouts, the System

object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the System object sends a buffer of samples from the top of the queue to the audio device. If the queue does not contain enough data to completely fill the buffer, the System object fills the remaining portion of the buffer with zeros.

## Methods

clone	Create audio player object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Write audio to audio output device

## Examples

Read in an AVI audio file, and play the file back using the standard audio output device:

```
hafr = dsp.AudioFileReader;  
hap = dsp.AudioPlayer('SampleRate',22050);  
  
while ~isDone(hafr)  
    audio = step(hafr);  
    step(hap,audio);  
end  
  
pause(hap.QueueDuration); % Wait until audio plays to the end
```

# dsp.AudioPlayer

---

```
release(hafr); % close input file, release resources  
release(hap); % close audio output device, release resources
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the [To Audio Device](#) block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.AudioFileReader](#) | [dsp.AudioRecorder](#)

## How To

- Set the Audio Hardware API

**Purpose** Create audio player object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an audio player object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# **dsp.AudioPlayer.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.AudioPlayer.getNumOutputs

---

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.AudioPlayer.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the audio player object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.AudioPlayer.step

---

**Purpose** Write audio to audio output device

**Syntax** `Y = step(H,AUDIO)`

**Description** `Y = step(H,AUDIO)` writes one frame of AUDIO samples to the selected audio output device, Y.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Purpose

Record audio data using computer's audio device

## Description

The AudioRecorder object records audio data using the computer's audio device.

To record audio data using the computer's audio device:

- 1 Define and set up your audio recorder object. See “Construction” on page 3-181.
- 2 Call `step` to record audio data according to the properties of `dsp.AudioRecorder`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from a frame of data using the process illustrated by the following figure.

## Construction

`H = dsp.AudioRecorder` returns an audio recorder object, `H`, that records audio samples using an audio input device in real-time.

`H = dsp.AudioRecorder('PropertyName',PropertyValue, ...)` returns an audio recorder object, `H`, with each property set to the specified value.

# dsp.AudioRecorder

---

## Properties

### DeviceName

Device from which to acquire audio data

Specify the device from which to acquire audio data. The default is `Default`, which is the computer's standard input device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key. The tab completion functionality shows all valid audio device names for your computer.

### SampleRate

Number of samples per second read from audio device

Specify the number of samples per second in the signal as an integer. The default is 44100. This property is tunable.

### NumChannels

Number of audio channels

Specify the number of audio channels as an integer. The default is 2.

### DeviceDataType

Data type used by device

Specify the data type used by the device to acquire audio data as `Determine from output data type`, `8-bit integer`, `16-bit integer`, `24-bit integer`, or `32-bit float`. The default is `Determine from output data type`.

### BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`.

### BufferSize

Buffer size

Specify as an integer the size of the buffer that the audio recorder object uses to communicate with the audio device. This property applies when you set the `BufferSizeSource` property to `Property`. The default is 4096. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun). The instant you receive the buffer from a device, you have samples that are relatively new and samples that are at least as old as the size of the buffer. Therefore, the buffer size introduces *latency*, which is the time required for the device to fill the queue and the buffer. `BufferSize` is half the size of the sound card buffer. The size of the buffer processed in each interrupt from the audio device affects the performance of the system. A frame of data cannot pass through the queue until the buffer is filled by the device, thus introducing latency. `BufferSize` has to be smaller than the effective queue duration. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to 'Property'. You can select `BufferSize` from the list of properties.

## QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is 1.0. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:

$$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}$$

To minimize latency, lower the `QueueDuration` or set it to 0.

However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer overrun occurs. To correct the overrun, make the queue duration larger than the buffer. If the MATLAB data throughput

# dsp.AudioRecorder

---

rate is higher than the device throughput rate, a buffer underrun occurs, causing the System object to wait for new samples to become available. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the audio device sends a buffer of samples to the top of the queue.

## **SamplesPerFrame**

Number of samples in the output signal

Specify the number of samples in the audio recorder's output as an integer. The default is 1024.

## **OutputDataType**

Data type of the output

Select the output data type as `uint8`, `int16`, `int32`, `single`, or `double`. The default is `single`.

## **Methods**

<code>clone</code>	Create audio recorder object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Record audio from computer's recording device

## Examples

Record ten seconds of speech from a microphone, and send the output to a .wav file:

```
har = dsp.AudioRecorder;
hmfw = dsp.AudioFileWriter('myspeech.wav','FileFormat','WAV');

disp('Speak into microphone now');

tic;
while toc < 10,
    step(hmfw, step(har));
end

release(har);
release(hmfw);
disp('Recording complete');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the From Audio Device block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.AudioFileReader](#) | [dsp.AudioPlayer](#)

## How To

- Set the Audio Hardware API

## **dsp.AudioRecorder.clone**

---

**Purpose** Create audio recorder object with same property values

**Syntax** `clone(H)`

**Description** `clone(H)` creates an audio recorder object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.AudioRecorder.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.AudioRecorder.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the audio recorder.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.AudioRecorder.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Record audio from computer's recording device

**Syntax** AUDIO = step(H)

**Description** AUDIO = step(H) reads one frame of audio samples from the selected audio input device.

# dsp.Autocorrelator

---

**Purpose** Autocorrelation sequence

**Description** The `Autocorrelator` object returns the autocorrelation sequence for a discrete-time, deterministic input, or the autocorrelation sequence estimate for a discrete-time, wide-sense stationary (WSS) random process at positive lags.

To obtain the autocorrelation sequence:

- 1 Define and set up your autocorrelator. See “Construction” on page 3-192.
- 2 Call `step` to compute the autocorrelation sequence according to the properties of `dsp.Autocorrelator`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.Autocorrelator` returns an autocorrelator, `H`, that computes the autocorrelation along the first dimension of an N-D array. By default, the autocorrelator computes the autocorrelation at lags from zero to  $N - 1$ , where  $N$  is the length of the input vector or the row dimension of the input matrix. Inputting a row vector results in a row of zero-lag autocorrelation sequence values, one for each column of the row vector. The default autocorrelator returns the unscaled autocorrelation and performs the computation in the time domain.

`H = dsp.Autocorrelator('PropertyName',PropertyValue, ...)` returns an autocorrelator, `H`, with each property set to the specified value.

**Properties** **MaximumLagSource**

Source of maximum lag

Specify how to determine the range of lags for the autocorrelation as `Auto` or `Property`. If the value of `MaximumLagSource` is `Auto`, the autocorrelator computes the autocorrelation over all nonnegative lags in the interval  $[0, N - 1]$ , where  $N$  is the length of the first dimension of the input. Otherwise, the object computes

the autocorrelation using lags in the range  $[0, \text{MaximumLag}]$ . The default is `Auto`.

## MaximumLag

Maximum positive lag

Specify the maximum lag as a positive integer. This property applies only when the `MaximumLagSource` property is `Property`. The `MaximumLag` must be less than the length of the input data. The default is 1.

## Scaling

Autocorrelation function scaling

Specify the scaling to apply to the output as `None`, `Biased`, `Unbiased`, or `Unity at zero-lag`. Set this property to `None` to generate the autocorrelation function without scaling. This option is appropriate if you are computing the autocorrelation of a nonrandom (deterministic) input.

The `Biased` option scales the autocorrelation by  $1/N$ , where  $N$  is the length of the input data. Scaling by  $1/N$  yields a biased, finite-sample approximation to the theoretical autocorrelation of a WSS random process. In spite of the bias, scaling by  $1/N$  has the desirable property that the sample autocorrelation matrix is nonnegative definite, a property possessed by the theoretical autocorrelation matrices of all wide-sense stationary random processes. The Fourier transform of the biased autocorrelation estimate is the *periodogram*, a widely used estimate of the power spectral density of a WSS process.

The `Unbiased` option scales the estimate of the autocorrelation by  $1/(N-1)$ . Scaling by  $1/(N-1)$  produces an unbiased estimate of the theoretical autocorrelation. However, using the unbiased option, you can obtain an estimate of the autocorrelation function that fails to have the nonnegative definite property.

Use the `Unity at zero-lag` option to normalize the autocorrelation estimate as identically one at lag zero. See

“Definitions” on page 3-196 for more detail on scaling. The default is `None`.

## **Method**

Domain for computing autocorrelations

Specify the domain for computing autocorrelations as `Time Domain` or `Frequency Domain`. You must set this property to `Time Domain` for fixed-point signals. The default is `Time Domain`.

## **Fixed-Point Properties**

### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Floor`. This property applies only if the object is not in full precision mode.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Full precision`

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` property is `Time Domain`. The default is `Full precision`.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and

# dsp.Autocorrelator

---

the `AccumulatorDataType` property to `Custom`. The default is `isnumerictype([],32,30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` property is `Time Domain`. The default is `Same as accumulator`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

## **Methods**

<code>clone</code>	Create autocorrelator object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Autocorrelation sequence

## **Definitions**

The autocorrelation of a deterministic discrete-time sequence,  $x(n)$  is:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0, 1, \dots, N-1$$

where  $h$  is the lag and  $*$  denotes the complex conjugate. If the input is a length  $N$  realization of a WSS stationary random process,  $r_x(h)$  is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where  $E\{\}$  is the expectation operator. The Unity at zero-lag normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N} \sum_{k=0}^{N-h-1} x^*(k)x(k+h)$$

## Examples

Compute autocorrelation for all positive lags:

```

hac1 = dsp.Autocorrelator;
% x is a column vector
x = [1:100]';
y = step(hac1, x);

```

---

Compute the autocorrelation of a sine wave in white Gaussian noise with approximate 95% upper and lower confidence limits:

```

S = rng('default');
% Sine wave with period N=4
x = 1.4*cos(pi/2*(1:100))'+randn(100,1);

```

## dsp.Autocorrelator

---

```
MaxLag = 20;
H = dsp.Autocorrelator('MaximumLagSource',...
    'Property','MaximumLag',MaxLag,'Scaling','Unity at zero-lag');
SigAutocorr = step(H,x);
stem(SigAutocorr,'b','markerfacecolor',[0 0 1]);
line(1:MaxLag+1,1.96/sqrt(100)*ones(MaxLag+1,1),...
    'linestyle','-','linewidth',2);
line(1:MaxLag+1,-1.96/sqrt(100)*ones(MaxLag+1,1),...
    'linestyle','-','linewidth',2);
axis([1 20 -1 1]);
title('Sine Wave + Noise Autocorrelation'); xlabel('Lag');
```

As this figure shows, the autocorrelation estimate demonstrates the four sample periodic sine wave with excursions outside the 95% white Gaussian noise confidence limits every two samples.

# **dsp.Autocorrelator**

---

## **Algorithms**

This object implements the algorithm, inputs, and outputs described on the Autocorrelation block reference page. The object properties correspond to the block parameters.

## **See Also**

`dsp.Crosscorrelator`

**Purpose** Create autocorrelator object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an autocorrelator object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

# dsp.Autocorrelator.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose** Number of outputs of step method

**Syntax** N = getNumOutputs(H)

**Description** N = getNumOutputs(H) returns the number of outputs, N, of the step method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.Autocorrelator.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the autocorrelator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.Autocorrelator.step

---

**Purpose** Autocorrelation sequence

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  computes the autocorrelation sequence  $Y$  for the columns of the input  $X$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	IIR filter using biquadratic structures
<b>Description</b>	<p>The <code>BiquadFilter</code> object implements an IIR filter structure using biquadratic or second-order sections (SOS).</p> <p>To implement an IIR filter structure using biquadratic or SOS:</p> <ol style="list-style-type: none"><li>1 Define and set up your biquadratic IIR filter. See “Construction” on page 3-207.</li><li>2 Call <code>step</code> to implement the IIR filter according to the properties of <code>dsp.BiquadFilter</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.BiquadFilter</code> returns a default biquadratic IIR filter, <code>H</code>, which independently filters each channel of the input over successive calls to the <code>step</code> method using the SOS section <code>[1 0.3 0.4 1 0.1 0.2]</code> with a direct-form II transposed structure.</p> <p><code>H = dsp.BiquadFilter('PropertyName',PropertyValue, ...)</code> returns a biquadratic filter object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>Structure</b></p> <p>Filter structure</p> <p>Specify the filter structure as one of   Direct form I   Direct form I transposed   Direct form II   Direct form II transposed  . The default is Direct form II transposed.</p> <p><b>SOSMatrixSource</b></p> <p>SOS matrix source</p> <p>Specify the source of the SOS matrix as one of   Property   Input port . The default is Property.</p> <p><b>SOSMatrix</b></p> <p>SOS matrix</p>

Specify the second-order section (SOS) matrix as an N-by-6 matrix, where N is the number of sections in the filter. The default is [1 0.3 0.4 1 0.1 0.2]. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The system function,  $H(z)$ , of a biquad filter is:

$$H(z) = \frac{\sum_{k=0}^2 b_k z^{-k}}{1 - \sum_{l=1}^2 a_l z^{-l}}$$

The coefficients are ordered in the rows of the SOS matrix as  $(b_0, b_1, b_2, 1, -a_1, -a_2)$ . You can use coefficients of real or complex values. This property applies only when you set the `SOSMatrixSource` property to `Property`. The leading denominator coefficient of the biquad filter,  $a_0$ , equals 1 for each filter section, regardless of the specified value. This property is tunable when the `OptimizeUnityScaleValues` property is `false`.

## ScaleValues

Scale values for each biquad section

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be either a scalar or a vector of length N+1, where N is the number of sections. If you set this property to a scalar, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to 1. If you set this property to a vector of N+1 values, each value is used for a separate section of the filter.

This property applies only when you set the `SOSMatrixSource` property to `Property`. The default is 1. This property is tunable when the `OptimizeUnityScaleValues` property is `false`.

## InitialConditions

Initial conditions for direct form II structures

Specify the initial conditions of the filter states when the `Structure` property is one of `| Direct form II | Direct form II transposed |`. The number of states or delay elements (zeros and poles) in a direct-form II biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix.

When you specify a scalar value, the biquad filter initializes all delay elements in the filter to that value. When you specify a vector of length equal to the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. The default is the scalar 0.

## **NumeratorInitialConditions**

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property applies only when you set the `Structure` property to one of `| Direct form I | Direct form I transposed |`. The number of states or delay elements in the numerator of a direct-form I biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the zeros side in the filter to that value. When you specify a vector of length equal to the number of delay elements on the zeros side in the

filter, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the zeros side in the filter, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. The default is the scalar 0.

## **DenominatorInitialConditions**

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the filter structure with the poles. This property only applies when you set the `Structure` property to one of `| Direct form I` `| Direct form I transposed |`. The number of denominator states, or delay elements, in a direct-form I (noncanonic) biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the poles side of the filter to that value. When you specify a vector of length equal to the number of delay elements on the poles side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

The object applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the poles side in the filter, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

When you specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. The default is the scalar 0.

## **OptimizeUnityScaleValues**

Optimize unity scale values

When this Boolean property is set to `true`, the biquad filter removes all unity scale gain computations. This reduces the number of computations and increases the fixed-point accuracy. This property applies only when you set the `SOSMatrixSource` property to `Property`. The default is `true`.

## **ScaleValuesInputPort**

How to specify scale values

Select how to specify scale values. This property applies only when the `SOSMatrixSource` property is `Input port`. By default, this property is `true`, and the scale values are specified via the input port. When this property is `false`, all scale values are 1.

## **FrameBasedProcessing**

Enable frame-based processing

Set this property to `true` to enable frame-based processing. When this property is `true`, the biquad filter treats each column as an independent channel. Set this property to `false` to enable sample-based processing. When this property is `false`, the biquad filter treats each element of the input as an individual channel. The default is `true`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

# dsp.BiquadFilter

---

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

## **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

## **MultiplicandDataType**

Multiplicand word and fraction lengths

Specify the multiplicand fixed-point data type as one of | Same as output | Custom |. This property applies only when you set the Structure property to Direct form I transposed. The default is Same as output.

## **CustomMultiplicandDataType**

Custom multiplicand word and fraction lengths

Specify the multiplicand fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when you set the MultiplicandDataType property to Custom. The default is numeric type([],32,30).

## **SectionInputDataType**

Section input word and fraction lengths

Specify the section input fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

## **CustomSectionInputDataType**

Custom section input word and fraction lengths

Specify the section input fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when you set the SectionInputDataType property to Custom. The default is numeric type([],16,15).

## **SectionOutputDataType**

Section output word and fraction lengths

Specify the section output fixed-point data type as one of | Same as section input | Custom |. The default is Same as section input.

## **CustomSectionOutputDataType**

Custom section output word and fraction lengths

Specify the section output fixed-point type as a signed, scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `SectionOutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

## **NumeratorCoefficientsDataType**

Numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point data type as one of | Same word length as input | Custom |. This property applies only when you set the `SOSMatrixSource` property to `Property`. Setting this property also sets the `DenominatorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value. The default is Same word length as input.

## **CustomNumeratorCoefficientsDataType**

Custom numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `SOSMatrixSource` property to `Property` and the `NumeratorCoefficientsDataType` property to `Custom`. The word length of the `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must be the same. The default is `numericType([],16,15)`.

## **DenominatorCoefficientsDataType**

Denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point data type as one of | Same word length as input | Custom |. This property applies only when you set the `SOSMatrixSource` property to `Property`. Setting this property also sets the `NumeratorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value. The default is Same word length as input.

## **CustomDenominatorCoefficientsDataType**

Custom denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `SOSMatrixSource` property to `Property` and the `DenominatorCoefficientsDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must have the same word lengths. The default is `numericType([],16,15)`.

## **ScaleValuesDataType**

Scale values word and fraction lengths

Specify the scale values fixed-point data type as one of | Same word length as input | Custom |. This property applies only when you set the `SOSMatrixSource` property to `Property`. Setting this property also sets the `NumeratorCoefficientsDataType` and `DenominatorCoefficientsDataType` properties to the same value. The default is Same word length as input.

## **CustomScaleValuesDataType**

Custom scale values word and fraction lengths

Specify the scale values fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies

only when you set the `SOSMatrixSource` property to `Property` and the `ScaleValuesDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must have the same word lengths. The default is `numerictype([],16,15)`.

## **NumeratorProductDataType**

Numerator product word and fraction lengths

Specify the product fixed-point data type as one of `| Same as input | Custom |`. Setting this property also sets the `DenominatorProductDataType` property to the same value. The default is `Same as input`.

## **CustomNumeratorProductDataType**

Custom numerator product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `NumeratorProductDataType` property to `Custom`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numerictype([],32,30)`.

## **DenominatorProductDataType**

Denominator product word and fraction lengths

Specify the product fixed-point data type as one of `| Same as input | Custom |`. Setting this property also sets the `NumeratorProductDataType` property to the same value. The default is `Same as input`.

## **CustomDenominatorProductDataType**

Custom denominator product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `DenominatorProductDataType`

to Custom. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numerictype([],32,30)`.

## **NumeratorAccumulatorDataType**

Numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point data type as one of `| Same as input | Same as product | Custom |`. Setting this property also sets the `DenominatorAccumulatorDataType` property to the same value. The default is `Same as product`.

## **CustomNumeratorAccumulatorDataType**

Custom numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `NumeratorAccumulatorDataType` property to `Custom`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties must have the same word lengths. The default is `numerictype([],32,30)`.

## **DenominatorAccumulatorDataType**

Denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point data type as one of `| Same as input | Same as product | Custom |`. Setting this property also sets the `NumeratorAccumulatorDataType` property to the same value. The default is `Same as product`.

## **CustomDenominatorAccumulatorDataType**

Custom denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `DenominatorAccumulatorDataType` property to `Custom`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties

must have the same word lengths. The default is `numericType([],32,30)`.

## **StateDataType**

State word and fraction lengths

Specify the state fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. This property applies when you set the `Structure` property to `Direct form II` or `Direct form II transposed`. The default is `Same as accumulator`.

## **CustomStateDataType**

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The default is `numericType([],16,15)`.

## **NumeratorStateDataType**

Numerator state word and fraction lengths

Specify the numerator state fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. Setting this property also sets the `DenominatorStateDataType` property to the same value. This property applies only when you set the `Structure` property to `Direct form I transposed`. The default is `Same as accumulator`.

## **CustomNumeratorStateDataType**

Custom numerator state word and fraction lengths

Specify the numerator state fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numericType([],16,15)`.

## **DenominatorStateDataType**

Denominator state word and fraction lengths

Specify the denominator state fixed-point data type as one of | Same as input | Same as accumulator | Custom |. Setting this property also sets the NumeratorStateDataType property to the same value. This property applies only when you set the Structure property to Direct form I transposed. The default is Same as accumulator.

## **CustomDenominatorStateDataType**

Custom denominator state word and fraction lengths

Specify the denominator state fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when you set the StateDataType property to Custom. The CustomNumeratorStateDataType and CustomDenominatorStateDataType properties must have the same word lengths. The default is numeric type ([ ], 16, 15).

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input | Same as accumulator | Custom |. The default is Same as accumulator.

## **CustomOutputDataType**

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when you set the OutputDataType property to Custom. The default is numeric type ([ ], 16, 15).

## Methods

clone	Create biquad filter object with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset states of biquad filter object
step	Filter input with biquad filter object

More “Analysis Methods for Filter System Objects” on page 2-2.

## Examples 1

Use a fourth order, lowpass biquadratic filter object with a normalized cutoff frequency of 0.4 to filter high frequencies from an input signal. Display the result as a power spectrum using the Spectrum Analyzer:

```
t = (0:1000)'/8e3;  
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t); % Input is 0.3 &  
                                     % 3kHz sinusoids  
hFromWS = dsp.SignalSource(xin, 100);  
hLog = dsp.SignalSink;  
  
[z,p,k] = ellip(4,1,60,.4); % Set up the filter
```

## dsp.BiquadFilter

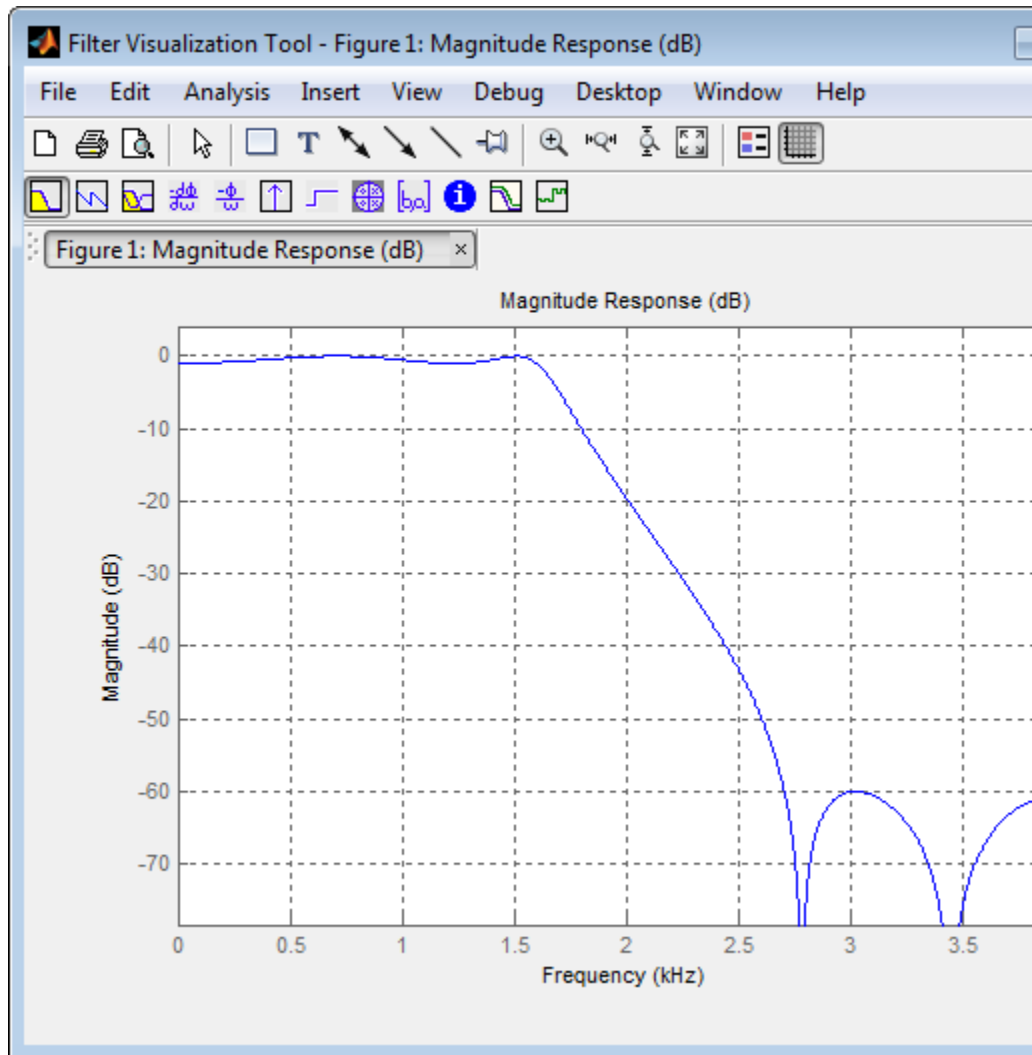

---

```
[s,g] = zp2sos(z,p,k);
hBqF=dsp.BiquadFilter('Structure','Direct form I', ...
    'SOSMatrix',s,'ScaleValues',g);

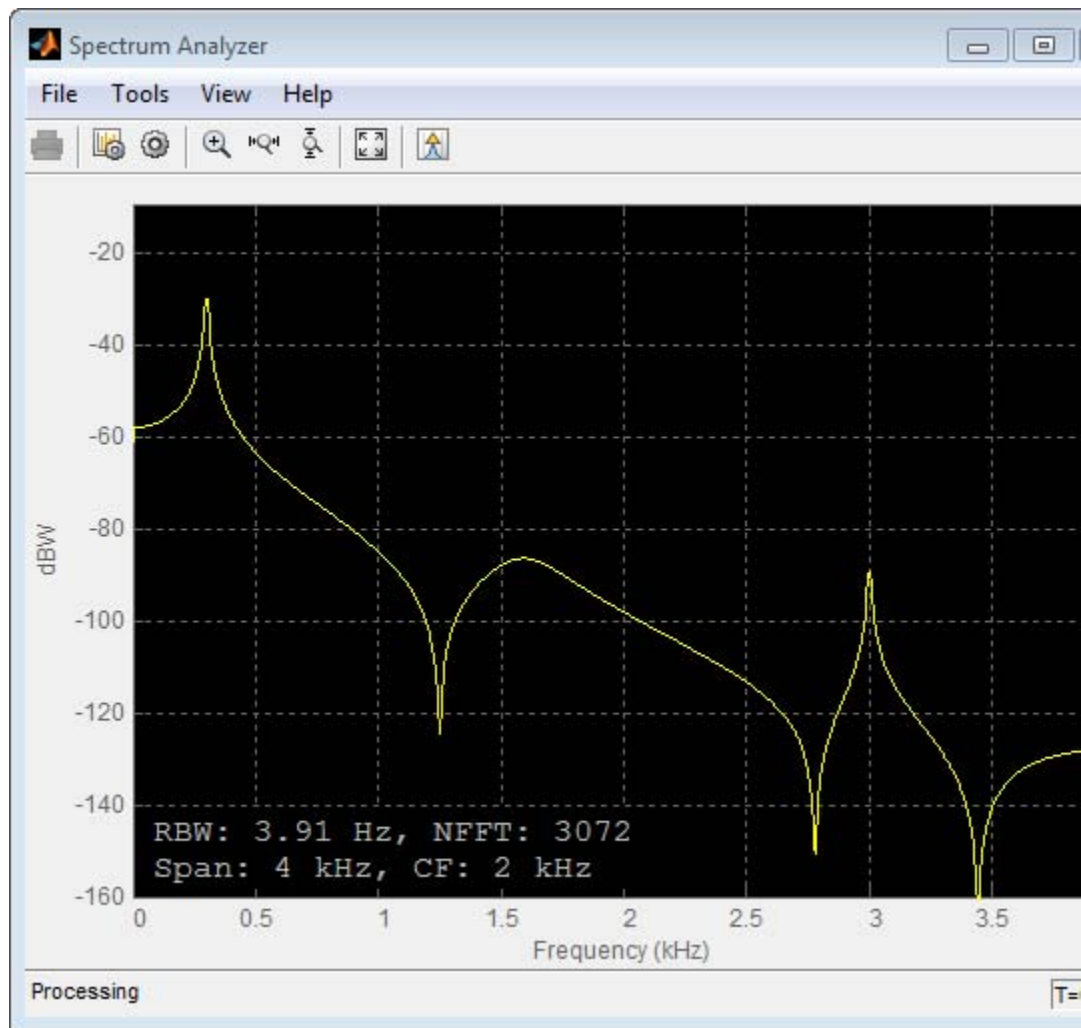

h = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'TwoSidedSpectrum',false,...
    'PowerUnits','dBW',...
    'YLimits', [-160 -10]);

while ~isDone(hFromWS)
    input = step(hFromWS);
    filteredOutput = step(hBqF,input);
    step(hLog,filteredOutput);
    step(h,filteredOutput)
end

filteredResult = hLog.Buffer;
fvtool(hBqF,'Fs',8000)
```

# dsp.BiquadFilter

2

Design and apply a lowpass biquad filter System object using design.

```
Hd = fdesign.lowpass('Fp,Fst,Ap,Ast',500,550,0.5,60,10000);  
D = design(Hd,'butter','systemobject',true)  
fvtool(D);
```

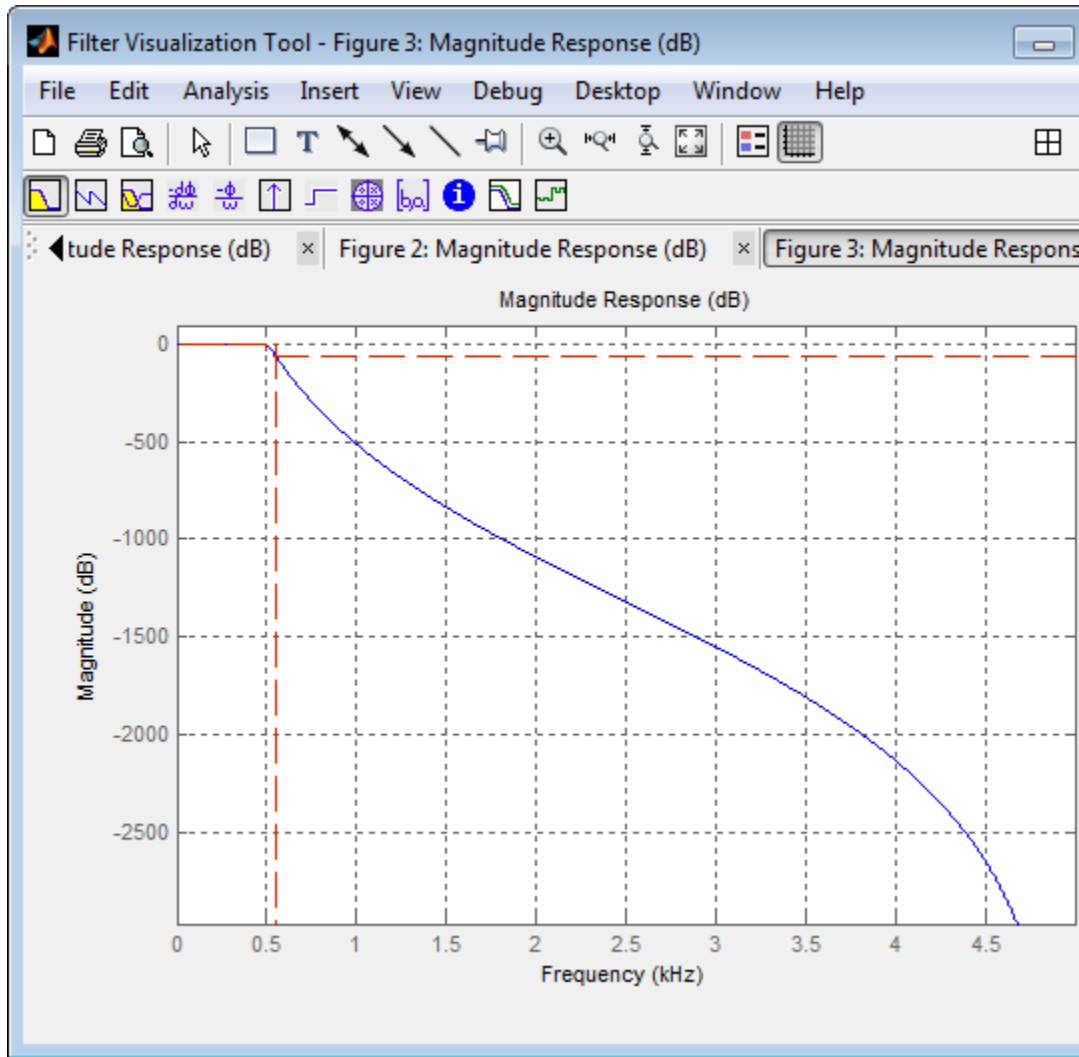

D =

System: dsp.BiquadFilter

Properties:

```
    Structure: 'Direct form II'  
    SOSMatrixSource: 'Property'  
    SOSMatrix: [42x6 double]  
    ScaleValues: [43x1 double]  
    InitialConditions: 0  
    OptimizeUnityScaleValues: true  
    FrameBasedProcessing: true
```

# dsp.BiquadFilter

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Biquad Filter block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source** – the biquad filter object does not accept `dfilt` objects as an `SOSMatrixSource`.
- **Action when the `a0` values of the SOS matrix are not one** – the biquad filter object assumes the zero-th-order denominator coefficient equals 1 regardless of the specified value. The biquad filter object does not support the `Error` or `Warn` options found in the corresponding block.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the `FrameBasedProcessing` Property of a System object” for more information.

## See Also

`dsp.DigitalFilter`

## **dsp.BiquadFilter.clone**

---

**Purpose** Create biquad filter object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a biquad filter object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

**Purpose**

Frequency response

**Syntax**

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

**Description**

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

# **dsp.BiquadFilter.fvtool**

---

**Purpose** Open filter visualization tool

**Syntax** `fvtool(H)`  
`fvtool(H, 'Arithmetic', ARITH, ...)`

**Description** `fvtool(H)` performs an analysis and computes the magnitude response of the filter System object H.

`fvtool(H, 'Arithmetic', ARITH, ...)` analyzes the filter System object H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.BiquadFilter.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**      `N = getNumOutputs(H)` returns the number of outputs, N, of the step method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Impulse response

**Syntax**  
`[h,t] = impz(H)`  
`[h,t] = impz(H,Name,Value)`  
`impz(H)`

**Description** `[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(H)` uses `FVTool` to plot the impulse response of the filter System object `H`.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

# **dsp.BiquadFilter.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the biquad filter object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Unwrapped phase response

**Syntax**

```
[phi,w] = phasez(H)  
[phi,w] = phasez(H,n)  
[phi,w] = phasez(H,Name,Value)  
phasez(H)
```

**Description**

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

# dsp.BiquadFilter.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Reset states of biquad filter object

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the biquad filter object,H, to the specified initial conditions. After the step method applies the biquad filter object to nonzero input data, the states may change. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

Example of resetting filter states:

```
n =0:20;
x = cos(pi/4*n)+sin(pi/2*n);
H = dsp.BiquadFilter;
y = step(H,x');
% Apply step method without invoking reset
y1 = step(H,x');
isequal(y,y1) % Returns a 0
% Reset filter states to zero
reset(H)
% Now invoke step method
y2 = step(H,x');
isequal(y,y2) % Returns a 1
```

# dsp.BiquadFilter.step

---

**Purpose** Filter input with biquad filter object

**Syntax**  
 $Y = \text{step}(H, X)$   
 $Y = \text{step}(H, X, \text{NUM}, \text{DEN})$   
 $Y = \text{step}(H, X, \text{NUM}, \text{DEN}, G)$

**Description**  $Y = \text{step}(H, X)$  filters the real or complex input signal  $X$ , and outputs the filtered values,  $Y$ . The biquad filter object filters each channel of the input signal over successive calls to the `step` method.

$Y = \text{step}(H, X, \text{NUM}, \text{DEN})$  filters the input using  $\text{NUM}$  as the numerator coefficients, and  $\text{DEN}$  as the denominator coefficients of the biquad filter.  $\text{NUM}$  must be a 3-by- $N$  numeric matrix and  $\text{DEN}$  must be a 2-by- $N$  numeric matrix, where  $N$  is the number of biquad filter sections. The object assumes that the first denominator coefficient of each section is 1. This configuration applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is `false`.

$Y = \text{step}(H, X, \text{NUM}, \text{DEN}, G)$  specifies the scale values,  $G$ , of the biquad filter.  $G$  must be a 1-by- $(N + 1)$  numeric vector, where  $N$  is the number of biquad filter sections. This configuration applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is `true`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Output, error, and weights using Block LMS adaptive algorithm
<b>Description</b>	<p>The <code>BlockLMSFilter</code> object computes output, error, and weights using the Block LMS adaptive algorithm.</p> <p>To compute the output, error, and weights:</p> <ol style="list-style-type: none"><li>1 Define and set up your adaptive FIR filter. See “Construction” on page 3-237.</li><li>2 Call <code>step</code> to compute the output, error, and weights according to the properties of <code>dsp.BlockLMSFilter</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H=dsp.BlockLMSFilter</code> returns an adaptive FIR filter, <code>H</code>, that filters the input signal and computes filter weights based on the Block Least Mean Squares (LMS) algorithm.</p> <p><code>H=dsp.BlockLMSFilter('PropertyName',PropertyValue,...)</code> returns an adaptive FIR filter, <code>H</code>, with each specified property set to the specified value.</p> <p><code>H=dsp.BlockLMSFilter(length,blocksize,'PropertyName',... PropertyValue,...)</code> returns an adaptive FIR filter, <code>H</code>, with the <code>Length</code> property set to <code>length</code>, the <code>BlockSize</code> property set to <code>blocksize</code>, and other specified properties set to the specified values.</p>
<b>Properties</b>	<p><b>Length</b></p> <p>Length of FIR filter weights vector</p> <p>Specify the length of the FIR filter weights vector as a positive integer scalar. The default is 32.</p> <p><b>BlockSize</b></p> <p>Number of samples acquired before weight adaptation</p> <p>Specify the number of samples of the input signal to acquire before the object updates the filter weights. The input frame length must be an integer multiple of the block size. The default is 32.</p>

## StepSizeSource

Source of adaptation step size

Choose to specify the adaptation step size factor as `Property` or `Input port`. The default is `Property`.

## StepSize

Adaptation step size

Specify the adaptation step size factor as a scalar, nonnegative numeric value. The default is `0.1`. This property applies only when you set the `StepSizeSource` property to `'Property'`. This property is tunable.

## LeakageFactor

Leakage factor used in Leaky LMS algorithm

Specify the leakage factor used in Leaky LMS algorithm as a scalar numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky LMS algorithm. The default is 1, providing no leakage in the adapting algorithm. This property is tunable.

## InitialWeights

Initial values of filter weights

Specify the initial values of the filter weights as a scalar or a vector of length equal to the `Length` property value. The default is 0.

## AdaptInputPort

Additional input to enable adaptation of filter weights.

Specify when the object should adapt the filter weights. By default, the value of this property is `false`, and the filter continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the `step` method. If the value of this input is nonzero, the filter continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

## WeightsResetInputPort

Additional input to enable weights reset

Specify whether the FIR filter can reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, a reset control input is provided to the `step` method, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the `step` method.

## WeightsResetCondition

Condition that triggers the resetting of filter weights

Specify the event to reset the filter weights as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The object resets the filter weights based on the values of this property and the reset input to the `step` method. This property applies only when you set the `WeightsResetInputPort` property to `true`. The default is `Non-zero`.

## WeightsOutputPort

Output filter weights

Set this property to `true` to output the adapted filter weights. The default is `true`.

## Methods

<code>clone</code>	Create adaptive block LMS filter object with same property values
<code>getNumInputs</code>	Number of expected inputs to <code>step</code> method
<code>getNumOutputs</code>	Number of outputs of <code>step</code> method
<code>isLocked</code>	Locked status for input attributes and nontunable properties

# dsp.BlockLMSFilter

---

release	Allow property value and input characteristics changes
reset	Reset internal states of adaptive FIR filter object
step	Filter inputs using Block LMS algorithm

## Examples

Remove noise using the Block LMS adaptive algorithm:

```
hblms = dsp.BlockLMSFilter(10, 5);
hblms.StepSize = 0.01;
hblms.WeightsOutputPort = false;
hfilt = dsp.DigitalFilter;
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10, [.5, .75]);
x = randn(1000,1); % Noise
d = step(hfilt, x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = step(hblms, x, d);
subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2), plot(err), title('Signal');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Block LMS Filter block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.LMSFilter](#) | [dsp.DigitalFilter](#)

**Purpose** Create adaptive block LMS filter object with same property values

**Syntax**

**Description** `C = clone(H)` creates a `BlockLMSFilter` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.BlockLMSFilter.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**       `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.BlockLMSFilter.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `BlockLMSFilter` object `H`.  
The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

# **dsp.BlockLMSFilter.reset**

---

**Purpose**            Reset internal states of adaptive FIR filter object

**Syntax**            reset(H)

**Description**        reset(H) sets the internal states of the BlockLMSFilter object H to their initial values.

## Purpose

Filter inputs using Block LMS algorithm

## Syntax

```
[Y,ERR,WTS] = step(H,X,D)
[Y,ERR] = step(H,X,D)
[...] = step(H,X,D,MU)
[...] = step(H,X,D,A)
[...] = step(H,X,D,R)
[Y,ERR,WTS] = step(H,X,D,MU,A,R)
```

## Description

`[Y,ERR,WTS] = step(H,X,D)` filters the input `X`, using `D` as the desired signal, and returns the filtered output in `Y`. The filter error is in `ERR`, and the estimated filter weights is in `WTS`. The filter weights update once for every block of data that the object processes.

`[Y,ERR] = step(H,X,D)` returns only the filtered output in `Y` and the filter error in `ERR`, when the `WeightsOutputPort` property is `false`.

`[...] = step(H,X,D,MU)` uses `MU` as the step size, when you set the `StepSizeSource` property to `Input port`.

`[...] = step(H,X,D,A)` uses `A` as the adaptation control, when you set the `AdaptInputPort` property to `true`. When `A` is nonzero, the filter continuously updates the filter weights. When `A` is zero, the filter weights remain constant.

`[...] = step(H,X,D,R)` uses `R` as a reset signal, when you set the `WeightsResetInputPort` property to `true`. Use the `WeightsResetCondition` property to set the reset trigger condition. If a reset event occurs, the filter resets the filter weights to their initial values.

`[Y,ERR,WTS] = step(H,X,D,MU,A,R)` filters input `X`, using `D` as the desired signal, `MU` as the step size, `A` as the adaptation control, and `R` as the reset signal. The objects returns the filtered output in `Y`, the filter error in `ERR`, and the adapted filter weights in `WTS`. Set the properties appropriately to provide all possible inputs.

## **dsp.BlockLMSFilter.step**

---

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Buffer input signal
<b>Description</b>	<p>The Buffer object buffers an input signal. The number of samples per channel in the input must equal the difference between the output buffer size and buffer overlap (i.e., <code>Length - OverlapLength</code>). When you set <code>FrameBasedProcessing</code> to <code>true</code>, the number of samples per channel equals the number of rows in the input. If you set <code>FrameBasedProcessing</code> to <code>false</code>, the number of samples per channel equals 1.</p> <p>To buffer an input signal:</p> <ol style="list-style-type: none"><li>1 Define and set up your buffer System object. See “Construction” on page 3-249.</li><li>2 Call <code>step</code> to buffer the input according to the properties of <code>dsp.Buffer</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H=dsp.Buffer</code> returns a buffer System object, <code>HBUFF</code>, used to buffer input signals with overlap.</p> <p><code>H=dsp.Buffer('PropertyName',PropertyValue,...)</code> returns a buffer object, <code>H</code>, with each specified property set to the specified value.</p> <p><code>H=dsp.Buffer(LEN,OVRLAP,ICS,'PropertyName',...PropertyVaue,...)</code> returns a buffer object, <code>H</code>, with <code>Length</code> property set to <code>LEN</code>, <code>OverlapLength</code> property set to <code>OVRLAP</code>, <code>InitialConditions</code> property set to <code>ICS</code> and other specified properties set to the specified values.</p>
<b>Properties</b>	<p><b>Length</b></p> <p>Number of samples to buffer</p> <p>Specify the number of consecutive samples from each input channel to buffer. You can set this property to any scalar integer greater than 0 of MATLAB built-in numeric data type. The default is 64.</p>

## OverlapLength

Amount of overlap between outputs

Specify the number of samples by which consecutive output frames overlap. You can set this property to any scalar integer greater than or equal to 0 of MATLAB built-in numeric data type. The default is 0.

## InitialConditions

Initial output

Specify the value of the object's initial output for cases of nonzero latency as a scalar, vector, or matrix. The default is 0.

## FrameBasedProcessing

Enable frame-based processing

If this property is set to `true`, each column of the input is treated as a separate channel for buffering. If the value of this property is `false`, each element of the input is treated as a separate channel. The default is `true`.

## Methods

<code>clone</code>	Create instance of an object with the same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes

reset	Reset the internal states of a System object
step	Buffer input signal based on past values

## Examples

Create a buffer of 256 samples with 128 sample overlap:

```
hreader=dsp.SignalSource(randn(1024,1),128);
hbuff=dsp.Buffer(256,128);

for i=1:8
    y=step(hbuff,step(hreader));
    % y is of length 256 with 128 samples
    % from previous input
end
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Buffer block reference page. The object properties correspond to the block properties, except as noted.

This object processes inputs as frames or as samples by setting the `FrameBasedProcessing` property. The corresponding block has a temporary **Treat Mx1 and unoriented sample-based signals as** parameter with `One channel` option for frame behavior and `M channels` option for sample behavior. See the Buffer block reference page and “Set the `FrameBasedProcessing` Property of a System object” for more information.

## See Also

`dsp.DelayLine` | `dsp.Delay`

# **dsp.Buffer.clone**

---

**Purpose** Create instance of an object with the same property values

**Syntax** `C=clone(H)`

**Description** `C=clone(H)` creates a Buffer System object C, with the same property values as H.

The `clone` method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.Buffer.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the Buffer System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.Buffer.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset the internal states of a System object

**Syntax** reset(H)

**Description** reset(H) resets the internal states of buffer to their initial values.

For many System objects, this method is a no-op. Objects that have internal states will describe in their help what the reset method does for that object.

The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

# dsp.Buffer.step

---

**Purpose** Buffer input signal based on past values

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  creates output  $Y$  based on current input and stored past values of  $X$  . Output length equals the `Length` property.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Estimate of autoregressive (AR) model parameters using Burg method
<b>Description</b>	<p>The BurgAREstimator object computes the estimate of the autoregressive (AR) model parameters using the Burg method.</p> <p>To compute the estimate of the AR model parameters:</p> <ol style="list-style-type: none"><li>1 Define and set up your System object. See “Construction” on page 3-259.</li><li>2 Call step to compute the estimate according to the properties of dsp.BurgAREstimator. The behavior of step is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p>H = dsp.BurgAREstimator returns a Burg BurgAREstimator System object, H, that performs parametric AR estimation using the Burg maximum entropy method.</p> <p>H = dsp.BurgAREstimator('PropertyName',PropertyValue,...) returns a Burg AR estimator object, H, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>AOutputPort</b></p> <p>Enable output of polynomial coefficients</p> <p>Set this property to true to output the polynomial coefficients, A, of the AR model the object computes. The default is true. Either the AOutputPort property, the KOutputPort property, or both must be true.</p> <p><b>KOutputPort</b></p> <p>Enable output of reflection coefficients</p> <p>Set this property to true to output the reflection coefficients, K, for the AR model that the object computes. The default is false. Either the AOutputPort property, the KOutputPort property, or both must be true.</p> <p><b>EstimationOrderSource</b></p>

# dsp.BurgAREstimator

---

Source of estimation order

Specify how to determine estimator order as Auto or Property. When you set this property to Auto, the object assumes the estimation order is one less than the length of the input vector. When you set this property to Property, the value in EstimationOrder is used. The default is Auto.

## EstimationOrder

Order of AR model

Set the AR model estimation order to a real positive integer. This property applies when you set the EstimationOrderSource to Property. The default is 4.

## Methods

clone	Create Burg AR Estimator object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Normalized estimate of AR model parameter

## Examples

Use the Burg AR Estimator System object to estimate the parameters of an AR model:

```
rng default; % Use default random number generator and seed
noise = randn(100,1); % Normalized white Gaussian noise
x = filter(1,[1 1/2 1/3 1/4 1/5],noise);
hburgarest = dsp.BurgAREstimator(...
```

```
'EstimationOrderSource', 'Property', ...  
'EstimationOrder', 4);  
[a, g] = step(hburgarest, x);  
x_est = filter(g, a, x);  
plot(1:100,[x x_est]);  
title('Original and estimated signals');  
legend('Original', 'Estimated');
```

# dsp.BurgAREstimator

---

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg AR Estimator block reference page. The object properties correspond to the block parameters, except:

**Output(s)** block parameter corresponds to the AOutputPort and the KOutputPort object properties.

## See Also

`dsp.LevinsonSolver`

**Purpose** Create Burg AR Estimator object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a BurgAREstimator System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.BurgAREstimator.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.BurgAREstimator.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.BurgAREstimator.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the BurgAREstimator System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.BurgAREstimator.step

---

**Purpose** Normalized estimate of AR model parameter

**Syntax**  
[A,G] = step(H,X)  
[K,G] = step(H,X)  
[A,K,G] = step(H,X)

**Description** [A,G] = step(H,X) computes the normalized estimate of the AR model parameters to fit the input, X, in the least square sense. The input X must be a column vector. Output A is a column vector that contains the normalized estimate of the AR model polynomial coefficients in descending powers of z. The scalar G is the AR model gain.

[K,G] = step(H,X) returns K, a column vector containing the AR model reflection coefficients when you set the KOutputPort property to true and the AOutputPort property to false.

[A,K,G] = step(H,X) returns the AR model polynomial coefficients A, reflection coefficients K, and the scalar gain G when the AOutputPort and KOutputPort properties are both true.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

## Purpose

Parametric spectral estimate using Burg method

## Description

The `BurgSpectrumEstimator` object computes a parametric spectral estimate of the input using the Burg method. The object fits an autoregressive (AR) model to the signal by minimizing the forward and backward prediction errors (via least-squares). The AR parameters are constrained to satisfy the Levinson-Durbin recursion.

To compute the parametric spectral estimate of the input:

- 1 Define and set up your System object. See “Construction” on page 3-269.
- 2 Call `step` to compute the estimate according to the properties of `dsp.BurgSpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.BurgSpectrumEstimator` returns an object, `H`, that estimates the power spectral density (PSD) of the input frame using the Burg method.

`H =`

`dsp.BurgSpectrumEstimator('PropertyName',PropertyValue,...)` returns a spectrum estimator, `H`, with each specified property set to the specified value.

## Properties

### EstimationOrderSource

Source of estimation order

Specify the source of the estimation order as `Auto` or `Property`. If you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. The default value is `Property`.

### EstimationOrder

Order of AR model

# dsp.BurgSpectrumEstimator

---

Specify the order of AR model as a real positive integer. This property applies only when you set the `EstimationOrderSource` property to `Property`. The default value is 6.

## **FFTLengthSource**

Source of FFT length

Specify the source of the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the object assumes the FFT length is one more than the estimation order. When you set this property to `Property`, the `FFTLength` property value must be an integer power of two.

## **FFTLength**

FFT length as power-of-two integer value

Specify the FFT length as a power-of-two numeric scalar. This property applies when you set the `FFTLengthSource` property to `Property`. The default value is 256.

## **SampleRate**

Sample rate of input time series

Specify the sampling rate of the original input time series as a positive numeric scalar in hertz. The default value is 1.

## **Methods**

<code>clone</code>	Create estimator object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
step	Estimate of power spectral density

## Examples

Estimate PSD using the Burg method:

```
x = randn(100,1);
h = dsp.BurgSpectrumEstimator('EstimationOrder', 4);
y = filter(1,[1 1/2 1/3 1/4 1/5],x); % Fourth order AR filter
p = step(h,y); % Uses default FFT length of 256

plot([0:255]/256, p);
title('Burg Method Spectral Density Estimate');
xlabel('Normalized frequency'); ylabel('Power/frequency');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg Method block reference page. The object properties correspond to the block properties.

## See Also

[dsp.BurgAREstimator](#) | [dsp.LevinsonSolver](#)

# **dsp.BurgSpectrumEstimator.clone**

---

**Purpose** Create estimator object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `BurgSpectrumEstimator` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

# dsp.BurgSpectrumEstimator.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.BurgSpectrumEstimator.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `BurgSpectrumEstimator` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.BurgSpectrumEstimator.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Estimate of power spectral density

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  outputs  $Y$ , a spectral estimate of input  $X$ , using the Burg method.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.CepstralToLPC

---

<b>Purpose</b>	Convert cepstral coefficients to linear prediction coefficients						
<b>Description</b>	<p>The <code>CepstralToLPC</code> object converts cepstral coefficients to linear prediction coefficients (LPC).</p> <p>To convert cepstral coefficients to LPC:</p> <ol style="list-style-type: none"><li>1 Define and set up your System object. <code>getNumOutputs</code>	Number of outputs of the method						

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	LPC coefficients from column of cepstral coefficients

## Examples

Convert cepstral coefficients to linear prediction coefficients (LPC):

```
cc=[0 0.9920 0.4919 0.3252 0.2418 , ...  
0.1917 0.1583 0.1344 0.1165 0.0956]';  
hcc2lpc=dsp.CepstralToLPC;  
a=step(hcc2lpc,cc);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the [LPC to/from Cepstral Coefficients](#) block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.LPCToCepstral](#) | [dsp.LSFToLPC](#) | [dsp.RCToLPC](#)

# **dsp.CepstralToLPC.clone**

---

**Purpose** Create cepstral to LPC object with same property values

**Syntax** `C=clone(H)`

**Description** `C=clone(H)` creates a `CepstralToLPC` System object `C`, with the same property values as `H`.

The `clone` method creates a new unlocked object.

**Purpose**                    Number of expected inputs to the `step` method

**Syntax**                    `N = getNumInputs(H)`

**Description**              `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.CepstralToLPC.getNumOutputs**

---

**Purpose**            Number of outputs of the `step` method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `CepstralToLPC` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.CepstralToLPC.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** LPC coefficients from column of cepstral coefficients

**Syntax** `A=step(H,CC)`  
`[A,P]=step(H,CC)`

**Description** `A=step(H,CC)` computes the linear prediction coefficients (LPC) coefficients, `A`, from the columns of cepstral coefficients, `CC`.  
`[A,P]=step(H,CC)` converts the columns of the cepstral coefficients `CC` to the LPCs and returns the prediction error power `P` when the `PredictionErrorOutputPort` property is true.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.Chirp

---

**Purpose** Generate swept-frequency cosine (chirp) signal

**Description** The Chirp object generates a swept-frequency cosine (chirp) signal.  
To generate the chirp signal:

- 1 Define and set up your chirp signal. See “Construction” on page 3-286.
- 2 Call `step` to generate the signal according to the properties of `dsp.Chirp`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.Chirp` returns a chirp signal, `H`, with unity amplitude.  
`H = dsp.Chirp('PropertyName',PropertyValue,...)` returns a chirp signal, `H`, with each specified property set to the specified value.

## Properties

### Type

Frequency sweep type

Specify the frequency sweep type as `Swept cosine`, `Linear`, `Logarithmic`, or `Quadratic`. This property specifies how the output instantaneous frequency sweep varies over time. The default value is `Linear`.

### SweepDirection

Sweep direction

Specify the sweep direction as either `Unidirectional` or `Bidirectional`. The default value is `Unidirectional`.

### InitialFrequency

Initial frequency (hertz)

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the initial instantaneous frequency in hertz of the output chirp signal. When you set the `Type` property to `Logarithmic`, the value of this property is one

less than the actual initial frequency of the sweep. Also, when the sweep is logarithmic, the initial frequency must be less than the target frequency, specified by the `TargetFrequency` property. This property is tunable. The default value is 1000.

### **TargetFrequency**

Target frequency (hertz)

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the instantaneous frequency of the output signal in hertz at the target time. When you set the `Type` property to `Swept Cosine`, the target frequency is the instantaneous frequency of the output at half the target time. Also, when the sweep is logarithmic, the target frequency must be greater than the initial frequency, specified by the `InitialFrequency` property. This property is tunable. The default value is 4000.

### **TargetTime**

Target time

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the target time in seconds at which the target frequency is reached. When you set the `Type` property to `Swept cosine`, this property specifies the time at which the sweep reaches  $2f_{tgt} - f_{init}$  Hz, where  $f_{tgt}$  is the `TargetFrequency` and  $f_{init}$  is the `InitialFrequency`. The target time should not be greater than the sweep time, specified by the `SweepTime` property. This property is tunable. The default value is 1.

### **SweepTime**

Sweep time

When you set the `SweepDirection` property to `Unidirectional`, the sweep time in seconds is the period of the output frequency sweep. When you set the `SweepDirection` property to `Bidirectional`, the sweep time is half the period of the output

frequency sweep. The sweep time should be no less than the target time, specified by the `TargetTime`. This property must be a positive numeric scalar and is tunable. The default value is 1.

## **InitialPhase**

Initial phase

Specify initial phase of the output in radians at time  $t = 0$ . This property is tunable. The default value is 0.

## **SampleRate**

Sample rate

Specify the sampling rate of the output in hertz as a positive numeric scalar. The default value is 8000.

## **SamplesPerFrame**

Samples per output frame

Specify the number of samples to buffer into each output as a positive integer. The default value is 1.

## **OutputDataType**

Output data type

Specify the output data type as `double` or `single`. The default value is `double`.

## **Methods**

<code>clone</code>	Create chirp object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties

---

release	Allow property value and input characteristics changes
reset	Reset internal states of chirp object
step	Generate chirp signal

## Examples

Generate a bidirectional swept chirp signal:

```
hchirp = dsp.Chirp(...  
    'SweepDirection', 'Bidirectional', ...  
    'TargetFrequency', 25, ...  
    'InitialFrequency', 0,...  
    'TargetTime', 1, ...  
    'SweepTime', 1, ...  
    'SamplesPerFrame', 400, ...  
    'SampleRate', 400);  
plot(step(hchirp));
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Chirp block reference page. The object properties correspond to the block parameters.

## See Also

dsp.SineWave

## **dsp.Chirp.clone**

---

**Purpose** Create chirp object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a Chirp object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

**Purpose**                    Number of expected inputs to step method

**Syntax**                    `N = getNumInputs(H)`

**Description**              `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.Chirp.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the Chirp object H.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.Chirp.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset internal states of chirp object

**Syntax** reset(H)

**Description** reset(H) sets the internal states of the Chirp object H to their initial values. After you reset H, the frequency sweep restarts from the beginning.

# dsp.Chirp.step

---

**Purpose** Generate chirp signal

**Syntax**  $Y = \text{step}(H)$

**Description**  $Y = \text{step}(H)$  returns a swept-frequency cosine output,  $Y$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Decimate input using Cascaded Integrator-Comb filter
<b>Description</b>	<p>The <code>CICDecimator</code> object decimates inputs using a Cascaded Integrator-Comb filter. Inputs and outputs to the object have signed fixed-point data types. You must have a Fixed-Point Designer license to use the <code>CICDecimator System</code> object.</p> <p>To decimate inputs using a CIC filter:</p> <ol style="list-style-type: none"><li>1 Define and set up your System object. See “Construction” on page 3-297.</li><li>2 Call <code>step</code> to decimate the input according to the properties of <code>dsp.CICDecimator</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.CICDecimator</code> returns a <code>CICDecimator System</code> object, <code>H</code>, that you can use to decimate the input with a cascaded integrator-comb (CIC) decimation filter.</p> <p><code>H = dsp.CICDecimator('PropertyName',PropertyValue,...)</code> returns a <code>CICDecimator</code> object, <code>H</code>, with each specified property set to the value you specify.</p> <p><code>H = dsp.CICDecimator(R,M,N,'PropertyName', PropertyValue, ...)</code> returns a <code>CICDecimator</code> object, <code>H</code>, with the <code>DecimationFactor</code> property set to <code>R</code>, the <code>DifferentialDelay</code> property set to <code>M</code>, the <code>NumSections</code> property set to <code>N</code>, and any other specified properties set to the values you specify.</p>
<b>Properties</b>	<p><b>DecimationFactor</b></p> <p>Decimation factor of filter</p> <p>Specify a positive integer amount by which the object decimates the input. The default is 2.</p> <p><b>DifferentialDelay</b></p> <p>Differential delay of filter comb sections</p>

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is 1.

## **NumSections**

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is 2.

## **FixedPointDataType**

Fixed-point property setting

Specify the fixed-point data type as one of | Full precision | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths |. The default is Full precision. When you set this property to:

- Full precision – the CICDecimator object automatically determines the word and fraction lengths of the filter sections and output.
- Minimum section word length – the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the OutputWordLength.
- Specify word lengths – the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the OutputWordLength and the SectionWordLengths properties.
- Specify word and fraction lengths, – the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the OutputFractionLength, OutputWordLength, SectionFractionLengths, and SectionWordLengths properties.

## **SectionWordLengths**

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length  $2 \times \text{NumSections}$ . This property applies only when you set the `FixedPointDataType` property to either `Specify word lengths` or `Specify word and fraction lengths`. The default is [16 16 16 16].

## SectionFractionLengths

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length  $2 \times \text{NumSections}$ . This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is 0.

## OutputWordLength

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the `FixedPointDataType` property to `Minimum section word lengths`, `Specify word lengths`, or `Specify word and fraction lengths`. The default is 32.

## OutputFractionLength

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is 0.

## Methods

<code>clone</code>	Create CIC Decimator object with same property values
<code>freqz</code>	Frequency response

# dsp.CICDecimator

---

fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset filter states of CIC decimator object
step	Decimate input using Cascaded Integrator-Comb filter

More “Analysis Methods for Filter System Objects” on page 2-2.

## Examples

Decimate signal by a factor of 4 (i.e., downsample the signal from 44.1 kHz to 11.025 kHz):

```
hciddec = dsp.CICDecimator(4);  
%   DecimationFactor = 4  
%   default NumSections = 2 and DifferentialDelay = 1  
hciddec.FixedPointDataType = 'Minimum section word lengths';  
hciddec.OutputWordLength = 16;  
  
% Create fixed-point sinusoidal input signal  
Fs = 44.1e3;           % Original sampling frequency  
n = (0:1023)';        % 1024 samples, 0.0232 sec signal  
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);  
  
% Create SignalSource System object
```

```
hsr = dsp.SignalSource(x, 64);

% Decimate output with 16 samples per frame
y = zeros(16,16);
for ii=1:16
    y(ii,:) = step(hcicdec, step( hsr ));
end

% Plot first frame of original and decimated signals.
% Output latency is 2 samples.
gainCIC = ...
    (hcicdec.DecimationFactor*hcicdec.DifferentialDelay)^hcicdec.NumSec;
stem(n(1:56)/Fs, double(x(4:59))); hold on;
stem(n(1:14)/(Fs/hcicdec.DecimationFactor),double(y(1,3:end))/gainCIC);
xlabel('Time (sec)');ylabel('Signal Amplitude');
legend('Original signal', 'Decimated signal', 'location', 'north');
hold off;
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CIC Decimation block reference page. The object properties correspond to the block properties, except:

- The **Rate options** block parameter is not supported by the dsp.CICDecimator object.

## See Also

dsp.CICInterpolator | dsp.FIRDecimator

## **dsp.CICDecimator.clone**

---

**Purpose** Create CIC Decimator object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `CICDecimator System` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with un-initialized states.

**Purpose** Frequency response

**Syntax**  
`[h,w] = freqz(H)`  
`[h,w] = freqz(H,n)`  
`[h,w] = freqz(H,Name,Value)`  
`freqz(H)`

**Description** `[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

# **dsp.CICDecimator.fvtool**

---

**Purpose** Open filter visualization tool

**Syntax** `fvtool(H)`  
`fvtool(H, 'Arithmetic', ARITH, ...)`

**Description** `fvtool(H)` performs an analysis and computes the magnitude response of the filter System object H.

`fvtool(H, 'Arithmetic', ARITH, ...)` analyzes the filter System object H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

**Purpose** Number of expected inputs to step method

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

## **dsp.CICDecimator.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Impulse response

**Syntax**  
`[h,t] = impz(H)`  
`[h,t] = impz(H,Name,Value)`  
`impz(H)`

**Description** `[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(H)` uses `FVTool` to plot the impulse response of the filter System object `H`.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

# dsp.CICDecimator.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the CICDecimator System object H.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Unwrapped phase response

**Syntax**

```
[phi,w] = phasez(H)  
[phi,w] = phasez(H,n)  
[phi,w] = phasez(H,Name,Value)  
phasez(H)
```

**Description**

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

# dsp.CICDecimator.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset filter states of CIC decimator object

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the CICDecimator System object H to zero.

## dsp.CICDecimator.step

---

**Purpose** Decimate input using Cascaded Integrator-Comb filter

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  decimates the fixed-point input  $X$  to produce a fixed-point output  $Y$  using the `CICDecimator` System object  $H$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Purpose

Interpolate signal using Cascaded Integrator-Comb filter

## Description

The `CICInterpolator` object interpolates inputs using a Cascaded Integrator-Comb (CIC) filter. Inputs and outputs to the object have signed fixed-point data types. You must have a Fixed-Point Designer license to use the `CICInterpolator` System object.

To interpolate inputs using a CIC filter:

- 1 Define and set up your System object. See “Construction” on page 3-313.
- 2 Call `step` to interpolate the input according to the properties of `dsp.CICInterpolator`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.CICInterpolator` returns a System object, `H`, that you can use to interpolate the input with a cascaded integrator-comb (CIC) interpolation filter.

`H = dsp.CICInterpolator('PropertyName',PropertyValue,...)` returns a CIC interpolation object, `H`, with each specified property set to the value you specify.

`H = dsp.CICInterpolator(R,M,N,'PropertyName',PropertyValue,...)` returns a `CICInterpolator` object, `H`, with the `InterpolationFactor` property set to `R`, the `DifferentialDelay` property set to `M`, the `NumSections` property set to `N`, and other specified properties set to the values you specify.

## Properties

### InterpolationFactor

Interpolation factor of filter

Specify a positive integer amount by which the object interpolates the input signal. The default is 2.

### DifferentialDelay

Differential delay of filter comb sections

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is 1.

## **NumSections**

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is 2.

## **FixedPointDataType**

Fixed-point property setting

Specify the fixed-point data type as one of | Full precision | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths |. The default is Full precision. When you set this property to:

- **Full precision** – the CICInterpolator object automatically determines the word and fraction lengths of the filter sections and output.
- **Minimum section word length** – the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the OutputWordLength.
- **Specify word lengths** – the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the OutputWordLength and the SectionWordLengths properties.
- **Specify word and fraction lengths** – the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the OutputFractionLength, OutputWordLength, SectionFractionLengths, and SectionWordLengths properties.

## **SectionWordLengths**

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length  $2 \times \text{NumSections}$ . This property applies only when you set the `FixedPointDataType` property to `Specify word lengths` or `Specify word and fraction lengths`. The default is [16 16 16 16].

## **SectionFractionLengths**

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length  $2 \times \text{NumSections}$ . This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is 0.

## **OutputWordLength**

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the `FixedPointDataType` property to `Minimum section word lengths`, `Specify word lengths`, or `Specify word and fraction lengths`. The default is 32.

## **OutputFractionLength**

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is 0.

# dsp.CICInterpolator

---

## Methods

clone	Create CIC Interpolator object with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset internal states of CIC Interpolator object
step	Interpolate signal using Cascaded Integrator-Comb filter

More “Analysis Methods for Filter System Objects” on page 2-2.

## Examples

Interpolate signal by a factor of 2 (upsample the signal from 22.05 kHz to 44.1 kHz):

```
hcicint = dsp.CICInterpolator(2);  
% default NumSections = 2, DifferentialDelay = 1  
  
% Create fixed-point sinusoidal input signal  
Fs = 22.05e3; % Original sampling frequency  
n = (0:511)'; % 512 samples, 0.0113 sec signal  
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

```
% Create SignalSource System object
hsr = dsp.SignalSource(x, 32);

% Interpolate output with 64 samples per frame
y = zeros(16,64);
for ii=1:16
    y(ii,:) = step(hcicint,step( hsr ));
end

% Plot first frame of original and interpolated signals.
% Output latency is 2 samples.
gainCIC = ...
    (hcicint.InterpolationFactor*hcicint.DifferentialDelay)...
    ^hcicint.NumSections/hcicint.InterpolationFactor;
stem(n(1:31)/Fs, double(x(1:31)), 'r', 'filled'); hold on;
stem(n(1:61)/(Fs*hcicint.InterpolationFactor), ...
    double(y(1,4:end))/gainCIC, 'b');
xlabel('Time (sec)');ylabel('Signal Amplitude');
legend('Original signal', 'Interpolated signal',...
    'location', 'north');
hold off;
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CIC Interpolation block reference page. The object properties correspond to the block properties, except:

- The **Framing** block parameter is not supported by the dsp.CICInterpolator object. The object always maintains the input frame rate.
- The **Rate options** block parameter is not supported by the dsp.CICInterpolator object.
- The **Input processing** block parameter is not supported by the dsp.CICInterpolator object.

# **dsp.CICInterpolator**

---

- The object does not have a property that allows you to specify the source of the coefficients. The object cannot import coefficients from an `mfilt` object.

## **See Also**

`dsp.CICDecimator` | `dsp.FIRInterpolator`

**Purpose** Create CIC Interpolator object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `CICInterpolator System` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with un-initialized states.

# dsp.CICInterpolator.freqz

---

**Purpose** Frequency response

**Syntax** `[h,w] = freqz(H)`  
`[h,w] = freqz(H,n)`  
`[h,w] = freqz(H,Name,Value)`  
`freqz(H)`

**Description** `[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

**Purpose** Open filter visualization tool

**Syntax** `fvtool(H)`  
`fvtool(H, 'Arithmetic', ARITH, ...)`

**Description** `fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H, 'Arithmetic', ARITH, ...)` analyzes the filter System object `H`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

# dsp.CICInterpolator.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.CICInterpolator.impz

---

**Purpose** Impulse response

**Syntax** `[h,t] = impz(H)`  
`[h,t] = impz(H,Name,Value)`  
`impz(H)`

**Description** `[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(H)` uses `FVTool` to plot the impulse response of the filter System object `H`.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `CICInterpolator` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.CICInterpolator.phasez

---

**Purpose** Unwrapped phase response

**Syntax**

```
[phi,w] = phasez(H)  
[phi,w] = phasez(H,n)  
[phi,w] = phasez(H,Name,Value)  
phasez(H)
```

**Description**

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

## **dsp.CICInterpolator.reset**

---

**Purpose**            Reset internal states of CIC Interpolator object

**Syntax**            reset(H)

**Description**       reset(H) resets the internal states of the CICInterpolator System object H to zero.

**Purpose** Interpolate signal using Cascaded Integrator-Comb filter

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  interpolates the fixed-point input  $X$  to produce a fixed-point output  $Y$  using the `CICInterpolator` System object  $H$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.Convolver

---

**Purpose** Convolution of two inputs

**Description** The `Convolver` computes the convolution of two inputs.

To compute the convolution of two inputs:

- 1 Define and set up your convolver. See “Construction” on page 3-330.
- 2 Call `step` to compute the convolution according to the properties of `dsp.Convolver`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.Convolver` returns a convolver object, `H`, that convolves two inputs. For N-D arrays, the convolver computes the convolution column-wise. For arrays, the inputs must have an equal number of columns. If one input is a vector and the other is an N-D array, the convolver computes the convolution of the vector with each column of the N-D array. Convolver inputs of length  $N$  and  $M$  results in a sequence of length  $N+M-1$ . Convolver matrices of size  $M$ -by- $N$  and  $P$ -by- $N$  results in a matrix of size  $(M+P-1)$ -by- $N$ .

`H = dsp.Convolver('PropertyName',PropertyValue, ...)` returns a convolver object, `H`, with each property set to the specified value.

**Properties** **Method**

Domain for computing convolutions

Specify the domain in which the convolver performs the convolutions as `Time Domain`, `Frequency Domain`, or `Fastest`. Computing convolutions in the time domain minimizes memory use. Computing convolutions in the frequency domain may require fewer computations depending on the input length. If the value of this property is `Fastest`, the object computes convolutions in the domain which minimizes the number of computations. The default is `Time Domain`.

## Fixed-Point Properties

### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

### ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

### CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([],32,30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numericType([],16,15)`.

## Methods

<code>clone</code>	Create convolver object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Convolution of inputs

## Examples

Convolution of two rectangular sequences:

```
hconv = dsp.Convolver;  
x = ones(10,1);  
y = step(hconv, x, x);  
% Result is a triangular sequence  
plot(y);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolution block reference page. The object properties correspond to the block parameters.

## See Also

`dsp.Autocorrelator` | `dsp.Crosscorrelator`

## **dsp.Convolver.clone**

---

**Purpose** Create convolver object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a convolver object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.Convolver.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** isLocked(H)

**Description** isLocked(H) returns the locked state of the convolver object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.Convolver.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Convolution of inputs

**Syntax**  $Y = \text{step}(H,A,B)$

**Description**  $Y = \text{step}(H,A,B)$  convolves the inputs A and B.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.Counter

---

**Purpose** Count up or down through specified range of numbers

**Description** The Counter object counts up or down through a specified range of numbers.

To count up or down through a specified range of numbers:

- 1 Define and set up your counter. See “Construction” on page 3-340.
- 2 Call `step` to count up or down according to the properties of `dsp.Counter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.Counter` returns a counter System object, `H`, that counts up when the input is nonzero.

`H = dsp.Counter('PropertyName',PropertyValue,...)` returns a counter System object, `H`, with each specified property set to the specified value.

## Properties

### Direction

Count up or down

Specify the counter direction as Up or Down. The default is Up. This property is tunable.

### CountEventInputPort

Add input to specify a count event

Set this property to `true` to enable a count event input for the internal counter. The internal counter increments or decrements whenever the count event input satisfies the condition you specify in the `CountEventCondition` property. When you set this property to `false`, the internal counter is free running, that is, the counter increments or decrements on every call to the `step` method. The default is `true`.

### CountEventCondition

Condition that increments, decrements, or resets internal counter

Specify the event at the count event input that increments or decrements the counter as `Rising edge`, `Falling edge`, `Either edge` or `Non-zero`.

If you set the `ResetInputPort` and `CountEventInputPort` properties to `true`, the counter is reset when the event you specify for the `CountEventCondition` occurs. This property applies only when you set the `CountEventInputPort` property to `true`.

## **CounterSizeSource**

Source of counter size data type

Specify the source of the counter size data type as `Property` or `Input port`. The default is `Property`.

## **CounterSize**

Range of integer values to count through

Specify the range of integer values to count through before recycling to zero as `8 bits`, `16 bits`, `32 bits` or `Maximum`. The default is `Maximum`.

## **MaximumCount**

Counter's maximum value

Specify the counter's maximum value as a numeric scalar value. This property applies only when you set the `CounterSizeSource` property to `Property` and the `CounterSize` property to `Maximum`. The default is `255`. This property is tunable.

## **InitialCount**

Counter initial value

Specify the initial value for the counter. The default is `0`. This property is tunable.

## **CountOutputPort**

Output count

Set this property to `true` to enable output of the internal count. The default is `true`. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

## **HitOutputPort**

Output hit events

Set this property to `true` to enable output of the hit events. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time. The default is `true`.

## **HitValues**

Values whose occurrence in count produce a true hit output

Specify an integer scalar or a vector of integers, whose occurrences in the count you want flagged as a hit. This property applies only when you set the `HitOutputPort` property to `true`.

## **ResetInputPort**

Add input to enable internal counter reset

When you set this property to `true`, specify a reset input to the `step` method. When the reset input receives the event you specify for the `CountEventCondition` property, the counter resets. If you set the `CountEventInputPort` property to `false`, the counter resets whenever the reset input is not zero.

## **SamplesPerFrame**

Number of samples in each output frame

Specify the number of samples in each output frame. This property applies only when you set the `CountEventInputPort` property to `false`, indicating a free-running counter. The default is 1.

## **CountOutputDataType**

Data type of count output

Specify the data type of the count output, CNT, as `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32` or `uint32`. This property applies when you set the `CountOutputPort` property to `true`. The default is `double`.

## Methods

<code>clone</code>	Create counter object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of Counter object
<code>step</code>	Increment or decrement the internal counter

## Examples

Use Counter System object for counting from 0 to 5:

```
hcounter = dsp.Counter('MaximumCount', 5, ...  
'CountOutputPort', true, ...  
'HitOutputPort', false, ...  
'ResetInputPort', false);  
sgnl = [0 1 0 1 0 1 0 1 0 1 0 1];  
for ii = 1:length(sgnl)  
    %count at every rising edge of the input signal.  
    cnt(ii) = step(hcounter, sgnl(ii));  
end  
cnt
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Counter block reference page. The object properties correspond to the block parameters.

- The CountEventCondition object property does not have a free-running option. Set the CountEventInputPort property to `false` to obtain the free-running option.
- The CounterSizeSource and CounterSize object properties correspond to the **Counter size** block parameter.
- The CountOutputPort and HitOutputPort correspond to the **Output** block parameter.
- There is no object property that corresponds to the **Hit data type** block parameter. The output type is logical in MATLAB. (This logical is different from the popup logical in the block. For the object, logical corresponds to Boolean in the block.)

**Purpose** Create counter object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `Counter` object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

## **dsp.Counter.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, from the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.Counter.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** isLocked(H)

**Description** isLocked(H) returns the locked state of the Counter System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

## **dsp.Counter.reset**

---

**Purpose**            Reset internal states of Counter object

**Syntax**            `reset(H)`

**Description**        `reset(H)` resets the internal states of the counter object H to their initial values.

**Purpose** Increment or decrement the internal counter

**Syntax**

```
[CNT,HIT] = step(H,EVENT,RESET)
CNT = step(H,EVENT,RESET)
HIT = step(H,EVENT,RESET)
[...] = step(H)
[...] = step(H,EVENT)
```

**Description** [CNT,HIT] = step(H,EVENT,RESET) increments, decrements, or resets the internal counter as specified by the values of the EVENT and RESET inputs. The output argument CNT denotes the present value of the counter. A trigger event at the EVENT input causes the counter to increment or decrement. A trigger event at the RESET input resets the counter to its initial state.

CNT = step(H,EVENT,RESET) returns the current value of the count when you set the CountOutputPort property to true, and the HitOutputPort property to false.

HIT = step(H,EVENT,RESET) returns a Boolean value indicating whether the count has reached any of the values specified by the HitValues property. This condition applies when you set the HitOutputPort property to true and the CountOutputPort property to false.

[...] = step(H) increments or decrements the free-running internal counter when you set the CountEventInputPort property to false and the ResetInputPort property to false.

[...] = step(H,EVENT) increments or decrements the internal counter when the EVENT input matches the event you specify for the CountEventCondition property and you set the ResetInputPort property to false.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Purpose

Cross-correlation of two inputs

## Description

The `Crosscorrelator` returns the cross-correlation sequence for two discrete-time deterministic inputs. This object can also return the cross-correlation sequence estimate for two discrete-time, jointly wide-sense stationary (WSS), random processes.

To obtain the cross-correlation for two discrete-time deterministic inputs:

- 1 Define and set up your cross-correlator. See “Construction” on page 3-353.
- 2 Call `step` to compute the cross-correlation according to the properties of `dsp.Crosscorrelator`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.Crosscorrelator` returns a cross-correlator object, `H`, that computes the cross-correlation of two inputs. For N-D arrays, the cross-correlator computes the correlation column-wise. The inputs must have an equal number of columns. If one input is a vector and the other is an N-D array, the cross-correlator computes the cross-correlation of the vector with each column of the N-D array. Cross correlating inputs of length  $N$  and  $M$  results in a cross-correlation sequence of length  $N+M-1$ . Cross correlating matrices of size  $M$ -by- $N$  and  $P$ -by- $N$  results in a matrix of cross-correlation sequences of size  $M+P-1$ -by- $N$ .

`H = dsp.Crosscorrelator('PropertyName',PropertyValue, ...)` returns a cross-correlator, `H`, with each property set to the specified value.

## Properties

### Method

Domain for computing correlations

Specify the domain for computing correlation as `Time Domain`, `Frequency Domain`, or `Fastest`. Computing correlations in the time domain minimizes memory use. Computing correlations

in the frequency domain may require fewer computations than computing in the time domain depending on the input length. If the value of this property is `Fastest`, the cross-correlator operates in the domain which minimizes the number of computations. The default is `Time Domain`.

## **Fixed-Point Properties**

### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of Full Precision, Same as first input, or Custom. The default is Full Precision.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when the ProductDataType property is Custom. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as Full Precision, Same as product, Same as first input, or Custom. The default is Full Precision.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when the AccumulatorDataType property is Custom. The default is `numericType([],32,30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of Same as accumulator, Same as product, Same as first input, or Custom. The default is Same as accumulator.

## **CustomOutputDataType**

Output word and fraction lengths

# dsp.Crosscorrelator

---

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numericType([], 16, 15)`.

## Methods

<code>clone</code>	Create cross-correlator object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Cross-correlation sequence

## Definitions

The cross-correlation of two length  $N$  deterministic inputs, or realizations of jointly WSS random processes,  $x$  and  $y$ , is:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \leq h \leq N-1 \\ r_{yx}^*(h) & -(N-1) \leq h \leq 0 \end{cases}$$

where  $h$  is the lag and  $*$  denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes,  $r_{xy}(h)$  is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where  $E\{\}$  is the expectation operator.

## Examples

Compute correlation between two signals:

```
hcorr = dsp.Crosscorrelator;
t=[0:0.001:1];
x1=sin(2*pi*2*t)+0.05*sin(2*pi*50*t);
x2=sin(2*pi*2*t);
y=step(hcorr,x1,x2); %computes cross-correlation of x1 and x2
figure,plot(t,x1,'b',t, x2, 'g');
legend('Input signal 1',' Input signal 2')
figure, plot(y); title('Correlated output')
```

---

Use cross-correlation to detect delay in jointly stationary white Gaussian noise inputs:

```
S = rng('default');
% white Gaussian noise input
x = randn(100,1);
% Create copy delayed by 10 samples
% x1[n]=x[n-10]
Hdelay = dsp.Delay(10);
x1= step(Hdelay,x);
Hxcorr = dsp.Crosscorrelator;
y = step(Hxcorr,x1,x);
lags = 0:99; %Positive lags
stem(lags,y(100:end),'markerfacecolor',[0 0 1]);
axis([0 99 -125 125]);
xlabel('Lags');
title('Cross-Correlation of Input Noise and Delayed Version');
```

# dsp.Crosscorrelator

The theoretical cross-correlation sequence is identically zero except at lag 10. Note this is not true in the sample cross-correlation sequence, but the estimate demonstrates a peak at the correct lag.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the [Correlation block reference page](#). The object properties correspond to the block parameters.

## See Also

[dsp.Autocorrelator](#) | [dsp.Convolver](#)

# **dsp.Crosscorrelator.clone**

---

**Purpose** Create cross-correlator object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a cross-correlator object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.Crosscorrelator.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**      `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the cross-correlator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.Crosscorrelator.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Cross-correlation sequence

**Syntax**  $Y = \text{step}(H,A,B)$

**Description**  $Y = \text{step}(H,A,B)$  computes the cross-correlation of A and B and returns the result in Y.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.CumulativeProduct

---

## Purpose

Cumulative product of channel, column, or row elements

## Description

The `CumulativeProduct` object computes the cumulative product of channel, column, or row elements.

To compute the cumulative product of channel, column, or row elements:

- 1 Define and set up your cumulative product object. See “Construction” on page 3-366.
- 2 Call `step` to compute the cumulative product according to the properties of `dsp.CumulativeProduct`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.CumulativeProduct` returns a cumulative product object, `H`, that computes the cumulative product of input matrix or input vector elements along the default `Dimension`.

`H = dsp.CumulativeProduct('PropertyName',PropertyValue,...)` returns a cumulative product object, `H`, with each specified property set to the specified value.

## Properties

### Dimension

Computation dimension for cumulative product

Specify the computation dimension as one of `| Channels (running product) | Rows | Columns |`. The default is `Channels (running product)`.

### ResetInputPort

Enable resetting cumulative product via input port

Set this property to `true` to enable resetting the cumulative product. When you set this property to `true`, specify a reset signal to the `step` method to reset the cumulative product. You can access this property when the `Dimension` property is set to `Channels (running product)`. The default is `false`.

## **ResetCondition**

Reset condition for cumulative product

Specify the event on the reset input port that causes resetting the cumulative product to one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the ResetInputPort property to true and the Dimension property to Channels (running product). The default is Rising edge.

## **FrameBasedProcessing**

Enable frame-based processing

Set this property to true to enable frame-based processing. Set this property to false to enable sample-based processing. You can access this property when the Dimension property is set to Channels (running product). The default is false.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest, | Round | Simplest | Zero |. The default is Floor.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

### **IntermediateProductDataType**

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

### **CustomIntermediateProductDataType**

# dsp.CumulativeProduct

---

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## **ProductDataType**

Product output word and fraction lengths

Specify the product output fixed-point data type as one of `| Same as input | Custom |`. The default is `Same as input`.

## **CustomProductDataType**

Custom product output word and fraction lengths

Specify the product output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Same as product output | Same as input | Custom |`. The default is `Same as input`.

## **CustomAccumulatorDataType**

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as product output | Same as input | Custom |. The default is Same as input.

## CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## Methods

<code>clone</code>	Create cumulative product object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset running cumulative product
<code>step</code>	Cumulative product of input along specified dimension for input

## Examples

Compute the cumulative product of a matrix:

```
hcprod = dsp.CumulativeProduct;  
x = magic(2);  
y = step(hcprod,x);  
y = step(hcprod,x)
```

# dsp.CumulativeProduct

---

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Product block reference page. The object properties correspond to the block parameters, except:

The **Reset port** block parameter corresponds to both the `ResetCondition` and `ResetInputPort` object properties.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the `FrameBasedProcessing` Property of a System object” for more information.

## See Also

`dsp.CumulativeSum`

**Purpose** Create cumulative product object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `CumulativeProduct` System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.CumulativeProduct.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.CumulativeProduct.getNumOutputs

---

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.CumulativeProduct.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `CumulativeProduct` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

# **dsp.CumulativeProduct.reset**

---

**Purpose**            Reset running cumulative product

**Syntax**            `reset(H)`

**Description**        `reset(H)` resets the running cumulative product for object H to zero.

**Purpose** Cumulative product of input along specified dimension for input

**Syntax**  
 $Y = \text{step}(H, X)$   
 $Y = \text{step}(H, X, R)$

**Description**  $Y = \text{step}(H, X)$  computes the cumulative product along the specified dimension for the input  $X$ .  
 $Y = \text{step}(H, X, R)$  resets the cumulative product object's state based on the `ResetCondition` property value and the value of the reset signal,  $R$  when the `ResetInputPort` property is true.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.CumulativeSum

---

**Purpose** Cumulative sum of channel, column, or row elements

**Description** The `CumulativeSum` object computes the cumulative sum of channel, column, or row elements.

To compute the cumulative sum of channel, column, or row elements:

- 1 Define and set up your cumulative sum object. See “Construction” on page 3-378.
- 2 Call `step` to compute the cumulative sum according to the properties of `dsp.CumulativeSum`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.CumulativeSum` returns a cumulative sum System object, `H`, which computes the running cumulative sum for each channel in the input.

`H = dsp.CumulativeSum('PropertyName',PropertyValue,...)` returns a cumulative sum object, `H`, with each specified property set to the specified value.

## Properties

### Dimension

Computation dimension for cumulative sum

Specify the computation dimension as one of `| Channels (running sum) | Rows | Columns |`. The default is `Channels (running sum)`.

### ResetInputPort

Enable resetting cumulative sum via input port.

Set this property to `true` to enable resetting the cumulative sum. When you set this property to `true`, you also specify a reset input to the `step` method to reset the cumulative sum. The default is `false`.

### ResetCondition

Reset condition for cumulative sum

Specify the event on the reset input port that resets the cumulative sum as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the ResetInputPort property to true. The default is Rising edge.

## **FrameBasedProcessing**

Enable frame-based processing

Set this property to true to enable frame-based processing. Set this property to false to enable sample-based processing. You can access this property when the Dimension property is Channels (running sum). The default is false.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor, Nearest, Round, Simplest | Zero |. The default is Floor.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

### **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

### **CustomAccumulatorDataType**

Custom accumulator word and fraction lengths

# dsp.CumulativeSum

---

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of one of `| Same as accumulator | Same as input | Custom |`. The default is `Same as accumulator`.

## **CustomOutputDataType**

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## **Methods**

<code>clone</code>	Create cumulative sum object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of cumulative sum object to zero
<code>step</code>	Cumulative sum along specified dimension for input

## Examples

Use a cumulative sum object to compute the cumulative sum of a matrix:

```
hcsun = dsp.CumulativeSum;  
x = magic(2);  
y = step(hcsun,x);  
y = step(hcsun,x)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Sum block reference page. The object properties correspond to the block properties, except:

The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the `FrameBasedProcessing` Property of a System object” for more information.

## See Also

`dsp.CumulativeProduct`

## **dsp.CumulativeSum.clone**

---

**Purpose** Create cumulative sum object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `CumulativeSum` object `C`, with same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.CumulativeSum.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**      `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `CumulativeSum` object `H`.  
The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.CumulativeSum.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset internal states of cumulative sum object to zero

**Syntax** reset(H)

**Description** reset(H) sets the states for the running cumulative sum object, H, to zero when the Dimension property is set to Channels (running sum).

# dsp.CumulativeSum.step

---

**Purpose** Cumulative sum along specified dimension for input

**Syntax**  
 $Y = \text{step}(H,X)$   
 $Y = \text{step}(H,X,R)$

**Description**  $Y = \text{step}(H,X)$  computes the cumulative sum along the specified dimension for the input  $X$ .  
 $Y = \text{step}(H,X,R)$  resets the System object state based on the `ResetCondition` property value and the value of the reset signal,  $R$ . You can only reset the state if the `ResetInputPort` property is `true`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

---

<b>Purpose</b>	Discrete cosine transform (DCT)
<b>Description</b>	<p>The DCT object computes the discrete cosine transform (DCT) of input.</p> <p>To compute the DCT of input:</p> <ol style="list-style-type: none"><li>1 Define and set up your DCT object. See “Construction” on page 3-389.</li><li>2 Call <code>step</code> to compute the DCT according to the properties of <code>dsp.DCT</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.DCT</code> returns a discrete cosine transform (DCT) object, <code>H</code>, used to compute the DCT of a real or complex input signal.</p> <p><code>H = dsp.DCT('PropertyName',PropertyValue, ...)</code> returns a DCT object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>SineComputation</b></p> <p>Method to compute sines and cosines</p> <p>Specify how the DCT object computes the trigonometric values as <code>Trigonometric function</code> or <code>Table lookup</code>. This property must be set to <code>Table lookup</code> for fixed-point inputs. The default is <code>Table lookup</code>.</p> <p><b>Fixed-Point Properties</b></p> <p><b>RoundingMethod</b></p> <p>Rounding method for fixed-point operations</p> <p>Specify the rounding method as one of <code>Ceiling</code>, <code>Convergent</code>, <code>Floor</code>, <code>Nearest</code>, <code>Round</code>, <code>Simplest</code>, or <code>Zero</code>. This property applies when you set the <code>SineComputation</code> property to <code>Table lookup</code>.</p> <p><b>OverflowAction</b></p> <p>Overflow action for fixed-point operations</p>

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table lookup`.

## **SineTableDataType**

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

## **CustomSineTableDataType**

Sine table word length

Specify the sine table fixed-point type as an unscaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `SineTableDataType` property to `Custom`. The default is `numericType([],16)`.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

### **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

### **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

## **Methods**

<code>clone</code>	Create discrete cosine transform object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Discrete cosine transform (DCT) of input

## Examples

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
hdct = dsp.DCT;
X = step(hdct, x);
% Set the DCT coefficients which represent less
% than 0.1% of the total energy to 0 and
% reconstruct the sequence using IDCT.
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
    ii = ii+1;
end
disp(['Number of DCT coefficients that represent 99.9%',...
    'of the total energy in the sequence: ',num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
hidct = dsp.IDCT;
xt = step(hidct, XXt);
plot(1:128,[x xt]);
legend('Original signal','Reconstructed signal',...
    'location','best');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the DCT block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.IDCT](#) | [dsp.FFT](#) | [dsp.IFFT](#)

**Purpose** Create discrete cosine transform object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an instance of the current discrete cosine transform object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.DCT.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.DCT.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the DCT object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.DCT.step

---

**Purpose** Discrete cosine transform (DCT) of input

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  computes the DCT of the input  $X$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Delay input by specified number of samples or frames
<b>Description</b>	<p>The Delay object delays an input by a specified number of samples or frames.</p> <p>To delay an input by a specified number of samples or frames:</p> <ol style="list-style-type: none"><li>1 Define and set up your delay object. See “Construction” on page 3-399.</li><li>2 Call <code>step</code> to delay the input according to the properties of <code>dsp.Delay</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.Delay</code> returns a delay object, <code>H</code>, to delay the input by one sample.</p> <p><code>H = dsp.Delay('PropertyName', PropertyValue, ...)</code> returns a delay object, <code>H</code>, with each property set to the specified value.</p> <p><code>H = dsp.Delay(LEN, 'PropertyName', PropertyValue, ...)</code> returns a delay object, <code>H</code>, with the <code>Length</code> property set to <code>LEN</code> and other specified properties set to the specified values.</p>
<b>Properties</b>	<p><b>Units</b></p> <p>Delay units as samples or frames</p> <p>Specify the delay units as one of <code>  Samples   Frames  </code>. This property applies when you set the <code>FrameBasedProcessing</code> property to <code>true</code>. The default is <code>Samples</code>.</p> <p><b>Length</b></p> <p>Amount of delay</p> <p>Specify amount of delay to apply to the input signal. You can set this property to a scalar, a vector, or an array containing nonnegative integers depending on the value of the <code>FrameBasedProcessing</code> property.</p>

If the `FrameBasedProcessing` property is `false`, the value can be a scalar by which to delay all input channels equally, or an N-D array of the same dimensions as the input whose values specify the number of sample intervals to delay each channel of the input.

If the `FrameBasedProcessing` property is `true`, the value can be an integer by which to equally delay all channels or a vector whose length equals the number of input columns (channels).

The default is 1.

## **InitialConditionsPerChannel**

Enable different initial conditions per channel

Set this property to `true` to specify different initial conditions per channel. The default value is `false`.

## **InitialConditionsPerSample**

Enable different initial conditions per sample

Set this property to `true` to specify different initial conditions per sample. The default value is `false`.

## **InitialConditions**

Initial output of delay object

Specify the initial output(s) of the delay object. You can set this property to a scalar, vector, matrix, or a cell array depending on the values of the `FrameBasedProcessing`, `InitialConditionsPerChannel`, `InitialConditionsPerSample`, and `Units` properties. The default is 0.

If the `FrameBasedProcessing` property is `false`, and the input is an N-D array, the dimensions of this property value have the following requirements:

- If the `InitialConditionsPerChannel` and `InitialConditionsPerSample` properties are both `false`, the property value must be a scalar. If the `InitialConditionsPerChannel` property is `true` and the

`InitialConditionsPerSample` property is false, the value must have the same dimensions as the input. If the `InitialConditionsPerChannel` property is false and the `InitialConditionsPerSample` property is true, the value must be a vector of length equal to the `Length` property value.

- If the `InitialConditionsPerChannel` and `InitialConditionsPerSample` properties are both true, the property value must be a cell array of the same size as the input signal. Each cell of the cell array contains the delay values for one channel, and must be a vector of length equal to the `Length` property value.

If the `FrameBasedProcessing` property is true, and the input is an  $M$ -by- $N$  matrix, the dimensions of this property value must be as follows:

- If the `InitialConditionsPerChannel` and `InitialConditionsPerSample` properties are both false, the property value must be a scalar.
- If the `InitialConditionsPerChannel` property is true and the `InitialConditionsPerSample` property is false, the value must be a vector of length  $N$ .
- If the `InitialConditionsPerChannel` property is false, the `InitialConditionsPerSample` property is true, and the `Units` property is `Frames`, the value must be a vector of length equal to the product of  $M$  and the `Length` property value.
- If the `InitialConditionsPerChannel` property is false, the `InitialConditionsPerSample` property is true, and the `Units` property is `Samples`, the value must be a vector of length equal to the `Length` property value.
- If the `InitialConditionsPerChannel` and `InitialConditionsPerChannel` properties are both true, the property value must be a cell array of size  $N$ . Each cell of the cell array contains the delay values for one channel.

- If the `Units` property is `Frames`, each cell must be a vector of length equal to the product of  $M$  and the `Length` property value.
- If the `Units` property is `Samples`, each cell must be a vector of length equal to the `Length` property value.

## **ResetInputPort**

Enable resetting delay states

Specify when the delay object should reset the delay states. By default, the value of this property is `false`, and the object does not reset the delay states. When this property is set to `true`, a reset control input is provided to the `step` method, and the `ResetCondition` property applies. The object resets the delay states based on the values of the `ResetCondition` property and the reset input to the `step` method.

## **ResetCondition**

Reset trigger setting for delay

Specify the event to reset the delay as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. The delay object resets the delay based on the values of this property and the reset input to the `step` method. This property applies when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

## **FrameBasedProcessing**

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

## Methods

<code>clone</code>	Create delay object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset delay states
<code>step</code>	Apply delay to input

## Examples

Delay input by five samples:

```
hdelay1 = dsp.Delay(5);  
% Output is [0 0 0 0 0 1 2 3 4 5]'  
y = step(hdelay1, (1:10)');
```

---

Delay input by one frame:

```
hdelay2 = dsp.Delay;  
hdelay2.Units = 'Frames';  
hdelay2.Length = 1;  
  
% Output is zeros(10,1)  
y1 = step(hdelay2, (1:10)');  
  
% Output is (1:10)'  
y2 = step(hdelay2, (11:20)');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Delay block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

## See Also

`dsp.VariableIntegerDelay` | `dsp.VariableFractionalDelay`.

**Purpose**

Create delay object with same property values

**Syntax**

```
C = clone(H)
```

**Description**

`C = clone(H)` creates a delay object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# **dsp.Delay.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.Delay.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the delay object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.Delay.reset

---

**Purpose**            Reset delay states

**Syntax**            reset(H)

**Description**        reset(H) resets the states of the delay object H to the values specified in the InitialConditions property.

After you invoke the step method for a nonzero input, the delay object states may change and invoking the step method again without invoking the reset method may produce different outputs for identical inputs.

For example:

```
H = dsp.Delay(5);
% Delay input by 5 samples
y = step(H, (1:10)');
% Output is [0 0 0 0 0 1 2 3 4 5]'
% Invoke step without reset
y1 = step(H, (1:10)');
% Output is [6 7 8 9 10 1 2 3 4 5]'
% Reset states
reset(H);
y2 = step(H, (1:10)');
% Output is [0 0 0 0 0 1 2 3 4 5]'
```

**Purpose** Apply delay to input

**Syntax**  
 $Y = \text{step}(H, X)$   
 $Y = \text{step}(H, X, R)$

**Description**  $Y = \text{step}(H, X)$  adds delay to input  $X$  to return output  $Y$ .  
 $Y = \text{step}(H, X, R)$  adds delay to  $X$ , and selectively resets the delay object's state based on the value of reset input  $R$  and the value of the `ResetCondition` property. You can use this option only when you set the `ResetInputPort` property to `true`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.DelayLine

---

**Purpose** Rebuffer sequence of inputs with one-sample shift

**Description** The `DelayLine` object rebuffers a sequence of inputs with one-sample shift.

To rebuffer a sequence of inputs with one-sample shift:

- 1 Define and set up your delay line object. See “Construction” on page 3-412.
- 2 Call `step` to rebuffer the sequence of inputs according to the properties of `dsp.DelayLine`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.DelayLine` returns a delay line System object, `H`, that buffers the input samples into a sequence of overlapping or underlapping matrix outputs.

`H = dsp.DelayLine('PropertyName',PropertyValue,...)` returns a delay line System object, `H`, with each specified property set to the specified value.

`H = dsp.DelayLine(DELAYSIZE,INITIAL,'PropertyName',PropertyValue,...)` returns a delay line System object, `H`, with the `Length` property set to `DELAYSIZE`, `InitialConditions` property set to `INITIAL` and other specified properties set to the specified values.

## Properties

### Length

Number of rows in output matrix

Specify the number of rows in the output matrix as a scalar positive integer. The default is 64.

### InitialConditions

Initial delay line output

Set the value of the object's initial output as one of | scalar | vector | matrix |.

For vector outputs, the following selections apply for the `InitialConditions` property:

- A vector of the same size
- A scalar value that you want repeated across all elements of the initial output

For matrix outputs, the following selections apply for the `InitialConditions` property:

- A matrix of the same size
- A vector (equal to the length of the number of matrix rows) that repeats across all columns of the initial output
- A scalar that repeats across all elements of the initial output

The default is 0.

### **DirectFeedthrough**

Enable passing input data to output without extra frame delay

When you set this property to `true`, there is no input data delay by an extra frame before it is available at the output buffer.

Instead, the input data is available immediately at the output.

When you set this property to `false`, there is one frame delay on the output. The default is `false`.

### **EnableOutputInputPort**

Enable selective output linearization

The object internally uses a circular buffer, even though the output is linear. To obtain a valid output, the object must linearize the circular buffer. When this property is `true`, the object uses an additional Boolean input to determine if a valid output calculation is needed. If Boolean the input value is 1, the object's output is linearized and thus valid. If Boolean the input value is 0, the output is not linearized and is invalid. This allows the object to be

# dsp.DelayLine

---

more efficient when each step does not require the tapped delay line output. When you set this property to `false`, the output is always linearized and valid. The default is `false`.

## HoldPreviousValue

Hold previous valid value for invalid output

If you set this property to `true`, the most recent, valid value is held on the output. If you set this property to `false`, the signal on the output is invalid data. This property applies only when you set the `EnableOutputInputPort` property to `true`. The default is `false`.

## Methods

<code>clone</code>	Create delay line object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of delay line object
<code>step</code>	Delayed version of input

## Examples

Use a delay line object with a delay line size of 4 samples:

```
hdelayline = dsp.DelayLine( ...  
    'Length', 4, ...  
    'DirectFeedthrough', true, ...  
    'InitialConditions', -2, ...  
    'EnableOutputInputPort', true, ...  
    'HoldPreviousValue', true);
```

```
en = logical([1 1 0 1 0]);
y = zeros(4,5);
for ii = 1:5
    y(:,ii) = step(hdelayline, ii, en(ii));
end
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Delay Line block reference page. The object properties correspond to the block properties, except as noted.

This object processes inputs as separate channels (frames). The corresponding block has a temporary **Treat Mx1 and unoriented sample-based signals as** parameter with a `One channel` option for frame-based behavior and an `M channels` option for sample-based behavior. See the Delay Line block reference page and “Set the FrameBasedProcessing Property of a System object” for more information.

## See Also

`dsp.Delay`

# **dsp.DelayLine.clone**

---

**Purpose** Create delay line object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `DelayLine` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.DelayLine.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, from the step method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `DelayLine` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.DelayLine.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset internal states of delay line object

**Syntax** reset(H)

**Description** reset(H) sets the internal delay buffers of the DelayLine object H to their initial conditions.

# dsp.DelayLine.step

---

**Purpose** Delayed version of input

**Syntax**  
 $Y = \text{step}(H, X)$   
 $Y = \text{step}(H, X, EN)$

**Description**  $Y = \text{step}(H, X)$  returns the delayed version of input  $X$ .  $Y$  is an output matrix with the same number of rows as the delay line size. Each column of  $X$  is treated as a separate channel.

The System object rebuffers a sequence of  $M_i$ -by- $N$  matrix inputs into a sequence of  $M_o$ -by- $N$  matrix outputs, where  $M_o$  is the output frame size specified by the Length property. Depending on whether  $M_o$  is greater than, less than, or equal to the input frame size,  $M_i$ , the output frames can be underlapped or overlapped. Each of the  $N$  input channels is rebuffered independently:

- When  $M_o > M_i$ , the output frame overlap is the difference between the output and input frame size,  $M_o - M_i$ .
- When  $M_o < M_i$ , the output is underlapped; the object discards the first  $M_i - M_o$  samples of each input frame so that only the last  $M_o$  samples are buffered into the corresponding output frame.
- When  $M_o = M_i$ , the output data is identical to the input data, but is delayed by the latency of the object.

$Y = \text{step}(H, X, EN)$  selectively outputs the delayed version of input  $X$  depending on the Boolean input  $EN$ . This occurs only when you set the EnableOutputInputPort property to true. If  $EN$  is false, use the HoldPreviousValue property to specify if the object should hold the previous output value(s).

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.DigitalDownConverter

---

**Purpose** Digitally downconvert input signal

**Description** The `DigitalDownConverter` object digitally downconverts the input signal.

To digitally downconvert the input signal:

- 1** Define and set up your digital down converter. See “Construction” on page 3-424.
- 2** Call `step` to downconvert the input according to the properties of `dsp.DigitalDownConverter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `h = dsp.DigitalDownConverter` returns a digital down-converter (DDC) System object, `h`. The object frequency downconverts the input signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. The object downsamples the frequency down-converted signal using a cascade of three decimation filters. When you set the `FilterSpecification` property to `Design` parameters, the DDC object designs the decimation filters according to the filter parameters that you set in the filter-related object properties. In this case the filter cascade consists of a CIC decimator, a CIC compensator and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.

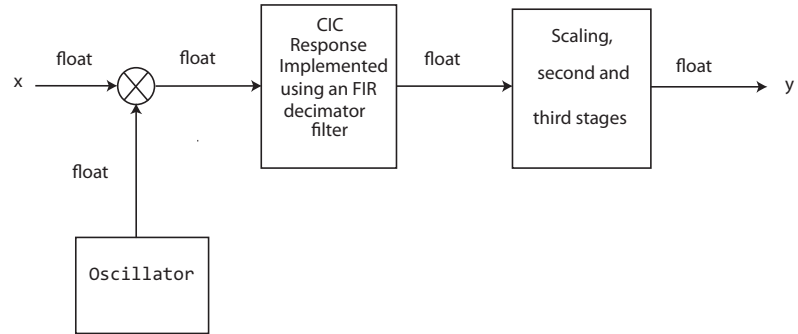

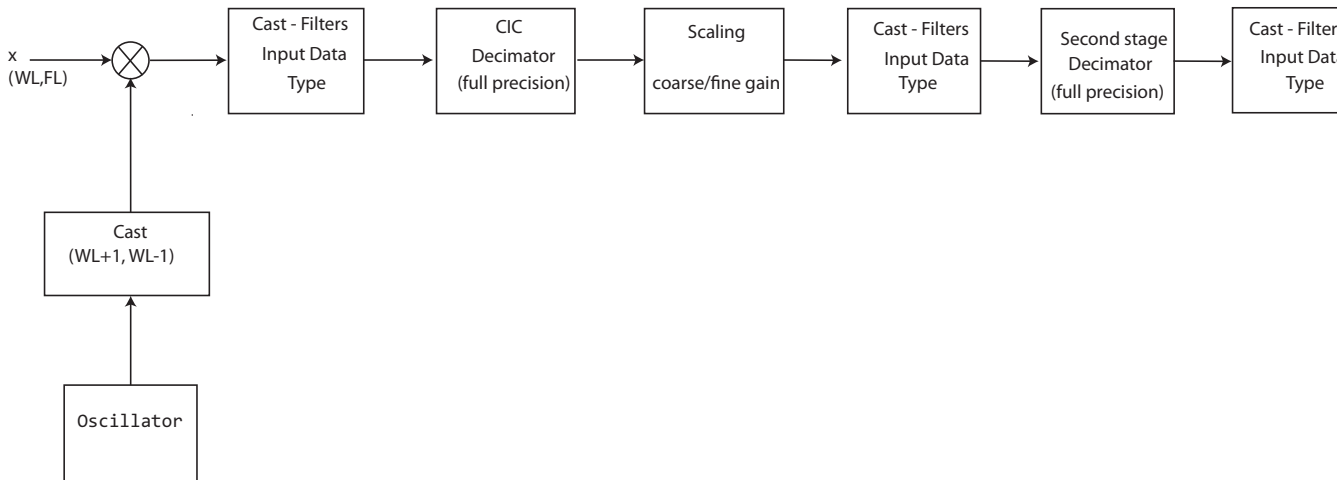

The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. When you set the **Oscillator** property to `InputPort`, the normalization factor does not include the oscillator power factor. Depending on the setting of the **DecimationFactor** property, you may be able to bypass the third filter stage. When the arithmetic is double or single precision, the CIC interpolator is implemented as a simple FIR interpolator with a boxcar response. A true CIC interpolator can only operate with fixed-point signals. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.

# dsp.DigitalDownConverter

The following block diagram represents the DDC arithmetic with signed fixed-point inputs.

- WL is the word length of the input, and FL is the fraction length of the input.
- The input of each filter is cast to the data type specified in the **FiltersInputDataType** and **CustomFiltersInputDataType** properties.
- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.
- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.

If the normalization gain is  $G$ , (where  $0 < G \leq 1$ ), then:

- $WLCic$  is the word length of the CIC decimator output and  $FLCic$  is the fraction length of the CIC decimator output
- $F1 = \text{abs}(\text{nextpow2}(G))$ , indicating the part of  $G$  achieved using bit shifts (coarse gain)

# dsp.DigitalDownConverter

---

- $F2$  = fraction length specified by the **FiltersInputDataType** and **CustomFiltersInputDataType** properties
- $fg = fi((2^{F1}) * G, true, 16)$ , indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

`h = dsp.DigitalDownConverter(Name, Value)` returns a DDC object, `h`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### SampleRate

Sample rate of input signal

Set this property to a positive scalar value, greater than or equal to twice the value of the `CenterFrequency` property. The default is 30 Megahertz.

### DecimationFactor

Decimation factor

Set this property to a positive, integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar the object automatically chooses the decimation factors for each of the three filtering stages. The scalar value you specify cannot be a prime number.

When you set this property to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively. When you set the `FilterSpecification` property to `Design` parameters, both elements of the `DecimationFactor` vector must be greater than one. When you set the `FilterSpecification` property to `Coefficients`, the first element of the `DecimationFactor` vector must be greater than 1.

When you set this property to a 1-by-3 vector, the  $i$ th element of the vector specifies the decimation factor for the  $i$ th filtering stage. When you set the `FilterSpecification` property to `Design parameters`, the first and second elements of the `DecimationFactor` vector must be greater than one and the third element must be 1 or 2. When you set the `FilterSpecification` property to `Coefficients`, the first element of the `DecimationFactor` vector must be greater than 1. When you set the `FilterSpecification` property to `Coefficients`, you must set the `DecimationFactor` property to a 1-by-3 or 1-by-2 vector. The default is 100.

## FilterSpecification

Filter specification

Set the filter specification as one of `Design parameters` | `Coefficients`. The default is `Design parameters`. The DDC object performs decimation using a cascade of three decimation filters. The first filter stage is always a CIC decimator. When you set the `FilterSpecification` property to `Design parameters`, the object designs the cascade of decimation filters internally, according to a set of parameters that you specify using the filter-related object properties. In this case, the second and third stages of the cascade consist of a CIC compensator, and a halfband or lowpass FIR decimator respectively. When you set the `FilterSpecification` property to `Coefficients`, you specify an arbitrary set of filter coefficients for the second and third filter stages using the `SecondFilterCoefficients`, and `ThirdFilterCoefficients` properties respectively. You specify the number of CIC sections using the `NumCICSections` property. In all cases, the third filter stage can be bypassed by setting the `DecimationFactor` property appropriately.

When the input data type is double or single the object implements an  $N$ -section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of  $N$  boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed point type.

## **MinimumOrderDesign**

Minimum order filter design

When you set this property to true the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. When you set this property to false, the object designs filters with orders that you specify in the `NumCICSections`, `SecondFilterOrder`, and `ThirdFilterOrder` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. This property applies when you set the `FilterSpecification` property to `Design` parameters. The default is true.

## **NumCICSections**

Number of sections of CIC decimator

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design` parameters and the `MinimumOrderDesign` property to false, or when you set the `FilterSpecification` property to `Coefficients`. The default is 3.

## **SecondFilterCoefficients**

Coefficients of second filter stage

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. Usually, the response of this filter should be that of a CIC compensator since a CIC decimation filter precedes the second filter stage. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is 1.

## **ThirdFilterCoefficients**

Coefficients of third filter stage

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the value of the `ThirdFilterCoefficients` property because the third filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is 1.

## **SecondFilterOrder**

Order of CIC compensation filter stage

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design` parameters and the `MinimumOrderDesign` property to `false`. The default is 12.

## **ThirdFilterOrder**

Order of third filter stage

Set this property to a positive, integer, even scalar. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the `ThirdFilterOrder` property because the third filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Design` parameters and the `MinimumOrderDesign` property to `false`. The default is 10.

## **Bandwidth**

Two sided bandwidth of input signal in Hertz

Set this property to a positive, integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. This property applies when you set the `FilterSpecification` property to `Design` parameters. The default is 200 kilohertz.

## **StopbandFrequencySource**

Source of stopband frequency

Specify the source of the stopband frequency as one of Auto | Property. The default is Auto. When you set this property to Auto, the object places the cutoff frequency of the cascade filter response at approximately  $F_c = \text{SampleRate}/M/2$  Hertz, where  $M$  is the total decimation factor that you specify in the DecimationFactor property. The object computes the stopband frequency as  $F_{stop} = F_c + TW/2$ .  $TW$  is the transition bandwidth of the cascade response computed as  $2*(F_c - F_p)$ , and the passband frequency,  $F_p$ , equals Bandwidth/2. This property applies when you set the FilterSpecification property to Design parameters.

## StopbandFrequency

Stopband frequency in Hertz

Set this property to a double precision positive scalar. This property applies when you set the FilterSpecification property to Design parameters and the StopbandFrequencySource property to Property. The default is 150 kilohertz.

## PassbandRipple

Passband ripple of cascade response in decibels.

Set this property to a double precision, positive scalar. When you set the MinimumOrderDesign property to true, the object designs the filters so that the cascade response meets the passband ripple that you specify in the PassbandRipple property. This property applies when you set the FilterSpecification property to Design parameters and the MinimumOrderDesign property to true. The default is 0.1 decibels.

## StopbandAttenuation

Stopband attenuation of cascade response in decibels

Set this property to a double precision, positive scalar. When you set the MinimumOrderDesign property to true, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the

StopbandAttenuation property. This property applies when you set the FilterSpecification property to Design parameters and the MinimumOrderDesign property to true. The default is 60 decibels.

## **Oscillator**

Type of oscillator

Specify the oscillator as one of Sine wave | NCO | Input port. The default is Sine wave. When you set this property to Sine wave, the object frequency down converts the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function. When you set this property to NCO the object performs frequency down conversion with a complex exponential obtained using a numerically controlled oscillator (NCO). When you set this property to Input port, the object performs frequency down conversion using the complex signal that you set as an input to the step method.

## **CenterFrequency**

Center frequency of input signal in Hertz

Specify this property as a double precision positive scalar that is less than or equal to half the value of the SampleRate property. The object down converts the input signal from the passband center frequency you specify in the CenterFrequency property, to 0 Hertz. This property applies when you set the Oscillator property to Sine wave or NCO. The default is 14 Megahertz.

## **NumAccumulatorBits**

Number of NCO accumulator bits

Specify this property as an integer scalar in the range [1 128]. This property applies when you set the Oscillator property to NCO. The default is 16.

## **NumQuantizedAccumulatorBits**

Number of NCO quantized accumulator bits

Specify this property as an integer scalar in the range [1 128]. The value you specify in this property must be less than the value you specify in the NumAccumulatorBits property. This property applies when you set the Oscillator property to NCO. The default is 12.

## **Dither**

Dither control for NCO

When you set this property to true, a number of dither bits specified in the NumDitherBits property will be used to apply dither to the NCO signal. This property applies when you set the Oscillator property to NCO. The default is true.

## **NumDitherBits**

Number of NCO dither bits

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the NumAccumulatorBits property. This property applies when you set the Oscillator property to NCO and the Dither property to true. The default is 4.

## **Fixed-Point Properties**

### **SecondFilterCoefficientsDataType**

Data type of second filter coefficients

Specify the second filter coefficients data type as Same as input | Custom. The default is Same as input. This property applies when you set the FilterSpecification property to Coefficients.

### **CustomSecondFilterCoefficientsDataType**

Fixed-point data type of second filter coefficients

Specify the second filter coefficients fixed-point type as a scaled numerictype object with a Signedness of Auto. This property

applies when you set the `SecondFilterCoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

## **ThirdFilterCoefficientsDataType**

Data type of third filter coefficients

Specify the third filter coefficients data type as `Same as input` | `Custom`. The default is `Same as input`. This property applies when you set the `FilterSpecification` property to `Coefficients`.

## **CustomThirdFilterCoefficientsDataType**

Fixed-point data type of third filter coefficients

Specify the third filter coefficients fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ThirdFilterCoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

## **FiltersInputDataType**

Data type of input of each filter stage

Specify the data type at the input of the first, second, and third (if it has not been bypassed) filter stages as one of `Same as input` | `Custom`. The default is `Same as input`. The object casts the data at the input of each filter stage according to the value you set in this property.

## **CustomFiltersInputDataType**

Fixed-point data type of input of each filter stage

Specify the filters input fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `FiltersInputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

## **OutputDataType**

Data type of output

# dsp.DigitalDownConverter

---

Specify the data type of output as `Same as input` | `Custom`. The default is `Same as input`.

## CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled numeric type object with a Signedness of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## Methods

<code>clone</code>	Create digital down converter object with same property values
<code>fvtool</code>	Visualize response of filter cascade
<code>getDecimationFactors</code>	Get decimation factors of each filter stage
<code>getFilterOrders</code>	Get orders of decimation filters
<code>getFilters</code>	Get handles to decimation filter objects
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>groupDelay</code>	Group delay of filter cascade
<code>isLocked</code>	Locked status for input attributes and non-tunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Digitally down convert input signal
<code>visualizeFilterStages</code>	Display response of filter stages

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz. Create a digital down converter object that down converts the signal to 0 Hz and down samples it by a factor of 20.

```
% Create a sine wave generator to obtain the 1 KHz
% sinusoidal signal with a sample rate of 6 KHz.
Fs = 6e3; % Sample rate
hSig = dsp.SineWave('Frequency',1000,'SampleRate',...
Fs,'SamplesPerFrame',1024);
x = step(hSig); % generate signal

% Create a DUC object. Use minimum order filter designs and set
% passband ripple to 0.2 dB and the stopband attenuation to 55 dB.
% Set the double sided signal bandwidth to 2 KHz.
hDUC = dsp.DigitalUpConverter(...
'InterpolationFactor', 20,...
'SampleRate', Fs,...
'Bandwidth', 2e3,...
'StopbandAttenuation', 55,...
'PassbandRipple',0.2,...
'CenterFrequency',50e3);

% Create a DDC object. Use minimum order filter designs and set the
% passband ripple to 0.2 dB and the stopband attenuation to 55 dB.
hDDC = dsp.DigitalDownConverter(...
'DecimationFactor',20,...
'SampleRate', Fs*20,...
'Bandwidth', 3e3,...
'StopbandAttenuation', 55,...
'PassbandRipple',0.2,...
'CenterFrequency',50e3);

% Create a spectrum estimator to visualize the signal spectrum before
```

# dsp.DigitalDownConverter

---

```
% up converting, after up converting, and after down converting.
window = hamming(floor(length(x)/10));
figure; pwelch(x,window,[],[],Fs,'centered')
title('Spectrum of baseband signal x')
```

```
% Up convert the signal and visualize the spectrum
xUp = step(hDUC,x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],20*Fs,'centered');
title('Spectrum of up converted signal xUp')
```

```
% Down convert the signal and visualize the spectrum
xDown = step(hDDC,xUp); % down convert
window = hamming(floor(length(xDown)/10));
figure; pwelch(xDown,window,[],[],Fs,'centered')
title('Spectrum of down converted signal xDown')
```

```
% Visualize the response of the decimation filters
visualizeFilterStages(hDDC)
```

For additional examples using this System object, see the following demos:

- Digital Up and Down Conversion for Family Radio Service
- Design and Analysis of a Digital Down Converter

## See Also

dsp.DigitalUpConverter

**Purpose** Create digital down converter object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `DigitalDownConverter System` object, `C`, with the same property values as `H`.

The `clone` method creates a new unlocked object with uninitialized states.

# dsp.DigitalDownConverter.fvtool

---

**Purpose** Visualize response of filter cascade

**Syntax**  
`fvtool(H)`  
`fvtool(H,...,'Arithmetic',ARITH,...)`  
`fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2,...)`

**Description** `fvtool(H)` plots the magnitude response of the cascade of filters. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). When you set the `FilterSpecification` property to `Design` parameters the method plots a mask based on the filter specifications.

`fvtool(H,...,'Arithmetic',ARITH,...)` specifies the arithmetic of the filter cascade. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state you must specify the arithmetic. When object `H` is in a locked state the arithmetic input is ignored.

`fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2,...)` launches `FVTool` and sets the specified `FVTool` properties to the specified values.

# dsp.DigitalDownConverter.getDecimationFactors

---

**Purpose** Get decimation factors of each filter stage

**Syntax** `M = getDecimationFactors(H)`

**Description** `M = getDecimationFactors(H)` returns a vector, `M`, with the decimation factors of each filter stage. If the third filter stage is bypassed, then `M` is a 1-by-2 vector containing the decimation factors of the first and second filter stages in the first and second elements respectively. If the third filter stage is not bypassed then `M` is a 1-by-3 vector containing the decimation factors of the first, second and third filter stages.

# dsp.DigitalDownConverter.getFilters

---

**Purpose** Get handles to decimation filter objects

**Syntax** `S = getFilters(H)`  
`getFilters(H, 'Arithmetic', ARITH)`

**Description** `S = getFilters(H)` returns a structure, `S`, with copies of the filter System objects and the CIC normalization factor that form the decimation filter cascade. The `ThirdFilterStage` structure field is empty if the third filter stage has been bypassed. The CIC normalization factor equals the inverse of the CIC filter gain. In some cases, this gain includes a correction factor to ensure that the cascade response meets the ripple specifications.

`getFilters(H, 'Arithmetic', ARITH)` specifies the arithmetic of the filter stages. You can set `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state, you must specify the arithmetic input. When object `H` is in a locked state, the arithmetic input is ignored.

When `H` is in an unlocked state, and you specify the arithmetic as `fixed-point`, the `getFilters` method returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalDownConverter` System object uses to process data when you call the `step` method. All other fixed-point properties are set to their default values.

When `H` is in a locked state, and the input to the `step` method is of a fixed-point data type, the `getFilters` method returns filter System objects. All fixed-point properties of these System objects are set to the exact values that the `dsp.DigitalDownConverter` System object uses to process the data.

# **dsp.DigitalDownConverter.getFilterOrders**

---

**Purpose** Get orders of decimation filters

**Syntax** `S = getFilterOrders(H)`

**Description** `S = getFilterOrders(H)` returns a structure, `S`, that contains the orders of the interpolation filter stages. The `ThirdFilterOrder` structure field will be empty if the third filter stage has been bypassed.

# dsp.DigitalDownConverter.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.DigitalDownConverter.getNumOutputs

---

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.DigitalDownConverter.groupDelay**

---

**Purpose**            Group delay of filter cascade

**Syntax**             $D = \text{groupDelay}(H,N)$   
                       $[D,F] = \text{groupDelay}(H,N)$

**Description**         $D = \text{groupDelay}(H,N)$  returns a vector of group delays,  $D$ , evaluated at  $N$  frequency points equally spaced around the upper half of the unit circle. If you don't specify  $N$ , it defaults to 8192.

$[D,F] = \text{groupDelay}(H,N)$  returns a vector of frequencies,  $F$ , at which the group delay has been computed.

**Purpose** Locked status for input attributes and non-tunable properties

**Syntax** `Y = isLocked(H)`

**Description** `Y = isLocked(H)` returns the locked state, `Y`, of the `DigitalUpConverter` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# **dsp.DigitalDownConverter.release**

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

**Purpose** Digitally down convert input signal

**Syntax**  
 $Y = \text{step}(H,X)$   
 $Y = \text{step}(H,X,Z)$

**Description**  $Y = \text{step}(H,X)$  takes a real or complex input column vector  $X$  and outputs a frequency down converted and down sampled signal  $Y$ . The length of input  $X$  must be a multiple of the decimation factor.  $X$  can be of data type double, single, signed integer, or signed fixed point (fi objects). The length of  $Y$  is equal to the length of  $X$  divided by the `DecimationFactor`. When the data type of  $X$  is double or single precision, the data type of  $Y$  is the same as that of  $X$ . When the data type of  $X$  is of a fixed point type, the data type of  $Y$  is defined by the `OutputDataType` property.

$Y = \text{step}(H,X,Z)$  uses the complex input,  $Z$ , as the oscillator signal used to frequency down convert input  $X$ , when you set the `Oscillator` property to `Input` port. The length of  $Z$  must be equal to the length of  $X$ .  $Z$  can be of data type double, single, signed integer, or signed fixed point (fi objects).

# dsp.DigitalDownConverter.visualizeFilterStages

---

**Purpose** Display response of filter stages

**Syntax**  
`visualizeFilterStages(H)`  
`visualizeFilterStages(H, 'Arithmetic', ARITH)`  
`hfvt = visualizeFilterStages(H)`

**Description** `visualizeFilterStages(H)` plots the magnitude response of the filter stages and of the cascade response. When you set the `FilterSpecification` property to `Design` parameters the method plots a mask based on the filter specifications. By default, the object plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(H, 'Arithmetic', ARITH)` specifies the arithmetic of the filter stages. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state you must specify the arithmetic. When object `H` is in a locked state the arithmetic input is ignored.

`hfvt = visualizeFilterStages(H)` returns the handle to the `FVTool` object.

<b>Purpose</b>	Static or time-varying digital filter
<b>Description</b>	<p>The <code>DigitalFilter</code> object filters each channel of the input using static or time-varying digital filter implementations.</p> <p>To filter each channel of the input using digital filter implementation:</p> <ol style="list-style-type: none"><li>1 Define and set up your IIR digital filter. See “Construction” on page 3-451.</li><li>2 Call <code>step</code> to filter each channel according to the properties of <code>dsp.DigitalFilter</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.DigitalFilter</code> returns a default IIR digital filter object, <code>H</code>, which independently filters each channel of the input over successive calls to the <code>step</code> method, using a specified digital filter implementation. The default numerator coefficients are <code>[1 2]</code> and denominator coefficients are <code>[1 0.1]</code>.</p> <p><code>H = dsp.DigitalFilter('PropertyName',PropertyValue, ...)</code> returns a digital filter object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>TransferFunction</b></p> <p>Type of filter transfer function</p> <p>Specify the type of digital filter transfer function as one of <code>  IIR (poles &amp; zeros)   IIR (all poles)   FIR (all zeros)  </code>. The default is <code>IIR (poles &amp; zeros)</code>.</p> <p><b>Structure</b></p> <p>Filter structure</p> <p>Specify the filter structure.</p> <p>When you set the <code>TransferFunction</code> property to <code>FIR (all zeros)</code>, you can specify the filter structure as one of <code> </code></p>

Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA | . The default is Direct form.

When you set the TransferFunction property to IIR (all poles), you can specify the filter structure as Direct form, Direct form transposed, or Lattice AR. The default is Direct form.

When you set the TransferFunction to IIR (poles & zeros), you can specify the filter structure as Direct form I, Direct form I transposed, Direct form II, Direct form II transposed, Biquad direct form I (SOS), Biquad direct form I transposed (SOS), Biquad direct form II (SOS), or Biquad direct form II transposed (SOS). The biquad filter structure does not apply when you set the CoefficientsSource property to Input port. The default is Direct form II transposed.

## **CoefficientsSource**

Source of filter coefficients

Specify the source of the filter coefficients as one of | Property | Input port | . The default is Property. When you specify Input port, the digital filter object updates the time-varying filter once every frame, when the FrameBasedProcessing property is true. When the FrameBasedProcessing property is false, it updates once every sample.

## **Numerator**

Numerator coefficients

Specify the filter numerator coefficients as a real or complex numeric vector. This property applies when you set the TransferFunction property to FIR (all zeros), the CoefficientsSource property to Property, and the Structure property is not set to Lattice MA. This property also applies when you set the TransferFunction property to IIR (poles & zeros), the CoefficientsSource to Property, and the

TransferFunction property to Direct form, Direct form symmetric, Direct form antisymmetric, or Direct form transposed. The default is [1 2]. This property is tunable.

## Denominator

Denominator coefficients

Specify the filter denominator coefficients as a real or complex numeric vector. This property applies when you set the TransferFunction property to IIR (all poles), the CoefficientsSource property to Property and the Structure property is not set to Lattice AR. This property also applies when you set the TransferFunction property to IIR (poles & zeros), the CoefficientsSource to Property, and the TransferFunction property to Direct form, Direct form symmetric, Direct form antisymmetric, or Direct form transposed. When the TransferFunction property is IIR (poles & zeros), the numerator and denominator must have the same complexity. The default is [1 0.1]. This property is tunable.

## ReflectionCoefficients

Reflection coefficients of lattice filter structure

Specify the reflection coefficients of a lattice filter as a real or complex numeric vector. This property applies when you set the TransferFunction property to FIR (all zeros), the Structure property to Lattice MA, and the CoefficientsSource property to Property. This property also applies when you set the TransferFunction property to IIR (all poles), the Structure property to Lattice AR, and the CoefficientsSource property to Property. The default is [0.2 0.4]. This property is tunable.

## SOSMatrix

SOS matrix of biquad filter structure

Specify the second-order section (SOS) matrix of a biquad filter as an  $M$ -by-6 matrix, where  $M$  is the number of sections in the

filter. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding filter section. The first three elements of each row are the numerator coefficients and the last three elements are the denominator coefficients. You can use real or complex coefficients. This property applies when you set the `TransferFunction` property to IIR (poles and zeros), the `CoefficientsSource` property to `Property`, and the `Structure` property to Biquad direct form I (SOS), Biquad direct form I transposed (SOS), Biquad direct form II (SOS), or Biquad direct form II transposed (SOS). The default is [1 0.3 0.4 1 0.1 0.2]. This property is tunable.

## ScaleValues

Scale values of biquad filter structure

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be a scalar or a vector of length  $M+1$ , where  $M$  is the number of sections. If you specify a scalar value, that value is used as the gain value before the first section of the second-order filter and the rest of the gain values are set to 1. If you specify a vector of  $M+1$  values, each value is used for a separate section of the filter. This property applies when you set the `TransferFunction` property to IIR (poles & zeros), the `CoefficientsSource` property to `Property`, and the `Structure` property to Biquad direct form I (SOS), Biquad direct form I transposed (SOS), Biquad direct form II (SOS), or Biquad direct form II transposed (SOS). The default is 1. This property is tunable.

## IgnoreFirstDenominatorCoefficient

Assume first denominator coefficient is 1

Setting this Boolean property to `true` reduces the number of computations to produce the digital filter output by omitting the first denominator term,  $a_0$ , (poles side) in the filter structure. The object output is invalid when you set this property to `true` when the first denominator coefficient is not always 1 for your time-varying filter. The object ignores this property for

fixed-point inputs, because this object does not support nonunity  $a_0$  coefficients for fixed-point inputs.

This property applies when you set the `CoefficientsSource` property to `Input port`, the `TransferFunction` property to `IIR (all poles)`, and the `Structure` property is not set to `Lattice AR`. This property also applies when you set the `CoefficientsSource` property to `Input port`, the `TransferFunction` property to `IIR (poles & zeros)`, and the `Structure` property to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `true`.

## InitialConditions

Initial conditions for all poles or all zeros filter

Specify the initial conditions of the filter states. When the `TransferFunction` property is `FIR (all zeros)` or `IIR (all poles)`, the number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures. When the `TransferFunction` property is `IIR (poles & zeros)`, the number of states for direct form II and direct form II transposed structures equals the  $\max(N, M) - 1$ , where  $N$  and  $M$  are the number of poles and zeros, respectively.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the digital filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property applies when you do not set the Structure property to Direct Form I, Direct Form I transposed, Biquad direct form I (SOS), or Biquad direct form I transposed (SOS). The default is 0.

## **NumeratorInitialConditions**

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property applies when you set the TransferFunction property to IIR (poles & zeros) and the Structure property is Direct form I, Direct form I transposed, Biquad direct form I (SOS), or Biquad direct form I transposed (SOS). The default is 0. See the InitialConditions property for information on setting initial conditions.

## **DenominatorInitialConditions**

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the direct form I (noncanonic) filter structure with the poles. This property applies when you set the TransferFunction property to IIR (poles & zeros) and the Structure property to Direct form I, Direct form I transposed, Biquad direct form I (SOS), or Biquad direct form I transposed (SOS). The default is 0. See the InitialConditions property for information on setting initial conditions.

## **FrameBasedProcessing**

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

## Fixed-Point Properties

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

### TapSumDataType

Tap sum word and fraction lengths

Specify the tap sum fixed-point data type as one of | `Same as input` | `Custom` |. This property applies when you set the `TransferFunction` property to `FIR (all zeros)` and the `Structure` property to either `Direct form symmetric` or `Direct form antisymmetric`. The default is `Same as input`.

### CustomTapSumDataType

Custom tap sum word and fraction lengths

Specify the tap sum fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `TapSumDataType` property to `Custom`. The default is `numericType([],32,30)`.

### MultiplicandDataType

Multiplicand word and fraction lengths

Specify the multiplicand fixed-point data type as one of | Same as output | Custom |. This property applies when you set the Structure property to either Direct form I transposed or Biquad direct form I transposed (SOS). The default is Same as output.

## **CustomMultiplicandDataType**

Custom multiplicand word and fraction lengths

Specify the multiplicand fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies when you set the MultiplicandDataType property to Custom. The default is numeric type ([ ], 32, 30).

## **SectionInputDataType**

Section input word and fraction lengths

Specify the section input fixed-point data type as one of | Same as input | Custom |. Setting this property also sets the SectionOutputDataType property to the same value. This property applies when you set the TransferFunction property to IIR (poles & zeros) and the Structure property to one of the biquad filter structures. The default is Same as input.

## **CustomSectionInputDataType**

Custom section input word and fraction lengths

Specify the section input fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies when you set the SectionInputDataType property to Custom. The CustomSectionInputDataType and CustomSectionOutputDataType property values must have equal word lengths. The default is numeric type ([ ], 16, 15).

## **SectionOutputDataType**

Section output word and fraction lengths

Specify the section output fixed-point data type as one of | Same as input | Custom |. Setting this property also sets

the `SectionInputDataType` property to the same value. This property applies when you set the `TransferFunction` property to IIR (poles & zeros) and the `Structure` property to one of the biquad filter structures. The default is `Same as input`.

## **CustomSectionOutputDataType**

Custom section output word and fraction lengths

Specify the section output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SectionOutputDataType` property to `Custom`. The `CustomSectionInputDataType` and `CustomSectionOutputDataType` property values must have equal word lengths. The default is `numericType([],16,15)`.

## **NumeratorCoefficientsDataType**

Numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point data type as one of `| Same word length as input | Custom |`. Setting this property also sets the `DenominatorCoefficientsDataType` and the `ScaleValuesDataType` properties, if applicable, to the same value. This property applies when you set the `CoefficientsSource` property to `Property` and the `TransferFunction` property is not set to IIR (all poles). The default is `Same word length as input`.

## **CustomNumeratorCoefficientsDataType**

Custom numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `NumeratorCoefficientsDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType` and `ScaleValuesDataType` properties, if applicable, must have equal word lengths. The default is `numericType([],16,15)`.

## **DenominatorCoefficientsDataType**

Denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point data type as one of | Same word length as input | Custom |. Setting this property also sets the `NumeratorCoefficientsDataType` and `ScaleValuesDataType` properties, if applicable, to the same value. This property applies when you set the `CoefficientsSource` property to `Property` and the `TransferFunction` property is not set to `FIR` (all zeros). The default is `Same word length as input`.

## **CustomDenominatorCoefficientsDataType**

Custom denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `DenominatorCoefficientsDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType` and `CustomScaleValuesDataType` properties, if they apply, must have equal word lengths. The default is `numericType([], 16, 15)`.

## **ScaleValuesDataType**

Scale values word and fraction lengths

Specify the scale values fixed-point data type as one of | Same word length as input | Custom |. Setting this property also sets the `NumeratorCoefficientsDataType` and the `DenominatorCoefficientsDataType` properties, if they apply, to the same value. This property applies when you set the `CoefficientsSource` property to `Property`, the `TransferFunction` property to `IIR` (poles & zeros), and the `Structure` property to one of the biquad filter structures. The default is `Same word length as input`.

## **CustomScaleValuesDataType**

Custom scale values word and fraction lengths

Specify the scale values fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsSource` property to `Property` and the `ScaleValuesDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and the `CustomScaleValuesDataType` properties, if applicable, must have equal word lengths. The default is `numericType([],16,15)`.

### **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of `| Same as input | Custom |`. The default is `Same as input`.

### **CustomProductDataType**

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

### **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type to one of `| Same as input | Same as product | Custom |`. The default is `Same as product`.

### **CustomAccumulatorDataType**

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom |. This property does not apply to any of the direct form or direct form I filter structures. The default is Same as accumulator.

## CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `StateDataType` property to `Custom`. The default is `numericType([],16,15)`.

## OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input | Same as accumulator | Custom |. The default is Same as accumulator.

## CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

## Methods

<code>clone</code>	Create static or time-varying digital filter with same property values
<code>getNumInputs</code>	Number of expected inputs to step method

<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of digital filter
<code>step</code>	Filter input with digital filter object

## Examples

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components:

```
t = [0:63]./32e3;
xin = (sin(2*pi*4e3*t)+sin(2*pi*12e3*t)) / 2;

hSR = dsp.SignalSource(xin', 4);
hLog = dsp.SignalSink;
hFilt = dsp.DigitalFilter;
hFilt.TransferFunction = 'FIR (all zeros)';
hFilt.Numerator = fir1(10,0.5);

while ~isDone(hSR)
    input = step(hSR);
    filteredOutput = step(hFilt,input);
    step(hLog,filteredOutput);
end

filteredResult = hLog.Buffer;
periodogram(filteredResult,[],[],32e3)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Digital Filter block reference page. The object properties correspond to the block parameters.

# dsp.DigitalFilter

---

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the `FrameBasedProcessing` Property of a System object” for more information.

## See Also

`dsp.BiquadFilter`

**Purpose** Create static or time-varying digital filter with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a digital filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.DigitalFilter.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.DigitalFilter.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the digital filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.DigitalFilter.reset

---

**Purpose**            Reset internal states of digital filter

**Syntax**            reset(H)

**Description**        reset(H) resets the filter states of the digital filter object,H, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the step method applies the digital filter object to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

For example:

```
H = dsp.DigitalFilter;
H.TransferFunction = 'FIR (all zeros)';
H.Numerator = fir1(20,0.25);
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

**Purpose** Filter input with digital filter object

**Syntax**

```
Y = step(HFILT,X)
Y = step(HFILT,X,COEFF)
Y = step(HFILT,X,NUM,DEN)
```

**Description** `Y = step(HFILT,X)` filters the real or complex input signal `X` using the digital filter, `H`, to produce the output `Y`. The digital filter object operates on each channel of the input signal independently over successive calls to `step` method.

`Y = step(HFILT,X,COEFF)` uses the time-varying numerator or denominator coefficients, `COEFF`, to filter the input signal `X` and produce the output `Y`. You can use this option when you set the `TransferFunction` property to either `FIR` (all zeros) or `IIR` (all poles) and the `CoefficientsSource` property to `Input` port.

`Y = step(HFILT,X,NUM,DEN)` uses the time-varying numerator coefficients `NUM` and the time-varying denominator coefficients `DEN` to filter the input signal `X` and produce the output `Y`. You can use this option when you set the `TransferFunction` property to `IIR` (poles and zeros) and the `CoefficientsSource` property to `Input` port.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

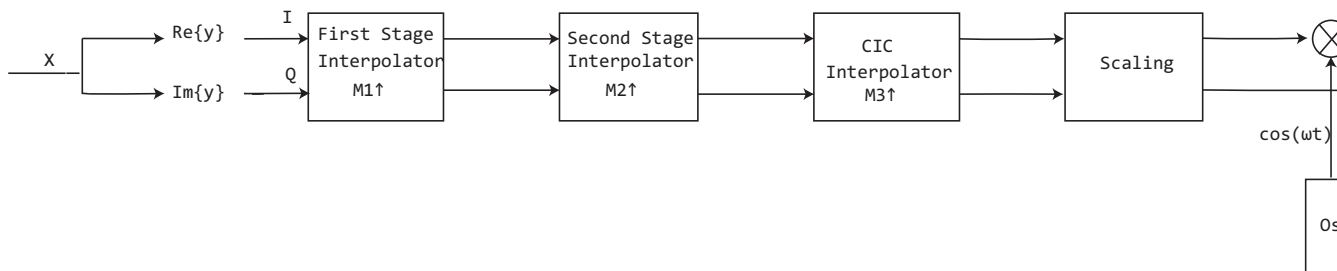

# dsp.DigitalUpConverter

**Purpose** Digitally upconvert input signal

**Description** The DigitalUpConverter object digitally upconverts the input signal. To digitally up convert the input signal:

- 1 Define and set up your digital up converter. See “Construction” on page 3-472.
- 2 Call `step` to upconvert the input according to the properties of `dsp.DigitalUpConverter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `h = dsp.DigitalUpConverter` returns a digital up-converter (DDC) System object, `h`. The object up samples the input signal using a cascade of three interpolation filters. This object frequency upconverts the up sampled signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. When you set the `FilterSpecification` property to 'Design parameters', the DUC object designs the interpolation filters according to the filter specifications that you set in the filter-related object properties. In this case the filter cascade consists of a first FIR interpolation stage, a CIC compensator, and a CIC interpolator. The following block diagram shows the architecture of the digital up converter.

The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. Depending on the setting of the **InterpolationFactor** property, you may be able to bypass the first filter stage. When the arithmetic is double or single precision, the CIC interpolator is implemented as a simple FIR interpolator with a boxcar response. A true CIC interpolator can only operate with fixed-point signals. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following diagram represents the DUC arithmetic with single or double-precision, floating-point inputs.

The following block diagram represents the DUC arithmetic with signed fixed-point inputs.

# dsp.DigitalUpConverter

---

- WL is the word length of the input, and FL is the fraction length of the input.
- The output of each filter is cast to the data type specified in the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties. The casting of the CIC output occurs after the scaling factor is applied.
- The oscillator output is cast to a word length equal to the **FiltersOutputDataType** word length plus one. The fraction length is equal to the **FiltersOutputDataType** word length minus one.
- The scaling at the output of the CIC interpolator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterprecast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.

If the normalization gain is  $G$ , (where  $0 < G \leq 1$ ), then:

- $WLCic$  is the word length of the CIC interpolator output and  $FLCic$  is the fraction length of the CIC interpolator output
- $F1 = \text{abs}(\text{nextpow2}(G))$ , indicating the part of  $G$  achieved using bit shifts (coarse gain)
- $F2 =$  fraction length specified by the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties
- $fg = \text{fi}((2^{F1}) * G, \text{true}, 16)$ , indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

`h = dsp.DigitalUpConverter('PropertyName', 'PropertyValue')` returns a DUC object, `h`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### SampleRate

Sample rate of input signal

Set this property to a positive scalar. The value of this property multiplied by the total interpolation factor must be greater than

or equal to twice the value of the `CenterFrequency` property. The default is `30e6`.

## **InterpolationFactor**

Set this property to a positive, integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers. When you set this property to a scalar the object automatically chooses the interpolation factors for each of the three filtering stages. The scalar value you specify cannot be a prime number. When you set this property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements respectively. When you set the `FilterSpecification` property to `Design parameters`, both elements of the `InterpolationFactor` vector must be greater than one. When you set the `FilterSpecification` property to `Coefficients`, the second element of the `InterpolationFactor` vector must be greater than 1. When you set this property to a 1-by-3 vector, the  $i^{\text{th}}$  element of the vector specifies the interpolation factor for the  $i^{\text{th}}$  filtering stage. When you set the `FilterSpecification` property to `Design parameters`, the second and third elements of the `InterpolationFactor` vector must be greater than one and the first element must be 1 or 2. When you set the `FilterSpecification` property to `Coefficients`, the third element of the `InterpolationFactor` vector must be greater than 1. When you set the `InterpolationFactor` property to `Coefficients`, you must set the `InterpolationFactor` property to a 1-by-3 or 1-by-2 vector . The default is 100.

## **FilterSpecification**

Set the filter specification as one of `Design parameters` | `Coefficients`. The default is `Design parameters`. The DUC object performs interpolation using a cascade of three interpolation filters. The third filter stage is always a CIC interpolator. When you set this property to `Design parameters`, the object designs the cascade of interpolation filters internally, according to a set of parameters that you specify using the

filter-related object properties. In this case, the first and second stages of the cascade consist of a halfband or lowpass FIR interpolator, and a CIC compensator respectively. When you set this property to `Coefficients`, you specify an arbitrary set of filter coefficients for the first and second stages using the `FirstFilterCoefficients`, and `SecondFilterCoefficients` properties respectively. You specify the number of CIC sections using the `NumCICSections` property. In all cases, the first filter stage can be bypassed by setting the `InterpolationFactor` property appropriately.

When the input data type is double or single the object implements an  $N$ -section CIC interpolation filter as an FIR filter with a response that corresponds to a cascade of  $N$  boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed point type.

### **MinimumOrderDesign**

Minimum order filter design.

When you set this property to true the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. When you set this property to false, the object designs filters with orders that you specify in the `FirstFilterOrder`, `SecondFilterOrder`, and `NumCICSections` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. This property applies when you set the `FilterSpecification` property to `Design` parameters. The default is true.

### **FirstFilterCoefficients**

Coefficients of first filter stage.

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the value of the `FirstFilterCoefficients` property because the first filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is 1.

## **SecondFilterOrder**

Order of CIC compensation filter stage

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design` parameters and the `MinimumOrderDesign` property to `false`. The default is 12.

## **SecondFilterCoefficients**

Coefficients of second filter stage.

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. Usually, the response of this filter should be that of a CIC compensator since a CIC interpolation filter follows the second filter stage. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is 1.

## **FirstFilterOrder**

Order of first filter stage

Set this property to a positive, integer, even scalar. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the `FirstFilterOrder` property because the first filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Design` parameters and the `MinimumOrderDesign` property to `false`. The default is 10.

## **NumCICSections**

Number of sections of CIC interpolator

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design` parameters and the `MinimumOrderDesign` property to `false`, or when you set the `FilterSpecification` property to `Coefficients`. The default is 3.

## **Bandwidth**

Two sided bandwidth of input signal in Hertz .

Set this property to a positive, integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. This property applies when you set the `FilterSpecification` property to `Design` parameters. The default is 200e3 Hertz.

## **StopbandFrequencySource**

Source of stopband frequency.

Specify the source of the stopband frequency as one of `Auto` | `Property`. The default is `Auto`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately  $F_c = \text{SampleRate}/2$  Hertz, and computes the stopband frequency as  $F_{stop} = F_c + TW/2$ .  $TW$  is the transition bandwidth of the cascade response, computed as  $2*(F_c - F_p)$ , and the passband frequency,  $F_p$ , equals `Bandwidth/2`. This property applies when you set the `FilterSpecification` property to `Design` parameters.

## **StopbandFrequency**

Stopband frequency in Hertz

Set this property to a double precision positive scalar. This property applies when you set the `FilterSpecification` property to `Design` parameters and the `StopbandFrequencySource` property to `Property`. The default is 150e3 Hertz.

## **PassbandRipple**

Passband ripple of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property. This property applies when you set the `FilterSpecification` property to `Design` parameters and the `MinimumOrderDesign` property to true. The default is 0.1 dB.

## **StopbandAttenuation**

Stopband attenuation of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property. This property applies when you set the `FilterSpecification` property to `Design` parameters and the `MinimumOrderDesign` property to true. The default is 60 dB.

## **Oscillator**

Type of oscillator.

Specify the oscillator as one of `Sine wave` | `NCO`. The default is `Sine wave`. When you set this property to `Sine wave`, the object frequency up converts the output of the interpolation filter cascade using a complex exponential signal obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO` the object performs frequency up conversion with a complex exponential obtained using a numerically controlled oscillator (NCO).

## **CenterFrequency**

Center frequency of output signal in Hertz .

Specify this property as a double precision, positive scalar. The value of this property must be less than or equal to half the product of the `SampleRate` property times the total interpolation

factor. The object up converts the input signal so that the output spectrum centers at the frequency you specify in the `CenterFrequency` property. The default is 14e6 Hertz.

## **NumAccumulatorBits**

Number of NCO accumulator bits

Specify this property as an integer scalar in the range [1 128]. This property applies when you set the `Oscillator` property to `NCO`. The default is 16.

See also `dsp.NCO`.

## **NumQuantizedAccumulatorBits**

Number of NCO quantized accumulator bits.

Specify this property as an integer scalar in the range [1 128]. The value you specify for this property must be less than the value you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO`. The default is 12.

See also `dsp.NCO`.

## **Dither**

Dither control for NCO .

When you set this property to true, the object uses the number of dither bits specified in the `NumDitherBits` property when applying dither to the NCO signal. This property applies when you set the `Oscillator` property to `NCO`. The default is true.

See also `dsp.NCO`.

## **NumDitherBits**

Number of NCO dither bits.

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits`

property. This property applies when you set the `Oscillator` property to `NCO` and the `Dither` property to `true`. The default is `4`.

See also `dsp.NCO`.

## Fixed-Point Properties

### FirstFilterCoefficientsDataType

Data type of first filter coefficients

Specify first filter coefficients data type as `Same as input` | `Custom`. The default is `Same as input`. This property applies when you set the `FilterSpecification` property to `Coefficients`.

### CustomFirstFilterCoefficientsDataType

Fixed-point data type of first filter coefficients

Specify the first filter coefficients fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `FirstFilterCoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

### SecondFilterCoefficientsDataType

Data type of second filter coefficients

Specify the second filter coefficients data type as `Same as input` | `Custom`. The default is `Same as input`. This property applies when you set the `FilterSpecification` property to `Coefficients`.

### CustomSecondFilterCoefficientsDataType

Fixed-point data type of second filter coefficients

Specify the second filter coefficients fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SecondFilterCoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

## FiltersOutputDataType

Data type of output of each filter stage

Specify the data type at the output of the first (if it has not been bypassed), second, and third filter stages as one of `Same as input` | `Custom`. The default is `Same as input`. The object casts the data at the output of each filter stage according to the value you set in this property. For the CIC stage, the casting is done after the signal has been scaled by the normalization factor.

## CustomFiltersOutputDataType

Fixed-point data type of output of each filter stage

Specify the filters output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `FiltersOutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## OutputDataType

Data type of output

Specify the data type of output as `Same as input` | `Custom`. The default is `Same as input`.

## CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## Methods

<code>clone</code>	Create digital up converter object with same property values
<code>fvtool</code>	Visualize response of filter cascade

# dsp.DigitalUpConverter

---

<code>getFilterOrders</code>	Get orders of interpolation filters
<code>getFilters</code>	Get handles to interpolation filter objects
<code>getInterpolationFactors</code>	Get interpolation factors of each filter stage
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>groupDelay</code>	Group delay of filter cascade
<code>isLocked</code>	Locked status for input attributes and non-tunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Process inputs using the object algorithm
<code>visualizeFilterStages</code>	Display response of filter stages

## Examples

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz.

```
% Create a sine wave generator to obtain the 1 KHz sinusoidal signal
% with a sample rate of 6 KHz.
Fs = 6e3; % Sample rate
hSig = dsp.SineWave('Frequency',1000,'SampleRate', Fs,'SamplesPerFrame',100);
x = step(hSig); % generate signal

% Create a DUC object. Use minimum order filter designs and set the
% passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Set
% the double sided signal bandwidth to 2 KHz.
hDUC = dsp.DigitalUpConverter(...
    'InterpolationFactor', 20,...
    'SampleRate', Fs,...
    'Bandwidth', 2e3,...
```

```
'StopbandAttenuation', 55,...
'PassbandRipple', 0.2,...
'CenterFrequency', 50e3);

% Create a spectrum estimator to visualize the signal spectrum before
% and after up converting.
window = hamming(floor(length(x)/10));
figure; pwelch(x,window,[],[],Fs,'centered')
title('Spectrum of baseband signal x')

% Up convert the signal and visualize the spectrum
xUp = step(hDUC,x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],20*Fs,'centered')
title('Spectrum of up converted signal xUp')

% Visualize the response of the interpolation filters
visualizeFilterStages(hDUC)
```

For additional examples using this System object, see the following demos:

- [Design and Analysis of a Digital Down Converter](#)

## See Also

`dsp.DigitalDownConverter`

# dsp.DigitalUpConverter.clone

---

**Purpose** Create digital up converter object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `DigitalUpConverter System` object, `C`, with the same property values as `H`.

The clone method creates a new unlocked object with uninitialized states.

**Purpose**

Visualize response of filter cascade

**Syntax**

```
fvtool(H)
fvtool(H,...,'Arithmetic',ARITH,...)
fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2)
```

**Description**

fvtool(H) plots the magnitude response of the cascade of filters. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). When you set the FilterSpecification property to Design parameters the method plots a mask based on the filter specifications.

fvtool(H,...,'Arithmetic',ARITH,...) specifies the arithmetic of the filter cascade. You set input ARITH to double, single, or fixed-point. When object H is in an unlocked state you must specify the arithmetic. When object H is in a locked state the arithmetic input is ignored.

fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2) launches FVTool and sets the specified FVTool properties to the specified values.

# dsp.DigitalUpConverter.getFilters

---

**Purpose** Get handles to interpolation filter objects

**Syntax** `S = getFilters(H)`  
`getFilters(H, 'Arithmetic', ARITH)`

**Description** `S = getFilters(H)` returns a structure, `S`, with copies of the filter System objects and the CIC normalization factor that form the interpolation filter cascade. The `FirstFilterStage` structure field is empty if the first filter stage has been bypassed. The CIC normalization factor equals the inverse of the CIC filter gain. In some cases, this gain includes a correction factor to ensure that the cascade response meets the ripple specifications.

`getFilters(H, 'Arithmetic', ARITH)` specifies the arithmetic of the filter stages. You set `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state, you must specify the arithmetic input. When object `H` is in a locked state, the arithmetic input is ignored.

When `H` is in an unlocked state, and you specify the arithmetic as `fixed-point`, the `getFilters` method returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalUpConverter` System object uses to process data when you call the `step` method. All other fixed-point properties are set to their default values.

When `H` is in a locked state, and the input to the `step` method is of a fixed-point data type, the `getFilters` method returns filter System objects. All fixed-point properties of these System objects are set to the exact values that the `dsp.DigitalUpConverter` System object uses to process the data.

**Purpose** Get orders of interpolation filters

**Syntax** `S = getFilterOrders(H)`

**Description** `S = getFilterOrders(H)` returns a structure, `S`, that contains the orders of the interpolation filter stages. The `FirstFilterOrder` structure field will be empty if the first filter stage has been bypassed.

# **dsp.DigitalUpConverter.getInterpolationFactors**

---

**Purpose** Get interpolation factors of each filter stage

**Syntax** `M = getInterpolationFactors(H)`

**Description** `M = getInterpolationFactors(H)` returns a vector, `M`, with the interpolation factors of each filter stage. If the first filter stage is bypassed, then `M` is a 1-by-2 vector containing the interpolation factors of the second and third stages in the first and second elements respectively. If the first filter stage is not bypassed then `M` is a 1-by-3 vector containing the interpolation factors of the first, second and third filter stages.

**Purpose** Number of expected inputs to step method

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of expected inputs, N, to the step method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.DigitalUpConverter.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Group delay of filter cascade

**Syntax**  
D = groupDelay(H,N)  
[D,F] = groupDelay(H,N)

**Description**  
D = groupDelay(H,N) returns a vector of group delays, D, evaluated at N frequency points equally spaced around the upper half of the unit circle. If you don't specify N, it defaults to 8192.  
[D,F] = groupDelay(H,N) returns a vector, F, of frequencies at which the group delay has been computed.

# **dsp.DigitalUpConverter.isLocked**

---

**Purpose** Locked status for input attributes and non-tunable properties

**Syntax** `Y = isLocked(H)`

**Description** `Y = isLocked(H)` returns the locked state, `Y`, of the `DigitalUpConverter` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

# dsp.DigitalUpConverter.step

---

**Purpose** Process inputs using the object algorithm

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  takes a real or complex input column vector  $X$  and outputs an up sampled and frequency up converted signal  $Y$ .  $X$  can be of data type double, single, signed integer, or signed fixed point (fi objects). The length of  $Y$  is equal to the length of  $X$  multiplied by the `InterpolationFactor`. When the data type of  $X$  is double or single precision, the data type of  $Y$  is the same as that of  $X$ . When the data type of  $X$  is of a fixed point type, the data type of  $Y$  is defined by the `OutputDataType` property.

**Purpose**

Display response of filter stages

**Syntax**

```
visualizeFilterStages(H)  
visualizeFilterStages(H, 'Arithmetic', ARITH)  
hfvt = visualizeFilterStages(H)
```

**Description**

`visualizeFilterStages(H)` plots the magnitude response of the filter stages and of the cascade response. When the `FilterSpecification` property is set to `Design` parameters the method plots a mask based on the filter specifications. By default, the object plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(H, 'Arithmetic', ARITH)` specifies the arithmetic of the filter stages. You set input `ARITH` to `'double'`, `'single'`, or `'fixed-point'`. When object `H` is in an unlocked state you must specify the arithmetic. When object `H` is in a locked state the arithmetic input is ignored.

`hfvt = visualizeFilterStages(H)` returns the handle to the `FVTool` object.

# dsp.DyadicAnalysisFilterBank

---

**Purpose** Dyadic analysis filter bank

**Description** The `DyadicAnalysisFilterBank` object uses a series of highpass and lowpass FIR filters to provide approximate octave band frequency decompositions of the input. Each filter output is downsampled by a factor of two. With the appropriate analysis filters and tree structure, the dyadic analysis filter bank is a discrete wavelet transform (DWT) or discrete wavelet packet transform (DWPT).

To obtain approximate octave band frequency decompositions of the input:

- 1 Define and set up your dyadic analysis filter bank. See “Construction” on page 3-498.
- 2 Call `step` to get the octave half band frequency decompositions of the input according to the properties of `dsp.DyadicAnalysisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.DyadicAnalysisFilterBank` constructs a dyadic analysis filter bank object, `H`, that computes the level-two discrete wavelet transform (DWT) of a column vector input. For a 2-D matrix input, the object transforms the columns using the Daubechies third-order extremal phase wavelet. The length of the input along the first dimension must be a multiple of 4.

`H = dsp.DyadicAnalysisFilterBank('PropertyName',PropertyValue, ...)` returns a dyadic analysis filter bank object, `H`, with each property set to the specified value.

**Properties** **Filter**

Type of filter used in subband decomposition

Specify the type of filter used to determine the high and lowpass FIR filters in the dyadic analysis filter bank as `Custom`, `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse`

Biorthogonal, or Discrete Meyer. All property values except Custom require Wavelet Toolbox software. If the value of this property is Custom, the filter coefficients are specified by the values of the CustomLowpassFilter and CustomHighpassFilter properties. Otherwise, the dyadic analysis filter bank object uses the Wavelet Toolbox function `wfilters` to construct the filters. The following table lists supported wavelet filters and example syntax to construct the filters:

Filter	Example Setting	Syntax for Analysis Filters
Haar	N/A	<code>[Lo_D,Hi_D]=wfilters('haar');</code>
Daubechies extremal phase	<code>WaveletOrder=3;</code>	<code>[Lo_D,Hi_D]=wfilters('db3');</code>
Symlets (Daubechies least-asymmetric)	<code>WaveletOrder=4;</code>	<code>[Lo_D,Hi_D]=wfilters('sym4');</code>
Coiflets	<code>WaveletOrder=1;</code>	<code>[Lo_D,Hi_D]=wfilters('coif1');</code>
Biorthogonal	<code>FilterOrder='[3/1]';</code>	<code>[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('bior3.1');</code>
Reverse biorthogonal	<code>FilterOrder='[3/1]';</code>	<code>[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('rbior3.1');</code>
Discrete Meyer	N/A	<code>[Lo_D,Hi_D]=wfilters('dmey');</code>

### CustomLowpassFilter

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in powers of  $z^{-1}$ . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomHighpassFilter property. This property applies when you set the Filter property to Custom. The default specifies a Daubechies third-order extremal phase scaling (lowpass) filter.

### CustomHighpassFilter

# dsp.DyadicAnalysisFilterBank

---

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in powers of  $z^{-1}$ . Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` property. This property applies when you set the `Filter` property to `Custom`. The default specifies a Daubechies 3rd-order extremal phase wavelet (highpass) filter.

## WaveletOrder

Order for orthogonal wavelets

Specify the order of the wavelet selected in the `Filter` property. This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`. The default is 2.

## FilterOrder

Analysis and synthesis filter orders for biorthogonal filters

Specify the order of the analysis and synthesis filter orders for biorthogonal filter banks as 1 / 1, 1 / 3, 1 / 5, 2 / 2, 2 / 4, 2 / 6, 2 / 8, 3 / 1, 3 / 3, 3 / 5, 3 / 7, 3 / 9, 4 / 4, or 5 / 5, 6 / 8. Unlike orthogonal wavelets, biorthogonal wavelets require different filters for the analysis (decomposition) and synthesis (reconstruction) of an input. The first number indicates the order of the synthesis (reconstruction) filter. The second number indicates the order of the analysis (decomposition) filter. This property applies when you set the `Filter` property to `Biorthogonal` or `Reverse Biorthogonal`. The default is 1 / 1.

## NumLevels

Number of filter bank levels used in analysis (decomposition)

Specify the number of filter bank analysis levels a positive integer. A level- $N$  asymmetric structure produces  $N+1$  output subbands. A level- $N$  symmetric structure produces  $2^N$  output subbands. The

default is 2. The size of the input along the first dimension must be a multiple of  $2^N$ , where  $N$  is the number of levels.

## TreeStructure

Structure of filter bank

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. The asymmetric structure decomposes only the lowpass filter output from each level. The symmetric structure decomposes the highpass and lowpass filter outputs from each level. If the analysis filters are scaling (lowpass) and wavelet (highpass) filters, the asymmetric structure is the discrete wavelet transform, while the symmetric structure is the discrete wavelet packet transform.

When this property is `Symmetric`, the output has  $2^N$  subbands each of size  $M/2^N$ . In this case,  $M$  is the length of the input along the first dimension and  $N$  is the value of the `NumLevels` property. When this property is `Asymmetric`, the output has  $N+1$  subbands. The following equation gives the length of the output in the  $k$ th subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \leq k \leq N \\ \frac{M}{2^N} & k = N + 1 \end{cases}$$

The default is `Asymmetric`.

## Methods

<code>clone</code>	Create dyadic analysis filter bank object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method

# dsp.DyadicAnalysisFilterBank

---

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset filter states
step	Decompose input with dyadic filter bank

## Examples

Denoise square wave input using dyadic analysis and synthesis filter banks:

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
hdydan1 = dsp.DyadicAnalysisFilterBank;

% The filter coefficients correspond to a 'haar' wavelet.
hdydan1.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydan1.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
hdydsyn = dsp.DyadicSynthesisFilterBank;
hdydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];

C = step(hdydan1, xn);

% Subband outputs
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);

% Set higher frequency coefficients to zero
% to remove the noise.
x_den = step(hdydsyn, [zeros(length(C1),1);...
zeros(length(C2),1);C3]);

subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Analysis Filter Bank block reference page. The object properties correspond to the block parameters, except:

The dyadic analysis filter bank object always concatenates the subbands into a single column vector for a column vector input, or into the columns of a matrix for a matrix input. This behavior corresponds to the block's behavior when you set the **Output** parameter to `Single` port.

## See Also

[dsp.DyadicSynthesisFilterBank](#) | [dsp.SubbandAnalysisFilter](#)

# **dsp.DyadicAnalysisFilterBank.clone**

---

**Purpose** Create dyadic analysis filter bank object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a dyadic analysis filter bank object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.DyadicAnalysisFilterBank.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.DyadicAnalysisFilterBank.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.DyadicAnalysisFilterBank.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the dyadic analysis filter bank object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.DyadicAnalysisFilterBank.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Reset filter states

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the dyadic analysis filter bank object, H, to their initial values of zero. After the step method applies the dyadic analysis filter bank to nonzero input data, the filter states may change. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

Example of resetting filter states:

```
X = [1 1 7 9 2 8 8 6]';  
H = dsp.DyadicAnalysisFilterBank('NumLevels',1);  
% Filter states are zero  
y = step(H,X);  
% Invoke step method again without resetting states  
y1 = step(H,X);  
isequal(y,y1) % Returns 0  
reset(H); % Reset filter states to zero  
y2 = step(H,X);  
isequal(y,y2) % Returns 1
```

# dsp.DyadicAnalysisFilterBank.step

---

**Purpose** Decompose input with dyadic filter bank

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  computes the subband decomposition of the input  $X$  and outputs the dyadic subband decomposition in  $Y$  as a single concatenated column vector or matrix of coefficients. Each column of  $X$  is treated as an independent input, and the number of rows of  $X$  must be a multiple of  $2^N$ , where  $N$  is the value of the NumLevels property. The elements of  $Y$  are ordered with the highest frequency subband first followed by subbands in decreasing frequency

**Examples** Subband ordering for level-two asymmetric tree structure:

```
t = 0:.001:1.023;
% Sampling frequency 1 kHz input length 1024
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
% Default asymmetric structure with
% Daubechies order 3 extremal phase wavelet
H = dsp.DyadicAnalysisFilterBank;
Y = step(H,xn);
% Level 2 yields 3 subbands (two detail-one approximation)
% Nyquist frequency is 500 Hz
D1 = Y(1:512); % subband approx. [250, 500] Hz
D2 = Y(513:768); % subband approx. [125, 250] Hz
Approx = Y(769:1024); % subband approx. [0,125] Hz
```

---

Subband ordering for symmetric tree structure:

```
t = 0:.001:1.023;
% Sampling frequency 1 kHz input length 1024
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1); % symmetric structure with
% Daubechies order 3 extremal phase wavelet
```

```
H = dsp.DyadicAnalysisFilterBank('TreeStructure',...  
    'Symmetric');  
Y = step(H,xn);  
D1 = Y(1:256); % subband approx. [375,500] Hz  
D2 = Y(257:512); % subband approx. [250,375] Hz  
D3 = Y(513:768); % subband approx. [125,250] Hz  
Approx = Y(769:1024); % subband approx. [0, 125] Hz
```

# dsp.DyadicSynthesisFilterBank

---

**Purpose** Reconstruct signals from subbands

**Description** The `DyadicSynthesisFilterBank` object reconstructs signals from subbands with smaller bandwidths and lower sample rates. The filter bank uses a series of highpass and lowpass FIR filters to repeatedly reconstruct the signal.

To reconstruct signals from subbands with smaller bandwidths and lower sample rates:

- 1 Define and set up your synthesis filter bank. See “Construction” on page 3-512.
- 2 Call `step` to reconstruct the signal according to the properties of `dsp.DyadicSynthesisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.DyadicSynthesisFilterBank` returns a synthesis filter bank, `H`, that reconstructs a signal from its subbands with smaller bandwidths and smaller sample rates.

`H = dsp.DyadicSynthesisFilterBank('PropertyName',PropertyValue,...)` returns a synthesis filter bank, `H`, with each specified property set to the specified value.

**Properties** **Filter**

Type of filter used in filter bank

Specify the type of filter used to determine the highpass and lowpass FIR filters in the filter bank as one of `Custom`, `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse Biorthogonal`, or `Discrete Meyer`. If you set this property to `Custom`, the `CustomLowpassFilter` and `CustomHighpassFilter` properties specify the filter coefficients. Otherwise, the object uses the Wavelet Toolbox `wfilters` function to construct the filters. Depending on the filter, the `WaveletOrder` or `FilterOrder`

property might apply. For a list of the supported wavelets, see the following table.

<b>Filter</b>	<b>Sample Setting for Related Filter Specification Properties</b>	<b>Corresponding Wavelet Toolbox Function Syntax</b>
Haar	None	wfilters('haar')
Daubechies	H.WaveletOrder = 4	wfilters('db4')
Symlets	H.WaveletOrder = 3	wfilters('sym3')
Coiflets	H.WaveletOrder = 1	wfilters('coif1')
Biorthogonal	H.FilterOrder = '[3/1]'	wfilters('bior3.1')
Reverse Biorthogonal	H.FilterOrder = '[3/1]'	wfilters('rbior3.1')
Discrete Meyer	None	wfilters('dmey')

In order to automatically design wavelet-based filters, install the Wavelet Toolbox product. Otherwise, use the CustomLowpassFilter and CustomHighpassFilter properties to specify lowpass and highpass FIR filters.

## CustomLowpassFilter

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of  $z$ . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomHighpassFilter property. This property applies only when you set the Filter property to Custom. To perfectly reconstruct a signal decomposed by the DyadicAnalysisFilterBank, design the filters in the

synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

## CustomHighpassFilter

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of  $z$ . Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` property. This property applies only when you set the `Filter` property to `Custom`. To perfectly reconstruct a signal decomposed by the `DyadicAnalysisFilterBank`, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

## WaveletOrder

Wavelet order

Specify the order of the wavelet selected in the `Filter` property. This property applies only when you set the `Filter` property to `Daubechies`, `Symlets` or `Coiflets`. The default is 2.

## FilterOrder

Wavelet order for synthesis filter stage

Specify the order of the wavelet for the synthesis filter stage as:

- First order: `'[1/1]'`, `'[1/3]'`, or `'[1/5]'`.
- Second order: `'[2/2]'`, `'[2/4]'`, `'[2/6]'`, or `'[2/8]'`.
- Third order: `'[3/1]'`, `'[3/3]'`, `'[3/5]'`, `'[3/7]'`, or `'[3/9]'`.
- Fourth order: `'[4/4]'`.

- Fifth order: '[5/5]'.
- Sixth order: '[6/8]'.

This property applies only when you set the `Filter` property to `Biorthogonal` or `Reverse Biorthogonal`. The default is '[1/1]'.

## NumLevels

Number of filter bank levels

Specify the number of filter bank levels as a scalar integer. An  $N$ -level asymmetric structure has  $N + 1$  input subbands, and an  $N$ -level symmetric structure has  $2^N$  input subbands. The default is 2.

rg

## TreeStructure

Structure of filter bank

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. In the asymmetric structure, the low-frequency subband input to each level is the output of the previous level, while the high-frequency subband input to each level is an input to the filter bank. In the symmetric structure, both the low- and high-frequency subband inputs to each level are outputs from the previous level. The default is `Asymmetric`.

## Methods

<code>clone</code>	Create synthesis filter bank object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of the step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties

# dsp.DyadicSynthesisFilterBank

---

release	Allow property value and input characteristics changes
reset	Reset internal states of dyadic synthesis filter bank object
step	Reconstruct signal from high- and low-frequency subbands

## Examples

Remove noise from a signal using filter banks:

```
t = 0:.0001:.0511;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
hdydanl = dsp.DyadicAnalysisFilterBank;

% The filter coefficients correspond to a 'haar' wavelet.
hdydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
hdydsyn = dsp.DyadicSynthesisFilterBank;
hdydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];

C = step(hdydanl, xn);

% Subband outputs
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);

% Set high-frequency coefficients to zero to remove noise.
x_den = step(hdydsyn, ...
    [zeros(length(C1),1); ...
    zeros(length(C2),1); ...
    C3]);

subplot(2,1,1), plot(xn); title('Original Noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

## **Algorithms**

This object implements the algorithm, inputs, and outputs described on the Dyadic Synthesis Filter Bank block reference page. The object properties correspond to the block parameters, except:

The object only receives data as a vector or matrix of concatenated subbands, as specified using the `step` method.

## **See Also**

`dsp.DyadicAnalysisFilterBank` | `dsp.SubbandSynthesisFilter`

# **dsp.DyadicSynthesisFilterBank.clone**

---

**Purpose** Create synthesis filter bank object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `DyadicSynthesisFilterBank` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.DyadicSynthesisFilterBank.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.DyadicSynthesisFilterBank.getNumOutputs**

---

**Purpose**            Number of outputs of the step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.DyadicSynthesisFilterBank.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `DyadicSynthesisFilterBank` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.DyadicSynthesisFilterBank.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Reset internal states of dyadic synthesis filter bank object

**Syntax** reset(H)

**Description** reset(H) sets the internal states of the dyadic synthesis filter bank object H to their initial values.

# dsp.DyadicSynthesisFilterBank.step

---

**Purpose** Reconstruct signal from high- and low-frequency subbands

**Syntax**  $X = \text{step}(H,S)$

**Description**  $X = \text{step}(H,S)$  reconstructs the concatenated subband input  $S$  to output  $X$ . Each column of input  $S$  contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands. The number of rows of  $S$  must be a multiple of  $2^N$ , where  $N$  is the value of the NumLevels property.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

---

<b>Purpose</b>	Discrete Fourier transform
<b>Description</b>	<p>The FFT object computes the discrete Fourier transform (DFT) of an input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:</p> <ul style="list-style-type: none"><li>• Double-signal algorithm</li><li>• Half-length algorithm</li><li>• Radix-2 decimation-in-time (DIT) algorithm</li><li>• Radix-2 decimation-in-frequency (DIF) algorithm</li><li>• An algorithm chosen by FFTW [1], [2]</li></ul> <p>To compute the DFT of an input:</p> <ol style="list-style-type: none"><li><b>1</b> Define and set up your FFT object. See “Construction” on page 3-525.</li><li><b>2</b> Call <code>step</code> to compute the DFT of the input according to the properties of <code>dsp.FFT</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.FFT</code> returns a FFT object, <code>H</code>, that computes the DFT of an <math>N</math>-D array. For column vectors or multidimensional arrays, the FFT object computes the DFT along the first dimension. If the input is a row vector, the FFT object computes a row of single-sample DFTs and issues a warning.</p> <p><code>H = dsp.FFT('PropertyName',PropertyValue, ...)</code> returns a FFT object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>FFTImplementation</b></p> <p>FFT implementation</p>

Specify the implementation used for the FFT as one of `Auto` | `Radix-2` | `FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

## **BitReversedOutput**

Order of output elements relative to input elements

Designate order of output channel elements relative to order of input elements. Set this property to `true` to output the frequency indices in bit-reversed order. The default is `false`, which corresponds to a linear ordering of frequency indices.

## **Normalize**

Divide butterfly outputs by two

Set this property to `true` if the output of the FFT should be divided by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

The default value of this property is `false` with no scaling.

## **FFTLengthSource**

Source of FFT length

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal. The default is `Auto`.

## **FFTLength**

FFT length

Specify the FFT length. This property applies when you set the `FFTLengthSource` property to `Property`. The default is `64`.

This property must be a power of two when the input is a fixed-point data type, or when you set the `BitReversedOutput` property to `true`, or when you set the `FFTImplementation` property to `Radix-2`.

## Fixed-Point Properties

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, `Zero`. The default is `Floor`.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

### SineTableDataType

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

### CustomSineTableDataType

Sine table word and fraction lengths

Specify the sine table fixed-point type as an unscaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` property to `Custom`. The default is `numericType([],16)`.

### ProductDataType

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

### CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when

you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator data type as `Full` precision, `Same as input`, `Same as product`, or `Custom`. The default is `Full` precision.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output data type as one of `Full` precision, `Same as input`, `Custom`. The default is `Full` precision.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

## **Methods**

<code>clone</code>	Create FFT object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Discrete Fourier transform of input

## Examples

Find frequency components of a signal in additive noise:

```

Fs = 800; L = 1000;
t = (0:L-1)'/Fs;
x = sin(2*pi*250*t) + 0.75*cos(2*pi*340*t);
y = x + .5*randn(size(x)); % noisy signal

hfft = dsp.FFT('FFTLengthSource', 'Property', ...
'FFTLength', 1024);

Y = step(hfft, y);

% Plot the single-sided amplitude spectrum
plot(Fs/2*linspace(0,1,512), 2*abs(Y(1:512)/1024));
title('Single-sided amplitude spectrum of noisy signal y(t)');
xlabel('Frequency (Hz)'); ylabel('|Y(f)|');

```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the FFT block reference page. The object properties correspond to the block parameters.

[dsp.IFFT](#) | [dsp.DCT](#) | [dsp.IDCT](#)

**Purpose** Create FFT object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an FFT object with the same property values as H. The clone method creates a new unlocked object.

# dsp.FFT.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose** Number of outputs of step method

**Syntax** `N = getNumOutputs(H)`

**Description** `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.FFT.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the FFT object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.FFT.step

---

**Purpose** Discrete Fourier transform of input

**Syntax**  $Y = \text{step}(H, X)$

**Description**  $Y = \text{step}(H, X)$  computes the FFT,  $Y$ , of the input  $X$  along the first dimension of  $X$ . When the `FFTLengthSource` property is `Auto`, the length of  $X$  along the first dimension must be a positive integer power of two. This length is also the FFT length. When the `FFTLengthSource` property is `Property`, the `FFTLength` property must be a positive integer power of two.

<b>Purpose</b>	FIR polyphase decimator
<b>Description</b>	<p>The FIRDecimator object resamples vector or matrix inputs along the first dimension. The object resamples at a rate <math>M</math> times slower than the input sampling rate, where <math>M</math> is the integer-valued downsampling factor. The decimation combines an FIR anti-aliasing filter with downsampling. The FIR decimator object uses a polyphase implementation of the FIR filter.</p> <p>To resample vector or matrix inputs along the first dimension:</p> <ol style="list-style-type: none"><li>1 Define and set up your FIR decimator. See “Construction” on page 3-537.</li><li>2 Call <code>step</code> to resample the vector or matrix inputs according to the properties of <code>dsp.FIRDecimator</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.FIRDecimator</code> returns an FIR decimator, <code>H</code>, which applies an FIR filter with a cutoff frequency of <math>0.4\pi</math> radians/sample to the input and downsamples the filter output by factor of 2.</p> <p><code>H = dsp.FIRDecimator('PropertyName',PropertyValue, ...)</code> returns an FIR decimator, <code>H</code>, with each property set to the specified value.</p> <p><code>H = dsp.FIRDecimator(DECIM, NUM, 'PropertyName',PropertyValue, ...)</code> returns an FIR decimator, <code>H</code>, with the integer-valued DecimationFactor property set to DECIM, the Numerator property set to NUM, and other specified properties set to the specified values.</p>
<b>Properties</b>	<p><b>DecimationFactor</b></p> <p>Decimation factor</p> <p>Specify the downsampling factor as a positive integer. The FIR decimator reduces the sampling rate of the input by this factor.</p>

The size of the input along the first dimension must be a multiple of the decimation factor. The default is 2.

## Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR filter in powers of  $z^{-l}$ . The following equation defines the system function for a filter of length  $L$ :

$$H(z) = \sum_{l=0}^{L-1} b_l z^{-l}$$

To prevent aliasing as a result of downsampling, the filter transfer function should have a normalized cutoff frequency no greater than  $1/\text{DecimationFactor}$ . You can specify the filter coefficients as a vector in the supported data types. The FIR decimator does not support `dfilt` or `mfilt` objects as sources of the filter coefficients. The default is `fir1(35,0.4)`.

## Structure

Filter structure

Specify the implementation of the FIR filter as either `Direct form` or `Direct form transposed`. The default is `Direct form`.

## Fixed-Point Properties

### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are

added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

## **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

## **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies only if the object is not in full precision mode.

## **CoefficientsDataType**

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

## **CustomCoefficientsDataType**

Coefficients word and fraction lengths

Specify the coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Full precision | Same as product | Same as input | Custom |. The default is Full precision.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as accumulator | Same as product | Same as input | Custom |. The default is Same as accumulator.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when

you set the `OutputDataType` property to `Custom`. The default is `numericType([1,16,15])`.

## Definitions

### Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into  $M$  different subfilters, where  $M$  is the downsampling, or decimation factor. Let  $h(n)$  denote the FIR filter impulse response of length  $L$  and  $u(n)$  the input signal. Decimating the filter output by a factor of  $M$  is equivalent to the downsampled convolution:

# dsp.FIRDecimator

---

$$y(n) = \sum_{l=0}^{L-1} h(l)u(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting  $M=2$ , the input values  $u(0), u(2), u(4), \dots$  are only combined with the filter coefficients  $h(0), h(2), h(4), \dots$ , and the input values  $u(1), u(3), u(5), \dots$  are only combined with the filter coefficients  $h(1), h(3), h(5), \dots$ . By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output. The following MATLAB code demonstrates how to construct the two polyphase subfilters for the default order 35 filter in the Numerator property and the default DecimationFactor property value of two:

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
    nzeros = M - rem(FiltLength, M);
    Num = [zeros(nzeros,1); Num]; % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of PolyphaseFilt are subfilters containing the two *phases* of the filter in Num. For a general downsampling factor of  $M$ , there are  $M$  phases and therefore  $M$  subfilters.

## Examples

Decimate a sum of sine waves with angular frequencies of  $\pi/4$  and  $2\pi/3$  radians/sample by a factor of two. To prevent aliasing, the

FIR decimator filters out the  $2\pi/3$  radians/sample component before downsampling:

```
x = cos(pi/4*[0:95]')+sin(2*pi/3*[0:95]');
H = dsp.FIRDecimator;
y = step(H,x);

% View group delay of default FIR filter
fvtool(fir1(35,0.4),1,'analysis','grpdelay');
% Group delay of the default linear-phase FIR filter
% is 17.5 samples. Downsampling by a factor of
% two expect an approx. 8.75 sample delay in the output
% y with the initial filter states of zero

subplot(211);
stem(x(1:length(x)/2),'b','markerfacecolor',[0 0 1]);
title('Input Signal');
subplot(212);
stem(y,'b','markerfacecolor',[0 0 1]);
title('Output--Lowpass filtered and downsampled by 2');
```

The figure shows that the delay in the decimated output is consistent with the group delay of the filter when the initial filter states are zero.

# dsp.FIRDecimator

Reduce the sampling rate of an audio signal by 1/2 and play it:

```
hmfr = dsp.AudioFileReader('OutputDataType',...  
    'single');  
hap = dsp.AudioPlayer(22050/2);  
hfirdec = dsp.FIRDecimator;  
  
while ~isDone(hmfr)  
    frame = step(hmfr);  
    y = step(hfirdec, frame);  
    step(hap, y);  
end  
  
release(hmfr);  
pause(0.5);  
release(hap);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Decimation block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source** – The FIR decimator object does not support `mfilt` objects.
- **Framing** – The FIR decimator object only supports `Maintain input frame rate`
- **Output buffer initial conditions** – The FIR decimator object does not support this parameter.
- **Rate options** – The FIR decimator object does not support this parameter.
- **Input processing** The FIR decimator object does not support this parameter.

### See Also

`dsp.FIRInterpolator` | `dsp.FIRRateConverter`

# **dsp.FIRDecimator.clone**

---

**Purpose** Create FIR decimator object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an FIR decimator object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

**Purpose** Frequency response

**Syntax**  
`[h,w] = freqz(H)`  
`[h,w] = freqz(H,n)`  
`[h,w] = freqz(H,Name,Value)`  
`freqz(H)`

**Description** `[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

# **dsp.FIRDecimator.fvtool**

---

**Purpose** Open filter visualization tool

**Syntax** `fvtool(H)`  
`fvtool(H, 'Arithmetic', ARITH, ...)`

**Description** `fvtool(H)` performs an analysis and computes the magnitude response of the filter System object H.

`fvtool(H, 'Arithmetic', ARITH, ...)` analyzes the filter System object H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.FIRDecimator.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Impulse response

**Syntax**  
`[h,t] = impz(H)`  
`[h,t] = impz(H,Name,Value)`  
`impz(H)`

**Description** `[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(H)` uses `FVTool` to plot the impulse response of the filter System object `H`.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

# **dsp.FIRDecimator.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the FIR decimator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Unwrapped phase response

**Syntax**

```
[phi,w] = phasez(H)  
[phi,w] = phasez(H,n)  
[phi,w] = phasez(H,Name,Value)  
phasez(H)
```

**Description**

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

# dsp.FIRDecimator.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset filter states of FIR decimator

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the FIR decimator object,H, to the initial values of zero. After the step method applies the FIR decimator to nonzero input data, the filter states may change. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

Example of resetting filter states:

```
H = dsp.FIRDecimator;
x = cos(pi/8*[0:1023]')+sin(pi/4*[0:1023]');
y = step(H,x);
% Invoke step method again without reset
y1 = step(H,x);
isequal(y,y1) % Returns 0
% Reset filter states
reset(H);
y2 = step(H,x);
isequal(y,y2) % Returns 1
```

## dsp.FIRDecimator.step

---

**Purpose** Decimate input by integer factor

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  outputs the filtered and downsampled values,  $Y$ , of the input signal,  $X$ . A  $K_i$ -by- $N$  input matrix is treated as  $N$  independent channels. The length of each column must be a multiple of the `DecimationFactor` property value. The FIR decimator operates on each channel separately and generates a  $K_o$ -by- $N$  output matrix where  $K_o = K_i/M$  with  $M$  the decimation factor. The object supports real and complex floating-point and fixed-point inputs, except for complex unsigned fixed-point inputs.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Static or time-varying FIR filter
<b>Description</b>	<p>The <code>FIRFilter</code> object filters each channel of the input using static or time-varying FIR filter implementations.</p> <p>To filter each channel of the input:</p> <ol style="list-style-type: none"> <li><b>1</b> Define and set up your FIR filter. See “Construction” on page 3-557.</li> <li><b>2</b> Call <code>step</code> to filter each channel of the input according to the properties of <code>dsp.FIRFilter</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li> </ol>
<b>Construction</b>	<p><code>H = dsp.FIRFilter</code> returns a default FIR filter object, <code>H</code>, which independently filters each channel of the input over successive calls to the <code>step</code> method, using a specified FIR filter implementation. The default numerator coefficients are <code>[0.5 0.5]</code>.</p> <p><code>H = dsp.FIRFilter('PropertyName',PropertyValue, ...)</code> returns an FIR filter system object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>Structure</b></p> <p>Filter structure</p> <p>Specify the filter structure.</p> <p>You can specify the filter structure as one of <code>  Direct form   Direct form symmetric   Direct form antisymmetric   Direct form transposed   Lattice MA  </code>. The default is <code>Direct form</code>.</p> <p><b>NumeratorSource</b></p> <p>Source of filter coefficients</p> <p>Specify the source of the filter coefficients as one of <code>  Property   Input port  </code>. The default is <code>Property</code>. When you specify <code>Input port</code>, the filter object updates the time-varying filter once</p>

every frame, when the `FrameBasedProcessing` property is true. When the `FrameBasedProcessing` property is false, it updates once every sample.

This applies when you set the `Structure` to `Direct form` | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed`.

## **ReflectionCoefficientsSource**

Source of filter coefficients

Specify the source of the Lattice filter coefficients as one of `Property` | `Input port` |. The default is `Property`. When you specify `Input port`, the filter object updates the time-varying filter once every frame, when the `FrameBasedProcessing` property is true. When the `FrameBasedProcessing` property is false, it updates once every sample.

This applies when you set the `Structure` to `Lattice MA`.

## **Numerator**

Numerator coefficients

Specify the filter coefficients as a real or complex numeric row vector. This property applies when you set the `NumeratorSource` property to `Property`, and the `Structure` property is not set to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `[0.5 0.5]`. This property is tunable.

## **ReflectionCoefficients**

Reflection coefficients of lattice filter structure

Specify the reflection coefficients of a lattice filter as a real or complex numeric row vector. This property applies when you set the `Structure` property to `Lattice MA`, and the `ReflectionCoefficientsSource` property to `Property`. The default is `[0.5 0.5]`. This property is tunable.

## **InitialConditions**

## Initial conditions for the FIR filter

Specify the initial conditions of the filter states. The number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the FIR filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. The default is 0.

## **FrameBasedProcessing**

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

## **Fixed-Point Properties**

### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

## **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

## **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

## **CoefficientsDataType**

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. This property applies when you set the `NumeratorSource` property to `Property`. The default is `Same word length as input`.

## **CustomCoefficientsDataType**

Custom coefficients word and fraction lengths

Specify the coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsDataType` property to `Custom`. The default is `numericType(true,16,15)`.

## **ReflectionCoefficientsDataType**

Reflection coefficients word and fraction lengths

Specify the reflection coefficients fixed-point data type as one of `Same word length as input` | `Custom` |. This property applies when you set the `ReflectionCoefficientsSource` property to `Property`. The default is `Same word length as input`.

## **CustomReflectionCoefficientsDataType**

Custom reflection coefficients word and fraction lengths

Specify the numerator fixed-point type as a signed or unsigned `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ReflectionCoefficientsDataType` property to `Custom`. The default is `numericType(true,16,15)`.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

## **CustomProductDataType**

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType(true,32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. The default is Full precision.

## **CustomAccumulatorDataType**

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType(true,32,30)`.

## **StateDataType**

State word and fraction lengths

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom |. This property does not apply to any of the direct form or direct form I filter structures. The default is Same as accumulator.

## **CustomStateDataType**

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `StateDataType` property to `Custom`. The default is `numericType(true,16,15)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input | Same as accumulator | Custom |. The default is Same as accumulator.

## **CustomOutputDataType**

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType(true,16,15)`.

## Methods

<code>clone</code>	Create static or time-varying FIR filter with same property values

More “Analysis Methods for Filter System Objects” on page 2-2.

## Examples 1

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components:

```
t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t);

hSR = dsp.SignalSource;
```

## dsp.FIRFilter

---

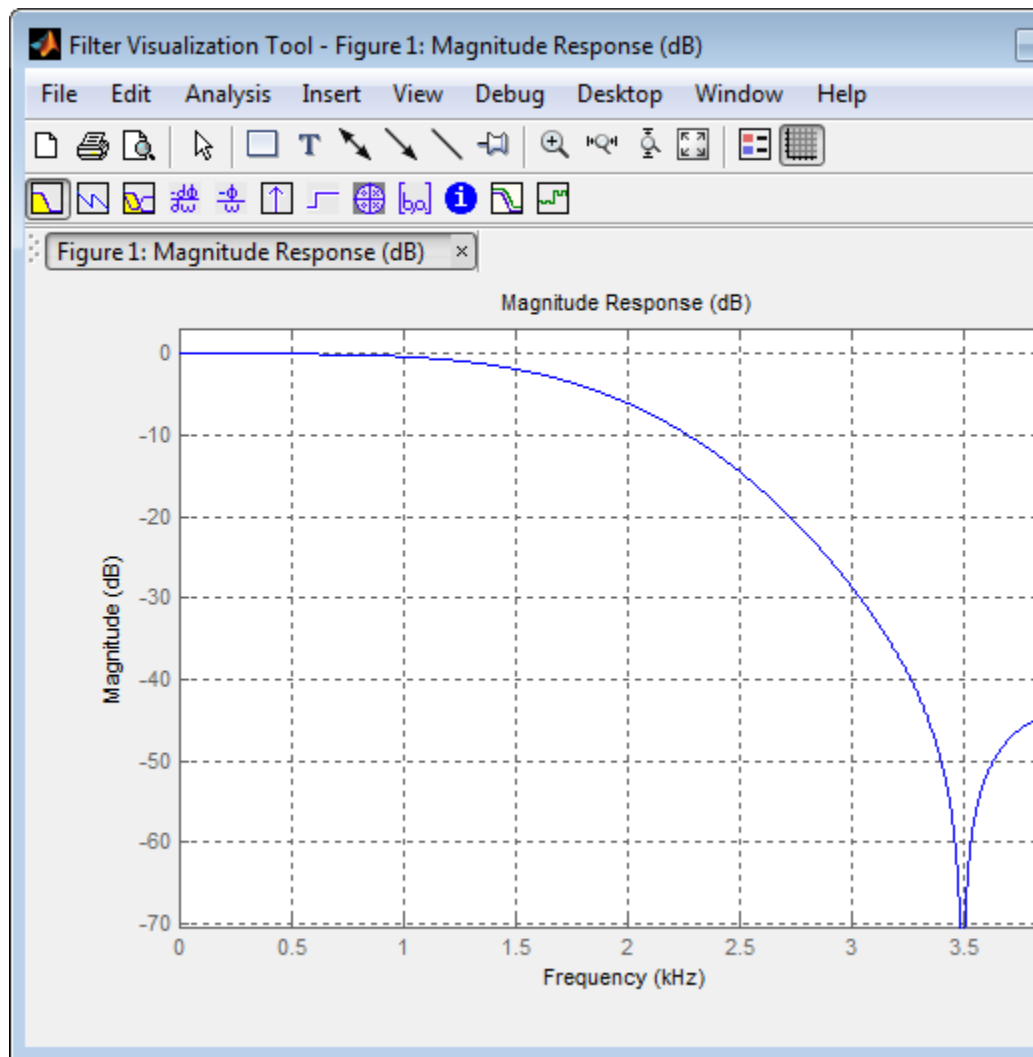

```
hSR.Signal = xin;
hLog = dsp.SignalSink;

hFIR = dsp.FIRFilter;
hFIR.Numerator = fir1(10,0.5);

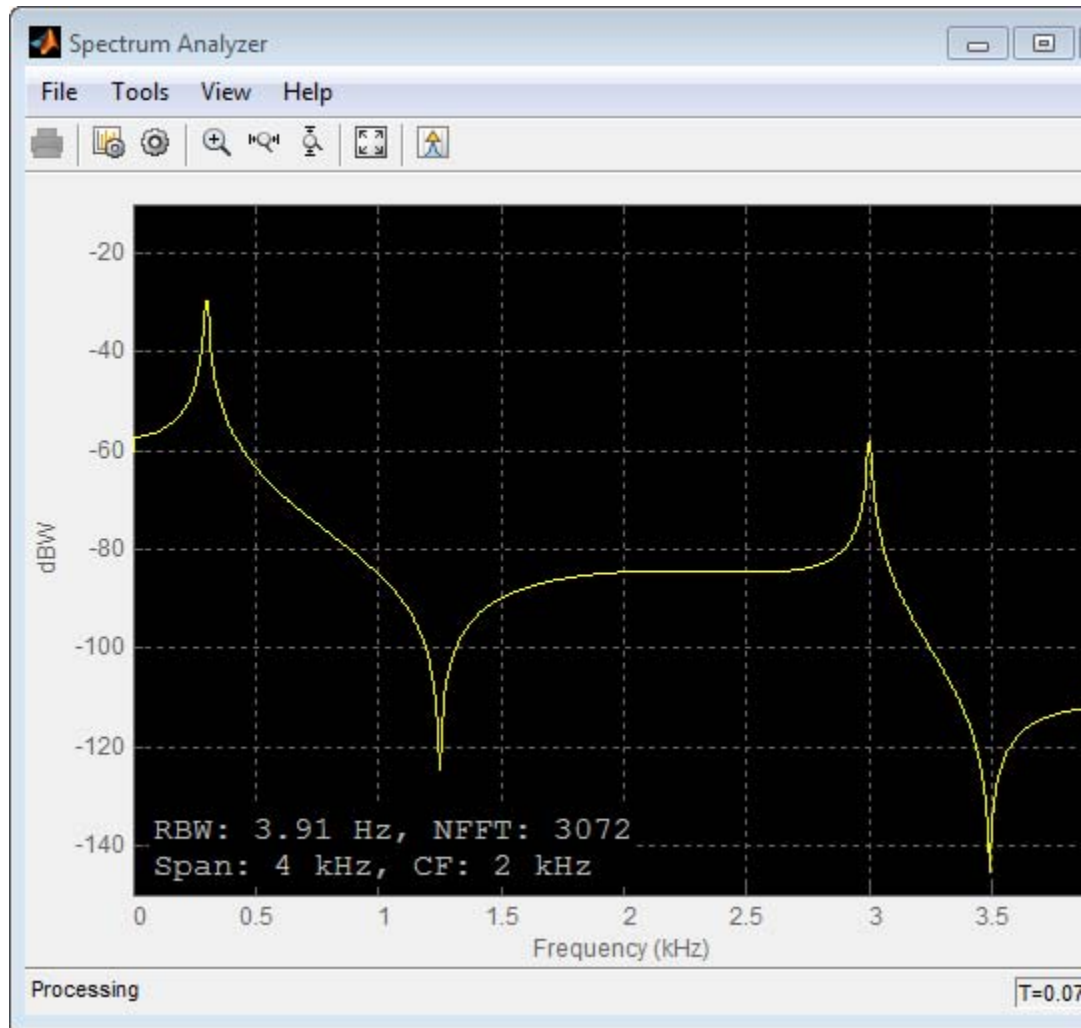

h = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'TwoSidedSpectrum',false,...
    'PowerUnits','dBW',...
    'YLimits', [-150 -10]);

while ~isDone(hSR)
    input = step(hSR);
    filteredOutput = step(hFIR,input);
    step(hLog,filteredOutput);
    step(h,filteredOutput)
end

filteredResult = hLog.Buffer;
fvtool(hFIR,'Fs',8000)
```

# dsp.FIRFilter

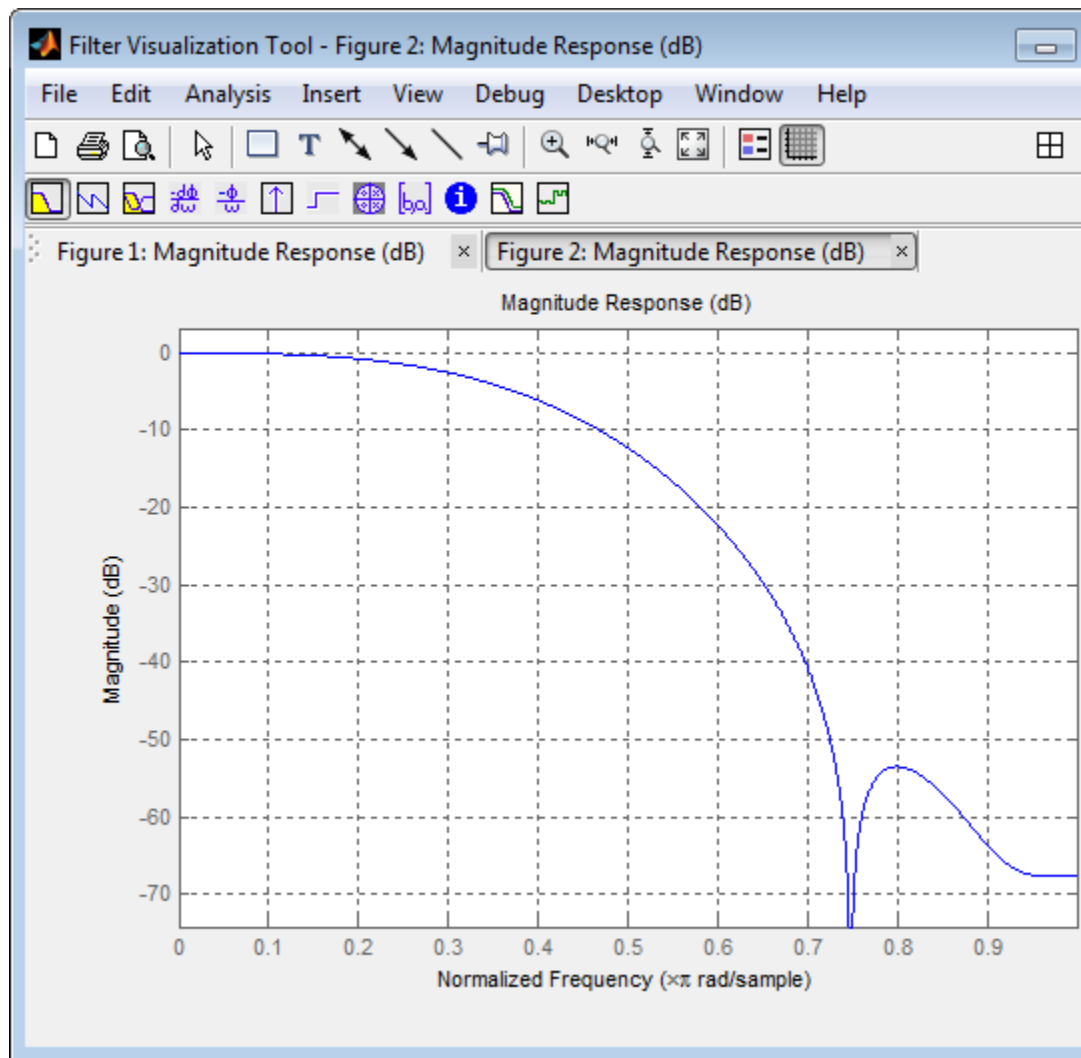

2

Design an FIR filter as a System object.

```
N = 10;  
Fc = 0.4;  
B = fir1(N,Fc);  
Hf1 = dsp.FIRFilter('Numerator',B);  
fvtool(Hf1)
```

# dsp.FIRFilter

This can also be achieved by using `fdesign` as a constructor and `design` to design the filter.

```
N = 10;  
Fc = 0.4;  
Hf = fdesign.lowpass('N,Fc',N,Fc);  
D = design(Hf,'systemobject',true)  
fvtool(D);
```

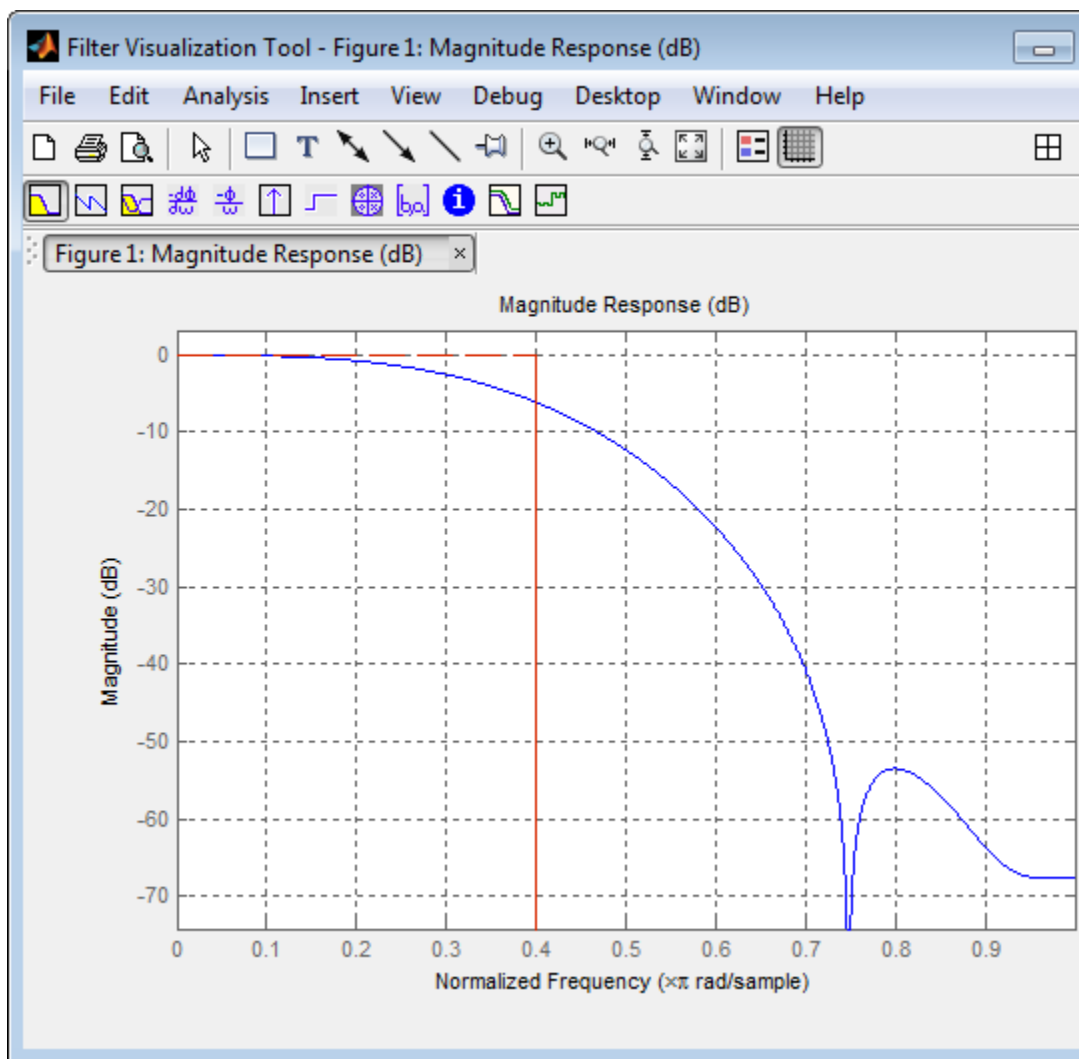

```
D =
```

```
System: dsp.FIRFilter
```

```
Properties:
```

```
    Structure: 'Direct form'  
    NumeratorSource: 'Property'  
        Numerator: [1x11 double]  
    InitialConditions: 0  
    FrameBasedProcessing: true
```

# dsp.FIRFilter

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete FIR Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

## See Also

`dsp.BiquadFilter`

# **dsp.FIRFilter.clone**

---

**Purpose** Create static or time-varying FIR filter with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a FIR filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

**Purpose**

Frequency response

**Syntax**

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

**Description**

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(H)` uses `FVTool` to plot the magnitude and unwrapped phase of the frequency response of the filter `System` object `H`.

# dsp.FIRFilter.fvtool

---

**Purpose** Open filter visualization tool

**Syntax** `fvtool(H)`  
`fvtool(H, 'Arithmetic', ARITH, ...)`

**Description** `fvtool(H)` performs an analysis and computes the magnitude response of the filter System object H.

`fvtool(H, 'Arithmetic', ARITH, ...)` analyzes the filter System object H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

**Purpose**                      Number of expected inputs to step method

**Syntax**                      `N = getNumInputs(H)`

**Description**                `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.FIRFilter.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Impulse response

**Syntax**  
`[h,t] = impz(H)`  
`[h,t] = impz(H,Name,Value)`  
`impz(H)`

**Description** `[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(H)` uses `FVTool` to plot the impulse response of the filter System object `H`.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

# **dsp.FIRFilter.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the FIR filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Unwrapped phase response

**Syntax**

```
[phi,w] = phasez(H)  
[phi,w] = phasez(H,n)  
[phi,w] = phasez(H,Name,Value)  
phasez(H)
```

**Description**

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

# dsp.FIRFilter.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset internal states of FIR filter

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the FIR filter object,H, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the step method applies the FIR filter object to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

For example:

```
H = dsp.FIRFilter;
H.Numerator = fir1(20,0.25);
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

# dsp.FIRFilter.step

---

**Purpose** Filter input with FIR filter object

**Syntax**  
 $Y = \text{step}(\text{HFIR}, X)$   
 $Y = \text{step}(\text{HFIR}, X, \text{COEFF})$

**Description**  $Y = \text{step}(\text{HFIR}, X)$  filters the real or complex input signal  $X$  using the FIR filter,  $H$ , to produce the output  $Y$ . When the input data is of a fixed-point type, it must be signed when the structure is set to `Direct form symmetric` or `Direct form antisymmetric`. The FIR filter object operates on each channel of the input signal independently over successive calls to `step` method.

$Y = \text{step}(\text{HFIR}, X, \text{COEFF})$  uses the time-varying coefficients, `COEFF`, to filter the input signal  $X$  and produce the output  $Y$ . You can use this option when you set the `NumeratorSource` or `ReflectionCoefficientsSource` property to `Input port`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Polyphase FIR interpolator
<b>Description</b>	<p>The <code>FIRInterpolator</code> object upsamples an input by the integer upsampling factor, <math>L</math>, followed by an FIR anti-imaging filter. The filter coefficients are scaled by the interpolation factor. A polyphase interpolation structure implements the filter. The resulting discrete-time signal has a sampling rate <math>L</math> times the original sampling rate.</p> <p>To upsample an input:</p> <ol style="list-style-type: none"><li>1 Define and set up your FIR interpolator. See “Construction” on page 3-583.</li><li>2 Call <code>step</code> to upsample the input according to the properties of <code>dsp.FIRInterpolator</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.FIRInterpolator</code> returns an FIR interpolator, <code>H</code>, which upsamples an input signal by a factor of 3 and applies an FIR filter to interpolate the output.</p> <p><code>H = dsp.FIRInterpolator('PropertyName',PropertyValue, ...)</code> returns an FIR interpolator, <code>H</code>, with each property set to the specified value.</p> <p><code>H = dsp.FIRInterpolator(INTERP, NUM, 'PropertyName',PropertyValue, ...)</code> returns an FIR interpolation object, <code>H</code>, with the <code>InterpolationFactor</code> property set to <code>INTERP</code>, the <code>Numerator</code> property set to <code>NUM</code>, and other properties set to the specified values.</p>
<b>Properties</b>	<p><b>InterpolationFactor</b></p> <p>Interpolation factor</p> <p>Specify the integer factor, <math>L</math>, by which to increase the sampling rate of the input signal. The polyphase implementation uses <math>L</math> polyphase subfilters to compute convolutions at the lower sample</p>

rate. The FIR interpolator delays and interleaves these lower-rate convolutions to obtain the higher-rate output. The property value defaults to 3.

## Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR anti-imaging filter as the coefficients of a polynomial in  $z^{-1}$ . Indexing from zero, the filter coefficients are:

$$H(z) = \sum_{n=0}^{N-1} b(n)z^{-n}$$

To act as an effective anti-imaging filter, the coefficients must correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the `InterpolationFactor`. The filter coefficients are scaled by the value of the `InterpolationFactor` property before filtering the signal. To form the  $L$  polyphase subfilters, `Numerator` is appended with zeros if necessary. The default is the output of `fir1(15,0.25)`.

## Fixed-Point Properties

### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects”.

## **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

## **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

## **CoefficientsDataType**

Coefficient word and fraction lengths

Specify the coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

## **CustomCoefficientsDataType**

Coefficient word and fraction lengths

Specify the coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when the `CoefficientsDataType` property is `Custom`. The default is `numericType([], 16, 15)`.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision` | `Same as product` | `Same as input` | `Custom` |. The default is `Full precision`.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([],32,30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numericType([],16,15)`.

## Methods

clone	Create FIR interpolator object with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset FIR interpolator filter states
step	Upsample and interpolate input

More “Analysis Methods for Filter System Objects” on page 2-2.

## Examples

Double the sampling rate of an audio signal from 22.05 kHz to 44.1 kHz, and play the audio:

```
hmfr = dsp.AudioFileReader('OutputDataType',...  
    'single');  
hap = dsp.AudioPlayer(44100);  
hfirint = dsp.FIRInterpolator(2, ...  
    firpm(30, [0 0.45 0.55 1], [1 1 0 0]));  
  
while ~isDone(hmfr)  
    frame = step(hmfr);  
    y = step(hfirint, frame);  
end
```

# dsp.FIRInterpolator

---

```
        step(hap, y);  
    end  
  
    pause(1);  
    release(hmfr);  
    release(hap);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Interpolation block reference page. The object properties correspond to the block parameters, except:

- The FIRInterpolator object does not have a property that corresponds to the **Input processing** parameter of the FIR Interpolation block.
- The **Rate options** block parameter is not supported by the FIRInterpolator object.

## See Also

dsp.FIRDecimator | dsp.FIRRateConverter

**Purpose**

Create FIR interpolator object with same property values

**Syntax**

`C = clone(H)`

**Description**

`C = clone(H)` creates an FIR interpolator, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

# dsp.FIRInterpolator.freqz

---

**Purpose** Frequency response

**Syntax**  
`[h,w] = freqz(H)`  
`[h,w] = freqz(H,n)`  
`[h,w] = freqz(H,Name,Value)`  
`freqz(H)`

**Description**

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

**Purpose** Open filter visualization tool

**Syntax** fvtool(H)  
fvtool(H, 'Arithmetic', ARITH, ...)

**Description** fvtool(H) performs an analysis and computes the magnitude response of the filter System object H.

fvtool(H, 'Arithmetic', ARITH, ...) analyzes the filter System object H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

# dsp.FIRInterpolator.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of output from the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.FIRInterpolator.impz

---

**Purpose** Impulse response

**Syntax** `[h,t] = impz(H)`  
`[h,t] = impz(H,Name,Value)`  
`impz(H)`

**Description** `[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(H)` uses `FVTool` to plot the impulse response of the filter System object `H`.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the FIR interpolator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.FIRInterpolator.phasez

---

**Purpose** Unwrapped phase response

**Syntax**  
`[phi,w] = phasez(H)`  
`[phi,w] = phasez(H,n)`  
`[phi,w] = phasez(H,Name,Value)`  
`phasez(H)`

**Description** `[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.FIRInterpolator.reset

---

**Purpose** Reset FIR interpolator filter states

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the FIR filter in the interpolator object, H, to their initial values of 0. The initial filter state values correspond to the initial conditions for the constant coefficient linear difference equation defining the FIR filter. After the step method applies the interpolator to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

Reset filter states to 0 to produce consistent output:

```
H = dsp.FIRInterpolator(2);
x =[1 -1]'; x = repmat(x,8,1);
y = step(H,x); % Filter states are nonzero
% Use reset method to set states to zero
reset(H);
% Apply FIR interpolator to input x
y1 = step(H,x);
isequal(y,y1)
% Returns a 1
```

**Purpose** Upsample and interpolate input

**Syntax**  $Y = \text{step}(H, X)$

**Description**  $Y = \text{step}(H, X)$  outputs the upsampled and interpolated values,  $Y$ , of the input signal  $X$ . A  $K$ -by- $N$  input matrix is treated as  $N$  independent channels. The FIR interpolator object interpolates each channel over the first dimension and generates a  $M$ -by- $N$  output matrix, where  $M$  is the product of  $K$  and the upsampling factor,  $L$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.FIRRateConverter

---

**Purpose** Sample rate converter

**Description** The FIRRateConverter performs sampling rate conversion by a rational factor on a vector or matrix input. The FIR rate converter cascades an interpolator with a decimator. The interpolator upsamples the input by the upsampling factor,  $L$ , followed by a lowpass FIR filter. The FIR filter acts both as an anti-imaging filter and an anti-aliasing filter prior to decimation. The decimator downsamples the output of upsampling and FIR filtering by the downsampling factor  $M$ . You must use upsampling and downsampling factors that are relatively prime, or coprime. The resulting discrete-time signal has a sampling rate  $L/M$  times the original sampling rate.

To perform sampling rate conversion:

- 1 Define and set up your FIR sample rate converter. See “Construction” on page 3-600.
- 2 Call `step` to perform sampling rate conversion according to the properties of `dsp.FIRRateConverter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.FIRRateConverter` returns a FIR sample rate converter, `H`, that resamples an input signal at a rate  $3/2$  times the original sampling rate.

`H = dsp.FIRRateConverter('PropertyName',PropertyValue, ...)` returns an FIR sample rate converter, `H`, with each property set to the specified value.

`H = dsp.FIRRateConverter(L,M,NUM,'PropertyName',PropertyValue, ...)` returns an FIR sample rate converter, `H`, with the `InterpolationFactor` property set to  $L$ , the `DecimationFactor` property set to  $M$ , the `Numerator` property set to  $NUM$ , and other specified properties set to the specified values.

**Properties** **InterpolationFactor**  
Interpolation factor

Specify the integer upsampling factor. The default is 3.

## **DecimationFactor**

Decimation factor

Specify the integer downsampling factor. The default is 2.

## **Numerator**

FIR filter coefficients

Specify the FIR filter coefficients in powers of  $z^{-1}$ . The length of filter coefficients must exceed the interpolation factor. Use a lowpass with normalized cutoff frequency no greater than  $\min(1/\text{InterpolationFactor}, 1/\text{DecimationFactor})$ . All initial filter states are zero. The default is `firpm(70,[0 0.28 0.32 1],[1 1 0 0])`.

## **Fixed-Point Properties**

### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### **RoundingMethod**

Rounding method for fixed-point operations

# **dsp.FIRRateConverter**

---

Specify the rounding method as one of | **Ceiling** | **Convergent** | **Floor** | **Nearest** | **Round** | **Simplest** | **Zero** |. The default is **Floor**. This property applies only if the object is not in full precision mode.

## **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | **Wrap** | **Saturate** |. The default is **Wrap**. This property applies only if the object is not in full precision mode.

## **CoefficientsDataType**

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point data type as one of | **Same word length as input** | **Custom** |. The default is **Same word length as input**.

## **CustomCoefficientsDataType**

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point type as a **numericType** object with a **Signedness** of **Auto**. This property applies only when the **CoefficientsDataType** property is **Custom**. The default is **numericType([],16,15)**.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of | **Full precision** | **Same as input** | **Custom** |. The default is **Full precision**.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled **numericType** object with a **Signedness** of **Auto**. This property applies only

when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Full precision` | `Same as product` | `Same as input` | `Custom` |.  
The default is `Full precision`.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |.  
The default is `Same as accumulator`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numerictype([],16,15)`.

## **Methods**

<code>clone</code>	Create FIR sample rate convertor object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method

# dsp.FIRRateConverter

---

<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset states of FIR sample rate converter
<code>step</code>	Resample input with FIR rate converter

## Examples

Resample a 100 Hz sine wave signal by a factor of 3:2:

```
hsin = dsp.SineWave(1, 100, 'SampleRate', 5000, 'SamplesPerFrame', 50);
```

```
% Create a FIR rate converter filter. The default interpolation  
% factor is 3 and decimation factor is 2.
```

```
hfirrc = dsp.FIRRateConverter;  
input = step(hsin);  
output = step(hfirrc, input);
```

```
% Plot the original and resampled signals.
```

```
ndelay = round(length(hfirrc.Numerator)/2/hfirrc.DecimationFactor);  
indx = ndelay+1:length(output);  
x = (0:length(indx)-1)/hsin.SampleRate*hfirrc.DecimationFactor/hfirrc.Int  
stem((0:38)/hsin.SampleRate, input(1:39)); hold on;  
stem(x, hfirrc.InterpolationFactor*output(indx), 'r');  
legend('Original', 'Resampled');
```

---

Resample and play an audio signal from 48 kHz to 32 kHz (Windows only):

```
if ispc %This example runs only on Windows  
    hmfr = dsp.AudioFileReader('audio48kHz.wav', ...
```

```
'OutputDataType', 'single', ...
'SamplesPerFrame', 300);
hap = dsp.AudioPlayer(32000);

% Create an FIRRateConverter System object with interpolation
% factor = 2, decimation factor = 3. Default FIR filter
% coefficients define a lowpass filter with normalized
% cutoff frequency of 1/3.
hfirrc = dsp.FIRRateConverter(2,3);

while ~isDone(hmfr)
    audio1 = step(hmfr);
    audio2 = step(hfirrc, audio1);
    step(hap, audio2);
end

release(hmfr);
release(hap);

else
    disp('This example runs only on Windows platforms.');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Rate Conversion block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.FIRInterpolator](#) | [dsp.FIRDecimator](#)

## **dsp.FIRRateConverter.clone**

---

**Purpose** Create FIR sample rate convertor object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an FIR sample rate converter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.FIRRateConverter.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.FIRRateConverter.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the FIR sample rate converter. The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.FIRRateConverter.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset states of FIR sample rate converter

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the FIR filter in the sample rate converter, H, to their initial values of 0. The initial filter state values correspond to the initial conditions for the constant coefficient linear difference equation defining the FIR filter. After the step method applies the FIR rate converter to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

Reset filter states to 0 to produce consistent output:

```
H = dsp.FIRRateConverter(2,4);
x =[1 -1]'; x = repmat(x,8,1);
y = step(H,x); % Filter states are nonzero
% Use reset method to set states to zero
reset(H);
% Apply sampling rate converter to input x
y1 = step(H,x);
isequal(y,y1)
% Returns a 1
```

## **dsp.FIRRateConverter.step**

---

**Purpose** Resample input with FIR rate converter

**Syntax**  $Y = \text{step}(H, X)$

**Description**  $Y = \text{step}(H, X)$  resamples the input  $X$  and returns the resampled signal  $Y$ . An  $M$ -by- $N$  matrix input is treated as  $N$  independent channels.

<b>Purpose</b>	Generate real or complex sinusoidal signals, optimized for HDL code generation
<b>Description</b>	The HDL NCO System object, like the dsp.NCO System object, generates real or complex sinusoidal signals. In addition, the NCO HDL-optimized System object provides hardware friendly control signals, optional reset signal, and an optional external dither input signal. It uses the same phase accumulation and lookup table technology as implemented in the NCO System object. However, the lookup table in the generated HDL is mapped to a ROM. Furthermore, a lookup table compression option is provided to significantly reduce the lookup table size with less than one LSB precision lost.
<b>Construction</b>	<p>HNCO = dsp.HDLNCO returns a numerically controlled oscillator (NCO) System object, HNCO, that generates a real or complex sinusoidal signal. The amplitude of the generated signal is always 1.</p> <p>HNCO = dsp.HDLNCO(Name,Value) returns an HDLNCO System object, HNCO, with additional options specified by one or more Name,Value pair arguments, where Name is a property name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN</p> <p>HNCO = dsp.HDLNCO(Inc,Name,Value) returns an HDLNCO System object, HNCO, with the PhaseIncrement property set to Inc, and the other specified properties set to the specified values.</p>

### Input Arguments

#### Inc

Value for PhaseIncrement property

**Default:** 100

## Properties

### PhaseIncrementSource

Set PhaseIncrementSource to Property to use the PhaseIncrement property.

```
hnc0 = dsp.HDLNCO('PhaseIncrementSource', 'Property', 'PhaseIncrement', phIncr, ... etc.
```

### PhaseIncrement

Specify the phase increment as an integer scalar. This property is applicable when the PhaseIncrementSource property is set to Property. The default value of this property is 100.

### PhaseOffsetSource

Set PhaseOffsetSource property to Property to use the PhaseOffset property.

```
hnc0 = dsp.HDLNCO('PhaseIncrementSource', 'Property', 'PhaseIncrement', phIncr, ...  
    'PhaseOffsetSource', 'Property', 'PhaseOffset', phOffset, ... etc.
```

### PhaseOffset

Specify the phase offset as an integer scalar. This property is applicable when the PhaseOffsetSource property is set to Property. The default value of PhaseOffset is 0.

### DitherSource

Set DitherSource property to Property to use the NumDitherBits property. Other options include Input port to specify that the dither value is determined by an input port or None to specify no dithering.

### NumDitherBits

Specify the number of dither bits as a positive integer. This property is applicable when the DitherSource property is set to Property. The default value of NumDitherBits is 4.

### PhaseQuantization

Set this property to true to enable quantization of the accumulated phase. The default value of PhaseQuantization is true.

**NumQuantizerAccumulatorBits**

Specify the number of quantizer accumulator bits as an integer scalar greater than 1 and less than the accumulator word length. NumQuantizerAccumulatorBits determines the number of entries in the lookup table of sine values.

This property is applicable when PhaseQuantization is true. The default value of this property is 12.

**LUTCompress**

Enable look up table compression method. Set this property to true to enable look up table compression method. The default value of this property is false.

**Waveform**

Specify the type of the output signal. Options are: Sine, Cosine, Complex exponential, and Sine and cosine.

**PhasePort**

Set PhasePort to true to show the current phase port. The default value of this property is false

**ResetAction**

Set ResetAction to true to enable the reset input port. The default value of this property is false.

**OverflowAction**

Overflow action for fixed-point operations. OverflowAction is a constant property with value Wrap.

**RoundingMethod**

Rounding method for fixed-point operations. RoundingMethod is a constant property with value Floor.

## **AccumulatorDataType**

Accumulator word- and fraction-length designations. This is a constant property with value `Binary point scaling`.

## **AccumulatorSigned**

Accumulator sign. Constant value is signed.

## **AccumulatorWL**

Accumulator word length. Default is 16.

## **AccumulatorFL**

Accumulator fraction length. Constant value is 0.

## **OutputDataType**

Specify the output signal data type. Options are: `double`, `single`, `Binary point scaling`. If you select `Binary point scaling`, you can set the output word length and fraction length.

## **OutputSigned**

Output data sign. Constant value is signed.

## **OutputWL**

Output data word length. The default is 16.

## **OutputFL**

Output data fraction length. The default is 14.

## **Methods**

<code>clone</code>	Create HDLNCO System object with same property values
<code>isLocked</code>	Locked status (logical)

release	Allow property value and input characteristics change
step	Process inputs using the object algorithm

## Examples

### Design an NCO Source

Design an NCO source according to given specifications.

Specifications:

```
F0 = 510;      % Output frequency = 510 Hz
df = 0.05;    % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/4000;  % Sample period = 1/8000 sec
dphi = pi/2;  % Desired phase offset = pi/2;
```

Calculate number of accumulator bits required for the given frequency resolution.

```
Nacc = ceil(log2(1/(df*Ts)));
actdf = 1/(Ts*2^Nacc); % Actual frequency resolution achieved
```

Calculate number of quantized accumulator bits required from the SFDR requirement.

```
Nqacc = ceil((minSFDR-12)/6);
```

Calculate the phase increment.

```
phIncr = round(F0*Ts*2^Nacc);
```

Calculate the phase offset.

```
phOffset = 2^Nacc*dphi/(2*pi);
```

Construct NCO HDL Optimized System object.

```
hnco = dsp.HDLNCO('PhaseIncrementSource', 'Property', ...
```

```
'PhaseIncrement', phIncr,...  
'PhaseOffset', phOffset,...  
'NumDitherBits', 4, ...  
'NumQuantizerAccumulatorBits', Nqacc,...  
'AccumulatorWL',Nacc);
```

```
for k= 1:1/Ts  
    y(k) = step(hnco,true);  
end
```

Plot the mean-square spectrum of the 510 Hz sine wave generated by the NCO.

```
sperd = spectrum.periodogram('hann'); ...  
sperd.SamplingFlag = 'periodic';  
msspectrum(sperd,double(y),'Fs',1/Ts);
```

## Algorithms

### Lookup Table Algorithm

The NCO HDL Optimized System object applies the Sunderland compression method when lookup table compression is enabled. Sunderland techniques use trigonometric function by dividing each phase into three phases.

$$\sin(A + B + C) = \sin(A + B)\cos C + \cos A \cos B \cos C - \sin A \sin B \sin C$$

If the phase has 12 bits in the quarter sinewave method, the 12 bit phase are divided as:

- A , the four most significant bits

$$(0 \leq A \leq \pi/2)$$

- B, the following four bits

$$(0 \leq B \leq \pi / 2 / 2^4)$$

- $C$ , the four least significant bits

$$(0 \leq C \leq \pi / 2 / 2^8)$$

The equation is then approximated by:

$$\sin(A + B + C) \approx \sin(A + B) + \cos A \sin C$$

Which uses one LUT for  $\sin(A+B)$  and one LUT for  $\cos(A)\sin(C)$ . See L. Cordesses, "Direct Digital Synthesis: A Tool for Periodic Wave Generation (Part 1)", IEEE Signal Processing Magazine, DSP Tips & Tricks column, pp. 50–54, Vol. 21, No. 4, July 2004.

# dsp.HDLNCO.clone

---

<b>Purpose</b>	Create HDLNCO System object with same property values
<b>Syntax</b>	<code>C = clone(H)</code>
<b>Description</b>	<code>C = clone(H)</code> creates another instance of the HDLNCO System object, H, with the same property values. The clone method creates a new unlocked object with uninitialized states.
<b>Input Arguments</b>	<b>H</b> HDLNCO System object
<b>Output Arguments</b>	<b>C</b> New instance of the HDLNCO System object, H, with the same property values. The new unlocked object contains uninitialized states.

<b>Purpose</b>	Locked status (logical)
<b>Syntax</b>	L = isLocked(H)
<b>Description</b>	<p>L = isLocked(H) returns the locked status, L, of the HDLNCO System object, H.</p> <p>The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.</p>
<b>Input Arguments</b>	<p><b>H</b></p> <p>HDLNCO System object</p>
<b>Output Arguments</b>	<p><b>L</b></p> <p>Logical value. Either 1 (true) or 0 (false).</p>

# dsp.HDLNCO.release

---

**Purpose** Allow property value and input characteristics change

**Syntax** `release(H)`

**Description** `release(H)` releases system resources (such as memory, file handles or hardware connections) of the HDLNCO System object, H, and allows all its properties and input characteristics to be changed.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Input Arguments**

**H**  
Instance of HDLNCO System object

## Purpose

Process inputs using the object algorithm

## Syntax

```
[Y,validOut] = step(HNCO,Inc,validIn)
[Y,validOut] = step(HNCO,validIn)
[Y,validOut] = step(HNCO,Offset,validIn)
[Y,validOut] = step(HNCO,Inc,Offset,validIn)
[Y,validOut] = step(HNCO,Dither,validIn)
[Y,validOut] = step(HNCO,Inc,Offset,Dither,validIn)
[Y,PHASE,validOut]= step(HNCO, ___ )
```

## Description

[Y,validOut] = step(HNCO,Inc,validIn) returns a sinusoidal signal, Y, generated by the HDLNCO System object, with the specified phase increment, INC. INC is added to the accumulator when validIn is high. validOut indicates the validity of output signal. INC must be a built-in integer or an fi object scalar. validIn/validOut are scalars with data type logical.

[Y,validOut] = step(HNCO,validIn) returns a sinusoidal signal, Y, when the PhaseIncrementSource and PhaseOffsetSource properties are both set to Property.

[Y,validOut] = step(HNCO,Offset,validIn) returns a sinusoidal signal, Y, with phase offset, Offset, when the PhaseOffsetSource property is set to Input port. Offset must be a built-in integer or an fi object scalar.

[Y,validOut] = step(HNCO,Inc,Offset,validIn) returns a sinusoidal signal, Y, with phase increment, INC, and phase offset, Offset, when the PhaseIncrementSource and the PhaseOffsetSource properties are both set to Input port.

[Y,validOut] = step(HNCO,Dither,validIn) returns a sinusoidal signal, Y, generated by the HDLNCO, System object with the dither, Dither, when the DitherSource property is set to Input port. Dither must be a built-in integer or an fi object scalar.

[Y,validOut] = step(HNCO,Inc,Offset,Dither,validIn) returns a sinusoidal signal, Y, with phase increment, INC, phase offset, Offset, and dither, Dither, when the PhaseIncrementSource, the

# comm.HDLNCO.step

---

PhaseOffsetSource , and the DitherSource properties are each set to Input port.

[Y,PHASE,validOut]= step(HNCO, \_\_\_ ) returns a sinusoidal signal, Y, and output Phase, when the PhasePort property is true. This syntax can include any of the input arguments in previous syntaxes.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

## Input Arguments

**H**  
HDLNCO System object

**X**

## Output Arguments

**Y**

<b>Purpose</b>	Histogram of input or sequence of inputs
<b>Description</b>	<p>The Histogram object generates a histogram for an input or a sequence of inputs.</p> <p>To generate a histogram for an input or a sequence of inputs:</p> <ol style="list-style-type: none"><li>1 Define and set up your histogram object. See “Construction” on page 3-625.</li><li>2 Call <code>step</code> to generate the histogram for an input according to the properties of <code>dsp.Histogram</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.Histogram</code> returns a histogram object, <code>H</code>, that computes the frequency distribution of the elements in each input matrix.</p> <p><code>H = dsp.Histogram('PropertyName',PropertyValue, ...)</code> returns a histogram object, <code>H</code>, with each specified property set to the specified value.</p> <p><code>H = dsp.Histogram(MIN,MAX,NUMBINS,'PropertyName',PropertyValue,...)</code> returns a histogram object, <code>H</code>, with the <code>LowerLimit</code> property set to <code>MIN</code>, <code>UpperLimit</code> property set to <code>MAX</code>, <code>NumBins</code> property set to <code>NUMBINS</code> and other specified properties set to the specified values.</p>
<b>Properties</b>	<p><b>LowerLimit</b></p> <p>Lower boundary</p> <p>Specify the lower boundary of the lowest-valued bin as a real-valued scalar. <code>NaN</code> and <code>Inf</code> are not valid values for this property. The default is 0. This property is tunable.</p> <p><b>UpperLimit</b></p> <p>Upper boundary</p>

# dsp.Histogram

---

Specify the upper boundary of the highest-valued bin as a real-valued scalar. NaN and Inf are not valid values for this property. The default is 10. This property is tunable.

## **NumBins**

Number of bins in histogram

Specify the number of bins in the histogram. The default is 11.

## **Dimension**

Specify how the histogram calculation is performed over the data as one of | All | Column |. The default is Column.

## **Normalize**

Enable output vector normalization

Specify whether the histogram object normalizes the output vector,  $v$ , so that  $sum(v) = 1$ . When you set this property to true, the output vector is normalized. When you set it to false, the object supports fixed-point operations and does not use this property for normalization. The default is false.

## **RunningHistogram**

Enable calculation over successive step method calls

Set this property to true to enable running histogram calculations for the input elements over successive calls to the step method. Set this property to false to compute a histogram for the current input. The default is false.

## **ResetInputPort**

Enable resetting in running histogram mode

Set this property to true to enable resetting the running histogram. When you set the property to true, specify a reset input to the step method that resets the running histogram. This property applies when you set the RunningHistogram property to true. When this property is false, the histogram object does not reset. The default is false.

## **ResetCondition**

Reset condition for running histogram mode

Specify the event that resets the running histogram as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the `ResetInputPort` property to true. The default is Non-zero

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

### **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

### **CustomProductDataType**

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

### **AccumulatorDataType**

# dsp.Histogram

---

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Same as product | Same as input | Custom |. The default is Same as input.

## CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## Methods

<code>clone</code>	Create histogram object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset histogram bin values to zero
<code>step</code>	Histogram for input data

## Examples

Compute a histogram with four bins, for possible input values 1 through 4:

```
hhist = dsp.Histogram(1,4,4);  
y = step(hhist, [1 2 2 3 3 3 4 4 4 4]');  
% y equals [1; 2; 3; 4] - one one, two twos, etc.
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Histogram block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.
- The **Find histogram over** block parameter corresponds to the `Dimension` property of the object.

# **dsp.Histogram.clone**

---

**Purpose** Create histogram object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a Histogram System object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.Histogram.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the Histogram System object. The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.Histogram.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

<b>Purpose</b>	Reset histogram bin values to zero
<b>Syntax</b>	<code>reset(H)</code>
<b>Description</b>	<code>reset(H)</code> sets the Histogram object bin values to zero when you set the <code>RunningHistogram</code> property to true.

# dsp.Histogram.step

---

**Purpose** Histogram for input data

**Syntax**  
`Y = step(H,X)`  
`Y = step(H,X,R)`

**Description** `Y = step(H,X)` returns a histogram `Y` for the input data `X`. When the `RunningHistogram` property is `true`, `Y` corresponds to the histogram of the input elements over successive calls to the `step` method.

`Y = step(H,X,R)` resets the histogram state based on the value of `R` and the object's `ResetCondition` property. You can reset the histogram state only when the `RunningHistogram` and the `ResetInputPort` properties are `true`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Inverse discrete cosine transform (IDCT)
<b>Description</b>	<p>The IDCT object computes the inverse discrete cosine transform (IDCT) of an input.</p> <p>To compute the IDCT of an input:</p> <ol style="list-style-type: none"><li>1 Define and set up your IDCT object. See “Construction” on page 3-637.</li><li>2 Call <code>step</code> to compute the IDCT of an input according to the properties of <code>dsp.IDCT</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.IDCT</code> returns a inverse discrete cosine transform (IDCT) object, <code>H</code>. This object computes the IDCT of a real or complex input signal using the <code>Table lookup</code> method.</p> <p><code>H = dsp.IDCT('PropertyName',PropertyValue,...)</code> returns an inverse discrete cosine transform (IDCT) object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>SineComputation</b></p> <p>Method to compute sines and cosines</p> <p>Specify how the IDCT object computes the trigonometric function values as <code>Trigonometric function</code> or <code>Table lookup</code>. You must set this property to <code>Table lookup</code> for fixed-point inputs. The default is <code>Table lookup</code>.</p> <p><b>Fixed-Point Properties</b></p> <p><b>RoundingMethod</b></p> <p>Rounding method for fixed-point operations</p> <p>Specify the rounding method as one of <code>Ceiling</code>, <code>Convergent</code>, <code>Floor</code>, <code>Nearest</code>, <code>Round</code>, <code>Simplest</code>, or <code>Zero</code>. This property applies when you set the <code>SineComputation</code> property to <code>Table lookup</code>.</p>

## **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table lookup`.

## **SineTableDataType**

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

## **CustomSineTableDataType**

Sine table word length

Specify the sine table fixed-point type as a signed, unscaled `numericType` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `SineTableDataType` property to `Custom`. The default is `numericType(true,16)`.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numericType(true,32,30)`.

**AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

**CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numericType(true,32,30)`.

**OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

**CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `OutputDataType` property to `Custom`. The default is `numericType(true,16,15)`.

## Methods

clone	Create inverse discrete cosine transform object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Inverse discrete cosine transform (IDCT) of input

## Examples

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
hdct = dsp.DCT;

X = step(hdct, x);
% Set the DCT coefficients which represent less
% than 0.1% of the total energy to 0 and
% reconstruct the sequence using IDCT.
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;

while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
    ii = ii+1;
end

disp(['Number of DCT coefficients that represent 99.9%',...
'of the total energy in the sequence: ',num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
```

```
hidct = dsp.IDCT;  
xt = step(hidct, XXt);  
  
plot(1:128,[x xt]);  
legend('Original signal','Reconstructed signal',...  
      'location','best');
```

**Algorithms**

This object implements the algorithm, inputs, and outputs described on the IDCT block reference page. The object properties correspond to the block parameters.

**See Also**

[dsp.DCT](#) | [dsp.FFT](#) | [dsp.IFFT](#).

## **dsp.IDCT.clone**

---

**Purpose** Create inverse discrete cosine transform object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a copy of the current IDCT object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.IDCT.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the IDCT object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.IDCT.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Inverse discrete cosine transform (IDCT) of input

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  computes the inverse discrete cosine transform,  $Y$ , of input  $X$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Purpose** Inverse discrete Fourier transform (IDFFT)

**Description** The IFFT object computes the inverse discrete Fourier transform (IDFFT) of the input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen by FFTW [1], [2]

To compute the IFFT of the input:

- 1** Define and set up your IFFT object. See “Construction” on page 3-648.
- 2** Call `step` to compute the IFFT of the input according to the properties of `dsp.IFFT`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.IFFT` returns an IFFT object, `H`, that computes the IDFT of a column vector or  $N$ -D array. For column vectors or  $N$ -D arrays, the IFFT object computes the IDFT along the first dimension of the array. If the input is a row vector, the IFFT object computes a row of single-sample IDFTs and issues a warning.

`H = dsp.IFFT('PropertyName',PropertyValue, ...)` returns an IFFT object, `H`, with each property set to the specified value.

**Properties** **FFTImplementation**

FFT implementation

Specify the implementation used for the FFT as one of Auto | Radix-2 | FFTW. When you set this property to Radix-2, the FFT length must be a power of two.

**BitReversedInput**

Enable bit-reversed order interpretation of input elements

Set this property to `true` if the order of Fourier transformed input elements to the IFFT object are in bit-reversed order. This property applies only when the `FFTLengthSource` property is Auto. The default is `false`, which denotes linear ordering.

**ConjugateSymmetricInput**

Enable conjugate symmetric interpretation of input

Set this property to `true` if the input is conjugate symmetric to yield real-valued outputs. The discrete Fourier transform of a real valued sequence is conjugate symmetric, and setting this property to `true` optimizes the IDFT computation method. Setting this property to `false` for conjugate symmetric inputs may result in complex output values with nonzero imaginary parts. This occurs due to rounding errors. Setting this property to `true` for nonconjugate symmetric inputs results in invalid outputs. This property applies only when the `FFTLengthSource` property is Auto. The default is `false`.

**Normalize**

Enable dividing output by FFT length

Specify whether to divide the IFFT output by the FFT length. The default is `true` and each element of the output is divided by the FFT length.

**FFTLengthSource**

Source of FFT length

Specify how to determine the FFT length as Auto or Property. When you set this property to Auto, the FFT length equals the number of rows of the input signal. This property applies only

when both the `BitReversedInput` and `ConjugateSymmetricInput` properties are false. The default is `Auto`.

## **FFTLength**

FFT length

Specify the FFT length as a numeric scalar. This property applies when you set the `BitReversedInput` and `ConjugateSymmetricInput` properties to false, and the `FFTLengthSource` property to `Property`. The default is 64.

This property must be a power of two when the input is a fixed-point data type, or when you set the `FFTImplementation` property to `Radix-2`.

When you set the `FFT implementation` property to `Radix-2`, or when you set the `BitReversedOutput` property to true, this value must be a power of two.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

### **SineTableDataType**

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

### **CustomSineTableDataType**

Sine table word and fraction lengths

Specify the sine table fixed-point type as an unscaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` property to `Custom`. The default is `numericType([],16)`.

### **ProductDataType**

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

### **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

### **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`. The default is `Full precision`.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

### **OutputDataType**

Output word and fraction lengths

Specify the output data type as Full precision, Same as input, or Custom. The default is Full precision.

## CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies when you set the OutputDataType property to Custom. The default is numeric type ([ ], 16, 15).

## Methods

clone	Create IFFT object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Inverse discrete Fourier transform of input

## Examples

Use DFT and IDFT to analyze the energy content in a sequence:

```
Fs = 40; L = 128;
t = (0:L-1)'/Fs;
x = sin(2*pi*10*t) + 0.75*cos(2*pi*15*t);
y = x + .5*randn(size(x)); % noisy signal
hfft = dsp.FFT;
hifft = dsp.IFFT('ConjugateSymmetricInput', true);
X = step(hfft, x);
[XX, ind] = sort(abs(X),1,'descend');
XXn = sqrt(cumsum(XX.^2))/norm(XX);
```

```
ii = find(XXn > 0.999, 1);
disp('Number of FFT coefficients that represent 99.9% ')
disp(['of the total energy in the sequence: ', num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
xt = step(hifft, XXt);
% Verify the reconstructed signal matches the original
norm(x-xt)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the IFFT block reference page. The object properties correspond to the block parameters, except:

**Output sampling mode** parameter is not supported by dsp.IFFT.

## dsp.IFFT.clone

---

**Purpose** Create IFFT object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an IFFT object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.IFFT.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the IFFT object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.IFFT.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Inverse discrete Fourier transform of input

**Syntax**  $Y = \text{step}(H, X)$

**Description**  $Y = \text{step}(H, X)$  computes the inverse discrete Fourier transform (IDFT),  $Y$ , of the input  $X$  along the first dimension of  $X$ . When the `FFTLengthSource` property is `Auto`, the length of  $X$  along the first dimension must be a positive integer power of two. When the `FFTLengthSource` property is `'Property'`, the length of  $X$  along the first dimension can be any positive integer and the `FFTLength` property must be a positive integer power of two.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.IIRFilter

---

**Purpose** Infinite Impulse Response (IIR) filter

**Description** The `IIRFilter` object filters each channel of the input using IIR filter implementations.

To filter each channel of the input:

- 1 Define and set up your IIR filter. See “Construction” on page 3-660.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.IIRFilter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `HIIIR = dsp.IIRFilter` returns an IIR filter System object, `HIIIR`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified IIR filter implementation.

`HIIIR = dsp.IIRFilter('PropertyName',PropertyValue, ...)` returns an IIR filter System object, `HIIIR`, with each property set to the specified value.

## Properties

### Structure

Filter structure

Specify the filter structure.

You can specify the filter structure as one of | Direct form I | Direct form I transposed | Direct form II | Direct form II transposed. The default is Direct form II transposed. This property is nontunable.

### Numerator

Filter numerator coefficients

Specify the numerator coefficients as a real or complex numeric row vector. The default is `[1 1]`. This property is tunable.

**Denominator**

Filter denominator coefficients

Specify the denominator coefficients as a real or complex numeric row vector. The default value of this property is [1 0.1]. This property is tunable.

**InitialConditions**

Initial conditions for the IIR filter

Specify the initial conditions of the filter states. This property is applicable when the structure is one of `Direct form II` | `Direct form II transposed`. The default value is 0. The number of states equals the  $\max(N,M) - 1$ , where N and M are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property is tunable.

**NumeratorInitialConditions**

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property is applicable when the Structure property is one of `Direct form I` | `Direct form I transposed`. The default value of this property is 0. The number

of states equals the  $\max(N, M) - 1$ , where  $N$  and  $M$  are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the IIR filter initializes all delay elements on the zeros side in the filter to that value. You can specify a vector of length equal to the number of delay elements on the zeros side in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

You can also specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. This property is tunable.

### **DenominatorInitialConditions**

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the filter structure with the poles. This property is applicable when the Structure property is one of `Direct form I` | `Direct form I transposed`. The default value of this property is `0`. The number of states equals the  $\max(N, M) - 1$ , where  $N$  and  $M$  are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the IIR filter initializes all delay elements on the poles side of the filter to that value. You can specify a vector of length equal to the number of delay elements on the poles side in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

You can also specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal. In this case, each

element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. This property is tunable.

## **FrameBasedProcessing**

Process input as frames or as samples

Set this property to `true` to enable frame-based processing. When this property is `true`, the IIR filter treats each column as an independent channel. Set this property to `false` to enable sample-based processing. When this property is `false`, the IIR filter treats each element of the input as an individual channel. The default is `true`. This property is nontunable.

## **NumeratorCoefficientsDataType**

Numerator coefficients word- and fraction-length designations

Specify the numerator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

## **DenominatorCoefficientsDataType**

Denominator coefficients word- and fraction-length designations

Specify the denominator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

## **Fixed-Point Properties**

### **NumeratorProductDataType**

Product word- and fraction-length designations on zeros side

Specify the numerator product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`. This property is nontunable.

### **DenominatorProductDataType**

Product word- and fraction-length designations on poles side

Specify the denominator product fixed-point data type as one of | Full precision | Same as input | Custom |. The default is Full precision. This property is nontunable.

## **NumeratorAccumulatorDataType**

Accumulator word- and fraction-length designations on zeros side

Specify the numerator accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. The default is Full precision. This property is nontunable.

## **DenominatorAccumulatorDataType**

Accumulator word- and fraction-length designations on poles side

Specify the denominator accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. The default is Full precision. This property is nontunable.

## **OutputDataType**

Output word- and fraction-length designations

Specify the output fixed-point data type as one of | Full precision | Same as input | Custom |. The default is Same as input. This property is nontunable.

## **StateDataType**

State word- and fraction-length designations

Specify the state fixed-point data type as one of | Same as input | Custom |. This property does not apply to Direct form I filter structure. The default is Same as input. This property is nontunable.

## **MultiplicandDataType**

Multiplicand word- and fraction-length designations

Specify the multiplicand fixed-point data type as one of | Same as input | Custom |. This property is applicable only when the Structure property is Direct form I transposed. The default is Same as input. This property is nontunable.

### **CustomNumeratorCoefficientsDataType**

Numerator coefficients word- and fraction-lengths

Specify the numerator coefficients fixed-point type as an autosigned numeric type object. This property is applicable when the NumeratorCoefficientsDataType property is Custom. The default value of this property is numeric type ([,16,15]). This property is nontunable.

### **CustomDenominatorCoefficientsDataType**

Denominator coefficients word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numeric type object. This property is applicable when the DenominatorCoefficientsDataType property is Custom. The default value of this property is numeric type ([, 16, 15) . This property is nontunable.

### **CustomNumeratorProductDataType**

Custom product word- and fraction-lengths on zeros side

Specify the numerator product fixed-point type as an autosigned scaled numeric type object. This property applies when you set the NumeratorProductDataType property to Custom. The default is numeric type ([,32,30). This property is nontunable.

### **CustomDenominatorProductDataType**

Custom product word- and fraction-lengths on poles side

Specify the denominator product fixed-point type as an autosigned scaled numeric type object. This property applies when you set the DenominatorProductDataType property to Custom. The default is numeric type ([,32,30). This property is nontunable.

## **CustomNumeratorAccumulatorDataType**

Custom accumulator word- and fraction-lengths on zeros side

Specify the numerator accumulator fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `NumeratorAccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`. This property is nontunable.

## **CustomDenominatorAccumulatorDataType**

Custom accumulator word- and fraction-lengths on poles side

Specify the denominator accumulator fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `DenominatorAccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`. This property is nontunable.

## **CustomStateDataType**

Custom state word- and fraction-lengths

Specify the state fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `StateDataType` property to `Custom`. The default is `numericType([],16,15)`. This property is nontunable.

## **CustomOutputDataType**

Custom output word- and fraction-lengths

Specify the output fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`. This property is nontunable.

## **CustomMultiplicandDataType**

Custom multiplicand word- and fraction-lengths

Specify the multiplicand fixed-point type as an autosigned scaled `numericType` object. This property applies when you set

the `MultiplicandDataType` property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

## Methods

<code>clone</code>	Create IIR filter with same property values
<code>freqz</code>	Frequency response
<code>fvtool</code>	Open filter visualization tool
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>impz</code>	Impulse response
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>phasez</code>	Unwrapped phase response
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of IIR filter
<code>step</code>	Filter input with IIR filter object

More “Analysis Methods for Filter System Objects” on page 2-2.

## Examples 1

Use `fvtool` to see the magnitude response of a lowpass IIR filter. Also use the Spectrum Analyzer to display the power spectrum of the output signal.

```
x = randn(2048,1);
x = x-mean(x);
Hsr = dsp.SignalSource;
Hsr.Signal = x;
Hlog = dsp.SignalSink;
```

## dsp.IIRFilter

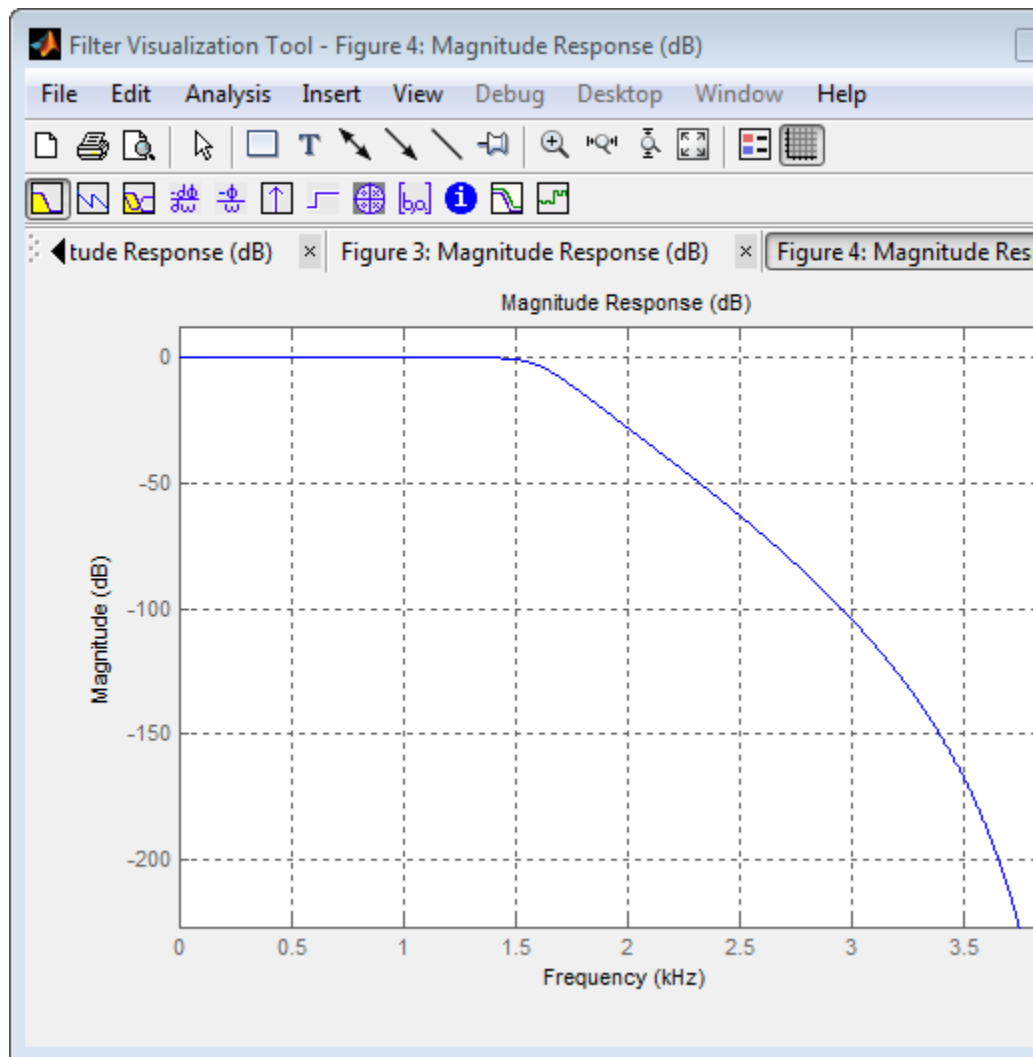

---

```
N = 10;
Fc = 0.4;
[b,a] = butter(N,Fc);
H = dsp.IIRFilter('Numerator',b,'Denominator',a);

h = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'TwoSidedSpectrum',false,...
    'PowerUnits','dBW',...
    'YLimits', [-220 -10]);

while ~isDone(Hsr)
    input = step(Hsr);
    output = step(H,input);
    step(h,output)
    step(Hlog,output);
end

Result = Hlog.Buffer;
fvtool(H,'Fs',8000)
```

# dsp.IIRFilter

2

Design an IIR filter as a System object.

There are two ways, either you first design the constructor and then design the filter as a System object that you can apply:

```
D = fdesign.comb('notch','N,BW',8,0.02);  
H = design(D,'systemobject',true)  
fvtool(H);
```

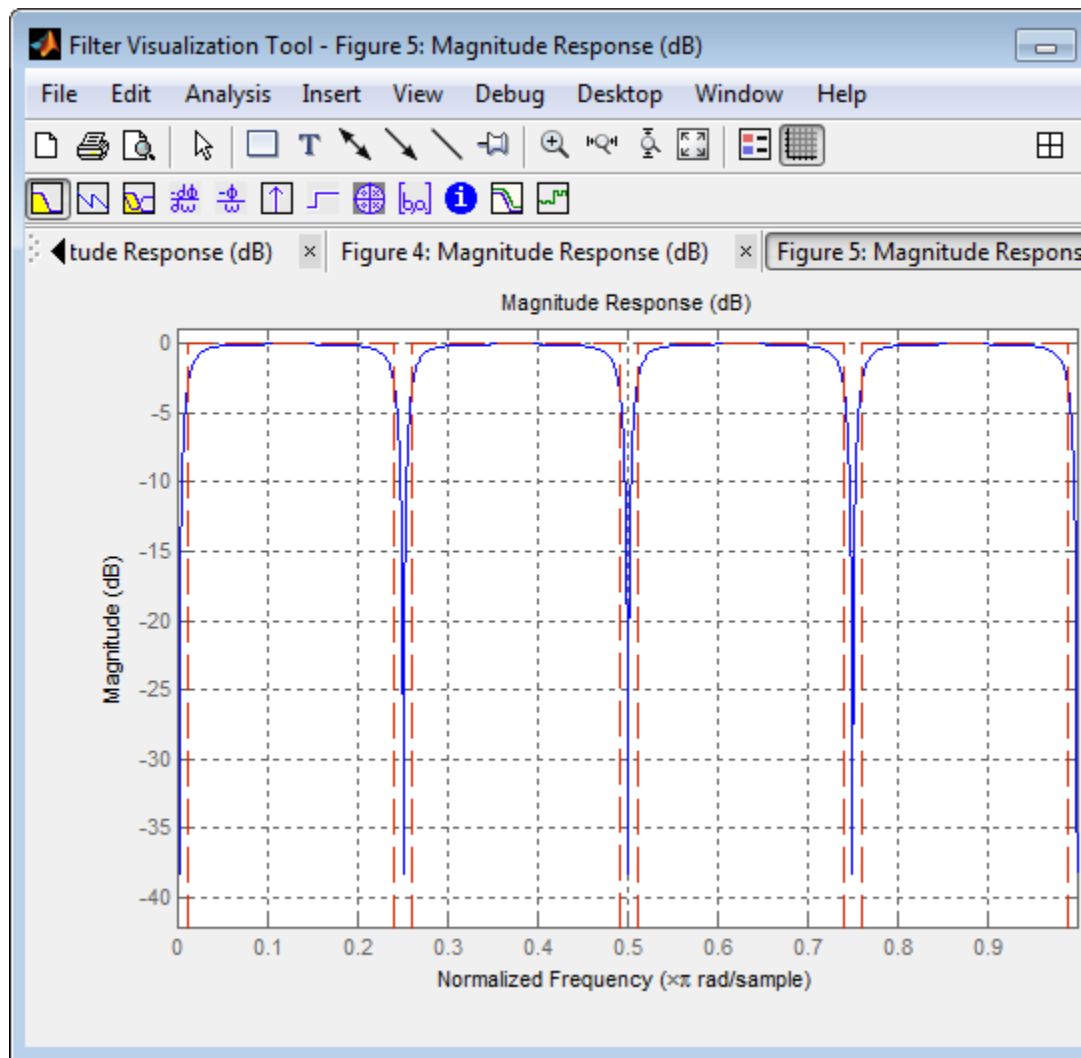

H =

System: dsp.IIRFilter

Properties:

```
    Structure: 'Direct form II'  
    Numerator: [0.887839755524806 0 0 0 0 0 0 0 -0.887839755524806]  
    Denominator: [1 0 0 0 0 0 0 0 -0.775679511049613]  
    InitialConditions: 0  
    FrameBasedProcessing: true
```

# dsp.IIRFilter

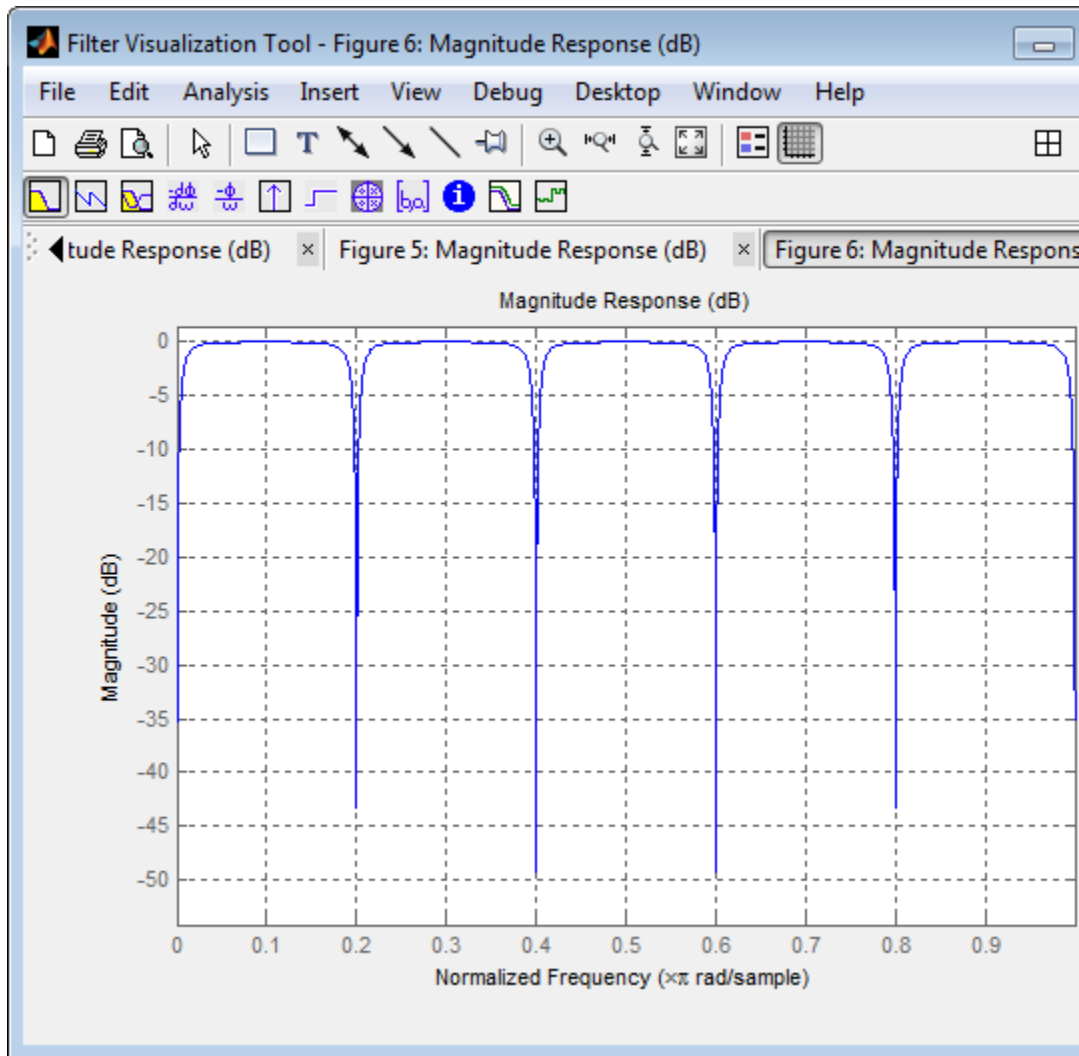

or, you have the filter coefficients, and then you use `dsp.IIRFilter`, to apply it:

```
b = [0.9 zeros(9,1)' -0.9];  
a = [1 zeros(9,1)' -0.8];  
H = dsp.IIRFilter('Numerator',b,'Denominator',a)  
fvtool(H);
```

# dsp.IIRFilter

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

## See Also

`dsp.BiquadFilter` | `dsp.FIRFilter` | `dsp.AllpoleFilter`

## **dsp.IIRFilter.clone**

---

**Purpose** Create IIR filter with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a IIR filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

**Purpose** Frequency response

**Syntax**

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

**Description** `[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

# **dsp.IIRFilter.fvtool**

---

**Purpose** Open filter visualization tool

**Syntax** `fvtool(H)`  
`fvtool(H, 'Arithmetic', ARITH, ...)`

**Description** `fvtool(H)` performs an analysis and computes the magnitude response of the filter System object H.

`fvtool(H, 'Arithmetic', ARITH, ...)` analyzes the filter System object H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

## **dsp.IIRFilter.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Impulse response

**Syntax**  
`[h,t] = impz(H)`  
`[h,t] = impz(H,Name,Value)`  
`impz(H)`

**Description** `[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(H)` uses `FVTool` to plot the impulse response of the filter System object `H`.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

# **dsp.IIRFilter.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the IIR filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Unwrapped phase response

**Syntax**

```
[phi,w] = phasez(H)  
[phi,w] = phasez(H,n)  
[phi,w] = phasez(H,Name,Value)  
phasez(H)
```

**Description**

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

# dsp.IIRFilter.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset internal states of IIR filter

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the IIR filter object, H, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the step method applies the IIR filter object to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

For example:

```
H = dsp.IIRFilter;
[b,a] = ellip(20, 0.5, 80, 0.25);
H.Numerator = b;
H.Denominator = a;
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

# dsp.IIRFilter.step

---

**Purpose** Filter input with IIR filter object

**Syntax**  $Y = \text{step}(H, X)$

**Description**  $Y = \text{step}(H, X)$  filters the real or complex input signal  $X$  using the IIR filter,  $H$ , to produce the output  $Y$ . When the input data is of a fixed-point type, it must be signed. The IIR filter object operates on each channel of the input signal independently over successive calls to step method.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

<b>Purpose</b>	Linear or FIR interpolation
<b>Description</b>	<p>The <code>Interpolator</code> object interpolates real-valued inputs using linear or polyphase FIR interpolation.</p> <p>To interpolate real-valued inputs:</p> <ol style="list-style-type: none"><li>1 Define and set up your interpolation object. See “Construction” on page 3-687.</li><li>2 Call <code>step</code> to interpolate the input according to the properties of <code>dsp.Interpolator</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.Interpolator</code> returns a handle to an interpolation object, <code>H</code>. The interpolation method defaults to <code>Linear</code> and the interpolation points default to a <math>5 \times 1</math> vector.</p> <p><code>H = dsp.Interpolator('PropertyName',PropertyValue,...)</code> returns an interpolation object, <code>H</code>, with the specified property name and value pairs.</p>
<b>Properties</b>	<p><b>InterpolationPointsSource</b></p> <p>Source of interpolation points</p> <p>You can select a value of <code>Property</code> or <code>Input port</code>. If you set this property to <code>Input port</code>, you must provide the interpolation points as an input to the <code>step</code> method when you interpolate the input. The default is <code>Property</code>.</p> <p><b>InterpolationPoints</b></p> <p>Interpolation points</p> <p>This property only applies when you set the <code>InterpolationPointsSource</code> property to <code>Property</code>. Specify the interpolation points as a column vector or a matrix with the same number of channels as the input.</p>

The valid range of the values in the interpolation vector is from 1 to the number of samples in each channel of the input. If you specify interpolation points outside the valid range, the object *clips* the point to the nearest point in the valid range. For example, if the input is [2 3.1 -2.1], the valid range of interpolation points is from 1 to 3. If you specify the following vector of interpolation points [-1 1.5 2 2.5 3 3.5], the interpolator object clips -1 to 1 and 3.5 to 3. This clipping results in the interpolation points [1 1.5 2 2.5 3 3]. The default is [1.1;4.8;2.67;1.6;3.2]. This property is tunable.

## Method

Interpolation method

Specify the interpolation method as `Linear` or `FIR`. When this property is `Linear`, the interpolator object interpolates data values by assuming that the data varies linearly between adjacent samples. When this property is `FIR`, the interpolator object uses polyphase interpolation to replace filtering (convolution) at the upsampled rate with a series of convolutions at the lower rate. The interpolator object always performs linear interpolation if there are insufficient low-rate samples to perform FIR interpolation as explained in the description of the `FilterHalfLength` property. The default is `Linear`.

## FilterHalfLength

Interpolation filter half length

This property applies only when you set the `Method` property to `FIR`. For a filter half length of  $P$ , the polyphase FIR subfilters have length  $2P$ . FIR interpolation always requires  $2P$  low-rate samples for every interpolation point.

- If the interpolation point does not correspond to a low-rate sample, FIR interpolation requires  $P$  low-rate samples below and  $P$  low-rate samples above the interpolation point.

- If the interpolation point corresponds to a low-rate sample, the  $2P$ -sample requirement includes the low-rate sample.
- If there are less than  $2P$  neighboring low-rate samples, the interpolator object uses linear interpolation.

For example, for an input [1 4 1 4 1 4 1 4], upsampling by a factor of four results in the equally spaced interpolation points `InterP = 1:0.25:8`; The points `InterP(9:12)` are [3.0 3.25 3.5 3.75]. Assuming a `FilterHalfLength` property equal to 2, interpolating at these points uses the four low-rate samples from the input with indices (2,3,4,5). If you set the `FilterHalfLength` property to 4 in this case, the interpolator object uses linear interpolation because there are not enough low-rate samples to perform FIR interpolation.

The longer the `FilterHalfLength` property, the better the quality of the interpolation. However, the costs are increased computation and requiring more low-rate samples below and above the interpolation point. In general, setting the `FilterHalfLength` property between 4 and 6 provides reasonably accurate interpolation.

## **InterpolationPointsPerSample**

Interpolation points per input sample

This property only applies when you set the `Method` property to FIR and indicates the upsampling factor,  $L$ . An upsampling factor of  $L$  inserts  $L-1$  zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter. The interpolator object uses a polyphase FIR implementation with `InterpolationPointsPerSample` subfilters of length  $2P$ , where  $P$  is the `FilterHalfLength` property. Denoting the low-rate samples in the upsampled input by  $nL$ ,  $n=1,2,\dots$ , the interpolator object uses exactly one of the `InterpolationPointsPerSample` subfilters, or filter arms, to interpolate at the points  $nL+i/L$ , where  $i=0,1,2,\dots,L-1$ .

# dsp.Interpolator

---

If you specify interpolation points which do not correspond to a polyphase subfilter, the object rounds the point down to the nearest interpolation point associated with a polyphase subfilter. For example, you set the `InterpolationPointsPerSample` property to 4 and interpolate at the points [3 3.2 3.4 3.6 3.8]. The interpolator object uses the first polyphase subfilter for the points [3.0 3.2], the second subfilter for the point 3.4, the third subfilter for the point 3.6, and the fourth subfilter for the point 3.8.

## Bandwidth

Normalized input bandwidth

This property applies only when you set the `Method` property to FIR. The normalized bandwidth is a real-valued scalar between 0 and 1, where 1 equals the Nyquist frequency, or 1/2 the sampling frequency ( $F_s$ ). You may know that your input does not have frequency content above some cutoff frequency less than the Nyquist frequency. You can use this information to improve the FIR interpolation filters by relaxing the stopband requirements in frequency regions where the signal has no energy. For example, if the input signal does not have frequency content above  $F_s/8$ , you can specify a value of 0.25 for the `Bandwidth` property. The default value is 0.5.

## Methods

<code>clone</code>	Create interpolator object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
step	Linear or FIR interpolation

## Definitions

A polyphase implementation of an FIR interpolation filter *splits* the lowpass FIR filter impulse response into a number of different subfilters. Let  $L$  represent the number of interpolation points per sample, or the upsampling factor, and  $P$  the half length of the polyphase subfilters. Indexing from zero, if  $h(n)$  is the impulse response of the FIR filter, the  $k$ -th subfilter is:

$$h_k(n) = h(k + nL) \quad k = 0, 1, \dots, L-1 \quad n = 0, 1, \dots, 2P-1$$

The following table describes the decomposition of an 18-coefficient FIR filter into 3 polyphase subfilters of length 6, the defaults for the FIR interpolator object:

Coefficients	Polyphase Subfilter
$h(0), h(3), h(6), \dots, h(15)$	$h_0(n)$
$h(1), h(4), h(7), \dots, h(16)$	$h_1(n)$
$h(2), h(5), h(8), \dots, h(17)$	$h_2(n)$

The following code shows how to find the polyphase subfilters for the default FIR interpolator object:

```
H = dsp.Interpolator('Method','FIR');
L = H.InterpolationPointsPerSample;
P = H.FilterHalfLength;
FiltCoeffs = intfilt(L,P,H.Bandwidth);
% Returns filter of length 2*P*L-1
FiltLen=length(FiltCoeffs);
FiltCols = ceil(FiltLen/2/L);
```

# dsp.Interpolator

---

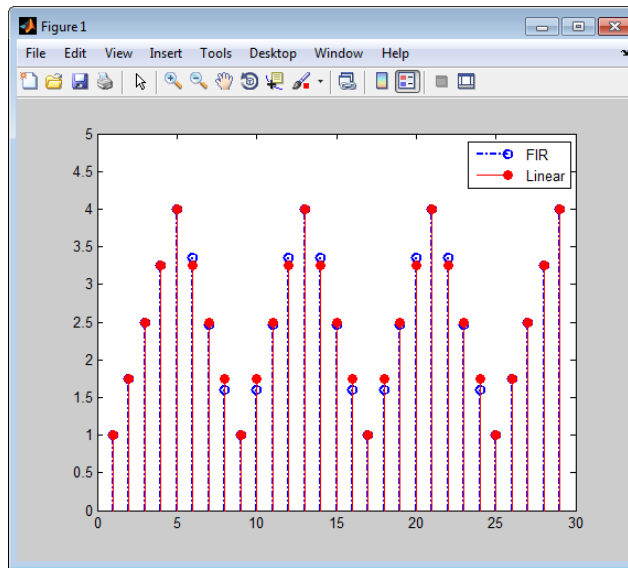

```
% We need 2*P*L coefficients
% Prepending a zero does not affect the filter magnitude
FiltCoeffs = [zeros(FiltCols*2*L-FiltLen,1); FiltCoeffs(:)];

% Each column of PolyPhaseCoeffs is a polyphase subfilter
PolyPhaseCoeffs = reshape(FiltCoeffs,FiltCols,2*L)';
```

## Examples

Compare linear interpolation with FIR interpolation:

```
x =[1 4];
x = repmat(x,1,4);
x1 = 1:0.25:8;
hFIR =dsp.Interpolator('Method','FIR','FilterHalfLength',2,...
'InterpolationPoints',x1,'InterpolationPointsPerSample',4);
hLin =dsp.Interpolator('InterpolationPoints',x1');
OutFIR = step(hFIR,x');
OutLin = step(hLin,x');
stem(OutFIR,'b-.','linewidth',2); hold on;
stem(OutLin,'r','markerfacecolor',[1 0 0]);
axis([0 30 0 5]); legend('FIR','Linear','Location','Northeast');
```

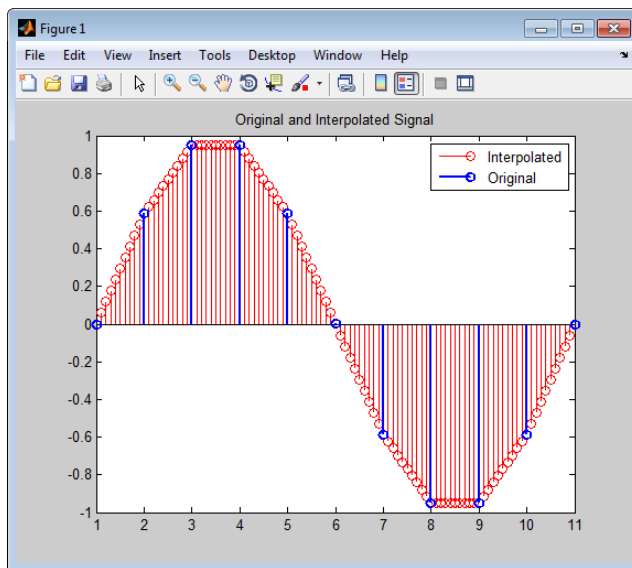

For the indices 1 to 5 and 25 to 29, the interpolator object uses linear interpolation in both cases. The reason for this is that there are not enough low-rate samples surrounding the interpolation points at those indices to use FIR interpolation with the specified filter length.

Interpolate a sinusoid with linear interpolation:

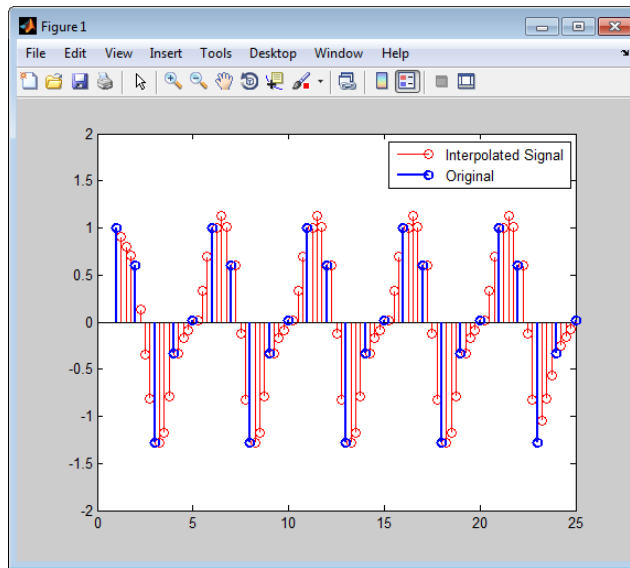

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
x1 = x(1:50:end);
I = 1:0.1:length(x1);
H = dsp.Interpolator('InterpolationPointsSource',...
    'Input port');
y = H.step(x1',I');
stem(I',y, 'r');
title('Original and Interpolated Signal');
hold on; stem(x1, 'Linewidth', 2);
legend('Interpolated','Original');
```

# dsp.Interpolator

Interpolate a sum of sinusoids with FIR interpolation and Input Port as the source of interpolation points:

```
Fs = 1000;
t = 0:(1/Fs):0.1-(1/Fs);
x = cos(2*pi*50*t)+0.5*sin(2*pi*100*t);
x1 = x(1:4:end);
I = 1:(1/4):length(x1);
% Decimate without aliasing
H = dsp.Interpolator('Method','FIR',...
'FilterHalfLength',3,'InterpolationPointsSource','Input Port');
y = H.step(x1,I);
stem(I,y,'r'); hold on;
axis([0 25 -2 2]);
stem(x1,'b','linewidth',2);
legend('Interpolated Signal','Original',...
'Location','Northeast');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Interpolation block reference page. The object properties correspond to the Simulink block parameters, except:

**Out of range interpolation points** — The interpolator object only has the `Clip` option. The Simulink block has the additional `Clip` and `warn` and `Error` options.

## See Also

`intfilt` | `dsp.FIRInterpolator` | `dsp.VariableFractionalDelay`

# **dsp.Interpolator.clone**

---

**Purpose** Create interpolator object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an interpolator object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.Interpolator.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the interpolator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# **dsp.Interpolator.release**

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Linear or FIR interpolation

**Syntax**  
`Y = step(H,X)`  
`Y = step(H,X,IPTS)`

**Description** `Y = step(H,X)` outputs the interpolated sequence, `Y`, of the input vector or matrix `X` as specified in the `InterpolationPoints` property.

`Y = step(H,X,IPTS)` outputs the interpolated sequence as specified by the input argument `IPTS` when the `InterpolationPointsSource` property is set to 'Input port'. `IPTS` a column vector or a matrix of interpolation points. If `IPTS` is a matrix, it must have the same number of channels as the input.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.LDLFactor

---

**Purpose** Factor square Hermitian positive definite matrices into components

**Description** The `LDLFactor` object factors square Hermitian positive definite matrices into lower, upper, and diagonal components. The object uses only the lower triangle of  $S$ .

To factor these matrices into lower, upper, and diagonal components:

- 1 Define and set up your LDL factor object. See “Construction” on page 3-702.
- 2 Call `step` to factor the matrices according to the properties of `dsp.LDLFactor`. The behavior of `step` is specific to each object in the toolbox.

**Construction**  $H = \text{dsp.LDLFactor}$  returns an LDL factor System object,  $H$ , that computes unit lower triangular  $L$  and diagonal  $D$  such that  $S = LDL'$  for square, symmetric/Hermitian, positive definite input matrix  $S$ .

$H = \text{dsp.LDLFactor}('PropertyName', PropertyValue, \dots)$  returns an LDL factor System object,  $H$ , with each specified property set to the specified value.

**Properties** **Fixed-Point Properties**

**AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`

**CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numeric type object with a `Signedness` of `Auto`. This property applies when you

set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **CustomIntermediateProductDataType**

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numericType(true,16,15)`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **IntermediateProductDataType**

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

## **OverflowAction**

# dsp.LDLFactor

---

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

## **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as: `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

## **Methods**

<code>clone</code>	Create an LDL Factor object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs for step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Decompose matrix into components

## **Examples**

Decompose a square Hermitian positive definite matrix using LDL factor:

```
A = gallery('randcorr',5);  
hldl = dsp.LDLFactor;
```

```
y = step(hld1, A);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LDL Factorization block reference page. The object properties correspond to the block parameters, except:

No object property that corresponds to the **Non-positive definite input** block parameter. The object does not issue any alerts for nonpositive definite inputs. The output is not a valid factorization. A partial factorization is in the upper left corner of the output.

## See Also

dsp.LUFactor

## **dsp.LDLFactor.clone**

---

**Purpose** Create an LDL Factor object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an LDLFactor System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.LDLFactor.getNumOutputs

---

**Purpose**            Number of outputs for step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `LDLFactor` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

## dsp.LDLFactor.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Decompose matrix into components

**Syntax**  $Y = \text{step}(H,S)$

**Description**  $Y = \text{step}(H,S)$  decomposes the matrix  $S$  into lower, upper, and diagonal components. The output  $Y$  is a composite matrix with the  $L$  as its lower triangular part and  $D$  as the diagonal and  $L'$  as its upper triangular part. If  $S$  is not positive definite the output  $Y$  is not a valid factorization.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.LevinsonSolver

---

**Purpose** Solve linear system of equations using Levinson-Durbin recursion

**Description** The LevinsonSolver object solves linear systems of equations using Levinson-Durbin recursion.

To solve linear systems of equations using Levinson-Durbin recursion:

- 1 Define and set up your System object. See “Construction” on page 3-712.
- 2 Call `step` to solve the system of equations according to the properties of `dsp.LevinsonSolver`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.LevinsonSolver` returns a System object, `H`, that solves a Hermitian Toeplitz system of equations using the Levinson-Durbin recursion.

`H = dsp.LevinsonSolver('PropertyName',PropertyValue,...)` returns a Levinson-Durbin object, `H`, with each specified property set to the specified value.

**Properties** **AOutputPort**

Enable polynomial coefficients output

Set this property to `true` to output the polynomial coefficients  $A$ . Both `AOutputPort` and `KOutputPort` properties cannot be `false` at the same time. For scalar inputs, set the `AOutputPort` property to `true`. The default is `false`.

**KOutputPort**

Enable reflection coefficients output

Set this property to `true` to output the reflection coefficients  $K$ . You cannot set both the `AOutputPort` and `KOutputPort` properties to `false` at the same time. For scalar inputs, you must set the `KOutputPort` property to `false`. The default is `true`.

**PredictionErrorOutputPort**

Enable prediction error output

Set this property to true to output the prediction error. The default is false.

## **ZerothLagZeroAction**

Action when value of lag zero is zero

Specify the output for an input with the first coefficient as zero. Select Ignore or Use zeros. The default is Use zeros.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as Ceiling, Convergent, Floor, Nearest, Round, Simplest, or Zero. The default is Floor.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as Wrap, Saturate. The default is Wrap.

### **ACoefficientDataType**

$A$  coefficient word and fraction lengths

This constant property has a value of Custom.

### **CustomACoefficientDataType**

$A$  coefficient word and fraction lengths

Specify the  $A$  coefficient fixed-point type as a scaled numeric type object with a Signedness of Auto. The default is `numericType([], 16, 15)`.

### **KCoefficientDataType**

$K$  coefficient word and fraction lengths

This constant property has a value of `Custom`.

## **CustomKCoefficientDataType**

$K$  coefficient word and fraction lengths

Specify the  $K$  coefficient fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([],16,15)`.

## **PredictionErrorDataType**

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

## **CustomPredictionErrorDataType**

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `PredictionErrorDataType` property is `Custom`. The default is `numericType([],16,15)`.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Custom`

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the Accumulator fixed-point data type as Same as input, Same as product, or Custom. The default is Custom.

## CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when the AccumulatorDataType property is Custom. The default is numeric type([ ], 32, 30).

## Methods

clone	Create Levinson solver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Reflection coefficients corresponding to columns of input

## Examples

Use the Levinson solver to compute polynomial coefficients from autocorrelation coefficients:

```
hlevinson = dsp.LevinsonSolver;  
hlevinson.AOutputPort = true;  
hlevinson.KOutputPort = false;  
x = (1:100)';  
hac = dsp.Autocorrelator(...  
    'MaximumLagSource', 'Property', ...  
    'MaximumLag', 10);
```

# dsp.LevinsonSolver

---

```
a = step(hac, x);  
c = step(hlevinson, a); % Compute polynomial coefficients
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Levinson-Durbin block reference page. The object properties correspond to the block parameters, except:

**Output(s)** block parameter corresponds to the AOutputPort and the KOutputPort object properties.

## See Also

dsp.Autocorrelator

<b>Purpose</b>	Create Levinson solver object with same property values
<b>Syntax</b>	<code>C = clone(H)</code>
<b>Description</b>	<code>C = clone(H)</code> creates a LevinsonSolver object System object C, with the same property values as H. The clone method creates a new unlocked object.

# dsp.LevinsonSolver.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.LevinsonSolver.isLocked

---

<b>Purpose</b>	Locked status for input attributes and nontunable properties
<b>Syntax</b>	<code>isLocked(H)</code>
<b>Description</b>	<p><code>isLocked(H)</code> returns the locked state of the LevinsonSolver System object.</p> <p>The <code>isLocked</code> method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the <code>step</code> method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the <code>isLocked</code> method returns a true value.</p>

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.LevinsonSolver.step

---

**Purpose** Reflection coefficients corresponding to columns of input

**Syntax**

```
K = step(H,X)
A = step(H,X)
[A, K] = step(H,X)
[... , P] = step(H,X)
```

**Description** `K = step(H,X)` returns reflection coefficients `K` corresponding to the columns of input `X`. `X` is typically a column or matrix of autocorrelation coefficients with lag 0 as the first element.

`A = step(H,X)` returns polynomial coefficients `A` when the `AOutputPort` property is true and the `KOutputPort` property is false.

`[A, K] = step(H,X)` returns polynomial coefficients `A` and reflection coefficients `K` when both the `AOutputPort` and `KOutputPort` properties are true.

`[... , P] = step(H,X)` also returns the error power `P` when the `PredictionErrorOutputPort` property is true.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Purpose

LMS adaptive filter

## Description

The `LMSFilter` implements an adaptive FIR filter object that returns the filtered output, the error vector, and filter weights. The LMS filter uses one of five different LMS algorithms.

To implement the adaptive FIR filter object:

- 1 Define and set up your adaptive FIR filter object. See “Construction” on page 3-723.
- 2 Call `step` to implement the filter according to the properties of `dsp.LMSFilter`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.LMSFilter` returns an adaptive FIR filter object, `H`, that computes the filtered output, filter error and the filter weights for a given input and desired signal using the Least Mean Squares (LMS) algorithm.

`H = dsp.LMSFilter('PropertyName', PropertyValue, ...)` returns an LMS filter object, `H`, with each property set to the specified value.

`H = dsp.LMSFilter(LEN, 'PropertyName', PropertyValue, ...)` returns an LMS filter object, `H`, with the `Length` property set to `LEN`, and other specified properties set to the specified values.

## Properties

### Method

Method to calculate filter weights

Specify the method used to calculate filter weights as `LMS`, `Normalized LMS`, `Sign-Error LMS`, `Sign-Data LMS`, or `Sign-Sign LMS`. The default is `LMS`.

### Length

Length of FIR filter weights vector

Specify the length of the FIR filter weights vector as a positive integer. The default is 32.

## **StepSizeSource**

How to specify adaptation step size

Choose how to specify the adaptation step size factor as `Property` or `Input port`. The default is `Property`.

## **StepSize**

Adaptation step size

Specify the adaptation step size factor as a nonnegative real number. For convergence of the normalized LMS method, set the step size greater than 0 and less than 2. This property only applies when the `StepSizeSource` property is `Property`. The default is 0.1. This property is tunable.

## **LeakageFactor**

Leakage factor used in LMS filter

Specify the leakage factor as a real number between 0 and 1 inclusive. A leakage factor of 1 corresponds to no leakage in the adapting method. The default is 1. This property is tunable.

## **InitialConditions**

Initial conditions of filter weights

Specify the initial values of the FIR filter weights as a scalar or vector of length equal to the `Length` property value. The default is 0.

## **AdaptInputPort**

Enable weight adaptation

Specify when the LMS filter should adapt the filter weights. By default, the value of this property is `false`, and the object continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the

step method. If the value of this input is nonzero, the object continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

## **WeightsResetInputPort**

Enable weight reset

Specify when the LMS filter should reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, a reset control input is provided to the `step` method, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the `step` method.

## **WeightsResetCondition**

Reset trigger setting for filter weights

Specify the event to reset the filter weights as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The LMS filter resets the filter weights based on the values of this property and the reset input to the `step` method. This property only applies when the `WeightsResetInputPort` property is `true`. The default is `Non-zero`.

## **WeightsOutputPort**

Enable returning filter weights

Set this property to `true` to output the adapted filter weights. The default is `true`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

## **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

## **StepSizeDataType**

Step size word and fraction lengths

Specify the step size fixed-point data type as `Same word length as first input` or `Custom`. Setting this property also sets the `LeakageFactorDataType` property to the same value. This property only applies when the `StepSizeSource` property is `Property`. The default is `Same word length as first input`.

## **CustomStepSizeDataType**

Step size word and fraction lengths

Specify the step size fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeSource` property is `Property` and the `StepSizeDataType` property is `Custom`. This property and the `CustomLeakageFactorDataType` property must have the same word lengths. The default is `numericType([],16,15)`.

## **LeakageFactorDataType**

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point data type as `Same word length as first input` or `Custom`. Setting this property also sets the `StepSizeDataType` property to the same value. This property only applies when the `StepSizeSource` property is `Property`. The default is `Same word length as first input`.

## **CustomLeakageFactorDataType**

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property only applies

when the `StepSizeSource` property is `Property` and the `LeakageFactorDataType` property is `Custom`. This property and the `CustomStepSizeDataType` property must have the same word lengths. The default is `numerictype([],16,15)`.

## **WeightsDataType**

Weights word and fraction lengths

Specify the filter weights fixed-point data type as `Same as first input` or `Custom`. The default is `Same as first input`.

## **CustomWeightsDataType**

Weights word and fraction lengths

Specify the filter weights fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `WeightsDataType` property is `Custom`. The default is `numerictype([],16,15)`.

## **EnergyProductDataType**

Energy product word and fraction lengths

Specify the energy product fixed-point data type as `Same as first input` or `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionProductDataType`, `StepSizeErrorProductDataType`, `WeightsUpdateProductDataType`, and `QuotientDataType` properties to the same value. The default is `Same as first input`.

## **CustomEnergyProductDataType**

Energy product word and fraction lengths

Specify the energy product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `Method` property is `Normalized LMS` and the `EnergyProductDataType` property is `Custom`. The `CustomEnergyProductDataType`,

CustomConvolutionProductDataType, CustomStepSizeErrorProductDataType, CustomWeightsUpdateProductDataType, and CustomQuotientDataType properties must have the same word lengths. The default is `numerictype([],32,20)`.

## **EnergyAccumulatorDataType**

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point data type as `Same as first input` or `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionAccumulatorDataType` property to the same value. The default is `Same as first input`.

## **CustomEnergyAccumulatorDataType**

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `Method` property is `Normalized LMS` and the `EnergyAccumulatorDataType` property is `Custom`. The `CustomEnergyProductDataType`, `CustomConvolutionProductDataType`, `CustomStepSizeErrorProductDataType`, `CustomWeightsUpdateProductDataType`, and `CustomQuotientDataType` properties must have the same word lengths. The default is `numerictype([],32,20)`.

## **ConvolutionProductDataType**

Convolution product word and fraction lengths

Specify the convolution product fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `EnergyProductDataType`, `StepSizeErrorProductDataType`, `WeightsUpdateProductDataType` and `QuotientDataType` properties to the same value. The default is `Same as first input`.

**CustomConvolutionProductDataType**

Convolution product word and fraction lengths

Specify the convolution product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property only applies when the `ConvolutionProductDataType` property is `Custom`. The `CustomEnergyProductDataType`, `CustomConvolutionProductDataType`, `CustomStepSizeErrorProductDataType`, `CustomWeightsUpdateProductDataType`, and `CustomQuotientDataType` properties must have the same word lengths. The default is `numericType([],32,20)`.

**ConvolutionAccumulatorDataType**

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `EnergyAccumulatorDataType` property to the same value. The default is `Same as first input`.

**CustomConvolutionAccumulatorDataType**

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property only applies when the `ConvolutionAccumulatorDataType` property is `Custom`. The `CustomEnergyAccumulatorDataType` and `CustomConvolutionAccumulatorDataType` properties must have the same word lengths. The default is `numericType([],32,20)`.

**StepSizeErrorProductDataType**

Step size error product word and fraction lengths

Specify the step size error product fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `ConvolutionProductDataType`, `EnergyProductDataType`, `WeightsUpdateProductDataType`, and `QuotientDataType`

properties to the same value. The default is Same as first input.

## **CustomStepSizeErrorProductDataType**

Step size error product word and fraction lengths

Specify the step size error product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeErrorProductDataType` property is `Custom`. The `CustomEnergyProductDataType`, `CustomConvolutionProductDataType`, `CustomStepSizeErrorProductDataType`, `CustomWeightsUpdateProductDataType`, and `CustomQuotientDataType` properties must have the same word lengths. The default is `numericType([],32,20)`.

## **WeightsUpdateProductDataType**

Weight update product word and fraction lengths

Specify the weight update product fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `ConvolutionProductDataType`, `EnergyProductDataType`, `StepSizeErrorProductDataType`, and `QuotientDataType` properties to the same value. The default is `Same as first input`.

## **CustomWeightsUpdateProductDataType**

Weight update product word and fraction lengths

Specify the weight update product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property only applies when the `WeightsUpdateProductDataType` property is `Custom`. The `CustomEnergyProductDataType`, `CustomConvolutionProductDataType`, `CustomStepSizeErrorProductDataType`, `CustomWeightsUpdateProductDataType`, and `CustomQuotientDataType` properties must have the same word lengths. The default is `numericType([],32,20)`.

**QuotientDataType**

Quotient word and fraction lengths

Specify the quotient fixed-point data type as Same as first input, Custom. This property only applies when the Method property is Normalized LMS. Setting this property also sets the ConvolutionProductDataType, EnergyProductDataType, StepSizeErrorProductDataType, and WeightsUpdateProductDataType properties to the same value. The default is Same as first input.

**CustomQuotientDataType**

Quotient word and fraction lengths

Specify the quotient fixed-point type as a scaled numerictype object with a Signedness of Auto. This property only applies when the Method property is Normalized LMS and the QuotientDataType property is Custom. The CustomEnergyProductDataType, CustomConvolutionProductDataType, CustomStepSizeErrorProductDataType, CustomWeightsUpdateProductDataType, and CustomQuotientDataType properties must have the same word lengths. The default is numerictype([],32,20).

**Methods**

clone	Create LMS filter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes

reset	Reset filter states for LMS filter
step	Apply LMS adaptive filter to input

## Examples

Determine system identification of an FIR filter:

```
hlms1 = dsp.LMSFilter(11, 'StepSize', 0.01);
hfilt = dsp.DigitalFilter; % System to be identified
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10, .25);
x = randn(1000,1); % input signal

d = step(hfilt, x) + 0.01*randn(1000,1); % desired signal
[y,e,w] = step(hlms1, x, d);

subplot(2,1,1), plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index'); ylabel('signal value');
subplot(2,1,2); stem([hfilt.Numerator.', w]);
legend('Actual', 'Estimated');
xlabel('coefficient #'); ylabel('coefficient value');
```

---

Cancel noise in a signal:

```
hlms2 = dsp.LMSFilter('Length', 11, ...
    'Method', 'Normalized LMS',...
    'AdaptInputPort', true, ...
    'StepSizeSource', 'Input port', ...
    'WeightsOutputPort', false);
hfilt2 = dsp.DigitalFilter(...
    'TransferFunction', 'FIR (all zeros)', ...
    'Numerator', fir1(10, [.5, .75]));
x = randn(1000,1); % Noise
d = step(hfilt2, x) + sin(0:.05:49.95)'; % Noise + Signal
```

```

a = 1; % adaptation control
mu = 0.05; % step size
[y, err] = step(hlms2, x, d, mu, a);

subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2), plot(err), title('Signal');

```

## Algorithms

This filter's algorithm is defined by the following equations.

$$\begin{aligned}
 y(n) &= \mathbf{w}^T(n-1)\mathbf{u}(n) \\
 e(n) &= d(n) - y(n) \\
 \mathbf{w}(n) &= \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)
 \end{aligned}$$

The various LMS adaptive filter algorithms available in this System object are defined as:

- LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \mathbf{u}^*(n)$$

- Normalized LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

- Sign-Error LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \mathbf{u}^*(n)$$

- Sign-Data LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \text{sign}(\mathbf{u}(n))$$

where  $\mathbf{u}(n)$  is real.

- Sign-Sign LMS:

## dsp.LMSFilter

---

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \text{sign}(\mathbf{u}(n))$$

where  $\mathbf{u}(n)$  is real.

The variables are as follows:

Variable	Description
$n$	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step $n$
$\mathbf{u}^*(n)$	The complex conjugate of the vector of buffered input samples at step $n$
$\mathbf{w}(n)$	The vector of filter weight estimates at step $n$
$y(n)$	The filtered output at step $n$
$e(n)$	The estimation error at step $n$
$d(n)$	The desired response at step $n$
$\mu$	The adaptation step size
$\alpha$	The leakage factor ( $0 < \alpha \leq 1$ )

### See Also

[dsp.BlockLMSFilter](#) | [dsp.DigitalFilter](#)

**Purpose** Create LMS filter object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an LMS filter object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

## **dsp.LMSFilter.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.LMSFilter.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the LMS filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.LMSFilter.reset

---

**Purpose** Reset filter states for LMS filter

**Syntax** reset(H)

**Description** reset(H) resets the filter states of the LMS FIR filter, H, to their initial values specified in the InitialConditions property. The initial filter state values correspond to the initial conditions for difference equation defining the adaptive filter. After the step method applies the LMS filter to nonzero input data, the states may be different. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

Example of resetting filter states:

```
hlms1 = dsp.LMSFilter(11, 'StepSize', 0.01);
hfilt = dsp.DigitalFilter; % System to be identified
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10, .25);
x = randn(1000,1); % input signal
d = step(hfilt, x) + 0.01*randn(1000,1); % desired signal
[y,e,w] = step(hlms1, x, d);
% Call step method again without resetting filter states
[y1,e1,w1] = step(hlms1,x,d);
isequal(y,y1) % Returns 0
% Now reset the filter states to zero
reset(hlms1)
% invoke step method
[y2,e2,w2] = step(hlms1,x,d);
isequal(y,y2) % Returns 1
```

**Purpose**

Apply LMS adaptive filter to input

**Syntax**

```
[Y,ERR,WTS] = step(H,X,D)
[Y, ERR] = step(H,X,D)
[...] = step(H,X,D,MU)
[...] = step(H,X,D,A)
[...] = step(H,X,D,R)
[Y,ERR,WTS] = step(H,X,D,MU,A,R)
```

**Description**

`[Y,ERR,WTS] = step(H,X,D)` applies the LMS filter object, `H` to the input `X`, using `D` as the desired signal. This approach returns the filtered output in `Y`, the filter error in `ERR`, and the estimated filter weights in `WTS`. The LMS filter estimates the filter weights needed to minimize the mean square error between the output and the desired signal.

`[Y, ERR] = step(H,X,D)` filters the input `X`, using `D` as the desired signal. This approach returns the filtered output in `Y` and the filter error in `ERR` when the `WeightsOutputPort` property is `false`.

`[...] = step(H,X,D,MU)` uses `MU` as the step size, when the `StepSizeSource` property is `'Input port'`.

`[...] = step(H,X,D,A)` uses `A` as the adaptation control, when the `AdaptInputPort` property is `true`. When `A` is nonzero, the LMS filter continuously updates the filter weights. When `A` is zero, the filter weights remain constant.

`[...] = step(H,X,D,R)` uses `R` as a reset signal when the `WeightsResetInputPort` property is `true`. The `WeightsResetCondition` property can be used to set the reset trigger condition. If a reset event occurs, the LMS filter resets the filter weights to their initial values.

`[Y,ERR,WTS] = step(H,X,D,MU,A,R)` filters the input `X` using `D` as the desired signal, `MU` as the step size, `A` as the adaptation control, and `R` as the reset signal. This approach returns the filtered output in `Y`, the filter error in `ERR`, and the adapted filter weights in `WTS`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Purpose

Display transitions of signals over time

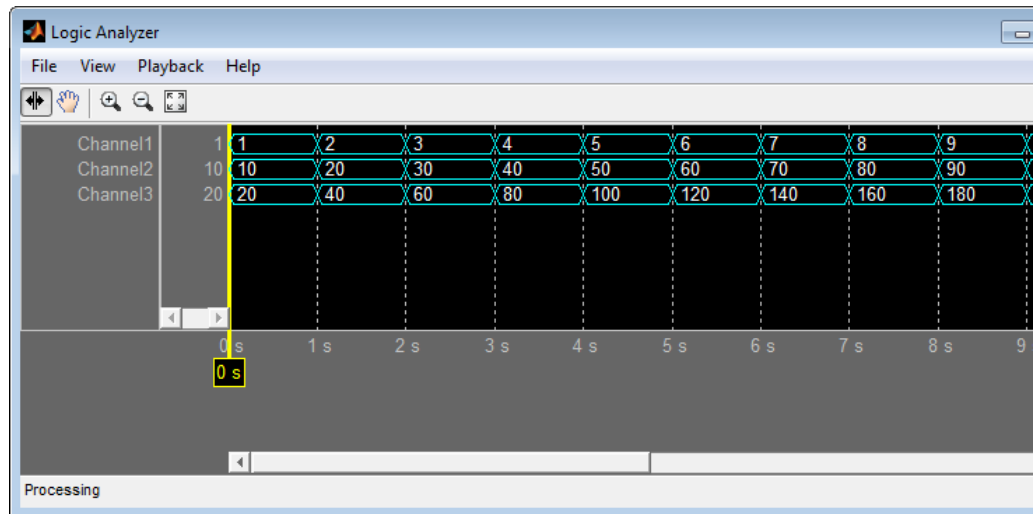

## Description

The LogicAnalyzer object, hereafter referred to as the scope, displays the transitions in time-domain signals.

To display the transitions of signals in the Logic Analyzer:

- 1 Define and set up your Logic Analyzer. See “Construction” on page 3-744.
- 2 Call `step` to display the transitions of the signals in the Logic Analyzer figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Logic Analyzer figure window and clear its associated data. Use the `hide` method to hide the Logic Analyzer window and the `show` method to make it visible.

See the following sections for more information on the Logic Analyzer Graphical User Interface:

- “Signal Display” on page 3-751
- “Toolbar” on page 3-754

## Construction

`H = dsp.LogicAnalyzer` creates a Logic Analyzer System object, `H`. This object displays the transitions of signals.

`H = dsp.LogicAnalyzer('Name', Value, ...)` creates a Logic Analyzer System object, `H`, with each specified property *Name* set to the specified value. You can specify *Name–Value* arguments in any order.

## Properties

### BackgroundColor

Background color for display

Specify the background color of the display to be either 'Black' or 'White'.

This property is Tunable.

**Default:** 'Black'

### DisplayChannelColor

Color for channels in the display

Specify the color for channels in the display to be one of the following options:

- 'Black'
- 'Blue'
- 'Green'
- 'Cyan'
- 'Red'
- 'Magenta'
- 'White'

This property is Tunable.

**Default:** 'Cyan'

## **DisplayChannelFontSize**

Font size for channels in display

Specify as a scalar nonnegative integer the font size in points for values shown in the channels in the display.

This property is Tunable.

**Default:** 10

## **DisplayChannelFormat**

Format for channels in display

Specify as a string the wave format from one of the following options:

- 'Analog'
- 'Digital'

This property is Tunable.

**Default:** 'Digital'

## **DisplayChannelHeight**

Height for channels in display

Specify as a scalar integer the height of the wave in the display in units of 16 pixels.

This property is Tunable.

**Default:** 1

## **DisplayChannelRadix**

Radix for channels in display

Specify as a string the radix of the display from one of the following options:

- 'Binary'
- 'Hexadecimal'
- 'Octal'
- 'Signed decimal'
- 'Unsigned decimal'

When the input signals are of class double, single, or logical, you should not set this property. This property is Tunable.

**Default:** 'Hexadecimal'

## **DisplayChannelSpacing**

Spacing for channels in display

Specify as a positive scalar integer the spacing between channels in the display in units of 4 pixels.

This property is Tunable.

**Default:** 1

## **MaxNumTimeSteps**

Maximum number of time steps

Specify as a finite numeric scalar the maximum number of samples for the input ports. The same maximum number of time steps is used for all inputs.

**Default:** 50000

## **Name**

Caption to display on scope window

Specify as a string the caption to display on the scope window.

This property is Tunable.

**Default:** 'Logic Analyzer'

## **NumInputPorts**

Number of input signals

Specify the number of input signals to display on the scope as a positive integer. You must invoke the `step` method with the same number of inputs as the value of this property.

**Default:** 1

## **Position**

Scope window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, [`left bottom width height`]. You can place the scope window in a specific position on your screen by modifying the values for this property.

This property is Tunable.

**Default:** The default depends on your screen resolution. By default, the scope window appears in the center of your screen with a width of 800 pixels and height of 600 pixels.

## **ReduceUpdates**

Reduce updates to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time the `step` method

is called. The simulation speed is faster when this property is set to true. This property is Tunable.

You can also modify this property from the scope figure. Opening the **Playback** menu and clearing the **Reduce Updates to Improve Performance** check box is the same as setting this property to false.

**Default:** true

## **SampleTime**

Sample time of inputs

Specify as a finite numeric scalar the sampling time of the input ports, in seconds. The same sample time is used for all inputs.

**Default:** 1

## **TimeDisplayOffset**

Time display offset

Specify the offset, in seconds, to apply to the  $x$ -axis (*time*-axis). This property can be either a numeric scalar or a vector of length equal to the number of input channels. If you specify this property as a scalar, then that value is the time display offset for all channels. If you specify a vector, each vector element is the time offset for the corresponding channel. For vectors with length less than the number of input channels, the scope sets the time display offsets for the remaining channels to 0. If a vector has a length greater than the number of input channels, the scope ignores extra vector elements. This property is Tunable.

See `TimeSpan` for information on the  $x$ -axis limits and time span settings.

**Default:** 0

## **TimeSpan**

Specify the time span, in seconds, as a positive, numeric scalar value. The  $x$ -axis limits are calculated as follows.

Minimum  $x$ -axis limit =  $\min(\text{TimeDisplayOffset})$

Maximum  $x$ -axis limit =  $\max(\text{TimeDisplayOffset}) + \text{TimeSpan}$

where `TimeDisplayOffset` and `TimeSpan` are the values of their respective properties.

This property is Tunable.

**Default:** 10

## Methods

<code>addCursor</code>	Add cursor to display
<code>addDivider</code>	Add divider to display
<code>addWave</code>	Add wave corresponding to specified input
<code>clone</code>	Create scope object with same property values
<code>deleteCursor</code>	Delete specified cursor
<code>deleteDisplayChannel</code>	Delete specified display channel
<code>getCursorInfo</code>	Return settings for specified cursor
<code>getCursorTags</code>	Return all cursor tags
<code>getDisplayChannelInfo</code>	Return settings for specified display channel
<code>getDisplayChannelTags</code>	Return all display channel tags
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>hide</code>	Hide scope window

# dsp.LogicAnalyzer

---

isLocked	Locked status for input attributes and nontunable properties
modifyCursor	Modify properties of specified cursor
modifyDisplayChannel	Modify properties of specified display channel
moveDisplayChannel	Move position of specified display channel
release	Allow property value and input characteristics changes
reset	Reset internal states of scope object
show	Make scope window visible
step	Display signal in scope figure

## Examples

The following examples illustrate how to use the Logic Analyzer object to view a variety of input signals in the time domain.

### Example: Display Simple Ramp Signals

Construct a dsp.LogicAnalyzer object. Run the step method to display the signals.

```
hla1 = dsp.LogicAnalyzer('NumInputPorts', 3);  
for ii = 1:20  
    step(hla1, ii, 10*ii, 20*ii);  
end
```

Run the release method to let property values and input characteristics change.

```
release(hla1);
```

Run the MATLAB clear function to close the scope window.

```
clear('hla1');
```

## Example: Display Fixed-Point Signals

Construct a `dsp.LogicAnalyzer` object. Run the `addWave` method to add both floating-point and fixed-point wave channels. Run the `step` method to display the signals.

```
hla2 = dsp.LogicAnalyzer('NumInputPorts', 2); % 2 inputs
hla2.TimeSpan = 12;
addWave(hla2, 'InputChannel', 1, 'Name', 'Index');
addWave(hla2, 'InputChannel', 2, 'Name', 'Fi_hex', 'Radix', 'Hexadecimal');
addWave(hla2, 'InputChannel', 2, 'Name', 'Fi_bin', 'Radix', 'Binary');
for ii = 1:20
    fival = fi(mod(ii-1, 16), 0, 4, 0);
    step(hla2, ii, fival);
end
```

Run the `release` method to let property values and input characteristics change.

```
release(hla2);
```

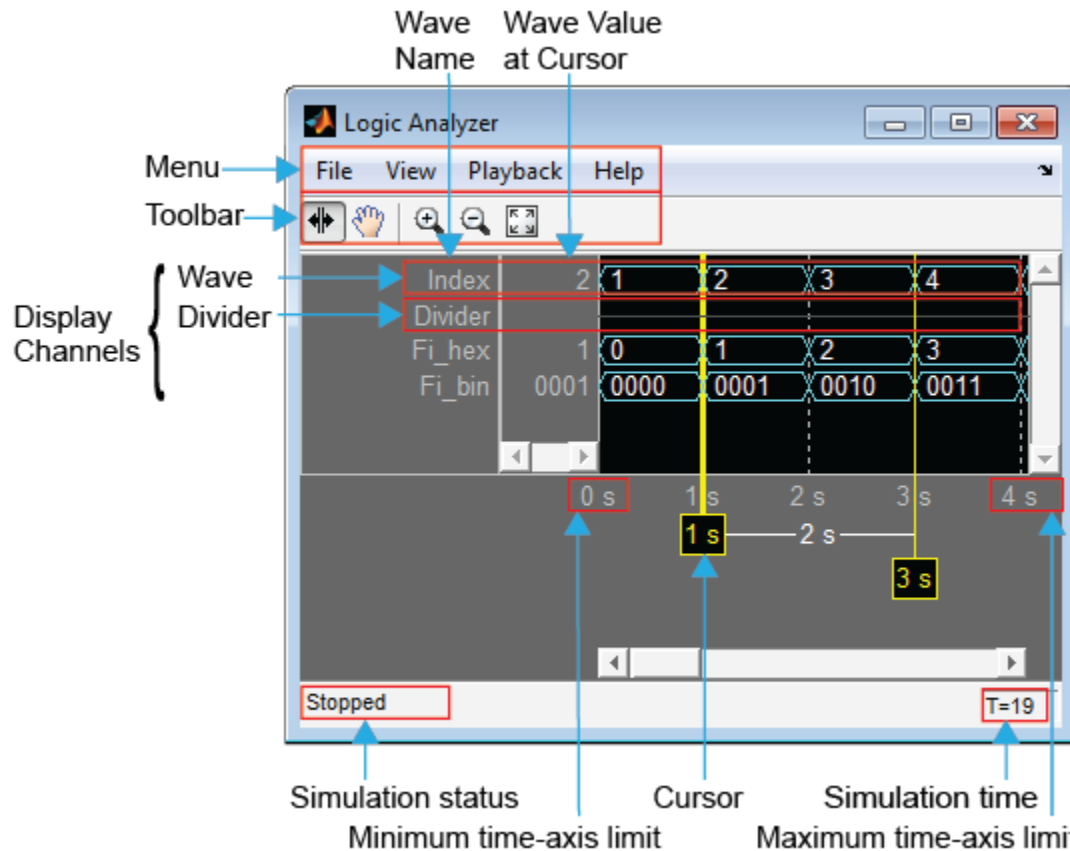

Run the MATLAB `clear` function to close the scope window.

```
clear('hla2');
```

## Signal Display

Logic Analyzer uses the `Time span` and `Time display offset` properties in order to determine the time range. To change the signal display settings, modify these properties. For example, if you set the `Time span` to 25 seconds, the scope displays 25 seconds' worth of simulation data at a time. If you also set the `Time display offset` to 5 seconds, the scope displays values on the *time*-axis from 5 to 30 seconds.

To communicate the simulation time that corresponds to the current display, the scope uses the **Simulation time** indicators on the scope window. The following figure highlights these and other important aspects of the Logic Analyzer window.

## Indicators

- **Display Channels** — The scope displays on the y-axis a number of display channels. Each display channel may contain either a wave or a divider and is identified by a unique tag. To get the tags for an existing display channel, call the `getDisplayChannelTags` method. To get information about an existing display channel, call the `getDisplayChannelInfo` method. To modify the properties of an existing display channel, call the `modifyDisplayChannel` method. To

move a display channel, call the `moveDisplayChannel` method. To delete a display channel, call the `deleteDisplayChannel` method.

- **Wave** — A *wave* is signal data in any format whose name and data are displayed on the *y*-axis. The display of a wave consists of its name, its value at the active cursor, and a visualization of its signal data over the time span. To add a new wave to the display, call the `addWave` method.
- **Divider** — The *divider* is a horizontal line that is intended to separate groups of signal data on the *y*-axis. To add a new divider to the display, call the `addDivider` method.
- **Cursor** — The scope displays on the *time*-axis a number of cursors. Cursors allow you to compare wave values at the same moment of time. To add a new cursor to the display, call the `addCursor` method. To modify the properties of an existing cursor, call the `modifyCursor` method. To delete a display channel, call the `deleteCursor` method.
- **Simulation status** — Provides the current status of the model simulation. The status can be either of the following conditions:
  - **Processing** — Occurs after you run the `step` method and before you run the `release` method.
  - **Stopped** — Occurs after you construct the scope object and before you first run the `step` method. This status also occurs after you run the `release` method.

The **Simulation status** is part of the **Status Bar** in the scope window. You can choose to hide or display the entire **Status Bar**. From the scope menu, select **View > Status Bar**.

- **Simulation time** — The amount of time that has passed since the scope object was first constructed or reset. Every time you call the `step` method, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the following

formula:  $t_{sim} = t_{sim} + \frac{\text{length}(x)}{\text{SampleRate}}$ . To set the sample rate, modify the `SampleTime` property.

The **Simulation time** is part of the **Status Bar** in the scope window. You can choose to hide or display the entire **Status Bar**. From the scope menu, select **View > Status Bar**.

- **Minimum *time-axis* limit** — The scope sets the minimum *time-axis* limit using the value of the **Time display offset** property.
- **Maximum *time-axis* limit** — The scope sets the maximum *time-axis* limit by summing the value of **Time display offset** parameter with the value of the **Time span** parameter.

## Toolbar

You can control whether the toolbar appears in the Logic Analyzer window. From the Logic Analyzer menu, select **View > Toolbar**. The Logic Analyzer toolbar contains the following buttons.

Button	Shortcut Keys	Description
	n/a	<b>Cursor</b> — When this tool is active, you can place a cursor on the scope window. The cursor shows you the time and allows you to compare the values of the input signals at that time.
	<b>Left arrow, Right arrow</b>	<b>Pan</b> — When this tool is active, you can pan on the scope window. To do so, click in the center of your area of interest, and drag your cursor to the left or right to move the position of the display. Alternatively, you can use the left and right arrows on your keyboard.
	<b>+, i</b>	<b>Zoom In</b> — Click this button to zoom in on the scope window. Use the <b>Pan</b> button to center the display on your area of interest before you zoom in.
	<b>-, o, _</b>	<b>Zoom Out</b> — Click this button to zoom out on the scope window.
	<b>f</b>	<b>Autoscale</b> — Click this button to scale the axes in the active scope window.

# dsp.LogicAnalyzer.addCursor

---

## Purpose

Add cursor to display

## Syntax

```
cursorTag = addCursor(H)
cursorTag = addCursor(H, 'Name', Value)
```

## Description

`cursorTag = addCursor(H)` adds in a cursor to the display. A tag value is returned, which can be used to modify and delete the cursor.

`cursorTag = addCursor(H, 'Name', Value)` adds in a cursor to the display with each specified property *Name* set to the specified value. You can specify *Name-Value* arguments in any order.

## Input Arguments

**H - The Logic Analyzer object to which you want to add a cursor**  
dsp.LogicAnalyzer object

**Example:** 'addCursor(H)' adds a cursor with the default characteristics.

**Example:** 'H.addCursor()' adds a cursor with the default characteristics.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as *Name1*, *Value1*, ..., *NameN*, *ValueN*.

**Example:** 'Location', 2, 'Color', 'Blue' specifies that a cursor should be moved to the 2-second mark and colored blue.

## 'Color' - Color of the cursor

string enumeration

Specify as a string the color of the cursor from one of the following options:

- 'Black'
- 'Blue'

- 'Cyan'
- 'Green'
- 'Magenta'
- 'Red'
- 'White'
- 'Yellow'

**Example:** 'Color', 'Blue'

## **Data Types**

char

**Default:** 'Yellow'

## **'Location' - Location of the cursor**

numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

**Example:** 'Location', '1.0'

## **Data Types**

double

**Default:** 0

## **'Locked' - Locked status of the cursor**

logical scalar

Specify as a logical scalar whether the cursor location should be locked.

- If you choose true, then the cursor's location cannot be changed. Logic Analyzer denotes this by assigning a default color of red.

## **dsp.LogicAnalyzer.addCursor**

---

- If you choose `false`, then the cursor's location can be changed. Logic Analyzer denotes this by assigning a default color of yellow.

**Example:** `'Locked', true`

### **Data Types**

`logical`

**Default:** `false`

<b>Purpose</b>	Add divider to display
<b>Syntax</b>	<pre>dividerTag = addDivider(H) dividerTag = addDivider(H, 'Name', Value)</pre>
<b>Description</b>	<p><code>dividerTag = addDivider(H)</code> adds in a divider to the display. A tag value is returned, which can be used to modify and delete the divider.</p> <p><code>dividerTag = addDivider(H, 'Name', Value)</code> adds in a divider to the display with each specified property <i>Name</i> set to the specified value. You can specify <i>Name-Value</i> arguments in any order.</p>
<b>Input Arguments</b>	<p><b>H - The Logic Analyzer object to which you want to add a divider</b> dsp.LogicAnalyzer object</p> <p><b>Example:</b> 'addDivider(H)' adds a divider with the default characteristics.</p> <p><b>Example:</b> 'H.addDivider()' adds a divider with the default characteristics.</p> <p><b>Divider Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <i>Name, Value</i> arguments. <i>Name</i> is the argument name and <i>Value</i> is the corresponding value. <i>Name</i> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <i>Name1, Value1, . . . , NameN, ValueN</i>.</p> <p><b>Example:</b> 'DisplayChannel', 2, 'Name', 'MyDivider' specifies that a divider should be added to display channel 2 and named "MyDivider".</p> <p><b>'DisplayChannel' - Channel on the display that shows this divider</b> scalar numeric value in the range (1, NumInputPorts)</p> <p>Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.</p>

# dsp.LogicAnalyzer.addDivider

---

**Example:** 'DisplayChannel',2

## **Data Types**

double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**Default:** NumInputPorts

## **'Height' - Height of the divider**

scalar integer

Specify as a scalar integer the height of the divider in the display in units of 16 pixels. When you choose 0, the value of the DisplayChannelHeight property in the Logic Analyzer is used.

**Example:** 'Height',2

## **Data Types**

double

**Default:** 0

## **'Name' - The name or label for the divider**

string

Specify as a string the name that you would like to set for the new divider.

**Example:** 'Name', 'MyDivider'

## **Data Types**

char

**Default:** ''

**Purpose** Add wave corresponding to specified input

**Syntax**  
`waveTag = addWave(H)`  
`waveTag = addWave(H, 'Name', Value)`

**Description** `waveTag = addWave(H)` adds in a wave corresponding to the specified input channel. A tag value is returned back, which can be used to modify and delete the wave.

`waveTag = addWave(H, 'Name', Value)` adds in a wave with each specified property *Name* set to the specified value. You can specify *Name-Value* arguments in any order.

**Input Arguments** **H - The Logic Analyzer object to which you want to add a wave**  
dsp.LogicAnalyzer object

**Example:** `'addWave(H)'` adds a wave with the default characteristics.

**Example:** `'H.addWave()'` adds a wave with the default characteristics.

### Wave Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name, Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as *Name1, Value1, . . . , NameN, ValueN*.

**Example:** `'InputChannel', 2, 'Color', 'Blue'` specifies that a wave should be added to input channel 1 and colored blue.

### 'Color' - Color of the wave

string enumeration

Specify as a string the color of the display from one of the following options:

- 'Black'
- 'Blue'

# dsp.LogicAnalyzer.addWave

---

- 'Cyan'
- 'Default'
- 'Green'
- 'Magenta'
- 'Red'
- 'White'
- 'Yellow'

When you choose 'Default', the value of the `DisplayChannelColor` property in the Logic Analyzer is used.

**Example:** 'Color', 'Blue'

## Data Types

char

**Default:** 'Default'

## 'DisplayChannel' - Channel on the display that shows this wave

scalar numeric value in the range (1,NumInputPorts)

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

**Example:** 'DisplayChannel', 2

## Data Types

double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**Default:** NumInputPorts

## 'FontSize' - Font size for values in the wave

scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the `DisplayChannelFontSize` property in the Logic Analyzer is used.

**Example:** `'FontSize',8`

## **Data Types**

double

**Default:** 0

## **'Format' - Display format for the wave**

string enumeration

Specify as a string the wave format from one of the following options:

- `'Analog'`
- `'Default'`
- `'Digital'`

When you choose `'Default'`, the value of the `DisplayChannelFormat` property in the Logic Analyzer is used.

**Example:** `'Format','Digital'`

## **Data Types**

char

**Default:** `'Default'`

## **'Height' - Height of the wave**

scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

# dsp.LogicAnalyzer.addWave

---

**Example:** 'Height',2

## Data Types

double

**Default:** 0

## 'InputChannel' - Input channel that corresponds to this wave

scalar integer in the range (1,NumInputPorts)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

**Example:** 'InputChannel',2

## Data Types

double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**Default:** 1

## 'Name' - The name or label for the wave

string

Specify as a string the name that you would like to set for the new wave.

**Example:** 'Name', 'MyWave'

## Data Types

char

**Default:** ''

## 'Radix' - Radix for the wave

string enumeration

Specify as a string the radix of the display from one of the following options:

- 'Binary'

- 'Default'
- 'Hexadecimal'
- 'Octal'
- 'Signed decimal'
- 'Unsigned decimal'

When the input signals are of class double, single, or logical, you should not set this property. When you choose 'Default', the value of the DisplayChannelRadix property in the Logic Analyzer is used.

**Example:** 'Radix','Hexadecimal'

## **Data Types**

char

**Default:** 'Default'

# dsp.LogicAnalyzer.clone

---

**Purpose** Create scope object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a scope object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

<b>Purpose</b>	Delete specified cursor
<b>Syntax</b>	<code>deleteCursor(H,tag)</code> <code>deleteCursor(H,'CursorTag',tag)</code>
<b>Description</b>	<code>deleteCursor(H,tag)</code> deletes the cursor specified by the input tag. <code>deleteCursor(H,'CursorTag',tag)</code> deletes the cursor specified by the input tag.
<b>Input Arguments</b>	<p><b>H - The Logic Analyzer object from which you want to delete a cursor</b> dsp.LogicAnalyzer object</p> <p><b>tag - The tag identifying which cursor to delete</b> string, randomly assigned</p> <p><b>Example:</b> <code>'deleteCursor(H,tag)'</code> deletes a cursor from Logic Analyzer.</p> <p><b>Example:</b> <code>'H.deleteCursor(tag)'</code> deletes a cursor from Logic Analyzer.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( <code>' '</code> ). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>Example:</b> <code>'CursorTag','C6'</code> specifies to delete the divider with tag <code>'C5'</code>.</p> <p><b>'CursorTag' - The tag identifying which cursor to delete</b> string, randomly assigned</p> <p><b>Example:</b> <code>'CursorTag','C6'</code></p> <p><b>Data Types</b> char</p>

# dsp.LogicAnalyzer.deleteDisplayChannel

---

**Purpose** Delete specified display channel

**Syntax** `deleteDisplayChannel(H,tag)`  
`deleteDisplayChannel(H,'DisplayChannelTag',tag)`

**Description** `deleteDisplayChannel(H,tag)` deletes the display channel, either a wave or a divider, specified by the input tag.

`deleteDisplayChannel(H,'DisplayChannelTag',tag)` deletes the display channel, either a wave or a divider, specified by the input tag.

**Input Arguments** **H - The Logic Analyzer object from which you want to delete a display channel**

dsp.LogicAnalyzer object

**tag - The tag identifying which display channel to delete**

string

**Example:** `'deleteDisplayChannel(H,tag)'` deletes a display channel from Logic Analyzer.

**Example:** `'H.deleteDisplayChannel(tag)'` deletes a display channel from Logic Analyzer.

**Data Types**

char

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'DisplayChannelTag','C5'` specifies to delete the divider with tag 'C5'.

**'DisplayChannelTag' - The tag identifying which display channel to delete**

# dsp.LogicAnalyzer.deleteDisplayChannel

---

string

**Example:** 'DisplayChannelTag', 'C5'

## **Data Types**

char

# dsp.LogicAnalyzer.getCursorInfo

---

**Purpose** Return settings for specified cursor

**Syntax** `getCursorInfo(H, 'CursorTag', tag)`

**Description** `getCursorInfo(H, 'CursorTag', tag)` returns the settings for the cursor or cursors, specified by the input tag.

**Input Arguments** **H - The Logic Analyzer object from which you want to return cursor settings**  
`dsp.LogicAnalyzer` object

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'CursorTag', 'C5'` specifies to return settings about the cursor with tag `'C5'`.

## **'CursorTag' - The tag or tags identifying the cursor or cursors about which to get information**

string or cell array of strings

**Example:** `'CursorTag', 'C5'`

**Example:** `'CursorTag', {'C4', 'C5'}`

## **Data Types**

char | cell

<b>Purpose</b>	Return all cursor tags
<b>Syntax</b>	T = getCursorTags(H)
<b>Description</b>	T = getCursorTags(H) returns all the cursor tags for the Logic Analyzer. You can use these tags to get information about a cursor using the dsp.LogicAnalyzer.getCursorInfo method, to modify a cursor using the dsp.LogicAnalyzer.modifyCursor method, or to delete a cursor using the dsp.LogicAnalyzer.deleteCursor method.
<b>Input Arguments</b>	<b>H - The Logic Analyzer object from which you want to return all cursor tags</b> dsp.LogicAnalyzer object
<b>Output Arguments</b>	<b>T - The cursor tags</b> cell array of strings <b>Example:</b> {'C1'} <b>Example:</b> {'C1', 'C2', 'C3'} <b>Data Types</b> cell

# dsp.LogicAnalyzer.getDisplayChannelInfo

---

<b>Purpose</b>	Return settings for specified display channel
<b>Syntax</b>	<code>getDisplayChannelInfo(H, 'DisplayChannelTag', tag)</code>
<b>Description</b>	<code>getDisplayChannelInfo(H, 'DisplayChannelTag', tag)</code> returns the settings for the display channel or channels, specified by the input tag.
<b>Input Arguments</b>	<p><b>H - The Logic Analyzer object from which you want to return display channel settings</b> <code>dsp.LogicAnalyzer</code> object</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name</code>, <code>Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1, Value1, ..., NameN, ValueN</code>.</p> <p><b>Example:</b> <code>'DisplayChannelTag', 'W5'</code> specifies to return display channel settings about the wave with tag <code>'W5'</code>.</p> <p><b>'DisplayChannelTag' - The tag or tags identifying the display channel or channels about which to get information</b> string or cell array of strings</p> <p><b>Example:</b> <code>'DisplayChannelTag', 'W5'</code></p> <p><b>Example:</b> <code>'DisplayChannelTag', {'W4', 'W5'}</code></p> <p><b>Data Types</b> char   cell</p>

# dsp.LogicAnalyzer.getDisplayChannelTags

---

<b>Purpose</b>	Return all display channel tags
<b>Syntax</b>	T = getDisplayChannelTags(H)
<b>Description</b>	T = getDisplayChannelTags(H) returns all the display channel tags for the Logic Analyzer. These tags are particularly useful for getting information about a wave or divider using the dsp.LogicAnalyzer.getDisplayChannelInfo method, for modifying a wave or divider using the dsp.LogicAnalyzer.modifyDisplayChannel method, or for deleting a wave or divider using the dsp.LogicAnalyzer.deleteDisplayChannel method.
<b>Input Arguments</b>	<b>H - The Logic Analyzer object from which you want to return all display channel tags</b> dsp.LogicAnalyzer object
<b>Output Arguments</b>	<b>T - The display channel tags</b> cell array of strings <b>Example:</b> {'W1'} <b>Example:</b> {'W1', 'W2', 'W3'} <b>Data Types</b> cell

# dsp.LogicAnalyzer.getNumInputs

---

**Purpose**                    Number of expected inputs to step method

**Syntax**                    `N = getNumInputs(H)`

**Description**            `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method. *N* equals the value of the `NumInputPorts` property.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method. The scope is a sink object, so `N` equals 0.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.LogicAnalyzer.hide

---

**Purpose** Hide scope window

**Syntax** `hide(H)`

**Description** `hide(H)` hides the scope window associated with System object, H.

**See Also** `dsp.LogicAnalyzer.show`

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the scope object H.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.LogicAnalyzer.modifyCursor

---

**Purpose** Modify properties of specified cursor

**Syntax**

```
modifyCursor(H,tag)
modifyCursor(H,'CursorTag',tag)
modifyCursor(H,tag,'Name',Value)
modifyCursor(H,'CursorTag',tag,'Name',Value)
```

**Description**

modifyCursor(H,tag) modifies the properties of the cursor specified by the input tag.

modifyCursor(H,'CursorTag',tag) modifies the properties of the cursor specified by the input tag.

modifyCursor(H,tag,'Name',Value) modifies the properties of the cursor specified by the input tag with each specified property *Name* set to the specified value. You can specify *Name–Value* arguments in any order.

modifyCursor(H,'CursorTag',tag,'Name',Value) modifies the properties of the cursor specified by the input tag with each specified property *Name* set to the specified value. You can specify *Name–Value* arguments in any order.

**Input Arguments**

**H - The Logic Analyzer object for which you want to modify a cursor**  
dsp.LogicAnalyzer object

**tag - The tag identifying which cursor to modify**  
string, randomly assigned

**Example:** 'modifyCursor(H,tag)' modifies a cursor in Logic Analyzer.

**Example:** 'H.modifyCursor(tag)' modifies a cursor in Logic Analyzer.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding

value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'Location',2,'Color','Blue' specifies that a cursor should be moved to the 2-second mark and colored blue.

## **'Color' - Color of the cursor**

string enumeration

Specify as a string the color of the cursor from one of the following options:

- 'Black'
- 'Blue'
- 'Cyan'
- 'Green'
- 'Magenta'
- 'Red'
- 'White'
- 'Yellow'

**Example:** 'Color','Blue'

## **Data Types**

char

**Default:** 'Yellow'

## **'Location' - Location of the cursor**

numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

**Example:** 'Location','1.0'

# **dsp.LogicAnalyzer.modifyCursor**

---

## **Data Types**

double

**Default:** 0

## **'Locked' - Locked status of the cursor**

logical scalar

Specify as a logical scalar whether the cursor location should be locked.

- If you choose `true`, then the cursor's location cannot be changed. Logic Analyzer denotes this by assigning a default color of red.
- If you choose `false`, then the cursor's location can be changed. Logic Analyzer denotes this by assigning a default color of yellow.

**Example:** 'Locked', true

## **Data Types**

logical

**Default:** false

# dsp.LogicAnalyzer.modifyDisplayChannel

---

<b>Purpose</b>	Modify properties of specified display channel
<b>Syntax</b>	<pre>modifyDisplayChannel(H,tag,'Name',Value) modifyDisplayChannel(H,'CursorTag',tag,'Name',Value)</pre>
<b>Description</b>	<p><code>modifyDisplayChannel(H,tag,'Name',Value)</code> modifies the properties of the display channel specified by the input <code>tag</code> with each specified property <code>Name</code> set to the specified value. You can specify <code>Name–Value</code> arguments in any order.</p> <p><code>modifyDisplayChannel(H,'CursorTag',tag,'Name',Value)</code> modifies the properties of the display channel specified by the input <code>tag</code> with each specified property <code>Name</code> set to the specified value. You can specify <code>Name–Value</code> arguments in any order.</p>
<b>Input Arguments</b>	<p><b>H - The Logic Analyzer object for which you want to modify a display channel</b> dsp.LogicAnalyzer object</p> <p><b>tag - The tag identifying which display channel to modify</b> string, randomly assigned</p> <p><b>Example:</b> 'modifyDisplayChannel(H,tag)' modifies a display channel in Logic Analyzer.</p> <p><b>Example:</b> 'H.modifyDisplayChannel(tag)' modifies a display channel in Logic Analyzer.</p> <p>The first section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a wave. The second section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a divider.</p> <p><b>Wave Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can</p>

# dsp.LogicAnalyzer.modifyDisplayChannel

---

specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'InputChannel',2,'Color','Blue' specifies that a wave should be added to input channel 1 and colored blue.

## 'Color' - Color of the wave

string enumeration

Specify as a string the color of the display from one of the following options:

- 'Black'
- 'Blue'
- 'Cyan'
- 'Default'
- 'Green'
- 'Magenta'
- 'Red'
- 'White'
- 'Yellow'

When you choose 'Default', the value of the DisplayChannelColor property in the Logic Analyzer is used.

**Example:** 'Color','Blue'

## Data Types

char

**Default:** 'Default'

## 'DisplayChannel' - Channel on the display that shows this wave

scalar numeric value in the range (1,NumInputPorts)

# dsp.LogicAnalyzer.modifyDisplayChannel

---

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

**Example:** 'DisplayChannel',2

## Data Types

double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**Default:** NumInputPorts

## 'FontSize' - Font size for values in the wave

scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the DisplayChannelFontSize property in the Logic Analyzer is used.

**Example:** 'FontSize',8

## Data Types

double

**Default:** 0

## 'Format' - Display format for the wave

string enumeration

Specify as a string the wave format from one of the following options:

- 'Analog'
- 'Default'
- 'Digital'

When you choose 'Default', the value of the DisplayChannelFormat property in the Logic Analyzer is used.

# dsp.LogicAnalyzer.modifyDisplayChannel

---

**Example:** 'Format','Digital'

## **Data Types**

char

**Default:** 'Default'

## **'Height' - Height of the wave**

scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the DisplayChannelHeight property in the Logic Analyzer is used.

**Example:** 'Height',2

## **Data Types**

double

**Default:** 0

## **'InputChannel' - Input channel that corresponds to this wave**

scalar integer in the range (1,NumInputPorts)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

**Example:** 'InputChannel',2

## **Data Types**

double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**Default:** 1

## **'Name' - The name or label for the wave**

string

Specify as a string the name that you would like to set for the new wave.

**Example:** 'Name', 'MyWave'

## Data Types

char

**Default:** ''

## 'Radix' - Radix for the wave

string enumeration

Specify as a string the radix of the display from one of the following options:

- 'Binary'
- 'Default'
- 'Hexadecimal'
- 'Octal'
- 'Signed decimal'
- 'Unsigned decimal'

When the input signals are of class double, single, or logical, you should not set this property. When you choose 'Default', the value of the DisplayChannelRadix property in the Logic Analyzer is used.

**Example:** 'Radix', 'Hexadecimal'

## Data Types

char

**Default:** 'Default'

## Divider Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can

# dsp.LogicAnalyzer.modifyDisplayChannel

---

specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'DisplayChannel',2,'Name','MyDivider' specifies that a divider should be added to display channel 2 and named “MyDivider”.

## **‘DisplayChannel’ - Channel on the display that shows this divider**

scalar numeric value in the range (1,NumInputPorts)

Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.

**Example:** 'DisplayChannel',2

### **Data Types**

double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**Default:** NumInputPorts

## **‘Height’ - Height of the divider**

scalar integer

Specify as a scalar integer the height of the divider in the display in units of 16 pixels. When you choose 0, the value of the DisplayChannelHeight property in the Logic Analyzer is used.

**Example:** 'Height',2

### **Data Types**

double

**Default:** 0

## **‘Name’ - The name or label for the divider**

string

Specify as a string the name that you would like to set for the new divider.

# dsp.LogicAnalyzer.modifyDisplayChannel

---

**Example:** 'Name', 'MyDivider'

## **Data Types**

char

**Default:** ''

# dsp.LogicAnalyzer.moveDisplayChannel

---

<b>Purpose</b>	Move position of specified display channel
<b>Syntax</b>	<code>moveDisplayChannel(H, 'DisplayChannelTag', tag, 'DisplayChannel', displaychannelvalue)</code>
<b>Description</b>	<code>moveDisplayChannel(H, 'DisplayChannelTag', tag, 'DisplayChannel', displaychannelvalue)</code> moves the display channel, either a wave or a divider, specified by the input <code>tag</code> , to the new location specified by the input <code>displaychannelvalue</code> .
<b>Input Arguments</b>	<b>H - The Logic Analyzer object in which you want to move a display channel</b> <code>dsp.LogicAnalyzer</code> object  <b>Name-Value Pair Arguments</b> Specify optional comma-separated pairs of <code>Name, Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1, Value1, ..., NameN, ValueN</code> .  <b>Example:</b> <code>'DisplayChannelTag', 'W1'</code> specifies to delete the divider with tag <code>'C5'</code> .  <b>'DisplayChannelTag' - The tag identifying which display channel to move</b> string  <b>Example:</b> <code>'DisplayChannelTag', 'W1'</code>  <b>Data Types</b> char  <b>'DisplayChannel' - The location identifying where the display channel should be moved</b> string  <b>Example:</b> <code>'DisplayChannel', 2</code>

## **Data Types**

double

# dsp.LogicAnalyzer.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

You should call the `release` method after calling the `step` method when there is no new data for the simulation. When you call the `release` method, the axes will automatically scale in the scope figure window. After calling the `release` method, any non-tunable properties can be set once again.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Algorithms** In operation, the `release` method is similar to the `mdlTerminate` function.

**See Also** `dsp.LogicAnalyzer.reset`

**Purpose** Reset internal states of scope object

**Syntax** `reset(H)`

**Description** `reset(H)` sets the internal states of the scope object `H` to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the scope figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

**Algorithms** In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

**See Also** `dsp.LogicAnalyzer` | `dsp.LogicAnalyzer.release`

# dsp.LogicAnalyzer.show

---

**Purpose**            Make scope window visible

**Syntax**            `show(H)`

**Description**        `show(H)` makes the scope window associated with System object, H, visible.

**See Also**            `dsp.LogicAnalyzer.hide`

**Purpose** Display signal in scope figure

**Syntax** `step(H,X)`  
`step(H,X1,X2,...,XN)`

**Description** `step(H,X)` displays the signal, X, in the scope figure.  
`step(H,X1,X2,...,XN)` displays the signals X1, X2,...,XN in the scope figure when you set the NumInputPorts property to N. In this case, X1, X2,...,XN can have different data types and dimensions.

# dsp.LowerTriangularSolver

---

**Purpose** Solve lower-triangular matrix equation

**Description** The `LowerTriangularSolver` object solves  $LX = B$  for  $X$  when  $L$  is a square, lower-triangular matrix with the same number of rows as  $B$ .

To solve  $LX = B$  for  $X$ :

- 1 Define and set up your linear system solver. See “Construction” on page 3-794.
- 2 Call `step` to solve the equation according to the properties of `dsp.LowerTriangularSolver`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.LowerTriangularSolver` returns a linear system solver, `H`, used to solve the linear system  $LX = B$ , where  $L$  is a lower (or unit-lower) triangular matrix.

`H = dsp.LowerTriangularSolver('PropertyName',PropertyValue,...)` returns a linear system solver, `H`, with each specified property set to the specified value.

**Properties** **OverwriteDiagonal**

Replace diagonal elements of input with ones

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input,  $L$ , with ones. Set this property to either `true` or `false`. The default is `false`.

**RealDiagonalElements**

Indicate that diagonal of complex input is real

When you set this property to `true`, the linear system solver optimizes computation speed if the diagonal elements of complex input,  $L$ , are real. This property applies only when you set the `OverwriteDiagonal` property to `false`. Set this property to either `true` or `false`. The default is `false`.

## Fixed-Point Properties

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

### ProductDataType

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

### CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

### AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`. The default is `Full precision`.

### CustomAccumulatorDataType

Accumulator word and fraction lengths

# dsp.LowerTriangularSolver

---

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## OutputDataType

Data type of output

Specify the output data type as `Same as first input` or `Custom`. The default is `Same as first input`.

## CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

## Methods

<code>clone</code>	Create lower triangular solver object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Solve matrix equation for specified inputs

## Examples

Solve a lower-triangular matrix equation:

```
hlowtriang = dsp.LowerTriangularSolver;
```

```
u = tril(rand(4, 4));  
b = rand(4, 1);  
% Check that result is the solution to the linear  
% equations.  
x1 = inv(u)*b  
x = step(hlowtriang, u, b)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Forward Substitution block reference page. The object properties correspond to the block parameters.

## See Also

`dsp.UpperTriangularSolver`

# **dsp.LowerTriangularSolver.clone**

---

**Purpose** Create lower triangular solver object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `LowerTriangularSolver` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

# **dsp.LowerTriangularSolver.getNumInputs**

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.LowerTriangularSolver.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `LowerTriangularSolver` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.LowerTriangularSolver.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Solve matrix equation for specified inputs

**Syntax**  $X = \text{step}(H,L,B)$

**Description**  $X = \text{step}(H,L,B)$  computes the solution,  $X$ , of the matrix equation  $LX = B$ , where  $L$  is a square, lower-triangular matrix with the same number of rows as the matrix  $B$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.LPCToAutocorrelation

---

<b>Purpose</b>	Convert linear prediction coefficients to autocorrelation coefficients
<b>Description</b>	<p>The LPCToAutocorrelation System object converts linear prediction coefficients to autocorrelation coefficients.</p> <p>To convert LPC to autocorrelation coefficients:</p> <ol style="list-style-type: none"><li>1 Define and set up your LPC to autocorrelation object. See “Construction” on page 3-804.</li><li>2 Call <code>step</code> to convert LPC according to the properties of <code>dsp.LPCToAutocorrelation</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.LPCToAutocorrelation</code> returns an LPC to autocorrelation System object, <code>H</code>, that converts linear prediction coefficients (LPC) to autocorrelation coefficients.</p> <p><code>H = dsp.LPCToAutocorrelation('PropertyName',PropertyValue,...)</code> returns an LPC to autocorrelation conversion object, <code>H</code>, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>PredictionErrorInputPort</b></p> <p>Enable prediction error power input</p> <p>Choose how to select the prediction error power. When you set this property to <code>true</code>, you must specify the prediction error power as a second input to the <code>step</code> method. When you set this property to <code>false</code>, the object assumes that the prediction error power is 1. The default is <code>false</code>.</p> <p><b>NonUnityFirstCoefficientAction</b></p> <p>Action to take when first LPC coefficient is not 1</p> <p>Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select <code>Replace with 1</code> or <code>Normalize</code>. The default is <code>Replace with 1</code>.</p>

## Methods

clone	Create LPC to autocorrelation object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Autocorrelation coefficients from LPC coefficients

## Examples

Convert the linear prediction coefficients to autocorrelation coefficients:

```
a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711].';  
hlpc2ac = dsp.LPCToAutocorrelation;  
ac = step(hlpc2ac, a);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC/RC to Autocorrelation block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to LPC to autocorrelation.

## See Also

dsp.LPCToLSF | dsp.LPCToRC | dsp.LPCToCepstral |  
dsp.RCToAutocorrelation

# dsp.LPCToAutocorrelation.clone

---

**Purpose** Create LPC to autocorrelation object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an `LPCToAutocorrelation System` object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.LPCToAutocorrelation.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.LPCToAutocorrelation.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the LPCToAutocorrelation System object H.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.LPCToAutocorrelation.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose**

Autocorrelation coefficients from LPC coefficients

**Syntax**

AC = step(H,A)  
AC = step(H,A,P)

**Description**

AC = step(H,A) converts the columns of the linear prediction coefficients, A, to autocorrelation coefficients, AC. The object assumes a prediction error power of 1.

AC = step(H,A,P) when you set the PredictionErrorInputPort property to true, converts the columns of the linear prediction coefficients, A, to autocorrelation coefficients, AC. This conversion uses P as the prediction error power. P must be a row vector with same number of columns as A.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

# dsp.LPCToCepstral

---

<b>Purpose</b>	Convert linear prediction coefficients to cepstral coefficients
<b>Description</b>	<p>The LPCToCepstral object converts linear prediction coefficients to cepstral coefficients.</p> <p>To convert LPC to cepstral coefficients:</p> <ol style="list-style-type: none"><li>1 Define and set up your LPC to cepstral converter. See “Construction” on page 3-812.</li><li>2 Call <code>step</code> to convert LPC according to the properties of <code>dsp.LPCToCepstral</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.LPCToCepstral</code> returns an LPC to cepstral converter object, <code>H</code>, that converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs).</p> <p><code>H = dsp.LPCToCepstral('PropertyName',PropertyValue,...)</code> returns an LPC to cepstral converter object, <code>H</code>, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>PredictionErrorInputPort</b></p> <p>Enable prediction error power input</p> <p>Choose how to set the prediction error power. When you set this property to <code>true</code>, you must specify the prediction error as a second input to the <code>step</code> method. When you set this property to <code>false</code>, the object assumes the prediction error power is 1. The default is <code>false</code>.</p> <p><b>CepstrumLengthSource</b></p> <p>Source of cepstrum length</p> <p>Select how to specify the length of cepstral coefficients: <code>Auto</code> or <code>Property</code>. The default is <code>Auto</code>. When this property is set to <code>Auto</code>, the length of each channel of the cepstral coefficients output is the</p>

same as the length of each channel of the input LPC coefficients. The default is Property.

### **CepstrumLength**

Number of output cepstral coefficients

Set the length of the output cepstral coefficients vector as a scalar numeric integer. This property applies when you set the CepstrumLengthSource property to Property. The default is 10.

### **NonUnityFirstCoefficientAction**

LPC coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select **Replace with 1** or **Normalize**. The default is **Replace with 1**.

## **Methods**

clone	Create LPC to cepstral object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Cepstral coefficients from columns of input LPC coefficients

## **Examples**

Convert the linear prediction coefficients (LPC) to cepstral coefficients:

```
hlevinson = dsp.LevinsonSolver;
hlevinson.AOutputPort = true; % Output polynomial coefficients
hac = dsp.Autocorrelator;
```

# dsp.LPCToCepstral

---

```
hac.MaximumLagSource = 'Property';
hac.MaximumLag = 9; % Compute autocorrelation lags between [0:9]
hlpc2cc = dsp.LPCToCepstral;
x = [1:100]';
a = step(hac, x);
A = step(hlevinson, a); % Compute LPC coefficients
CC = step(hlpc2cc, A); % Convert LPC to CC.
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from Cepstral Coefficients block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to LPCs to cepstral coefficients.

## See Also

[dsp.CepstralToLPC](#) | [dsp.LPCToLSF](#) | [dsp.LPCToRC](#)

**Purpose**

Create LPC to cepstral object with same property values

**Syntax**

`C = clone(H)`

**Description**

`C = clone(H)` creates an LPCToCepstral System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

## dsp.LPCToCepstral.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose** Number of outputs of step method

**Syntax** N = getNumOutputs(H)

**Description** N = getNumOutputs(H) returns the number of outputs, N, from the step method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.LPCToCepstral.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the LPCToCepstral System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.LPCToCepstral.step

---

**Purpose** Cepstral coefficients from columns of input LPC coefficients

**Syntax**  
CC = step(H,A)  
CC = step(H,A,P)

**Description** CC = step(H,A) computes the cepstral coefficients, CC, from the columns of input linear prediction coefficients, A. The object assumes the prediction error power is 1.

CC = step(H,A,P) when you set the PredictionErrorInputPort property to true, computes the cepstral coefficients, CC, from the columns of input linear prediction coefficients, A. This conversion uses P as the prediction error power.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

<b>Purpose</b>	Convert linear prediction coefficients to line spectral frequencies
<b>Description</b>	<p>The LPCToLSF object converts linear prediction coefficients to line spectral frequencies.</p> <p>To convert LPC to LSF:</p> <ol style="list-style-type: none"><li>1 Define and set up your LPC to LSF converter. See “Construction” on page 3-821.</li><li>2 Call <code>step</code> to convert LPC according to the properties of <code>dsp.LPCToLSF</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.LPCToLSF</code> returns a System object, <code>H</code>, that converts linear prediction coefficients (LPCs) to line spectral frequencies (LSFs).</p> <p><code>H = dsp.LPCToLSF('PropertyName',PropertyValue,...)</code> returns an LPC to LSF System object, <code>H</code>, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>NumCoarseGridPoints</b></p> <p>Number of coarse subintervals used for finding roots (LSP values)</p> <p>Specify the number of coarse subintervals, <math>n</math>, used for finding line spectral pairs (LSP) values as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range <math>(-1, 1)</math>. The System object finds these roots using the Chebyshev polynomial root finding method. To compute LSF outputs, the object computes the arc cosine of the LSPs, outputting values ranging from 0 to <math>\pi</math> radians. The object divides the interval <math>(-1, 1)</math> into <math>n</math> subintervals and looks for roots in each subinterval. If you set <math>n</math> too small in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is 64. This property is tunable.</p> <p><b>NumBisects</b></p> <p>Value of bisection refinement used for finding roots</p>

Specify the root bisection refinement value,  $k$ , used in the Chebyshev polynomial root finding method, where each line spectral pair (LSP) output is within

$\frac{1}{(n \cdot 2^k)}$  of the actual LSP value. Here  $n$  is the value of the NumCoarseGridPoints property, and the object searches a maximum of  $k \cdot (n - 1)$  points for finding the roots. You must set the NumBisects property value  $k$ , to a positive scalar integer. The default is 4. This property is tunable.

### **ExceptionOutputPort**

Produces output with validity status of LSF output

Set this property to `true` to return a second output that indicates whether the computed LSF values are valid. The output is a vector with a length equal to the number of channels. A logical value of 1 indicates valid output. A logical value of 0 indicates invalid output. The LSF outputs are invalid when the object fails to find all the LSF values or when the input LPCs are unstable. The default is `false`.

### **OverwriteInvalidOutput**

Enable overwriting invalid output with previous output

Specify the action that the System object should take for invalid LSF outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object does not take any action on invalid outputs and ignores the outputs.

### **FirstOutputValuesSource**

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies when you

set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When you set this property to `Auto`, the object uses a default value for the first output. The default value corresponds to the LSF representation of an allpass filter.

### **FirstOutputValues**

Value of the first output

Specify a numeric vector of LSF values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, you can set this property to a matrix with the same number of channels as the input, or one vector that is applied to every channel. The default is an empty vector. This property applies when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

### **NonUnityFirstCoefficientAction**

Action to take when first LPC coefficient is not 1

Specify the action the object takes when the first coefficient of each channel of the LPC input is not 1 as `Replace with 1` or `Normalize`. The default is `Replace with 1`.

## **Methods**

<code>clone</code>	Create LPC To LSF object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes

reset	Reset values for overwriting invalid outputs to their initial values
step	Convert LPC coefficients to line spectral frequencies

## Examples

Convert to linear prediction coefficients to line spectral frequencies:

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';  
hlpc2lsf = dsp.LPCToLSF;  
y = step(hlpc2lsf, a); % Convert to LSF coefficients
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except:

There is no object property that corresponds to the **Output** block parameter. The object only supports LSF outputs in the range  $(0, \Pi)$

## See Also

[dsp.LSFToLPC](#) | [dsp.LPCToLSP](#)

**Purpose** Create LPC To LSF object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an LPCToLSF System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.LPCToLSF.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.LPCToLSF.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** isLocked(H)

**Description** isLocked(H) returns the locked state of the LPCToLSF System object.  
The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

## **dsp.LPCToLSF.reset**

---

<b>Purpose</b>	Reset values for overwriting invalid outputs to their initial values
<b>Syntax</b>	<code>reset(H)</code>
<b>Description</b>	<code>reset(H)</code> resets the values for overwriting the invalid outputs to their initial values.

**Purpose** Convert LPC coefficients to line spectral frequencies

**Syntax** `LSF = step(H,A)`  
`[..., STATUS] = step(H,A)`

**Description** `LSF = step(H,A)` converts the LPC coefficients, `A`, to line spectral frequencies, `LSF`, in the range  $(0 \text{ pi})$ . The System object operates along the columns of the input `A`.

`[..., STATUS] = step(H,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.LPCToLSP

---

**Purpose** Convert linear prediction coefficients to line spectral pairs

**Description** The LPCToLSP object converts linear prediction coefficients to line spectral pairs.

To convert LPC to LSP:

- 1 Define and set up your LPC to LSP converter. See “Construction” on page 3-832.
- 2 Call `step` to convert LPC according to the properties of `dsp.LPCToLSP`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.LPCToLSP` returns a System object, `H`, that converts linear prediction coefficients (LPCs) to line spectral pairs (LSPs).  
`H = dsp.LPCToLSP('PropertyName',PropertyValue,...)` returns an LPC to LSF System object, `H`, with each specified property set to the specified value.

**Properties** **NumCoarseGridPoints**

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals,  $n$ , used for finding line spectral pairs (LSP) values, as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range  $(-1, 1)$ . The System object finds these roots using the Chebyshev polynomial root finding method. The object divides the interval  $(-1, 1)$  into  $n$  subintervals and looks for roots in each subinterval. If  $n$  is set to too small a number in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is 64. This property is tunable.

**NumBisects**

Value of bisection refinement used for finding roots

Specify the root bisection refinement value,  $k$ , that the Chebyshev polynomial uses in the root finding method. For each line spectral pair (LSP) the output is within

$$\frac{1}{n \cdot 2^k}$$

of the actual LSP value. Here  $n$  is the value of the NumCoarseGridPoints property and the object searches a maximum of

$$k \cdot (n-1)$$

points for finding the roots. The NumBisects property value  $k$ , must be a positive scalar integer. The default is 4. This property is tunable.

#### **ExceptionOutputPort**

Produces output with validity status of LSP output

Set this property to `true` to return a second output that indicates whether the computed LSP values are valid. The object outputs a vector length equal to the number of channels. A logical value of 1 indicates the output is valid. A logical value of 0 indicates the output is invalid. The LSP outputs are invalid when the object fails to find all the LSP values or when the input LPCs are unstable. The default is `false`.

#### **OverwriteInvalidOutput**

Enable overwriting invalid output with previous output

Specify the action that the object takes for invalid LSP outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object takes no action on invalid outputs and ignores the outputs.

#### **FirstOutputValuesSource**

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies only when you set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When this property is `Auto`, the object uses a default value for the first output. The default value corresponds to the LSP representation of an allpass filter.

## **FirstOutputValues**

Value of first output

Specify a numeric vector of LSP values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, set this property can to a matrix with the same number of channels as the input or one vector that you apply to every channel. The default is an empty vector. This property applies only when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

## **NonUnityFirstCoefficientAction**

First coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not equal to 1. Specify as one of `Replace with 1` or `Normalize`. The default is `Replace with 1`.

## **Methods**

<code>clone</code>	Create LPC To LSP object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset values for overwriting invalid outputs to their initial values
step	Convert linear prediction coefficients to line spectral pairs

## Examples

Convert the LPC coefficients to LSP coefficients:

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
hlpc2lsp = dsp.LPCToLSP;
y = step(hlpc2lsp, a); % Convert to LSP coefficients
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except:

No object property corresponds to the **Output** block parameter. The object only supports LSP outputs.

## See Also

dsp.LSPToLPC | dsp.LPCToLSF

## **dsp.LPCToLSP.clone**

---

**Purpose** Create LPC To LSP object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a LPCToLSP System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.LPCToLSP.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the LPCToLSP System object. The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.LPCToLSP.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

<b>Purpose</b>	Reset values for overwriting invalid outputs to their initial values
<b>Syntax</b>	reset(H)
<b>Description</b>	reset(H) resets the values for overwriting the invalid outputs to their initial values.

# dsp.LPCToLSP.step

---

**Purpose** Convert linear prediction coefficients to line spectral pairs

**Syntax** LSF = step(H,A)  
[ ..., STATUS] = step(H,A)

**Description** LSF = step(H,A) converts the LPC coefficients, A , to line spectral pairs normalized in the range (-1 1), LSP. The object operates along the columns of the input A.

[ ..., STATUS] = step(H,A) also returns the status flag, STATUS, indicating if the current output is valid when the ExceptionOutputPort property is true.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

<b>Purpose</b>	Convert linear prediction coefficients to reflection coefficients
<b>Description</b>	<p>The LPCToRC object converts linear prediction coefficients to reflection coefficients.</p> <p>To convert LPC to reflection coefficients:</p> <ol style="list-style-type: none"><li>1 Define and set up your LPC to RC converter. See “Construction” on page 3-843.</li><li>2 Call <code>step</code> to convert LPC according to the properties of <code>dsp.LPCToRC</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.LPCToRC</code> returns an LPC to RC System object, <code>H</code>, that converts linear prediction coefficients (LPC) to reflection coefficients (RC).</p> <p><code>H = dsp.LPCToRC('PropertyName',PropertyValue,...)</code> returns an LPC to RC conversion object, <code>H</code>, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>PredictionErrorOutputPort</b></p> <p>Enable normalized prediction error power output</p> <p>Set this property to <code>true</code> to return the normalized error power as a vector with one element per input channel. Each element varies between zero and one. The default is <code>true</code>.</p> <p><b>ExceptionOutputPort</b></p> <p>Produces output with stability status of filter represented by LPC coefficients</p> <p>Set this property to <code>true</code> to return the stability status of the filter. A logical value of 1 indicate a stable filter. A logical value of 0 indicate an unstable filter. The default is <code>false</code>.</p> <p><b>NonUnityFirstCoefficientAction</b></p> <p>Action to take when first LPC coefficient is not 1</p>

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select `Replace` with 1 or `Normalize`. The default is `Replace` with 1.

## Methods

<code>clone</code>	Create LPC to RC object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Convert columns of linear prediction coefficients to reflection coefficients

## Examples

Convert the linear prediction coefficients to reflection coefficients:

```
load mtlb

hlevinson = dsp.LevinsonSolver;
hlevinson.AOutputPort = true;
hlevinson.KOutputPort = false;

hac = dsp.Autocorrelator;
hlpc2rc = dsp.LPCToRC;
hac.MaximumLagSource = 'Property';

% Compute autocorrelation for lags between [0:10]
hac.MaximumLag = 10;
a = step(hac, mtlb);
A = step(hlevinson, a); % Compute LPC coefficients
```

```
[K, P] = step(hlpc2rc, A); % Convert to RC
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from RC block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.
- The `NonUnityFirstCoefficientAction` object property corresponds to the **If first input value is not 1** block parameter. There is neither a `Normalize` and `warn` nor an `Error` option for the object.

## See Also

`dsp.RCToLPC` | `dsp.LPCToAutocorrelation`

## **dsp.LPCToRC.clone**

---

**Purpose** Create LPC to RC object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a LPCToRC System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.LPCToRC.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the LPCToRC System object H. The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.LPCToRC.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Convert columns of linear prediction coefficients to reflection coefficients

**Syntax**

```
[K,P] = step(H,A)
K = step(H,A)
[... , S] = step(H,A)
```

**Description** [K,P] = step(H,A) converts the columns of linear prediction coefficients, A, to reflection coefficients K and outputs the normalized prediction error power, P.

K = step(H,A) when you set the PredictionErrorOutputPort property to false, converts the columns of linear prediction coefficients, A, to reflection coefficients K.

[... , S] = step(H,A) also outputs the LPC filter stability, S, when you set the ExceptionOutputPort property to true.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

# dsp.LSFToLPC

---

**Purpose** Convert line spectral frequencies to linear prediction coefficients

**Description** The LSFToLPC object converts line spectral frequencies to linear prediction coefficients.

To convert LSF to LPC:

- 1 Define and set up your LSF to LPC converter. See “Construction” on page 3-852.
- 2 Call `step` to convert LSF according to the properties of `dsp.LSFToLPC`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.LSFToLPC` returns an LSF to LPC System object, `H`, which converts line spectral frequencies (LSFs) to linear prediction coefficients (LPCs).

Methods		
	<code>clone</code>	Create LSF to LPC object with same property values
	<code>getNumInputs</code>	Number of expected inputs to <code>step</code> method
	<code>getNumOutputs</code>	Number of outputs of <code>step</code> method
	<code>isLocked</code>	Locked status for input attributes and nontunable properties
	<code>release</code>	Allow property value and input characteristics changes
	<code>step</code>	Convert input line spectral frequencies to linear prediction coefficients

**Examples** Convert line spectral frequencies to linear prediction coefficients:

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]'
```

```
hlpc2lsf = dsp.LPCToLSF;  
ylsf = step(hlpc2lsf, a);  
hlsf2lpc = dsp.LSFToLPC;  
ylpc = step(hlsf2lpc, ylsf) % Check values are same as a.
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LSF/LSP to LPC Conversion block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Input** block parameter. The object's behavior corresponds to the block's behavior when you set the **Input** parameter to LSF in range  $(0, \pi)$ .

## See Also

dsp.LPCToLSF | dsp.LSPToLPC

## **dsp.LSFToLPC.clone**

---

**Purpose** Create LSF to LPC object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an LSFToLPC System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.LSFToLPC.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the LSFToLPC System object. The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.LSFToLPC.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

<b>Purpose</b>	Convert input line spectral frequencies to linear prediction coefficients
<b>Syntax</b>	$A = \text{step}(H, \text{LSF})$
<b>Description</b>	$A = \text{step}(H, \text{LSF})$ converts the input line spectral frequencies, (LSF), in the range $(0, \pi)$ , LSF , to linear prediction coefficients, A. The input can be a vector or a matrix, where each column of the matrix is treated as a separate channel.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.LSPToLPC

---

**Purpose** Convert line spectral pairs to linear prediction coefficients

**Description** The LSPToLPC object converts line spectral pairs to linear prediction coefficients.

To convert LSP to LPC:

- 1 Define and set up your LSP to LPC converter. See “Construction” on page 3-860.
- 2 Call `step` to convert LSP according to the properties of `dsp.LSPToLPC`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.LSPToLPC` returns an LSP to LPC System object, `H`, which converts line spectral pairs (LSPs) to linear prediction coefficients (LPCs).

## Methods

<code>clone</code>	Create LSP to LPC object with same property values
<code>getNumInputs</code>	Number of expected inputs to <code>step</code> method
<code>getNumOutputs</code>	Number of outputs of <code>step</code> method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Convert input line spectral pairs to linear prediction coefficients

## Examples

Convert line spectral pairs to linear prediction coefficients:

```
y1sp = [0.7080 0.0103 -0.3021 -0.3218 -0.7093]';  
h1sp2lpc = dsp.LSPToLPC;
```

```
y1pc = step(hlsp2lpc, y1sp)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LSF/LSP to LPC Conversion block reference page. The object properties correspond to the block parameters, except:

No object property corresponds to the **Input** block parameter. The object converts LSP in the range  $(-1, 1)$  to LPC.

## **dsp.LSPToLPC.clone**

---

**Purpose** Create LSP to LPC object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an LSPToLPC System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.LSPToLPC.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the LSPToLPC System object. The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.LSPToLPC.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Convert input line spectral pairs to linear prediction coefficients

**Syntax**  $A = \text{step}(H, \text{LSP})$

**Description**  $A = \text{step}(H, \text{LSP})$  converts the input line spectral pairs in the range  $(-1, 1)$ , LSP, to linear prediction coefficients, A. The input can be a vector or a matrix, where each column of the matrix is treated as a separate channel.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.LUFactor

---

## Purpose

Factor square matrix into lower and upper triangular matrices

## Description

The LUFactor object factors a square matrix into lower and upper triangular matrices.

To factor a square matrix into lower and upper triangular matrices:

- 1 Define and set up your System object. See “Construction” on page 3-868.
- 2 Call `step` to factor the square matrix according to the properties of `dsp.LUFactor`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.LUFactor` returns an LUFactor System object, `H`, which factors a row permutation of a square input matrix  $A$  as  $A_p = L \cdot U$ , where  $L$  is the unit-lower triangular matrix, and  $U$  is the upper triangular matrix. The row-pivoted matrix  $A_p$  contains the rows of  $A$  permuted as indicated by the permutation index vector  $P$ . The equivalent MATLAB code is `Ap = A(P, :)`.

`H = dsp.LUFactor('PropertyName', PropertyValue, ...)` returns an LUFactor object, `H`, with each specified property set to the specified value.

## Properties

### ExceptionOutputPort

Set to `true` to output singularity of input

Set this property to `true` to output the singularity of the input as logical data type values of `true` or `false`. An output of `true` indicates that the current input is singular, and an output of `false` indicates the current input is nonsingular.

### Fixed-Point Properties

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as  
|Ceiling|Convergent|Floor|Nearest|Round|Simplest|  
Zero|. The default is Floor.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as Wrap or Saturate. The default is Wrap.

### **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as Full precision, Same as input or Custom. The default is Full precision.

### **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

### **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as Full precision, Same as input, Same as product or Custom. The default is Full precision.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

# dsp.LUFactor

---

## OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

## CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

## Methods

<code>clone</code>	Create LU Factor object with same property values
<code>getNumInputs</code>	Number of expected inputs to <code>step</code> method
<code>getNumOutputs</code>	Number of outputs of <code>step</code> method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Decompose matrix into lower and upper triangular matrices

## Examples

Decompose a square matrix into the lower and upper components:

```
hlu = dsp.LUFactor;  
x = rand(4)  
[LU, P] = step(hlu, x);  
L = tril(LU,-1)+diag(ones(size(LU,1),1));  
U = triu(LU);  
y = L*U
```

```
% Check back whether this equals the permuted x  
xp = x(P,:)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LU Factorization block reference page. The object properties correspond to the block parameters.

## See Also

dsp.LDLFactor

# **dsp.LUFactor.clone**

---

**Purpose** Create LU Factor object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an LUFactor object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, of the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.LUFactor.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the LUFactor object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.LUFactor.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Decompose matrix into lower and upper triangular matrices

**Syntax**  
[LU,P] = step(H,A)  
[LU,P,S] = step(H,A)

**Description** [LU,P] = step(H,A) decomposes the matrix A into lower and upper triangular matrices. The output LU is a composite matrix with lower triangle elements from L and upper triangle elements from U . The permutation vector P is the second output.

[LU,P,S] = step(H,A) returns an additional output S indicating if the input is singular when the ExceptionOutputPort property is set to true.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

# dsp.MatFileReader

---

**Purpose** Read MAT file

**Description** The `MatFileReader` object reads V7.3 MAT files.

To read V7.3 MAT files:

- 1 Define and set up your System object. See “Construction” on page 3-878.
- 2 Call `step` to read the MAT file according to the properties of `dsp.MatFileReader`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.MatFileReader` returns a System object, `H`, to read data from a V7.3 MAT file.

`H = dsp.MatFileReader('PropertyName',PropertyValue,...)` returns a MAT file reader System object, `H`, with each specified property set to the specified value.

`H = dsp.MatFileReader(FILENAME,VARIABLENAME'PropertyName',PropertyValue,...)` returns a MAT file reader System object, `H`, with the `Filename` property set to `FILENAME`, the `VariableName` property set to `VARIABLENAME`, and other specified properties set to the specified values.

## Properties

### Filename

Name of MAT file from which to read

Specify the name of a MAT file as a string. Specify the full path for the file only if the file is not on the MATLAB path. The default file name is `Untitled.mat`.

### VariableName

Name of the variable to read

Name of the variable stored in and read from the MAT file. The default variable name is `x`.

## FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

## SamplesPerFrame

Number of samples per output frame

Specify the number of elements to read from the MAT file each time the `step` method is called. This property applies when `FrameBaseProcessing` is `true`. The default number of samples per frame is 1.

## Methods

<code>clone</code>	Create MAT file reader object with same property values
<code>isDone</code>	End-of-file status
<code>isLocked</code>	Locked status (logical) for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of multimedia file reader to read from beginning of file
<code>step</code>	Read data from a variable in the MAT file

## Examples

Use `dsp.MatFileReader` and `dsp.MatFileWriter` to stream data.

```
filename = [tempname '.mat']; % Create variable name
```

```
originalData = rand(40,2);
```

# dsp.MatFileReader

---

```
save(filename,'originalData','-v7.3'); % Write to MAT file

H = dsp.MatFileReader(filename,'VariableName',...
    'originalData','SamplesPerFrame', 4);
while ~isDone(H) % Stream data into MATLAB
    finalData = step(H);
end
```

## See Also

dsp.MatFileWriter

**Purpose** Create MAT file reader object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `MatFileReader` System object `C`, with the same property values as `H`.

The `clone` method creates a new unlocked object with uninitialized states.

# dsp.MatFileReader.isLocked

---

**Purpose** Locked status (logical) for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `MatFileReader` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** End-of-file status

**Syntax** STATUS = isDone(H)

**Description** STATUS = isDone(H) returns a logical value, STATUS. When the MatFileReader object, H , reaches the end of the MAT file, STATUS is true.

# dsp.MatFileReader.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

<b>Purpose</b>	Reset internal states of multimedia file reader to read from beginning of file
<b>Syntax</b>	<code>reset(H)</code>
<b>Description</b>	<code>reset(H)</code> resets the <code>MatFileReader</code> object to read from the beginning of the file.

# dsp.MatFileReader.step

---

**Purpose** Read data from a variable in the MAT file

**Syntax** `X = step(H)`

**Description** `X = step(H)` reads data,  $X$ , from a variable stored in a MAT-file. The variable is assumed to be  $N$ -dimensional and a MATLAB built-in datatype. If the `FrameBasedProcessing` property is true, the data is read into MATLAB by reading along the first dimension. If `FrameBasedProcessing` is false, the data is read into MATLAB along the last dimension.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Purpose** Write MAT file

**Description** The MatFileWriter object writes data to a V7.3 MAT file.

To write data to a V7.3 MAT file:

- 1** Define and set up your System object. See “Construction” on page 3-887.
- 2** Call step to write data according to the properties of dsp.MatFileWriter. The behavior of step is specific to each object in the toolbox.

**Construction** H = dsp.MatFileWriter returns a MAT file writer System object, H, that writes data to a V7.3 MAT file.

H = dsp.MatFileWriter('PropertyName',PropertyValue,...) returns a MAT file writer System object, H, with each specified property set to the specified value.

H = dsp.MatFileWriter(FILENAME,'PropertyName',PropertyValue,...) returns a MAT file writer System object, H, with Filename property set to FILENAME and other specified properties set to the specified values.

## Properties

### Filename

Name of MAT file to write

Specify the name of a MAT file as a string. Specify the full path for the file only if the file is not on the MATLAB path. The default file name is Untitled.mat.

### VariableName

Name of the variable to write

Name of the variable to which to write. This variable is stored in the MAT file. The default variable name is x.

### FrameBasedProcessing

# dsp.MatFileWriter

---

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. In frame-based mode, this System object streams the data to the first dimension. In sample-based mode, a new dimension is appended to the end of the data set. The default is `true`.

## Methods

<code>clone</code>	Create MAT file writer object with the same property values
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Write one frame of MAT file data

## Examples

Use `dsp.MatFileWriter` and `dsp.MatFileReader` to stream data.

```
% First, create a variable name
filename = [tempname '.mat'];

% Next, write that variable to a MAT-file.
hmfw = dsp.MatFileWriter(filename, 'VariableName', 'originalData')
for i=1:10
    originalData = rand(4,2);
    step(hmfw, originalData);
end
release(hmfw); % This will close the MAT file

% Finally, load the variable back into MATLAB.
data = load(filename, 'originalData');
```

## See Also

`dsp.MatFileReader`

**Purpose** Create MAT file writer object with the same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `MatFileWriter` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.MatFileWriter.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `MatFileWriter` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. `release` also closes the file. This method lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.MatFileWriter.step

---

**Purpose** Write one frame of MAT file data

**Syntax** `step(H,X)`

**Description** `step(H,X)` writes one frame of data,  $X$ , to the variable stored in the MAT file. The variable is assumed to be N-dimensional and a MATLAB built-in data type. If the `FrameBasedProcessing` property is `true`, the data is written to the file by concatenating along the first dimension. If `FrameBasedProcessing` is `false`, the data is written by appending an additional dimension to the end of the data set.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Find maximum value of input or sequence of inputs
<b>Description</b>	<p>The Maximum object finds the maximum values of an input or sequence of inputs.</p> <p>To compute the maximum value of an input or sequence of inputs:</p> <ol style="list-style-type: none"><li>1 Define and set up your System object. See “Construction” on page 3-893.</li><li>2 Call <code>step</code> to find the maximum according to the properties of <code>dsp.Maximum</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.Maximum</code> returns an object, <code>H</code>, that computes the value and index of the maximum elements in an input or a sequence of inputs along the specified <code>Dimension</code>.</p> <p><code>H = dsp.Maximum('PropertyName',PropertyValue,...)</code> returns a maximum-finding object, <code>H</code>, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>ValueOutputPort</b></p> <p>Output maximum value</p> <p>Set this property to <code>true</code> in order to output the maximum of the input. This property applies only when you set the <code>RunningMaximum</code> property to <code>false</code>. The default is <code>true</code>.</p> <p><b>RunningMaximum</b></p> <p>Calculate over single input or multiple inputs</p> <p>When you set this property to <code>true</code>, the object computes the maximum value over successive calls to the <code>step</code> method. When you set this property to <code>false</code>, the object computes the maximum value over the current input. The default is <code>false</code>.</p> <p><b>IndexOutputPort</b></p>

Output index of maximum value

Set this property to `true` to output the index of the maximum value of the input. This property applies only when you set the `RunningMaximum` property to `false`. The default is `true`.

## **ResetInputPort**

Additional input to enable resetting of running maximum

Set this property to `true` to enable resetting the running maximum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running maximum. This property applies only when you set the `RunningMaximum` property to `true`. The default is `false`.

This property applies only when you set the `RunningMaximum` property to `true`. The default is `false`.

## **ResetCondition**

Condition that triggers resetting of running maximum

Specify the event that resets the running maximum as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

## **IndexBase**

Numbering base for index of maximum value

Specify whether to start the index numbering from `One` or `Zero` when computing the index of the maximum value. This property applies only when you set the `IndexOutputPort` property to `true`. The default is `One`.

## **Dimension**

Dimension to operate along

Specify how the maximum calculation is performed over the data as one of `| All | Row | Column | Custom |`. This property applies when you set the `RunningMaximum` property to `false`. The default is `Column`.

## **CustomDimension**

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the maximum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the Dimension property to Custom. The default is 1.

## **ROIProcessing**

Enable region-of-interest processing

Set this property to true to enable calculation of the maximum value within a particular region of an image. This property applies when you set the Dimension property to All and the RunningMaximum property to false. The default is false.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the ROIForm property as Rectangles.

## **ROIForm**

Type of region of interest

Specify the type of region of interest as one of | Rectangles | Lines | Label matrix | Binary mask |. This property applies only when you set the ROIProcessing property to true. The default is Rectangles.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the as Rectangles.

## **ROIPortion**

Calculate over entire ROI or just perimeter

Specify whether to calculate the maximum over the Entire ROI or the ROI perimeter. This property applies only when you set the ROIForm property to Rectangles. The default is Entire ROI.

## **ROIStatistics**

Calculate statistics for each ROI or one for all ROIs

Specify whether to calculate Individual statistics for each ROI or a Single statistic for all ROIs. This property applies only when you set the ROIForm property to Rectangles, Lines, or Label matrix.

## **ValidityOutputPort**

Output flag indicating if any part of ROI is outside input image

When you set the ROIForm property to one of | Lines | Rectangles |, set this property to true to return the validity of the specified ROI being completely inside of the image. When you set the ROIForm property to Label Matrix, set this property to true to return the validity of the specified label numbers. The default is false.

## **FrameBasedProcessing**

Process input as frames or samples

Set this property to true to enable frame-based processing for 2-D inputs. Set this property to false to enable sample-based processing. The object always performs sample-based processing for N-D inputs where N is greater than 2. This property applies when you set the RunningMaximum to true. The default is true.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

### **OverflowAction**

Action to take when integer input is out-of-range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

## **ProductDataType**

Data type of product

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as product | Same as input | Custom |. The default is Same as product.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **Methods**

<code>clone</code>	Create maximum-finding object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method

# dsp.Maximum

---

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset computation of running maximum
step	Maximum value

## Examples

Find a maximum value and its index:

```
hmax1 = dsp.Maximum;  
x = randn(100,1);  
[y, I] = step(hmax1, x);
```

---

Compute a running maximum:

```
hmax2 = dsp.Maximum;  
hmax2.RunningMaximum = true;  
x = randn(100,1);  
y = step(hmax2, x);  
% y(i) is the maximum of all values in the vector x(1:i)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Maximum block reference page. The object properties correspond to the block parameters, except:

**Treat sample-based row input as a column** block parameter is not supported by the dsp.Maximum object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input**

**processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

### See Also

dsp.Minimum | dsp.Mean

# **dsp.Maximum.clone**

---

**Purpose** Create maximum-finding object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a Maximum object C, with the same property values as H. The `clone` method creates a new unlocked object with uninitialized states.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.Maximum.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `Maximum` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.Maximum.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose**            Reset computation of running maximum

**Syntax**            `reset(H)`

**Description**        `reset(H)` resets the computation of the running maximum for the `Maximum` object `H`.

# dsp.Maximum.step

---

## Purpose

Maximum value

## Syntax

```
[VAL,IND] = step(H,X)
VAL = step(H,X)
IND = step(H,X)
VAL = step(H,X,R)
[...] = step(H,I,ROI)
[...] = step(H,I,LABEL,LABELNUMBERS)
[... ,FLAG] = step(H,I,ROI)
[... ,FLAG] = step(H,I,LABEL,LABELNUMBERS)
```

## Description

`[VAL,IND] = step(H,X)` returns the maximum value, VAL, and the index or position of the maximum value, IND, along the specified Dimension of X.

`VAL = step(H,X)` returns the maximum value, VAL, of the input X. When the `RunningMaximum` property is true, VAL corresponds to the maximum value over successive calls to the `step` method.

`IND = step(H,X)` returns the zero- or one-based index IND of the maximum value. To enable this type of processing, set the `IndexOutputPort` property to true and the `ValueOutputPort` and `RunningMaximum` properties to false.

`VAL = step(H,X,R)` resets the state of H based on the value of reset signal, R, and the `ResetCondition` property. To enable this type of processing, set the `RunningMaximum` property to true and the `ResetInputPort` property to true.

`[...] = step(H,I,ROI)` computes the maximum of an input image, I, within the given region of interest, ROI. To enable this type of processing, set the `ROIProcessing` property to true and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`[...] = step(H,I,LABEL,LABELNUMBERS)` computes the maximum of an input image, I, for a region whose labels are specified in the vector LABELNUMBERS. To enable this type of processing, set the `ROIProcessing` property to true and the `ROIForm` property to `Label matrix`.

[... ,FLAG] = step(H,I,ROI) returns FLAG, indicating whether the given region of interest is within the image bounds. To enable this type of processing, set the ROIProcessing and ValidityOutputPort properties to true and the ROIForm property to Lines, Rectangles or Binary mask.

[... ,FLAG] = step(H,I,LABEL,LABELNUMBERS) returns FLAG, indicating whether the input label numbers are valid. To enable this type of processing, set the ROIProcessing and ValidityOutputPort properties to true and the ROIForm property to Label matrix.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the ROIForm property as Rectangles.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

# dsp.Mean

---

**Purpose** Find mean value of input or sequence of inputs

**Description** The Mean object finds the mean of an input or sequence of inputs.

To compute the mean of an input or sequence of inputs:

- 1 Define and set up your System object. See “Construction” on page 3-908.
- 2 Call `step` to compute the mean according to the properties of `dsp.Mean`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.Mean` returns an object, `H`, that computes the mean of an input or a sequence of inputs.

`H = dsp.Mean('PropertyName',PropertyValue,...)` returns a mean-finding object, `H`, with each specified property set to the specified value.

## Properties

### RunningMean

Calculate over single input or multiple inputs

When you set this property to `true`, the object calculates the mean over successive calls to the `step` method. When you set this property to `false`, the object computes the mean over the current input. The default is `false`.

### ResetInputPort

Additional input to enable resetting of running mean

Set this property to `true` to enable resetting of the running mean. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running mean. This property applies only when you set the `RunningMean` property to `true`. The default is `false`.

### ResetCondition

Condition that triggers resetting of running mean

Specify the event that resets the running maximum as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies only when you set the ResetInputPort property to true. The default is Non-zero.

### **Dimension**

Dimension to operate along

Specify how the mean calculation is performed over the data as one of | All | Row | Column | Custom |. This property applies when you set the RunningMean property to false. The default is Column.

### **CustomDimension**

Numerical dimension to calculate over

Specify the integer dimension, indexed from one, of the input signal over which the object calculates the mean. The value cannot exceed the number of dimensions in the input signal. This property only applies when you set the Dimension property to Custom. The default is 1.

### **ROIProcessing**

Enable region-of-interest processing

Set this property to true to enable calculation of the mean within a particular region of an image. This property applies when you set the Dimension property to All and the RunningMean property to false. The default is false.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the ROIForm property as Rectangles.

### **ROIForm**

Type of region of interest

Specify the type of region of interest as one of | Rectangles | Lines | Label matrix |. This property applies only when you set the ROIProcessing property to true. The default is Rectangles.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the as Rectangles.

## **ROIPortion**

Calculate over entire ROI or just perimeter

Specify whether to calculate the mean over the Entire ROI or the ROI perimeter. This property applies only when you set the ROIForm property to Rectangles. The default is Entire ROI.

## **ROIStatistics**

Calculate statistics for each ROI or one for all ROIs

Specify whether to calculate Individual statistics for each ROI or a Single statistic for all ROIs. This property applies only when you set the ROIForm property to Rectangles, Lines, or Label matrix. The default is Individual statistics for each ROI.

## **ValidityOutputPort**

Output flag indicating if any part of ROI is outside input image

When you set the ROIForm property to one of | Lines | Rectangles | Binary mask |, set this property to true to return the validity of the specified ROI being completely inside of the image. When you set the ROIForm property to Label Matrix, set this property to true to return the validity of the specified label numbers. The default is false.

## **FrameBasedProcessing**

Process input as frames or samples

Set this property to true to enable frame-based processing for 2-D inputs. Set this property to false to enable sample-based

processing. The object always performs sample-based processing for N-D inputs where N is greater than 2. This property applies when you set the `RunningMean` to true. The default is true.

### **Fixed-Point Properties**

#### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

#### **OverflowAction**

Action to take when integer input is out-of-range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

#### **AccumulatorDataType**

Data type of accumulator

Specify the accumulator fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

#### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

#### **OutputDataType**

Data type of output

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

## CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([],32,30)`.

## Methods

<code>clone</code>	Create mean object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of mean-finding object
<code>step</code>	Mean value

## Examples

Compute the mean of a signal:

```
hmean1 = dsp.Mean;  
x = randn(100,1);  
y = step(hmean1, x);
```

---

Compute the running mean of a signal:

```
hmean2 = dsp.Mean;  
hmean2.RunningMean = true;  
x = randn(100,1);
```

```
y = step(hmean2, x);  
% y(i) is the mean of all values in the vector x(1:i)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Mean block reference page. The object properties correspond to the block parameters, except:

**Treat sample-based row input as a column** block parameter is not supported by the `dsp.Mean` object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the `FrameBasedProcessing` Property of a System object” for more information.

## See Also

`dsp.Maximum` | `dsp.Minimum`

# dsp.Mean.clone

---

**Purpose** Create mean object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a Mean object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.Mean.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the Mean object H.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.Mean.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset internal states of mean-finding object

**Syntax** reset(H)

**Description** reset(H) sets the internal states of the Mean object H to their initial values.

# dsp.Mean.step

---

**Purpose** Mean value

**Syntax**

```
Y = step(H,X)
Y = step(H,X,R)
Y = step(H,X,ROI)
Y = step(H,X,LABEL,LABELNUMBERS)
[Y,FLAG] = step(H,X,ROI)
[Y,FLAG] = step(H,X,LABEL,LABELNUMBERS)
```

**Description** `Y = step(H,X)` computes the mean of `X`. When you set the `RunningMean` property to `true`, `Y` corresponds to the mean successive calls to the `step` method.

`Y = step(H,X,R)` resets the computation of the running mean based on the value of the reset signal, `R`, and the `ResetCondition` property. To enable this type of processing, set the `RunningMean` property to `true` and the `ResetInputPort` property to `true`.

`Y = step(H,X,ROI)` computes the mean of input image `X` within the given region of interest `ROI`. To enable this type of processing, set the `ROIProcessing` property to `true` and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`Y = step(H,X,LABEL,LABELNUMBERS)` computes the mean of the input image, `X`, for the region whose labels are specified in the vector `LABELNUMBERS`. The regions are defined and labeled in the matrix `LABEL`. To enable this type of processing, set the `ROIProcessing` property to `true` and the `ROIForm` property to `Label matrix`.

`[Y,FLAG] = step(H,X,ROI)` returns `FLAG`, indicating whether the given region of interest `ROI`, is within the image bounds. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`[Y,FLAG] = step(H,X,LABEL,LABELNUMBERS)` returns `FLAG` which indicates whether the input label numbers are valid. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Label matrix`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the value of this property as `Rectangles`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.Median

---

**Purpose** Median value of input

**Description** The Median object computes the median value of the input. The object can compute the median along each dimension (row or column) of the input or of the entire input.

To compute the median of the input:

- 1** Define and set up your median System object. See “Construction” on page 3-922.
- 2** Call `step` to compute the median according to the properties of `dsp.Median`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.Median` returns a median System object, `H`, that computes the median along the columns of the input using the `Quick sort` sorting method.

`H = dsp.Median('PropertyName',PropertyValue,...)` returns a median System object, `H`, with each property set to the value you specify.

## Properties

### SortMethod

Sort method

Specify the method the object should use to sort the data before computing the median. You can specify `Quick sort` or `Insertion sort`. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting less than 32 elements. If you are using the Median object to generate code, you should use the insertion sort algorithm to prevent recursive function calls in your generated code. The default is `Quick sort`.

### Dimension

Dimension to operate along

Specify the dimension along which the object computes the median values. You can specify one of | All | Row | Column | Custom |. The default is Column.

## **CustomDimension**

Numerical dimension to operate along

Specify the dimension of the input signal (as a one-based value), over which the object computes the median. The cannot exceed the number of dimensions in the input signal. This property applies only when you set the Dimension property to Custom. The default is 1.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

### **ProductDataType**

Product word and fraction lengths

Specify the product data type as one of | Same as input | Custom |. The default is Same as input.

### **CustomProductDataType**

Product word and fraction lengths

Specify the product data type as a scaled `numericType` object with a Signedness of Auto. This property applies only when

you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator data type as one of `| Same as product | Same as input | Custom |`. The default is `Same as product`.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the fixed-point accumulator data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output data type as one of `| Same as accumulator | Same as product | Same as input | Custom |`. The default is `Same as accumulator`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the data type of the output as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

## **Methods**

<code>clone</code>	Create median object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Median value

## Examples

Compute the median value of the input column:

```
h = dsp.Median;  
x = [7 -9 0 -1 2 0 3 5 -9]';  
y = step(h, x)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Median block reference page. The object properties correspond to the block properties, except:

**Treat sample-based row input as a column** block parameter is not supported by the dsp.Median System object.

## See Also

dsp.Mean | dsp.Minimum | dsp.Maximum | dsp.Variance

## **dsp.Median.clone**

---

**Purpose** Create median object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a median object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.Median.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the Median System object H. The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.Median.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Median value

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  computes the median value of the input  $X$  and returns the result in  $Y$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.Minimum

---

## Purpose

Find minimum values of input or sequence of inputs

## Description

The Minimum object finds the minimum value of an input or sequence of inputs.

To compute the minimum value of an input or sequence of inputs:

- 1 Define and set up your System object. See “Construction” on page 3-932.
- 2 Call `step` to compute the minimum according to the properties of `dsp.Minimum`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.Minimum` returns an object, `H`, that computes the value and/or index of the minimum elements in an input or a sequence of inputs over the specified `Dimension`.

`H = dsp.Minimum('PropertyName',PropertyValue,...)` returns a minimum-finding object, `H`, with each specified property set to the specified value.

## Properties

### ValueOutputPort

Output minimum value

Set this property to `true` in order to output the minimum value of the input. This property applies only when you set the `RunningMinimum` property to `false`. The default is `true`.

### RunningMinimum

Calculate over single input or multiple inputs

When you set this property to `true`, the object computes the minimum value over successive calls to the `step` method. When you set this property to `false`, the object computes the minimum value over the current input. The default is `false`.

### IndexOutputPort

Output index of minimum value

Set this property to `true` to output the index of the minimum value of the input. This property applies only when you set the `RunningMinimum` property to `false`. The default is `true`.

## **ResetInputPort**

Additional input to enable resetting of running minimum

Set this property to `true` to enable resetting of the running minimum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running minimum. This property applies only when you set the `RunningMinimum` property to `true`. The default is `false`.

## **ResetCondition**

Condition that triggers resetting of running minimum

Specify the event that resets the running minimum as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

## **IndexBase**

Numbering base for index of minimum value

Specify the numbering used when computing the index of the minimum value as starting from either `One` or `Zero`. This property applies only when you set the `IndexOutputPort` property to `true`. The default is `One`.

## **Dimension**

Dimension to operate along

Specify how the minimum calculation is performed over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningMinimum` property to `false`. The default is `Column`.

## **CustomDimension**

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the minimum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` property to `Custom`. The default is 1.

## **ROIProcessing**

Enable region-of-interest processing

Set this property to `true` to enable calculation of the minimum value within a particular region of an image. This property applies when you set the `Dimension` property to `All` and the `RunningMinimum` property to `false`. The default is `false`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

## **ROIForm**

Type of region of interest

Specify the type of region of interest as one of `Rectangles` | `Lines` | `Label matrix` | `Binary mask` |. This property applies only when you set the `ROIProcessing` property to `true`. The default is `Rectangles`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the as `Rectangles`.

## **ROIPortion**

Calculate over entire ROI or just perimeter

Specify whether to calculate the minimum over the `Entire ROI` or the `ROI perimeter`. This property applies only when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

## **ROIStatistics**

Calculate statistics for each ROI or one for all ROIs

Specify whether to calculate `Individual` statistics for each ROI or a `Single` statistic for all ROIs. This property applies only when you set the `ROIForm` property to `Rectangles`, `Lines`, or `Label matrix`.

## **ValidityOutputPort**

Output flag indicating if any part of ROI is outside input image

When you set the `ROIForm` property to `Lines` or `Rectangles`, set this property to `true` to return the validity of the specified ROI being completely inside of the image. When you set the `ROIForm` property to `Label Matrix`, set this property to `true` to return the validity of the specified label numbers. The default is `false`.

## **FrameBasedProcessing**

Process input as frames or samples

Set this property to `true` to enable frame-based processing for 2-D inputs. Set this property to `false` to enable sample-based processing. The object always performs sample-based processing for N-D inputs where N is greater than 2. This property applies when you set the `RunningMinimum` to `true`. The default is `true`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

### **OverflowAction**

Action to take when integer input is out-of-range

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`.

## **ProductDataType**

Data type of product

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType property to Custom. The default is numeric type([],32,30).

## **AccumulatorDataType**

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as product | Same as input | Custom |. The default is Same as product.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType property to Custom. The default is numeric type([],32,30).

## **Methods**

clone	Create minimum-finding object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of minimum-finding object
step	Operate on inputs to calculate outputs

## Examples

Find a minimum value and its index:

```
hmin1 = dsp.Minimum;  
x = randn(100,1);  
[y, I] = step(hmin1, x);
```

---

Compute a running minimum:

```
hmin2 = dsp.Minimum;  
hmin2.RunningMinimum = true;  
x = randn(100,1);  
y = step(hmin2, x);  
% y(i) is the minimum of all values in the vector x(1:i)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Minimum block reference page. The object properties correspond to the block parameters, except:

**Treat sample-based row input as a column** block parameter is not supported by the dsp.Minimum object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input**

# dsp.Minimum

---

**processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

## See Also

dsp.Maximum | dsp.Mean

<b>Purpose</b>	Create minimum-finding object with same property values
<b>Syntax</b>	<code>C = clone(H)</code>
<b>Description</b>	<code>C = clone(H)</code> creates a Minimum object C, with the same property values as H. The <code>clone</code> method creates a new unlocked object with uninitialized states.

# **dsp.Minimum.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.Minimum.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `Minimum` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

## **dsp.Minimum.reset**

---

**Purpose**            Reset internal states of minimum-finding object

**Syntax**            reset(H)

**Description**        reset(H) sets the internal states of the Minimum object H to their initial values.

## Purpose

Operate on inputs to calculate outputs

## Syntax

```
[VAL,IND] = step(H,X)
VAL = step(H,X)
IND = step(H,X)
VAL = step(H,X,R)
[...] = step(H,I,ROI)
[...] = step(H,I,LABEL,LABELNUMBERS)
[... ,FLAG] = step(H,I,ROI)
[... ,FLAG] = step(H,I,LABEL,LABELNUMBERS)
```

## Description

`[VAL,IND] = step(H,X)` returns the minimum value, `VAL`, and the index or position of the minimum value, `IND`, along the specified Dimension of `X`.

`VAL = step(H,X)` returns the minimum value, `VAL`, of the input `X`. When the `RunningMinimum` property is true, `VAL` corresponds to the minimum value over successive calls to the `step` method.

`IND = step(H,X)` returns the zero- or one-based index `IND` of the minimum value when the `IndexOutputPort` property is true and the `ValueOutputPort` property is false. You must set the `RunningMinimum` property to false to use this syntax.

`VAL = step(H,X,R)` resets the state of `H` based on the value of reset signal, `R`, and the `ResetCondition` property. To enable this type of processing, set the `RunningMinimum` property to true and the `ResetInputPort` property to true.

`[...] = step(H,I,ROI)` computes the minimum of an input image, `I`, within the given region of interest, `ROI`. To enable this type of processing, set the `ROIProcessing` property to true and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`[...] = step(H,I,LABEL,LABELNUMBERS)` computes the minimum of an input image, `I`, for a region whose labels are specified in the vector `LABELNUMBERS`. This property applies only when you set the `ROIProcessing` property to true and the `ROIForm` property to `Label matrix`.

[ ...,FLAG] = step(H,I,ROI) returns FLAG, indicating whether the given region of interest is within the image bounds. To enable this type of processing, set the ROIProcessing and ValidityOutputPort properties to true and the ROIForm property to Lines, Rectangles or Binary mask.

[ ...,FLAG] = step(H,I,LABEL,LABELNUMBERS) returns FLAG, indicating whether the input label numbers are valid. To enable this type of processing, set the ROIProcessing and ValidityOutputPort properties to true and the ROIForm property to Label matrix.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the value of the ROIForm property as Rectangles.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

**Purpose** Read video frames, audio samples, or both from multimedia file

---

**Note** MultimediaFileReader will be removed in a future release. Use AudioFileReader instead. See dsp.AudioFileReader.

---

**Description** The MultimediaFileReader object reads video frames, audio samples, or both from a multimedia file.

To read video frames, audio samples, or both from a multimedia file:

- 1** Define and set up your multimedia file reader. See “Construction” on page 3-947.
- 2** Call `step` to read from a multimedia file according to the properties of `signalblks.MultimediaFileReader`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = signalblks.MultimediaFileReader` returns a multimedia file reader System object, `H`, to read video and/or audio from a multimedia file.

`H = signalblks.MultimediaFileReader('PropertyName',PropertyValue,...)` returns a multimedia file reader System object, `H`, with each specified property set to the specified value.

`H = signalblks.MultimediaFileReader(FILENAME,'PropertyName',PropertyValue,...)` returns a multimedia file reader System object, `H`, with `Filename` property set to `FILENAME` and other specified properties set to the specified values.

**Properties** **Filename**

Name of multimedia file from which to read

# signalblks.MultimediaFileReader

---

Specify the name of a multimedia file as a string. Specify the full path for the file only if the file is not on the MATLAB path. On UNIX platforms, the multimedia file reader only supports uncompressed AVI files. The default is `speech_dft.avi`.

## **PlayCount**

Number of times to play file

Specify a positive integer or `inf` to represent the number of times to play the file. The default is `inf`.

## **AudioOutputPort**

Choose to output audio data

Use this property to control the audio output from the multimedia file reader. This property applies only when a multimedia file contains both audio and video streams. The default is `true`.

## **VideoOutputPort**

Choose to output video data

Use this property to control the video output from the multimedia file reader. This property only applies when a multimedia file contains both audio and video streams. The default is `false`.

## **SamplesPerAudioFrame**

Number of samples per audio frame

Specify the number of samples per audio frame as a positive scalar integer value. This property applies when the multimedia file contains only audio data. The default is `1024`.

## **ImageColorSpace**

Choose whether output is RGB, intensity, or YCbCr

Specify whether you want the multimedia file reader to output RGB, Intensity, or YCbCr 4:2:2 video frames. This property applies only when the multimedia file contains video. The default is RGB.

## VideoOutputDataType

Data type of video data output

Set the data type of the video data output from the multimedia file reader. The multimedia file reader supports the following output data types: `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32` or `Inherit`. This property applies if the multimedia file contains video. The default is `single`.

## AudioOutputDataType

Data type of audio samples output

Set the data type of the audio data output from the multimedia file reader. The multimedia file reader supports the following output data types: `double`, `single`, `int16`, `uint8`. This property applies only if the multimedia file contains audio. The default is `int16`.

## Methods

<code>clone</code>	Create multimedia file reader object with same property values
<code>close</code>	Release resources
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>info</code>	Information about specific multimedia file
<code>isDone</code>	End-of-file status (logical)
<code>isLocked</code>	Locked status for input attributes and nontunable properties

# signalblks.MultimediaFileReader

---

reset	Reset internal states of multimedia file reader to read from beginning of file
step	Output one frame of video frames, audio samples, or both to multimedia signal

## Examples

Read an audio file and play the file back using the standard audio output device:

```
hmfr = signalblks.MultimediaFileReader('speech_dft.avi');
hap = dsp.AudioPlayer('SampleRate', 22050);
while ~isDone(hmfr)
    audio = step(hmfr);
    step(hap, audio);
end
close(hmfr); % close the input file
close(hap); % close the audio output device
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs EOF as the last output.
- The **Multimedia outputs** block parameter corresponds to both the AudioOutputPort and the VideoOutputPort object properties.
- The object has no corresponding property for the **Image signal** block parameter. The object always outputs an  $M$ -by- $N$ -by- $P$  color video signal.

**See Also**

`signalblks.MultimediaFileWriter`

# signalblks.MultimediaFileReader.clone

---

**Purpose** Create multimedia file reader object with same property values

---

**Note** MultimediaFileReader will be removed in a future release. Use AudioFileReader instead. See dsp.AudioFileReader.clone.

---

**Syntax** C = clone(H)

**Description** C = clone(H) creates a MultimediaFileReader System object C, with the same property values as H.

The clone method creates a new unlocked object with uninitialized states.

**Purpose** Release resources

---

**Note** MultimediaFileReader will be removed in a future release. Use AudioFileReader instead. See dsp.AudioFileWriter.release .

---

**Syntax** close(H)

**Description** close(H) releases system resources (such as memory, file handles or hardware connections).

# signalblks.MultimediaFileReader.getNumInputs

---

**Purpose** Number of expected inputs to step method

---

**Note** MultimediaFileReader will be removed in a future release. Use AudioFileReader instead. See dsp.AudioFileReader.getNumInputs.

---

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of outputs, N, to the step method

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(H).

# signalblks.MultimediaFileReader.getNumOutputs

---

**Purpose** Number of outputs of step method

---

**Note** MultimediaFileReader will be removed in a future release. Use AudioFileReader instead. See dsp.AudioFileReader.getNumOutputs.

---

**Syntax** N = getNumOutputs(H)

**Description** N = getNumOutputs(H) returns the number of outputs, N, of the step method

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

# signalblks.MultimediaFileReader.info

**Purpose** Information about specific multimedia file

---

**Note** MultimediaFileReader will be removed in a future release. Use AudioFileReader instead. See dsp.AudioFileReader.info.

---

**Syntax** S = info(H)

**Description** S = info(H) returns a MATLAB structure, S, with information about the multimedia file specified in the Filename property. The number of fields for S varies depending on the audio or video content of the file. The possible fields and values for the structure S are shown in the following table.

Field	Value
Audio	Logical value indicating if the file has audio content.
Video	Logical value indicating if the file has video content.
AudioSampleRate	Audio sampling rate of the multimedia file in hertz. This field is available when the file has audio content.
AudioNumBits	Number of bits used to encode the audio stream. This field is available when the file has audio content.
AudioNumChannels	Number of audio channels. This field is available when the file has audio content.
FrameRate	Frame rate of the video stream in frames per second. The value may vary from the actual frame rate of the recorded video, and considers any synchronization issues between audio and video streams when the file contains both audio and video content. This variation indicates that video frames may be dropped if the audio stream leads the video stream by more than 1/(actual video frames per second). This field is available when the file has video content.

Field	Value
VideoSize	Video size as a two-element numeric vector of the form [VideoWidthInPixels, VideoHeightInPixels]. This field is available when the file has video content.
VideoFormat	Video signal format. This field is available when the file has video content.

# signalblks.MultimediaFileReader.isDone

---

**Purpose** End-of-file status (logical)

---

**Note** `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.isDone`.

---

**Syntax** STATUS = `isDone`(H)

**Description** STATUS = `isDone`(H) returns a logical value, STATUS , when the `MultimediaFileReader` object, H , reaches the end of the multimedia file. If you set the `PlayCount` property to a value greater than 1 , STATUS is true each time the object reaches the end of the file. STATUS is the same as the EOF output value in the process method syntax.

# signalblks.MultimediaFileReader.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

---

**Note** `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.isLocked`.

---

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `MultimediaFileReader` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# signalblks.MultimediaFileReader.reset

---

**Purpose** Reset internal states of multimedia file reader to read from beginning of file

---

**Note** `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.reset`.

---

**Syntax** `reset(H)`

**Description** `reset(H)` resets the `MultimediaFileReader` object to read from the beginning of the file.

**Purpose** Output one frame of video frames, audio samples, or both to multimedia signal

---

**Note** MultimediaFileReader will be removed in a future release. Use AudioFileReader instead. See dsp.AudioFileReader.step.

---

**Syntax**

```
AUDIO = step(H)
I = step(H)
[I,AUDIO] = step(H)
[... ,EOF] = step(H)
[Y,CB,CR] = step(H)
[Y,CB,CR,AUDIO] = step(H)
```

**Description**

AUDIO = step(H) outputs one frame of audio samples, AUDIO. This behavior requires the AudioOutputPort property to be true and an input file that contains audio data. After the object plays the file the number of times PlayCount specifies, AUDIO contains silence.

I = step(H) outputs one frame of multidimensional video signal, I. To obtain this behavior, set the VideoOutputPort property to true and use an input file that contains video data.

[I,AUDIO] = step(H) outputs one frame of multidimensional video signal, I , and one frame of audio samples, AUDIO . This behavior requires the AudioOutputPort and VideoOutputPort properties to be true and an input file that contains audio and video data.

[... ,EOF] = step(H) gives the end-of-file indicator in EOF. EOF is true each time the output contains the last audio sample and/or video frame in the file.

[Y,CB,CR] = step(H) outputs one frame of YCbCr 4:2:2 video data in the color components Y, CB, and CR. This behavior applies when you set the VideoOutputPort property to true, the ImageColorSpace property to YCbCr 4:2:2, and an input file which contains video data.

## signalblks.MultimediaFileReader.step

---

[Y,CB,CR,AUDIO] = step(H) outputs one frame of YCbCr 4:2:2 video data in the color components Y, CB, and CR, and one frame of audio samples in AUDIO. This applies when you set the AudioOutputPort and VideoOutputPort properties to true, the ImageColorSpace property to YCbCr 4:2:2, and an input file which contains audio and video data.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Purpose** Write video frames, audio samples, or both to multimedia file

---

**Note** MultimediaFileWriter will be removed in a future release. Use AudioFileWriter instead. See dsp.AudioFileWriter.

---

**Description** The MultimediaFileWriter object writes video frames, audio samples, or both to a multimedia file.

To write video frames, audio samples, or both to a multimedia file:

- 1** Define and set up your multimedia file writer. See “Construction” on page 3-963.
- 2** Call step to write to a multimedia file according to the properties of signalblks.MultimediaFileWriter. The behavior of step is specific to each object in the toolbox.

**Construction** H = signalblks.MultimediaFileWriter returns a multimedia file writer System object, H, that writes video frames, audio samples, or both to a multimedia file (such as an AVI file).

H =  
signalblks.MultimediaFileWriter('PropertyName',PropertyValue,...)  
returns a multimedia file writer System object, H, with each specified property set to the specified value.

H =  
signalblks.MultimediaFileWriter(FILENAME,'PropertyName',PropertyValue...)  
returns a multimedia file writer System object, H, with Filename property set to FILENAME and other specified properties set to the specified values.

**Properties** **Filename**

Name of multimedia file to which to write

Specify the name of the multimedia file as a string. The default is `output.avi`.

## **FileFormat**

Multimedia file format

Specify which multimedia file format the object writes. On Microsoft platforms, select AVI, WAV, WMV, or WMA. These abbreviations correspond to the following file formats:

- WAV: Microsoft WAVE Files
- WMV: Windows Media Video
- WMA: Windows Media Audio
- AVI: Audio-Video Interleave

The default setting for this property is AVI.

On all other platforms, the only selection is AVI.

## **AudioInputPort**

Choose to write audio data

Use this property to specify whether the multimedia file writer object writes audio samples to a multimedia file. When you enable both this property and `VideoInputPort`, ensure that the video and audio input signals have the same frame period. Adjust the frame size (or number of rows) of the audio signal so that the frame period of the video signal is the same as the frame period of the audio signal. Calculate frame size by dividing the audio signal frequency by the frame rate of the video signal. The audio signal frequency is in samples per second (specified by `SampleRate`). The video signal frame rate is in frames per second (specified by `FrameRate`). The default selection for this property is `true`.

The multimedia file object takes a column vector as an input. Every column is a separate channel and each row corresponds to a single audio sample.

## **VideoInputPort**

Choose to write video data

Use this property to specify whether the multimedia file writer object writes video frames to a multimedia file. When you enable both this property and the `AudioInputPort` property, ensure that the video and audio input signals have the same frame period. Adjust frame size (or number of rows) for the audio signal so the frame period is equal of both the video signal and the audio signal. Calculate frame size by dividing the audio signal frequency by the frame rate of the video signal. The audio signal frequency is in samples per second (specified by `SampleRate`). The video signal frame rate is in frames per second (specified by `FrameRate`). The default selection for this property is `false`

## **AudioCompressor**

Algorithm that compresses audio data

Specify the type of compression algorithm the multimedia file writer uses to compress the audio data. Compression reduces the size of the multimedia file. Select `None` (uncompressed) to save uncompressed audio data to a multimedia file. The other options available reflect the audio compression algorithms installed on your system. This property is only available when writing WAV or AVI files on Windows platforms.

## **VideoCompressor**

Algorithm that compresses video data

Specify the type of compression algorithm to multimedia file writer uses to compress the video data. This compression reduces the size of the multimedia file. Choose `None` (uncompressed) to save uncompressed video data to a multimedia file. The other options reflect the available video compression algorithms installed on your system. This property is only available when writing AVI files on Windows platforms.

## **SampleRate**

# signalblks.MultimediaFileWriter

---

Sampling rate of audio data stream

Specify the sampling rate of the input audio data as a positive numeric scalar. The default is 44100. This property only applies when you set the `AudioInputPort` property to `true`.

## **FrameRate**

Frame rate of video data stream

Specify the frame rate of the video data in frames per second as a positive numeric scalar. The default is 30. This property only applies when you set the `VideoInputPort` property to `true`.

## **AudioDataType**

Data type of the uncompressed audio

Specify the type of uncompressed audio data written to the file. This property only applies when writing uncompressed WAV files.

## **FileColorSpace**

Color space to use when creating a file

Specify the color space of AVI files as `RGB` or `YCbCr 4:2:2`. This property only applies on Windows platforms when you set the `FileFormat` property to `AVI`. The default is `RGB`.

## **Methods**

<code>clone</code>	Create multimedia file writer object with the same property values
<code>close</code>	Release resources
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
step	Write one frame of audio output samples

## Examples

Decimate an audio signal, and write signal to disk as an AVI file:

```
hmfr = signalblks.MultimediaFileReader...
    ('AudioOutputDataType','double');
hfirdec = dsp.FIRDecimator; % decimate by 2
hmfw = signalblks.MultimediaFileWriter...
    ('speech_dft_11025.avi', ...
    'SampleRate', 22050/2);

while ~isDone(hmfr)
    audio = step(hmfr);
    audiod = step(hfirdec, audio);
    step(hmfw, audiod);
end

close(hmfr);
close(hmfw);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the To Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The **Write** block parameter corresponds to both the AudioOutputPort and the VideoOutputPort object properties.
- The FrameRate and SampleRate properties are not available on the block. The block inherits these signals from the input line connected to the ports.

# signalblks.MultimediaFileWriter

---

## **See Also**

`signalblks.MultimediaFileReader`

**Purpose**

Create multimedia file writer object with the same property values

---

**Note** MultimediaFileWriter will be removed in a future release. Use AudioFileWriter instead. See dsp.AudioFileWriter.clone.

---

**Syntax**

C = clone(H)

**Description**

C = clone(H) creates a MultimediaFileWriter System object C, with the same property values as H. The clone method creates a new unlocked object.

# signalblks.MultimediaFileWriter.close

---

**Purpose** Release resources

---

**Note** MultimediaFileWriter will be removed in a future release. Use AudioFileWriter instead. See dsp.AudioFileWriter.release.

---

**Syntax** close(H)

**Description** close(H) releases system resources (such as memory, file handles or hardware connections).

# signalblks.MultimediaFileWriter.getNumInputs

---

**Purpose** Number of expected inputs to step method

---

**Note** MultimediaFileWriter will be removed in a future release. Use AudioFileWriter instead. See dsp.AudioFileWriter.getNumInputs.

---

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of expected inputs, N, of the step method

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(H).

# signalblks.MultimediaFileWriter.getNumOutputs

---

**Purpose** Number of outputs of step method

---

**Note** MultimediaFileWriter will be removed in a future release. Use AudioFileWriter instead. See dsp.AudioFileWriter.getNumOutputs.

---

**Syntax** N = getNumOutputs(H)

**Description** N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

# signalblks.MultimediaFileWriter.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

---

**Note** MultimediaFileWriter will be removed in a future release. Use AudioFileWriter instead. See dsp.AudioFileWriter.isLocked.

---

**Syntax** isLocked(H)

**Description** isLocked(H) returns the locked state of the MultimediaFileWriter System object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

# signalblks.MultimediaFileWriter.step

---

## Purpose

Write one frame of audio output samples

---

**Note** `MultimediaFileWriter` will be removed in a future release. Use `AudioFileWriter` instead. See `dsp.AudioFileWriter.step`.

---

## Syntax

```
step(H,AUDIO)
step(H,I)
step(H,I,AUDIO)
step(H,Y,Cb,Cr)
step(H,Y,CB,CR)
step(H,Y,CB,CR,AUDIO)
```

## Description

`step(H,AUDIO)` writes one frame of audio samples, `AUDIO`, to the output file when you enable the `AudioInputPort` property. `AUDIO` is either a vector or an  $M$ -by-2 matrix for mono or stereo inputs, respectively.

`step(H,I)` writes one frame of video, `I`, to the output file when you enable the `VideoInputPort` property. `I` is an  $M$ -by- $N$ -by-3 color video signal.

`step(H,I,AUDIO)` writes one frame of video, `I`, and one frame of audio samples, `AUDIO`, to the output file when you enable both the `AudioInputPort` and `VideoInputPort` properties.

`step(H,Y,Cb,Cr)` writes one frame of video with `Y`, `Cb`, `Cr` components to the file. This applies only when you set the `FileColorSpace` property to `YCbCr 4:2:2`

`step(H,Y,CB,CR)` writes one frame of `YCbCr 4:2:2` data in the color components `Y`, `CB`, and `CR`, to the output file when you set the `VideoInputPort` property to `true`. The width of `CB` and `CR` must be half of the width of `Y`, and the value of the `FileColorSpace` property must be set to `YCbCr 4:2:2`.

`step(H,Y,CB,CR,AUDIO)` writes one frame of `YCbCr 4:2:2` data in the color components `Y`, `CB`, and `CR`, and one frame of audio samples, `AUDIO`, to the output file when you set both the `AudioInputPort` and

VideoInputPort properties to true. The width of CB and CR must be half of the width of Y, and the value of the FileColorSpace property must be set to YCbCr 4:2:2.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Purpose** Generate real or complex sinusoidal signals

**Description** The numerically controlled oscillator, or NCO, object generates real or complex sinusoidal signals. The amplitude of the generated signal is always 1.

To generate real or complex sinusoidal signals:

- 1 Define and set up your NCO System object. See “Construction” on page 3-976.
- 2 Call `step` to generate the signals according to the properties of `dsp.NCO`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.NCO` returns an NCO System object, `H`, that generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel.

`H = dsp.NCO('PropertyName',PropertyValue,...)` returns an NCO System object, `H`, with each specified property set to the specified value.

## Properties

### PhaseIncrementSource

Source of phase increment

Indicate how to specify the phase increment: `Property` or `Input port`. The default is `Input port`.

### PhaseIncrement

Phase increment

Specify the phase increment as an integer scalar. This property applies only when you set the `PhaseIncrementSource` property to `Property`. The default is 100.

### PhaseOffsetSource

Source of phase offset

Specify the phase offset as Property or Input port. The default is Property.

**PhaseOffset**

Phase offset

Specify the phase offset as an integer scalar. This property applies only when you set the PhaseOffsetSource property to Property. The default is 0.

**Dither**

Enable adding internal dithering to NCO algorithm

Set this property to true to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator from the Communications System Toolbox product. The default is true.

**NumDitherBits**

Number of dither bits

Specify the number of dither bits as a positive integer. This property applies only when you set the Dither property to true. The default is 4.

**PhaseQuantization**

Enable quantization of accumulated phase

Set this property to true to enable quantization of the accumulated phase. The default is true.

**NumQuantizerAccumulatorBits**

Number of quantizer accumulator bits

Specify the number of quantizer accumulator bits as an integer scalar greater than 1 and less than the accumulator word length. This property determines the number of entries in the lookup table of sine values. This property applies only when you set the PhaseQuantization property to true. The default is 12.

## **PhaseQuantizationErrorOutputPort**

Enable output of phase quantization error

Set this property to `true` to output the phase quantization error. This property applies only when you set the `PhaseQuantization` property to `true`. The default is `false`.

## **Waveform**

Type of output signal

Specify the type of the output signal: `Sine`, `Cosine`, `Complex exponential` or `Sine and cosine`. The default is `Sine`.

## **SamplesPerFrame**

Number of output samples per frame

Specify the number of samples per frame of the output signal. This property applies only when you set the `PhaseOffsetSource` property to `Property`. The default is `1`. When the `PhaseOffsetSource` property is `Input port`, and the `PhaseIncrementSource` property is `Property`, the number of rows or frame size of the phase offset input determines the number of samples per frame of the output signal. When you set both the `PhaseOffsetSource` and `PhaseIncrementSource` properties to `Input port`, the number of rows in the inputs must be `1`, and the samples per frame of the output signal is `1`.

## **OutputDataType**

Output data type

Specify the output data type as one of `double`, `single` or `Custom`. The default is `Custom`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

This constant property has a value `Floor`.

### **OverflowAction**

Overflow action for fixed-point operations

This constant property has a value `Wrap`.

### **AccumulatorDataType**

Accumulator word and fraction lengths

This constant property has a value `Custom`.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as an unscaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([],16)`.

### **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,14)`.

## **Methods**

<code>clone</code>	Create NCO object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>info</code>	Characteristic information about generated signal

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset accumulator of NCO object
step	Sinusoidal signal with specified phase increment

## Examples

Design an NCO source according to given specifications:

```
F0 = 510; % Output frequency = 510 Hz
df = 0.05; % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/8000; % Sample period = 1/8000 sec
dphi = pi/2; % Desired phase offset = pi/2;
```

Calculate number of accumulator bits required for the given frequency resolution

```
Nacc = ceil(log2(1/(df*Ts)));
% Actual frequency resolution achieved
actdf = 1/(Ts*2^Nacc);
% Calculate number of quantized accumulator bits
% required from the SFDR requirement
Nqacc = ceil((minSFDR-12)/6);
% Calculate the phase increment
phIncr = round(F0*Ts*2^Nacc);
% Calculate the phase offset
phOffset = 2^Nacc*dphi/(2*pi);

hnco = dsp.NCO('PhaseIncrementSource', 'Property', ...
'PhaseIncrement', phIncr,...
'PhaseOffset', phOffset,...
'NumDitherBits', 4, ...
'NumQuantizerAccumulatorBits', Nqacc,...
```

```
'SamplesPerFrame', 1/Ts, ...  
'CustomAccumulatorDataType', numerictype([],Nacc));  
  
y = step(hnco);  
% Plot the mean-square spectrum of the 510 Hz sinewave  
% generated by the NCO  
periodogram(double(y),hann(length(y),'periodic'),[],1/Ts,'power');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the NCO block reference page. The object properties correspond to the block properties, except:

There is no object property that corresponds to the **Sample time** block parameter. The objects assumes a sample time of one second.

## See Also

dsp.SineWave

# dsp.NCO.clone

---

**Purpose** Create NCO object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an NCO system object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.NCO.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Characteristic information about generated signal

**Syntax** `S = info(H)`

**Description** `S = info(H)` returns a structure containing characteristic information, `S`, about the signal being generated by the NCO System object, `H`. The number of fields of `S`, and their values vary depending on the property value settings of `H`. For description of the possible fields and their values, see the following table.

Field	Value
NumPointsLUT	Number of data points for lookup table. The lookup table is implemented as a quarter-wave sine table.
SineLUTSize	Quarter-wave sine lookup table size in bytes.
TheoreticalSFDR	Theoretical spurious free dynamic range (SFDR) in dBc. This field applies when you set the <code>PhaseQuantization</code> property to <code>true</code> .
FrequencyResolution	Frequency resolution of the NCO in Hz. The sample time of the output signal is assumed to be 1 sec.

# dsp.NCO.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** isLocked(H)

**Description** isLocked(H) returns the locked state of the NCO System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

## **dsp.NCO.reset**

---

**Purpose**            Reset accumulator of NCO object

**Syntax**            reset(H)

**Description**        reset(H) resets the accumulator of the NCO System object, H, to zero.

<b>Purpose</b>	Sinusoidal signal with specified phase increment
<b>Syntax</b>	<pre>Y = step(H, INC) Y = step(H) Y = step(H, OFFSET) Y = step(H, INC, OFFSET) [Y, QERR] = step(H, ...)</pre>
<b>Description</b>	<p><code>Y = step(H, INC)</code> returns a sinusoidal signal, <code>Y</code>, generated by the NCO with the specified phase increment, <code>INC</code>. <code>INC</code> must be a built-in integer or a <code>fi</code> object comprising either a scalar or a row vector, where each row element corresponds to a separate channel.</p> <p><code>Y = step(H)</code> when the <code>PhaseIncrementSource</code> and <code>PhaseOffsetSource</code> properties are both <code>Property</code>, returns a sinusoidal signal, <code>Y</code>.</p> <p><code>Y = step(H, OFFSET)</code> returns a sinusoidal signal, <code>Y</code>, with phase offset, <code>OFFSET</code>, when the <code>PhaseOffsetSource</code> property is <code>Input port</code>. <code>OFFSET</code> must be a built-in integer or a <code>fi</code> object. The number of rows of <code>OFFSET</code> determines the number of samples per frame of the output signal. The number of columns of the <code>OFFSET</code> determines the number of channels of the output signal.</p> <p><code>Y = step(H, INC, OFFSET)</code> returns a sinusoidal signal, <code>Y</code>, with phase increment, <code>INC</code>, and phase offset, <code>OFFSET</code>, when the <code>PhaseIncrementSource</code> and the <code>PhaseOffsetSource</code> properties are both <code>Input port</code>. <code>INC</code> and <code>OFFSET</code> must both be row vectors of the same length, where the length determines the number of channels in the output signal.</p> <p><code>[Y, QERR] = step(H, ...)</code> when the <code>PhaseQuantization</code> and the <code>PhaseQuantizationErrorOutputPort</code> properties are both <code>true</code>, returns a sinusoidal signal, <code>Y</code>, and output quantization error, <code>QERR</code>.</p>

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Vector normalization along specified dimension
<b>Description</b>	<p>The Normalizer object performs vector normalization along rows, columns, or specified dimension.</p> <p>To perform vector normalization:</p> <ol style="list-style-type: none"><li>1 Define and set up your normalization object. See “Construction” on page 3-991.</li><li>2 Call <code>step</code> to perform vector normalization according to the properties of <code>dsp.Normalizer</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.Normalizer</code> returns a normalization object, <code>H</code>, that normalizes the input over each column by the squared 2-norm of the column plus a bias term of <math>1e-10</math> used to protect against divide-by-zero.</p> <p><code>H = dsp.Normalizer('PropertyName',PropertyValue, ...)</code> returns a normalization object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>Method</b></p> <p>Type of normalization to perform</p> <p>Specify the type of normalization to perform as 2-norm or Squared 2-norm. The 2-norm mode supports floating-point signals only. The Squared 2-norm supports both fixed-point and floating-point signals. The default is Squared 2-norm.</p> <p><b>Bias</b></p> <p>Real number added in denominator to avoid division by zero</p> <p>Specify the real number to add in the denominator to avoid division by zero. The default is <math>1e-10</math>. This property is tunable.</p> <p><b>Dimension</b></p> <p>Dimension to operate along</p>

# dsp.Normalizer

---

Specify whether to normalize along `Column`, `Row`, or `Custom`. The default is `Column`.

## **CustomDimension**

Numerical dimension to operate along

Specify the one-based value of the dimension over which to normalize. The value of this parameter cannot exceed the number of dimensions in the input signal. This property applies when `Dimension` property is `Custom`. The default is 1.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

### **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of `Same as input` or `Custom`.

### **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default to `numericType([],32,32)`.

## AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of Same as product, Same as input, Custom. The default is Same as product.

## CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of Same as accumulator, Same as product, Same as input, Custom. The default is Same as product.

## CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([],32,32)`.

## Methods

<code>clone</code>	Create normalization object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method

# dsp.Normalizer

---

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Normalize input along specified dimension

## Examples

Normalize a matrix:

```
hnorm = dsp.Normalizer;  
x = magic(3);  
y = step(hnorm, x);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Normalization block reference page. The object properties correspond to the block parameters, except:

- **Treat sample-based row input as column** — The block allows you to input a row vector and normalize the row vector as a column vector. The normalization object always normalizes along the value of the `Dimension` property.
- The normalization object does not support the **Minimum** and **Maximum** options for data output.

## See Also

`dsp.ArrayVectorMultiplier`

**Purpose** Create normalization object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a normalizer object, `C`, with the same property values. The clone method creates a new unlocked object.

# dsp.Normalizer.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.Normalizer.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the normalization object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

# dsp.Normalizer.step

---

**Purpose** Normalize input along specified dimension

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  returns a normalized output  $Y$ . The input  $X$  must be floating-point for the 2-norm mode, and either fixed-point and floating-point for the Squared 2-norm mode.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Purpose

Determine extrema (maxima or minima) in input signal

## Description

The PeakFinder object determines the extrema (maxima or minima) in the input signal.

To compute the extrema in the input signal:

- 1 Define and set up your peak finder. See “Construction” on page 3-1001.
- 2 Call `step` to compute the extrema according to the properties of `dsp.PeakFinder`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.PeakFinder` returns a peak finder System object, `H`, that compares the current signal value to the previous and next values to determine if the current value is an extremum.

`H = dsp.PeakFinder('PropertyName',PropertyValue,...)` returns a peak finder System object, `H`, with each specified property set to the specified value.

## Properties

### PeakType

Looking for maxima, minima, or both

Specify whether the object is looking for maxima, minima, or both. You can set this property to `oMaxima`, `Minima`, `Maxima` and `Minima`. The default is `Maxima` and `Minima`.

### PeakIndicesOutputPort

Enable output of extrema indices

Set this property to `true` to output the extrema indices. The default is `false`.

### PeakValuesOutputPort

Enable output of extrema values

# dsp.PeakFinder

---

Set this property to `true` to output the extrema values. The default is `false`.

## **MaximumPeakCount**

Number of extrema to look for in each input signal

The object stops searching the input signal for extrema after the maximum number of extrema has been found. The value of this property must be an integer greater than or equal to one. The default is 10.

## **IgnoreSmallPeaks**

Enable ignoring peaks below threshold

Set this property to `true` if you want to eliminate the detection of peaks whose amplitudes are within a specified threshold of neighboring values. The default is `false`.

## **PeakThreshold**

Threshold below which peaks are ignored

Specify the noise threshold value. This property defines the current input value as a maximum if:

- The current input value minus the previous input value is greater than the threshold, and
- The current input value minus next input value is greater than the threshold.

This property applies when you set the `IgnoreSmallPeaks` property to `true`. The default is 0.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

The rounding method is a constant property set to `Floor`.

## OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as Wrap or Saturate. The default is Wrap.

## Methods

clone	Create peak finder object with same property values
getNumInputs	Number of expected inputs to the step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Number of extrema in input signal

## Examples

Determine whether each value of an input signal is local maximum or minimum:

```
hpeaks1 = dsp.PeakFinder;
hpeaks1.PeakIndicesOutputPort = true;
hpeaks1.PeakValuesOutputPort = true;

x1 = [9 6 10 3 4 5 0 12]';
% Find the peaks of each input
% [prev;cur;next]: {[9;6;10],[6;10;3],...}
[cnt1, idx1, val1, pol1] = step(hpeaks1, x1);
```

---

Determine peak values for a fixed-point input signal:

# dsp.PeakFinder

---

```
hpeaks2 = dsp.PeakFinder('PeakType', 'Maxima', ...  
    'PeakValuesOutputPort', true, ...  
    'MaximumPeakCount', 2, ...  
    'IgnoreSmallPeaks', true, ...  
    'PeakThreshold', 0.25, ...  
    'OverflowAction', 'Saturate');  
x2 = fi([-1;0.5;0],true,16,15);  
[cnt2, val2] = step(hpeaks2, x2);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Peak Finder block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.Maximum](#) | [dsp.Minimum](#)

**Purpose** Create peak finder object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a PeakFinder System object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

# **dsp.PeakFinder.getNumInputs**

---

**Purpose**            Number of expected inputs to the step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.PeakFinder.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `PeakFinder System` object. The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.PeakFinder.step

---

**Purpose** Number of extrema in input signal

**Syntax**  
YCNT = step(H,X)  
[YCNT,IDX] = step(H,X)  
[... , VAL] = step(H,X)  
[... , POL] = step(H,X)

**Description** YCNT = step(H,X) returns the number of extrema (minima, maxima, or both) YCNT in input signal X.

[YCNT,IDX] = step(H,X) when the `PeakIndicesOutputPort` property is true, returns the number of extrema YCNT and peak indices IDX in input signal X.

[... , VAL] = step(H,X) also returns the peak values VAL in input signal X when the `PeakValuesOutputPort` property is true.

[... , POL] = step(H,X) also returns the extrema polarity POL in input signal X when the `PeakType` property is `Maxima` and `Minima` and the `PeakIndicesOutputPort` property is true. The polarity is 1 for maxima and 0 for minima.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Peak-to-peak value
<b>Description</b>	<p>The PeakToPeak object computes the peak-to-peak value of an input. To obtain the peak-to-peak value:</p> <ol style="list-style-type: none"><li>1 Define and set up your peak-to-peak calculation. See “Construction” on page 3-1011.</li><li>2 Call <code>step</code> to compute the peak-to-peak value for an input vector according to the properties of <code>dsp.PeakToPeak</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.PeakToPeak</code> creates a peak-to-peak System object, <code>H</code>, that computes the difference between the maximum and minimum value in an input or a sequence of inputs.</p> <p><code>H = dsp.PeakToPeak('PropertyName',PropertyValue,...)</code> returns an <code>PeakToPeak</code> System object, <code>H</code>, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>CustomDimension</b></p> <p>Dimension to operate along. Specify the dimension as a positive integer along which the peak-to-peak difference is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when the <code>Dimension</code> property is 'Custom'.</p> <p><b>Default:</b> 1</p> <p><b>Dimension</b></p> <p>Dimension to operate along. Specify the dimension along which to calculate the peak-to-peak ratio as one of 'All', 'Row', 'Column', or 'Custom'. This property applies when the <code>RunningPeakToPeak</code> property is <code>false</code>. If you set this property to 'Custom', specify the dimension using the <code>CustomDimension</code> property.</p>

**Default:** 'Column'

## **FrameBasedProcessing**

Process input in frames or as samples. Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies when the `RunningPeakToPeak` property is `true`.

**Default:** `true`

## **ResetCondition**

Reset condition for running peak-to-peak mode. Specify the event to reset the running peak-to-peak as one of 'Rising edge', 'Falling edge', 'Either edge', or 'Non-zero'. This property applies when the `ResetInputPort` property is `true`.

## **ResetInputPort**

Enables resetting in running peak-to-peak mode. Set this property to `true` to enable resetting the running peak-to-peak. When the property is set to `true`, a reset input must be specified to the call of `step` to reset the running peak-to-peak difference. This property applies when the `RunningPeakToPeak` property is `true`.

**Default:** `false`

## **RunningPeakToPeak**

Calculation over successive calls to `step`. Set this property to `true` to enable the calculation of the peak-to-peak difference over successive calls to the `step`.

**Default:** `false`

## Methods

clone	Clones the current instance of the peak-to-peak object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status (logical) for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset the running peak-to-peak object
step	Compute peak-to-peak value

## Examples

### Peak-to-Peak Value of Vector

Determine the peak-to-peak value for a vector input.

```
in1 = (1:10)';  
h1 = dsp.PeakToPeak;  
y1 = step(h1, in1);
```

### Peak-to-Peak Value of Matrix Input

Determine the peak-to-peak value of a matrix input.

```
in2 = magic(4);  
h2 = dsp.PeakToPeak;  
h2.Dimension = 'All';  
y2 = step(h2, in2)
```

---

## **See Also**

[dsp.Maximum](#) | [dsp.PeakToRMS](#) |

<b>Purpose</b>	Clones the current instance of the peak-to-peak object
<b>Syntax</b>	<code>clone(H)</code>
<b>Description</b>	<code>clone(H)</code> clones the current instance of the peak-to-peak object, H.

# **dsp.PeakToPeak.getNumInputs**

---

**Purpose**            Number of expected inputs to the `step` method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the peak-to-peak object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose** Number of outputs of the `step` method

**Syntax** `N = getNumOutputs(H)`

**Description** `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method for the peak-to-peak object, `H`.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.PeakToPeak.isLocked**

---

**Purpose** Locked status (logical) for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the peak-to-peak object H.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

# **dsp.PeakToPeak.reset**

---

**Purpose**            Reset the running peak-to-peak object

**Syntax**            reset(H)

**Description**        reset(H) resets the running peak-to-peak value for the object H.

**Purpose** Compute peak-to-peak value

**Syntax**  
`Y = step(H,X)`  
`Y = step(H,X,R)`

**Description** `Y = step(H,X)` computes the peak-to-peak value, `Y`, of the floating-point input vector `X`. When the `RunningPeakToPeak` property is `true`, `Y` corresponds to the peak-to-peak value of the input elements over successive calls to the `step` method.

`Y = step(H,X,R)` computes the peak-to-peak value of the input elements over successive calls to the `step` method. The object optionally resets its state based on the reset input signal, `R`, and the value of the `ResetCondition` property. This is possible when you set both the `RunningPeakToPeak` and the `ResetInputPort` properties to `true`.

# dsp.PeakToRMS

---

**Purpose** Peak-to-root-mean-square value of vector

**Description** The PeakToRMS object calculates the peak-to-root-mean-square ratio of a vector.

To compute the peak-to-root-mean-square ratio:

- 1** Define and set up your peak-to-root-mean-square calculation. See “Construction” on page 3-1022.
- 2** Call `step` to calculate the peak-to-root-mean-square value for an input vector according to the properties of `dsp.PeakToRMS`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.PeakToRMS` creates a peak-to-root-mean-square System object, `H`, that returns the ratio of the maximum magnitude (peak) to the root-mean-square (RMS) value in an input or a sequence of inputs.

`H = dsp.PeakToRMS('PropertyName',PropertyValue,...)` returns an `PeakToRMS` System object, `H`, with each specified property set to the specified value.

## Properties

### CustomDimension

Numerical dimension to operate along. Specify the dimension as a positive integer along which the peak-to-RMS ratio is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when `Dimension` property is 'Custom'.

**Default:** 1

### DecibelScaledOutput

Report output in decibels (dB). Set this property to `true` to enable output in dB. Set this property to `false` to report output as a ratio.

**Default:** `true`

## **Dimension**

Dimension to operate along. Specify the dimension along which to calculate the peak-to-RMS ratio as one of 'All', 'Row', 'Column', or 'Custom'. This property applies when the `RunningPeakToRMS` property is false. If you set this property to 'Custom', specify the dimension using the `CustomDimension` property.

**Default:** 'Column'

## **FrameBasedProcessing**

Process input in frames or as samples. Set this property to true to enable frame-based processing. Set this property to false to enable sample-based processing. This property applies when the `RunningPeakToRMS` property is true.

**Default:** true

## **ResetCondition**

Reset condition for running peak-to-RMS mode. Specify the event to reset the running peak-to-RMS as one of 'Rising edge', 'Falling edge', 'Either edge', or 'Non-zero'. This property applies when the `ResetInputPort` property is true.

## **ResetInputPort**

Enables resetting in running peak-to-RMS mode. Set this property to true to enable resetting. When the property is set to true, a reset input must be specified in the call to `step` to reset the running peak-to-RMS ratio. This property applies when the `RunningPeakToRMS` property is true.

**Default:** false

## **RunningPeakToRMS**

# dsp.PeakToRMS

---

Calculation over successive calls to `step`. Set this property to `true` to enable the calculation of the peak-to-RMS ratio over successive calls to the `step`.

**Default:** `false`

## Methods

<code>clone</code>	Clones the current instance of the peak-to-root-mean-square object
<code>getNumInputs</code>	Number of expected inputs to the method
<code>getNumOutputs</code>	Number of outputs of the method
<code>isLocked</code>	Locked status (logical) for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset the running peak-to-root-mean-square object
<code>step</code>	Compute peak-to-RMS ratio

## Definitions

### Peak-magnitude-to-RMS Level

The peak-magnitude-to-RMS level is

$$\frac{\|X\|_{\infty}}{\sqrt{\frac{1}{N} \sum_{n=1}^N |X_n|^2}}$$

where the  $l$ -infinity norm and RMS values are computed along the specified dimension.

## Examples

### Peak-to-RMS Ratio of Vector Input

Determine the peak-to-RMS ratio of a vector input.

```
in1 = (1:10)';  
h1 = dsp.PeakToRMS;  
y1 = step(h1,in1);
```

### Peak-to-RMS Ratio of Matrix Input

Determine the peak-to-RMS ratio of a matrix input.

```
in2 = magic(4);  
h2 = dsp.PeakToRMS;  
h2.Dimension = 'All';  
y2 = step(h2, in2)
```

## **dsp.PeakToRMS.clone**

---

**Purpose** Clones the current instance of the peak-to-root-mean-square object

**Syntax** `clone(H)`

**Description** `clone(H)` clones the current instance of the peak-to-root-mean-square (RMS) object H.

**Purpose** Number of expected inputs to the step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the step method for the peak-to-root-mean-square object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.PeakToRMS.getNumOutputs

---

**Purpose**            Number of outputs of the `step` method

**Syntax**            `N = getNumOutputs(H)`

**Description**       `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

<b>Purpose</b>	Locked status (logical) for input attributes and nontunable properties
<b>Syntax</b>	isLocked(H)
<b>Description</b>	isLocked(H) returns the locked state of the peak-to-root-mean-square object H.

# **dsp.PeakToRMS.release**

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose**            Reset the running peak-to-root-mean-square object

**Syntax**            `reset(H)`

**Description**        `reset(H)` resets the running peak-to-root-mean-square value for the object H.

# **dsp.PeakToRMS.step**

---

**Purpose**            Compute peak-to-RMS ratio

**Syntax**             $Y = \text{step}(H,X)$   
                       $Y = \text{step}(H,X,R)$

**Description**       $Y = \text{step}(H,X)$  computes the peak-to-RMS ratio,  $Y$ , of the floating-point input vector  $X$ . When the `RunningPeakToRMS` property is `true`,  $Y$  corresponds to the peak-to-RMS ratio of the input elements over successive calls to the `step` method.

$Y = \text{step}(H,X,R)$  computes the peak-to-RMS ratio of the input elements over successive calls to the `step` method. The object optionally resets its state based on the reset input signal,  $R$ , and the value of the `ResetCondition` property. This is possible when you set both the `RunningPeakToRMS` and the `ResetInputPort` properties to `true`.

<b>Purpose</b>	Unwrap signal phase
<b>Description</b>	<p>The PhaseUnwrapper object unwraps the signal phase input specified in radians.</p> <p>To unwrap the signal phase input:</p> <ol style="list-style-type: none"><li>1 Define and set up your System object. See “Construction” on page 3-1033.</li><li>2 Call <code>step</code> to unwrap the signal phase according to the properties of <code>dsp.PhaseUnwrapper</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.PhaseUnwrapper</code> returns a System object, H. This System object adds or subtracts appropriate multiples of <math>2\pi</math> to each input element to remove phase discontinuities (unwrap).</p> <p><code>H = dsp.PhaseUnwrapper('PropertyName',PropertyValue,...)</code> returns an unwrapped System object, H, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>InterFrameUnwrap</b></p> <p>Enable unwrapping of phase discontinuities between successive frames</p> <p>Set this property to <code>false</code> to unwrap phase discontinuities only within the frame. Set this property to <code>true</code> to also unwrap phase discontinuities between successive frames. This property applies when you set the <code>FrameBasedProcessing</code> to <code>true</code>. The default is <code>true</code>.</p> <p><b>Tolerance</b></p> <p>Jump size as true phase discontinuity</p> <p>Specify the jump size that the phase unwrapper recognizes as a true phase discontinuity. The default is set to <math>\pi</math> (rather than a smaller value) to avoid altering legitimate signal features.</p>

# dsp.PhaseUnwrapper

---

To increase the phase wrapper sensitivity, set the `Tolerance` property to a value slightly less than  $\pi$ .

## FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

## Methods

<code>clone</code>	Create phase unwrapper object with same property values
<code>getNumInputs</code>	Number of expected inputs to the method
<code>getNumOutputs</code>	Number of outputs of the method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of Phase Unwrapper System object
<code>step</code>	Unwrap input phase signal input

## Examples

Unwrap input phase data:

```
hunwrap = dsp.PhaseUnwrapper;  
p = [0 2/5 4/5 -4/5 -2/5 0 2/5 4/5 -4/5 -2/5 0 2/5 ...  
    4/5 -4/5, -2/5]*pi;  
y = step(hunwrap, p');  
figure,stem(p); hold  
stem(y, 'r');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Unwrap block reference page. The object properties correspond to the Simulink block parameters.

Objects and blocks interpret frames differently. Objects process inputs as frames or as samples by setting the `FrameBasedProcessing` property. Blocks process inputs as frames or as samples by inheriting the frame information from the input ports. See “Set the `FrameBasedProcessing` Property of a System object” for more information.

**Description** `clone(H)` clones the current instance of the phase unwrapper object H.

# dsp.PhaseUnwrapper.getNumInputs

---

**Purpose**

Number of expected inputs to the step method

**Syntax**

`N = getNumInputs(H)`

**Description**

`N = getNumInputs(H)` returns the number of expected inputs to the step method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.PhaseUnwrapper.getNumOutputs**

---

**Purpose**            Number of outputs of the `step` method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of the `step` method  
The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

<b>Purpose</b>	Locked status for input attributes and nontunable properties
<b>Syntax</b>	isLocked(H)
<b>Description</b>	isLocked(H) returns the locked state of the phase unwrapper object H.

# dsp.PhaseUnwrapper.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset internal states of Phase Unwrapper System object

**Syntax** reset(H)

**Description** reset(H) resets the  $2\pi$  multiplier k to 0 for the phase unwrapper object H. See “Frame-Based Processing” on page 1-1713 for details.

# dsp.PhaseUnwrapper.step

---

**Purpose** Unwrap input phase signal input

**Syntax**  $Y = \text{step}(H, X)$

**Description**  $Y = \text{step}(H, X)$  unwraps the input signal  $X$  in radians for the root mean square (RMS) object  $H$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Purpose

Pulse metrics of bilevel waveforms

## Description

The `PulseMetrics` object computes rise times, fall times, pulse widths, and cycle metrics including pulse period, pulse separation, and duty cycle for bilevel waveforms.

To obtain pulse metrics for a bilevel waveform:

- 1 Define and set up your pulse metrics. See “Construction” on page 3-1043.
- 2 Call `step` to compute the pulse metrics according to the properties of `dsp.PulseMetrics`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.PulseMetrics` creates a pulse metrics System object, `H`. The object computes the rise time, fall time, and width of a pulse. `dsp.PulseMetrics` also computes cycle metrics such as pulse separations, periods, and duty cycles. Because a pulse contains two transitions, the object contains a superset of the capability defined in `dsp.TransitionMetrics`.

`H = dsp.PulseMetrics('PropertyName',PropertyValue,...)` returns a `PulseMetrics` System object, `H`, with each specified property set to the specified value.

## Properties

### CycleOutputPort

Enable cycle metrics. If `CycleOutputPort` is `true`, cycle metrics are reported for each pulse period.

**Default:** `false`

### MaximumRecordLength

Maximum samples to preserve between calls to `step`. This property requires a positive integer that specifies the maximum number of samples to save between calls to the `step` method. When the number of samples to be saved exceeds this length, the

oldest excess samples are discarded. This property applies when the `RunningMetrics` property is true and is tunable.

**Default:** 1000

## **PercentReferenceLevels**

Lower-, middle-, and upper-percent reference levels. This property contains a three-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the lower and upper states of the waveform when computing the duration of each transition.

**Default:** [10 50 90]

## **PercentStateLevelTolerance**

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

**Default:** 2

## **Polarity**

Polarity of pulse to extract. This property specifies the type of pulse to extract by the polarity of the leading transition. Valid values for this property are 'positive' or 'negative'.

**Default:** 'positive'

## **PostshootOutputPort**

Enable posttransition aberration metrics. If this property is set to true, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins

at the end of each transition and whose duration is the value of `PostshootSeekFactor` times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

**Default:** false

### **PostshootSeekFactor**

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PostshootOutputPort` property is set to true and is tunable.

**Default:** 3

### **PreshootOutputPort**

Enable pretransition aberration metrics. If `PreshootOutputPort` is set to true, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

**Default:** 'false'

### **PreshootSeekFactor**

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PreshootOutputPort` property is set to true and is tunable.

**Default:** 3

## **RunningMetrics**

Enable metrics over all calls to `step`. If `RunningMetrics` is set to `false`, metrics are computed for each call to `step` independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to `step`. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object will defer reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to `step` is made with enough data to compute all enabled metrics for that transition.

**Default:** `false`

## **SampleRate**

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero. This property applies when the `TimeInputPort` property is set to `false`.

**Default:** 1

## **SettlingOutputPort**

Enable settling metrics. If the `SettlingOutputPort` property is set to `true`, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last

transition. The metrics are reported for the transition the next time step is called if the `RunningMetrics` property is set to `true`.

**Default:** `false`

## **SettlingSeekDuration**

Duration of time over which to search for settling. This property value is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `PulseMetrics` object will report `NaN` for all settling metrics. This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

**Default:** `0.02`

## **StateLevels**

Low- and high-state levels. This property is a 2–element numeric row vector that contains the low- and high-state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

**Default:** `[0 2.3]`

## **StateLevelsSource**

Auto or manual state-level computation. If `StateLevelsSource` is set to `'Auto'`, the first record sent to `step` is sent to `dsp.StateLevels` with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

**Default:** `'Property'`

# dsp.PulseMetrics

---

## TimeInputPort

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to `step` to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

**Default:** `false`

## TransitionOutputPort

Enable transition metrics. If the `TransitionOutputPort` property is set to `true`, transition metrics are reported for the initial and final transitions of each pulse.

**Default:** `false`

## Methods

<code>clone</code>	Clones the current instance of the pulse metrics object
<code>getNumInputs</code>	Number of expected inputs to the method
<code>getNumOutputs</code>	Number of outputs of the method
<code>isLocked</code>	Locked status (logical) for input attributes and nontunable properties
<code>plot</code>	Plots signal and metrics computed in last call to

reset	Reset the running pulse metrics object
step	Pulse metrics of bilevel waveforms

## Examples

### Width, Period, and Duty Cycle

Determine the width, period, and duty cycle of a 5 V pulse sampled at 4 MHz.

Load the data and sampling instants.

```
load('pulseex.mat', 'x', 't');
```

Construct your pulse metrics System object. Set the `TimeInputPort` property to `true` to specify the sampling instants as an input to `step`. Set the `CycleOutputPort` property to `true` to obtain metrics for each pulse. Because the input is a 5V pulse, set the `StateLevels` property to `[0 5]`.

```
hpm1 = dsp.PulseMetrics('TimeInputPort',true, ...  
                        'CycleOutputPort', true, ...  
                        'StateLevels',[0 5])
```

Call `step` to compute the cycle metrics and plot the result.

```
[pulse, cycle] = step(hpm1,x,t);  
plot(hpm1)  
text(t(2),-0.5,['Duty Cycle: ',num2str(cycle.DutyCycle)]);
```

### Slew Rates for 2.3 V Digital Clock

Find the slew rates of the leading and trailing edges of a 2.3 V digital clock sampled at 4 MHz.

Construct your pulse metrics System object. Set the `TransitionOutputPort` property to `true` to report transition metrics for the initial and final transitions. Set the `StateLevelsSource` property to `'Auto'` to estimate the state levels from the data.

# dsp.PulseMetrics

---

```
hpm2 = dsp.PulseMetrics('SampleRate',4e6, ...  
                        'TransitionOutputPort', true, ...  
                        'StateLevelsSource','Auto');
```

Compute the pulse and transition metrics and plot the result.

```
[pulse, transition] = step(hpm2,x);  
plot(hpm2)
```

**Purpose** Clones the current instance of the pulse metrics object

**Syntax** `clone(H)`

**Description** `clone(H)` clones the current instance of the pulse metrics object H.

# **dsp.PulseMetrics.getNumInputs**

---

**Purpose**            Number of expected inputs to the `step` method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the pulse metrics object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.PulseMetrics.getNumOutputs

---

**Purpose** Number of outputs of the `step` method

**Syntax** `N = getNumOutputs(H)`

**Description** `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.PulseMetrics.isLocked**

---

**Purpose** Locked status (logical) for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the pulse metrics object H.

**Purpose** Plots signal and metrics computed in last call to step

**Syntax** plot(H)

**Description** plot(H) plots the signal and metrics resulting from the last call of the step method.

By default plot displays

- the low and high state levels and the state-level boundaries defined by the PercentStateLevelTolerance property.
- the lower-, middle-, and upper-reference levels.
- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When the TransitionOutputPort property is set to true, the locations of the upper and lower crossings are also plotted. When the PreshootOutputPort or PostShootOutputPort properties are set to true, the corresponding overshoots and undershoots are plotted as inverted or noninverted triangles. When the SettlingOutputPort property is set to true, the locations where the signal enters and remains within the lower and upper state boundaries over the specified seek duration are plotted.

# **dsp.PulseMetrics.reset**

---

**Purpose**            Reset the running pulse metrics object

**Syntax**            reset(H)

**Description**

reset(H) clears information from previous calls to step.

## Purpose

Pulse metrics of bilevel waveforms

## Syntax

```
PULSE = step(H,X)
[PULSE,CYCLE] = step(H,X)
[PULSE, TRANSITION] = step(H,X)
[PULSE,PRESHOOT] = step(H,X)
[PULSE,POSTSHOOT] = step(H,X)
[PULSE,SETTLING] = step(H,X)
[...] = step(H,X,T)
```

## Description

`PULSE = step(H,X)` returns a structure array, `PULSE`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `X`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

`PULSE` fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse
- `NegativeCross` — Instants where the negative-going transitions cross the mid-reference level of each pulse
- `Width` — Absolute difference between `PositiveCross` and `NegativeCross` of each pulse
- `RiseTime` — Duration between the linearly-interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- `FallTime` — Duration between the linearly-interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

`[PULSE,CYCLE] = step(H,X)` returns a structure array, `CYCLE`, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field

corresponds to the number of complete pulse periods found in the real-valued column vector input, `X`. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found in the input `X` does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to `step` detects the next transition.

CYCLE fields:

- `Period` — Duration between the first transition of the current pulse and the first transition of the next pulse
- `Frequency` — Reciprocal of the period
- `Separation` — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse
- `Width` — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `PULSE` structure.
- `DutyCycle` — Ratio of the width to the period for each pulse

`[PULSE, TRANSITION] = step(H,X)` returns a structure array, `TRANSITION`, when you set the `TransitionOutputPort` property to `true`. The fields of `TRANSITION` contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

`TRANSITION` fields:

- `Duration` — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels

- **SlewRate** — Ratio of absolute difference between the upper and lower reference levels to the transition duration
- **MiddleCross** — Linearly-interpolated instant in time where the transition first crosses the mid-reference level
- **LowerCross** — Linearly-interpolated instant where the signal crosses the lower-reference level
- **UpperCross** — Linearly-interpolated instant where the signal crosses the upper-reference level

[PULSE, PRESHOOT] = step(H,X) returns a structure array, PRESHOOT, when you set the PreshootOutputPort property to true. The fields of PRESHOOT contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the POSTSHOOT structure array.

[PULSE, POSTSHOOT] = step(H,X) returns a structure, POSTSHOOT, when you set the PostshootOutputPort property to true. The fields of POSTSHOOT contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

PRESHOOT and POSTSHOOT fields:

- **Overshoot** — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- **Undershoot** — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- **OvershootLevel** — Level of the overshoot
- **UndershootLevel** — Level of the undershoot
- **OvershootInstant** — Instant that corresponds to the overshoot
- **UndershootInstant** — Instant that corresponds to the undershoot

[PULSE, SETTLING] = step(H,X) returns a structure array, SETTLING, when you set the SettlingOutputPort property to true. The fields of SETTLING correspond to the settling metrics for each transition. Each

## **dsp.PulseMetrics.step**

---

field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

SETTLING fields:

- **Duration** — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified `PercentStateLevelTolerance` of the waveform amplitude over the specified settling seek duration
- **Instant** — Instant in time where the signal enters and remains within the specified tolerance
- **Level** — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the System object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

```
[ PULSE, CYCLE, TRANSITION, PRESHOOT, POSTSHOOT, SETTLING ] =  
step(H,X) which returns the PULSE, CYCLE, TRANSITION, PRESHOOT,  
POSTSHOOT, and SETTLING structures when the CycleOutputPort,  
PreshootOutputPort, PostshootPort, and SettlingOutputPort  
properties are true. You may enable or disable any combination of  
output ports. However, the output arguments are defined in the order  
shown here.
```

```
[ ... ] = step(H,X,T) performs the above metrics with respect to a  
sampled signal, whose sample values, X, and sample instants, T, are  
real-valued column vectors of the same length. The additional input T  
applies only when you set the TimeInputPort property to true.
```

<b>Purpose</b>	Convert reflection coefficients to autocorrelation coefficients
<b>Description</b>	<p>The RCToAutocorrelation object converts reflection coefficients to autocorrelation coefficients.</p> <p>To convert reflection coefficients to autocorrelation coefficients:</p> <ol style="list-style-type: none"><li>1 Define and set up your System object. See “Construction” on page 3-1061.</li><li>2 Call <code>step</code> to convert reflection coefficients according to the properties of <code>dsp.RCToAutocorrelation</code>. <b>Construction</b>	<p><code>H = dsp.RCToAutocorrelation</code> returns an RCToAutocorrelation System object, H. This object converts reflection coefficients to autocorrelation coefficients, assuming an error power of 1.</p> <p>H = <code>dsp.RCToAutocorrelation('PropertyName',PropertyValue,...)</code> returns an object, H, that converts reflection coefficients into autocorrelation coefficients, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>PredictionErrorInputPort</b></p> <p>Enable prediction error power input</p> <p>Choose how to select the prediction error power. When you set this property to <code>true</code>, you must specify the prediction error power as a second input to the <code>step</code> method. When you set this property to <code>false</code>, the object assumes a prediction error power of 1. The default is <code>false</code>.</p>

# dsp.RCToAutocorrelation

---

## Methods

clone	Create RC to autocorrelation object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert columns of reflection coefficients to autocorrelation coefficients

## Examples

Convert reflection coefficients to autocorrelation coefficients:

```
k = [-0.8091 0.2525 -0.5044 0.4295 -0.2804 0.0711].';  
hrc2ac = dsp.RCToAutocorrelation;  
ac = step(hrc2ac, k);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC/RC to Autocorrelation block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter.
- **PredictionErrorInputPort** is a pop-up menu choice on the block. Setting the PredictionErrorInputPort object property to false corresponds to selecting Assume P = 1 in the pop-up menu. Setting PredictionErrorInputPort to true corresponds to selecting Via input port from the pop-up menu.

# dsp.RCToAutocorrelation.clone

---

<b>Purpose</b>	Create RC to autocorrelation object with same property values
<b>Syntax</b>	<code>C = clone(H)</code>
<b>Description</b>	<code>C = clone(H)</code> creates a <code>RCToAutocorrelation System</code> object <code>C</code> , with the same property values as <code>H</code> . The clone method creates a new unlocked object.

# dsp.RCToAutocorrelation.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.RCToAutocorrelation.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `RCToAutocorrelationSystem` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.RCToAutocorrelation.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Convert columns of reflection coefficients to autocorrelation coefficients

**Syntax** AC = step(H,K)  
AC = step(H,K,P)

**Description** AC = step(H,K) converts the columns of the reflection coefficients, K, to autocorrelation coefficients, AC.

AC = step(H,K,P) when you set the PredictionErrorInputPort property to true, converts the columns of the reflection coefficients, K, to autocorrelation coefficients, AC, using P as the prediction error power. P must be a row vector with same number of columns as in K.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

# dsp.RCToLPC

---

**Purpose** Convert reflection coefficients to linear prediction coefficients

**Description** The RCToLPC object converts reflection coefficients to linear prediction coefficients.

To convert reflection coefficients to LPC:

- 1** Define and set up your RC to LPC System object. See “Construction” on page 3-1070.
- 2** Call `step` to convert RC to LPC according to the properties of `dsp.RCToLPC`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.RCToLPC` returns an RC to LPC System object, `H`, that converts reflection coefficients (RC) to linear prediction coefficients (LPC).

`H = dsp.RCToLPC('PropertyName',PropertyValue,...)` returns an RC to LPC conversion object, `H`, with each specified property set to the specified value.

**Properties** **PredictionErrorOutputPort**

Enable normalized prediction error power output

Set this property to `true` to return the normalized error power as a vector with one element per input channel. Each element varies between 0 and 1. The default is `true`.

**ExceptionOutputPort**

Produce output with stability status of filter represented by LPC coefficients

Set this property to `true` to return the stability of the filter. The output is a vector of a length equal to the number of channels. A logical value of 1 indicates a stable filter. A logical value of 0 indicates an unstable filter. The default is `false`.

**Methods**

clone	Creates instance of object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert columns of reflection coefficients to linear prediction coefficients

**Examples**

Convert reflection coefficients to linear prediction coefficients:

```

hlevinson = dsp.LevinsonSolver;
hac = dsp.Autocorrelator;
hac.MaximumLagSource = 'Property';
hac.MaximumLag = 10; % Compute autocorrelation
                    % lags between [0:10]
hrc2lpc = dsp.RCToLPC;

x = (1:100)';
a = step(hac, x);
k = step(hlevinson, a); % Compute reflection coefficients
[A, P] = step(hrc2lpc, k);

```

**Algorithms**

This object implements the algorithm, inputs, and outputs described on the LPC to/from RC block reference page. The object properties correspond to the block parameters, except:

There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.

# **dsp.RCToLPC**

---

## **See Also**

[dsp.LPCToRC](#) | [dsp.LPCToAutocorrelation](#)

**Purpose** Creates instance of object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an RCToLPC System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# **dsp.RCToLPC.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs to the step method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.RCToLPC.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the RCToLPC System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.RCToLPC.step

---

**Purpose** Convert columns of reflection coefficients to linear prediction coefficients

**Syntax**

```
[A,P] = step(H,K)
A = step(H,K)
[... , S] = step(H,K)
```

**Description** [A,P] = step(H,K) converts the columns of the reflection coefficients, K, to linear prediction coefficients, A, and outputs the normalized prediction error power, P.

A = step(H,K) when the PredictionErrorOutputPort property is false, converts the columns of the reflection coefficients, K, to linear prediction coefficients, A.

[... , S] = step(H,K) also outputs the LPC filter stability, S, when the ExceptionOutputPort property is true.

---

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

<b>Purpose</b>	Compute output, error and coefficients using Recursive Least Squares (RLS) algorithm						
<b>Description</b>	<p>The RLSFilter object filters each channel of the input using RLS filter implementations.</p> <p>To filter each channel of the input:</p> <ol style="list-style-type: none"><li>1 Define and set up your RLS filter. <b>Method</b>	Method to calculate the filter coefficients						
	You can specify the method used to calculate filter coefficients as one of   Conventional RLS [1] [2]   Householder RLS [3] [4]   Sliding-window RLS [1][2]   Householder sliding-window RLS [4]   QR decomposition [1] [2]. The default value is Conventional RLS. This property is nontunable.						
<b>Length</b>							

Length of filter coefficients vector

Specify the length of the RLS filter coefficients vector as a scalar positive integer value. The default value is 32. This property is nontunable.

## **SlidingWindowBlockLength**

Width of the sliding window

Specify the width of the sliding window as a scalar positive integer value greater than or equal to the Length property value. This property is applicable only when the Method property is set to Sliding-window RLS or Householder sliding-window RLS. The default value is 48. This property is nontunable.

## **ForgettingFactor**

RLS forgetting factor

Specify the RLS forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this property value to 1 denotes infinite memory, while adapting to find the new filter. The default value is 1. This property is tunable.

## **InitialCoefficients**

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the Length property value. The default value is 0. This property is tunable.

## **InitialInverseCovariance**

Initial inverse covariance

Specify the initial values of the inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix, with each dimension equal to the Length property value. If you set a scalar value, the InverseCovariance property is initialized to a diagonal matrix with diagonal elements equal to that scalar value. This property applies only when the Method

property is set to `Conventional RLS` or `Sliding-window RLS`. The default value is 1000. This property is tunable.

## **InitialSquareRootInverseCovariance**

Initial square root inverse covariance

Specify the initial values of the square root inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootInverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value. This property applies only when the `Method` property is set to `Householder RLS` or `Householder sliding-window RLS`. The default value is `sqrt(1000)`. This property is tunable.

## **InitialSquareRootCovariance**

Initial square root covariance

Specify the initial values of the square root covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootCovariance` property is initialized to a diagonal matrix with diagonal elements equal to the scalar value. This property applies only when the `Method` property is set to `QR-decomposition RLS`. The default value is `sqrt(1/1000)`. This property is tunable.

## **LockCoefficients**

Lock coefficient updates

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients continuously updated). This property is tunable.

# dsp.RLSFilter

---

## Methods

clone	Create System object with same property values
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of a System object
step	Process inputs using object algorithm

## Examples

### System Identification of an FIR Filter

```
hrls1 = dsp.RLSFilter(11, 'ForgettingFactor', 0.98);
hfilt = dsp.FIRFilter('Numerator',fir1(10, .25)); % Unknown System
x = randn(1000,1); % input signal
d = step(hfilt, x) + 0.01*randn(1000,1); % desired signal
[y,e] = step(hrls1, x, d);
w = hrls1.Coefficients;
subplot(2,1,1), plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index'); ylabel('signal value');
subplot(2,1,2); stem([hfilt.Numerator; w].');
legend('Actual','Estimated');
xlabel('coefficient #'); ylabel('coefficient value');
```

### Noise Cancellation

```
hrls2 = dsp.RLSFilter('Length', 11, 'Method', 'Householder RLS');
hfilt2 = dsp.FIRFilter('Numerator',fir1(10, [.5, .75]));
x = randn(1000,1); % Noise
d = step(hfilt2, x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = step(hrls2, x, d);
```

```
subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2), plot(err), title('Signal');
```

## Algorithms

The `dsp.RLSFilter` System object, when Conventional RLS is selected, recursively computes the least squares estimate (RLS) of the FIR filter weights. The System object estimates the filter weights or coefficients, needed to convert the input signal into the desired signal. The input signal can be a scalar or a column vector. The desired signal must have the same data type, complexity, and dimensions as the input signal. The corresponding RLS filter is expressed in matrix form as  $\mathbf{P}(n)$  :

$$\mathbf{k}(n) = \frac{\lambda^{-1}\mathbf{P}(n-1)\mathbf{u}(n)}{1 + \lambda^{-1}\mathbf{u}^H(n)\mathbf{P}(n-1)\mathbf{u}(n)}$$

$$y(n) = \mathbf{w}^T(n-1)\mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}(n)e(n)$$

$$\mathbf{P}(n) = \lambda^{-1}\mathbf{P}(n-1) - \lambda^{-1}\mathbf{k}(n)\mathbf{u}^H(n)\mathbf{P}(n-1)$$

where  $\lambda^{-1}$  denotes the reciprocal of the exponential weighting factor. The variables are as follows:

Variable	Description
$n$	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step $n$
$\mathbf{P}(n)$	The inverse correlation matrix at step $n$
$\mathbf{k}(n)$	The gain vector at step $n$
$\mathbf{w}(n)$	The vector of filter tap estimates at step $n$
$y(n)$	The filtered output at step $n$

Variable	Description
$e(n)$	The estimation error at step $n$
$d(n)$	The desired response at step $n$
$\lambda$	The forgetting factor

$\mathbf{u}$ ,  $\mathbf{w}$ , and  $\mathbf{k}$  are all column vectors.

## See Also

`dsp.FIRFilter` | `dsp.LMSFilter` | `dsp.AffineProjectionFilter`

**Purpose** Create System object with same property values

**Syntax** `C = clone(OBJ)`

**Description** `C = clone(OBJ)` creates another instance of the System object, `OBJ`, with the same property values. The `clone` method creates a new unlocked object with uninitialized states.

**See Also** `dsp.RLSFilter.step` | `dsp.RLSFilter.isLocked` | `dsp.RLSFilter.reset`

# dsp.RLSFilter.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** L = isLocked(OBJ)

**Description** L = isLocked(OBJ) returns a logical value, L, which indicates whether input attributes and nontunable properties are locked for the System object, OBJ. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. Once this occurs, the isLocked method returns a true value.

**See Also** dsp.RLSFilter.step | dsp.RLSFilter.release

<b>Purpose</b>	Allow property value and input characteristics changes
<b>Syntax</b>	<code>release(Obj)</code>
<b>Description</b>	<p><code>release(Obj)</code> releases system resources, such as memory, file handles, and hardware connections of the System object, <code>Obj</code>, and allows all its properties and input characteristics to be changed.</p> <p>Once you call the <code>release</code> method on a System object, subsequent calls to <code>setup</code>, <code>step</code>, <code>reset</code>, or <code>release</code> are not supported for code generation.</p>
<b>See Also</b>	<code>dsp.RLSFilter.isLocked</code>   <code>dsp.RLSFilter.step</code>

# **dsp.RLSFilter.reset**

---

**Purpose**            Reset the internal states of a System object

**Syntax**            `reset(Obj)`

**Description**        `reset(Obj)` resets the internal states of the System object, `Obj`, to their initial values.

For many System objects, this method is nonoperational. Objects that have internal states describe in their **help** what the reset method does for that object. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

**Purpose** Process inputs using object algorithm

**Syntax**  $Y = \text{step}(\text{OBJ}, x)$   
 $[Y1, \dots, YN] = \text{step}(\text{OBJ}, x)$

**Description**  $Y = \text{step}(\text{OBJ}, x)$  processes the input data,  $x$ , to produce the output,  $Y$ , for the System object,  $\text{OBJ}$ .  $[Y1, \dots, YN] = \text{step}(\text{OBJ}, x)$  produces  $N$  outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

**Purpose** Root mean square of vector elements

**Description** The RMS object computes the root mean square (RMS) value.

To compute the RMS value of your input:

- 1 Define and set up your RMS calculation. See “Construction” on page 3-1090.
- 2 Call `step` to compute the RMS value for an input according to the properties of `dsp.RMS`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.RMS` returns a System object, `H`, that computes the root mean square (RMS) of an input or a sequence of inputs over the specified `Dimension`.

`H = dsp.RMS('PropertyName',PropertyValue,...)` returns an RMS System object, `H`, with each specified property set to the specified value.

## Properties

### RunningRMS

Enable calculating RMS over time

Set this property to `true` to enable calculating the RMS over successive calls to the `step` method.

**Default:** `false`

### ResetInputPort

Enable resetting in running RMS mode

Set this property to `true` to enable resetting the running RMS. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running RMS. This property applies when you set the `RunningRMS` property to `true`.

**Default:** `false`

**ResetCondition**

Reset condition for running RMS mode

Specify the event to reset the running RMS as one of **Rising edge**, **Falling edge**, **Either edge**, or **Non-zero**. **Non-zero** resets the running RMS each time a nonzero sample is acquired. See “Rising and Falling Edges” on page 3-1092 for definitions of rising and falling edges. This property applies when you set the **ResetInputPort** property to **true**.

**Default:** Non-zero

**Dimension**

Dimension to compute RMS value along

Specify the dimension along which to calculate the RMS as one of **All**, **Row**, **Column**, or **Custom**. This property applies only when you set the **RunningRMS** property to **false**. Specifying the **Dimension** property as **All** computes the RMS value over the entire input.

**Default:** Column

**CustomDimension**

Numerical dimension to operate along

Specify the dimension (one-based scalar integer value) of the input signal, along which the RMS is computed. The cannot exceed the number of dimensions in the input signal. This property applies when you set the **Dimension** property to **Custom**.

**Default:** 1

**FrameBasedProcessing**

Enable frame-based processing

Set this property to **true** to enable frame-based processing for 2-dimensional inputs. Set this property to **false** to

enable sample-based processing. The object always performs sample-based processing for N-D inputs where N is greater than 2. This property applies when you set the RunningRMS property to true.

**Default:** true

## Methods

clone	Clones the current instance of the root mean square object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset the running root mean square object
step	Root mean square of input

## Definitions

### Root-Mean-Square Level

The root-mean-square level of a vector,  $X$ , is

$$X_{\text{RMS}} = \sqrt{\frac{1}{N} \sum_{n=1}^N |X_n|^2}$$

with the summation performed along the specified dimension.

### Rising and Falling Edges

A rising edge:

- Rises from a negative value to a positive value or zero.
- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

A falling edge:

- Falls from a positive value to a negative value or zero.
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

## Examples

### RMS Value of Vector Input

Compute the RMS value of a vector consisting of the integers 1 to 10.

Create a row vector of the integers 1 to 10. Construct the RMS System object with the Dimension property set to 'literal'. Compute the RMS value.

```
x = 1:10;  
hrms = dsp.RMS('Dimension','row');  
rmsval = step(hrms,x);
```

### RMS Value of Matrix Input

Compute the RMS value of a matrix with the Dimension property set to 'All'.

```
in2 = magic(4);  
hrms2d = dsp.RMS;  
hrms2d.Dimension = 'All';  
y_rms2 = step(hrms2d, in2);
```

The output is equivalent to reshaping the 4-by-4 matrix into a 16-by-1, or 1-by-16 vector and computing the RMS value for the vector.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the RMS block reference page. The object properties correspond to the Simulink block parameters, except:

- **Treat sample-based row input as a column** block parameter is not supported by the dsp.RMS object.
- **Reset Port** block parameter corresponds to both the ResetCondition and the ResetInputPort object properties.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

**See Also**

[dsp.Mean](#) | [dsp.StandardDeviation](#) | [dsp.Variance](#).

# dsp.RMS.clone

---

**Purpose** Clones the current instance of the root mean square object

**Syntax** `clone(H)`

**Description** `clone(H)` clones the current instance of the root mean square (RMS) object H

**Purpose**                    Number of expected inputs to the `step` method

**Syntax**                    `N = getNumInputs(H)`

**Description**              `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the root mean square (RMS) object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.RMS.getNumOutputs

---

**Purpose**            Number of outputs of the `step` method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** isLocked(H)

**Description** isLocked(H) returns the locked state of the root mean square (RMS) object H.

# dsp.RMS.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose**            Reset the running root mean square object

**Syntax**            reset(H)

**Description**        reset(H) resets the running root mean square (RMS) for the object H.

# dsp.RMS.step

---

**Purpose** Root mean square of input

**Syntax**  
 $Y = \text{step}(H,X)$   
 $Y = \text{step}(H,X,R)$

**Description**  $Y = \text{step}(H,X)$  computes the root mean square (RMS) output,  $Y$ , of input vector  $X$ . When the `RunningRMS` property is true,  $Y$  corresponds to the RMS of the input elements over successive calls to the `step` method.

$Y = \text{step}(H,X,R)$  resets the running RMS state based on the value of  $R$ , the reset signal, and the `ResetCondition` property. This computation is possible when you set both the `RunningRMS` and the `ResetInputPort` properties to true.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Convert each index value into quantized output value
<b>Description</b>	<p>The <code>ScalarQuantizerDecoder</code> object converts each index value into a quantized output value. The specified codebook defines the set of all possible quantized output values or codewords. Input index values less than 0 are set to 0 and index values greater <math>N - 1</math> are set to <math>N - 1</math>. <math>N</math> is the length of the codebook vector.</p> <p>To convert an index value into a quantized output value:</p> <ol style="list-style-type: none"><li>1 Define and set up your scalar quantizer decoder. See “Construction” on page 3-1103.</li><li>2 Call <code>step</code> to convert the index value according to the properties of <code>dsp.ScalarQuantizerDecoder</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>

# dsp.ScalarQuantizerDecoder

---

## OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as `Same` as `input`, `double`, `single` or `Custom`. The default is `double`.

## Fixed-Point Properties

### CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numericType` object. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType(true,16)`.

## Methods

<code>clone</code>	Create scalar quantizer decoder object with same property values
<code>getNumInputs</code>	Number of expected inputs to <code>step</code> method
<code>getNumOutputs</code>	Number of outputs of <code>step</code> method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Operate on inputs to calculate outputs

## Examples

Given a codebook and index values as inputs, determine the corresponding output quantized values:

```
codebook = single([-2.1655 -1.3238 -0.7365 -0.2249 0.2726, ...
```

```
0.7844 1.3610 2.1599]);  
indices = uint8([1 3 5 7 6 4 2 0]);  
hsqdec = dsp.ScalarQuantizerDecoder;  
hsqdec.CodebookSource = 'Input port';  
qout = step(hsqdec, indices, codebook);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the [Scalar Quantizer Decoder](#) block reference page. The object properties correspond to the block parameters, except:

There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to  $N$  to  $N - 1$ .

## See Also

[dsp.ScalarQuantizerEncoder](#) | [dsp.VectorQuantizerDecoder](#)

# dsp.ScalarQuantizerDecoder.clone

---

**Purpose** Create scalar quantizer decoder object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `ScalarQuantizerDecoder` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

# **dsp.ScalarQuantizerDecoder.getNumInputs**

---

**Purpose**                    Number of expected inputs to step method

**Syntax**                    `N = getNumInputs(H)`

**Description**            `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.ScalarQuantizerDecoder.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `ScalarQuantizerDecoder` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.ScalarQuantizerDecoder.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose** Operate on inputs to calculate outputs

**Syntax**  
`Q = step(H, I)`  
`Q = step(H,I,C)`

**Description** `Q = step(H, I)` returns the quantized output values `Q` corresponding to the input indices `I`. The data type of `I` can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The `OutputDataType` property determines the data type for `Q`.

`Q = step(H,I,C)` uses input `C` as the codebook values when you set the `CodebookSource` property to `Input port`. The data type of `C` can be `double`, `single`, or `fixed-point`. The output `Q` has the same data type as the codebook input `C`.

# dsp.ScalarQuantizerEncoder

---

**Purpose** Associate input value with index value of quantization region

**Description** The `ScalarQuantizerEncoder` object encodes each input value by associating that value with the index value of the quantization region. Then, the object outputs the index of the associated region.

To encode an input value by associating it with an index value of the quantization region:

- 1 Define and set up your scalar quantizer encoder. See “Construction” on page 3-1112.
- 2 Call `step` to encode the input value according to the properties of `dsp.ScalarQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.ScalarQuantizerEncoder` returns a scalar quantizer encoder System object, `H`. This object maps each input value to a quantization region by comparing the input value to the user-specified boundary points.

`H = dsp.ScalarQuantizerEncoder('PropertyName',PropertyValue,...)` returns a scalar quantizer encoder object, `H`, with each specified property set to the specified value.

**Properties**

**BoundaryPointsSource**  
Source of boundary points  
Specify how to determine the boundary points and codebook values as `Property` or `Input port`. The default is `Property`.

**Partitioning**  
Quantizer is bounded or unbounded  
Specify the quantizer as `Bounded` or `Unbounded`. The default is `Bounded`.

**BoundaryPoints**

## Boundary points of quantizer regions

Specify the boundary points of quantizer regions as a vector. The vector values must be in ascending order. Let [p0 p1 p2 p3 ... pN] denote the boundary points property in the quantizer. If the quantizer is bounded, the object uses this property to specify [p0 p1 p2 p3 ... pN]. If the quantizer is unbounded, the object uses this property to specify [p1 p2 p3 ... p(N-1)] and sets p0 = -Inf and pN = +Inf. This property applies when you set the BoundaryPointsSource property to Property. The default is 1:10. This property is tunable.

## SearchMethod

Find quantizer index by linear or binary search

Specify whether to find the appropriate quantizer index using a linear search or a binary search as one of Linear or Binary. The computational cost of the linear search method is of the order  $P$  and the computational cost of the binary search method is of the order

$$\log_2(P)$$

where  $P$  is the number of boundary points. The default is Linear.

## TiebreakerRule

Behavior when input equals boundary point

Specify whether the input value is assigned to the lower indexed region or higher indexed region when the input value equals boundary point by selecting Choose the lower index or Choose the higher index. The default is Choose the lower index.

## CodewordOutputPort

Enable output of codeword value

Set this property to true to output the codeword values that correspond to each index value. The default is false.

## QuantizationErrorOutputPort

# dsp.ScalarQuantizerEncoder

---

Enable output of quantization error

Set this property to `true` to output the quantization error for each input value. The quantization error is the difference between the input value and the quantized output value. The default is `false`.

## **Codebook**

Codebook

Specify the codebook as a vector of quantized output values that correspond to each region. If the `Partitioning` property is `Bounded` and the boundary points vector has length `N`, you must set this property to a vector of length `N-1`. If the `Partitioning` property is `Unbounded` and the boundary points vector has length `N`, you must set this property to a vector of length `N+1`. This property applies when you set the `BoundaryPointsSource` property to `Property` and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is `true`. The default is `1.5:9.5`. This property is tunable.

## **ClippingStatusOutputPort**

Enable output of clipping status

Set this property to `true` to output the clipping status. The output is a 1 when an input value is outside the range defined by the `BoundaryPoints` property. When the value is inside the range, the exception output is a 0. This property applies when you set the `Partitioning` property to `Bounded`. The default is `false`.

## **OutputIndexDataType**

Data type of the index output

Specify the data type of the index output from the object as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

## OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

## Methods

<code>clone</code>	Create an instance of an object with the same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Operate on inputs to calculate outputs

## Examples

Quantize the varying fractional inputs between zero and five to the closest integers, and then plot the results:

```
hsqe = dsp.ScalarQuantizerEncoder;  
hsqe.BoundaryPoints = [-.001 .499 1.499 ...  
    2.499 3.499 4.499 5.001];  
hsqe.CodewordOutputPort = true;  
hsqe.Codebook = [0 1 2 3 4 5];  
input = (0:0.02:5)';  
[index, quantizedValue] = step(hsqe, input);  
plot(1:length(input), [input quantizedValue]);
```

# dsp.ScalarQuantizerEncoder

---

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Encoder block reference page. The object properties correspond to the block parameters.

## See Also

`dsp.ScalarQuantizerDecoder` | `dsp.VectorQuantizerEncoder`

**Purpose** Create an instance of an object with the same property values

**Syntax**

**Description** `C = clone(H)` creates a `ScalarQuantizerEncoder` object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.ScalarQuantizerEncoder.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.ScalarQuantizerEncoder.getNumOutputs**

---

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.ScalarQuantizerEncoder.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `ScalarQuantizerEncoder` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.ScalarQuantizerEncoder.step

---

**Purpose** Operate on inputs to calculate outputs

**Syntax**

```
INDEX= step(HSQE,INPUT)
[...] = step(HSQE,INPUT,BPOINTS)
[...] = step(HSQE,INPUT,BPOINTS,CODEBOOK)
[... ,CODEWORD] = step(HSQE, ...)
[... , QERR] = step(HSQE, ...)
[... ,CLIPSTATUS] = step(HSQE, ...)
```

**Description**

INDEX= step(HSQE,INPUT) returns the INDEX of the quantization region to which the INPUT belongs. The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

[...] = step(HSQE,INPUT,BPOINTS) when the BoundaryPointsSource property is Input port, uses input BPOINTS as the boundary points .

[...] = step(HSQE,INPUT,BPOINTS,CODEBOOK) uses input BPOINTS as the boundary points and input CODEBOOK as the codebook when the BoundaryPointsSource property is Input port and either the CodewordOutputPort property or the QuantizationErrorOutputPort property is true.

[... ,CODEWORD] = step(HSQE, ...) outputs the CODEWORD values that corresponds to each index value when the CodewordOutputPort property is true.

[... , QERR] = step(HSQE, ...) outputs the quantization error QERR for each input value when the QuantizationErrorOutputPort property is true.

[... ,CLIPSTATUS] = step(HSQE, ...) also returns output CLIPSTATUS as the clipping status output port for each input value when the Partitioning property is Bounded and the ClippingStatusOutputPort property is true. If an input value is outside the range defined by the BoundaryPoints property, CLIPSTATUS is true. If an input value is inside the range, CLIPSTATUS is false.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.SignalSink

---

**Purpose** Log simulation data in buffer

**Description** The `SignalSink` object logs MATLAB simulation data. This object accepts any numeric data type.

To log MATLAB simulation data :

- 1 Define and set up your signal sink. See “Construction” on page 3-1124.
- 2 Call `step` to log the simulation data according to the properties of `dsp.SignalSink`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.SignalSink` returns a signal sink, `H`, that logs 2-D input data in the object.

`H = dsp.SignalSink('PropertyName',PropertyValue,...)` returns a signal sink, `H`, with each specified property set to the specified value.

**Properties** **FrameBasedProcessing**

Process input as frames or samples

To enable frame-based processing for 2-D inputs, set this property to `true`. When you set this property to `false`, the object performs sample-based processing on 2-D inputs. The signal sink object always performs sample-based processing for N-D inputs when `N` is greater than 2. The default is `true`.

**BufferLength**

Maximum number of input frames or samples to log

Specify the maximum number of frames to log when the object is performing frame-based processing, or the maximum number of samples to log when the object is performing sample-based processing. The object always preserves the most recent data in the buffer. When you specify a buffer length that is greater than the input length, the object pads the end of the logged data with

zeros. To capture all input data without extra padding, set the `BufferLength` property to `inf`. The default is `inf`.

## Decimation

Decimation factor

Setting this property to any positive integer  $d$  causes the signal sink to write data at every  $d$ th sample. The default is 1.

## FrameHandlingMode

Output dimensionality for frame-based inputs

Set the dimension of the output array for frame-based inputs as 2-D array (`concatenate`) or 3-D array (`separate`). Concatenation occurs along the first dimension for 2-D array (`concatenate`). This property applies only when you set the `FrameBasedProcessing` property to `true`. The default is 2-D array (`concatenate`).

## Buffer

Logged Data (read only)

The signal sink writes simulation data into a buffer. Specify the maximum length of the buffer with the `BufferLength` property.

## Methods

<code>clone</code>	Create signal logger object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes

# dsp.SignalSink

---

reset	Reset internal states of signal logger object
step	Store signal in buffer

## Examples

Log input data.

```
hlog = dsp.SignalSink;
for i=1:10
    y = sin(i);
    step(hlog,y);
end
log = hlog.Buffer; % log = sin([1;2;3;4;5;6;7;8;9;10])
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Signal To Workspace block reference page. The object properties correspond to the block properties, except:

The object always generates fixed-point output for fixed-point input.

Objects and blocks interpret frames differently. Objects process inputs as frames or as samples by setting the `FrameBasedProcessing` property. Blocks process inputs as frames or as samples by inheriting the frame information from the input ports. See “Set the `FrameBasedProcessing` Property of a System object” for more information.

## See Also

`dsp.SignalSource`

**Purpose** Create signal logger object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `SignalSink` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# **dsp.SignalSink.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.SignalSink.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `SignalSink` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Reset internal states of signal logger object

**Syntax** reset(H)

**Description** reset(H) sets the internal states of the SignalSink object H to their initial values.

# dsp.SignalSink.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Store signal in buffer

**Syntax** `step(H,Y)`

**Description** `step(H,Y)` buffers the signal `Y`. The buffer may be accessed at any time from the `Buffer` property of `H`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.SignalSource

---

**Purpose** Import variable from workspace

**Description** The `SignalSource` object imports a variable from the MATLAB workspace.

To import a variable from the MATLAB workspace:

- 1 Define and set up your signal source. See “Construction” on page 3-1134.
- 2 Call `step` to import the variable according to the properties of `dsp.SignalSource`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.SignalSource` returns a signal source System object, `H`, that outputs the variable one sample or frame at a time.

`H = dsp.SignalSource('PropertyName',PropertyValue,...)` returns a signal source object, `H`, with each specified property set to the specified value.

`H = dsp.SignalSource(signal,spf,'PropertyName',PropertyValue,...)` returns a signal source object, `H`, with the `Signal` property set to `signal`, the `SamplesPerFrame` property set to `spf`, and other specified properties set to the specified values.

## Properties

### Signal

Variable or expression containing the signal

Specify the name of the workspace variable from which to import the signal, or a valid expression specifying the signal. The default is `[1:10]`.

### SamplesPerFrame

Number of samples per output frame

Specify the number of samples to buffer into each output frame. This property must be 1 when you specify a 3-D array in the Signal property. The default is 1.

## SignalEndAction

Action after final signal values are generated

Specify the output after all of the specified signal samples have been generated as one of Set to zero, Hold final value, or Cyclic repetition. The default is Set to zero.

## Methods

clone	Create signal reader object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isDone	End-of-file status for signal reader object
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of signal reader object
step	Read one sample or frame of signal

## Examples

Create a signal source to output one sample at a time:

```
hsr1 = dsp.SignalSource;  
hsr1.Signal = randn(1024, 1);  
y1 = zeros(1024,1);  
idx = 1;
```

# dsp.SignalSource

---

```
while(~isDone(hsr1))
    y1(idx) = step(hsr1);
    idx = idx+1;
end
```

---

Create a signal source to output vectors:

```
hsr2 = dsp.SignalSource(randn(1024, 1), 128);
y2 = step(hsr2); % y2 is a 128-by-1 frame of samples
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the [Signal From Workspace](#) block reference page. The object properties correspond to the block parameters, except:

The object does not have properties that correspond to the **Sample time** or **Warn when frame size does not evenly divide input length** block parameters.

## See Also

`dsp.SignalSink`

**Purpose** Create signal reader object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `SignalSource` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with un-initialized states.

# dsp.SignalSource.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.SignalSource.isDone

---

**Purpose** End-of-file status for signal reader object

**Syntax** `isDone(H)`

**Description** `isDone(H)` returns a logical value indicating whether or not the `SignalSource` object, `H`, has reached the end of the imported signal. If the `SignalEndAction` property is set to `Cyclic` repetition, this method will return `true` every time the reader reaches the end.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `SignalSource` object `H`.  
The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# **dsp.SignalSource.reset**

---

**Purpose**            Reset internal states of signal reader object

**Syntax**            reset(H)

**Description**       reset(H) resets the signal reader object H, to start reading from the beginning of the imported signal.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

# dsp.SignalSource.step

---

**Purpose** Read one sample or frame of signal

**Syntax**  $Y = \text{step}(H)$

**Description**  $Y = \text{step}(H)$  outputs one sample or frame of data,  $Y$ , from each column of the imported signal. The imported signal is the variable or expression you specify for the **Signal** property of the **SignalSource** System object  $H$ .

---

**Note** The object performs an initialization the first time the **step** method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the **release** method to unlock the object.

---

**Purpose**

Discrete-time sinusoid

**Description**

The SineWave object generates a discrete-time sinusoid. The sine wave object generates a real-valued sinusoid or a complex exponential. A real-valued, discrete-time sinusoid is defined as:

$$y(n) = A \sin(2\pi fn + \phi)$$

where  $A$  is the amplitude,  $f$  is the frequency in hertz, and  $\phi$  is the initial phase, or phase offset, in radians. A complex exponential is defined as:

$$y(n) = Ae^{j(2\pi fn + \phi)}$$

For both real and complex sinusoids, the amplitude, frequency, and phase offsets can be scalars or length- $N$  vectors, where  $N$  is the desired number of channels in the output. When you specify at least one of these properties as a length- $N$  vector, scalar values specified for the other properties are applied to each of the  $N$  channels.

To generate a discrete-time sinusoid:

- 1** Define and set up your sine wave. See “Construction” on page 3-1145.
- 2** Call `step` to generate the sinusoid according to the properties of `dsp.SineWave`. The behavior of `step` is specific to each object in the toolbox.

**Construction**

`H = dsp.SineWave` returns a sine wave object, `H`, that generates a real-valued sinusoid with an amplitude of 1, a frequency of 100 Hz, and a phase offset of 0. By default, the sine wave object only generates one sample.

`H = dsp.SineWave('PropertyName', PropertyValue, ...)` returns a sine wave object, `H`, with each property set to the specified value.

`H = dsp.SineWave(AMP, FREQ, PHASE, 'PropertyName', PropertyValue, ...)` returns a sine wave object, `H`, with the `Amplitude` property set to `AMP`, the `Frequency` property set to

FREQ, the PhaseOffset property set to PHASE, and the other specified properties set to the specified values.

## Properties

### Amplitude

Amplitude of the sine wave

Specify the amplitude as a length- $N$  vector containing the amplitudes of the sine waves in each of  $N$  output channels, or a scalar to apply to all  $N$  channels. The vector length must equal that specified for the Frequency and PhaseOffset properties. The default value is 1. This property is nontunable.

### Frequency

Frequency of the sine wave

Specify a length- $N$  vector containing frequencies, in hertz, of the sine waves in each of  $N$  output channels, or a scalar to apply to all  $N$  channels. The vector length must equal that specified for the Amplitude and PhaseOffset properties. You can specify positive, zero, or negative frequencies. The default is 100. This property is tunable when the Method property is Trigonometric function.

### PhaseOffset

Phase offset of the sine wave in radians

A length- $N$  vector containing the phase offsets, in radians, of the sine waves in each of  $N$  output channels, or a scalar to apply to all  $N$  channels. The vector length must equal that specified for the Amplitude and Frequency properties. The default value is 0. This property is tunable when the Method property is Trigonometric function.

### ComplexOutput

Indicates whether the sine wave is complex or real

Set to true to output a complex exponential. The default value is false.

### Method

Method used to generate sinusoids

The sinusoids are generated by either the Trigonometric function, Table lookup, or Differential methods. The trigonometric function method computes the sinusoid by sampling the continuous-time sinusoid. The table lookup method precomputes the unique samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time and precomputed update terms. The default value is Trigonometric function.

### **TableOptimization**

Optimizes the table of sine values for speed or memory

Optimizes the table of sine values for Speed or Memory. When optimized for speed, the table contains  $k$  elements, and when optimized for memory, the table contains  $k/4$  elements, where  $k$  is the number of input samples in one full period of the sine wave. This property applies only when the Method property is Table lookup. The default value is Speed.

### **SampleRate**

Sampling rate for the sine wave

Specify the sampling rate of the output, in hertz, as a positive numeric scalar. The default is 1000.

### **SamplesPerFrame**

Number of samples per frame

Specify the number of consecutive samples from each sinusoid to buffer into the output frame. The default is 1.

### **OutputDataType**

Output data type

# dsp.SineWave

---

Specify the output data type as `double`, `single`, or `Custom`. The default value is `double`.

## Fixed-Point Properties

### CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default value is `numericType([ ]1,16)`.

## Methods

<code>clone</code>	Create sine wave object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset sine wave to the beginning
<code>step</code>	Discrete-time sine wave

## Examples

Generate a sine wave with an amplitude of 2, frequency of 10 Hz, and initial phase of 0:

```
hsin1 = dsp.SineWave(2, 10);  
hsin1.SamplesPerFrame = 1000;  
y = step(hsin1);  
plot(y);
```

Generate two sine waves offset by a phase of  $\pi/2$  radians:

```
hsin2 = dsp.SineWave;  
hsin2.Frequency = 10;  
hsin2.PhaseOffset = [0 pi/2];  
hsin2.SamplesPerFrame = 1000;  
y = step(hsin2);  
plot(y);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Sine Wave block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.Chirp](#) | [dsp.NCO](#)

# **dsp.SineWave.clone**

---

**Purpose** Create sine wave object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a sine wave object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.SineWave.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the sine wave object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.SineWave.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Reset sine wave to the beginning

**Syntax** reset(H)

**Description** reset(H) resets the sine wave object to the beginning ( $n=0$ ). If you invoke the `step` method without first invoking the `reset` method, the sine wave object generates additional samples of the original sinusoid. As an example:

```
H = dsp.SineWave('Amplitude',1,'Frequency',1/4,'SamplesPerFrame',7);
% 7 samples of a sine wave with frequency of 1/4 Hz
y = step(H);
% Call step method without reset
y1 = step(H);
stem([y; y1])
% y1 is a continuation of y
% Now reset
reset(H);
y2 = step(H);
% y2 starts at n=0 and equals y
isequal(y,y2)
```

# **dsp.SineWave.step**

---

**Purpose**            Discrete-time sine wave

**Syntax**             $Y = \text{step}(H)$

**Description**         $Y = \text{step}(H)$  produces the sine wave  $Y$  using the specifications in the object  $H$ .

## **Purpose**

Display frequency spectrum of time-domain signals

## **Description**

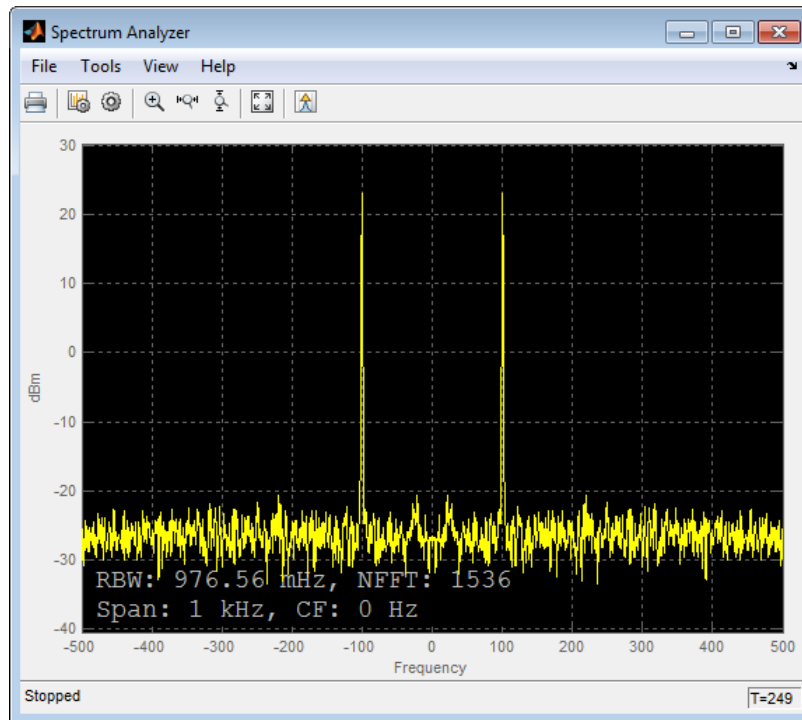

The `SpectrumAnalyzer` object, hereafter referred to as the scope, displays the frequency spectrum of time-domain signals.

To display the spectra of signals in the Spectrum Analyzer:

- 1** Define and set up your Spectrum Analyzer. See “Construction” on page 3-1159.
- 2** Call `step` to display the frequency spectrum of the signals in the Spectrum Analyzer figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Spectrum Analyzer figure window and clear its associated data. Use the `hide` method to hide the Spectrum Analyzer window and the `show` method to make it visible.

# dsp.SpectrumAnalyzer

See the following sections for more information on the Spectrum Analyzer Graphical User Interface:

- “Signal Display” on page 3-1174
- “Toolbar” on page 3-1181
- “Spectrum Settings” on page 3-1184
- “Measurements Panels” on page 3-1190
- “Visuals — Spectrum Properties” on page 3-1196
- “Style Dialog Box” on page 3-1197
- “Tools — Plot Navigation Properties” on page 3-1200

- “Algorithms” on page 3-1202

---

**Note** For information about the Spectrum Analyzer block, see Spectrum Analyzer.

---

---

**Note** If you own the MATLAB Coder product, you can generate C or C++ code from MATLAB code in which an instance of this system object is created. When you do so, the scope system object is automatically declared as an *extrinsic* variable. In this manner, you are able to see the scope display in the same way that you would see a figure using the `plot` function, without directly generating code from it. For the full list of system objects supporting code generation, see “DSP System Toolbox System Objects” in the MATLAB Coder documentation.

---

## Construction

`H = dsp.SpectrumAnalyzer` creates a Spectrum Analyzer System object, `H`. This object displays the frequency spectrum of real- and complex-valued floating- and fixed-point signals.

`H = dsp.SpectrumAnalyzer('Name', Value, ...)` creates a Spectrum Analyzer System object, `H`, with each specified property *Name* set to the specified value. You can specify *Name–Value* arguments in any order.

## Properties

### CenterFrequency

Frequency over which span is centered

Specify as a real scalar the center frequency, in hertz, of the span over which the Spectrum Analyzer computes and plots the spectrum. This property applies when you set the `FrequencySpan` property to `'Span and center frequency'`. The overall span, defined by the `Span` and `CenterFrequency` properties, must fall within the Nyquist frequency interval. When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval

# dsp.SpectrumAnalyzer

---

is  $\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset$  hertz.  
When the `PlotAsTwoSidedSpectrum` property is set to false, the

interval is  $\left[ 0, \frac{SampleRate}{2} \right] + FrequencyOffset$  hertz.

This property is Tunable.

**Default:** 0

## **FFTLength**

FFT length

Specify as a positive, scalar integer the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. This property applies only when you set the `FFTLengthSource` property to 'Property'.

This property is Tunable.

**Default:** 128

## **FFTLengthSource**

Source of the FFT length value

Specify the source of the FFT length value as one of 'Auto' or 'Property'.

- When you set this property to 'Auto', the Spectrum Analyzer sets the FFT length to the data segment length required to achieve the specified resolution bandwidth.
- When you set this property to 'Property', specify the number of FFT points using the `FFTLength` property.

This property is Tunable.

**Default:** 'Auto'

## FrequencyOffset

Frequency offset

Specify as a real, scalar value a frequency offset, in hertz. The *frequency*-axis values, which you also specify, are offset by the value specified in this property. The overall span must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is true, the Nyquist interval

is  $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

When you set the `PlotAsTwoSidedSpectrum` property to false,

the Nyquist interval is  $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

You can control the overall span in different ways based on how you set the `FrequencySpan` property.

**Default:** 0

## FrequencyScale

Frequency scale

Specify the frequency scale as either 'Linear' or 'Log'. When you set this property to 'Log', the Spectrum Analyzer displays the frequencies on the x-axis on a logarithmic scale. To use the 'Log' setting, you must also set the `PlotAsTwoSidedSpectrum` property to false. When the `PlotAsTwoSidedSpectrum` property is true, you must set this property to 'Linear'.

This property is Tunable.

**Default:** 'Linear'

## FrequencySpan

# dsp.SpectrumAnalyzer

---

Frequency span mode

Specify the frequency span mode as one of 'Full', 'Span and center frequency', or 'Start and stop frequencies'.

- When you set this property to 'Full', the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is true, the Nyquist interval is

$\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset$  hertz. If you set the `PlotAsTwoSidedSpectrum` property to false, the

Nyquist interval is  $\left[ 0, \frac{SampleRate}{2} \right] + FrequencyOffset$  hertz.

- When you set this property to 'Span and center frequency', the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `Span` and `CenterFrequency` properties.
- When you set this property to 'Start and stop frequencies', the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `StartFrequency` and `StopFrequency` properties.

This property is Tunable.

**Default:** 'Full'

## **Name**

Caption to display on Spectrum Analyzer window

Specify as a string the caption to display on the scope window. This property is Tunable.

**Default:** 'Spectrum Analyzer'

## OverlapPercent

Overlap percentage

Specify as a real, scalar value, the percentage overlap between the previous and current buffered data segments. The value must be greater than or equal to zero and less than 100. This property is Tunable.

**Default:** 80

## PlotAsTwoSidedSpectrum

Two sided spectrum flag

Set this property to `true` to compute and plot two-sided spectral estimates. Set this property to `false` to compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued. When the input signal is complex valued, you must set this property to `true`.

When this property is `false`, Spectrum Analyzer uses *power folding*. The  $y$ -axis values are twice the amplitude that they would be if this property were set to `true`, except at 0 and the Nyquist frequency. A one-sided PSD contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see the `pwelch` function reference page.

**Default:** `true`

## PlotMaxHoldTrace

Max-hold trace flag

Set this property to `true` to compute and plot the maximum-hold spectrum of each input channel. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations.

This property is Tunable.

See also: `PlotMinHoldTrace`, `PlotNormalTrace`.

**Default:** `false`

## **PlotMinHoldTrace**

Min-hold trace flag

Set this property to `true` to compute and plot the minimum-hold spectrum of each input channel. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations.

This property is Tunable.

See also: `PlotMaxHoldTrace`, `PlotNormalTrace`.

**Default:** `false`

## **PlotNormalTrace**

Normal trace flag

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Note that even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations.

This property is Tunable.

See also: `PlotMaxHoldTrace`, `PlotMinHoldTrace`.

**Default:** `true`

## **Position**

Spectrum Analyzer window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, `[left bottom width height]`. You can place the scope window in a specific position

on your screen by modifying the values to this property. This property is Tunable.

**Default:** The default depends on your screen resolution. By default, the Spectrum Analyzer window appears in the center of your screen with a width of 410 pixels and height of 300 pixels.

## PowerUnits

Power units

Specify the units in which the Spectrum Analyzer displays power values as either 'dBm', 'dBW', or 'Watts'.

This property is Tunable.

**Default:** 'dBm'

## RBW

Resolution bandwidth

Specify as a real, positive scalar the resolution bandwidth (RBW), in hertz. RBW controls the spectral resolution of Spectrum Analyzer. This property applies only when you set the RBWSource property to 'Property'. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater

than two:  $\frac{span}{RBW} > 2$ . You can specify the overall span in different ways based on how you set the FrequencySpan property.

This property is Tunable.

See also: RBWSource.

**Default:** 9.76

## RBWSource

Source of resolution bandwidth value

Specify the source of the resolution bandwidth (RBW) as either 'Auto' or 'Property'.

- When you set this property to 'Auto', the Spectrum Analyzer adjusts the spectral estimation resolution. This adjustment ensures that there are 1024 RBW intervals over the defined frequency span.
- When you set this property to 'Property', specify the resolution bandwidth directly when you set the RBW property.

This property is Tunable.

See also: RBW.

**Default:** 'Auto'

## **ReducePlotRate**

Reduce plot rate to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time it computes the power spectrum. The simulation speed is faster when this property is set to `true`. This property is Tunable.

**Default:** `true`

## **ReferenceLoad**

Reference load

Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values.

This property is Tunable.

**Default:** 1

## **SampleRate**

Sample rate of input

Specify the sample rate, in hertz, of the input signals.

The sample rate must be a finite numeric scalar.

**Default:** 10e3

## **ShowGrid**

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable.

**Default:** `false`

## **ShowLegend**

Show or hide legend

When you set this property to `true`, the scope displays a legend with automatic string labels for each input channel. When you set this property to `false`, the scope does not display a legend. See `FrameBasedProcessing` for information on input channels. This property is Tunable.

**Default:** `false`

## **SidelobeAttenuation**

Sidelobe attenuation of window

Specify as a real, positive scalar the window sidelobe attenuation, in decibels (dB). This property applies only when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The value must be greater than or equal to 45.

This property is Tunable.

**Default:** 60

## Span

Frequency span over which spectrum is computed and plotted

Specify as a real, positive scalar the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum.

This property applies only when you set the `FrequencySpan` property to 'Span and center frequency'. The overall span, defined by this property and the `CenterFrequency` property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is true, the Nyquist interval

is  $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

When you set the `PlotAsTwoSidedSpectrum` property to false,

the Nyquist interval is  $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

This property is Tunable.

See also: `CenterFrequency`, `PlotAsTwoSidedSpectrum`.

**Default:** 10e3

## SpectralAverages

Number of spectral averages

Specify as a positive, scalar integer the number of spectral averages. The Spectrum Analyzer computes the current power spectrum estimate by averaging the last  $N$  power spectrum estimates. This property defines the number of spectral averages,  $N$ .

This property is Tunable.

**Default:** 10

## SpectrumType

Spectrum type

Specify the spectrum type as one of 'Power' or 'Power density'.

- When you set this property to 'Power', the Spectrum Analyzer shows the power spectrum.
- When you set this property to 'Power density', the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.

This property is Tunable.

**Default:** 'Power'

## StartFrequency

Start frequency over which spectrum is computed

Specify as a real scalar the start frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to 'Start and stop frequencies'. The overall span, which is defined by StopFrequency and this property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is true, the Nyquist interval

is  $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz. If you set the PlotAsTwoSidedSpectrum property to false, the

Nyquist interval is  $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

This property is Tunable.

See also: StopFrequency, PlotAsTwoSidedSpectrum.

# dsp.SpectrumAnalyzer

---

**Default:** -5e3

## StopFrequency

Stop frequency over which spectrum is computed

Specify as a real scalar the stop frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum.

This property applies only when you set the FrequencySpan property to 'Start and stop frequencies'. The overall span, defined by this property and the StartFrequency property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is set to true, the interval

is  $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz. When the PlotAsTwoSidedSpectrum property is set to false, the

interval is  $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

This property is Tunable.

See also: StartFrequency, PlotAsTwoSidedSpectrum.

**Default:** 5e3

## Title

Display title

Specify the display title as a string. This property is Tunable.

**Default:** ''

## Window

Window function

Specify a window function for the spectral estimator as one of the options in the following table. For information on any window

function, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Function in Signal Processing Toolbox
'Rectangular'	rectwin
'Chebyshev'	chebwin
'Flat Top'	flattopwin
'Hamming'	hamming
'Hann'	hann
'Kaiser'	kaiser

This property is Tunable.

**Default:** 'Hann'

## YLabel

The label for the  $y$ -axis

Specify as a string the text for the scope to display to the left of the  $y$ -axis. This property is Tunable.

Regardless of this property, Spectrum Analyzer always displays power units as one of 'dBm', 'dBW', 'Watts', 'dBm/Hz', 'dBW/Hz', 'Watts/Hz'.

See also: PowerUnits.

**Default:** ''

## YLimits

The limits for the  $y$ -axis

Specify the  $y$ -axis limits as a 2-element numeric vector, [ymin ymax]. This property is Tunable.

# dsp.SpectrumAnalyzer

---

The units directly depend upon the PowerUnits property.

**Default:** [-80, 20]

## Methods

clone	Create spectrum scope object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
hide	Hide Spectrum Analyzer window
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of Spectrum Analyzer object
show	Make Spectrum Analyzer window visible
step	Update spectrum in Spectrum Analyzer figure

## Examples

View a two-sided power spectrum of a sine wave with noise on the Spectrum Analyzer.

```
hsin = dsp.SineWave('Frequency',100,'SampleRate',1000);
hsin.SamplesPerFrame = 1000;
hsa = dsp.SpectrumAnalyzer('SampleRate',hsin.SampleRate);
for ii = 1:250
    x = step(hsin) + 0.05*randn(1000,1);
    step(hsa, x);
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(hsa);
```

Run the MATLAB `clear` function to close the Spectrum Analyzer window.

```
clear('hsa');
```

View a one-sided power spectrum made from the sum of five real sine waves with different amplitudes and frequencies.

```
Fs = 100e6; % Sampling frequency  
fSz = 5000; % Frame size
```

```
hsin1 = dsp.SineWave(1e0, 5e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);  
hsin2 = dsp.SineWave(1e-1, 15e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);  
hsin3 = dsp.SineWave(1e-2, 25e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);  
hsin4 = dsp.SineWave(1e-3, 35e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);  
hsin5 = dsp.SineWave(1e-4, 45e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);
```

```
hsb = dsp.SpectrumAnalyzer;  
hsb.SampleRate = Fs;  
hsb.SpectralAverages = 1;  
hsb.PlotAsTwoSidedSpectrum = false;  
hsb.RBWSource = 'Auto';  
hsb.PowerUnits = 'dBW';  
hsb.Position = [749 227 976 721];  
for idx = 1:1e2  
    y1 = step(hsin1);  
    y2 = step(hsin2);  
    y3 = step(hsin3);  
    y4 = step(hsin4);  
    y5 = step(hsin5);  
    step(hsb, y1+y2+y3+y4+y5+0.0001*randn(fSz, 1));  
end
```

# dsp.SpectrumAnalyzer

---

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(hsb);
```

Run the MATLAB `clear` function to close the Spectrum Analyzer window.

```
clear('hsb');
```

## Signal Display

The Spectrum Analyzer indicates the spectrum computation settings that are represented in the current display. Check the **Resolution Bandwidth**, **Number of FFT Points**, **Frequency Span**, and **Center Frequency** indicators on the axes in the scope window for this information. These indicators relate to the **Minimum Frequency-Axis limit** and **Maximum Frequency-Axis limit** values on the *frequency*-axis of the scope window. The values specified by these indicators may be changed by modifying parameters in the **Spectrum Settings** panel. You can also view the object state and the amount of time data that correspond to the current display. Check the **Simulation Status** and **Simulation time** indicators on the status bar in the scope window for this information. The following figure highlights these aspects of the Spectrum Analyzer window.

- **Frequency Span** — The range of values shown on the *frequency*-axis on the Spectrum Analyzer window.

## Details

Spectrum Analyzer sets the frequency span using the values of parameters on the **Main options** pane of the **Spectrum Settings** panel.

- **Span (Hz) and CF (Hz) visible** — The **Frequency Span** value equals the **Span** parameter in the **Main options** pane. You can also get or set this value from the **Span** property when the **FrequencySpan** property is set to 'Span and Center Frequency'.
- **FStart (Hz) and FStop (Hz)** — The **Frequency Span** value equals the difference of the **FStop** and **FStart** parameters in the **Main options** pane, as given by the formula:  $f_{span} = f_{stop} - f_{start}$ . You can also get or set these values from the **StartFrequency** and **StopFrequency** properties when the **FrequencySpan** property is set to 'Start and stop frequencies'.

By default, the **Full Span** check box in the **Main options** pane is enabled, and its equivalent `FrequencySpan` property is set to 'Full'. In this case, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the **Two-sided spectrum** check box in the **Trace options** pane is enabled, and its equivalent `PlotAsTwoSidedSpectrum` property is true, the Nyquist

interval is  $\left[-\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2}\right] + \text{FrequencyOffset}$  hertz. If you set the `PlotAsTwoSidedSpectrum` property to false, the

Nyquist interval is  $\left[0, \frac{\text{SampleRate}}{2}\right] + \text{FrequencyOffset}$  hertz.

- **Resolution Bandwidth** — The smallest positive frequency, or frequency interval, that can be resolved.

## Details

Spectrum Analyzer sets the resolution bandwidth using the value of the **RBW** parameter on the **Main options** pane of the **Spectrum Settings** panel. You can also get or set this value from the `RBW` property when `RBWSource` is set to 'Property'. By default, the **RBW** parameter on the **Main options** pane and the related `RBWSource` property are set to 'Auto'. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 **RBW** intervals over the specified **Frequency Span**.

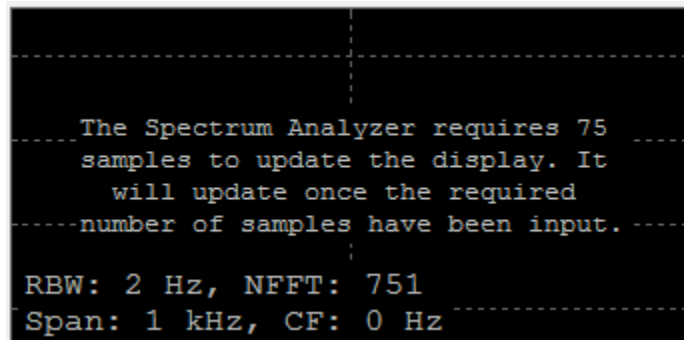

You can set the resolution bandwidth to whatever value you choose. For this reason, there is a minimum boundary on the number of input samples required to compute a spectral update. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to *RBW* by the following equation:

$$N_{\text{samples}} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{\text{Overlap} \% \times \text{RBW}}$$

Overlap percentage,  $O_p$ , is the value of the **Overlap %** parameter in the **Frequency Options**

pane of the **Spectrum Settings** panel.  $NENBW$  is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Frequency Options** pane.  $F_s$  is the sample rate. In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.

Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input.

- **Number of FFT Points** — The Fast Fourier Transform (FFT) length.

## Details

Spectrum Analyzer sets the number of FFT points using the value of the **NFFT** parameter on the **Trace options** pane of the **Spectrum Settings** panel. You can also get or set this value from the `FFTLength` property when the `FFTLengthSource` property is set to 'Property'. By default, the **NFFT** parameter on the **Trace options** pane and the related `FFTLengthSource` property are set to 'Auto'. In this case, the Spectrum Analyzer sets the number of FFT points to the data segment length needed to achieve the specified **Resolution Bandwidth**.

- **Center Frequency** — The value shown at the middle point of the *frequency*-axis on the Spectrum Analyzer display.

## Details

Spectrum Analyzer sets the center frequency using the values of parameters on the **Main options** pane of the **Spectrum Settings** panel.

- **Span (Hz) and CF (Hz) visible** — The **Center Frequency** value equals the **CF** parameter in the **Main options** pane. You can also get or set this value from the `CenterFrequency` property when the `FrequencySpan` property is set to 'Span and Center Frequency'.
- **FStart (Hz) and FStop (Hz) visible** — The **Center Frequency** value equals half the sum of the **FStop** and **FStart** parameters in the **Main options** pane, as given by the

formula:  $f_{center} = \frac{f_{start} + f_{stop}}{2}$ . You can also get or set these values from the `StartFrequency` and `StopFrequency` properties when the `FrequencySpan` property is set to 'Start and stop frequencies'.

- **Minimum Frequency-Axis limit** — The value shown at the far-left side of the frequency-axis on the Spectrum Analyzer window. Spectrum Analyzer sets the minimum *frequency*-axis limit using the values of the parameters on the **Main options** pane of the **Spectrum Settings** panel.

## Details

- **Span (Hz) and CF (Hz) visible** — The **Minimum Frequency-Axis limit** value equals the difference between the center frequency and half the frequency span, as given by the

following formula:  $f_{min} = f_{center} - \frac{f_{span}}{2}$ . In this case, you can modify the minimum *frequency*-axis limit by changing the **Span** and **CF** parameters in the **Main options** pane. You can also get

or set these values from the `Span` and `CenterFrequency` properties when the `FrequencySpan` property is set to 'Span and Center Frequency'.

- `FStart` (Hz) and `FStop` (Hz) visible — The **Minimum Frequency-Axis limit** value equals the **FStart** parameter in the **Main options** pane. You can also get or set this value from the `StartFrequency` property when the `FrequencySpan` property is set to 'Start and stop frequencies'.
- **Maximum Frequency-Axis limit** — The value shown at the far-right side of the *frequency*-axis on the Spectrum Analyzer window. Spectrum Analyzer sets the maximum *frequency*-axis limit using the values of the parameters on the **Main options** pane of the **Spectrum Settings** panel.

## Details

- `Span` (Hz) and `CF` (Hz) visible — The **Maximum Frequency-Axis limit** value equals the sum of the center frequency and half the frequency span, as given by the following

formula:  $f_{max} = f_{center} + \frac{f_{span}}{2}$ . In this case, you can modify the maximum *frequency*-axis limit by changing the **Span** and **CF** parameters in the **Main options** pane. You can also get or set these values from the `Span` and `CenterFrequency` properties when the `FrequencySpan` property is set to 'Span and Center Frequency'.

- `FStart` (Hz) and `FStop` (Hz) visible — The **Maximum Frequency-Axis limit** value equals the **FStop** parameter in the **Main options** pane. You can also get or set this value from the `StopFrequency` property when the `FrequencySpan` property is set to 'Start and stop frequencies'.
- **Simulation Status** — Provides the current status of the model simulation.

## Details

The status can be one of the following conditions:

- **Processing** — Occurs after you construct the SpectrumAnalyzer object and before you run the `release` method.
- **Stopped** — Occurs after you run the `release` method.

The **Simulation Status** is part of the **Status Bar** in the Spectrum Analyzer window. You can choose to hide or display the entire **Status Bar**. From the Spectrum Analyzer menu, select **View > Status Bar**.

- **Simulation time** — The amount of time that has progressed since the Spectrum Analyzer System object was first constructed or reset.

## Details

Every time you call the `step` method, the simulation time increases by the number of rows in the input signal divided by the sample

rate, as given by the following formula:  $t_{sim} = t_{sim} + \frac{\text{length}(x)}{\text{SampleRate}}$ . At the beginning of a simulation, you can modify the **SampleRate** parameter on the **Main options** pane of the **Spectrum Settings** panel. You can also set the sample rate using the `SampleRate` property.

The **Simulation time** indicator is a component of the **Status Bar** in the Spectrum Analyzer window. You can choose to hide or display the entire **Status Bar**. From the Spectrum Analyzer menu, select **View > Status Bar**.

For more information, see “Spectrum Settings” on page 3-1184.

## Reduce Plot Rate to Improve Performance

By default, Spectrum Analyzer updates the display periodically at a rate not exceeding 20 hertz. If you want Spectrum Analyzer to plot a spectrum on every simulation time step, you can disable the **Reduce Plot Rate to Improve Performance** option. In the Spectrum

Analyzer menu, select **Tools > Reduce Plot Rate to Improve Performance** to clear the check box. Tunable.

---

**Note** When this check box is selected, Spectrum Analyzer may display a misleading spectrum in some situations. For example, if the input signal is wide-band with non-stationary behavior, such as a chirp signal, Spectrum Analyzer might display a stationary spectrum. The reason for this behavior is that Spectrum Analyzer buffers the input signal data and only updates the display periodically at approximately 20 times per second. Therefore, Spectrum Analyzer does not render changes to the spectrum that occur and elapse between updates, which gives the impression of an incorrect spectrum. To ensure that spectral estimates are as accurate as possible, clear the **Reduce Plot Rate to Improve Performance** check box. When you clear this box, Spectrum Analyzer calculates spectra whenever there is enough data, rendering results correctly.

---

## Toolbar

The Spectrum Analyzer toolbar contains the following buttons.

### Print, Settings, and Properties Buttons

Button	Menu Location	Shortcut Keys	Description
	<b>File &gt; Print</b>	<b>Ctrl+P</b>	Print the current Spectrum Analyzer window. To enable printing, run the release method.  To print the current scope window to a figure rather than sending it to your printer, select <b>File &gt; Print to figure</b> .
	<b>View &gt; Spectrum Settings</b>	N/A	Open or close the <b>Spectrum Settings</b> panel. You can modify the settings in this panel to control the manner in which the spectrum is calculated.

# dsp.SpectrumAnalyzer

Button	Menu Location	Shortcut Keys	Description
			See the “Spectrum Settings” on page 3-1184 section for more information.
	View > Properties	N/A	Open the <b>Visuals — Spectrum Options</b> dialog box. See the “Visuals — Spectrum Properties” on page 3-1196 section for more information.

## Axes Control Buttons

	Tools > Zoom In	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw a rectangular area of interest inside the scope window.
	Tools > Zoom X	N/A	When this tool is active, you can zoom in on the <i>x</i> -axis. To do so, click inside the scope window, or click and drag your cursor along the <i>x</i> -axis over your area of interest.

	<b>Tools &gt; Zoom Y</b>	N/A	<p>When this tool is active, you can zoom in on the <i>y</i>-axis. To do so, click inside the scope window, or click and drag your cursor along the <i>y</i>-axis over your area of interest.</p>
	<b>Tools &gt; Scale Axes Limits</b>	<b>Ctrl+A</b>	<p>Click this button to scale the axes in the active scope window.</p> <p>Alternatively, you can enable automatic axes scaling by selecting one of the following options from the <b>Tools</b> menu:</p> <ul style="list-style-type: none"> <li>• <b>Automatically Scale Axes Limits</b> — When you select this option, the scope scales the axes as needed during simulation.</li> <li>• <b>Scale Axes Limits after 10 Updates</b> — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation.</li> <li>• <b>Scale Axes Limits at Stop</b> — When you select this option, the scope scales the axes each time the simulation is stopped.</li> </ul>

---

**Note** The axes control (zoom) buttons do not change the settings related to frequency span for Spectrum Analyzer. These buttons are purely graphical. Spectrum computations are not affected when you zoom.

---

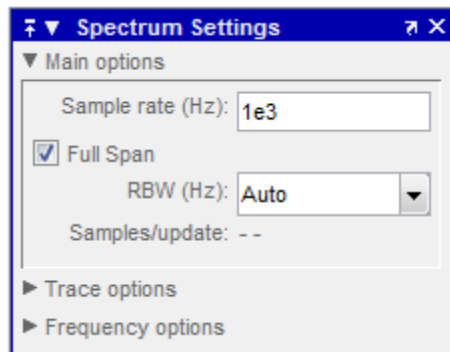

## Measurements Buttons

	<b>Tools &gt; Measurements &gt; Peak Finder</b>	NA	Click to close the <b>Peak Finder</b> panel. This panel displays maxima and the frequencies at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified.  See the “Peak Finder Panel” on page 3-1333 section for more information.
---	---	----	--

You can control whether this toolbar appears in the Spectrum Analyzer window. From the Spectrum Analyzer menu, select **View > Toolbar**.

## Spectrum Settings

The **Spectrum Settings** panel appears at the right side of the Spectrum Analyzer figure. This panel enables you to modify settings to control the manner in which the spectrum is calculated. You can choose to hide or display the **Spectrum Settings** panel. In the Spectrum Analyzer menu, select **View > Spectrum Settings**. Alternatively, in the Spectrum Analyzer toolbar, select the Spectrum Settings  button.

The **Spectrum Settings** panel is separated into three panes, labeled **Main Options**, **Trace Options**, and **Frequency Options**. You can expand each pane to see the available options.

## Main Options Pane

The **Main Options** pane enables you to modify the main options.

- **Sample rate (Hz)** — The sample rate, in hertz, of the input signals. This parameter is also known as sampling frequency.
- **Full span** — Enable this check box to have Spectrum Analyzer compute and plot the spectrum over the entire *Nyquist* frequency interval. By default, when the **Two-sided spectrum** check box is also enabled, the Nyquist interval is

$\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset$  hertz. If you clear the **Two-sided spectrum** check box, the Nyquist interval

is  $\left[ 0, \frac{SampleRate}{2} \right] + FrequencyOffset$  hertz. Enabling this check box is equivalent to setting the `FrequencySpan` property to 'Full'. Tunable.

- **Span (Hz)** and **CF (Hz)**, or **FStart (Hz)** and **FStop (Hz)** — When **Span (Hz)** is showing in the **Main Options** pane, you define the range of values shown on the *frequency*-axis on the Spectrum Analyzer window using frequency span and center frequency. From the drop-down list, select **FStart (Hz)** to define the range of *frequency*-axis values using start frequency and stop frequency instead.
  - **Span (Hz)** — The frequency span, in hertz. This parameter defines the range of values shown on the *frequency*-axis on the Spectrum Analyzer window. When this parameter is set to a numeric value, then it is equivalent to the `Span` property when the `FrequencySpan` property is set to 'Span and Center Frequency'. Tunable.
  - **CF (Hz)** — The center frequency, in hertz. This parameter defines the value shown at the middle point of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the

CenterFrequency property when the FrequencySpan property is set to 'Span and Center Frequency'. Tunable.

- **FStart (Hz)** — The start frequency, in hertz. This parameter defines the value shown at the leftmost side of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the StartFrequency property when the FrequencySpan property is set to 'Start and stop frequencies'. Tunable.
- **FStop (Hz)** — The stop frequency, in hertz. The parameter defines the value shown at the rightmost side of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the StopFrequency property when the FrequencySpan property is set to 'Start and stop frequencies'. Tunable.
- **RBW (Hz)** — The resolution bandwidth, in hertz. This parameter defines the smallest positive frequency that can be resolved. By default, this parameter is set to Auto. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 *RBW* intervals over the specified **Frequency Span**. This case is equivalent to when you set the RBWSource property to 'Auto'.

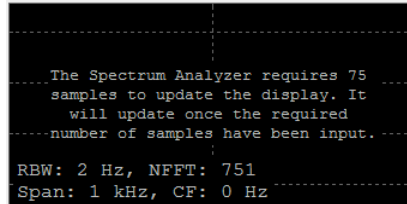

If you set this parameter to a numeric value, then you must specify a value that ensures there are at least two *RBW* intervals over the specified frequency span. In other words, the ratio of the overall

span to *RBW* must be at least two:  $\frac{span}{RBW} > 2$ . In this case, this parameter is equivalent to the *RBW* property, when RBWSource is set to 'Property'. Tunable.

- **Samples/update** — The number of input samples required to compute one spectral update. You cannot modify this parameter; it is shown here for display purposes only. This parameter is directly related to *RBW* by the following equation:

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}. \quad NENBW \text{ is the normalized effective noise bandwidth, a factor of the windowing method used,}$$

which is shown in the **Frequency Options** pane.  $F_s$  is the sample rate. If the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display as shown in the following figure.

```
.....  
.....  
..... The Spectrum Analyzer requires 75  
..... samples to update the display. It  
..... will update once the required  
..... number of samples have been input. ....  
.....  
..... RBW: 2 Hz, NFFT: 751  
..... Span: 1 kHz, CF: 0 Hz  
.....
```

## Trace Options Pane

The **Trace Options** pane enables you to modify the trace options.

- **Type** — The type of spectrum to display. Available options are **Power** and **Power density**. When you set this parameter to **Power**, the Spectrum Analyzer shows the power spectrum. When you set this parameter to **Power density**, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude of the spectrum normalized to a bandwidth of 1 hertz. This parameter is equivalent to the `SpectrumType` property. Tunable.
- **Units** — The units of the spectrum. Available options are **dBm**, **dBW**, and **Watts**. This parameter is equivalent to the `PowerUnits` property. Tunable.
- **Averages** — Specify as a positive, scalar integer the number of spectral averages. Spectrum Analyzer computes the current power spectrum estimate by averaging the last  $N$  power spectrum estimates. This property defines the number of spectral averages,  $N$ . This parameter is equivalent to the `SpectralAverages` property. Tunable.
- **NFFT** — The number of Fast Fourier Transform (FFT) points. This parameter defines the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are **Auto** or a positive, scalar integer. By default, when this parameter is

set to Auto, Spectrum Analyzer sets the number of FFT points to the data segment length needed to achieve the resolution bandwidth you specified. This case is equivalent to when you set the `FFTLengthSource` property to 'Auto'.

When this parameter is set to a positive integer, this parameter is equivalent to the `n` parameter that you can set when you run the MATLAB `fft` function. In this case, this parameter is also equivalent to `FFTLength` when you set `FFTLengthSource` to 'Property'. Tunable.

- **Ref. load** — The reference load, in ohms, used to scale the spectrum. Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values. This parameter is equivalent to the `ReferenceLoad` property. Tunable.
- **Normal trace** — Normal trace view. By default, when this check box is enabled, Spectrum Analyzer calculates and plots the power spectrum or power spectrum density computed by the *Welch* estimator. The Welch estimator performs a smoothing operation by averaging a number of spectral estimates. To clear this check box, you must first select either the **Max hold trace** or the **Min hold trace** check box. This parameter is equivalent to the `PlotNormalTrace` property. Tunable.
- **Max hold trace** — Maximum hold trace view. Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained. This parameter is equivalent to the `PlotMaxHoldTrace` property. Tunable.
- **Min hold trace** — Minimum hold trace view. Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained. This parameter is equivalent to the `PlotMinHoldTrace` property. Tunable.
- **Two-sided spectrum** — Select this check box to enable two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input

signal is complex-valued. This parameter is equivalent to the `PlotAsTwoSidedSpectrum` property.

## Frequency Options Pane

The **Frequency Options** pane enables you to modify the frequency options.

- **Scale** — Linear or logarithmic scale. When the frequency span contains negative frequency values, Spectrum Analyzer disables the logarithmic option. This parameter is equivalent to the `FrequencyScale` property. Tunable.
- **Offset** — The constant frequency offset to apply to the entire spectrum. This constant offset parameter is simply added to the values on the *frequency*-axis in the Spectrum Analyzer window. It is not used in any spectral computations. You must take this parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within Nyquist limits. The Nyquist interval

is  $\left[ -\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset}$  hertz if **Two-sided spectrum** is selected, and

$\left[ 0, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset}$  hertz otherwise. This parameter is equivalent to the `FrequencyOffset` property.

- **Overlap (%)** — The segment overlap percentage. This parameter defines the amount of overlap between the previous and current buffered data segments. The value must be greater than or equal to zero and less than 100. This parameter is equivalent to the `OverlapPercent` property. Tunable.
- **Window** — The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the segment length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see

“Windows” in the Signal Processing Toolbox documentation. This parameter is equivalent to the Window property. Tunable.

- **Attenuation (dB)** — The sidelobe attenuation, in decibels (dB). This property applies only when you set the **Window** parameter to Chebyshev or Kaiser. You must specify a value greater than or equal to 45. This parameter is equivalent to the SidelobeAttenuation property. Tunable.
- **NENBW** — Normalized Effective Noise Bandwidth of the window. You cannot modify this parameter; it is a readout shown here for display purposes only. This parameter is a measure of the noise performance of the window. It is the width of a rectangular filter that accumulates the same noise power with the same peak power gain. NENBW can be calculated from the windowing function using

the following equation: 
$$NENBW = N_{segment} \frac{\sum_{n=1}^{N_{segment}} w^2(n)}{N}$$
. The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

**Measurements Panels** The Measurements panels are the other two panels that appear to the right side of the Spectrum Analyzer figure. These panels are labeled **Trace selection** and **Peak finder**.

### Measurements Panel Buttons

Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

Button	Description
	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button  .
	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button  again.
	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button  in the new window.
	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button  again.
	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button  to show each pane that is hidden in the current panel. Click the pane collapse button  to hide each pane that is shown in the current panel.

## Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. The Measurements

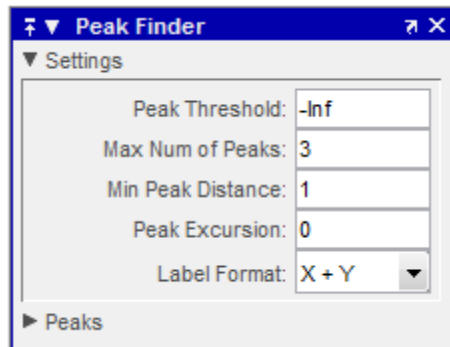

panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.

You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools > Measurements > Trace Selection**.

## Peak Finder Panel

The **Peak Finder** panel displays maxima and the  $x$ -axis values at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools > Measurements > Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder  button.

The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

## Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer between 1 and 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.

The *peak threshold* is a minimum value necessary for a sample value to be a peak. The *peak excursion* is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the THRESHOLD parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
  - X+Y — Display both *x*-axis and *y*-axis values.

- X — Display only  $x$ -axis values.
- Y — Display only  $y$ -axis values.

## Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.

The numerical values displayed in the **Value** column are equivalent to the `pk`s output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button (▼) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (▲). A filled sort button indicates that the peak values are currently sorted by this category. If the sort button is not filled (◻), then the peak values are sorted by the other category. The **Max Num of Peaks** parameter still controls the number of peaks listed.

# dsp.SpectrumAnalyzer

---

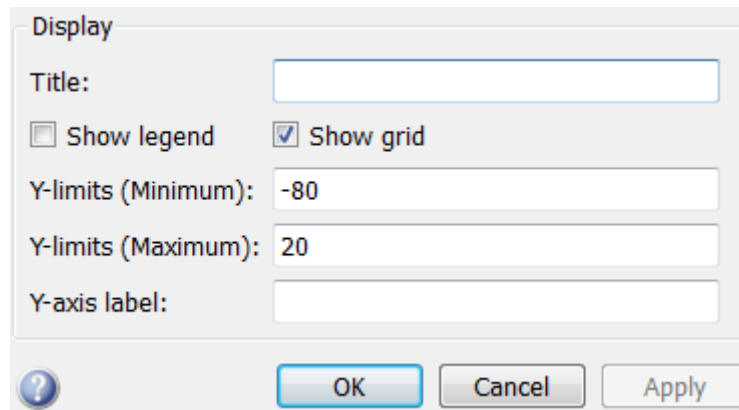

Use the check boxes to control which peaks are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peaks. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

## Visuals – Spectrum Properties

The Visuals—Spectrum Properties dialog box controls the visual configuration settings of the Spectrum Analyzer display. From the Spectrum Analyzer menu, select **View > Configuration Properties** to open this dialog box. Alternatively, in the Spectrum Analyzer toolbar, click the Configuration Properties  button.

### Display Pane

The **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows.

The screenshot shows the 'Display' pane of the Visuals—Spectrum Properties dialog box. It includes the following elements:

- Title:** A text input field.
- Show legend:** A checkbox that is currently unchecked.
- Show grid:** A checkbox that is currently checked.
- Y-limits (Minimum):** A text input field containing the value '-80'.
- Y-limits (Maximum):** A text input field containing the value '20'.
- Y-axis label:** A text input field.
- Buttons:** A help button (question mark), an 'OK' button, a 'Cancel' button, and an 'Apply' button.

#### **Title**

Specify the display title as a string. This property is Tunable.

By default, the display has no title.

## Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. Tunable.

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View > Style**.

## Show grid

When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable.

## Y-limits (Minimum)

Specify the minimum value of the *y*-axis. Tunable.

## Y-limits (Maximum)

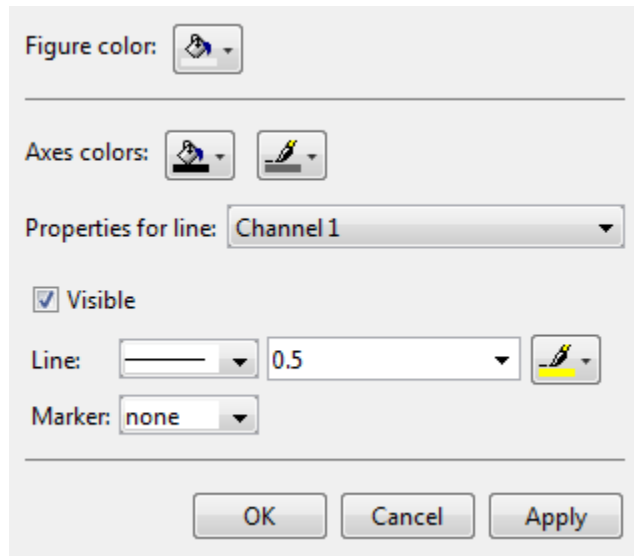

Specify the maximum value of the *y*-axis. Tunable.

## Y-axis label

Specify the text for the scope to display to the left of the *y*-axis. Regardless of this property, Spectrum Analyzer always displays power units after this text as one of 'dBm', 'dBW', 'Watts', 'dBm/Hz', 'dBW/Hz', or 'Watts/Hz'. Tunable.

## Style Dialog Box

In the **Style** dialog box, you can customize the style of displays. You are able to change the color of the figure, the background and foreground colors of the axes, and properties of the lines. From the Spectrum Analyzer menu, select **View > Style** to open this dialog box.

## Properties

The **Style** dialog box allows you to modify the following properties of the Spectrum Analyzer figure:

### Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

### Axes colors

Specify the color that you want to apply to the background of the axes.

### Properties for line

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

### Visible

Specify whether the selected channel should be visible. If you clear this check box, the line disappears.

### Line

Specify the line style, line width, and line color for the selected channel.

## Marker

Specify marks for the selected channel to show at its data points. This parameter is similar to the Marker property for the MATLAB Handle Graphics plot objects. You can choose any of the marker symbols from the following table.

Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
•	Point
+	Plus sign
*	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle
☆	Five-pointed star (pentagram)
☆☆	Six-pointed star (hexagram)

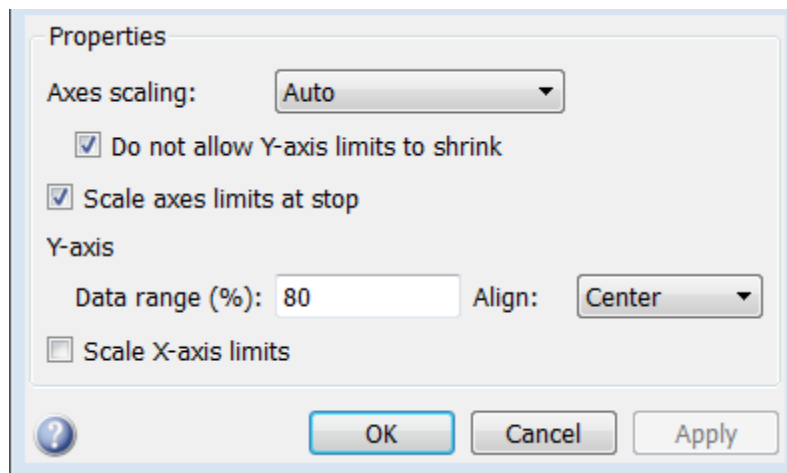

# dsp.SpectrumAnalyzer

## Tools — Plot Navigation Properties

The Tools—Plot Navigation Properties dialog box allows you to automatically zoom in on and zoom out of your data. You can also scale the axes of the Spectrum Analyzer. In the Spectrum Analyzer menu, select **Tools > Axes Scaling Options** to open this dialog box.

### Properties

The Tools—Plot Navigation Properties dialog box appears as follows.

### Axes Scaling

Specify when the scope should automatically scale the axes. You can select one of the following options:

- **Manual** — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools > Scale axes limits**.
  - Press the **Scale Axes Limits** toolbar button.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.

- **Auto** — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- **After N Updates** — Selecting this option causes the scope to scale the axes after a specified number of updates. Selecting this option shows the **Number of updates** edit box.

This parameter is Tunable.

By default, this parameter is set to Auto, and the scope does not shrink the y-axis limits when scaling the axes.

### **Do not allow Y-axis limits to shrink**

When you select this parameter, the y-axis limits are only allowed to grow during axes scaling operations. If you clear this check box, the y-axis limits may shrink during axes scaling operations.

This parameter appears only when you select Auto for the **Axis Scaling** parameter. When you set the **Axes Scaling** parameter to Manual or After N Updates, the y-axis limits are allowed to shrink. Tunable.

### **Number of updates**

Specify as a positive integer the number of updates after which to scale the axes. This parameter appears only when you select After N Updates for the **Axes Scaling** parameter. Tunable.

### **Scale axes limits at stop**

Select this check box to scale the axes limits when the simulation stops. The y-axis are always scaled. The x-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

### **Y-axis Data range (%)**

Set the percentage of the y-axis that the scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this parameter to 100, the Scope scales the y-axis limits such that your data uses the entire y-axis range. If you then set this parameter to 30, the scope increases the y-axis range such that your data uses only 30% of the y-axis range. Tunable.

## **Y-axis Align**

Specify where the scope should align your data with respect to the y-axis when it scales the axes. You can select **Top**, **Center**, or **Bottom**. Tunable.

## **Scale X-axis limits**

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. Tunable.

## **X-axis Data range (%)**

Set the percentage of the *x*-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this parameter to 100, the Scope scales the *x*-axis limits such that your data uses the entire *x*-axis range. If you then set this parameter to 30, the Scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** parameter to specify data placement with respect to the *x*-axis.

This parameter appears only when you select the **Scale X-axis limits** check box. Tunable.

## **X-axis Align**

Specify how the Scope should align your data with respect to the *x*-axis: **Left**, **Center**, or **Right**. This parameter appears only when you select the **Scale X-axis limits** check box. Tunable.

## **Algorithms**

Spectrum Analyzer uses the **RBW** setting in the **Spectrum Settings** panel to determine the length of each data segment. Then, it partitions the input signal into a number of data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

- 1 Spectrum Analyzer requires that a minimum number of samples have been provided before it computes a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, *RBW*, by the following equation.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth,  $NENBW$ , is a factor of the windowing method. Spectrum Analyzer shows  $NENBW$  in the **Frequency Options** pane of the **Spectrum Settings** panel. Overlap percentage,  $O_p$ , is the value of the **Overlap %** parameter in the **Frequency Options** pane of the **Spectrum Settings** panel.  $F_s$  is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** panel.

- a The segment length required to compute one spectral update,  $N_{segment}$ , is directly related to the resolution bandwidth and normalized effective noise bandwidth by the following equation.

$$N_{segment} = \frac{NENBW \times F_s}{RBW}$$

- b The number of input samples required to compute one spectral update,  $N_{samples}$ , is directly related to the segment length and the amount of segment overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{segment}$$

When you increase the overlap percentage, fewer input samples are needed to compute a new spectral update. For example, if the segment length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

# dsp.SpectrumAnalyzer

$O_p$	$N_{samples}$
0%	100
50%	50
80%	20

- c The normalized effective noise bandwidth,  $NENBW$ , is a window constant determined by the window length,  $N_{segment}$ , and the type of window used. If  $w[n]$  denotes the vector of  $N_{segment}$  window coefficients, then  $NENBW$  is given by the following equation.

$$NENBW = N_{segment} \frac{\sum_{n=1}^{N_{segment}} w^2(n)}{\left[ \sum_{n=1}^{N_{segment}} w(n) \right]^2}$$

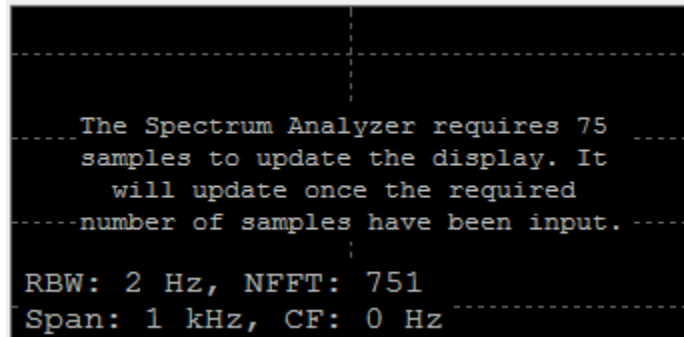

- d You can set the resolution bandwidth using the value of the **RBW** parameter on the **Main options** pane of the **Spectrum Settings** panel. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two, as given in the following equation.

$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to **Auto**. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW** to

**Auto**, it is calculated by the following equation.  $RBW_{auto} = \frac{span}{1024}$

In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.

Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input. Notice that this behavior differs from the Spectrum Scope block in versions R2012b and earlier. If the **Buffer input** check box was selected, the Spectrum Scope block computed a spectral update using the number of samples given by the **Buffer size** parameter. Otherwise, the Spectrum Scope block computed a spectral update using the number of samples in each frame.

- 2 Spectrum Analyzer calculates and plots the power spectrum or power spectrum density computed by the modified *Periodogram* estimator. For more information about the Periodogram method, see *periodogram* in the Signal Processing Toolbox documentation. The power spectral density (PSD) is given by the following equation.

$$PSD(f) = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{F_s \times \sum_{n=1}^{N_{segment}} w^2[n]}$$

# dsp.SpectrumAnalyzer

---

In this equation,  $x[n]$  is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping data segments as possible, each segment denoted as  $x^{(p)}[n]$ , and computes their periodograms. Spectrum Analyzer displays a running average of the  $P$  most current periodograms.

The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{\text{spectrum}}(f) = PSD(f) \times RBW = PSD(f) \times \frac{F_s \times NENBW}{N_{\text{segment}}} = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{\left[ \sum_{n=1}^{N_{\text{segment}}} w[n] \right]^2}$$

Spectrum Analyzer | dsp.TimeScope | dsp.ArrayPlot |  
dsp.LogicAnalyzer

**Purpose**

Create spectrum scope object with same property values

**Syntax**

```
C = clone(H)
```

**Description**

`C = clone(H)` creates a `SpectrumAnalyzer` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.SpectrumAnalyzer.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method. *N* equals the value of the `NumInputPorts` property.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.SpectrumAnalyzer.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method. The Spectrum Analyzer is a sink object, so `N` equals 0.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.SpectrumAnalyzer.hide**

---

**Purpose** Hide Spectrum Analyzer window

**Syntax** `hide(H)`

**Description** `hide(H)` hides the Spectrum Analyzer window, associated with System object, H.

**See Also** `dsp.SpectrumAnalyzer` | `dsp.SpectrumAnalyzer.show`

<b>Purpose</b>	Locked status for input attributes and nontunable properties
<b>Syntax</b>	<code>isLocked(H)</code>
<b>Description</b>	<p><code>isLocked(H)</code> returns the locked state of the <code>SpectrumAnalyzer</code> object <code>H</code>.</p> <p>The <code>isLocked</code> method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the <code>step</code> method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the <code>isLocked</code> method returns a true value.</p>

# dsp.SpectrumAnalyzer.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

You should call the `release` method after calling the `step` method when there is no new data for the simulation. When you call the `release` method, the axes will automatically scale in the Spectrum Analyzer figure window. After calling the `release` method, any non-tunable properties can be set once again.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Algorithms** In operation, the `release` method is similar to the `mdlTerminate` function.

**See Also** `dsp.SpectrumAnalyzer` | `dsp.SpectrumAnalyzer.reset`

<b>Purpose</b>	Reset internal states of Spectrum Analyzer object
<b>Syntax</b>	<code>reset(H)</code>
<b>Description</b>	<p><code>reset(H)</code> sets the internal states of the <code>SpectrumAnalyzer</code> object <code>H</code> to their initial values.</p> <p>You should call the <code>reset</code> method after calling the <code>step</code> method when you want to clear the Spectrum Analyzer figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the <code>reset</code> method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB <code>clf</code> function. Do not call the <code>reset</code> method after calling the <code>release</code> method.</p>
<b>Algorithms</b>	In operation, the <code>reset</code> method is similar to a consecutive execution of the <code>mdlTerminate</code> function and the <code>mdlInitializeConditions</code> function.
<b>See Also</b>	<code>dsp.SpectrumAnalyzer</code>   <code>dsp.SpectrumAnalyzer.release</code>

# dsp.SpectrumAnalyzer.show

---

**Purpose**            Make Spectrum Analyzer window visible

**Syntax**            `show(H)`

**Description**        `show(H)` makes the Spectrum Analyzer window, associated with System object, H, visible.

**See Also**            `dsp.SpectrumAnalyzer` | `dsp.SpectrumAnalyzer.hide`

**Purpose** Update spectrum in Spectrum Analyzer figure

**Syntax** `step(H,X)`

**Description** `step(H,X)` updates the spectrum of the signal, X, in the Spectrum Analyzer figure.

# dsp.StandardDeviation

---

**Purpose** Standard deviation of input or sequence of inputs

**Description** The StandardDeviation object computes the standard deviation for an input or sequence of inputs.

To compute the standard deviation for an input or sequence of inputs:

- 1** Define and set up your standard deviation object. See “Construction” on page 3-1216.
- 2** Call `step` to compute the standard deviation according to the properties of `dsp.StandardDeviation`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.StandardDeviation` returns a standard deviation System object, `H`, that computes the standard deviation for the columns of input.

`H = dsp.StandardDeviation('PropertyName',PropertyValue,...)` returns a standard deviation System object, `H`, with each specified property set to the specified value.

**Properties** **RunningStandardDeviation**

Enable calculation over successive calls to the `step` method

Set this property to `true` to enable the calculation of standard deviation over successive calls to the `step` method. The default is `false`.

**ResetInputPort**

Enable resetting in running standard deviation mode

Set this property to `true` to enable resetting for the running standard deviation. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running standard deviation. This property applies only when you set the `RunningStandardDeviation` property to `true`. The default is `false`.

**ResetCondition**

Reset condition for running standard deviation mode

Specify event to reset the running standard deviation as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies only when you set the ResetInputPort property to true. The default is Non-zero.

## **Dimension**

Dimension to operate along

Specify how the standard deviation calculation is performed over the data as one of | All | Row | Column | Custom |. This property applies only when you set the RunningStandardDeviation property to false. The default is Column.

## **CustomDimension**

Numerical dimension to operate along

Specify the dimension (one-based value) of the input signal, over which the object computes the standard deviation. The cannot exceed the number of dimensions for the input signal. This property applies when you set the Dimension property to Custom. The default is 1.

## **ROIProcessing**

ROIProcessing

Enable region of interest processing

Set this property to true to enable calculating the standard deviation within a particular region for each image. This property applies only when you set the RunningStandardDeviation property to false and the Dimension property is All. The default is false.

Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, Rectangles is the only selection that applies for the ROIForm property.

# dsp.StandardDeviation

---

## **ROIForm**

Type of region of interest

Specify the type of region of interest as one of | `Rectangles` | `Lines` | `Label matrix` | `Binary mask` |. This property applies only when you set the `ROIProcessing` property to `true`. The default is `Rectangles`.

Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, `Rectangles` is the only selection that applies for the `ROIForm` property.

## **ROIPortion**

Calculate over entire ROI or just perimeter

Specify the region over which to calculate the standard deviation as one of | `Entire ROI` | `ROI perimeter` |. This property applies if the `ROIForm` property is `Rectangles`. The default is `Entire ROI`.

## **ROIStatistics**

Statistics for each ROI, or one for all ROIs

Specify what statistics to calculate as one of | `Individual statistics for each ROI` | `Single statistic for all ROIs` |. This property applies when you set the `ROIForm` property to `Rectangles`, `Lines`, or `Label matrix`. The default is `Individual statistics for each ROI`.

## **ValidityOutputPort**

Enable output of validity check of ROI or label numbers

Indicate whether to return the validity of the specified ROI being completely inside image when the `ROIForm` property is `Lines`, `Rectangles` or `Binary mask`. Indicate whether to return the validity of the specified label numbers when the `ROIForm` property is `Label Matrix`. This property applies when you set the `ROIForm` property to anything except `Binary Mask`. The default is `false`.

## FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies only when you set the `RunningStandardDeviation` property to `true`. The default is `true`.

## Methods

<code>clone</code>	Create standard deviation object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset states for running standard deviation computation
<code>step</code>	Calculate standard deviation of input

## Examples

Compute running standard deviation of a signal:

```
hstd2 = dsp.StandardDeviation;  
hstd2.RunningStandardDeviation = true;  
x = randn(100,1);  
y = step(hstd2,x);  
% y(i) is the standard deviation of all values  
% in the vector x(1:i)
```

# dsp.StandardDeviation

---

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Standard Deviation block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to the `ResetInputPort` and `ResetCondition` object properties.
- **Treat sample-based row input as a column** block parameter is not supported by the `dsp.StandardDeviation` object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the `FrameBasedProcessing` Property of a System object” for more information.

## See Also

`dsp.Variance` | `dsp.Maximum` | `dsp.Minimum` | `dsp.Mean`

**Purpose** Create standard deviation object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `StandardDeviation` object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

# **dsp.StandardDeviation.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.StandardDeviation.getNumOutputs**

---

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.StandardDeviation.isLocked

---

<b>Purpose</b>	Locked status for input attributes and nontunable properties
<b>Syntax</b>	<code>isLocked(H)</code>
<b>Description</b>	<p><code>isLocked(H)</code> returns the locked state of the <code>StandardDeviation</code> object <code>H</code>.</p> <p>The <code>isLocked</code> method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the <code>step</code> method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the <code>isLocked</code> method returns a true value.</p>

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# **dsp.StandardDeviation.reset**

---

**Purpose**            Reset states for running standard deviation computation

**Syntax**            `reset(H)`

**Description**        `reset(H)` sets the internal states of the `StandardDeviation` object `H` to their initial values when computing the running standard deviation.

## Purpose

Calculate standard deviation of input

## Syntax

```
Y = step(H,X)
Y = step(H,X,R)
Y = step(H,X,ROI)
Y = step(H,X,LABEL,LABELNUMBERS)
[Y, FLAG] = step(H,X,ROI)
[Y, FLAG] = step(H,X,LABEL,LABELNUMBERS)
```

## Description

`Y = step(H,X)` computes the standard deviation, `Y`, of input `X`. The object computes the standard deviation over successive calls to the `step` method when the `RunningStandardDeviation` property is true.

`Y = step(H,X,R)` resets its state based on the value of reset signal `R` and the `ResetCondition` property. You can use this option only when the `RunningStandardDeviation` property is true.

`Y = step(H,X,ROI)` uses additional input `ROI` as the region of interest when the `ROIProcessing` property is set to true and the `ROIForm` property is set to `Lines`, `Rectangles` or `Binary mask`.

`Y = step(H,X,LABEL,LABELNUMBERS)` computes the standard deviation of input image `X` for region labels contained in vector `LABELNUMBERS`, with matrix `LABEL` marking pixels of different regions. This option is available when the `ROIProcessing` property is set to true and the `ROIForm` property is set to `Label matrix`.

`[Y, FLAG] = step(H,X,ROI)` returns `FLAG` which indicates whether the given region of interest is within the image bounds when the `ValidityOutputPort` property is true.

`[Y, FLAG] = step(H,X,LABEL,LABELNUMBERS)` returns `FLAG` which indicates whether the input label numbers are valid when the `ValidityOutputPort` property is true.

## **dsp.StandardDeviation.step**

---

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	State-level estimation for bilevel rectangular waveform
<b>Description</b>	<p>The StateLevels object estimates the state levels of a bilevel rectangular waveform.</p> <p>To estimate the state levels of a bilevel waveform:</p> <ol style="list-style-type: none"><li>1 Define and set up your state-level estimation. See “Construction” on page 3-1229.</li><li>2 Call <code>step</code> to estimate the state levels for an input vector according to the properties of <code>dsp.StateLevels</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.StateLevels</code> creates a state-level estimation System object, <code>H</code>, that estimates state levels in a bilevel rectangular waveform using the histogram method with 100 bins.</p> <p><code>H = dsp.StateLevels('PropertyName',PropertyVaLue,...)</code> returns an StateLevels System object, <code>H</code>, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>HistogramBounds</b></p> <p>Minimum and maximum levels of the histogram. Specify the range of the histogram as a 2-element real-valued row vector. Signal values outside the range defined by this property are ignored. This property applies when you set the Method property to 'Histogram mode' or 'Histogram mean', and either RunningStateLevels is true, or the HistogramBoundsSource property is set to 'Property'.</p> <p><b>Default:</b> [0 5]</p> <p><b>HistogramBoundsSource</b></p> <p>Source of histogram bounds. Specify how to determine the histogram bounds as one of 'Auto' or 'Property'. When you set this property to 'Auto', the histogram bounds are determined by</p>

# dsp.StateLevels

---

the minimum and maximum input values. When you set this property to 'Property', the histogram bounds are determined by the value of the HistogramBounds property. This property applies when you set the Method property to 'Histogram mode' or 'Histogram mean', and the RunningStateLevels property is false.

**Default:** 'Auto'

## **HistogramNumBins**

Number of bins in the histogram. Specify the number of bins in the histogram. This property applies when you set the Method property to 'Histogram mode' or 'Histogram mean'.

**Default:** 100

## **HistogramOutputPort**

Enable histogram output. Set this property to true to output the histogram used in the computation of the state levels. This property applies when you set the Method property to 'Histogram mode' or 'Histogram mean'.

**Default:** false

## **Method**

Algorithm used to compute state levels. Specify the method used to compute state levels as one of 'Histogram mean', 'Histogram mode', or 'Peak to peak'.

**Default:** 'Histogram mode'

## **RunningStateLevels**

Calculation over successive calls to step. Set this property to true to enable computation of the state levels over successive calls to the step. Otherwise, compute the state levels of the current

input. When you set the `RunningStateLevels` property to `false` and you are using a histogram to compute your state levels, you must set the `HistogramBoundsSource` property to `'Property'`.

## Methods

<code>clone</code>	Clones the current instance of the state levels object
<code>getNumInputs</code>	Number of expected inputs to the method
<code>getNumOutputs</code>	Number of outputs of the method
<code>isLocked</code>	Locked status (logical) for input attributes and nontunable properties
<code>plot</code>	Plot signal, state levels, and histogram
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of state levels object
<code>step</code>	Estimate state levels for bilevel rectangular waveform

## Definitions

### State

A particular level, which can be associated with an upper and lower state boundary. States are ordered from the most negative to the most positive. In a bilevel waveform, the most negative state is the low state. The most positive state is the high state.

### State-Level Tolerances

Each state level can have associated lower- and upper-state boundaries. These state boundaries are defined as the state level plus or minus a scalar multiple of the difference between the high state and low state.

## dsp.StateLevels

---

To provide a useful tolerance region, the scalar is typically a small number such as 2/100 or 3/100. In general, the  $\alpha\%$  tolerance region for the low state is defined as

$$S_1 \pm \frac{\alpha}{100}(S_2 - S_1)$$

where  $S_1$  is the low-state level and  $S_2$  is the high-state level. Replace the first term in the equation with  $S_2$  to obtain the  $\alpha\%$  tolerance region for the high state.

The following figure illustrates lower and upper 2% state boundaries (tolerance regions) for a positive-polarity bilevel waveform. The estimated state levels are indicated by a dashed red line.

**Examples**

**State Levels of 2.3 V Underdamped Noisy Clock**

Compute and plot the state levels of a 2.3 V underdamped noisy clock.

# dsp.StateLevels

---

Load the clock data in the variable, *x*, and the sampling instants in the variable, *t*.

```
load('clockex.mat', 'x', 't');
```

Estimate the state levels.

```
h = dsp.StateLevels;  
levels = step(h, x);
```

Plot the clock data along with the estimated state levels and histograms.

```
plot(h)
```

## Algorithms

The StateLevels System object uses the histogram method to estimate the states of a bilevel waveform. The histogram method is described in [1]. To summarize the method:

- 1 Determine the maximum and minimum amplitudes and amplitude range of the data.
- 2 For the specified number of histogram bins, determine the bin width as the ratio of the amplitude range to the number of bins.
- 3 Sort the data values into the histogram bins.
- 4 Identify the lowest-indexed histogram bin,  $i_{low}$ , and highest-indexed histogram bin,  $i_{high}$ , with nonzero counts.
- 5 Divide the histogram into two subhistograms. The lower-histogram bins are  $i_{low} \leq i \leq 1/2(i_{high} - i_{low})$ .

The upper-histogram bins are  $i_{low} + 1/2(i_{high} - i_{low}) \leq i \leq i_{high}$ .

- 6 Compute the state levels by determining the mode or mean of the lower and upper histograms.

# **dsp.StateLevels.clone**

---

**Purpose** Clones the current instance of the state levels object

**Syntax** `clone(H)`

**Description** `clone(H)` clones the current instance of the state levels object H.

**Purpose** Number of expected inputs to the step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the step method for the state levels object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.StateLevels.getNumOutputs**

---

**Purpose**            Number of outputs of the `step` method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status (logical) for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the state levels object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# **dsp.StateLevels.plot**

---

**Purpose** Plot signal, state levels, and histogram

**Syntax** `plot(H)`

**Description** `plot(H)` plots the signal and state levels computed in the last call to the `step` method. If the `Method` property of the state levels object is set to `'Histogram mode'` or `'Histogram Mean'`, the histogram is plotted in a subplot below the signal.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

## **dsp.StateLevels.reset**

---

**Purpose**            Reset internal states of state levels object

**Syntax**            reset(H)

**Description**        reset(H) resets the state levels object, H, to clear information accumulated from previous calls to step.

**Purpose** Estimate state levels for bilevel rectangular waveform

**Syntax** LEVELS = step(H,X)  
[LEVELS,HISTOGRAM] = step(H,X)

**Description** LEVELS = step(H,X) returns a 2-element row vector, LEVELS, containing the estimated state levels for X. X is a real-valued column vector.

[LEVELS,HISTOGRAM] = step(H,X) returns a double-precision column vector, HISTOGRAM, containing the histogram of the sample values in X. You can obtain this output only when you set the Method property to either 'Histogram mean' or 'Histogram mode', and you set the HistogramOutputPort property to true.

# dsp.SubbandAnalysisFilter

---

**Purpose** Decompose signal into high-frequency and low-frequency subbands

**Description** The SubbandAnalysisFilter object decomposes a signal into high-frequency and low-frequency subbands.

To decompose a signal into high-frequency and low-frequency subbands:

- 1 Define and set up your two-channel subband analysis filter. See “Construction” on page 3-1244.
- 2 Call `step` to decompose the signal according to the properties of `dsp.SubbandAnalysisFilter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.SubbandAnalysisFilter` returns a two-channel subband analysis filter, `H`, that decomposes the input signal into a high-frequency subband and a low-frequency subband, each with half the bandwidth of the input.

`H = dsp.SubbandAnalysisFilter('PropertyName',PropertyValue,...)` returns a two-channel subband analysis filter, `H`, with each specified property set to the specified value.

`H = dsp.SubbandAnalysisFilter(lpc,hpc,'PropertyName',PropertyValue,...)` returns a two-channel subband analysis filter, `H`, with the `LowpassCoefficients` property set to `lpc`, the `HighpassCoefficients` property set to `hpc`, and other specified properties set to the specified values.

**Properties** **LowpassCoefficients**

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of  $z$ . For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of

this property specify a filter based on a third-order Daubechies wavelet.

## **HighpassCoefficients**

Highpass FIR filter coefficient

Specify a vector of highpass FIR filter coefficients, in descending powers of  $z$ . For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `LowpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

## **Fixed-Point Properties**

### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

# dsp.SubbandAnalysisFilter

---

## **OverflowAction**

Action to take when integer input is out of range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap. This property applies only if the object is not in full precision mode.

## **CoefficientsDataType**

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | Same word length as input | Custom |. The default is Same word length as input.

## **CustomCoefficientsDataType**

Coefficients word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numericType([],16,15)`.

## **ProductDataType**

Data type of product

Specify the product data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Data type of accumulator

Specify the accumulator data type as one of `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **OutputDataType**

Data type of output

Specify the output data type as one of `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,14)`.

## **Methods**

<code>clone</code>	Create subband analysis filter object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties

# dsp.SubbandAnalysisFilter

---

release	Allow property value and input characteristics changes
reset	Reset filter states of subband analysis filter object
step	Decompose signal into high- and low-frequency subbands

## Examples

Perfectly reconstruct a signal using subband analysis and synthesis filters:

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
ha = dsp.SubbandAnalysisFilter(lod, hid);
hs = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = step(ha, u); % Two channel analysis
y = step(hs, hi, lo); % Two channel synthesis

% Plot difference between original and reconstructed signals
% with filter latency compensated
plot(u(1:end-7)-y(8:end));
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Analysis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandAnalysisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Analysis Subband Filter block. The object assumes the input is frame based and always maintains the input frame rate.
- The **Rate options** block parameter is not supported by the `dsp.SubbandAnalysisFilter` object.

## See Also

`dsp.SubbandSynthesisFilter` | `dsp.DyadicAnalysisFilterBank`

**Purpose** Create subband analysis filter object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` create a `SubbandAnalysisFilter` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# **dsp.SubbandAnalysisFilter.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.SubbandAnalysisFilter.getNumOutputs**

---

## **Purpose**

Number of outputs of step method

## **Syntax**

`N = getNumOutputs(H)`

## **Description**

`N = getNumOutputs(H)` returns the number of outputs from the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.SubbandAnalysisFilter.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `SubbandAnalysisFilter` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# **dsp.SubbandAnalysisFilter.reset**

---

<b>Purpose</b>	Reset filter states of subband analysis filter object
<b>Syntax</b>	<code>reset(H)</code>
<b>Description</b>	<code>reset(H)</code> sets the filter states of the <code>SubbandAnalysisFilter</code> object <code>H</code> to 0.

**Purpose** Decompose signal into high- and low-frequency subbands

**Syntax**  $[HI, LO] = \text{step}(H, SIG)$

**Description**  $[HI, LO] = \text{step}(H, SIG)$  decomposes the input signal, SIG, into a high-frequency subband, HI, and a low-frequency subband, LO.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.SubbandSynthesisFilter

---

**Purpose** Reconstruct signal from high-frequency and low-frequency subbands

**Description** The `SubbandSynthesisFilter` object reconstructs a signal from high-frequency and low-frequency subbands.

To reconstruct a signal from high-frequency and low-frequency subbands:

- 1 Define and set up your two-channel subband synthesis filter. See “Construction” on page 3-1256.
- 2 Call `step` to reconstruct the signal according to the properties of `dsp.SubbandSynthesisFilter`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.SubbandSynthesisFilter` returns a two-channel subband synthesis filter, `H`, that reconstructs a signal from its high-frequency subband and low-frequency subband. Each subband contains half the bandwidth of the original signal.

`H = dsp.SubbandSynthesisFilter('PropertyName',PropertyValue,...)` returns a two-channel subband synthesis filter, `H`, with each specified property set to the specified value.

`H = dsp.SubbandSynthesisFilter(lpc,hpc,'PropertyName',PropertyValue,...)` returns a two-channel subband synthesis filter, `H`. The object has the `LowpassCoefficients` property set to `lpc`, the `HighpassCoefficients` property set to `hpc`, and other specified properties set to the specified values.

**Properties** **LowpassCoefficients**

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of  $z$ . For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of

this property specify a filter based on a third-order Daubechies wavelet.

## **HighpassCoefficients**

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of  $z$ . For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `LowpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

## **Fixed-Point Properties**

### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

# dsp.SubbandSynthesisFilter

---

## **OverflowAction**

Action to take when integer input is out of range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap. This property applies only if the object is not in full precision mode.

## **CoefficientsDataType**

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | Same word length as input | Custom |. The default is Same word length as input.

## **CustomCoefficientsDataType**

Coefficient word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numericType([],16,15)`.

## **ProductDataType**

Data type of product

Specify the product data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **AccumulatorDataType**

Data type of accumulator

Specify the accumulator data type as one of | Full precision | Same as input | Same as product | Custom |. The default is Full precision.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## **OutputDataType**

Data type of output

Specify the output data type as one of | Same as accumulator | Same as product | Same as input | Custom |. The default is Same as accumulator.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,14)`.

## **Methods**

<code>clone</code>	Create subband synthesis filter object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties

# dsp.SubbandSynthesisFilter

---

release	Allow property value and input characteristics changes
reset	Reset internal states of subband synthesis filter object
step	Reconstruct signal from high- and low-frequency subbands

## Examples

Perfectly reconstruct a signal using subband analysis and synthesis filters:

```
load dspwlets; % Load filter coefficients lod,
               % hid, lor and hir
ha = dsp.SubbandAnalysisFilter(lod, hid);
hs = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = step(ha, u); % Two channel analysis
y = step(hs, hi, lo); % Two channel synthesis

% Plot difference between original and reconstructed
% signals with filter latency compensated
plot(u(1:end-7)-y(8:end));
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Synthesis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandSynthesisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Synthesis Subband Filter block. The object only performs sample-based processing and always maintains the input frame rate.
- The **Rate options** block parameter is not supported by the `SubbandSynthesisFilter` object.

**See Also**

# **dsp.SubbandSynthesisFilter.clone**

---

**Purpose** Create subband synthesis filter object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `SubbandSynthesisFilter` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.SubbandSynthesisFilter.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.SubbandSynthesisFilter.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.SubbandSynthesisFilter.isLocked

---

<b>Purpose</b>	Locked status for input attributes and nontunable properties
<b>Syntax</b>	<code>isLocked(H)</code>
<b>Description</b>	<p><code>isLocked(H)</code> returns the locked state of the <code>SubbandSynthesisFilter</code> object <code>H</code>.</p> <p>The <code>isLocked</code> method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the <code>step</code> method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the <code>isLocked</code> method returns a true value.</p>

# dsp.SubbandSynthesisFilter.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose**            Reset internal states of subband synthesis filter object

**Syntax**            reset(H)

**Description**       reset(H) sets the internal states of the SubbandSynthesisFilter object H to their initial values.

# dsp.SubbandSynthesisFilter.step

---

**Purpose** Reconstruct signal from high- and low-frequency subbands

**Syntax**  $Y = \text{step}(H, HI, LO)$

**Description**  $Y = \text{step}(H, HI, LO)$  reconstructs a signal from a high-frequency subband, HI, and a low-frequency subband, LO.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

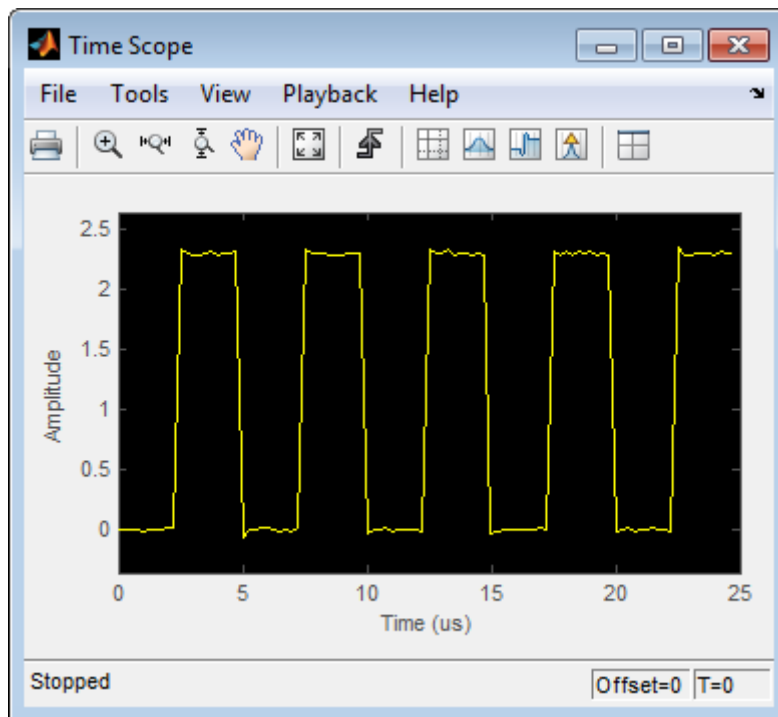

**Purpose** Time domain signal display

**Description** The TimeScope object displays time-domain signals.

To display time-domain signals in the Time Scope:

- 1 Define and set up your Time Scope. See “Construction” on page 3-1271.
- 2 Call `step` to display the signal in the Time Scope figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Time Scope figure window.

See the following sections for information on the Time Scope System object:

- “Construction” on page 3-1271
- “Properties” on page 3-1271
- “Methods” on page 3-1281

See the following sections for information on the Time Scope Graphical User Interface:

- “Displaying Multiple Signals” on page 3-1281
- “Signal Display” on page 3-1285
- “Toolbar” on page 3-1289
- “Measurements Panels” on page 3-1294
- “Style Dialog Box” on page 3-1336
- “Core — General UI Options” on page 3-1340
- “Visuals — Time Domain Options” on page 3-1342
- “Tools — Plot Navigation Options” on page 3-1350
- “Sources — Streaming Properties” on page 3-1354

For examples on how to use the Time Scope System object, see “Examples” on page 3-1354.

---

**Note** For information about the Time Scope block, see Time Scope.

---

---

**Note** If you own the MATLAB Coder product, you can generate C or C++ code from MATLAB code in which an instance of this system object is created. When you do so, the scope system object is automatically declared as an *extrinsic* variable. In this manner, you are able to see the scope display in the same way that you would see a figure using the `plot` function, without directly generating code from it. For the full list of system objects supporting code generation, see “DSP System Toolbox System Objects” in the MATLAB Coder documentation.

---

## Construction

`H = dsp.TimeScope` returns a Time Scope System object, `H`. This object displays real- and complex-valued floating and fixed-point signals in the time domain.

`H = dsp.TimeScope('PropertyName',PropertyValue,...)` creates a Time Scope System object, `H`, with each specified property *PropertyName* set to the specified value.

`H = dsp.TimeScope(NUMINPUTS,SAMPLERATE,'PropertyName',PropertyValue,...)` creates a Time Scope System object, `H`. This object has the `NumInputPorts` property set to *NUMINPUTS*, the `SampleRate` property set to *SAMPLERATE*, and other specified properties set to the specified values. *NUMINPUTS* and *SAMPLERATE* are value-only arguments. You can specify *PropertyName-PropertyValue* arguments in any order.

## Properties

### ActiveDisplay

Active display for display-specific properties

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this parameter to control which display should have its axes colors, line properties, marker properties, and visibility changed. This property is Tunable.

Setting this property controls which display is used for ShowGrid, ShowLegend, Title, PlotAsMagnitudePhase, YLabel, and YLimits.

**Default:** 1

## FrameBasedProcessing

Process input in frames or as samples

When you set this property to `true`, you enable frame-based processing. When you set this property to `false`, you enable sample-based processing.

**Default:** `true`

## LayoutDimensions

Layout grid dimensions

Specify the layout grid dimensions as a 2-element vector: `[numberOfRows, numberOfColumns]`. You can use no more than four rows or four columns. This property is Tunable.

**Default:** `[1,1]`

## MaximizeAxes

Maximize axes control

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- **Auto** — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.

- **On** — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- **Off** — In this mode, none of the axes appear maximized.

This property is Tunable.

**Default:** 'Auto'

## **Name**

Caption to display on the Time Scope window

Specify as a string the caption to display on the scope window. This property is Tunable.

**Default:** 'Time Scope'

## **NumInputPorts**

Number of input signals

Specify the number of input signals to display on the scope as a positive integer. You must invoke the `step` method with the same number of inputs as the value of this property.

**Default:** 1

## **PlotAsMagnitudePhase**

Plot signal magnitude and phase

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes within the same active display. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes within the same active display. This property is particularly useful for complex-valued input signals. Selecting this check box affects the phase for real-valued input signals.

When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees. This property is Tunable.

When set, `ActiveDisplay` controls which displays are updated. The active display shows the magnitude of the input signal on the top axes and its phase, in degrees, on the bottom axes.

**Default:** `false`

## PlotType

Option to control the type of plot

Specify the type of plot to use for all the input signals displayed in the scope window.

- When you set this property to `'Line'`, the scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.
- When you set this property to `'Stairs'`, the scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable.

**Default:** `'Line'`

## Position

Time Scope window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is Tunable.

**Default:** The default depends on your screen resolution. By default, the Time Scope window appears in the center of your screen with a width of 410 pixels and height of 300 pixels.

## ReduceUpdates

Reduce updates to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time the `step` method is called. The simulation speed is faster when this property is set to `true`. This property is Tunable.

You can also modify this property from the Time Scope GUI. Opening the **Simulation** menu and clearing the **Reduce Updates to Improve Performance** check box is the same as setting this property to `false`.

**Default:** `true`

## SampleRate

Sample rate of inputs

Specify the sample rate, in hertz, of the input signals.

You can specify a scalar or as a numeric vector with length equal to the value of `NumInputPorts`. The inverse of the sample rate determines the spacing between points on the *time*-axis in the displayed signal. When you set `SampleRate` to a scalar value and `NumInputPorts` is greater than 1, the object uses the same sample rate for all inputs.

**Default:** 1

## ShowGrid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable.

When set, `ActiveDisplay` controls which display is updated.

**Default:** `false`

## ShowLegend

When you set this property to `true`, the scope displays a legend with automatic string labels for each input channel. When you set this property to `false`, the scope does not display a legend. See `FrameBasedProcessing` for information on input channels. This property is Tunable.

When set, `ActiveDisplay` controls which display is updated.

**Default:** `false`

## TimeAxisLabels

*Time*-axis labels

Specify how *time*-axis labels should appear in the scope displays as one of 'All', 'Bottom', or 'None'.

- When you set this property to 'All', *time*-axis labels appear in all displays.
- When you set this property to 'Bottom', *time*-axis labels appear in the bottom display of each column.
- When you set this property to 'None', there are no labels in any displays.

This property is Tunable.

**Default:** 'All'

## **TimeDisplayOffset**

Time display offset

Specify the offset, in seconds, to apply to the *time*-axis. This property can be either a numeric scalar or a vector of length equal to the number of input channels. If you specify this property as a scalar, then that value is the time display offset for all channels. If you specify a vector, each vector element is the time offset for the corresponding channel. For vectors with length less than the number of input channels, the time display offsets for the remaining channels are set to 0. If a vector has a length greater than the number of input channels, the extra vector elements are ignored. This property is Tunable.

See `FrameBasedProcessing` for information on input channels. See `TimeSpan` and `TimeSpanSource` for information on the *x*-axis limits and time span settings.

**Default:** 0

## **TimeSpan**

Time span

Specify the time span, in seconds, as a positive, numeric scalar value. This property applies when `FrameBasedProcessing` is `false`. This property also applies when `FrameBasedProcessing` is `true` and `TimeSpanSource` is `Property`. The *time*-axis limits are calculated as follows.

- Minimum *time*-axis limit =  $\min(\text{TimeDisplayOffset})$
- Maximum *time*-axis limit =  $\max(\text{TimeDisplayOffset}) + \text{TimeSpan}$

where `TimeDisplayOffset` and `TimeSpan` are the values of their respective properties. This property is Tunable.

**Default:** 10

## **TimeSpanOverrunAction**

Wrap or scroll when the `TimeSpan` value is overrun

Specify how the scope displays new data beyond the visible time span. You can select one of the following options:

- **Wrap** — In this mode, the scope displays new data until the data reaches the maximum *time*-axis limit. When the data reaches the maximum *time*-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum *time*-axis limit.
- **Scroll** — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

This parameter is Tunable.

**Default:** 'Wrap'

## **TimeSpanSource**

Source of time span

Specify the source of the time span for frame-based input signals as one of 'Auto' or 'Property'. This property applies when `FrameBasedProcessing` is set to true. When you set this property to 'Property', the object derives the *x*-axis limits from the `TimeDisplayOffset` and `TimeSpan` properties. When you set this property to Auto, the *time*-axis limits are the following:

- Minimum *time*-axis limit =  $\min(\text{TimeDisplayOffset})$
- Maximum *time*-axis limit =  $\max(\text{TimeDisplayOffset}) + \max(1/\text{SampleRate}.*\text{FrameSize})$

where `TimeDisplayOffset` and `SampleRate` are the values of their respective properties. `FrameSize` is a vector equal to the number of rows in each input signal. This property is Tunable.

**Default:** 'Property'

## TimeUnits

Units of the *time*-axis

Specify the units used to describe the *time*-axis. You can select one of the following options:

- **Metric** — In this mode, the scope converts the times on the *time*-axis to the most appropriate measurement units. These can include milliseconds, microseconds, nanoseconds, minutes, days, etc. The scope chooses the appropriate measurement units based on the minimum *time*-axis limit and the maximum *time*-axis limit of the scope window.
- **Seconds** — In this mode, the scope always displays the units on the *time*-axis as seconds.
- **None** — In this mode, the scope does not display any units on the *time*-axis. The scope only shows the word Time on the *time*-axis.

This property is Tunable.

**Default:** 'Metric'

## Title

Display title

Specify the display title as a string. This property is Tunable.

When set, `ActiveDisplay` controls which display is updated.

**Default:** ''

## **YLabel**

The label for the  $y$ -axis

Specify as a string the text for the scope to display to the left of the  $y$ -axis. This property is Tunable.

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two  $y$ -axis labels are read-only values. The  $y$ -axis labels are set to 'Magnitude' and 'Phase' for the magnitude plot and the phase plot, respectively. When set, `ActiveDisplay` controls which display is updated.

**Default:** 'Amplitude' if `PlotAsMagnitudePhase` is `false`

## **YLimits**

The limits for the  $y$ -axis

Specify the  $y$ -axis limits as a 2-element numeric vector, [ $y_{min}$   $y_{max}$ ]. This property is Tunable.

When `PlotAsMagnitudePhase` is `true`, this property specifies the  $y$ -axis limits of only the magnitude plot. The  $y$ -axis limits of the phase plot are always `[-180, 180]`. When set, `ActiveDisplay` controls which display is updated.

**Default:** `[-10, 10]`, if `PlotAsMagnitudePhase` is `false`, or `[0, 10]`, if `PlotAsMagnitudePhase` is `true`.

## Methods

clone	Create time scope object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
hide	Hide time scope window
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of time scope object
show	Make time scope window visible
step	Display signal in time scope figure

## Displaying Multiple Signals

### Multiple Signal Input

You can configure the Time Scope to show multiple signals within the same display or on separate displays. By default, the signals appear as different-colored lines on the same display. The signals can have different dimensions, sample rates, and data types. Each signal can be either real or complex valued. You can set the number of input ports on the Time Scope in the following ways:

- Set the NumInputPorts property. This property is nontunable, so you should set it before you run the step method.
- Run the show method to open the scope window. In the scope menu, select **File > Number of Input Ports**.

An input signal may contain multiple channels, depending on its dimensions. Multiple channels of data always appear as different-colored lines on the same display.

## Multiple Signal Names

By default, if the input signal has multiple channels, the scope uses an index number to identify each channel of that signal. For example, a 2-channel signal would have the following default names in the channel legend: Channel 1, Channel 2. To show the legend, select **View > Configuration Properties**, click the **Display** tab, and select the **Show Legend** check box. If there are a total of 6 input channels, the following legend appears in the display.

## Multiple Signal Colors

By default, the scope has a black axes background and chooses line colors for each channel in a manner similar to the Simulink Scope block. When the scope axes background is black, it assigns each channel of each input signal a line color in the following order:

- 1 Yellow
- 2 Magenta
- 3 Cyan
- 4 Red
- 5 Green
- 6 Gray

If there are more than 6 channels, then the scope repeats this order to assign line colors to the remaining channels. To choose line colors for each channel in a manner similar to the MATLAB `plot` function, change the axes background color to any color except black. To change the axes background color to white, select **View > Style**, click the Axes

background color button () , and select white from the color palette. Run the simulation again. The following legend appears in the display.

When the scope axes background is not black, it assigns each channel of each input signal a line color in the following order:

- 1** Blue
- 2** Dark Green
- 3** Red
- 4** Cyan
- 5** Purple
- 6** Dark Yellow
- 7** Black

If there are more than 7 channels, then the scope repeats this order to assign line colors to the remaining channels. To manually modify any line color, select **View > Style** to open the Style dialog box. Next to

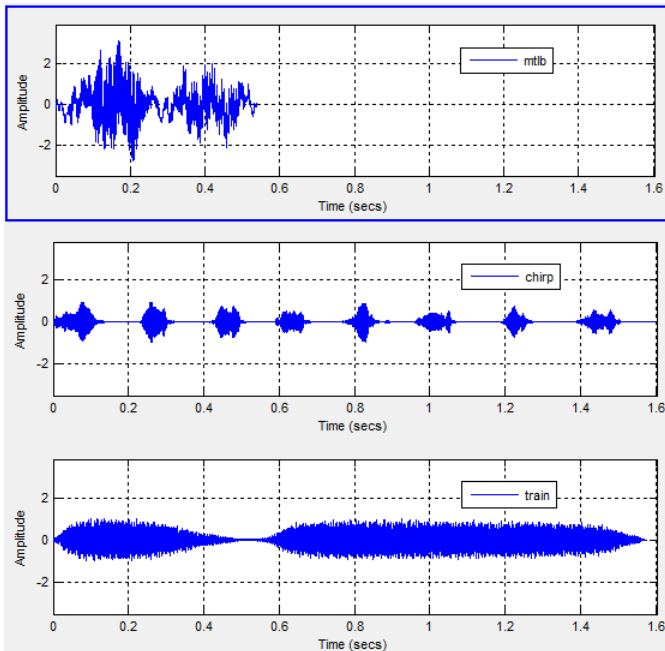

**Properties for line**, select the signal name whose color you want to change. Then, next to **Line**, click the Line color button (  ) and select any color from the palette.

## Multiple Displays

You can display multiple channels of data on different displays in the scope window. In the scope toolbar, select **View > Layout**, or select the Layout button (  ). This feature allows you to tile the window into a number of separate displays, up to a grid of 4 rows and 4 columns. For example, if there are three inputs to the scope, you can display the signals in separate displays by selecting row 3, column 1, as shown in the following figure.

After you select row 3, column 1, the scope window is partitioned into three separate displays, as shown in the following figure.

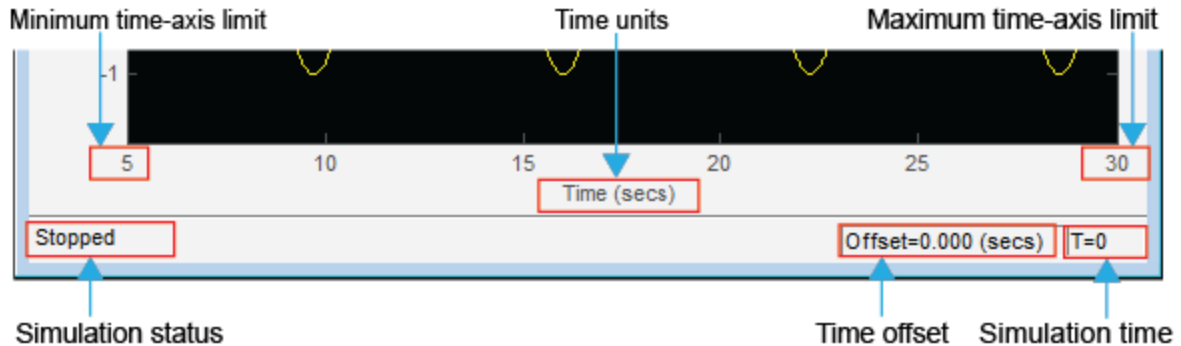

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The scope dialog boxes reference the active display.

## Signal Display

Time Scope uses the **Time span** and **Time display offset** parameters in order to determine the time range. To change the signal display settings, select **View > Configuration Properties** to bring up the Visuals—Time Domain Properties dialog box. Then, modify the values for the **Time span** and **Time display offset** parameters on the **Main** tab. For example, if you set the **Time span** to 25 seconds, the scope displays 25 seconds' worth of simulation data at a time. If you also set the **Time display offset** to 5 seconds, the scope displays values on the time axis from 5 to 30 seconds. The values on the *time*-axis of the Time Scope display remain the same throughout simulation.

To communicate the simulation time that corresponds to the current display, the scope uses the **Time units**, **Time offset**, and **Simulation**

**time** indicators on the scope window. The following figure highlights these and other important aspects of the Time Scope window.

## Time Indicators

- **Minimum time-axis limit** — The Time Scope sets the minimum *time*-axis limit using the value of the **Time display offset** parameter on the **Main** tab of the Visuals—Time Domain Properties dialog box. If you specify a vector of values for the **Time display offset** parameter, the scope uses the smallest of those values to set the minimum *time*-axis limit.
- **Maximum time-axis limit** — The Time Scope sets the maximum *time*-axis limit by summing the value of **Time display offset** parameter with the value of the **Time span** parameter. If you specify a vector of values for the **Time display offset** parameter, the scope sets the maximum *time*-axis limit by summing the largest of those values with the value of the **Time span** parameter.
- **Time units** — The units used to describe the *time*-axis. The Time Scope sets the time units using the value of the **Time Units** parameter on the **Time** tab of the Configuration Properties dialog box. By default, this parameter is set to **Metric** (based on **Time Span**) and displays in metric units such as milliseconds, microseconds, minutes, days, etc. You can change it to **Seconds** to always display the *time*-axis values in units of seconds. You can

change it to `None` to not display any units on the *time*-axis. When you set this parameter to `None`, then Time Scope shows only the word `Time` on the *time*-axis.

To hide both the word `Time` and the values on the *time*-axis, set the **Show time-axis labels** parameter to `None`. To hide both the word `Time` and the values on the *time*-axis in all displays except the bottom ones in each column of displays, set this parameter to `Bottom Displays Only`. This behavior differs from the Simulink Scope block, which always shows the values but never shows a label on the *x*-axis.

For more information, see “Visuals — Time Domain Options” on page 3-1342.

## Simulation Indicators

- **Simulation status** — Provides the current status of the model simulation. The status can be either of the following conditions:
  - **Processing** — Occurs after you run the `step` method and before you run the `release` method.
  - **Stopped** — Occurs after you construct the scope object and before you first run the `step` method. This status also occurs after you run the `release` method.

The **Simulation status** is part of the **Status Bar** in the scope window. You can choose to hide or display the entire **Status Bar**. From the scope menu, select **View > Status Bar**.

- **Time offset** — The **Time offset** value helps you determine the simulation times for which the scope is displaying data. The value is always in the range  $0 \leq \text{Time offset} \leq \text{Simulation time}$ . Therefore, add the **Time offset** to the fixed time span values on the *time*-axis to get the overall simulation time.

For example, if you set the **Time span** to 20 seconds, and you see a **Time offset** of 0 (secs) on the scope window. This value indicates that the scope is displaying data for the first 0 to 20 seconds of simulation time. If the **Time offset** changes to 20 (secs), the scope

# dsp.TimeScope

displays data for simulation times from 20 seconds to 40 seconds. The scope continues to update the **Time offset** value until the simulation is complete.

- **Simulation time** — The amount of time that has progressed since the Time Scope object was first constructed or reset. Every time you call the `step` method, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the

following formula:  $t_{sim} = t_{sim} + \frac{\text{length}(x)}{\text{SampleRate}}$ . You can set the sample rate using the `SampleRate` property.

The **Simulation time** is part of the **Status Bar** in the Time Scope window. You can choose to hide or display the entire **Status Bar**. From the Time Scope menu, select **View > Status Bar**.

## Axes Maximization

When the scope is in maximized axes mode, the following figure highlights the important indicators on the scope window.

To toggle this mode, in the scope menu, select **View > Configuration Properties**. In the **Main** pane, locate the **Maximize axes** parameter.

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- **Auto** — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- **On** — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- **Off** — In this mode, none of the axes appear maximized.

This property is Tunable.

The default setting is `Auto`.

## Reduce Updates to Improve Performance

By default, the scope updates the displays periodically at a rate not exceeding 20 hertz. If you would like the scope to update on every simulation time step, you can disable the **Reduce Updates to Improve Performance** option. However, as a recommended practice, leave this option enabled because doing so can significantly improve the speed of the simulation.

In the Time Scope menu, select **Playback > Reduce Updates to Improve Performance** to clear the check box. Alternatively, use the **Ctrl+R** shortcut to toggle this setting. You can also set the `ReduceUpdates` property to `false` to disable this option.

## Toolbar

The Time Scope toolbar contains the following buttons.

## Print Button

Button	Menu Location	Shortcut Keys	Description
	<b>File &gt; Print</b>	<b>Ctrl+P</b>	<p>Print the current scope window. Printing is available only when the scope display is not changing.</p> <p>To print the current scope window to a figure rather than sending it to your printer, select <b>File &gt; Print to figure</b>.</p>

## Axes Control Buttons

	<b>Tools &gt; Zoom In</b>	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw a rectangular area of interest inside the scope window.
	<b>Tools &gt; Zoom X</b>	N/A	When this tool is active, you can zoom in on the x-axis. To do so, click inside the scope window, or click and drag your cursor along the x-axis over your area of interest.
	<b>Tools &gt; Zoom Y</b>	N/A	When this tool is active, you can zoom in on the y-axis. To do so, click inside the scope window, or click and drag your cursor along the y-axis over your area of interest.

	<p><b>Tools &gt; Pan</b></p>	<p>N/A</p>	<p>When this tool is active, you can pan on the scope window. To do so, click in the center of your area of interest and drag your cursor to the left, right, up, or down, to move the position of the display.</p>
	<p><b>Tools &gt; Scale Axes Limits</b></p>	<p><b>Ctrl+A</b></p>	<p>Click this button to scale the axes in the active scope window.</p> <p>Alternatively, you can enable automatic axes scaling by selecting one of the following options from the <b>Tools</b> menu:</p> <ul style="list-style-type: none"> <li>• <b>Automatically Scale Axes Limits</b> — When you select this option, the scope scales the axes as needed during simulation.</li> <li>• <b>Scale Axes Limits after 10 Updates</b> — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation.</li> </ul>

			<ul style="list-style-type: none"> <li>• <b>Scale Axes Limits at Stop</b> — When you select this option, the scope scales the axes each time the simulation is stopped.</li> </ul>
--	--	--	--

## Measurements Buttons

	<b>Tools &gt; Triggers</b>	N/A	<p>Open or close the <b>Triggers</b> panel. This panel allows you to pause the display only when certain events occur. You can use the Triggers panel when you want to align or search for interesting events. Triggers can be configured to both select and align specific regions of interest in the display area of the scope.</p> <p>See the “Triggers Panel” on page 3-1296 section for more information.</p>
	<b>Tools &gt; Measurements &gt; Cursor Measurements</b>	N/A	<p>Open or close the <b>Cursor Measurements</b> panel. This panel puts screen cursors on all the displays.</p> <p>See the “Cursor Measurements Panel” on page 3-1315 section for more information.</p>

	<b>Tools &gt; Measurements &gt; Signal Statistics</b>	N/A	<p>Open or close the <b>Signal Statistics</b> panel. This panel displays the maximum, minimum, peak-to-peak difference, mean, median, RMS values of a selected signal, and the times at which the maximum and minimum occur.</p> <p>See the “Signal Statistics Panel” on page 3-1317 section for more information.</p>
	<b>Tools &gt; Measurements &gt; Bilevel Measurements</b>	N/A	<p>Open or close the <b>Bilevel Measurements</b> panel. This panel displays information about a selected signal’s transitions, overshoots or undershoots, and cycles.</p> <p>See the “Bilevel Measurements Panel” on page 3-1319 section for more information.</p>
	<b>Tools &gt; Measurements &gt; Peak Finder</b>	N/A	<p>Open or close the <b>Peak Finder</b> panel. This panel displays maxima and the times at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified.</p> <p>See the “Peak Finder Panel” on page 3-1333 section for more information.</p>

## Other Buttons

	<b>View &gt; Layout</b>	N/A	Arrange the layout of displays in the Time Scope. This feature allows you to tile your screen into a number of separate displays, up to a grid of 4 rows and 4 columns. You may find multiple displays useful when the Time Scope takes multiple input signals. The default display is 1 row and 1 column. See the “Multiple Displays” on page 3-1284 section for more information.
---	-------------------------	-----	---

You can control whether this toolbar appears in the Time Scope window. From the Time Scope menu, select **View > Toolbar**.

## Measurements Panels

The Measurements panels are the five panels that appear to the right side of the Time Scope GUI. These panels are labeled **Trace selection**, **Cursor measurements**, **Signal statistics**, **Bilevel measurements**, and **Peak finder**.

The Time Domain Measurements panels only appear if the **Measurements** tool is enabled in the Time Scope — Tools:Plot Navigation Options dialog box. To open this dialog box, in the Time Scope menu, select **File > Configuration** and click the **Tools** pane. If you disable the tool by clearing the **Enabled** check box, the Time Domain Measurements tools no longer display in the Time Scope GUI. You can reenble the tool at any time by selecting the **Enabled** check box. See the “Tools — Plot Navigation Options” on page 3-1350 section for more information.

## Measurements Panel Buttons

Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

Button	Description
	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button  .
	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button  again.
	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button  in the new window.
	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button  again.
	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button  to show each pane that is hidden in the current panel. Click the pane collapse button  to hide each pane that is shown in the current panel.

## Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. The Measurements

panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.

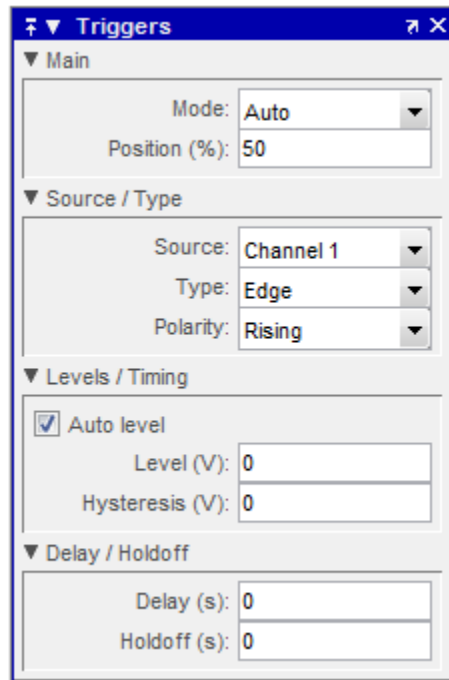

You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools > Measurements > Trace Selection**.

## Triggers Panel

The **Triggers** panel allows you to pause the display only when certain events occur. You can use the Triggers panel when you want to align or search for interesting events. You can be configure triggers to both select and align specific regions of interest in the display area of the scope. You can also choose to hide or display the **Triggers** panel. In

the scope toolbar, click the Triggers button (  ). Alternatively, in the scope menu, select **Tools > Triggers**.

When the **Triggers** panel is displayed, triangle pointers appear at the top and right side of the axes on each display. These markers indicate the time position (▲) and level (◀) at the event. The color of the markers corresponds to the color of the source signal.

### Main Pane

The **Main** pane lets you choose how often the display updates and in what position the trigger indicator appears.

- **Mode** — Define how often the display should update.
  - **Auto** — The scope makes acquisitions when either a trigger event occurs or a periodic timer event expires.

- **Normal** — The scope makes acquisitions only when a trigger event occurs.
- **Once** — The scope makes acquisitions and updates display only once, for the first trigger event encountered.
- **Off** — The scope does not make acquisitions. Triggering is disabled. This setting is equivalent to hiding the **Triggers** panel. If mode is set to either **Normal** or **Once** and the Triggers panel does not encounter any event, the display remains blank. Set **Mode** to **Auto** if you want the scope to display signal data regularly, in addition to trigger events.

---

**Note** When **Mode** is set to anything except **Off**, the scope disables panning.

---

- **Position (%)** — Specify, as a percentage of the total time span within the active display, the horizontal position in which the trigger indicator appears. A position value of 0 corresponds to the minimum *time*-axis value at the far-left side of the display. A position value of 100 corresponds to the maximum *time*-axis value at the far-right side of the display. Drag the trigger position indicator to the left or right to adjust its position.

## Source / Type Pane

The **Source / Type** pane lets you choose the source of the trigger and the type of events on which to stop.

- **Source** — Assign the trigger source to a particular channel. If the input signal has multiple channels, the scope assigns an index number to identify each channel of that signal. For more information, see “Multiple Signal Input” on page 1-1501.
- **Type** — Select the type of trigger to use.

- **Edge** — Trigger when the scope crosses a level threshold. In the case of a rising edge, the scope enables the trigger event when the signal value becomes less than the level threshold minus hysteresis. The scope disables the trigger event when the signal becomes greater than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold, as shown in the following figure.

In the case of a falling edge, the scope enables the trigger event when the signal value becomes greater than the level threshold plus hysteresis. The scope disables the trigger event when the

signal becomes less than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold, as shown in the following figure.

- **Pulse Width** — Trigger when the scope encounters a pulse whose width falls inside or outside specified time limits. You specify the range of valid time limits in the **Levels / Timing** pane. In the case of a positive-polarity pulse, the scope encounters a trigger event when the signal crosses the low threshold for the second time. The scope measures the pulse width as the time between the first and

second crossings of the middle threshold, located halfway between the high and low thresholds, as shown in the following figure.

---

**Note** A *Glitch*-type trigger looks for a pulse or spike whose duration is less than a specified amount. You can implement a *Glitch* type trigger by using a **Pulse Width** type trigger and manually setting the **Max Width** parameter.

---

# dsp.TimeScope

- **Transition** — Trigger on a rising or falling edge that crosses two levels, high and low, inside or outside a specified time interval. You specify the range of valid transition times in the **Levels / Timing** pane. In the case of a rising transition, the scope encounters the trigger event when the signal crosses the high threshold. The transition time is when the signal crosses the middle threshold, located halfway between the high and low thresholds, as shown in the following figure.

- **Runt** — Trigger on a runt pulse, which crosses one threshold, high or low, but not both. In the case of a positive-polarity runt

pulse, the scope encounters a trigger event when the signal crosses the low threshold the second time, without ever crossing the high threshold. The scope measures the runt width as the time between the first and second crossings of the low threshold, as shown in the following figure.

---

**Note** You can also replicate a **Runt**-type trigger by using a **Window**-type trigger and setting **Polarity** to **Inside**.

---

# dsp.TimeScope

- **Window** — Trigger when the input signal stays within or outside the region defined by the high and low thresholds for a period of time. In the case of an inside window, the scope encounters a trigger event when the signal enters and exits the inside region, as shown in the following figure.

In the case of an outside window, the scope encounters a trigger event when the signal enters and exits the outside region, as shown in the following figure.

The scope encounters a trigger event when the signal crosses either the high or low threshold the second time.

- Timeout** — Trigger when the input signal stays above or below a voltage threshold longer than a specified time. In the case of a timeout trigger with polarity set to `Either` and a timeout duration of 7.50 seconds, the scope can encounter the trigger event 7.50 seconds after the signal crosses the level threshold the last time, as shown in the following figure.

# dsp.TimeScope

Alternatively, the scope can encounter the trigger event when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the level threshold, as shown in the following figure.

- Polarity** — Select the polarity of the trigger type. The option you choose for **Type** directly affects the options available for **Polarity**, as shown in the following table.

Trigger Type	Polarity Options
Edge	Rising, Falling, Either
Pulse Width	Positive, Negative, Either
Transition	Rise Time, Fall Time, Either

Trigger Type	Polarity Options
Runt	Positive, Negative, Either
Window	Inside, Outside, Either
Timeout	Rising, Falling, Either

When you set **Type** to **Edge**, the polarity options are:

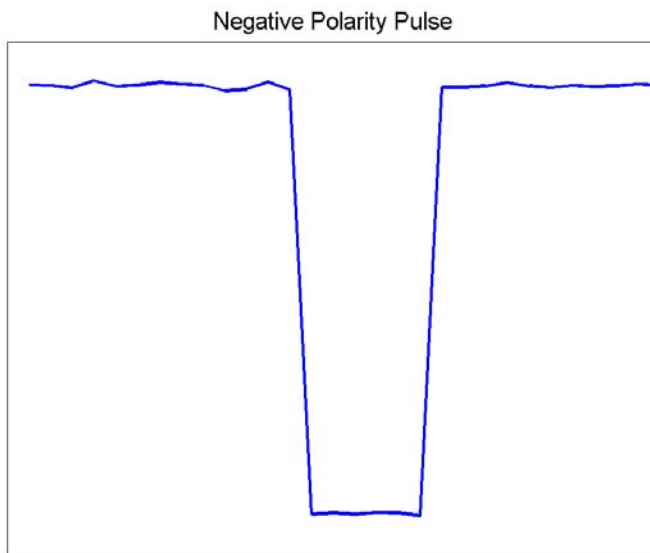

- **Rising** — Trigger on a *rising edge*, a transition from a low-state level to a high-state level.
- **Falling** — Trigger on a *falling edge*, transition from a high-state level to a low-state level.
- **Either** — Trigger on both rising edges and falling edges.

When you set **Type** to **Pulse Width** or **Runt**, the polarity options are:

- **Positive** — Trigger on a positive-polarity pulse, as shown in the following figure.

- **Negative** — Trigger on a negative-polarity pulse, as shown in the following figure.

- **Either** — Trigger on both positive-polarity and negative-polarity pulses.

When you set **Type** to **Transition**, the polarity options are:

- **Rise Time** — Trigger based on how long the signal takes to transition from the low threshold to the high threshold.
- **Fall Time** — Trigger based on how long the signal takes to transition from the high threshold to the low threshold.
- **Either** — Trigger based on how long it takes to make either a rising or falling transition.

When you set **Type** to **Window**, the polarity options are:

- **Inside** — Trigger when the signal stays within the low and high levels for a specified time duration.
- **Outside** — Trigger when the signal stays outside of the low and high levels for a specified time duration.

- **Either** — Trigger on both inside and outside windows.

When you set **Type** to **Timeout**, the polarity options are:

- **Rising** — Trigger when the signal does not cross the reference level from below.
- **Falling** — Trigger when the signal does not cross the reference level from above.
- **Either** — Trigger when the signal does not cross the reference level from either direction.

## Levels / Timing Pane

The **Levels / Timing** pane enables you to set the trigger level and hysteresis value. The option you choose for **Type** directly affects which level and timing parameters are available, as shown in the following table.

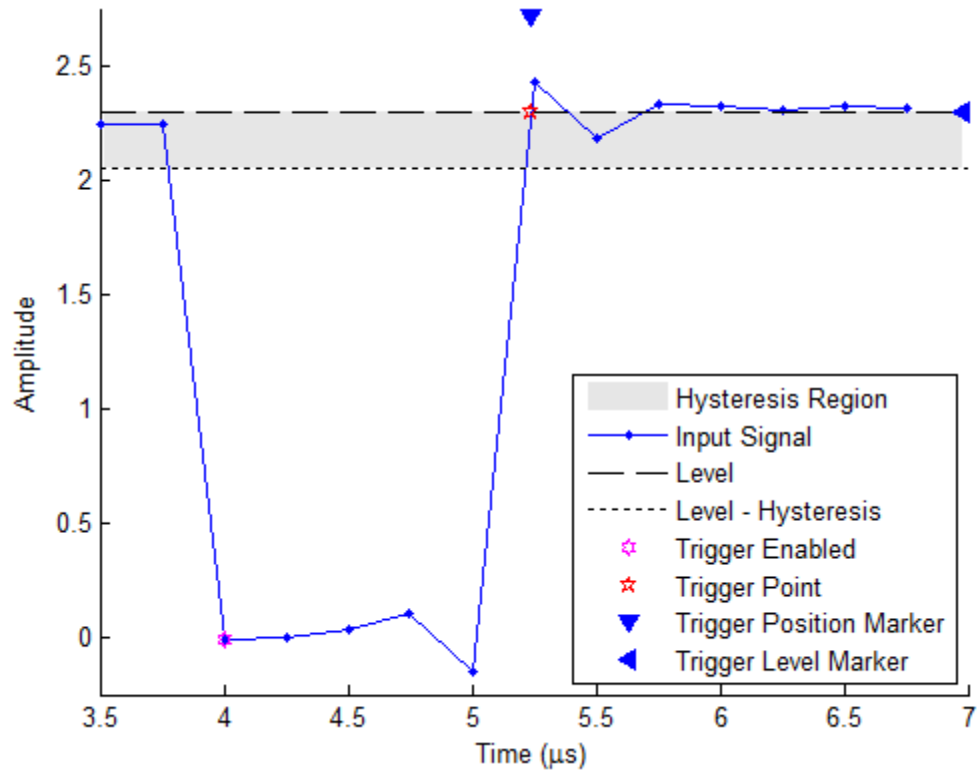

Trigger Type	Level Parameters	Auto-Level Setting	Timing Parameters
Edge	Level, Hysteresis	Level = 50%	n/a
Pulse Width	High, Low	High = 90%, Low = 10%	Min Width, Max Width
Transition	High, Low	High = 90%, Low = 10%	Min Time, Max Time
Runt	High, Low	High = 90%, Low = 10%	Min Width, Max Width
Window	High, Low	High = 90%, Low = 10%	Min Time, Max Time
Timeout	Level, Hysteresis	n/a	Timeout

- **Auto level** — Enable the Triggers panel to automatically choose the level parameters. If you set the trigger type to **Edge**, this option sets

the **Level** parameter to 50% of the range of the source signal. If you set the trigger type to **Timeout**, the Triggers panel does not show this option. Setting the trigger type to other menu choices results in **High** and **Low** parameter adjustment. **Auto level** sets the **High** parameter to 90% of the range of the source signal and the **Low** parameter to 10% of the range of the source signal.

- **Level (V)** — Specify, in volts, the trigger level. This parameter is visible when you set **Type** to **Edge** or **Timeout**.
- **Hysteresis (V)** — Specify, in volts, the hysteresis or noise reject value. This parameter is visible when you set **Type** to **Edge** or **Timeout**. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. In the case of an edge trigger with rising polarity, the scope ignores any times that the signal crosses the trigger level within the hysteresis region, as shown in the following figure.

You can reduce the hysteresis region size by decreasing the hysteresis value. If you set the hysteresis value to 0.07 in this example, then the scope also considers the second rising edge to be a trigger event, as shown in the following figure.

# dsp.TimeScope

- **High (V)** — Specify, in volts, the value that denotes a positive polarity, or high-state level. This parameter is visible when you set **Type** to Pulse Width, Transition, Runt, or Window.
- **Low (V)** — Specify, in volts, the value that denotes a negative polarity, or low-state level. This parameter is visible when you set **Type** to Pulse Width, Transition, Runt, or Window.
- **Min Width (s)** — Specify, in seconds, the minimum pulse width. This parameter is visible when you set **Type** to Pulse Width or Runt.
- **Max Width (s)** — Specify, in seconds, the maximum pulse width. This parameter is visible when you set **Type** to Pulse Width or Runt.

- **Min Time (s)** — Specify, in seconds, the minimum duration. This parameter is visible when you set **Type** to Transition or Window.
- **Max Time (s)** — Specify, in seconds, the maximum duration. This parameter is visible when you set **Type** to Transition or Window.
- **Timeout (s)** — Specify, in seconds, the timeout duration. This parameter is visible when you set **Type** to Timeout.

## Delay / Holdoff Pane

The **Delay / Holdoff** pane enables you to offset the trigger position by a fixed delay or set the minimum possible time between trigger events.

- **Delay (s)** — Specify, in seconds, the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify, in seconds, the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event is encountered. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the portion of a burst that is of interest.

## Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. You can choose to hide or display the **Cursor Measurements** panel. In the Scope menu, select **Tools > Measurements > Cursor Measurements**. Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

	Time (secs)	Value
1	1.875	0
2 :	5.625	8.941 m
$\Delta t$	3.750	$\Delta V$ 8.941 m
$1 / \Delta t$		266.667 mHz
$\Delta V / \Delta t$		2.384 V/ks

## Settings Pane

The **Settings** pane enables you to modify the type of screen cursors used to calculate time and value measurements.

- **Screen Cursors**— Shows screen cursors.
- **Horizontal**— Shows horizontal screen cursors.
- **Vertical**— Shows vertical screen cursors.
- **Waveform Cursors**— Shows cursors that attach to the input signals.
- **Lock Cursor Spacing**— Locks the time difference between the two cursors.

## Measurements Pane

The **Measurements** pane shows the time and value measurements.

- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.
- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.

- $\Delta t$ — Shows the absolute value of the difference in the times between cursor number one and cursor number two.
- $\Delta V$ — Shows the absolute value of the difference in signal amplitudes between cursor number one and cursor number two.
- $1/\Delta t$ — Shows the rate, the reciprocal of the absolute value of the difference in the times between cursor number one and cursor number two.
- $\Delta V/\Delta t$ — Shows the slope, the ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times between cursors.

### Signal Statistics Panel

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the *x*-axis indices at which the maximum and minimum values occur. You can choose to hide or display the **Signal Statistics** panel. In the Scope menu, select **Tools > Measurements > Signal Statistics**. Alternatively, in the scope toolbar, click the Signal Statistics  button.

↕ ▼ Signal Statistics	
	Value
Max	3.294
Min	-2.688
Peak to Peak	5.982
Mean	179.905 m
Median	26.242 m
RMS	702.371 m

## Signal Statistics Measurements

The **Signal Statistics** panel shows statistics about the portion of the input signal within the  $x$ -axis and  $y$ -axis limits of the active display. The statistics shown are:

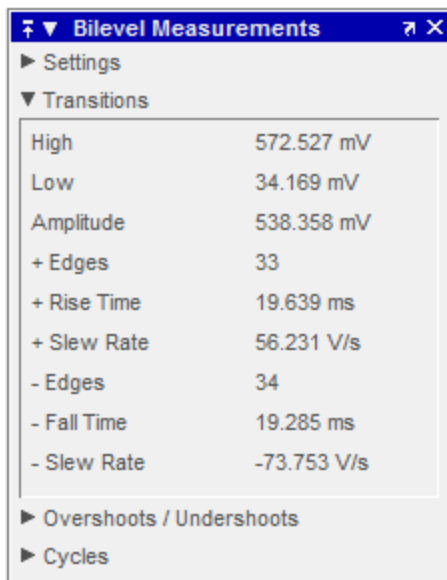

- **Max** — Shows the maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.
- **Min** — Shows the minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.
- **Peak to Peak** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.
- **Mean** — Shows the average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.
- **Median** — Shows the median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.
- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the Scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the  $x$ -axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli*-. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

## Bilevel Measurements Panel

The **Bilevel Measurements** panel shows information about a selected signal's transitions, overshoots or undershoots, and cycles. You can choose to hide or display the **Bilevel Measurements** panel. In the Scope menu, select **Tools > Measurements > Bilevel Measurements**. Alternatively, in the Scope toolbar, you can select the Bilevel Measurements  button.

The **Bilevel Measurements** panel is separated into four panes, labeled **Settings**, **Transitions**, **Overshoots / Undershoots**, and **Cycles**. You can expand each pane to see the available options.

## Settings Pane

The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level, as shown in the following figure.

- **Auto State Level** — When this check box is selected, the Bilevel measurements panel autodetects the high- and low- state levels of a bilevel waveform. For more information on the algorithm this option uses, see the Signal Processing Toolbox `statelevels` function

reference. When this check box is cleared, you may enter in values for the high- and low- state levels manually.

- **High** — Used to manually specify the value that denotes a positive polarity, or high-state level, as shown in the following figure.

- **Low** — Used to manually specify the value that denotes a negative polarity, or low-state level, as shown in the following figure.

- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. In the following figure, the mid-reference level is shown as the horizontal line, and its corresponding mid-reference level instant is shown as the vertical line.

- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, `D`, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

### Transitions Pane

The **Transitions** pane displays calculated measurements associated with the input signal changing between its two possible state level values, high and low.

A positive-going transition, or *rising edge*, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. The following figure shows a positive-going transition.

Whenever there is a plus sign (+) next to a text label, this symbol refers to measurement associated with a rising edge, a transition from a low-state level to a high-state level.

A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. The following figure shows a negative-going transition.

Whenever there is a minus sign (–) next to a text label, this symbol refers to measurement associated with a falling edge, a transition from a high-state level to a low-state level.

The Transition measurements assume that the amplitude of the input signal is in units of volts. You must convert all input signals to volts for the Transition measurements to be valid.

- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals:Time Domain Options dialog box. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals:Time Domain Options dialog box. For

more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.

- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.
- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `risetime` function reference.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray in the following figure.

For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrates` function reference.

- – **Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.
- – **Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `falltime` function reference.
- – **Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. For more information on the algorithm

this measurement uses, see the Signal Processing Toolbox `slewrates` function reference.

## Overshoots/Undershoots

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. *Overshoot* and *undershoot* refer to the amount that a signal respectively exceeds and falls below its final steady-state value. *Preshoot* refers to the amount prior to a transition that a signal varies from its initial steady-state value. This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.

The next figure shows preshoot, overshoot, and undershoot for a falling-edge transition.

- + **Preshoot** — Average lowest aberration in the region immediately preceding each rising transition.
- + **Overshoot** — Average highest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.
- + **Undershoot** — Average lowest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.
- + **Settling Time** — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.

You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

- – **Preshoot** — Average highest aberration in the region immediately preceding each falling transition.
- – **Overshoot** — Average highest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.
- – **Undershoot** — Average lowest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.
- – **Settling Time** — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can

modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

## Cycles

The **Cycles** pane displays calculated measurements pertaining to repetitions or trends in the displayed portion of the input signal.

- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots in the following figure.

For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulseperiod` function reference.

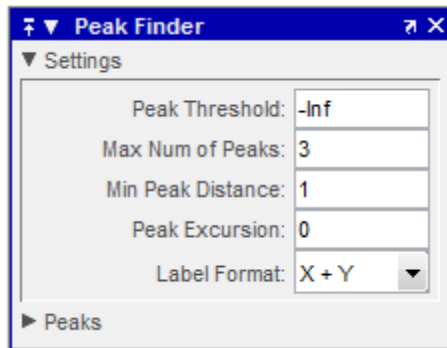

- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.
- **- Pulses** — Number of negative-polarity pulses counted.
- **- Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- **- Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.

When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that

particular rising edge. However, this feature does not apply to the **High** and **Low** measurements.

## Peak Finder Panel

The **Peak Finder** panel displays maxima and the  $x$ -axis values at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools > Measurements > Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder  button.

The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

### Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.

- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer between 1 and 99. This setting is equivalent to the NPEAKS parameter, which you can set when you run the findpeaks function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the MINPEAKDISTANCE parameter, which you can set when you run the findpeaks function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.

The *peak threshold* is a minimum value necessary for a sample value to be a peak. The *peak excursion* is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by

the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both  $x$ -axis and  $y$ -axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
  - $X+Y$  — Display both  $x$ -axis and  $y$ -axis values.
  - $X$  — Display only  $x$ -axis values.
  - $Y$  — Display only  $y$ -axis values.

### Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.

The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button () to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (). A filled sort button indicates that the peak values are currently sorted by this category. If the sort button is not filled (), then the peak values are sorted by the other category. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peaks are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peaks. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

## Style Dialog Box

In the **Style** dialog box, you can customize the style of displays. You are able to change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. From the scope menu, select **View > Style** to open this dialog box.

## Properties

The **Style** dialog box allows you to modify the following properties of the scope figure:

### Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

### Plot type

Specify the type of plot to use. The default setting is **Line**. Valid values for **Plot type** are:

- **Line** — Displays input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.

- **Stairs** — Displays input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.
- **Auto** — Displays input signal as a line graph if it is a continuous signal and displays input signal as a stairstep graph if it is a discrete signal.

This parameter is Tunable.

### **Active display**

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this parameter to control which display should have its axes colors, line properties, marker properties, and visibility changed. This property is Tunable.

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is 1.

### **Axes colors**

Specify the color that you want to apply to the background of the axes for the active display.

### **Properties for line**

Specify the signal for which you want to modify the visibility, line properties, and marker properties.

### **Visible**

Specify whether the selected signal on the active display should be visible. If you clear this check box, the line disappears.

### **Line**

Specify the line style, line width, and line color for the selected signal on the active display.

## Marker

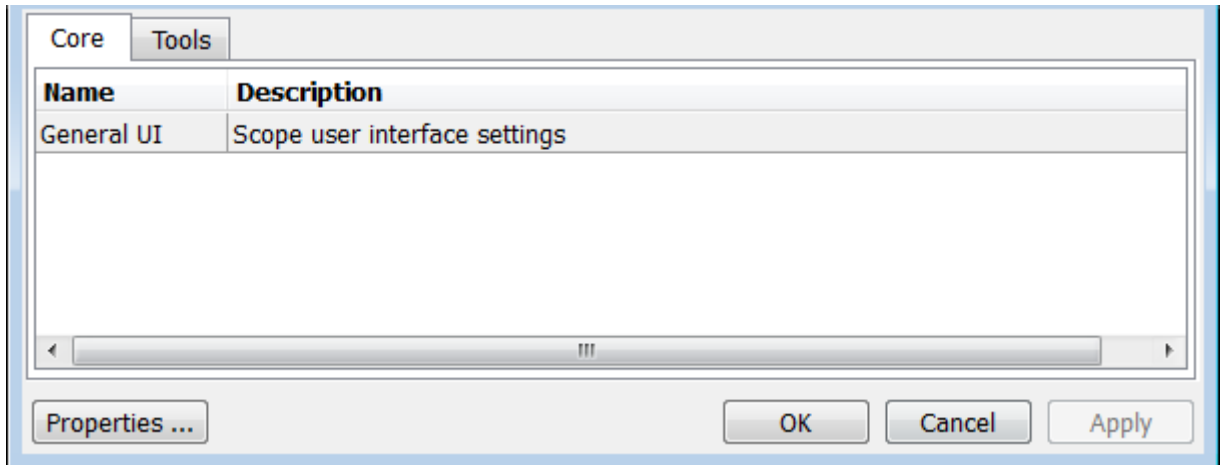

Specify marks for the selected signal on the active display to show at data points. This parameter is similar to the Marker property for the MATLAB Handle Graphics plot objects. You can choose any of the marker symbols from the following table.

Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
•	Point
+	Plus sign
*	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle
☆	Five-pointed star (pentagram)
☆☆	Six-pointed star (hexagram)

# dsp.TimeScope

## Core — General UI Options

The Core:General UI Options dialog box controls the general settings for the Scope GUI. From the Scope menu bar, select **File > Configuration** to open the Configuration dialog box. Click on the **Core** pane, and the following dialog box appears.

To open the Core:General UI Options dialog box, select **General UI** and click **Properties**. The following dialog box appears.

## General UI Options

## Open message log

Use this parameter to control when the Message Log window opens. The Message Log window helps you debug any issues with the Scope.

Using the drop-down list, you can choose to open the Message Log window under any of the following conditions:

- for any new messages
- for warn/fail messages
- only for fail messages
- manually

You can open the Message Log at any time by selecting **Help > Message Log**. The Message Log dialog box provides a system-level record of loaded configuration settings and registered extensions. The Message Log displays summaries and details of each message, and you can filter the display of messages by **Type** and **Category**.

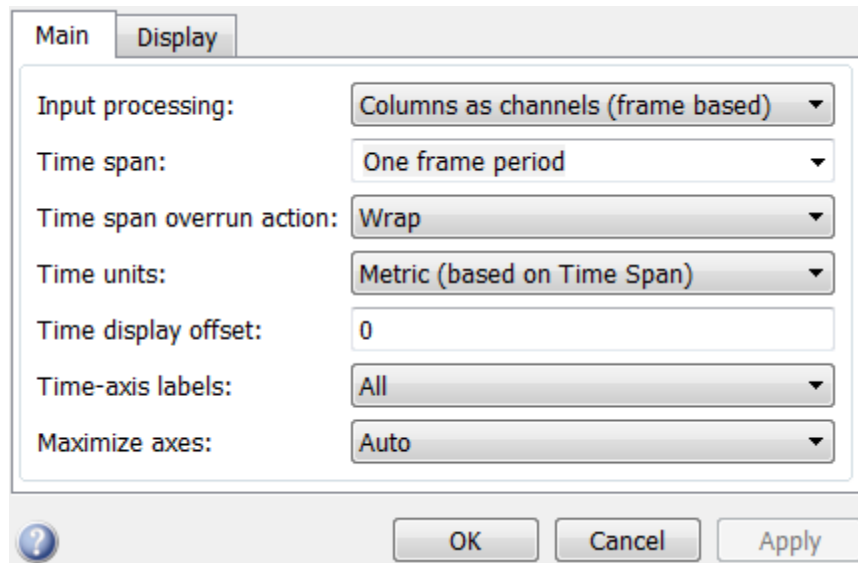

- The **Type** parameter allows you to select which types of messages to display in the Message Log. You can select **All**, **Info**, **Warn**, or **Fail**.
- The **Category** parameter allows you to select the category of messages to display in the Message Log. You can select **All**, **Configuration**, or **Extension**.
  - The scope uses **Configuration** messages to indicate when new configuration files are loaded.
  - The scope uses **Extension** messages to indicate when components are registered. For example, you may see a **Simulink registered** message, indicating that a component has been successfully registered with Simulink and is available for configuration.

## Visuals – Time Domain Options

The Visuals — Time Domain Options dialog box controls the visual configuration settings of the Time Scope displays. From the Time Scope menu, select **View > Configuration Properties** to open this dialog box.

### Main Pane

The **Main** pane of the Time Scope Visuals—Time Domain Options dialog box appears as follows.

### Input processing

Specify whether the Time Scope should treat the input signal as Columns as channels (frame based) or Elements as channels (sample based).

Frame-based processing is only available for discrete input signals. For more information about frame-based input channels, see the “What Is Frame-Based Processing?” section in the DSP System Toolbox documentation. For an example that uses the Time Scope block and

frame-based input signals, see the Display Time-Domain Data in the Time Scope section in the DSP System Toolbox documentation.

## Time span

Specify the time span, either by selecting a predefined option or by entering a numeric value in seconds. You can select one of the following options:

- **Auto** — In this mode, the Time Scope automatically calculates the appropriate value for time span from the difference between the simulation “Start time” and “Stop time” parameters. This option is available only for the Time Scope block but not for the `dsp.TimeScope` System object.
- **One frame period** — In this mode, the Time Scope uses the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to `Columns as channels (frame based)`. This option is not available when you set the **Input processing** parameter to `Elements as channels (sample based)`.
- `<user defined>` — In this mode, you specify the time span by replacing the text `<user defined>` with a numeric value in seconds.

The scope sets the *time*-axis limits using the value of this parameter and the value of the **Time display offset** parameter. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the *time*-axis limits as shown in the following figure.

# dsp.TimeScope

This parameter is Tunable.

## Time span overrun action

Specify how the scope displays new data beyond the visible time span. You can select one of the following options:

- **Wrap** — In this mode, the scope displays new data until the data reaches the maximum *time*-axis limit. When the data reaches the maximum *time*-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum *time*-axis limit.
- **Scroll** — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

This parameter is Tunable.

The default setting is **Wrap**.

## Time units

Specify the units used to describe the *time*-axis. The default setting is **Metric**. You can select one of the following options:

- **Metric** — In this mode, Time Scope converts the times on the *time*-axis to some metric units such as milliseconds, microseconds, days, etc. Time Scope chooses the appropriate metric units, based on the minimum *time*-axis limit and the maximum *time*-axis limit of the scope window.
- **Seconds** — In this mode, Time Scope always displays the units on the *time*-axis as seconds.
- **None** — In this mode, Time Scope displays no units on the *time*-axis. Time Scope shows only the word Time on the *time*-axis.

This parameter is Tunable.

### **Time display offset**

This parameter allows you to offset the values displayed on the *time*-axis by a specified number of seconds. When you specify a scalar value, the scope offsets all channels equally. When you specify a vector of offset values, the scope offsets each channel independently. Tunable.

When you specify a **Time display offset** vector of length  $N$ , the scope offsets the input channels as follows:

- When  $N$  is equal to the number of input channels, the scope offsets each channel according to its corresponding value in the offset vector.
- When  $N$  is less than the number of input channels, the scope applies the values you specify in the offset vector to the first  $N$  input channels. The scope does not offset the remaining channels.
- When  $N$  is greater than the number of input channels, the scope offsets each input channel according to the corresponding value in the offset vector. The scope ignores all values in the offset vector that do not correspond to a channel of the input.

The scope computes the *time*-axis range using the values of the **Time display offset** and **Time span** parameters. For example, if you set the **Time display offset** to  $5e-6$  and the **Time span** to  $25e-6$ , the scope sets the *time*-axis limits as shown in the following figure.

# dsp.TimeScope

Similarly, when you specify a vector of values, the scope sets the minimum *time*-axis limit using the smallest value in the vector. To set the maximum *time*-axis limit, the scope sums the largest value in the vector with the value of the **Time span** parameter. For more information, see “Signal Display” on page 1-1507.

## Show time-axis labels

Specify how to display the time units used to describe the *time*-axis. The default setting is All. You can select one of the following options:

- All — In this mode, the *time*-axis labels appear in all displays.
- None — In this mode, the *time*-axis labels do not appear in the displays.
- Bottom Displays Only — In this mode, the *time*-axis labels appear in only the bottom row of the displays.

Tunable.

## Maximize axes

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

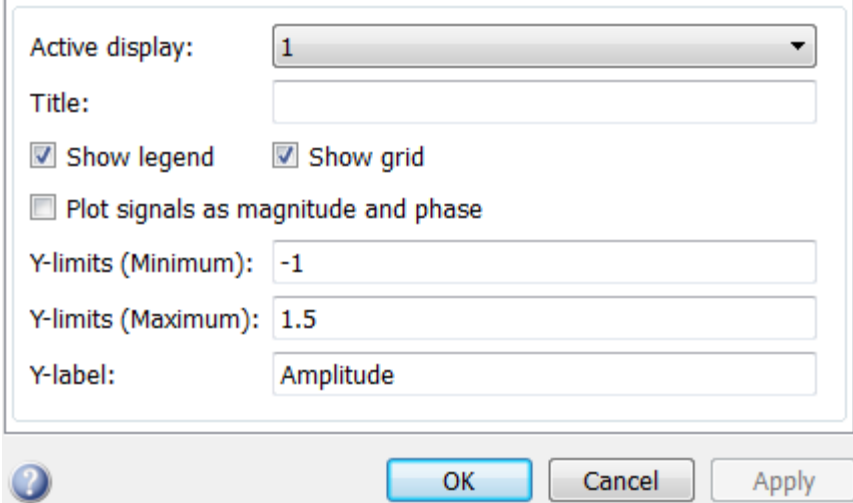

- **Auto** — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- **On** — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- **Off** — In this mode, none of the axes appear maximized.

This property is Tunable.

The default setting is `Auto`.

## Display Pane

The **Display** pane of the Visuals—Time Domain Options dialog box appears as follows.

The screenshot shows a dialog box titled "Display Pane" with the following controls:

- Active display:** A dropdown menu with the value "1" selected.
- Title:** An empty text input field.
- Show legend:** A checked checkbox.
- Show grid:** A checked checkbox.
- Plot signals as magnitude and phase:** An unchecked checkbox.
- Y-limits (Minimum):** A text input field containing "-1".
- Y-limits (Maximum):** A text input field containing "1.5".
- Y-label:** A text input field containing "Amplitude".

At the bottom of the dialog box, there is a help icon (question mark in a circle) on the left, and three buttons: "OK", "Cancel", and "Apply" on the right.

### Active display

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this parameter to control which display should

have its axes colors, line properties, marker properties, and visibility changed. This property is Tunable.

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is 1.

### **Title**

Specify the active display title as a string. By default, the active display has no title. Tunable.

### **Show legend**

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. Tunable.

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View > Style**.

### **Show grid**

When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable.

### **Plot signals as magnitude and phase**

When you select this check box, the scope splits the display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal is complex valued, the scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes, as shown in the following figure.

Selecting this check box and clicking the **Apply** or **OK** button changes the display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.

This feature is particularly useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box always

produces the same behavior. The phase is 0 for nonnegative input and 180 degrees for negative input. Tunable.

### **Y-limits (Minimum)**

Specify the minimum value of the  $y$ -axis. Tunable.

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this parameter always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a minimum value of  $-180$  degrees.

### **Y-limits (Maximum)**

Specify the maximum value of the  $y$ -axis. Tunable.

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this parameter always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a maximum value of 180 degrees.

### **Y-label**

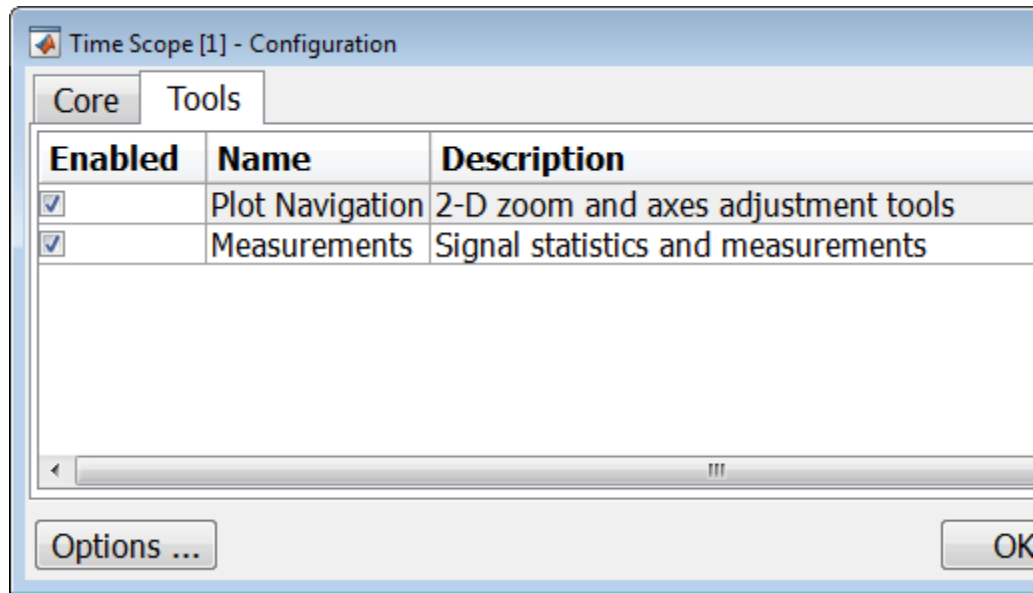

Specify as a string the text for the scope to display to the left of the  $y$ -axis. This property is Tunable.

This parameter becomes invisible when you select the **Plot signal(s) as magnitude and phase** check box. When you enable that parameter, the  $y$ -axis label always appears as **Magnitude** on the top axes and **Phase** on the bottom axes.

## **Tools — Plot Navigation Options**

The Time Scope — Tools:Plot Navigation Options dialog box provides you with the ability to automatically zoom in on and zoom out of your data, and to scale the axes of the Time Scope. In the Time Scope menu, select **Tools > Axes Scaling Options** to open this dialog box.

Alternatively, you can open this dialog box from the Time Scope — Configuration dialog box. In the Time Scope menu, select **File > Configuration** to open the Time Scope — Configuration dialog box. Click the **Tools** pane, and the following dialog box appears.

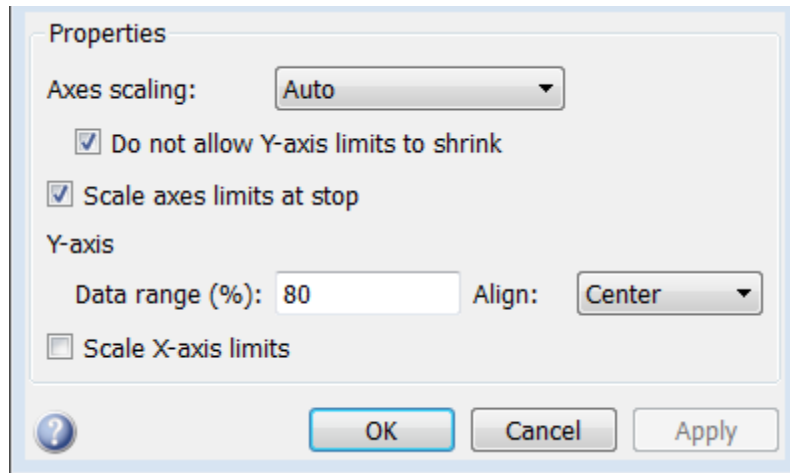

The **Tools** pane in the Time Scope – Configuration dialog box contains the tools that appear on the Time Scope GUI. By default, the **Plot Navigation** tool is enabled. If you disable the tool by clearing the **Enabled** check box, the axes scaling and zoom tools no longer display in the Time Scope GUI. You can reenable the tool at any time by selecting the **Enabled** check box.

By default, the **Measurements** tool is also enabled. If you disable the tool by clearing the **Enabled** check box, the Time Domain Measurements tools no longer display in the Time Scope GUI. See the “Measurements Panels” on page 3-1294 section for more information. You can reenable the tool at any time by selecting the **Enabled** check box.

To open the Time Scope — Tools:Plot Navigation Options dialog box, select the **Plot Navigation** tool, and then click the **Options** button.

### Properties

The Tools—Plot Navigation Properties dialog box appears as follows.

## Axes Scaling

Specify when the scope should automatically scale the axes. You can select one of the following options:

- **Manual** — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools > Scale axes limits**.
  - Press the **Scale Axes Limits** toolbar button.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- **Auto** — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- **After N Updates** — Selecting this option causes the scope to scale the axes after a specified number of updates. Selecting this option shows the **Number of updates** edit box.

This parameter is Tunable.

By default, this parameter is set to `Manual`.

### **Do not allow Y-axis limits to shrink**

When you select this parameter, the *y*-axis limits are only allowed to grow during axes scaling operations. If you clear this check box, the *y*-axis limits may shrink during axes scaling operations.

This parameter appears only when you select `Auto` for the **Axis Scaling** parameter. When you set the **Axes Scaling** parameter to `Manual` or `After N Updates`, the *y*-axis limits are allowed to shrink. Tunable.

### **Number of updates**

Specify as a positive integer the number of updates after which to scale the axes. This parameter appears only when you select `After N Updates` for the **Axes Scaling** parameter. Tunable.

### **Scale axes limits at stop**

Select this check box to scale the axes limits when the simulation stops. The *y*-axis are always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

### **Y-axis Data range (%)**

Set the percentage of the *y*-axis that the scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this parameter to 100, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this parameter to 30, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable.

### **Y-axis Align**

Specify where the scope should align your data with respect to the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. Tunable.

### **Scale X-axis limits**

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. Tunable.

### **X-axis Data range (%)**

Set the percentage of the *x*-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this parameter to 100, the Scope scales the *x*-axis

limits such that your data uses the entire  $x$ -axis range. If you then set this parameter to 30, the Scope increases the  $x$ -axis range such that your data uses only 30% of the  $x$ -axis range. Use the  $x$ -axis **Align** parameter to specify data placement with respect to the  $x$ -axis.

This parameter appears only when you select the **Scale X-axis limits** check box. Tunable.

### **X-axis Align**

Specify how the Scope should align your data with respect to the  $x$ -axis: Left, Center, or Right. This parameter appears only when you select the **Scale X-axis limits** check box. Tunable.

## **Sources – Streaming Properties**

The Sources:Streaming Properties dialog box lets you control the number of input signal samples that Time Scope holds in memory. In the Time Scope menu, select **View > Data History Properties** to open this dialog box.

### **Data History Properties**

### **Buffer length**

Specify the number of data points for each input signal that the scope holds in its memory cache. The number of data points equals the product of the number of channels in the signal and the number of time samples.

The default setting is 50000.

## **Examples**

The first few examples illustrate how to use the Time Scope object to view a variety of input signals in the time domain.

- “Example: Display Simple Sine Wave Input Signal” on page 3-1355
- “Example: View Sine Wave Input Signals at Different Sample Rates and Offsets” on page 3-1356
- “Example: Display Complex-valued Input Signal” on page 3-1357
- “Example: Display Input Signal of Changing Size” on page 3-1359

The remaining examples demonstrate how to use the Measurements Panels in the Time Scope GUI to glean information about the input signals.

- “Example: Use Bilevel Measurements Panel with Clock Input Signal” on page 3-1360
- “Example: Find Heart Rate Using Peak Finder Panel with ECG Input Signal” on page 3-1363

## **Example: Display Simple Sine Wave Input Signal**

Construct `dsp.SineWave` and `dsp.TimeScope` objects. Run the `step` method to display the signal.

```
hsin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);  
hsin.SamplesPerFrame = 10;  
hts1 = dsp.TimeScope('SampleRate', hsin.SampleRate,'TimeSpan', 0.1);  
for ii = 1:10  
    x = step(hsin);  
    step(hts1, x);  
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(hts1)
```

Run the MATLAB `clear` function to close the Time Scope window.

```
clear hts1 hsin x;
```

## Example: View Sine Wave Input Signals at Different Sample Rates and Offsets

Construct `dsp.SineWave` and `dsp.FirDecimator` objects. Use the `dsp.FirDecimator` object to create a new signal that equals the original signal, but decimated by a factor of 2. Construct a `dsp.TimeScope` object with 2 input ports. Run the `step` method to display the signal.

```
Fs = 1000; % Sampling frequency
hsin1 = dsp.SineWave('Frequency',50,...
    'SampleRate',Fs, ...
    'SamplesPerFrame', 100);
% Create FIRDecimator System object to decimate by 2
hfilt = dsp.FIRDecimator;
% Create TimeScope System object with 2 input ports (channels)
hts2 = dsp.TimeScope(2, [Fs Fs/2], ...
    'TimeDisplayOffset', [0 38/Fs], ...
    'TimeSpan', 0.25, ...
    'YLimits',[-1 1], ...
    'ShowLegend', true);
for ii = 1:2
    xsine = step(hsin1);
    xdec = step(hfilt,xsine);
    step(hts2, xsine, xdec);
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(hts2)
```

Run the MATLAB `clear` function to close the Time Scope window.

```
clear hts2 Fs hsin1 hfilt ii xsine xdec;
```

## Example: Display Complex-valued Input Signal

Create a vector representing a complex-valued sinusoidal signal and construct a `dsp.TimeScope` object. Run the `step` method to display the signal.

```
fs = 1000; t = (0:1/fs:10)';  
CxSine = cos(2*pi*0.2*t) + 1i*sin(2*pi*0.2*t);  
CxSineSum = cumsum(CxSine);  
figure(101); subplot(2,1,1); stairs(t,abs(CxSineSum)); % Plot magnitude  
subplot(2,1,2); stairs(t,(180/pi)*angle(CxSineSum)); % Plot phase  
h1 = dsp.TimeScope(1, fs, 'TimeSpanSource', 'Auto');  
step(h1,CxSineSum);
```

By default, when the input is a complex-valued signal, Time Scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes within the same active display, as shown in the following figure.

# dsp.TimeScope

Change the `PlotAsMagnitudePhase` property to true.

```
set(h1, 'PlotAsMagnitudePhase', true);
```

Time Scope now plots the magnitude and phase of the input signal on two separate axes within the same active display. The active display changes to show the magnitude of the input signal on the top axes and its phase, in degrees, on the bottom axes, as shown in the following figure.

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h1);
```

Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
close(101);
clear h1 fs t CxSine CxSineSum
```

### Example: Display Input Signal of Changing Size

Create a vector that represents a two-channel constant signal. Create another vector that represents a three-channel constant signal. Construct a `dsp.TimeScope` object with 2 input ports. Run the `step` method to display the signal.

## dsp.TimeScope

---

```
fs = 10;
sigdim2 = [ones(5*fs,1), 1+ones(5*fs,1)]; % 2-dim 0-5s
sigdim3 = [2+ones(5*fs,1), 3+ones(5*fs,1), 4+ones(5*fs,1)]; % 3-dim 5-10s
h2 = dsp.TimeScope(2, fs, 'TimeSpanSource', 'Property');
set(h2, 'PlotType', 'Stairs');
set(h2, 'TimeSpanOverrunAction', 'Scroll');
set(h2, 'TimeDisplayOffset', [0,0,5]);
step(h2,[sigdim2; sigdim3(:,1:2)], sigdim3(:,3));
```

In this example, the size of the input signal to the Time Scope block changes as the simulation progresses. When the simulation time is less than 5 seconds, Time Scope plots only the signal *sigdim2*, which has two channels. After 5 seconds, Time Scope also plots the signal *sigdim3*, which has three channels.

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h2);
```

Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
clear h2 fs sigdim2 sigdim3
```

### **Example: Use Bilevel Measurements Panel with Clock Input Signal**

Load the clock data into the variable, *x*. Find the sample time, *ts*.

```
load clockex;
ts = t(2)-t(1);
```

Construct a `dsp.TimeScope` object. Run the `step` method to display the signal.

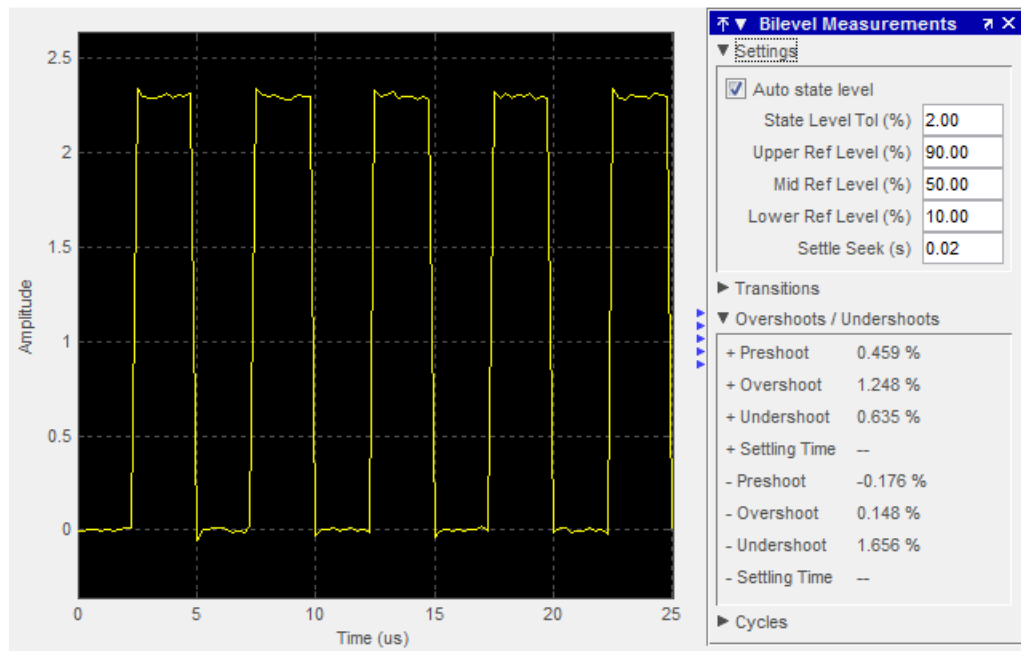

```
h4 = dsp.TimeScope(1, 1/ts, 'TimeSpanSource', 'Auto');
step(h4,x);
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h4);
```

To show the **Bilevel Measurements** panel, in the Time Scope menu, select **Tools > Measurements > Bilevel Measurements**. To collapse the **Transitions** pane, click the pane collapse button (▼) next to that label. To expand the **Settings** pane and the **Overshoots / Undershoots** pane, click the pane expand button (▶) next to each label. The Time Scope figure appears as shown in the following figure.

As you can see in the figure, the value for the rising edge **Settling Time** parameter is initially not displayed. The reason for this is that the default value for the **Settle Seek** parameter is too large for this example. In this case, the settle seek time is longer than the entire

# dsp.TimeScope

simulation duration. Enter a value for settle seek of  $2e-6$ , and press the **Enter** key. Time Scope now displays a rising edge settling time value of 118.392 ns.

This settling time value displayed is actually the statistical average of the settling times for all five rising edges. To show the settling time for only one rising edge, you can zoom in on that transition. In the Time

Scope toolbar, click the Zoom X button (). Then, click the display near a value of 2 microseconds on the *time*-axis. Drag to the right and release near a value of 4 microseconds on the *time*-axis. Time Scope updates the rising edge **Settling Time** value to reflect the new time window, as shown in the following figure.

Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
clear h4 x t ts
```

### Example: Find Heart Rate Using Peak Finder Panel with ECG Input Signal

First, create the electrocardiogram (ECG) signal.

```
x1 = 3.5*ecg(2700).';  
y1 = sgolayfilt(kron(ones(1,13),x1),0,21);  
n = (1:30000)';  
del = round(2700*rand(1));  
mhb = y1(n + del);  
ts = 0.00025;
```

This example uses the Savitzky-Golay filter in Signal Processing Toolbox. For more information, see the `sgolayfilt` function reference page or run the `sgolaydemo` example.

Construct a `dsp.TimeScope` object. Run the `step` method to display the signal.

```
h5 = dsp.TimeScope(1, 1/ts, 'TimeSpanSource', 'Auto');  
step(h5,mhb);
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h5);
```

To show the **Peak Finder** panel, in the Time Scope menu, select **Tools > Measurements > Peak Finder**. To expand the **Settings** pane, click the pane expand button () next to that label. Enter a value for **Max Num of Peaks** of 10, and press the **Enter** key. Time Scope now displays in the **Peaks** pane a list of 10 peak amplitude values, and the times at which they occur, as shown in the following figure.

# dsp.TimeScope

As you can see from the list of peak values, there is a constant time difference of 0.675 seconds between each heartbeat. Therefore, the heart rate of the ECG signal is given by the following equation`.

$$\frac{60 \frac{\text{sec}}{\text{min}}}{0.675 \frac{\text{sec}}{\text{beat}}} = 88.89 \frac{\text{beats}}{\text{min}} (\text{bpm})$$

Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
clear h5 x1 y1 n del mhb ts
```

## See Also

Time Scope | `dsp.SpectrumAnalyzer` | `sptool`

**Purpose** Create time scope object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `TimeScope` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.TimeScope.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method. *N* equals the value of the `NumInputPorts` property.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose** Number of outputs of step method

**Syntax** `N = getNumOutputs(H)`

**Description** `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method. The time scope is a sink object, so `N` equals 0.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.TimeScope.hide**

---

**Purpose** Hide time scope window

**Syntax** `hide(H)`

**Description** `hide(H)` hides the time scope window, associated with System object, H.

**See Also** `dsp.TimeScope.show`

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the TimeScope object H.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.TimeScope.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

You should call the `release` method after calling the `step` method when there is no new data for the simulation. When you call the `release` method, the axes will automatically scale in the Time Scope figure window. After calling the `release` method, any non-tunable properties can be set once again.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

## Examples

View a sine wave on the time scope. When you finish the simulation, release system resources. Note that when you run the `release` method, the axes automatically scale.

```
hsin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
hsin.SamplesPerFrame = 10;

hts1 = dsp.TimeScope('SampleRate', hsin.SampleRate,'TimeSpan', 0.1);
for ii = 1:10
    x = step(hsin);
    step(hts1, x);
end

release(hts1);
```

View two sine waves with different sample rates and time offsets. When you finish the simulation, release system resources. Note that when you run the release method, the axes automatically scale.

```
Fs = 1000; % Sampling frequency

hsin1 = dsp.SineWave('Frequency',50,...
    'SampleRate',Fs, ...
    'SamplesPerFrame', 100);

% Create FIRDecimator System object to decimate by 2
hfilt = dsp.FIRDecimator;

% Create TimeScope System object with 2 input
% ports (channels)
hts2 = dsp.TimeScope(2, [Fs Fs/2], ...
    'TimeDisplayOffset', [0 38/Fs], ...
    'TimeSpan', 0.25, ...
    'YLimits',[-1 1], ...
    'LegendSource', 'Auto');

for ii = 1:2
    xsine = step(hsin1);
    xdec = step(hfilt,xsine);
    step(hts2, xsine, xdec);
end

release(hts2);
```

## Algorithms

In operation, the release method is similar to the mdlTerminate function.

## See Also

`dsp.TimeScope.reset`

# dsp.TimeScope.reset

---

**Purpose** Reset internal states of time scope object

**Syntax** reset(H)

**Description** reset(H) sets the internal states of the TimeScope object H to their initial values.

You should call the reset method after calling the step method when you want to clear the Time Scope figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the reset method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB clf function. Do not call the reset method after calling the release method.

## Examples

View a sine wave on the time scope. When you finish the simulation, pause for 5 seconds and then reset the screen. Then, view a different sine wave on the same time scope.

```
hsin = dsp.SineWave('Frequency', 100, 'SampleRate', 1000, 'SamplesPerFrame', 100);
hsin1 = dsp.SineWave('Frequency', 50, 'SampleRate', 1000, 'SamplesPerFrame', 100);

hts1 = dsp.TimeScope('SampleRate', hsin.SampleRate, 'TimeSpan', 0.1);
for ii = 1:10
    x = step(hsin);
    step(hts1, x);
end

% Pause and then reset internal states
pause(5);
reset(hts1);

for ii = 1:10
    x = step(hsin1);
    step(hts1, x);
end
```

```
release(hts1);
```

## Algorithms

In operation, the reset method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

## See Also

`dsp.TimeScope` | `dsp.TimeScope.release`

# dsp.TimeScope.show

---

**Purpose**            Make time scope window visible

**Syntax**            show(H)

**Description**        show(H) makes the time scope window, associated with System object, H, visible.

**See Also**            dsp.TimeScope.hide

**Purpose** Display signal in time scope figure

**Syntax** `step(H,X)`  
`step(H,X1,X2,...,XN)`

**Description** `step(H,X)` displays the signal, X, in the time scope figure.  
`step(H,X1,X2,...,XN)` displays the signals X1, X2,...,XN in the time scope figure when you set the NumInputPorts property to N. In this case, X1, X2,...,XN can have different data types and dimensions.

# dsp.TransitionMetrics

---

**Purpose** Transition metrics of bilevel waveforms

**Description** The TransitionMetrics object extracts information such as duration, slew rate, and reference-level crossings for each transition found in the bilevel waveform. The TransitionMetrics object can additionally return preshoot, postshoot and settling metrics for the regions immediately before and after each transition.

To obtain transition metrics for a bilevel waveform:

- 1** Define and set up your transition metrics. See “Construction” on page 3-1376.
- 2** Call `step` to calculate the transition metrics according to the properties of `dsp.TransitionMetrics`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.TransitionMetrics` creates a transition metrics System object, `H`. The object computes the rise time, fall time and width of a pulse. TransitionMetrics additionally computes cycle metrics such as pulse separations, periods, and duty cycles.

`H = dsp.TransitionMetrics('PropertyName',PropertyValue,...)` returns a TransitionMetrics System object, `H`, with each specified property set to the specified value.

**Properties** **MaximumRecordLength**

Maximum samples to preserve between calls to `step`. This property requires a positive integer that specifies the maximum number of samples to save between calls to the `step` method. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded. This property applies when `RunningMetrics` is true and is tunable.

**Default:** 1000

**PercentReferenceLevels**

Lower-, middle-, and upper-percent reference levels. This property contains a 3-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the low and high states of the waveform when computing the duration of each transition.

**Default:** [10 50 90]

### **PercentStateLevelTolerance**

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

**Default:** 2

### **PostshootOutputPort**

Enable posttransition aberration metrics. If this property is set to true, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of PostshootSeekFactor times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

**Default:** false

### **PostshootSeekFactor**

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition.

# dsp.TransitionMetrics

---

This property is enabled only when the `PostshootOutputPort` property is set to `true` and is tunable.

**Default:** 3

## **PreshootOutputPort**

Enable pretransition aberration metrics. If the `PreshootOutputPort` property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

**Default:** false

## **PreshootSeekFactor**

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PreshootOutputPort` property is set to `true` and is tunable.

**Default:** 3

## **RunningMetrics**

Enable metrics over all calls to `step`. If `RunningMetrics` is set to `false`, metrics are computed for each call to `step` independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to `step`. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object defers reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call

to step is made with enough data to compute all enabled metrics for that transition.

**Default:** false

## **SampleRate**

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero. This property applies when the `TimeInputPort` property is set to `false`.

**Default:** 1

## **SettlingOutputPort**

Enable settling metrics. If `SettlingOutputPort` is set to `true`, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, NaN is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last transition. The metrics are reported for the transition the next time step is called if the `RunningMetrics` property is set to `true`.

**Default:** false

## **SettlingSeekDuration**

Duration of time over which to search for settling. This property is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `TransitionMetrics` object reports NaN for all

# dsp.TransitionMetrics

---

settling metrics. This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

**Default:** 0.02

## StateLevels

Low- and high-state levels. This property is a 2-element numeric row vector that contains the low and high state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

**Default:** [0 2.3]

## StateLevelsSource

Auto or manual state level computation. If the `StateLevelsSource` property is set to 'Auto', the first record sent to `step` is sent to `dsp.StateLevels` with the default settings to determine the state levels of the incoming waveform. If this property is set to 'Property', the object uses the values the user specifies in the `StateLevels` property.

**Default:** 'Property'

## TimeInputPort

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to `step` to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

**Default:** false

## Methods

<code>clone</code>	Clones the current instance of the transition metrics object
<code>getNumInputs</code>	Number of expected inputs to the method
<code>getNumOutputs</code>	Number of outputs of the method
<code>isLocked</code>	Locked status (logical) for input attributes and nontunable properties
<code>plot</code>	Plots signal and metrics computed in last call to
<code>reset</code>	Reset the running transition metrics object
<code>step</code>	Transition metrics of bilevel waveform

## Examples

### Transition and Preshoot Information of a 2.3 V Step Waveform

Compute transition and preshoot information of a 2.3 V step waveform sampled at 4 MHz

Load the data.

```
load('transitionex.mat', 'x');
```

Construct your transition metrics System object. Set the `SampleRate` property to 4 MHz, set the `StateLevelsSource` property to 'Auto' to estimate the state levels from the data, set the `PreshootOutputPort` property to `true` to output pretransition aberration metrics when you call `step`.

```
htm1 = dsp.TransitionMetrics('SampleRate',4e6, ...  
                             'StateLevelsSource','Auto', ...  
                             'PreshootOutputPort',true)
```

# dsp.TransitionMetrics

---

Call `step` to compute the transition and preshoot information. Plot the result.

```
[transition, preshoot] = step(htm1, x)
plot(htm1)
```

## Transition, Postshoot, and Settling Information of a 2.3 V Step Waveform

Compute transition, postshoot, and settling information of a 2.3 V step waveform sampled at 4 MHz.

Load the data along with the sampling instants.

```
load('transitionex.mat', 'x', 't');
```

Construct your transition metrics object setting the `TimeInputPort` property to `true` and the `StateLevels` property to match waveform state levels. To output the postshoot information and settling information when you call `step`, set the `PostShootOutputPort` and `SettlingOutputPort` properties to `true`. Set the settling seek duration to 2 microseconds.

```
htm2 = dsp.TransitionMetrics('TimeInputPort',true, ...
                             'StateLevels',[0 2.3], ...
                             'PostshootOutputPort',true, ...
                             'SettlingOutputPort',true, ...
                             'SettlingSeekDuration',2e-6)
```

Compute the transition, postshoot, and settling information with `step` and plot the result.

```
[transition, postshoot, settling] = step(htm2,x,t)
plot(htm2)
```

`dsp.StateLevels` | `dsp.PulseMetrics` |

<b>Purpose</b>	Clones the current instance of the transition metrics object
<b>Syntax</b>	<code>clone(H)</code>
<b>Description</b>	<code>clone(H)</code> clones the current instance of the transition metrics object H.

# **dsp.TransitionMetrics.getNumInputs**

---

**Purpose**            Number of expected inputs to the step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method for the transition metrics object *H*.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.TransitionMetrics.getNumOutputs

---

**Purpose** Number of outputs of the `step` method

**Syntax** `N = getNumOutputs(H)`

**Description** `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.TransitionMetrics.isLocked**

---

<b>Purpose</b>	Locked status (logical) for input attributes and nontunable properties
<b>Syntax</b>	<code>isLocked(H)</code>
<b>Description</b>	<code>isLocked(H)</code> returns the locked state of the transition metrics object H.

**Purpose** Plots signal and metrics computed in last call to step

**Syntax** plot(H)

**Description** plot(H) plots the signal and metrics resulting from the last call of the step method.

By default plot displays

- the low and high state levels and the state-level boundaries defined by the PercentStateLevelTolerance property.
- the lower-, middle-, and upper-reference levels.
- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When you set the TransitionOutputPort property to true, the locations of the upper and lower crossings are also plotted. When the PreshootOutputPort or PostShootOutputPort properties are set to true, the corresponding overshoots and undershoots are plotted as inverted or non-inverted triangles. When the SettlingOutputPort property is set to true, the locations where the signal enters and remains within the upper- and lower-state boundaries over the specified seek duration are plotted.

# **dsp.TransitionMetrics.reset**

---

**Purpose**            Reset the running transition metrics object

**Syntax**            reset(H)

**Description**

reset(H) clears information from previous calls to step.

## Purpose

Transition metrics of bilevel waveform

## Syntax

```
PULSE = step(H,X)
[PULSE,CYCLE] = step(H,X)
[PULSE,TRANSITION] = step(H,X)
[PULSE,PRESHOOT] = step(H,X)
[PULSE,POSTSHOOT] = step(H,X)
[PULSE,SETTLING] = step(H,X)
[...] = step(H,X,T)
```

## Description

`PULSE = step(H,X)` returns a structure array, `PULSE`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `X`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

`PULSE` fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse
- `NegativeCross` — Instants where the negative-going transitions cross the mid-reference level of each pulse
- `Width` — Absolute difference between `PositiveCross` and `NegativeCross` of each pulse
- `RiseTime` — Duration between the linearly-interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- `FallTime` — Duration between the linearly-interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

`[PULSE,CYCLE] = step(H,X)` returns a structure array, `CYCLE`, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field

## dsp.TransitionMetrics.step

---

corresponds to the number of complete pulse periods found in the real-valued column vector input,  $X$ . You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found the input,  $X$ , does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to `step` detects the next transition.

CYCLE fields:

- `Period` — Duration between the first transition of the current pulse and the first transition of the next pulse
- `Frequency` — Reciprocal of the period
- `Separation` — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse
- `Width` — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `PULSE` structure.
- `DutyCycle` — Ratio of the width to the period for each pulse

`[PULSE,TRANSITION] = step(H,X)` returns a structure array, `TRANSITION`, when you set the `TransitionOutputPort` property to `true`. The fields of `TRANSITION` contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

TRANSITION fields:

- `Duration` — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels

- **SlewRate** — Ratio of absolute difference between the upper- and lower-reference levels to the transition duration
- **MiddleCross** — Linearly-interpolated instant where the transition first crosses the mid-reference level
- **LowerCross** — Linearly-interpolated instant where the signal crosses the lower-reference level
- **UpperCross** — Linearly-interpolated instant where the signal crosses the upper-reference level

[PULSE, PRESHOOT] = step(H,X) returns a structure array, PRESHOOT, when you set the PreshootOutputPort property to true. The fields of PRESHOOT contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the POSTSHOOT structure.

[PULSE, POSTSHOOT] = step(H,X) returns a structure array, POSTSHOOT, when you set the PostshootOutputPort property to true. The fields of POSTSHOOT contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

PRESHOOT and POSTSHOOT fields:

- **Overshoot** — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- **Undershoot** — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- **OvershootLevel** — Level of the overshoot
- **UndershootLevel** — Level of the undershoot
- **OvershootInstant** — Instant that corresponds to the overshoot
- **UndershootInstant** — Instant that corresponds to the undershoot

[PULSE, SETTLING] = step(H,X) returns a structure, SETTLING, when you set the SettlingOutputPort property to true. The fields of

## **dsp.TransitionMetrics.step**

---

SETTLING correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

SETTLING fields:

- **Duration** — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified `PercentStateLevelTolerance` of the waveform amplitude over the specified settling seek duration
- **Instant** — Instant in time where the signal enters and remains within the specified tolerance
- **Level** — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the System object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

```
[ PULSE, CYCLE, TRANSITION, PRESHOOT, POSTSHOOT, SETTLING ] =  
step(H,X) which returns the PULSE, CYCLE, TRANSITION, PRESHOOT,  
POSTSHOOT, and SETTLING structure arrays when the CycleOutputPort,  
PreshootOutputPort, PostshootPort, and SettlingOutputPort  
properties are true. You may enable or disable any combination of  
output ports. However, the output arguments are defined in the order  
shown here.
```

```
[ ... ] = step(H,X,T) performs the above metrics with respect to a  
sampled signal, whose sample values, X, and sample instants, T, are  
real-valued column vectors of the same length. The additional input T  
applies only when you set the TimeInputPort property to true.
```

<b>Purpose</b>	Receive UDP packets from network
<b>Description</b>	<p>The <code>UDPReceiver</code> object receives UDP packets from the network.</p> <p>To receive UDP packets from the network:</p> <ol style="list-style-type: none"><li>1 Define and set up your UDP receiver. See “Construction” on page 3-1393.</li><li>2 Call <code>step</code> to receive the UDP packets according to the properties of <code>dsp.UDPReceiver</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.UDPReceiver</code> returns a UDP receiver System object, <code>H</code>, that receives UDP packets from a specified port.</p> <p><code>H = dsp.UDPReceiver('PropertyName',PropertyVaLue, ...)</code> returns a window object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>LocalIPPort</b></p> <p>Local port on which to receive data</p> <p>Specify the port on which to receive data. The default is 25000.</p> <p><b>RemoteIPAddress</b></p> <p>Address from which data was sent</p> <p>Specify the remote IP address from which to receive data. The default is '0.0.0.0', which indicates that data is accepted from any remote IP address.</p> <p><b>ReceiveBufferSize</b></p> <p>Maximum size of internal buffer</p> <p>Specify the size of the buffer that receives UDP packets, in bytes. The default is 8192.</p> <p><b>MaximumMessageLength</b></p>

# dsp.UDPReceiver

---

Maximum size of output message

Specify the size of the output message. If received packets exceed the specified value, their contents are truncated. The default is 255.

## MessageDataType

Data type of the message

Specify the data type of the message as | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | logical |. The default is uint8.

## Methods

clone	Create UDP receiver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Multiply input by window

## Examples

Send some UDP packets, and calculate the number of successfully transmitted bytes:

```
hudpr = dsp.UDPReceiver;  
hudps = dsp.UDPSender;  
  
bytesSent = 0;  
bytesReceived = 0;  
dataLength = 128;
```

```
for k = 1:20
    dataSent = uint8(255*rand(1,dataLength));
    bytesSent = bytesSent + dataLength;
    step(hudps, dataSent);
    dataReceived = step(hudpr);
    bytesReceived = bytesReceived + length(dataReceived);
end

release(hudps);
release(hudpr);

fprintf('Bytes sent:      %d\n', bytesSent);
fprintf('Bytes received: %d\n', bytesReceived);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the UDP Receive block reference page. The object properties correspond to the block parameters, except:

- The **Output variable-size signal** parameter is not included in the System object.
- The **Sample time** parameter is not included in the System object.

## See Also

dsp.UDPSender

# dsp.UDPReceiver.clone

---

**Purpose** Create UDP receiver object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a UDP receiver object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.UDPReceiver.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**      `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `Y = isLocked(H)`

**Description** `Y = isLocked(H)` returns the locked state, `Y`, of the UDP receiver object. The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.UDPReceiver.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Multiply input by window

**Syntax** P = step (H)

**Description**

P = step (H) receives one UDP packet, P, from the network.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

The first time you call the `step` method on a `UDPReceiver` object, the object also allocates resources and begins listening for data. As a result, the first `step` call may not receive data.

# dsp.UDPSender

---

**Purpose** Send UDP packets to network

**Description** The UDPSender object sends UDP packets to the network.  
To send UDP packets to the network:

- 1 Define and set up your UDP sender. See “Construction” on page 3-1402.
- 2 Call `step` to send the packets according to the properties of `dsp.UDPSender`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.UDPSender` returns a UDP sender object, `H`, that sends UDP packets to a specified port.

`H = dsp.UDPSender('PropertyName',PropertyValue, ...)` returns a UDP sender object, `H`, with each property set to the specified value.

## Properties

### RemoteIPAddress

Remote address to which to send data

Specify the remote (i.e., host) IP address to which the data is sent. The default is '127.0.0.1', which is the local host.

### RemoteIPPort

Remote port to which to send data

Specify the port at the remote IP address to which the data is sent. The default is 25000.

### LocalIPPortSource

Source of the LocalIPPort property

Specify how to determine the port on the host as | Auto | Property |. If you specify Auto, the object selects the port dynamically from the available ports. If you specify Property, the object uses the source specified in the LocalIPPort property. The default is Auto.

## LocalIPPort

Local port from which to send data

Specify the port from which to send data. This property applies when you set the LocalIPPortSource property to Auto. The default is 25000.

## Methods

clone	Create UDP sender object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Send a UDP packet to network

## Examples

Send a number of UDP packets, and calculate the number of successfully transmitted bytes:

```
hudpr = dsp.UDPReceiver;  
hudps = dsp.UDPSEnder;  
  
bytesSent = 0;  
bytesReceived = 0;  
dataLength = 128;  
  
for k = 1:20  
    dataSent = uint8(255*rand(1,dataLength));  
    bytesSent = bytesSent + dataLength;  
    step(hudps, dataSent);  
    dataReceived = step(hudpr);  
end
```

# dsp.UDPsender

---

```
        bytesReceived = bytesReceived + length(dataReceived);
    end

    release(hudps);
    release(hudpr);

    fprintf('Bytes sent:      %d\n', bytesSent);
    fprintf('Bytes received: %d\n', bytesReceived);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the UDP Send block reference page. The object properties correspond to the block parameters.

## See Also

dsp.UDPReceiver

**Purpose** Create UDP sender object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a UDP sender object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.UDPSEnder.getNumInputs

---

**Purpose**                Number of expected inputs to step method

**Syntax**                `getNumInputs(H)`

**Description**        `getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.UDPsender.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** isLocked(H)

**Description** isLocked(H) returns the locked state of the UDP sender object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `Y = release(H)`

**Description** `Y = release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

## dsp.UDPsender.step

---

**Purpose** Send a UDP packet to network

**Syntax** `Y = step(H,PACKET)`

**Description** `Y = step(H,PACKET)` sends one UDP packet, `PACKET`, to the network.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Decode integer input into floating-point output
<b>Description</b>	<p>The <code>UniformDecoder</code> object decodes integer input into floating-point output. The decoder adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.</p> <p>To decode an integer input into a floating-point output:</p> <ol style="list-style-type: none"><li>1 Define and set up your uniform decoder. See “Construction” on page 3-1411.</li><li>2 Call <code>step</code> to decode the input according to the properties of <code>dsp.UniformDecoder</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.UniformDecoder</code> returns a uniform decoder, <code>H</code>, that performs the inverse operation of the <code>UniformEncoder</code> object, reconstructing quantized floating-point values from encoded integer input.</p> <p><code>H = dsp.UniformDecoder('PropertyName',PropertyValue,...)</code> returns a uniform decoder, <code>H</code>, with each specified property set to the specified value.</p> <p><code>H = dsp.UniformDecoder(peakvalue,numbits,'PropertyName',PropertyValue,...)</code> returns a uniform decoder, <code>H</code>, with the <code>PeakValue</code> property set to <code>peakvalue</code>, the <code>NumBits</code> property set to <code>numbits</code>, and other specified properties set to the specified values.</p>
<b>Properties</b>	<p><b>PeakValue</b></p> <p>Largest amplitude represented in encoded input</p> <p>Specify the largest amplitude represented in the encoded input as a nonnegative numeric scalar. To correctly decode values encoded with the <code>UniformEncoder</code> object, set the <code>PeakValue</code> property in both objects to the same value. For more information on setting this property, see the <code>PeakValue</code> property description on the <code>dsp.UniformEncoder</code> reference page. The default is 1.</p>

# dsp.UniformDecoder

---

## NumBits

Number of input bits used to encode data

Specify the number of bits used to encode the input data as an integer value between 2 and 32. The value of this property can be less than the total number of bits supplied by the input data type. To correctly decode values encoded with the `UniformEncoder` object, set the `NumBits` property in both objects to the same value. For more information on setting this property, see the `NumBits` property description on the `dsp.UniformEncoder` reference page. The default is 3.

## OverflowAction

Action to take when integer input is out of range

Specify the behavior of the uniform decoder when the integer input is out of range as `Saturate` or `Wrap`. The value of the `NumBits` property specifies the representable range of the input. The default is `Saturate`.

## OutputDataType

Output data type as single or double

Specify the data type of the output as `single` or `double`. The default is `double`.

## Methods

<code>clone</code>	Create uniform decoder object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
step	Decode integer input into quantized floating-point output

## Examples

Decode an encoded sequence:

```
hue = dsp.UniformEncoder;
hue.PeakValue = 2;
hue.NumBits = 4;
hue.OutputDataType = 'Signed integer';
x = (0:0.25:2)'; % Create an input sequence
hud = dsp.UniformDecoder;
hud.PeakValue = 2;
hud.NumBits = 4;
x_encoded = step(hue, x);
% Check that the last element has been saturated.
x_decoded = step(hud, x_encoded);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Uniform Decoder block reference page. The object properties correspond to the block parameters.

## See Also

`dsp.UniformEncoder`

# dsp.UniformDecoder.clone

---

**Purpose** Create uniform decoder object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `UniformDecoder` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object. The clone method creates an instance of an object. The property values, but not internal states, are copied into the new instance of the object.

# dsp.UniformDecoder.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.UniformDecoder.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `UniformDecoder` object `H`.  
The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.UniformDecoder.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Decode integer input into quantized floating-point output

**Syntax**  $Y = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  reconstructs quantized floating-point output  $Y$  from the encoded integer input  $X$ . Input  $X$  can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.UniformEncoder

---

<b>Purpose</b>	Quantize and encode floating-point input into integer output
<b>Description</b>	<p>The <code>UniformEncoder</code> object quantizes floating-point input, using the precision you specify in the <code>NumBits</code> property, and encodes the quantized input into integer output. The operations of the uniform encoder adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.</p> <p>To quantize and encode a floating-point input into an integer output:</p> <ol style="list-style-type: none"><li>1 Define and set up your uniform encoder. See “Construction” on page 3-1420.</li><li>2 Call <code>step</code> to encode the input according to the properties of <code>dsp.UniformEncoder</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.UniformEncoder</code> returns a uniform encoder, <code>H</code>, that quantizes floating-point input samples and encodes them as integers using <math>2N</math>-level quantization, where <math>N</math> is an integer.</p> <p><code>H = dsp.UniformEncoder('PropertyName',PropertyValue,...)</code> returns an uniform encoder, <code>H</code>, with each specified property set to the specified value.</p> <p><code>H = dsp.UniformEncoder(peakvalue,numbits,'PropertyName',PropertyValue,...)</code> returns a uniform encoder, <code>H</code>, with the <code>PeakValue</code> property set to <code>peakvalue</code>, the <code>NumBits</code> property set to <code>numbits</code>, and other specified properties set to the specified values.</p>
<b>Properties</b>	<p><b>PeakValue</b></p> <p>Largest input amplitude to be encoded</p> <p>Specify the largest input amplitude to be encoded, as a nonnegative numeric scalar. If the real or imaginary input are outside of the interval <math>[-P,(1 - 2^{(1-B)})P]</math>, where <math>P</math> is the peak value and <math>B</math> is the value of the <code>NumBits</code> property, the uniform encoder</p>

saturates (independently for complex inputs) at those limits. The default is 1.

## NumBits

Number of bits needed to represent output

Specify the number of bits needed to represent the integer output as an integer value between 2 and 32. The number of levels at which the uniform encoder quantizes the floating-point input is  $2^B$ , where  $B$  is the number of bits. The default is 8.

## OutputDataType

Data type of output

Specify the data type of the output as `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, and signed outputs are `int8`, `int16`, or `int32`. The quantized inputs are linearly (uniformly) mapped to the intermediate integers in the interval  $[0, 2^{(B-1)}]$  when you set this property to `Unsigned integer`, and in the interval  $[-2^{(B-1)}, 2^{(B-1)} - 1]$  when you set this property to `Signed integer`. The variable  $B$  in both expressions corresponds to the value of the `NumBits` property.

## Methods

<code>clone</code>	Create uniform encoder object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Quantize and encode input

# dsp.UniformEncoder

---

## Examples

Encode a sequence:

```
hue = dsp.UniformEncoder;
hue.PeakValue = 2;
hue.NumBits = 4;
hue.OutputDataType = 'Signed integer';
x = [-1:0.01:1]'; % Create an input sequence
x_encoded = step(hue, x);
plot(x, x_encoded, '.');
xlabel('Input'); ylabel('Encoded Output'); grid
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Uniform Encoder block reference page. The object properties correspond to the block parameters.

## See Also

dsp.UniformDecoder

**Purpose**

Create uniform encoder object with same property values

**Syntax**

`C = clone(H)`

**Description**

`C = clone(H)` creates a `UniformEncoder` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

# dsp.UniformEncoder.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.UniformEncoder.getNumOutputs

---

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.UniformEncoder.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `UniformEncoder` object `H`.  
The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

# dsp.UniformEncoder.step

---

**Purpose** Quantize and encode input

**Syntax**  $Y = \text{step}(H, X)$

**Description**  $Y = \text{step}(H, X)$  quantizes and encodes the input  $X$  to  $Y$ . Input  $X$  can be real or complex, double-, or single-precision values. The uniform encoder chooses the output data type according to the following table.

Number of Bits	Unsigned Integer	Signed Integer
2 to 8	uint8	int8
9 to 16	uint16	int16
17 to 32	uint32	int32

The row corresponds to the value of the NumBits property, and the column corresponds to the value of the OutputDataType property.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Purpose

Solve upper-triangular matrix equation

## Description

The UpperTriangularSolver object solves  $UX = B$  for  $X$  when  $U$  is a square, upper-triangular matrix with the same number of rows as  $B$ .

To solve  $UX = B$ :

- 1 Define and set up your linear system solver. See “Construction” on page 3-1429.
- 2 Call `step` to solve the equation according to the properties of `dsp.UpperTriangularSolver`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.UpperTriangularSolver` returns a linear system solver, `H`, used to solve  $UX = B$  where  $U$  is an upper (or unit-upper) triangular matrix.

`H =`

`dsp.UpperTriangularSolver('PropertyName',PropertyValue,...)` returns a linear system solver, `H`, with each specified property set to the specified value.

## Properties

### OverwriteDiagonal

Replace diagonal elements of input with ones

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input,  $U$ , with ones. Set this property to either `true` or `false`. The default is `false`.

### RealDiagonalElements

Indicate that diagonal of complex input is real

When you set this property to `true`, the linear system solver optimizes computation speed if the diagonal elements of complex input,  $U$ , are real. This property applies only when you set the `OverwriteDiagonal` property to `false`. Set this property to either `true` or `false`. The default is `false`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

### **ProductDataType**

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

### **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

### **AccumulatorDataType**

Data type of accumulator

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`. The default is `Full precision`.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

## OutputDataType

Data type of output

Specify the output data type as `Same as first input` or `Custom`. The default is `Same as first input`.

## CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

## Methods

<code>clone</code>	Create upper triangular solver object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Solve matrix equation for specified inputs

## Examples

Solve an upper-triangular matrix equation:

```
huptriang = dsp.UpperTriangularSolver;
```

# dsp.UpperTriangularSolver

---

```
u = triu(rand(4, 4));  
b = rand(4, 1);  
% Check that result is the solution to the linear  
% equations.  
x1 = inv(u)*b  
x = step(huptriang, u, b)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Backward Substitution block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.LowerTriangularSolver](#)

**Purpose** Create upper triangular solver object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates an `UpperTriangularSolver` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

# **dsp.UpperTriangularSolver.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.UpperTriangularSolver.getNumOutputs

---

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.UpperTriangularSolver.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `UpperTriangularSolver` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

# dsp.UpperTriangularSolver.step

---

**Purpose** Solve matrix equation for specified inputs

**Syntax**  $X = \text{step}(H,U,B)$

**Description**  $X = \text{step}(H,U,B)$  computes the solution,  $X$ , of the matrix equation  $UX = B$ , where  $U$  is a square, upper-triangular matrix with the same number of rows as the matrix  $B$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Delay input by time-varying fractional number of sample periods
<b>Description</b>	<p>The <code>VariableFractionalDelay</code> object delays the input by a time-varying fractional number of sample periods.</p> <p>To delay the input by a time-varying fractional number of sample periods:</p> <ol style="list-style-type: none"><li>1 Define and set up your variable fractional delay object. See “Construction” on page 3-1439.</li><li>2 Call <code>step</code> to delay the input according to the properties of <code>dsp.VariableFractionalDelay</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.VariableFractionalDelay</code> returns a variable fractional delay System object, <code>H</code>, that delays a discrete-time input by a time-varying fractional number of sample periods.</p> <p><code>H = dsp.VariableFractionalDelay('PropertyName',PropertyValue,...)</code> returns a variable fractional delay System object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>InterpolationMethod</b></p> <p>Interpolation method</p> <p>Specify the method by which the block interpolates between adjacent stored samples to obtain a value for the sample indexed by the input. You can set this property to one of   <code>Linear</code>   <code>FIR</code>   <code>Farrow</code>  . When you set this property to <code>FIR</code>, the object uses the Signal Processing Toolbox <code>intfilt</code> function to compute an FIR filter for interpolation. The default is <code>Linear</code>.</p> <p><b>FilterHalfLength</b></p> <p>FIR interpolation filter half-length</p>

# dsp.VariableFractionalDelay

---

Specify the half-length of the FIR interpolation filter as a positive scalar integer. This property applies only when you set the `InterpolationMethod` property to `FIR`. For periodic signals, a larger value of this property (that is, a higher order filter) yields a better estimate of the delayed output sample. Setting this property to a value between 4 and 6 (that is, a 7th to 11th order filter) is usually adequate. The default is 4.

## **FilterLength**

Length of Farrow filter

Specify the length of the FIR filter implemented using the Farrow structure, as a positive scalar integer. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is 4.

## **InterpolationPointsPerSample**

Number of interpolation points per input sample

Specify the number of interpolation points per input sample at which a unique FIR interpolation filter is computed. You must specify the number of interpolation points per input sample as a positive scalar integer. This property applies only when you set the `InterpolationMethod` property to `FIR`. The default is 10.

## **Bandwidth**

Normalized input bandwidth

Specify the bandwidth to which you want to constrain the interpolated output samples. You must enter the bandwidth as a scalar value between 0 and 1. You can use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above  $F_s/4$  (where  $F_s$  is the sampling frequency), you can specify a value of 0.5 for the `Bandwidth` property. A value of 1 for the `Bandwidth` property corresponds to half the sampling frequency ( $F_s$ ). This property applies only when you set the `InterpolationMethod` property to `FIR`. The default is 1.

## InitialConditions

Initial values in memory

Specify the values with which the object's memory is initialized. The dimensions of this property can vary depending on the setting of the `FrameBasedProcessing` property, and whether you want fixed or time-varying initial conditions. The default is 0.

When you set the `FrameBasedProcessing` property to `false`, the object supports N-D input arrays. For an M-by-N-by-P sample-based input array `U`, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the value of the `InterpolationMethod` property:
  - If you set the `InterpolationMethod` property to `Linear`, set the `InitialConditions` property to an array of dimension Mx-by-N-by-P-by-D. The object uses the values in this array to initialize memory samples `U(2:D+1)`, where D is the value of the `MaximumDelay` property.
  - If you set the `InterpolationMethod` property to either `FIR` or `Farrow`, set the `InitialConditions` property to an array of dimension M-by-N-by-P-by-(D+L). The object uses the values in this array to initialize memory samples `U(2:D+1)`, where D is the value of the `MaximumDelay` property. For FIR interpolation, L is the value of the `FilterHalfLength` property. For Farrow interpolation, L equals `floor` of half the value of the `FilterLength` property (`floor(FilterLength/2)`).

When you set the `FrameBasedProcessing` property to `true`, the object treats each of the N input columns as a frame containing M sequential time samples from an independent channel.

# dsp.VariableFractionalDelay

---

For an M-by-N frame-based input matrix U, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the value of the `InterpolationMethod` property. To specify different time-varying initial conditions for each channel, set the `InitialConditions` property as follows:
  - If you set the `InterpolationMethod` property to `Linear`, set the `InitialConditions` property to an array of size 1-by-N-by-D, where D is the value of the `MaximumDelay` property.
  - If you set the `InterpolationMethod` property to `FIR` or `Farrow`, set the `InitialConditions` property to an array of size 1-by-N-by-(D+L), where D is the value of the `MaximumDelay` property. For FIR interpolation, L is the value of the `FilterHalfLength` property. For Farrow interpolation, L equals floor of half the value of the `FilterLength` property (`floor(FilterLength/2)`).

## **MaximumDelay**

Maximum delay

Specify the maximum delay the object can produce for any sample. The maximum delay must be a positive scalar integer value. The object clips input delay values greater than the `MaximumDelay` to the `MaximumDelay`. The default is 100.

## **DirectFeedthrough**

Allow direct feedthrough

When you set this property to `true`, the object allows direct feedthrough. When you set this property to `false`, the object increases the minimum possible delay by one. The default is `true`.

## **FIRSmallDelayAction**

Action for small input delay values in FIR interpolation mode

Specify the action the object should take for small input delay values when using the FIR interpolation method. You can set this property to `Clip` to the minimum value necessary for centered kernel, or `Switch` to linear interpolation if kernel cannot be centered. This property applies only when you set the `InterpolationMethod` property to `FIR`. The default is `Clip` to the minimum value necessary for centered kernel.

## **FarrowSmallDelayAction**

Action for small input delay values in Farrow interpolation mode

Specify the action the object should take for small input delay values when using the Farrow interpolation method. You can set this property to `Clip` to the minimum value necessary for centered kernel, or `Use off-centered kernel`. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Clip` to the minimum value necessary for centered kernel.

## **FrameBasedProcessing**

Treat input as frame based or sample based

Set this property to `true` to enable frame-based processing. When you do so, the object accepts `M-by-N` input matrices and treats each of the `N` input columns as a frame containing `M` sequential time samples from an independent channel. Set this property to `false` to enable sample-based processing. When you do so, the object supports `N-D` inputs and treats each element of the input as a separate channel. The default is `true`.

## **Fixed-Point Properties**

### **RoundingMethod**

# dsp.VariableFractionalDelay

---

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent, | Floor | Nearest | Round | Simplest | Zero |. The default is Zero.

## **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

## **CoefficientsDataType**

Coefficient word and fraction lengths

Specify the coefficients data type as one of | Same word length as input | Custom |. The default is Same word length as input.

## **CustomCoefficientsDataType**

Coefficients word length

Specify the coefficients word length as an `numericType` object with a `Signedness` of `Auto`. If the `InterpolationMethod` is `Linear`, specify that the `numericType` object is unsigned; otherwise the object should be signed. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numericType([],32)`.

## **ProductPolynomialValueDataType**

Product polynomial values word and fraction lengths

Specify the product polynomial value data type as one of | Same as first input | Custom |. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is Same as first input.

## **CustomProductPolynomialValueDataType**

Product polynomial values word and

**fraction lengths** Specify the product polynomial values fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` property to `Farrow` and the `ProductPolynomialValueDataType` property to `Custom`. The default is `numericType([],32,10)`.

## **AccumulatorPolynomialValueDataType**

Accumulator polynomial value word and fraction lengths

Specify the accumulator polynomial value data type as one of `| Same as first input | Custom |`. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Same as first input`.

## **CustomAccumulatorPolynomialValueDataType**

Accumulator polynomial value word and fraction lengths

Specify the data type of the accumulator polynomial values as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` property to `Farrow` and the `AccumulatorPolynomialValueDataType` property to `Custom`. The default is `numericType([],32,10)`.

## **MultiplicandPolynomialValueDataType**

Multiplicand polynomial value word and fraction lengths

Specify the multiplicand polynomial values data type as one of `| Same as first input | Custom |`. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Same as first input`.

## **CustomMultiplicandPolynomialValueDataType**

Multiplicand polynomial value word and fraction lengths

Specify the fixed-point data type of the multiplicand polynomial values as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` property to `Farrow` and the

# **dsp.VariableFractionalDelay**

---

MultiplicandPolynomialValueDataType property to Custom. The default is `numericType([],32,10)`.

## **ProductDataType**

Product word and fraction lengths

Specify the product data type as one of | Same as first input | Custom |. The default is Same as first input.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product data type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,10)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator data type as one of | Same as product | Same as first input | Custom |. The default is Same as product.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the fixed-point accumulator data type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,10)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output data type as one of | Same as accumulator | Same as first input | Custom |. The default is Same as accumulator.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the data type of the output as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([],32,10)`.

## Methods

<code>clone</code>	Create variable fractional delay object with same property values
<code>getNumInputs</code>	Number of expected inputs to <code>step</code> method
<code>getNumOutputs</code>	Number of outputs of <code>step</code> method
<code>info</code>	Characteristic information about valid delay range
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of variable fractional delay object
<code>step</code>	Delay input by time-varying fractional number of sample periods

## Examples

Delay a signal by a varying fractional number of sample periods:

```
hsr = dsp.SignalSource;  
hvfd = dsp.VariableFractionalDelay;  
hLog = dsp.SignalSink;  
  
for ii = 1:10  
    delayedSig = step(hvfd, step(hsr), ii/10);  
    step(hLog, delayedSig);  
end
```

# dsp.VariableFractionalDelay

---

```
end

sigd = hLog.Buffer;

% The output sigd corresponds to the values of the delayed signal
% that are sampled at fixed-time intervals. For visualization
% purposes, we can instead plot the time instants at which the
% amplitudes of signal samples are constant by treating the
% signals as the sampling instants.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Variable Fractional Delay block reference page. The object properties correspond to the block properties, except:

When you set the `DirectFeedthrough` property of the `System` object to `true`, the object allows direct feedthrough. This behavior is different from the way the block behaves when you select the corresponding **Disable direct feedthrough by increasing minimum possible delay by one** check box on the block dialog. When you enable this block parameter, the block does not allow direct feedthrough.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the `FrameBasedProcessing` Property of a `System` object” for more information.

## See Also

`dsp.VariableIntegerDelay` | `dsp.Delay` | `dsp.DelayLine`

**Purpose** Create variable fractional delay object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `VariableFractionalDelay` System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.VariableFractionalDelay.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.VariableFractionalDelay.getNumOutputs**

---

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.VariableFractionalDelay.info**

---

**Purpose** Characteristic information about valid delay range

**Syntax** `S = info(H)`

**Description** `S = info(H)` returns a structure, `S`, containing characteristic information about the `VariableFractionalDelay` System object, `H`. `S` has one field, `ValidDelayRange` which is a string containing the possible range of delay values based on the current property values of the `VariableFractionalDelay` object. The `ValidDelayRange` is in the format `[MinValidDelay, MaxValidDelay]`. The object clips all input delay values to be within this `ValidDelayRange`.

# **dsp.VariableFractionalDelay.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `VariableFractionalDelay` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.VariableFractionalDelay.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.VariableFractionalDelay.reset

---

<b>Purpose</b>	Reset internal states of variable fractional delay object
<b>Syntax</b>	reset(H)
<b>Description</b>	reset(H) resets the internal states of the VariableFractionalDelay System object H to their initial values.

# dsp.VariableFractionalDelay.step

---

**Purpose** Delay input by time-varying fractional number of sample periods

**Syntax**  $Y = \text{step}(H,X,D)$

**Description**  $Y = \text{step}(H,X,D)$  delays the input  $X$  by  $D$  samples, where  $D$  should be less than or equal to the value specified in the `MaximumDelay` property.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Delay input by time-varying integer number of sample periods
<b>Description</b>	<p>The <code>VariableIntegerDelay</code> object delays input by time-varying integer number of sample periods.</p> <p>To delay the input by a time-varying integer number of sample periods:</p> <ol style="list-style-type: none"><li>1 Define and set up your variable integer delay object. See “Construction” on page 3-1457.</li><li>2 Call <code>step</code> to delay the input according to the properties of <code>dsp.VariableIntegerDelay</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.VariableIntegerDelay</code> returns a variable integer delay System object, <code>H</code>, that delays discrete-time input by a time-varying integer number of sample periods.</p> <p><code>H = dsp.VariableIntegerDelay('PropertyName',PropertyValue,...)</code> returns a variable integer delay System object, <code>H</code>, with each property set to the specified value.</p>
<b>Properties</b>	<p><b>MaximumDelay</b></p> <p>Maximum delay</p> <p>Specify the maximum delay the object can produce for any sample. The maximum delay must be a positive scalar integer value. The object clips input delay values greater than the <code>MaximumDelay</code> to the <code>MaximumDelay</code>. The default is 100.</p> <p><b>InitialConditions</b></p> <p>Initial values in memory</p> <p>Specify the values with which the object’s memory is initialized. The dimensions of this property can vary depending on the setting of the <code>FrameBasedProcessing</code> property, and whether you want fixed or time-varying initial conditions. The default is 0.</p>

# dsp.VariableIntegerDelay

---

When you set the `FrameBasedProcessing` property to `false`, the object supports N-D input arrays. For an M-by-N-by-P sample-based input array `U`, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- To specify time-varying initial conditions, set the `InitialConditions` property to an array of dimension M-by-N-by-P-by-D. The object uses the values in this array to initialize memory samples `U(2:D+1)`, where D is the value of the `MaximumDelay` property.

When you set the `FrameBasedProcessing` property to `true`, the object treats each of the N input columns as a frame containing M sequential time samples from an independent channel. For an M-by-N frame-based input matrix `U`, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- To specify different time-varying initial conditions for each channel, set the `InitialConditions` property to an array of size 1-by-N-by-D, where D is the value of the `MaximumDelay` property.

## **DirectFeedthrough**

Allow direct feedthrough

When you set this property to `true`, the object allows direct feedthrough. When you set this property to `false`, the object increases the minimum possible delay by one. The default is `true`.

## **FrameBasedProcessing**

Treat input as frame based or sample based

Set this property to `true` to enable frame-based processing. When you do so, the object accepts M-by-N input matrices and treats each of the N input columns as a frame containing M sequential time samples from an independent channel. Set this property to `false` to enable sample-based processing. When you do so, the object supports N-D inputs and treats each element of the input as a separate channel. The default is `true`.

## Methods

<code>clone</code>	Create variable integer delay object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>reset</code>	Reset internal states of variable integer delay object
<code>step</code>	Delay input by time-varying integer number of sample periods

## Examples

Delay a signal by a varying integer number of sample periods:

```
h = dsp.VariableIntegerDelay;  
x = 1:100;  
ii = 0;  
k = 0;  
yout = [];  
  
while(ii+10 <= 100)
```

# dsp.VariableIntegerDelay

---

```
y = step(h, x(ii+1:ii+10)', k*ones(10,1));
yout = [yout;y];
ii = ii+10;
k = k+1;
end

stem(x, 'b');
hold on; stem(yout, 'r');
legend('Original Signal', 'Variable Integer Delayed Signal')
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Variable Integer Delay block reference page. The object properties correspond to the block properties, except:

When you set the `DirectFeedthrough` property of the System object to `true`, the object allows direct feedthrough. This behavior is different from the way the block behaves when you select the corresponding **Disable direct feedthrough by increasing minimum possible delay by one** check box on the block dialog. When you enable this block parameter, the block does not allow direct feedthrough.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

## See Also

[dsp.VariableFractionalDelay](#) | [dsp.Delay](#) | [dsp.DelayLine](#)

**Purpose** Create variable integer delay object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a `VariableIntegerDelay` System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# dsp.VariableIntegerDelay.getNumInputs

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.VariableIntegerDelay.getNumOutputs

---

**Purpose**

Number of outputs of step method

**Syntax**

`N = getNumOutputs(H)`

**Description**

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.VariableIntegerDelay.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `VariableIntegerDelay` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# **dsp.VariableIntegerDelay.reset**

---

**Purpose**                Reset internal states of variable integer delay object

**Syntax**                reset(H)

**Description**        reset(H) resets the internal states of the VariableIntegerDelay System object H to their initial values.

**Purpose** Delay input by time-varying integer number of sample periods

**Syntax**  $Y = \text{step}(H, X, D)$

**Description**  $Y = \text{step}(H, X, D)$  delays the input  $X$  by  $D$  samples, where  $D$  should be less than or equal to the value specified in the `MaximumDelay` property and greater than or equal to 0. The object clips delay values greater than the `MaximumDelay` to the `MaximumDelay`, and clips values less than zero to zero. If you enter a noninteger delay value, the object rounds that value to the nearest integer value.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.Variance

---

## Purpose

Variance of input or sequence of inputs

## Description

The Variance object computes variance for an input or sequence of inputs.

To compute the variance of an input or sequence of inputs:

- 1 Define and set up your variance System object. See “Construction” on page 3-1468.
- 2 Call `step` to compute the variance according to the properties of `dsp.Variance`. The behavior of `step` is specific to each object in the toolbox.

## Construction

`H = dsp.Variance` returns a variance System object, `H`, that computes the variance of an input or a sequence of inputs over the specified Dimension.

`H = dsp.Variance('PropertyName',PropertyValue,...)` returns a variance System object, `H`, with each specified property set to the specified value.

## Properties

### RunningVariance

Enable calculation over time

Set this property to `true` to enable variance calculation over successive calls to the `step` method. The default is `false`.

### ResetInputPort

Enable reset input port

Set this property to `true` to enable reset input port. When you set the property to `true`, specify a reset input for the `step` method. The running variance resets anytime the variance object achieves the condition you specify for the `ResetCondition` property. This property applies when you set the `RunningVariance` property to `true`. The default is `false`.

### ResetCondition

Reset condition for running variance mode

Specify which event resets the running variance as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the ResetInputPort property to true.

## **Dimension**

Dimension to operate along

Specify how the object performs the variance calculation over the data as one of | All | Row | Column | Custom |. This property applies when you set the RunningVariance property to false. The default is Column.

## **CustomDimension**

Numerical dimension to operate along

Specify the input signal dimension (one-based value) the object uses to compute variance. The cannot exceed the number of dimensions in the input signal. This property applies when you set the Dimension property to Custom. The default is 1.

## **ROIProcessing**

Enable region-of-interest processing

Set this property to true to enable calculating the variance within a particular region of each image. This property applies when you set the RunningVariance property to false and the Dimension property to All. The default is false. Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, Rectangles is the only selection for the ROIForm property.

## **ROIForm**

Define the type of region of interest.

Specify the type of region of interest as one of | Rectangles | Lines | Label matrix | Binary mask |. This property applies

when you set the `ROIProcessing` property to `true`. The default is `Rectangle`.

## **ROIPortion**

Calculate over entire ROI or just perimeter

Specify the region over which to calculate variance as one of `| Entire ROI | ROI perimeter |`. This property applies when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

## **ROIStatistics**

Statistics for each ROI or one for all ROIs

Specify if statistics calculations are one of `| Individual statistics for each ROI | Single statistic for all ROIs |`. This property applies when `ROIForm` property is not `Binary mask`. The default is `Individual statistics for each ROI`.

## **ValidityOutputPort**

Enable output of validity check of ROI or label numbers

Indicate whether to return the validity of the specified ROI being completely inside image when the `ROIForm` property is `Lines` or `Rectangles`. Indicate whether to return the validity of the specified label numbers when the `ROIForm` property is `Label Matrix`. This property applies when you set the `ROIForm` property to anything except `Binary Mask`. The default is `false`.

## **FrameBasedProcessing**

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies when you set the `RunningVariance` property to `true`. The default is `true`.

## Fixed-Point Properties

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

### InputSquaredProductDataType

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

### CustomInputSquaredProductDataType

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point type as a scaled numericType object with a Signedness of Auto. This property applies when you set the InputSquaredProductDataType property to Custom. The default is numericType([],32,15).

### InputSumSquaredProductDataType

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point data type as one of | Same as input-squared product | Custom |. The default is Same as input-squared product.

### CustomInputSumSquaredProductDataType

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `InputSumSquaredProductDataType` property to `Custom`. The default is `numericType([],32,23)`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Same as input-squared product` | `Same as input` | `Custom` |. The default is `Same as input-squared product`.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,0)`.

## **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as input-squared product` | `Same as input` | `Custom` |. The default is `Same as input-squared product`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property only applies when the `OutputDataType` property to `Custom`. The default is `numericType([],16,0)`.

## Methods

clone	Create variance object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset variance to zero
step	Variance of input

## Examples

Compute the running variance for a signal:

```
hvar = dsp.Variance;  
hvar.RunningVariance = true;  
x = randn(100,1);  
y = step(hvar, x);  
% y(i) is the running variance of all values in the vector x(1:i)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Variance block reference page. The object properties correspond to the block parameters, except:

- **Treat sample-based row input as a column** block parameter is not supported by the `dsp.Variance` object.
- **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object

## dsp.Variance

---

uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the `FrameBasedProcessing` Property of a System object” for more information.

### See Also

[dsp.Mean](#) | [dsp.RMS](#) | [dsp.StandardDeviation](#)

**Purpose** Create variance object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a Variance System object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

# **dsp.Variance.getNumInputs**

---

**Purpose**            Number of expected inputs to step method

**Syntax**            `N = getNumInputs(H)`

**Description**      `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose** Number of outputs of step method

**Syntax** `N = getNumOutputs(H)`

**Description** `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# dsp.Variance.isLocked

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** isLocked(H)

**Description** isLocked(H) returns the locked state of the Variance System object. The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

## **dsp.Variance.reset**

---

**Purpose**            Reset variance to zero

**Syntax**            reset(H)

**Description**        reset(H) sets the variance to zero when the RunningVariance property is true.

## Purpose

Variance of input

## Syntax

```
Y = step(H,X)
Y = step(H,X,R)
VAR2D = step(H,X,ROI)
VAR2D = step(H,X,LABEL,LABELNUMBERS)
[VAR2D,FLAG] = step(H,X,ROI)
[VAR2D,FLAG] = step(H,X,LABEL,LABELNUMBERS)
```

## Description

`Y = step(H,X)` computes the variance, `Y`, of input `X` over successive calls to the `step` method, when the `RunningVariance` property is true.

`Y = step(H,X,R)` resets its state based on the value of reset signal `R`, the `ResetInputPort` property and the `ResetCondition` property. This option applies when the `RunningVariance` property is true and the `ResetInputPort` property is set to true.

`VAR2D = step(H,X,ROI)` computes the variance of input image, `X`, within the given region of interest, `ROI`, when the `ROIProcessing` property is true and the `ROIForm` property is `Lines`, `Rectangles` or `Binary mask`. Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, the `ROIForm` property only supports `Rectangles`.

`VAR2D = step(H,X,LABEL,LABELNUMBERS)` computes the variance of input image, `X`, for region labels contained in vector `LABELNUMBERS`, with matrix `LABEL` marking pixels of different regions. This option is available when the `ROIProcessing` property is true and the `ROIForm` property is `Label matrix`.

`[VAR2D,FLAG] = step(H,X,ROI)` returns `FLAG` which indicates whether the given region of interest is within the image bounds when both the `ROIProcessing` and `ValidityOutputPort` properties are true and the `ROIForm` property is set to `Lines`, `Rectangles` or `Binary mask`.

`[VAR2D,FLAG] = step(H,X,LABEL,LABELNUMBERS)` returns `FLAG` which indicates whether the input label numbers are valid when both the `ROIProcessing` and `ValidityOutputPort` properties are true and the `ROIForm` property is set to `Label matrix`.

## **dsp.Variance.step**

---

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

<b>Purpose</b>	Vector quantizer codeword for given index value
<b>Description</b>	<p>The <code>VectorQuantizerDecoder</code> object returns the vector quantizer codeword for a given index value. Each column of the <code>Codebook</code> property is a codeword.</p> <p>To obtain the vector quantizer codeword for a given index value:</p> <ol style="list-style-type: none"><li>1 Define and set up your vector quantizer decoder. See “Construction” on page 3-1483.</li><li>2 Call <code>step</code> to get the vector quantizer codeword according to the properties of <code>dsp.VectorQuantizerDecoder</code>. The behavior of <code>step</code> is specific to each object in the toolbox.</li></ol>
<b>Construction</b>	<p><code>H = dsp.VectorQuantizerDecoder</code> creates a vector quantizer decoder System object, <code>H</code>, that returns a vector quantizer codeword corresponding to a given, zero-based index value.</p> <p><code>H = dsp.VectorQuantizerDecoder('PropertyName',PropertyValue,...)</code> returns a vector quantizer decoder, <code>H</code>, with each specified property set to the specified value.</p>
<b>Properties</b>	<p><b>CodebookSource</b></p> <p>Source of codebook values</p> <p>Specify the codebook source as <code>Property</code> or <code>Input port</code>. When you select <code>Property</code>, the object reads the codebook from the <code>codebook</code> property. When you select <code>Input port</code>, the object reads the codebook from the input of the <code>step</code> method.</p> <p>The default is <code>Property</code>.</p> <p><b>Codebook</b></p> <p>codebook</p>

# dsp.VectorQuantizerDecoder

---

Specify quantized output values as a  $k$ -by- $N$  matrix, where  $k \geq 1$  and  $N \geq 1$ . Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. This property applies when you set the `CodebookSource` property to `Property`. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

This property is tunable.

## OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as: `Same as input`, `double`, `single` or `Custom`. This property applies only when you set `CodebookSource` to `Property`. The default is `double`.

## Fixed-Point Properties

### CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numericType` object. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType(true, 16)`.

## Methods

<code>clone</code>	Create vector quantizer decoder object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Quantized output values corresponding to input indices

## Examples

Given index values as an input, determine the corresponding vector quantized codewords for a specified codebook:

```
hvfdec = dsp.VectorQuantizerDecoder;  
hvfdec.Codebook = [1 10 100;2 20 200;3 30 300];  
indices = uint8([1 0 2 0]);  
qout = step(hvfdec, indices)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Decoder block reference page. The object properties correspond to the block parameters, except:

There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to  $N$  to  $N-1$ .

# **dsp.VectorQuantizerDecoder.clone**

---

**Purpose** Create vector quantizer decoder object with same property values

**Syntax**

**Description** `C = clone(H)` creates a `VectorQuantizerDecoder` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

# **dsp.VectorQuantizerDecoder.getNumInputs**

---

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.VectorQuantizerDecoder.getNumOutputs**

---

**Purpose**                Number of outputs of step method

**Syntax**                `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `VectorQuantizerDecoder` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.VectorQuantizerDecoder.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose**

Quantized output values corresponding to input indices

**Syntax**

$Q = \text{step}(H, I)$   
 $Q = \text{step}(H, I, C)$

**Description**

$Q = \text{step}(H, I)$  returns the quantized output values  $Q$  corresponding to the input indices  $I$ . The data type of  $I$  can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The `OutputDataType` property determines the data type of  $Q$ .

$Q = \text{step}(H, I, C)$  uses input  $C$  as the codebook values when the `CodebookSource` property is `Input port`. The data type of  $C$  can be `double`, `single`, or `fixed-point`. The output  $Q$  has the same data type as the codebook input  $C$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.VectorQuantizerEncoder

---

**Purpose** Vector quantization encoding

**Description** The `VectorQuantizerEncoder` object performs vector quantization encoding. The object finds the nearest codeword by computing a distortion based on Euclidean or weighted Euclidean distance.

To perform vector quantization encoding:

- 1 Define and set up your vector quantizer encoder. See “Construction” on page 3-1492.
- 2 Call `step` to perform the quantization encoding according to the properties of `dsp.VectorQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.VectorQuantizerEncoder` returns a vector quantizer encoder System object, `H`. This object finds a zero-based index of the nearest codeword for each given input column vector.

`H = dsp.VectorQuantizerEncoder('PropertyName',PropertyValue,...)` returns a vector quantizer encoder System object, `H`, with each specified property set to the specified value.

## Properties

### CodebookSource

Source of codebook values

Specify how to determine the codebook values as `Property` or `Input port`. The default is `Property`.

### Codebook

Codebook

Specify the codebook to which the input column vector or matrix is compared, as a  $k$ -by- $N$  matrix. Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. The codeword vectors must have the same number of rows as the input. The first codeword vector corresponds to an index

value of 0, the second codeword vector corresponds to an index value of 1, and so on. This property applies when you set the CodebookSource property to Property. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

This property is tunable.

## **DistortionMeasure**

Distortion calculation method

Specify how to calculate the distortion as Squared error or Weighted squared error. If you set this property to Squared error, the object calculates the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. If you set this property to Weighted squared error, the object calculates the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values. The default is Squared error.

## **WeightsSource**

Source of weighting factor

Specify how to determine weighting factor as Property or Input port. This property applies when you set the DistortionMeasure property to Weighted squared error. The default is Property.

## **Weights**

Weighting factor

Specify the weighting factor as a vector of length equal to the number of rows of the input. This property applies when you set the DistortionMeasure property to Weighted squared error and WeightsSource property is Property. The default is [1 1 1]. This property is tunable.

# dsp.VectorQuantizerEncoder

---

## **TiebreakerRule**

Behavior when input column vector is equidistant from two codewords.

Specify whether to represent the input column vector by the lower index valued codeword or higher indexed valued codeword when an input column vector is equidistant from two codewords. You can set this property to `Choose the lower index` or `Choose the higher index`. The default is `Choose the lower index`.

## **CodewordOutputPort**

Enable output of codeword value

Set this property to `true` to output the codeword vectors nearest to the input column vectors. The default is `false`.

## **QuantizationErrorOutputPort**

Enable output of quantization error

Set this property to `true` to output the quantization error value that results when the object represents the input column vector by the nearest codeword. The default is `false`.

## **OutputIndexDataType**

Data type of index output

Specify the data type of the index output as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`.

## **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Same as input`, or `Custom`. The default is `Same as product`.

## **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`.

## **Methods**

<code>clone</code>	Create vector quantizer encoder object with same property values
<code>getNumInputs</code>	Number of expected inputs to <code>step</code> method
<code>getNumOutputs</code>	Number of outputs of <code>step</code> method

# dsp.VectorQuantizerEncoder

---

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Quantization region to which input belongs

## Examples

Find the indices of nearest codewords based on Euclidean distances:

```
hvfqenc = dsp.VectorQuantizerEncoder(...
    'Codebook', [-1 -1 1 1;1 -1 -1 1], ...
    'CodewordOutputPort', true, ...
    'QuantizationErrorOutputPort', true, ...
    'OutputIndexDataType', 'uint8');
% Generate an input signal with some additive noise
x = sign(rand(2,40)-0.5) + 0.1*randn(2,40);
[ind, cw, err] = step(hvfqenc, x);
plot(cw(1,:), cw(2,:), 'r0', x(1,:), x(2,:), 'g. ');
legend('Quantized', 'Inputs', 'location', 'best');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Encoder block reference page. The object properties correspond to the block parameters.

## See Also

[dsp.VectorQuantizerDecoder](#) | [dsp.ScalarQuantizerEncoder](#)

**Purpose** Create vector quantizer encoder object with same property values

**Syntax**

**Description** `C = clone(H)` creates a `VectorQuantizerEncoder` object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.VectorQuantizerEncoder.getNumInputs

---

**Purpose**                Number of expected inputs to step method

**Syntax**                `N = getNumInputs(H)`

**Description**        `N = getNumInputs(H)` returns the number of expected inputs, *N*, to the step method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.VectorQuantizerEncoder.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of the step method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

# **dsp.VectorQuantizerEncoder.isLocked**

---

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the `VectorQuantizerEncoder` System object H.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.VectorQuantizerEncoder.step

---

**Purpose** Quantization region to which input belongs

**Syntax**

```
INDEX = step(H, INPUT)
INDEX = step(H, ..., CODEBOOK)
INDEX = step(H, ..., WEIGHTS)
[ ..., CODEWORD ] = step(H, ...)
[ ..., QERR ] = step(H, ...)
```

**Description** `INDEX = step(H, INPUT)` returns `INDEX`, a scalar or column vector representing the quantization region(s) to which `INPUT` belongs. `INPUT` can be a column vector of size  $k$ -by-1 or an  $M$  multichannel matrix of dimensions  $k$ -by- $M$ , where  $k$  is the length of each codeword in the codebook. All inputs to the object can be real floating-point or fixed-point values and must be of the same data type. The output index values can be signed or unsigned integers.

`INDEX = step(H, ..., CODEBOOK)` uses the codebook given in input `CODEBOOK`, a  $k$ -by- $N$  matrix with  $N$  codewords each of length  $k$ . This option is available when the `CodebookSource` property is `Input port`.

`INDEX = step(H, ..., WEIGHTS)` uses the input vector `WEIGHTS` to emphasize or de-emphasize certain input values when calculating the distortion measure. `WEIGHTS` must be a vector of length equal to the number of rows of `INPUT`. This option is available when the `DistortionMeasure` property is `Weighted squared error` and the `WeightsSource` property is `Input port`.

`[ ..., CODEWORD ] = step(H, ...)` outputs the `CODEWORD` values that correspond to each index value when the `CodewordOutputPort` property is `true`.

`[ ..., QERR ] = step(H, ...)` outputs the quantization error `QERR` for each input value when the `QuantizationErrorOutputPort` property is `true`.

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.Window

---

**Purpose** Window object

**Description** The Window object applies a window to an input signal.

To apply a window to an input signal:

- 1 Define and set up your window. See “Construction” on page 3-1504.
- 2 Call `step` to apply the window according to the properties of `dsp.Window`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.Window` returns a window object, `H`, that applies a Hamming window with symmetric sampling.

`H = dsp.Window('PropertyName',PropertyValue, ...)` returns a window object, `H`, with each property set to the specified value.

`H = dsp.Window(WINDOW,'PropertyName',PropertyValue, ...)` returns a window object, `H`, with the `WindowFunction` property set to `WINDOW` and other properties set to the specified values.

## Properties

### WindowFunction

Type of window

Specify the type of window to apply as Bartlett, Blackman, Boxcar, Chebyshev, Hamming, Hann, Hanning, Kaiser, Taylor, Triang. This property is tunable. The default is Hamming.

### WeightsOutputPort

Enable the output of window weights

Set this property to `true` to output the window weights. The weights are an  $M$ -by-1 vector with  $M$  equal to the first dimension of the input. The default is `false`.

### StopbandAttenuation

Level of stopband attenuation in decibels

Specify the level of stopband attenuation in decibels. This property only applies when the `WindowFunction` property is `Chebyshev`. The default is 50. This property is tunable.

## **Beta**

Kaiser window parameter

Specify the Kaiser window parameter as a real number. Increasing the absolute value of `Beta` widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This property only applies when `WindowFunction` property is `Kaiser`. The default is 10. This property is tunable.

## **NumConstantSidelobes**

Number of constant sidelobes

Specify the number of constant sidelobes as an integer greater than zero. This property only applies when `WindowFunction` property is `Taylor`. The default is 4. This property is tunable.

## **MaximumSidelobeLevel**

Maximum sidelobe level relative to mainlobe

Specify, in decibels, the maximum sidelobe level relative to the mainlobe as a real number less than or equal to zero. The default is -30, which produces sidelobes with peaks 30 dB down from the mainlobe peak. This property only applies when `WindowFunction` property is `Taylor`. This property is tunable.

## **Sampling**

Window sampling for generalized-cosine windows

Specify the window sampling for generalized-cosine windows as `Symmetric` or `Periodic`. This property only applies when `WindowFunction` property is `Blackman`, `Hamming`, `Hann`, or `Hanning`. This property is tunable.

## **Fixed-Point Properties**

### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

### **WindowDataType**

Window word and fraction lengths

Specify the window fixed-point data type as one of `Same word length as input` or `Custom`. The default is `Same word length as input`.

## **CustomWindowDataType**

Window word and fraction lengths

Specify the window fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `WindowDataType` property to `Custom`. The default is `numericType([],16,15)`.

## **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

## **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([],16,15)`.

## **OutputDataType**

Output data type

Specify the output fixed-point data type as one of `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

## **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you

# dsp.Window

---

set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

## Methods

<code>clone</code>	Create window object with same property values
<code>getNumInputs</code>	Number of expected inputs to step method
<code>getNumOutputs</code>	Number of outputs of step method
<code>isLocked</code>	Locked status for input attributes and nontunable properties
<code>release</code>	Allow property value and input characteristics changes
<code>step</code>	Multiply input by window

## Examples

Apply Hamming window to input signal:

```
hwin = dsp.Window( ...  
'WindowFunction', 'Hamming', ...  
'WeightsOutputPort',true);  
x = rand(64,1);  
[y, w] = step(hwin, x);  
% View the window's time and frequency domain responses  
wvtool(w);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the [Window Function block reference page](#). The object properties correspond to the block parameters, except:

- **Operation** — The window object does not support the `Generate window` option.
- **Operation** — The `Generate and apply window` option on the block corresponds to the `WeightsOutputPort` property set to `true` on the window object.

- The window object only supports frame-based processing.

| `sigwin.triang` | `wvtool`

# **dsp.Window.clone**

---

**Purpose** Create window object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a window object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

**Purpose** Number of expected inputs to step method

**Syntax** `N = getNumInputs(H)`

**Description** `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# dsp.Window.getNumOutputs

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the window object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.Window.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Multiply input by window

**Syntax**  $Y = \text{step}(H,X)$   
 $[Y, W] = \text{step}(H,X)$

**Description**  $Y = \text{step}(H,X)$  generates the windowed output,  $Y$ , of the input,  $X$ , using the specified window.

$[Y, W] = \text{step}(H,X)$  returns the window values  $W$  when the `WeightsOutputPort` property is true.

# dsp.ZeroCrossingDetector

---

**Purpose** Zero crossing detector

**Description** The ZeroCrossingDetector object counts the number of times the signal crosses zero, or changes sign. The zero crossing detector supports both floating-point and fixed-point data types.

To count the number of times a signal crosses zero or changes sign:

- 1 Define and set up your zero crossing detector. See “Construction” on page 3-1516.
- 2 Call `step` to count the number of times according to the properties of `dsp.ZeroCrossingDetector`. The behavior of `step` is specific to each object in the toolbox.

**Construction** `H = dsp.ZeroCrossingDetector` returns a zero crossing detector object, `H`, that counts the number of zero crossings in the real-valued, floating-point, or fixed-point frame-based vector or matrix.

`H = dsp.ZeroCrossingDetector('PropertyName',PropertyValue, ...)` returns a zero crossing detector object, `H`, with each property set to the specified value.

**Properties** **FrameBasedProcessing**

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

If the `FrameBasedProcessing` property is `true`:

- The zero crossing detector treats a column vector or the columns of a matrix as single, independent channels.
- The zero crossing detector treats a length  $N$  row vector as  $N$  independent channels.

If the `FrameBasedProcessing` property is `false`:

- The zero crossing detector treats each entry of a vector or matrix as an independent channel.

## Methods

clone	Create zero crossing detection object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Count zero crossings in input

## Examples

Find number of zero crossings in electrocardiogram data:

```
EcgData = ecg(500)';  
Hzerocross = dsp.ZeroCrossingDetector;  
NumZeroCross = step(Hzerocross, EcgData); % Equal to 4  
plot(1:500, EcgData, 'b', [0 500], [0 0], 'r', 'linewidth', 2);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Zero Crossing block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

# **dsp.ZeroCrossingDetector.clone**

---

**Purpose** Create zero crossing detection object with same property values

**Syntax** `C = clone(H)`

**Description** `C = clone(H)` creates a zero crossing detector object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

# dsp.ZeroCrossingDetector.getNumInputs

---

**Purpose** Number of expected inputs to step method

**Syntax** N = getNumInputs(H)

**Description** N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

# **dsp.ZeroCrossingDetector.getNumOutputs**

---

**Purpose**            Number of outputs of step method

**Syntax**            `N = getNumOutputs(H)`

**Description**        `N = getNumOutputs(H)` returns the number of outputs, N, of step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

**Purpose** Locked status for input attributes and nontunable properties

**Syntax** `isLocked(H)`

**Description** `isLocked(H)` returns the locked state of the zero crossing detector object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a true value.

# dsp.ZeroCrossingDetector.release

---

**Purpose** Allow property value and input characteristics changes

**Syntax** `release(H)`

**Description** `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note** You can use the `release` method on a `System` object in code generated from MATLAB, but once you release its resources, you cannot use that `System` object again.

---

**Purpose** Count zero crossings in input

**Syntax**  $Y = \text{step}(H, X)$

**Description**  $Y = \text{step}(H, X)$  counts the number of zero crossings,  $Y$ , in the vector or matrix input  $X$ .

---

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# matlab.System

---

## Purpose

Base class for System objects

## Description

`matlab.System` is the base class for System objects. In your class definition file, you must subclass your object from this base class (or from another class that derives from this base class). Subclassing allows you to use the implementation and service methods provided by this base class to build your object. You use this syntax as the first line of your class definition file to directly inherit from the `matlab.System` base class, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.System
```

---

**Note** You must set `Access=protected` for each `matlab.System` method you use in your code.

---

## Methods

<code>cloneImpl</code>	Copy System object
<code>getDiscreteStateImpl</code>	Discrete state property values
<code>getNumInputsImpl</code>	Number of input arguments passed to step and setup methods
<code>getNumOutputsImpl</code>	Number of outputs returned by method
<code>isInactivePropertyImpl</code>	Active or inactive flag for properties
<code>loadObjectImpl</code>	Load saved System object from MAT file
<code>processInputSizeChangeImpl</code>	Action when input size changes
<code>processTunedPropertiesImpl</code>	Action when tunable properties change
<code>releaseImpl</code>	Release resources

<code>resetImpl</code>	Reset System object states
<code>saveObjectImpl</code>	Save System object in MAT file
<code>setPropertyies</code>	Set property values from name-value pair inputs
<code>setupImpl</code>	Initialize System object
<code>stepImpl</code>	System output and state update equations
<code>validateInputsImpl</code>	Validate inputs to step method
<code>validatePropertiesImpl</code>	Validate property values

## Attributes

In addition to the attributes available for MATLAB objects, you can apply the following attributes to any property of a custom System object.

<code>Nontunable</code>	After an object is locked (after <code>step</code> or <code>setup</code> has been called), use <code>Nontunable</code> to prevent a user from changing that property value. By default, all properties are tunable. The <code>Nontunable</code> attribute is useful to lock a property that has side effects when changed. This attribute is also useful for locking a property value assumed to be constant during processing. You should always specify properties that affect the number of input or output ports as <code>Nontunable</code> .
<code>Logical</code>	Use <code>Logical</code> to limit the property value to a logical, scalar value. Any scalar value that can be converted to a logical is also valid, such as 0 or 1.

`PositiveInteger` Use `PositiveInteger` to limit the property value to a positive integer value.

`DiscreteState` Use `DiscreteState` to mark a property so it will display its state value when you use the `getDiscreteState` method.

To learn more about attributes, see “Property Attributes” in the MATLAB Object-Oriented Programming documentation.

## Examples

Create a simple `System` object, `AddOne`, which subclasses from `matlab.System`. You place this code into a MATLAB file, `AddOne.m`.

```
classdef AddOne < matlab.System
%ADDONE Compute an output value that increments the input by one

    methods (Access=protected)
        % stepImpl method is called by the step method.
        function y = stepImpl(~,x)
            y = x + 1;
        end
    end
end
```

To use this object, create an instance of `AddOne`, provide an input, and use the `step` method:

```
hAdder = AddOne;
x = 1;
y = step(hAdder,x)
```

---

Assign the `Nontunable` attribute to the `InitialValue` property, which you define in your class definition file.

```
properties (Nontunable)
    InitialValue
```

end

## How To

- “Object-Oriented Programming”
- Class Attributes
- Property Attributes
- “Method Attributes”
- “Define Basic System Objects”
- “Define Property Attributes”

# matlab.System.cloneImpl

---

**Purpose** Copy System object

**Syntax** cloneImpl(obj)

**Description** cloneImpl(obj) copies a System object by using the saveObjectImpl and loadObjectImpl methods. The default cloneImpl copies an object and its current state but does not copy any private or protected properties. If the object you clone is locked and you use the default cloneImpl, the new object will also be locked. If you define your own cloneImpl and the associated saveObjectImpl and loadObjectImpl, you can specify whether to clone the object's state and whether to clone the object's private and protected properties.

cloneImpl is called by the clone method.

---

**Note** You must set Access=protected for this method.

---

**Input Arguments**

**obj** System object handle of object to clone.

**Examples** Use the cloneImpl method to copy a System object

```
methods (Access=protected)
    function obj2 = cloneImpl(obj1)
        s = saveObject (obj1);
        obj2 = loadObject(s);
    end
end
```

**See Also** saveObjectImpl | loadObjectImpl

**How To**

- “Clone System Object”

**Purpose** Discrete state property values

**Syntax** `s = getDiscreteStateImpl(obj)`

**Description** `s = getDiscreteStateImpl(obj)` returns a struct `s` of state values. The field names of the struct are the object's `DiscreteState` property names. To restrict or change the values returned by `getDiscreteState` method, you can override this `getDiscreteStateImpl` method.

`getDiscreteStatesImpl` is called by the `getDiscreteState` method, which is called by the `setup` method.

---

**Note** You must set `Access=protected` for this method.

---

**Input Arguments**

**obj**  
System object handle

**Output Arguments**

**s**  
Struct of state values.

**Examples**

```
methods (Access=protected)
    function s = getDiscreteState(obj)
    end
end
```

**See Also** `setupImpl`

**How To**

- “Define Property Attributes”

# matlab.System.getNumInputsImpl

---

**Purpose** Number of input arguments passed to step and setup methods

**Syntax** `num = getNumInputsImpl(obj)`

**Description** `num = getNumInputsImpl(obj)` returns the number of inputs `num` (excluding the System object handle) expected by the `step` method. The default implementation returns 1, which requires one input from the user, in addition to the System object handle. To specify a value other than 1, you must use include the `getNumInputsImpl` method in your class definition file.

`getNumInputsImpl` is called by the `getNumInputs` method and by the `setup` method if the number of inputs has not been determined already.

---

**Note** You must set `Access=protected` for this method.

Do not set any object properties in this `getNumInputsImpl` method.

---

**Input Arguments**

**obj**  
System object handle

**Output Arguments**

**num**  
Number of inputs expected by the `step` method for the specified object.

**Default:** 1

**Examples** Specify the number of inputs (2, in this case) expected by the `step` method.

```
methods (Access=protected)
    function num = getNumInputsImpl(obj)
        num = 2;
    end
```

```
end
```

---

Specify that the `step` method will not accept any inputs.

```
methods (Access=protected)
    function num = getNumInputsImpl(~)
        num = 0;
    end
end
```

## See Also

[setupImpl](#) | [stepImpl](#) | [getNumOutputsImpl](#)

## How To

- “Change Number of Step Inputs or Outputs”

# matlab.System.getNumOutputsImpl

---

**Purpose** Number of outputs returned by step method

**Syntax** num = getNumOutputsImpl (obj)

**Description** num = getNumOutputsImpl (obj) returns the number of outputs from the step method. The default implementation returns 1 output. To specify a value other than 1, you must use include the getNumOutputsImpl method in your class definition file.

getNumOutputsImpl is called by the getNumOutputs method, if the number of outputs has not been determined already.

---

**Note** You must set Access=protected for this method.

Do not set any object properties in this getNumOutputsImpl method.

---

**Input Arguments**

**obj**  
System object handle

**Output Arguments**

**num**  
Number of outputs to be returned by the step method for the specified object.

**Examples** Specify the number of outputs (2, in this case) returned from the step method.

```
methods (Access=protected)
    function num = getNumOutputsImpl(obj)
        num = 2;
    end
end
```

---

Specify that the step method does not return any outputs.

```
methods (Access=protected)
    function num = getNumOutputsImpl(-)
        num = 0;
    end
end
```

## How To

- “Change Number of Step Inputs or Outputs”

# matlab.System.isInactivePropertyImpl

---

**Purpose** Active or inactive flag for properties

**Syntax** `flag = isInactivePropertyImpl(obj,prop)`

**Description** `flag = isInactivePropertyImpl(obj,prop)` specifies whether a public, non-state property is inactive for the current object configuration. An *inactive property* is a property that is not relevant to the object, given the values of other properties. Inactive properties are not shown if you use the `disp` method to display object properties. If you attempt to use public access to directly access or use `get` or `set` on an inactive property, a warning occurs.

`isInactiveProperty` is called by the `disp` method and by the `get` and `set` methods.

---

**Note** You must set `Access=protected` for this method.

---

**Input Arguments**

**obj**  
System object handle

**prop**  
Public, non-state property name

**Output Arguments**

**flag**  
Logical scalar value indicating whether the input property `prop` is inactive for the current object configuration.

**Examples**

Display the `InitialValue` property only when the `UseRandomInitialValue` property value is `false`.

```
methods (Access=protected)
function flag = isInactivePropertyImpl(obj,propertyName)
    if strcmp(propertyName,'InitialValue')
        flag = obj.UseRandomInitialValue;
```

```
        else
            flag = false;
        end
    end
end
```

## See Also

setProperties

## How To

- “Hide Inactive Properties”

# matlab.System.loadObjectImpl

---

<b>Purpose</b>	Load saved System object from MAT file
<b>Syntax</b>	<code>loadObjectImpl(obj)</code>
<b>Description</b>	<code>loadObjectImpl(obj)</code> loads a saved System object, <code>obj</code> , from a MAT file. Your <code>loadObjectImpl</code> method should correspond to your <code>saveObjectImpl</code> method to ensure that all saved properties and data are loaded.
<b>Input Arguments</b>	<b>obj</b> System object handle
<b>Examples</b>	Load a saved System object. In this case, the object contains a child object, protected and private properties, and a discrete state. <pre>methods(Access=protected) function loadObjectImpl(obj, s, wasLocked)     % Load child System objects     obj.child = matlab.System.loadObject(s.child);      % Save protected &amp; private properties     obj.protected = s.protected;     obj.pdependentprop = s.pdependentprop;      % Save state only if locked when saved     if wasLocked         obj.state = s.state;     end      % Call base class method     loadObjectImpl@matlab.System(obj,s,wasLocked); end end</pre>
<b>See Also</b>	<code>saveObjectImpl</code>

## How To

- “Load System Object”
- “Save System Object”

# matlab.System.processInputSizeChangeImpl

---

**Purpose** Action when input size changes

**Syntax** `processInputSizeChangeImpl(obj,input1,...,inputN)`

**Description** `processInputSizeChangeImpl(obj,input1,...,inputN)` specifies the actions to perform when any step method input changes size (after the first call to step).

`processInputSizeChangeImpl` is called by the step method before the `stepImpl` method is called.

---

**Note** You must set `Access=protected` for this method.

---

**Tips** Use this method when property values or settings depend on the size of the input. For example, you may want to reset some or all of the states in the object when the input sizes change.

**Input Arguments** **obj**  
System object handle

**input1,...,inputN**  
Inputs to the System object `step` method.

**Examples** Use `processInputSizeChangeImpl` to have the object reset if the input size changes. In this case, `ResetOnSizeChange` is a property of the object. If `ResetOnSizeChange` is true, then `reset` is called what an input size changes.

```
methods (Access=protected)
function processInputSizeChangeImpl(obj, ~)
    if obj.ResetOnSizeChange
        reset(obj);
    end
end
```

end

## See Also

[resetImpl](#) | [stepImpl](#)

## How To

- “Process Input Size Change”

# matlab.System.processTunedPropertiesImpl

---

**Purpose** Action when tunable properties change

**Syntax** `processTunedPropertiesImpl(obj)`

**Description** `processTunedPropertiesImpl(obj)` specifies the actions to perform when one or more tunable property values change. This method is called as part of the next call to the `step` method after a tunable property value changes. A property is tunable only if its `Nontunable` attribute is `false`, which is the default.

`processTunedPropertiesImpl` is called by the `step` method.

---

**Note** You must set `Access=protected` for this method.

---

**Tips** Use this method when a tunable property affects a different property value. For example, two property values determine when to calculate a lookup table. You want to perform that calculation when either property changes. You also want the calculation to be done only once if both properties change before the next call to the `step` method.

**Input Arguments**

**obj** System object handle

**Examples** Use `processTunedPropertiesImpl` to recalculate the lookup table if the value of either the `NumNotes` or `MiddleC` property changes.

```
methods (Access=protected)
function processTunedPropertiesImpl(obj)
    % Generate a lookup table of note frequencies
    obj.pLookupTable = obj.MiddleC * (1+log(1:obj.NumNotes)/log(12));
end
end
```

**See Also** `validatePropertiesImpl` | `setProperties`

## How To

- “Validate Property and Input Values”
- “Define Property Attributes”

# matlab.System.releaseImpl

---

**Purpose** Release resources

**Syntax** `releaseImpl(obj)`

**Description** `releaseImpl(obj)` releases any resources used by the System object, such as file handles. This method also performs any necessary cleanup tasks. To release resources for a System object, you must use `releaseImpl` instead of a destructor.

`releaseImpl` is called by the `release` method. `releaseImpl` is also called when the object is deleted or cleared from memory, or when all references to the object have gone out of scope.

---

**Note** You must set `Access=protected` for this method.

---

**Input Arguments**

**obj**  
System object handle

**Examples** Use the `releaseImpl` method to close a file.

```
methods (Access=protected)
function releaseImpl(obj)
    fclose(obj.pFileID);
end
end
```

**See Also** `resetImpl`

**How To**

- “Release System Object Resources”

<b>Purpose</b>	Reset System object states
<b>Syntax</b>	<code>resetImpl(obj)</code>
<b>Description</b>	<p><code>resetImpl(obj)</code> defines the state reset equations for the System object. Typically you reset the states to a set of initial values.</p> <p><code>resetImpl</code> is called by the <code>reset</code> method. It is also called by the <code>setup</code> method, after the <code>setupImpl</code> method.</p>

---

**Note** You must set `Access=protected` for this method.

---

**Input Arguments**

**obj**  
System object handle

**Examples**

Use the `reset` method to reset the counter `pCount` property to zero.

```
methods (Access=protected)
function resetImpl(obj)
    obj.pCount = 0;
end
end
```

**See Also**

`releaseImpl`

**How To**

- “Reset Algorithm State”

# matlab.System.saveObjectImpl

---

**Purpose** Save System object in MAT file

**Syntax** `saveObjectImpl(obj)`

**Description** `saveObjectImpl(obj)` defines what System object `obj` property and state values are saved in a MAT file when a user calls `save` on that object. `save` calls `saveObject`, which then calls `saveObjectImpl`. If you do not define a `saveObjectImpl` method for your System object class, only public properties are saved. To save any private or protected properties or state information, you must define a `saveObjectImpl` in your class definition file.

You should save the state of an object only if the object is locked. When the user loads that saved object, it loads in that locked state.

To save child object information, you use the associated `saveObject` method within the `saveObjectImpl` method.

End users can use `load`, which calls `loadObjectImpl` to load a System object into their workspace.

**Input Arguments**

**obj**  
System object handle

**Examples** Define what is saved for the System object. Call the base class version of `saveObjectImpl` to save public properties. Then, save any child System objects and any protected and private properties. Finally, save the state, if the object is locked.

```
methods(Access=protected)
function s = saveObjectImpl(obj)
    s = saveObjectImpl@matlab.System(obj);
    s.child = matlab.System.saveObject(obj.child);
    s.protected = obj.protected;
    s.pdependentprop = obj.pdependentprop;
    if isLocked(obj)
        s.state = obj.state;
```

```
        end
    end
end
```

## See Also

loadObjectImpl

## How To

- “Save System Object”
- “Load System Object”

# matlab.System.setProperties

---

**Purpose** Set property values from name-value pair inputs

**Syntax** `setProperties(obj,numargs,name1,value1,name2,value2,...)`  
`setProperties(obj,numargs,arg1,...,argm,name1,value1,name2,value2,...)`

**Description** `setProperties(obj,numargs,name1,value1,name2,value2,...)` provides the name-value pair inputs to the System object constructor. Use this syntax if every input must specify both name and value.

---

**Note** To allow standard name-value pair handling at construction, define `setProperties` for your System object.

---

`setProperties(obj,numargs,arg1,...,argm,name1,value1,name2,value2,...)` provides the value-only inputs, followed by the name-value pair inputs to the System object during object construction. Use this syntax if you want to allow users to specify one or more inputs by their values only.

## Input Arguments

### **obj**

System objectSystem object handle

### **numargs**

Number of inputs passed in by the object constructor

### **name\***

Name of property

### **value\***

Value of the property

### **arg\***

Value of property (for value-only input to the object constructor)

## Examples

Set up the object so users can specify property values via name-value pairs when constructing the object.

```
methods
    function obj = MyFile(varargin)
        setProperties(obj,nargin,varargin{:});
    end
end
```

## How To

- “Set Property Values at Construction Time”

# matlab.System.setupImpl

---

**Purpose** Initialize System object

**Syntax** `setupImpl(obj,input1, input2,...)`

**Description** `setupImpl(obj,input1, input2,...)` sets up a System object. To acquire resources for a System object, you must use `setupImpl` instead of a constructor. `setupImpl` executes the first time the `step` method is called on an object after that object has been created. It also executes the next time `step` is called after an object has been released. . The number of inputs must match the number of inputs defined in the `getNumInputsImpl` method. You pass the inputs into `setupImpl` to use the input sizes, datatypes, etc. in the one-time calculations.

`setupImpl` is called by the `setup` method, which is done automatically as the first subtask of the `step` method on an unlocked System object.

---

**Note** You must set `Access=protected` for this method.

---

**Tips** To validate properties or inputs use the `validatePropertiesImpl`, `validateInputsImpl`, or `setProperties` methods. Do not include validation in `setupImpl`.

**Input Arguments** **obj**  
System object handle

**input\***  
Inputs to the `setup` method

**Examples** Open a file for writing using the `setupImpl` method.

```
methods (Access=protected)
function setupImpl(obj,data)
    obj.pFileID = fopen(obj.FileName, 'wb');
    if obj.pFileID < 0
```

```
        error('Opening the file failed');  
    end  
end  
end
```

# matlab.System.stepImpl

---

<b>Purpose</b>	System output and state update equations
<b>Syntax</b>	<code>[output1,output2,...] = stepImpl(obj,input1,input2,...)</code>
<b>Description</b>	<code>[output1,output2,...] = stepImpl(obj,input1,input2,...)</code> defines the algorithm to execute when you call the <code>step</code> method on the specified object <code>obj</code> . The <code>step</code> method calculates the outputs and updates the object's state values using the inputs, properties, and state update equations.  <code>stepImpl</code> is called by the <code>step</code> method.

---

**Note** You must set `Access=protected` for this method.

---

**Tips** The number of input arguments and output arguments must match the values returned by the `getNumInputsImpl` and `getNumOutputsImpl` methods, respectively

**Input Arguments**

**obj**  
System object handle

**input\***  
Inputs to the `step` method

**Output Arguments**

**output**  
Output returned from the `step` method.

**Examples** Use the `stepImpl` method to increment two numbers.

```
methods (Access=protected)
function [y1,y2] = stepImpl(obj,x1,x2)
    y1 = x1 + 1;
    y2 = x2 + 1;
end
```

[getNumInputsImpl](#) | [getNumOutputsImpl](#) | [validateInputsImpl](#)

**How To**

- “Define Basic System Objects”
- “Change Number of Step Inputs or Outputs”

# matlab.System.validateInputsImpl

---

**Purpose** Validate inputs to step method

**Syntax** `validateInputsImpl(obj,input1,input2,...)`

**Description** `validateInputsImpl(obj,input1,input2,...)` validates inputs to the step method at the beginning of initialization. Validation includes checking data types, complexity, cross-input validation, and validity of inputs controlled by a property value.

`validateInputsImpl` is called by the `setup` method before `setupImpl`. `validateInputsImpl` executes only once.

---

**Note** You must set `Access=protected` for this method.

---

**Input Arguments**

**obj**  
System object handle

**input\***  
Inputs to the setup method

**Examples** Validate that the input is numeric.

```
methods (Access=protected)
function validateInputsImpl(~,x)
    if ~isnumeric(x)
        error('Input must be numeric');
    end
end
end
```

**See Also** `validatePropertiesImpl` | `setupImpl`

**How To** • “Validate Property and Input Values”

**Purpose** Validate property values

**Syntax** `validatePropertiesImpl(obj)`

**Description** `validatePropertiesImpl(obj)` validates interdependent or interrelated property values at the beginning of object initialization, such as checking that the dependent or related inputs are the same size. `validatePropertiesImpl` is the first method called by the `setup` method. `validatePropertiesImpl` also is called before the `processTunablePropertiesImpl` method.

---

**Note** You must set `Access=protected` for this method.

---

**Input Arguments**

**obj**  
System object handle

**Examples** Validate that the `useIncrement` property is true and that the value of the `increment` property is greater than zero.

```
methods (Access=protected)
    function validatePropertiesImpl(obj)
        if obj.useIncrement && obj.increment < 0
            error('The increment value must be positive');
        end
    end
end
```

**How To**

- “Validate Property and Input Values”

# matlab.system.mixin.FiniteSource

---

**Purpose** Finite source mixin class

**Description** `matlab.system.mixin.FiniteSource` is a class that defines the `isDone` method, which reports the state of a finite data source, such as an audio file.

To use this method, you must subclass from this class in addition to the `matlab.System` base class. You use the following syntax as the first line of your class definition file, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.System &...  
    matlab.system.mixin.FiniteSource
```

**Methods** `isDoneImpl` End-of-data flag

**See Also** `matlab.System`

**Tutorials** • “Define Finite Source Objects”

**How To** • “Object-Oriented Programming”  
• Class Attributes  
• Property Attributes

<b>Purpose</b>	End-of-data flag
<b>Syntax</b>	<code>status = isDoneImpl(obj)</code>
<b>Description</b>	<p><code>status = isDoneImpl(obj)</code> indicates if an end-of-data condition has occurred. The <code>isDone</code> method should return <code>false</code> when data from a finite source has been exhausted, typically by having read and output all data from the source. You should also define the result of future reads from an exhausted source in the <code>isDoneImpl</code> method.</p> <p><code>isDoneImpl</code> is called by the <code>isDone</code> method.</p>
<b>Input Arguments</b>	<p><b>obj</b></p> <p>System object handle</p>
<b>Output Arguments</b>	<p><b>status</b></p> <p>Logical value, <code>true</code> or <code>false</code>, that indicates if an end-of-data condition has occurred or not, respectively.</p>
<b>Examples</b>	<p>Set up <code>isDoneImpl</code> so the <code>isDone</code> method checks whether the object has completed eight iterations.</p> <pre>methods (Access=private)     function bdone = isDoneImpl(obj)         bdone = obj.NumIters==8;     end end</pre>
<b>See Also</b>	<code>matlab.system.mixin.FiniteSource</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Define Finite Source Objects”</li></ul>

# matlab.system.StringSet

---

**Purpose** Set of valid string values

**Description** `matlab.system.StringSet` defines a list of valid string values for a property. This class validates the string in the property and enables tab completion for the property value. A *StringSet* allows only predefined or customized strings as values for the property.

A `StringSet` uses two linked properties, which you must define in the same class. One is a public property that contains the current string value. This public property is displayed to the user. The other property is a hidden property that contains the list of all possible string values. This hidden property should also have the transient attribute so its value is not saved to disk when you save the System object.

The following considerations apply when using `StringSets`:

- The string property that holds the current string can have any name.
- The property that holds the `StringSet` must use the same name as the string property with the suffix “Set” appended to it. The string set property is an instance of the `matlab.system.StringSet` class.
- Valid strings, defined in the `StringSet`, must be declared using a cell array. The cell array cannot be empty nor can it have any empty strings. Valid strings must be unique and are case-insensitive.
- The string property must be set to a valid `StringSet` value.

**Examples** Set the string property, `Flavor`, and the `StringSet` property, `FlavorSet`, in this example.

```
properties
    Flavor='Chocolate';
end

properties (Hidden,Transient)
    FlavorSet = ...
        matlab.system.StringSet({'Vanilla','Chocolate'});
end
```

- Class Attributes
- Property Attributes
- “Limit Property Values to Finite String Set”

# spbscopes.SpectrumAnalyzerConfiguration

---

- Purpose** Configure Spectrum Analyzer for programmatic access
- Description** The `spbscopes.SpectrumAnalyzerConfiguration` object contains the scope configuration information for the Spectrum Analyzer block.
- Construction** Call the `get_param` function, specifying a Spectrum Analyzer block.  
`htsc = get_param(gcbh, 'ScopeConfiguration')` constructs a new Spectrum Analyzer Configuration object.

## Properties

### CenterFrequency

Frequency over which span is centered

Specify as a real scalar the center frequency, in hertz, of the span over which the Spectrum Analyzer computes and plots the spectrum. This property applies when you set the `FrequencySpan` property to 'Span and center frequency'. The overall span, defined by the `Span` and `CenterFrequency` properties, must fall within the Nyquist frequency interval. When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval

is  $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.  
When the `PlotAsTwoSidedSpectrum` property is set to `false`, the

interval is  $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

This property is Tunable.

**Default:** 0

### FFTLength

FFT length

Specify as a positive, scalar integer the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. This

property applies only when you set the `FFTLengthSource` property to 'Property'.

This property is Tunable.

**Default:** 128

## **FFTLengthSource**

Source of the FFT length value

Specify the source of the FFT length value as one of 'Auto' or 'Property'.

- When you set this property to 'Auto', the Spectrum Analyzer sets the FFT length to the data segment length required to achieve the specified resolution bandwidth.
- When you set this property to 'Property', specify the number of FFT points using the `FFTLength` property.

This property is Tunable.

**Default:** 'Auto'

## **FrequencyOffset**

Frequency offset

Specify as a real, scalar value a frequency offset, in hertz. The *frequency*-axis values, which you also specify, are offset by the value specified in this property. The overall span must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is true, the Nyquist interval

is  $\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset$  hertz.  
When you set the `PlotAsTwoSidedSpectrum` property to false,

# spbscopes.SpectrumAnalyzerConfiguration

---

the Nyquist interval is  $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz. You can control the overall span in different ways based on how you set the `FrequencySpan` property.

**Default:** 0

## FrequencyScale

Frequency scale

Specify the frequency scale as either 'Linear' or 'Log'. When you set this property to 'Log', the Spectrum Analyzer displays the frequencies on the *x*-axis on a logarithmic scale. To use the 'Log' setting, you must also set the `PlotAsTwoSidedSpectrum` property to false. When the `PlotAsTwoSidedSpectrum` property is true, you must set this property to 'Linear'.

This property is Tunable.

**Default:** 'Linear'

## FrequencySpan

Frequency span mode

Specify the frequency span mode as one of 'Full', 'Span and center frequency', or 'Start and stop frequencies'.

- When you set this property to 'Full', the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is true, the Nyquist interval is

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset \text{ hertz. If}$$

you set the `PlotAsTwoSidedSpectrum` property to `false`, the

Nyquist interval is  $\left[0, \frac{\text{SampleRate}}{2}\right] + \text{FrequencyOffset}$  hertz.

- When you set this property to 'Span and center frequency', the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `Span` and `CenterFrequency` properties.
- When you set this property to 'Start and stop frequencies', the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `StartFrequency` and `StopFrequency` properties.

This property is Tunable.

**Default:** 'Full'

## **Name**

Caption to display on Spectrum Analyzer window

Specify as a string the caption to display on the scope window. This property is Tunable.

**Default:** 'Spectrum Analyzer'

## **OpenAtSimulationStart**

Open scope when starting simulation

Set this property to `true` to open the scope when the simulation starts. Set this property to `false` to prevent the scope from opening at the start of simulation.

**Default:** `true`

## **OverlapPercent**

Overlap percentage

# spbscopes.SpectrumAnalyzerConfiguration

---

Specify as a real, scalar value, the percentage overlap between the previous and current buffered data segments. The value must be greater than or equal to zero and less than 100. This property is Tunable.

**Default:** 80

## **PlotAsTwoSidedSpectrum**

Two sided spectrum flag

Set this property to `true` to compute and plot two-sided spectral estimates. Set this property to `false` to compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued. When the input signal is complex valued, you must set this property to `true`.

When this property is `false`, Spectrum Analyzer uses *power folding*. The *y*-axis values are twice the amplitude that they would be if this property were set to `true`, except at 0 and the Nyquist frequency. A one-sided PSD contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see the `pwelch` function reference page.

**Default:** `true`

## **PlotMaxHoldTrace**

Max-hold trace flag

Set this property to `true` to compute and plot the maximum-hold spectrum of each input channel. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations.

This property is Tunable.

See also: `PlotMinHoldTrace`, `PlotNormalTrace`.

**Default:** false

## **PlotMinHoldTrace**

Min-hold trace flag

Set this property to `true` to compute and plot the minimum-hold spectrum of each input channel. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations.

This property is Tunable.

See also: `PlotMaxHoldTrace`, `PlotNormalTrace`.

**Default:** false

## **PlotNormalTrace**

Normal trace flag

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Note that even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations.

This property is Tunable.

See also: `PlotMaxHoldTrace`, `PlotMinHoldTrace`.

**Default:** true

## **Position**

Spectrum Analyzer window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, `[left bottom width height]`. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is Tunable.

# spbscopes.SpectrumAnalyzerConfiguration

---

**Default:** The default depends on your screen resolution. By default, the Spectrum Analyzer window appears in the center of your screen with a width of 410 pixels and height of 300 pixels.

## PowerUnits

Power units

Specify the units in which the Spectrum Analyzer displays power values as either 'dBm', 'dBW', or 'Watts'.

This property is Tunable.

**Default:** 'dBm'

## RBW

Resolution bandwidth

Specify as a real, positive scalar the resolution bandwidth (RBW), in hertz. RBW controls the spectral resolution of Spectrum Analyzer. This property applies only when you set the RBWSource property to 'Property'. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater

than two:  $\frac{span}{RBW} > 2$ . You can specify the overall span in different ways based on how you set the FrequencySpan property.

This property is Tunable.

See also: RBWSource.

**Default:** 9.76

## RBWSource

Source of resolution bandwidth value

Specify the source of the resolution bandwidth (RBW) as either 'Auto' or 'Property'.

- When you set this property to 'Auto', the Spectrum Analyzer adjusts the spectral estimation resolution. This adjustment ensures that there are 1024 RBW intervals over the defined frequency span.
- When you set this property to 'Property', specify the resolution bandwidth directly when you set the RBW property.

This property is Tunable.

See also: RBW.

**Default:** 'Auto'

## **ReducePlotRate**

Reduce plot rate to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time it computes the power spectrum. The simulation speed is faster when this property is set to `true`. This property is Tunable.

**Default:** `true`

## **ReferenceLoad**

Reference load

Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values.

This property is Tunable.

**Default:** 1

## **SampleRate**

Sample rate of input

# spbscopes.SpectrumAnalyzerConfiguration

---

Specify the sample rate, in hertz, of the input signals.

The sample rate must be a finite numeric scalar.

**Default:** 10e3

## ShowGrid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable.

**Default:** `false`

## ShowLegend

Show or hide legend

When you set this property to `true`, the scope displays a legend with automatic string labels for each input channel. When you set this property to `false`, the scope does not display a legend. See `FrameBasedProcessing` for information on input channels. This property is Tunable.

**Default:** `false`

## SidelobeAttenuation

Sidelobe attenuation of window

Specify as a real, positive scalar the window sidelobe attenuation, in decibels (dB). This property applies only when you set the Window property to `'Chebyshev'` or `'Kaiser'`. The value must be greater than or equal to 45.

This property is Tunable.

**Default:** 60

## Span

Frequency span over which spectrum is computed and plotted

Specify as a real, positive scalar the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to 'Span and center frequency'. The overall span, defined by this property and the `CenterFrequency` property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is true, the Nyquist interval

is  $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

When you set the `PlotAsTwoSidedSpectrum` property to false,

the Nyquist interval is  $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

This property is Tunable.

See also: `CenterFrequency`, `PlotAsTwoSidedSpectrum`.

**Default:** 10e3

## SpectralAverages

Number of spectral averages

Specify as a positive, scalar integer the number of spectral averages. The Spectrum Analyzer computes the current power spectrum estimate by averaging the last  $N$  power spectrum estimates. This property defines the number of spectral averages,  $N$ .

This property is Tunable.

**Default:** 10

## SpectrumType

# spbscopes.SpectrumAnalyzerConfiguration

---

Spectrum type

Specify the spectrum type as one of 'Power' or 'Power density'.

- When you set this property to 'Power', the Spectrum Analyzer shows the power spectrum.
- When you set this property to 'Power density', the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.

This property is Tunable.

**Default:** 'Power'

## StartFrequency

Start frequency over which spectrum is computed

Specify as a real scalar the start frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to 'Start and stop frequencies'. The overall span, which is defined by StopFrequency and this property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is true, the Nyquist interval

is  $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz. If you set the PlotAsTwoSidedSpectrum property to false, the

Nyquist interval is  $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

This property is Tunable.

See also: StopFrequency, PlotAsTwoSidedSpectrum.

**Default:** -5e3

## StopFrequency

Stop frequency over which spectrum is computed

Specify as a real scalar the stop frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum.

This property applies only when you set the FrequencySpan property to 'Start and stop frequencies'. The overall span, defined by this property and the StartFrequency property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is set to true, the interval

is  $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

When the PlotAsTwoSidedSpectrum property is set to false, the

interval is  $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$  hertz.

This property is Tunable.

See also: StartFrequency, PlotAsTwoSidedSpectrum.

**Default:** 5e3

## Title

Display title

Specify the display title as a string. This property is Tunable.

**Default:** ''

## TreatMby1SignalsAsOneChannel

Treat unoriented sample-based input signal as a column vector

Set this property to true to treat  $M$ -by-1 and unoriented sample-based inputs as a column vector, or one channel. Set this property to false to treat  $M$ -by-1 and unoriented sample-based inputs as a 1-by- $M$  row vector.

# spbscopes.SpectrumAnalyzerConfiguration

---

**Default:** true

## Window

Window function

Specify a window function for the spectral estimator as one of the options in the following table. For information on any window function, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Function in Signal Processing Toolbox
'Rectangular'	rectwin
'Chebyshev'	chebwin
'Flat Top'	flattopwin
'Hamming'	hamming
'Hann'	hann
'Kaiser'	kaiser

This property is Tunable.

**Default:** 'Hann'

## YLabel

The label for the  $y$ -axis

Specify as a string the text for the scope to display to the left of the  $y$ -axis. This property is Tunable.

Regardless of this property, Spectrum Analyzer always displays power units as one of 'dBm', 'dBW', 'Watts', 'dBm/Hz', 'dBW/Hz', 'Watts/Hz'.

See also: PowerUnits.

# spbscopes.SpectrumAnalyzerConfiguration

---

**Default:** ''

## **YLimits**

The limits for the  $y$ -axis

Specify the  $y$ -axis limits as a 2-element numeric vector, [ymin ymax]. This property is Tunable.

The units directly depend upon the PowerUnits property.

**Default:** [-80, 20]

## **Examples**

### **Example: Construct a Spectrum Analyzer Configuration Object**

Create a new Simulink model with a randomly-generated name.

```
sysname=char(randi(26,1,7)+96);  
new_system(sysname);
```

Add a new Spectrum Analyzer block to the model.

```
add_block('built-in/SpectrumAnalyzer',[sysname,'/SpectrumAnalyzer'])
```

Call the `get_param` function to retrieve the default Spectrum Analyzer block configuration properties.

```
hsac = get_param([sysname,'/SpectrumAnalyzer'],'ScopeConfiguration')
```

```
hsac =
```

```
SpectrumAnalyzerConfiguration with properties:
```

```
                Name: 'SpectrumAnalyzer'  
OpenAtSimulationStart: 1  
                Position: [755 450 410 300]  
                SampleRate: '10e3'  
                SpectrumType: 'Power'
```

# spbscopes.SpectrumAnalyzerConfiguration

---

```
FrequencySpan: 'Full'  
    Span: '10e3'  
CenterFrequency: '0'  
StartFrequency: '-5e3'  
StopFrequency: '5e3'  
    RBWSource: 'Auto'  
    RBW: '9.76'  
OverlapPercent: '80'  
    Window: 'Hann'  
SidelobeAttenuation: '60'  
SpectralAverages: '10'  
    FFTLengthSource: 'Auto'  
    FFTLength: '128'  
    PowerUnits: 'dBm'  
    ReferenceLoad: '1'  
PlotMaxHoldTrace: 0

**Purpose** Adaptive filter

**Syntax** `ha = adaptfilt.algorithm('input1',input2,...)`

**Description** `ha = adaptfilt.algorithm('input1',input2,...)` returns the adaptive filter object `ha` that uses the adaptive filtering technique specified by *algorithm*. When you construct an adaptive filter object, include an *algorithm* specifier to implement a specific adaptive filter. Note that you do not enclose the *algorithm* option in single quotation marks as you do for most strings. To construct an adaptive filter object you must supply an *algorithm* string — there is no default algorithm, although every constructor creates a default adaptive filter when you do not provide input arguments such as `input1` or `input2` in the calling syntax.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Algorithms

For adaptive filter (`adaptfilt`) objects, the *algorithm* string determines which adaptive filter algorithm your `adaptfilt` object implements. Each available algorithm entry appears in one of the tables along with a brief description of the algorithm. Click on the algorithm in the first column to get more information about the associated adaptive filter technique.

**Least Mean Squares (LMS) Based FIR Adaptive Filters**

<b>adaptfilt.algorithm String</b>	<b>Algorithm Used to Generate Filter Coefficients</b>
adaptfilt.adjlms	Use the Adjoint LMS FIR adaptive filter algorithm
adaptfilt.blms	Use the Block LMS FIR adaptive filter algorithm
adaptfilt.blmsfft	Use the FFT-based Block LMS FIR adaptive filter algorithm
adaptfilt.dlms	Use the delayed LMS FIR adaptive filter algorithm
adaptfilt.filtxlms	Use the filtered-x LMS FIR adaptive filter algorithm
adaptfilt.lms	Use the LMS FIR adaptive filter algorithm
adaptfilt.nlms	Use the normalized LMS FIR adaptive filter algorithm
adaptfilt.sd	Use the sign-data LMS FIR adaptive filter algorithm
adaptfilt.se	Use the sign-error LMS FIR adaptive filter algorithm
adaptfilt.ss	Use the sign-sign LMS FIR adaptive filter algorithm

For further information about an adapting algorithm, refer to the reference page for the algorithm.

## Recursive Least Squares (RLS) Based FIR Adaptive Filters

<b>adaptfilt.algorithm String</b>	<b>Algorithm Used to Generate Filter Coefficients</b>
adaptfilt.ftf	Use the fast transversal least squares adaptation algorithm
adaptfilt.qrdrls	Use the QR-decomposition RLS adaptation algorithm
adaptfilt.hrls	Use the householder RLS adaptation algorithm
adaptfilt.hswrls	Use the householder SWRLS adaptation algorithm
adaptfilt.rls	Use the recursive-least squares (RLS) adaptation algorithm
adaptfilt.swrls	Use the sliding window (SW) RLS adaptation algorithm
adaptfilt.swftf	Use the sliding window FTF adaptation algorithm

For more complete information about an adapting algorithm, refer to the reference page for the algorithm.

## Affine Projection (AP) FIR Adaptive Filters

<b>adaptfilt.algorithm String</b>	<b>Algorithm Used to Generate Filter Coefficients</b>
adaptfilt.ap	Use the affine projection algorithm that uses direct matrix inversion
adaptfilt.apru	Use the affine projection algorithm that uses recursive matrix updating
adaptfilt.bap	Use the block affine projection adaptation algorithm

To find more information about an adapting algorithm, refer to the reference page for the algorithm.

**FIR Adaptive Filters in the Frequency Domain (FD)**

<b>adaptfilt.algorithm String</b>	<b>Algorithm Used to Generate Filter Coefficients</b>
adaptfilt.fdaf	Use the frequency domain adaptation algorithm
adaptfilt.pbfdaf	Use the partition block version of the FDAF algorithm
adaptfilt.pbufdaf	Use the partition block unconstrained version of the FDAF algorithm
adaptfilt.tdafdct	Use the transform domain adaptation algorithm using DCT
adaptfilt.tdafdft	Use the transform domain adaptation algorithm using DFT
adaptfilt.ufdaf	Use the unconstrained FDAF algorithm for adaptation

For more information about an adapting algorithm, refer to the reference page for the algorithm.

**Lattice Based (L) FIR Adaptive Filters**

<b>adaptfilt.algorithm String</b>	<b>Algorithm Used to Generate Filter Coefficients</b>
adaptfilt.gal	Use the gradient adaptive lattice filter adaptation algorithm
adaptfilt.lsl	Use the least squares lattice adaptation algorithm
adaptfilt.qrdsl	Use the QR decomposition least squares lattice adaptation algorithm

For more information about an adapting algorithm, refer to the reference page for the algorithm.

## Properties for All Adaptive Filter Objects

Each reference page for an algorithm and `adaptfilt.algorithm` object specifies which properties apply to the adapting algorithm and how to use them.

## Methods for Adaptive Filter Objects

As is true with all objects, methods enable you to perform various operations on `adaptfilt` objects. To use the methods, you apply them to the object handle that you assigned when you constructed the `adaptfilt` object.

Most of the analysis methods that apply to `dfilt` objects also work with `adaptfilt` objects. Methods like `freqz` rely on the filter coefficients in the `adaptfilt` object. Since the coefficients change each time the filter adapts to data, you should view the results of using a method as an analysis of the filter at a moment in time for the object. Use caution when you apply an analysis method to your adaptive filter objects — always check that your result approached your expectation.

In particular, the Filter Visualization Tool (FVTool) supports all of the `adaptfilt` objects. Analyzing and viewing your `adaptfilt` objects is straightforward — use the `fvtool` method with the name of your object

```
fvtool(objectname)
```

to launch FVTool and work with your object.

Some methods share their names with functions in Signal Processing Toolbox software, or even functions in this toolbox. Functions that share names with methods behave in a similar way. Using the same name for more than one function or method is called *overloading* and is common in many toolboxes.

Method	Description
<code>adaptfilt/coefficients</code>	Return the instantaneous adaptive filter coefficients
<code>adaptfilt/filter</code>	Apply an <code>adaptfilt</code> object to your signal
<code>adaptfilt/freqz</code>	Plot the instantaneous adaptive filter frequency response
<code>adaptfilt/grpdelay</code>	Plot the instantaneous adaptive filter group delay
<code>adaptfilt/impz</code>	Plot the instantaneous adaptive filter impulse response.
<code>adaptfilt/info</code>	Return the adaptive filter information.
<code>adaptfilt/isfir</code>	Test whether an adaptive filter is a finite impulse response (FIR) filter.
<code>adaptfilt/islinphase</code>	Test whether an adaptive filter is linear phase
<code>adaptfilt/ismaxphase</code>	Test whether an adaptive filter is maximum phase
<code>adaptfilt/isminphase</code>	Test whether an adaptive filter is minimum phase
<code>adaptfilt/isreal</code>	True whether an adaptive filter has real coefficients
<code>adaptfilt/isstable</code>	Test whether an adaptive filter is stable
<code>adaptfilt/maxstep</code>	Return the maximum step size for an adaptive filter
<code>adaptfilt/msepred</code>	Return the predicted mean square error
<code>adaptfilt/msesim</code>	Return the measured mean square error via simulation.

Method	Description
<code>adaptfilt/phasez</code>	Plot the instantaneous adaptive filter phase response
<code>adaptfilt/reset</code>	Reset an adaptive filter to initial conditions
<code>adaptfilt/stepz</code>	Plot the instantaneous adaptive filter step response
<code>adaptfilt/tf</code>	Return the instantaneous adaptive filter transfer function
<code>adaptfilt/zerophase</code>	Plot the instantaneous adaptive filter zerophase response
<code>adaptfilt/zpk</code>	Return a matrix containing the instantaneous adaptive filter zero, pole, and gain values
<code>adaptfilt/zplane</code>	Plot the instantaneous adaptive filter in the Z-plane

## Working with Adaptive Filter Objects

The next sections cover viewing and changing the properties of `adaptfilt` objects. Generally, modifying the properties is the same for `adaptfilt`, `dfilt`, and `mfilt` objects and most of the same methods apply to all.

### Viewing Object Properties

As with any object, you can use `get` to view a `adaptfilt` object's properties. To see a specific property, use

```
get(ha, 'property')
```

To see all properties for an object, use

```
get(ha)
```

## Changing Object Properties

To set specific properties, use

```
set(ha, 'property1', value1, 'property2', value2, ...)
```

You must use single quotation marks around the property name so MATLAB treats them as strings.

## Copying an Object

To create a copy of an object, use `copy`.

```
ha2 = copy(ha)
```

---

**Note** Using the syntax `ha2 = ha` copies only the object handle and does not create a new object — `ha` and `ha2` are not independent. When you change the characteristics of `ha2`, those of `ha` change as well.

---

## Using Filter States

Two properties control your adaptive filter states.

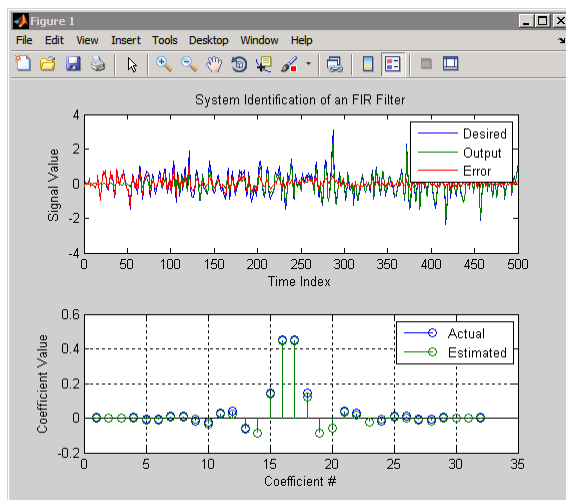

- `States` — stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions.
- `PersistentMemory` — resets the filter before filtering. The default value is `false` which causes the properties that are modified by the filter, such as `coefficients` and `states`, to be reset to the value you specified when you constructed the object, before you use the object to filter data. Setting `PersistentMemory` to `true` allows the object to retain its current properties between filtering operations, rather than resetting the filter to its property values at construction.

## Examples

Construct an LMS adaptive filter object and use it to identify an unknown system. For this example, use 500 iteration of the adapting process to determine the unknown filter coefficients. Using the LMS

algorithm represents one of the most straightforward technique for adaptive filters.

```
x = randn(1,500); % Input to the filter
b = fir1(31,0.5); % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n; % Desired signal
mu = 0.008; % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value'); grid on;
```

`dfilt` | `filter` | `mfilt`

<b>Purpose</b>	FIR adaptive filter that uses adjoint LMS algorithm
<b>Syntax</b>	<code>ha = adaptfilt.adjlims(l,step,leakage,pathcoeffs,pathest,... errstates,pstates,coeffs,states)</code>
<b>Description</b>	<p><code>ha = adaptfilt.adjlims(l,step,leakage,pathcoeffs,pathest,... errstates,pstates,coeffs,states)</code> constructs object <code>ha</code>, an FIR adjoint LMS adaptive filter. <code>l</code> is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. <code>l</code> defaults to 10 when you omit the argument. <code>step</code> is the adjoint LMS step size. It must be a nonnegative scalar. When you omit the <code>step</code> argument, <code>step</code> defaults to 0.1.</p> <p><code>leakage</code> is the adjoint LMS leakage factor. It must be a scalar between 0 and 1. When <code>leakage</code> is less than one, you implement a leaky version of the <code>adjlims</code> algorithm to determine the filter coefficients. <code>leakage</code> defaults to 1 specifying no leakage in the algorithm.</p> <p><code>pathcoeffs</code> is the secondary path filter model. This vector should contain the coefficient values of the secondary path from the output actuator to the error sensor.</p> <p><code>pathest</code> is the estimate of the secondary path filter model. <code>pathest</code> defaults to the values in <code>pathcoeffs</code>.</p> <p><code>errstates</code> is a vector of error states of the adaptive filter. It must have a length equal to the filter order of the secondary path model estimate. <code>errstates</code> defaults to a vector of zeros of appropriate length. <code>pstates</code> contains the secondary path FIR filter states. It must be a vector of length equal to the filter order of the secondary path model. <code>pstates</code> defaults to a vector of zeros of appropriate length. The initial filter coefficients for the secondary path filter compose vector <code>coeffs</code>. It must be a length <code>l</code> vector. <code>coeffs</code> defaults to a length <code>l</code> vector of zeros. <code>states</code> is a vector containing the initial filter states. It must be a vector of length <code>l+ne-1</code>, where <code>ne</code> is the length of <code>errstates</code>. When you omit <code>states</code>, it defaults to an appropriate length vector of zeros.</p>

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Specifies the adaptive filter algorithm the object uses during adaptation
Coefficients	Length <code>l</code> vector with zeros for all elements	Adjoint LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need <code>l</code> entries in <code>coefficients</code> . Updated filter coefficients are returned in <code>coefficients</code> when you use <code>s</code> as an output argument.
ErrorStates	[0,...,0]	A vector of the error states for your adaptive filter, with length equal to the order of your secondary path filter.
FilterLength	10	The number of coefficients in your adaptive filter.
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.

Property	Default Value	Description
SecondaryPathCoeffs	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.
SecondaryPathEstimate	pathcoeffs values	An estimate of the secondary path filter model.
SecondaryPathStates	Length of the secondary path filter. All elements are zeros.	The states of the secondary path filter, the unknown system
States	$l+ne+1$ , where $ne$ is <code>length(errstates)</code>	Contains the initial conditions for your adaptive filter and returns the states of the FIR filter after adaptation. If omitted, it defaults to a zero vector of length equal to $l+ne+1$ . When you use <code>adaptfilt.adjlims</code> in a loop structure, use this element to specify the initial filter states for the adapting FIR filter.
Stepsize	0.1	Sets the adjoint LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to <code>false</code> .

## Examples

Demonstrate active noise control of a random noise signal that runs for 1000 samples.

```
x = randn(1,1000);      % Noise source
g = fir1(47,0.4);      % FIR primary path system model
n = 0.1*randn(1,1000); % Observation noise signal
d = filter(g,1,x)+n;   % Signal to be canceled (desired)
b = fir1(31,0.5);      % FIR secondary path system model
mu = 0.008;           % Adjoint LMS step size
ha = adaptfilt.adjilms(32,mu,1,b);
[y,e] = filter(ha,x,d);
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value'); grid on;
```

Reviewing the figure shows that the adaptive filter attenuates the original noise signal as you expect.

# adaptfilt.ap

---

**Purpose** FIR adaptive filter that uses direct matrix inversion

**Syntax** `ha = adaptfilt.ap(1,step,projectord,offset,coeffs,states,...  
errstates,epsstates)`

**Description** `ha = adaptfilt.ap(1,step,projectord,offset,coeffs,states,...  
errstates,epsstates)` constructs an affine projection FIR adaptive filter `ha` using direct matrix inversion.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ap`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>1</code> defaults to 10.
<code>step</code>	Affine projection step size. This is a scalar that should be a value between zero and one. Setting <code>step</code> equal to one provides the fastest convergence during adaptation. <code>step</code> defaults to 1.
<code>projectord</code>	Projection order of the affine projection algorithm. <code>projectord</code> defines the size of the input signal covariance matrix and defaults to two.
<code>offset</code>	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the <code>offset</code> you specify. <code>offset</code> should be positive. <code>offset</code> defaults to one.

<b>Input Argument</b>	<b>Description</b>
coeffs	Vector containing the initial filter coefficients. It must be a length 1 vector, the number of filter coefficients. coeffs defaults to length 1 vector of zeros when you do not provide the argument for input.
states	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + projectord - 2).
errstates	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to (projectord - 1).
epsstates	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with (projectord - 1) elements.

## Properties

Since your `adaptfilt.ap` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.ap` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

<b>Name</b>	<b>Range</b>	<b>Description</b>
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
ProjectionOrder	1 to as large as needed.	Projection order of the affine projection algorithm. ProjectionOrder defines the size of the input signal covariance matrix and defaults to two.
OffsetCov	Matrix of values	Contains the offset covariance matrix
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector, the number of filter coefficients. coeffs defaults to length 1 vector of zeros when you do not provide the argument for input.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .
ErrorStates	Vector of elements	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to $(\text{projectord} - 1)$ .
EpsilonStates	Vector of elements	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with $(\text{projectord} - 1)$ elements.

Name	Range	Description
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to true.

## Examples

Quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. Run the adaptation for 1000 iterations.

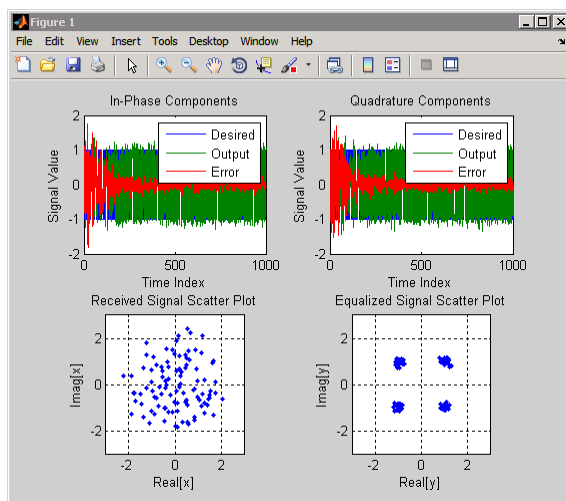

```
D = 16; % Number of samples of delay
b = exp(j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr= 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + j*sign(randn(1,ntr+D)); % Baseband Signal
n = 0.1*(randn(1,ntr+D) + j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
mu = 0.1; % Step size
po = 4; % Projection order
offset = 0.05; % Offset for covariance matrix
ha = adaptfilt.ap(32,mu,po,offset);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
```

```

legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square'); xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;

```

The four plots shown reveal the QPSK process at work.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.apru`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. <code>1</code> defaults to 10.
<code>step</code>	Affine projection step size. This is a scalar that should be a value between zero and one. Setting <code>step</code> equal to one provides the fastest convergence during adaptation. <code>step</code> defaults to 1.
<code>projectord</code>	Projection order of the affine projection algorithm. <code>projectord</code> defines the size of the input signal covariance matrix and defaults to two.
<code>offset</code>	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. <code>offset</code> should be positive. <code>offset</code> defaults to one.

<b>Input Argument</b>	<b>Description</b>
coeffs	Vector containing the initial filter coefficients. It must be a length 1 vector, the number of filter coefficients. coeffs defaults to length 1 vector of zeros when you do not provide the argument for input.
states	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + projectord - 2).
errstates	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to (projectord - 1).
epsstates	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with (projectord - 1) elements.

## Properties

Since your `adaptfilt.apru` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.apru` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

<b>Name</b>	<b>Range</b>	<b>Description</b>
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
ProjectionOrder	1 to as large as needed.	Projection order of the affine projection algorithm. <code>ProjectionOrder</code> defines the size of the input signal covariance matrix and defaults to two.
OffsetCov	Matrix of values	Contains the offset covariance matrix
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector, the number of filter coefficients. <code>coeffs</code> defaults to length 1 vector of zeros when you do not provide the argument for input.
States	Vector of elements, data type double	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .
ErrorStates	Vector of elements	Vector of the adaptive filter error states. <code>errstates</code> defaults to a zero vector with length equal to $(\text{projectord} - 1)$ .
EpsilonStates	Vector of elements	Vector of the epsilon values of the adaptive filter. <code>epsstates</code> defaults to a vector of zeros with $(\text{projectord} - 1)$ elements.

Name	Range	Description
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to true.

## Examples

Demonstrate quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. This example runs the adaptation process for 1000 iterations.

```
D = 16; % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr= 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % Baseband
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
mu = 0.1; % Step size
po = 4; % Projection order
offset = 0.05; % Offset
ha = adaptfilt.apru(32,mu,po,offset); [y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
```

```

legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');
axis('square'); xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;

```

In the following component and scatter plots, you see the results of QPSK equalization.

# adaptfilt.bap

---

**Purpose** FIR adaptive filter that uses block affine projection

**Syntax** `ha = adaptfilt.bap(1,step,projectord,offset,coeffs,states)`

**Description** `ha = adaptfilt.bap(1,step,projectord,offset,coeffs,states)` constructs a block affine projection FIR adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.bap`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>1</code> defaults to 10.
<code>step</code>	Affine projection step size. This is a scalar that should be a value between zero and one. Setting <code>step</code> equal to one provides the fastest convergence during adaptation. <code>step</code> defaults to 1.
<code>projectord</code>	Projection order of the affine projection algorithm. <code>projectord</code> defines the size of the input signal covariance matrix and defaults to two.
<code>offset</code>	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. <code>offset</code> should be positive. <code>offset</code> defaults to one.

Input Argument	Description
coeffs	Vector containing the initial filter coefficients. It must be a length 1 vector, the number of filter coefficients. <code>coeffs</code> defaults to length 1 vector of zeros when you do not provide the argument for input.
states	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .

## Properties

Since your `adaptfilt.bap` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.bap` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ProjectionOrder	1 to as large as needed.	Projection order of the affine projection algorithm. <code>ProjectionOrder</code> defines the size of the input signal covariance matrix and defaults to two.
OffsetCov	Matrix of values	Contains the offset covariance matrix

Name	Range	Description
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector, the number of filter coefficients. <code>coeffs</code> defaults to length 1 vector of zeros when you do not provide the argument for input.
States	Vector of elements, data type double	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to true.

## Examples

Show an example of quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

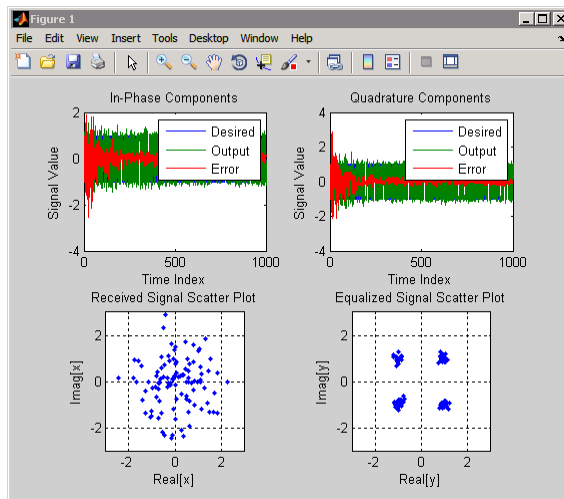

```
D = 16; % delay
```

```

b = exp(1j*pi/4)*[-0.7 1];           % Numerator coefficients
a = [1 -0.7];                       % Denominator coefficients
ntr= 1000;                           % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n;                 % Received signal
x = r(1+D:ntr+D);                   % Input signal (received signal)
d = s(1:ntr);                       % Desired signal (delayed QPSK signal)
mu = 0.5;                           % Step size
po = 4;                             % Projection order
offset = 1.0;                       % Offset for covariance matrix
ha = adaptfilt.bap(32,mu,po,offset);
[y,e] = filter(ha,x,d); subplot(2,2,1);
plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;

```

Using the block affine projection object in QPSK results in the plots shown here.

States	Vector of elements	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to 1
Leakage		Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
BlockLength	Vector of length 1	Size of the blocks of data processed in each iteration

Property	Default Value	Description
StepSize	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution. Use <code>maxstep</code> to determine the maximum usable step size.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to <code>false</code> .

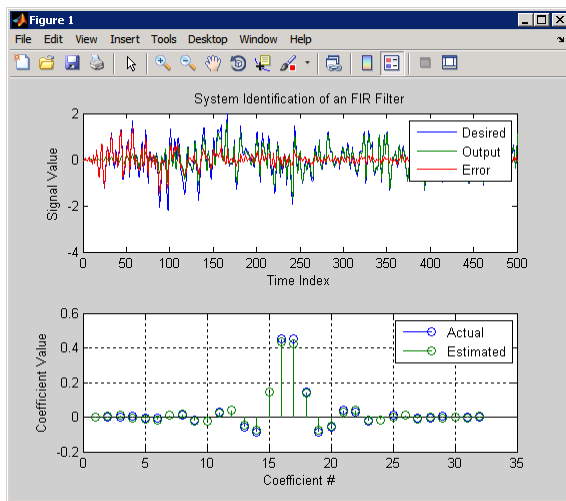

## Examples

Use an adaptive filter to identify an unknown 32nd-order FIR filter. In this example 500 input samples result in 500 iterations of the adaptation process. You see in the plot that follows the example code that the adaptive filter has determined the coefficients of the unknown system under test.

```
x = randn(1,500);           % Input to the filter
b = fir1(31,0.5);         % FIR system to be identified
no = 0.1*randn(1,500);    % Observation noise signal
d = filter(b,1,x)+no;     % Desired signal
mu = 0.008;              % Block LMS step size
n = 5;                   % Block length
ha = adaptfilt.blms(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
```

```
title('System Identification of an FIR Filter');  
legend('Desired','Output','Error');  
xlabel('Time Index'); ylabel('Signal Value');  
subplot(2,1,2); stem([b.',ha.coefficients.']);  
legend('Actual','Estimated');  
xlabel('Coefficient #'); ylabel('Coefficient Value');  
grid on;
```

Based on looking at the figures here, the adaptive filter correctly identified the unknown system after 500 iterations, or fewer. In the lower plot, you see the comparison between the actual filter coefficients and those determined by the adaptation process.

## See Also

[adaptfilt.blmsfft](#) | [adaptfilt.fdaf](#) | [adaptfilt.lms](#)

## Purpose

FIR adaptive filter that uses FFT-based BLMS

## Syntax

```
ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs,
states)
```

## Description

`ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs,states)` constructs an FIR block LMS adaptive filter object `ha` where `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10. `step` is the block LMS step size. It must be a nonnegative scalar. The function `maxstep` may be helpful to determine a reasonable range of step size values for the signals you are processing. `step` defaults to 0.

`leakage` is the block LMS leakage factor. It must also be a scalar between 0 and 1. When `leakage` is less than one, the `adaptfilt.blmsfft` implements a leaky block LMS algorithm. `leakage` defaults to 1 (no leakage). `blocklen` is the block length used. It must be a positive integer such that

$$\text{blocklen} + \text{length}(\text{coeffs})$$

is a power of two; otherwise, an `adaptfilt.blms` algorithm is used for adapting. Larger block lengths result in faster execution times, with poor adaptation characteristics as the cost of the speed gained. `blocklen` defaults to 1. Enter your initial filter coefficients in `coeffs`, a vector of length `l`. When omitted, `coeffs` defaults to a length `l` vector of all zeros. `states` contains a vector of initial filter states; it must be a length `l` vector. `states` defaults to a length `l` vector of all zeros when you omit the `states` argument in the calling syntax.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector where 1 is the number of filter coefficients. <code>coefficients</code> defaults to length 1 vector of zeros when you do not provide the argument for input.
States	Vector of elements of length 1	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to 1
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
BlockLength	Vector of length 1	Size of the blocks of data processed in each iteration

Property	Default Value	Description
StepSize	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution. Use <code>maxstep</code> to determine the maximum usable step size.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

### Examples

Identify an unknown FIR filter with 32 coefficients using 512 iterations of the adapting algorithm.

```
x = randn(1,512);           % Input to the filter
b = fir1(31,0.5);          % FIR system to be identified
no = 0.1*randn(1,512);     % Observation noise signal
d = filter(b,1,x)+no;      % Desired signal
mu = 0.008;                % Step size
n = 16;                    % Block length
ha = adaptfilt.blmsfft(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d(1:500);y(1:500);e(1:500)]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error'); xlabel('Time Index');
```

```
ylabel('Signal Value');  
subplot(2,1,2); stem([b.',ha.coefficients.']);  
legend('actual','estimated'); grid on;  
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

As a result of running the adaptation process, filter object `ha` now matches the unknown system FIR filter `b`, based on comparing the filter coefficients derived during adaptation.

**Purpose** FIR adaptive filter that uses delayed LMS

**Syntax** `ha = adaptfilt.dlms(1,step,leakage,delay,errstates,coeffs, ...states)`

**Description** `ha = adaptfilt.dlms(1,step,leakage,delay,errstates,coeffs, ...states)` constructs an FIR delayed LMS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

### Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.dlms`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
step	LMS step size. It must be a nonnegative scalar. You can use <code>maxstep</code> to determine a reasonable range of step size values for the signals being processed. <code>step</code> defaults to 0.
leakage	Your LMS leakage factor. It must be a scalar between 0 and 1. When <code>leakage</code> is less than one, <code>adaptfilt.lms</code> implements a leaky LMS algorithm. When you omit the <code>leakage</code> property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
delay	Update delay given in time samples. This scalar should be a positive integer — negative delays do not work. <code>delay</code> defaults to 1.

Input Argument	Description
errstates	Vector of the error states of your adaptive filter. It must have a length equal to the update delay ( <code>delay</code> ) in samples. <code>errstates</code> defaults to an appropriate length vector of zeros.
coeffs	Vector of initial filter coefficients. it must be a length <code>l</code> vector. <code>coeffs</code> defaults to length <code>l</code> vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length <code>l-1</code> vector. <code>states</code> defaults to a length <code>l-1</code> vector of zeros.

## Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input. LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter

<b>Property</b>	<b>Default Value</b>	<b>Description</b>
		prior to adapting. You need 1 entries in <code>coeffs</code> .
Delay	1	Specifies the update delay for the adaptive algorithm.
ErrorStates	Vector of zeros with the number of elements equal to delay	A vector comprising the error states for the adaptive filter.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.

Property	Default Value	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
StepSize	0.1	Sets the LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .

## Examples

System identification of a 32-coefficient FIR filter. Refer to the figure that follows to see the results of the adapting filter process.

```
x = randn(1,500);      % Input to the filter
b = fir1(31,0.5);     % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n;  % Desired signal
mu = 0.008;          % LMS step size.
```

```

delay = 1; % Update delay
ha = adaptfilt.dlms(32,mu,1,delay);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');

```

Using a delayed LMS adaptive filter in the process to identify an unknown filter appears to work as planned, as shown in this figure.

# adaptfilt.fdaf

---

**Purpose** FIR adaptive filter that uses frequency-domain with bin step size normalization

**Syntax** `ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen,offset,...coeffs,states)`

**Description** `ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen,offset,...coeffs,states)` constructs a frequency-domain FIR adaptive filter `ha` with bin step size normalization. If you omit all the input arguments you create a default object with `l = 10` and `step = 1`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.fdaf`.

Input Argument	Description
<code>l</code>	Adaptive filter length (the number of coefficients or taps). <code>l</code> must be a positive integer; it defaults to 10 when you omit the argument.
<code>step</code>	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. <code>step</code> defaults to 1.
<code>leakage</code>	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. <code>leakage</code> defaults to 1 — no leakage provided in the algorithm.
<code>delta</code>	Initial common value of all of the FFT input signal powers. Its initial value should be positive. <code>delta</code> defaults to 1.

<b>Input Argument</b>	<b>Description</b>
<code>lambda</code>	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. <code>lambda</code> should lie in the range (0,1]. <code>lambda</code> defaults to 0.9.
<code>blocklen</code>	Block length for the coefficient updates. This must be a positive integer. For faster execution, ( <code>blocklen + 1</code> ) should be a power of two. <code>blocklen</code> defaults to 1.
<code>offset</code>	Offset for the normalization terms in the coefficient updates. Use this to avoid divide by zeros or by very small numbers when any of the FFT input signal powers become very small. <code>offset</code> defaults to zero.
<code>coeffs</code>	Initial time-domain coefficients of the adaptive filter. <code>coeff</code> should be a length <code>l</code> vector. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by the <code>blocklen</code> .
<code>states</code>	The adaptive filter states. <code>states</code> defaults to a zero vector that has length equal to <code>l</code> .

## Properties

Since your `adaptfilt.fdaf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.fdaf` objects. To show you the properties that apply, this table lists and describes each property for the `adaptfilt.fdaf` filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor	(0, 1]	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. Same as the input argument <code>lambda</code> .
BlockLength	Any integer	Block length for the coefficient updates. This must be a positive integer. For faster execution, $(\text{blocklen} + 1)$ should be a power of two. <code>blocklen</code> defaults to 1.
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in <code>coeffs</code> .
FFTStates		States for the FFT operation.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage		Leakage parameter of the adaptive filter. if this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. <code>leakage</code> defaults to 1 — no leakage provided in the algorithm.

<b>Name</b>	<b>Range</b>	<b>Description</b>
Offset	Any positive real value	Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. <code>offset</code> defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power		A vector of 2*1 elements, each initialized with the value <code>delta</code> from the input arguments. As you filter data, <code>Power</code> gets updated by the filter process.
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates

**Examples**

Quadrature Phase Shift Keying (QPSK) adaptive equalization using 1024 iterations of a 32-coefficient FIR filter. After this example code, a figure demonstrates the equalization results.

```
D = 16; % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr= 1024; % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); %QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
del = 1; % Initial FFT input powers
mu = 0.1; % Step size
lam = 0.9; % Averaging factor
ha = adaptfilt.fdaf(32,mu,1,del,lam);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

# adaptfilt.filtxllms

---

**Purpose** FIR adaptive filter that uses filtered-x LMS

**Syntax** `ha = adaptfilt.filtxllms(1,step,leakage,pathcoeffs,pathest,...errstates,pstates,coeffs,states)`

**Description** `ha = adaptfilt.filtxllms(1,step,leakage,pathcoeffs,pathest,...errstates,pstates,coeffs,states)` constructs an filtered-x LMS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.filtxllms`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
step	Filtered LMS step size. it must be a nonnegative scalar. step defaults to 0.1.
leakage	is the filtered-x LMS leakage factor. it must be a scalar between 0 and 1. If it is less than one, a leaky version of <code>adaptfilt.filtxllms</code> is implemented. leakage defaults to 1 (no leakage).
pathcoeffs	is the secondary path filter model. this vector should contain the coefficient values of the secondary path from the output actuator to the error sensor.
pathest	is the estimate of the secondary path filter model. pathest defaults to the values in pathcoeffs.

Input Argument	Description
<code>fstates</code>	is a vector of filtered input states of the adaptive filter. <code>fstates</code> defaults to a zero vector of length equal to $(l - 1)$ .
<code>pstates</code>	are the secondary path FIR filter states. it must be a vector of length equal to the $(\text{length}(\text{pathcoeffs}) - 1)$ . <code>pstates</code> defaults to a vector of zeros of appropriate length.
<code>coeffs</code>	is a vector of initial filter coefficients. it must be a length $l$ vector. <code>coeffs</code> defaults to length $l$ vector of zeros.
<code>states</code>	Vector of initial filter states. <code>states</code> defaults to a zero vector of length equal to the larger of $(\text{length}(\text{pathcoeffs}) - 1)$ and $(\text{length}(\text{pathest}) - 1)$ .

## Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length $l$ vector where $l$ is the number of filter coefficients. <code>coeffs</code> defaults to length $l$ vector of zeros when you do not

Property	Default Value	Description
		provide the argument for input.
FilteredInputStates	1-1	Vector of filtered input states with length equal to 1 - 1.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
States	Vector of elements	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$
SecondaryPathCoeffs	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor
SecondaryPathEstimate	pathcoeffs values	An estimate of the secondary path filter model

Property	Default Value	Description
SecondaryPathStates	Vector of size (length (pathcoeffs) -1) with all elements equal to zero.	The states of the secondary path FIR filter — the unknown system
StepSize	0.1	Sets the filtered-x algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

## Examples

Demonstrate active noise control of a random noise signal over 1000 iterations.

As the figure that follows this code demonstrates, the filtered-x LMS filter successfully controls random noise in this context.

```
x = randn(1,1000);      % Noise source
g = fir1(47,0.4);      % FIR primary path system model
n = 0.1*randn(1,1000); % Observation noise signal
d = filter(g,1,x)+n;   % Signal to be cancelled
b = fir1(31,0.5);      % FIR secondary path system model
mu = 0.008;           % Filtered-X LMS step size
ha = adaptfilt.filtxllms(32,mu,1,b);
[y,e] = filter(ha,x,d); plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value'); grid on;
```

**Purpose** Fast transversal LMS adaptive filter

**Syntax** `ha = adaptfilt.ftf(1,lambda,delta,gamma,gstates,coeffs,states)`

**Description** `ha = adaptfilt.ftf(1,lambda,delta,gamma,gstates,coeffs,states)` constructs a fast transversal least squares adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

**Input Arguments**

Entries in the following table describe the input arguments for `adaptfilt.ftf`.

<b>Input Argument</b>	<b>Description</b>
<code>1</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>1</code> defaults to 10.
<code>lambda</code>	RLS forgetting factor. This is a scalar that should lie in the range $(1-0.5/1, 1]$ . <code>lambda</code> defaults to 1.
<code>delta</code>	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. <code>delta</code> defaults to one.
<code>gamma</code>	Conversion factor. <code>gamma</code> defaults to one specifying soft-constrained initialization.
<code>gstates</code>	States of the Kalman gain updates. <code>gstates</code> defaults to a zero vector of length 1.

Input Argument	Description
coeffs	Length 1 vector of initial filter coefficients. coeffs defaults to a length 1 vector of zeros.
states	Vector of initial filter States. states defaults to a zero vector of length (1-1).

## Properties

Since your `adaptfilt.ftf` filter is an object, it has properties that define its operating behavior. Note that many of the properties are also input arguments for creating `adaptfilt.ftf` objects. To show you the properties that apply, this table lists and describes each property for the fast transversal least squares filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPrediction		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector where 1 is the number of filter coefficients. coeffs defaults to length 1 vector of zeros when you do not provide the argument for input.

<b>Name</b>	<b>Range</b>	<b>Description</b>
ConversionFactor		Conversion factor. Called $\gamma$ when it is an input argument, it defaults to the matrix $[1 \ -1]$ that specifies soft-constrained initialization.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor		RLS forgetting factor. This is a scalar that should lie in the range $(1-0.5/1, 1]$ . $\lambda$ defaults to 1.
FwdPrediction		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. $\delta$ defaults to one.
KalmanGain		Empty when you construct the object, this gets populated after you run the filter.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <b>PersistentMemory</b> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to <b>false</b> .
States	Vector of elements, data type double	Vector of the adaptive filter states. <b>states</b> defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .

## Examples

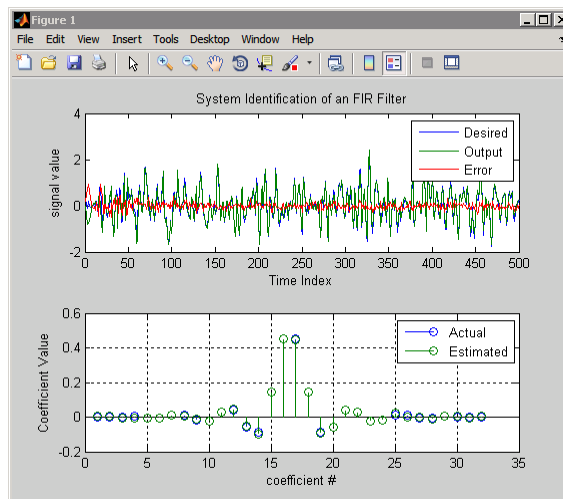

System Identification of a 32-coefficient FIR filter by running the identification process for 500 iterations.

```
x = randn(1,500); % Input to the filter
b = fir1(31,0.5); % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n; % Desired signal
N = 31; % Adaptive filter order
lam = 0.99; % RLS forgetting factor
del = 0.1; % Soft-constrained initialization factor
ha = adaptfilt.ftf(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
```

```
xlabel('Time Index'); ylabel('signal value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('coefficient #'); ylabel('Coefficient Value');
```

For this example of identifying an unknown system, the figure shows that the adaptation process identifies the filter coefficients for the unknown FIR filter within the first 150 iterations.

# adaptfilt.gal

---

**Purpose** FIR adaptive filter that uses gradient lattice

**Syntax** `ha = adaptfilt.gal(1,step,leakage,offset,rstep,delta,lambda,...rcoeffs,coeffs,states)`

**Description** `ha = adaptfilt.gal(1,step,leakage,offset,rstep,delta,lambda,...rcoeffs,coeffs,states)` constructs a gradient adaptive lattice FIR filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.gal`.

Input Argument	Description
1	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the reflection coefficients plus one. 1 defaults to 10.
step	Joint process step size of the adaptive filter. This scalar should be a value between zero and one. <code>step</code> defaults to 0.
leakage	Leakage factor of the adaptive filter. It must be a scalar between 0 and 1. Setting leakage less than one implements a leaky algorithm to estimate both the reflection and the joint process coefficients. <code>leakage</code> defaults to 1 (no leakage).

Input Argument	Description
offset	Specifies an optional offset for the denominator of the step size normalization term. It must be a scalar greater or equal to zero. A non-zero offset is useful to avoid divide-by-near-zero conditions when the input signal amplitude becomes very small. <code>offset</code> defaults to 1.
rstep	Reflection process step size of the adaptive filter. This scalar should be a value between zero and one. <code>rstep</code> defaults to <code>step</code> .
delta	Initial common value of the forward and backward prediction error powers. It should be a positive value. 0.1 is the default value for <code>delta</code> .
lambda	Specifies the averaging factor used to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. <code>lambda</code> should lie in the range (0, 1]. <code>lambda</code> defaults to the value (1 - <code>step</code> ).
rcoeffs	Vector of initial reflection coefficients. It should be a length (l-1) vector. <code>rcoeffs</code> defaults to a zero vector of length (l-1).
coeffs	Vector of initial joint process filter coefficients. It must be a length l vector. <code>coeffs</code> defaults to a length l vector of zeros.
states	Vector of the backward prediction error states of the adaptive filter. <code>states</code> defaults to a zero vector of length (l-1).

## Properties

Since your `adaptfilt.gal` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.gal` objects. To show you

the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Specifies the averaging factor used to compute the exponentially-windowed forward and backward prediction error powers for the coefficient updates. Same as the input argument <code>lambda</code> .
BkwdPredErrorPower		Returns the minimum mean-squared prediction error. Refer to [2] in the bibliography for details about linear prediction
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
FwdPredErrorPower		Returns the minimum mean-squared prediction error in the forward direction. Refer to [2] in the bibliography for details about linear prediction.

Name	Range	Description
Leakage	0 to 1	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky GAL algorithm. <code>leakage</code> defaults to 1 — no leakage provided in the algorithm.
Offset		Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when input signal amplitude becomes very small. <code>offset</code> defaults to one.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to <code>false</code> .
ReflectionCoeffs		Coefficients determined for the reflection portion of the filter during adaptation.

Name	Range	Description
ReflectionCoeffsStep		Size of the steps used to determine the reflection coefficients.
States	Vector of elements	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .
StepSize	0 to 1	Specifies the step size taken between filter coefficient updates

## Examples

Perform a Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter over 1000 iterations.

```

D = 16; % Number of delay samples
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients
a = [1 -0.7]; % Denominator coefficients
ntr= 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
L = 32; % filter length
mu = 0.007; % Step size
ha = adaptfilt.gal(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');

```

```
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

To see the results, look at this figure.

# adaptfilt.hrls

---

**Purpose** FIR adaptive filter that uses householder (RLS)

**Syntax** `ha = adaptfilt.hrls(1,lambda,sqrtinvcov,coeffs,states)`

**Description** `ha = adaptfilt.hrls(1,lambda,sqrtinvcov,coeffs,states)` constructs an FIR householder RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.hrls`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>1</code> defaults to 10.
<code>lambda</code>	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. <code>lambda</code> defaults to 1 meaning the adaptation process retains infinite memory.
<code>sqrtinvcov</code>	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
<code>coeffs</code>	Vector of initial filter coefficients. It must be a length <code>1</code> vector. <code>coeffs</code> defaults to being a length <code>1</code> vector of zeros.
<code>states</code>	Vector of initial filter states. It must be a length <code>1-1</code> vector. <code>states</code> defaults to a length <code>1-1</code> vector of zeros.

## Properties

Since your `adaptfilt.hrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.hrls` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor	Scalar	RLS forgetting factor. This is a scalar and should lie in the range $(0, 1]$ . Same as input argument <code>lambda</code> . It defaults to 1 meaning the adaptation process retains infinite memory.
KalmanGain	Vector of size $(1,1)$	Empty when you construct the object, this gets populated after you run the filter.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. Defaults to false.
SqrtInvCov	Matrix of doubles	Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 - 1).

## Examples

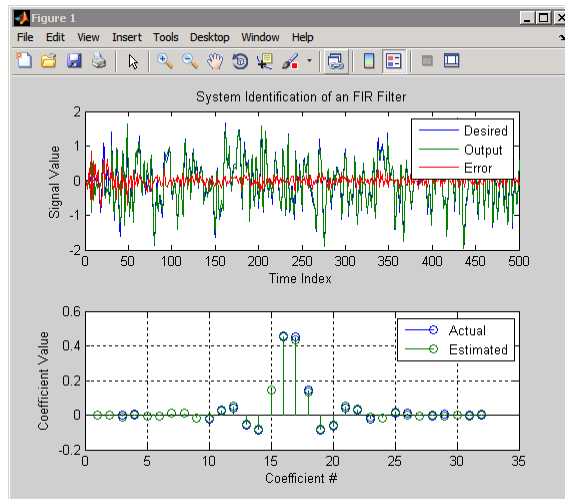

Use 500 iterations of an adaptive filter object to identify a 32-coefficient FIR filter system. Both the example code and the resulting figure show the successful filter identification through adaptive filter processing.

```
x = randn(1,500); % Input to the filter
b = fir1(31,0.5); % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n; % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99; % RLS forgetting factor
ha = adaptfilt.hrls(32,lam,G0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
```

```

title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.','ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');

```

**See Also**

# adaptfilt.hswrls

---

**Purpose** FIR adaptive filter that uses householder sliding window RLS

**Syntax** `ha = adaptfilt.hswrls(1,lambda,sqrtinvcov,swblocklen,dstates,coeffs,states)`

**Description** `ha = adaptfilt.hswrls(1,lambda,sqrtinvcov,swblocklen,dstates,coeffs,states)` constructs an FIR householder sliding window recursive-least-square adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.hswrls`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
lambda	Recursive least square (RLS) forgetting factor. This is a scalar and should lie in the range (0, 1]. lambda defaults to 1 meaning the adaptation process retains infinite memory.
sqrtinvcov	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
swblocklen	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Input Argument	Description
<code>dstates</code>	Desired signal states of the adaptive filter. <code>dstates</code> defaults to a zero vector with length equal to $(\text{swblocklen} - 1)$ .
<code>coeffs</code>	Vector of initial filter coefficients. It must be a length <code>l</code> vector. <code>coeffs</code> defaults to being a length <code>l</code> vector of zeros.
<code>states</code>	Vector of initial filter states. It must be a length $(1 + \text{swblocklen} - 2)$ vector. <code>states</code> defaults to a length $(1 + \text{swblocklen} - 2)$ vector of zeros.

## Properties

Since your `adaptfilt.hswrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.hswrls` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input.

Name	Range	Description
DesiredSignalStates	Vector	Desired signal states of the adaptive filter. <code>dstates</code> defaults to a zero vector with length equal to $(\text{swblocklen} - 1)$ .
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor	Scalar	Root-least-square (RLS) forgetting factor. This is a scalar and should lie in the range $(0, 1]$ . Same as input argument <code>lambda</code> . It defaults to 1 meaning the adaptation process retains infinite memory.
KalmanGain	(1,1) vector	Empty when you construct the object, this gets populated after you run the filter.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. Defaults to false.

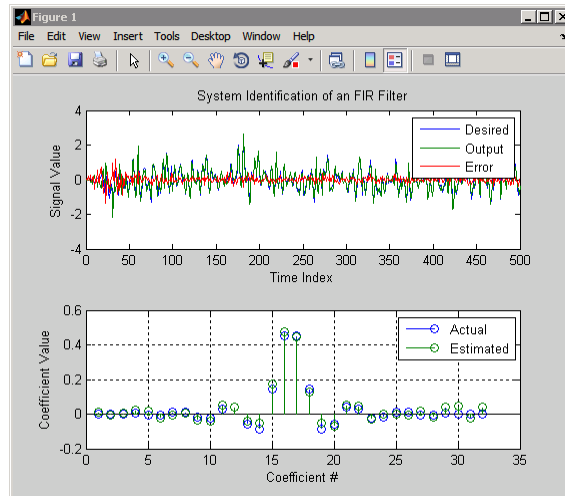

Name	Range	Description
SqrtInvCov	1-by-1 Matrix	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
States	Vector of elements, data type double	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .
SwBlockLength	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. <code>swblocklen</code> defaults to 16.

## Examples

System Identification of a 32-coefficient FIR filter.

```
x = randn(1,500);      % Input to the filter
b = fir1(31,0.5);     % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;           % RLS forgetting factor
N = 64;               % block length
ha = adaptfilt.hswrls(32,lam,G0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

In the pair of plots shown in the figure you see the comparison of the desired and actual output for the adapting filter and the coefficients of both filters, the unknown and the adapted.

**Purpose** FIR adaptive filter that uses LMS

**Syntax** `ha = adaptfilt.lms(1,step,leakage,coeffs,states)`

**Description** `ha = adaptfilt.lms(1,step,leakage,coeffs,states)` constructs an FIR LMS adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

### Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lms`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
step	LMS step size. It must be a nonnegative scalar. You can use <code>maxstep</code> to determine a reasonable range of step size values for the signals being processed. <code>step</code> defaults to 0.1.
leakage	Your LMS leakage factor. It must be a scalar between 0 and 1. When <code>leakage</code> is less than one, <code>adaptfilt.lms</code> implements a leaky LMS algorithm. When you omit the <code>leakage</code> property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.

<b>Input Argument</b>	<b>Description</b>
coeffs	Vector of initial filter coefficients. it must be a length 1 vector. coeffs defaults to length 1 vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length 1-1 vector. states defaults to a length 1-1 vector of zeros.

## Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the `adaptfilt.lms` object, their default values, and a brief description of the property.

<b>Property</b>	<b>Range</b>	<b>Property Description</b>
Algorithm	None	Reports the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector where 1 is the number of filter coefficients. coeffs defaults to a length 1 vector of zeros when you do not provide the vector as an input argument.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Property	Range	Property Description
Leakage	0 to 1	LMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. <code>leakage</code> defaults to 1 (no leakage).
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. <code>PersistentMemory</code> returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 - 1)$ .
StepSize	0 to 1	LMS step size. It must be a scalar between zero and one. Setting this step size value to one provides the fastest convergence. <code>step</code> defaults to 0.1.

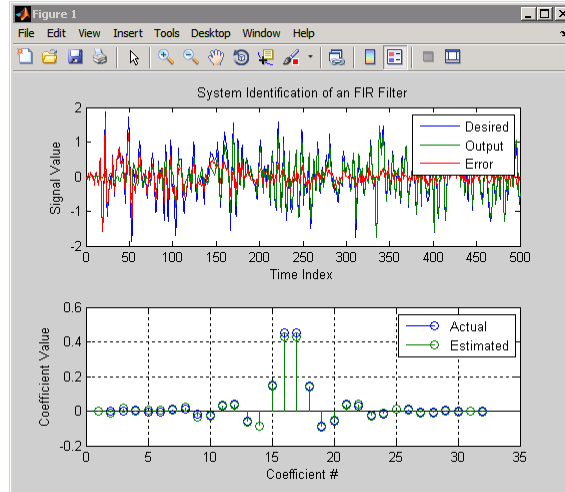

### Examples

Use 500 iterations of an adapting filter system to identify and unknown 32nd-order FIR filter.

```
x = randn(1,500); % Input to the filter
```

```
b = fir1(31,0.5); % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n; % Desired signal
mu = 0.008; % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value'); grid on;
```

Using LMS filters in an adaptive filter architecture is a time honored means for identifying an unknown filter. By running the example code provided you can demonstrate one process to identify an unknown FIR filter.

# adaptfilt.lsl

---

**Purpose** Least squares lattice adaptive filter

**Syntax** `ha = adaptfilt.lsl(1,lambda,delta,coeffs,states)`

**Description** `ha = adaptfilt.lsl(1,lambda,delta,coeffs,states)` constructs a least squares lattice adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lsl`.

Input Argument	Description
<code>1</code>	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. <code>L</code> defaults to 10.
<code>lambda</code>	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. <code>lambda</code> defaults to 1. <code>lambda = 1</code> denotes infinite memory while adapting to find the new filter.
<code>delta</code>	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. <code>delta</code> defaults to 1.
<code>coeffs</code>	Vector of initial joint process filter coefficients. It must be a length <code>1</code> vector. <code>coeffs</code> defaults to a length <code>1</code> vector of all zeros.
<code>states</code>	Vector of the backward prediction error states of the adaptive filter. <code>states</code> defaults to a length <code>1</code> vector of all zeros, specifying soft-constrained initialization for the algorithm.

## Properties

Since your `adaptfilt.lsl` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.lsl` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
BkwdPrediction		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.

Name	Range	Description
ForgettingFactor		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.
FwdPrediction		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. delta defaults to one.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing.

Name	Range	Description
		States that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to 1.

## Examples

Demonstrate Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter running for 1000 iterations. After you review the example code, the figure shows the results of running the example to use QPSK adaptive equalization with a 32nd-order FIR filter. The error between the in-phase and quadrature components, as shown by the errors plotted in the upper plots, falls to near zero. Also, the equalized signal shows the clear quadrature nature.

```
D = 16; % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr= 1000; % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
lam = 0.995; % Forgetting factor
del = 1; % initialization factor
ha = adaptfilt.lsl(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
```

```
legend('Desired','Output','Error');  
xlabel('Time Index'); ylabel('Signal Value');  
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);  
title('Received Signal Scatter Plot'); axis('square');  
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;  
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);  
title('Equalized Signal Scatter Plot'); grid on;  
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');
```

[adaptfilt.qrdsl](#) | [adaptfilt.gal](#) | [adaptfilt.ftf](#) | [adaptfilt.rls](#)

## Purpose

Normalized least mean squares adaptive filter

## Syntax

`ha = adaptfilt.nlms(1,step,leakage,offset,coeffs,states)`

## Description

`ha = adaptfilt.nlms(1,step,leakage,offset,coeffs,states)` constructs a normalized least-mean squares (NLMS) FIR adaptive filter object named `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.nlms`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
step	NLMS step size. It must be a scalar between 0 and 2. Setting this step size value to one provides the fastest convergence. <code>step</code> defaults to 1.
leakage	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. <code>leakage</code> defaults to 1 (no leakage).

Input Argument	Description
offset	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the input signal amplitude becomes very small). When you omit it, offset defaults to zero.
coeffs	Vector composed of your initial filter coefficients. Enter a length 1 vector. coeffs defaults to a vector of zeros with length equal to the filter order.
states	Your initial adaptive filter states appear in the states vector. It must be a vector of length 1-1. states defaults to a length 1-1 vector with zeros for all of the elements.

## Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for normalized LMS objects, their default values, and a brief description of the property.

<b>Property</b>	<b>Range</b>	<b>Property Description</b>
Algorithm	None	Reports the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector where 1 is the number of filter coefficients. <code>coeffs</code> defaults to length 1 vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
Leakage	0 to 1	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. <code>leakage</code> defaults to 1 (no leakage).
Offset	0 or greater	Specifies an optional offset for the denominator of the step size normalization term. You must specify <code>offset</code> to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the input signal amplitude becomes very small). When you omit it, <code>offset</code> defaults to zero.

Property	Range	Property Description
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 - 1).
StepSize	0 to 1	NLMS step size. It must be a scalar between zero and one. Setting this step size value to one provides the fastest convergence. step defaults to one.

## Examples

To help you compare this algorithm's performance to other LMS-based algorithms, such as BLMS or LMS, this example demonstrates the NLMS adaptive filter in use to identify the coefficients of an unknown FIR filter of order equal to 32 — an example used in other adaptive filter examples.

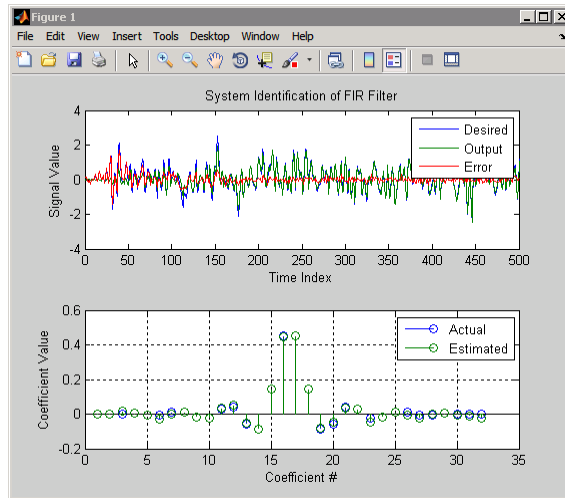

```
x = randn(1,500); % Input to the filter
b = fir1(31,0.5); % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n; % Desired signal
mu = 1; % NLMS step size
offset = 50; % NLMS offset
```

```

ha = adaptfilt.nlms(32,mu,1,offset);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:500,[d;y;e]);
legend('Desired','Output','Error');
title('System Identification of FIR Filter');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2);
stem(['b', ha.coefficients]);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');

```

As you see from the figure, the nlms variant again closely matches the actual filter coefficients in the unknown FIR filter.

# adaptfilt.pbfdaf

---

**Purpose** Partitioned block frequency-domain FIR adaptive filter

**Syntax** `ha = adaptfilt.pbfdaf(1,step,leakage,delta,lambda,blocklen,offset,coeffs,states)`

**Description** `ha = adaptfilt.pbfdaf(1,step,leakage,delta,lambda,blocklen,offset,coeffs,states)` constructs a partitioned block frequency-domain FIR adaptive filter `ha` that uses bin step size normalization during adaptation.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.pbfdaf`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>L</code> defaults to 10.
<code>step</code>	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. <code>step</code> defaults to 1.
<code>leakage</code>	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. <code>leakage</code> defaults to 1— no leakage.
<code>delta</code>	Initial common value of all of the FFT input signal powers. Its initial value should be positive. <code>delta</code> defaults to 1.

<b>Input Argument</b>	<b>Description</b>
<code>lambda</code>	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. <code>lambda</code> should lie in the range (0,1]. <code>lambda</code> defaults to 0.9.
<code>blocklen</code>	Block length for the coefficient updates. This must be a positive integer such that $(1/\text{blocklen})$ is also an integer. For faster execution, <code>blocklen</code> should be a power of two. <code>blocklen</code> defaults to two.
<code>offset</code>	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. <code>offset</code> defaults to zero.
<code>coeffs</code>	Initial time-domain coefficients of the adaptive filter. It should be a vector of length 1. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
<code>states</code>	Specifies the filter initial conditions. <code>states</code> defaults to a zero vector of length 1.

## Properties

Since your `adaptfilt.pbfdaf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.pbfdaf` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. AvgFactor should lie in the range (0,1]. AvgFactor defaults to 0.9. Called lambda as an input argument.
BlockLength		Block length for the coefficient updates. This must be a positive integer such that (1/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.

<b>Name</b>	<b>Range</b>	<b>Description</b>
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. Leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. offset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Name	Range	Description
Power		A vector of 2*1 elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. step defaults to 1.

## Examples

An example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```

D = 16; % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr = 1000; % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
del = 1; % Initial FFT input powers
mu = 0.1; % Step size
lam = 0.9; % Averaging factor
N = 8; % Block size
ha = adaptfilt.pbfdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');

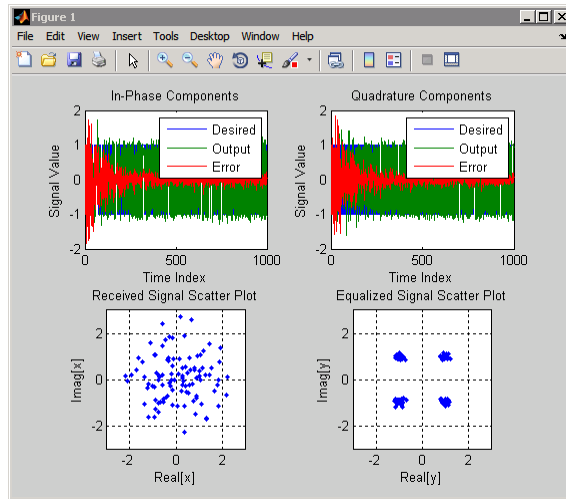

```

```

xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');
axis('square'); xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;subplot(2,2,4); plot(y(ntr-100:ntr),'.');
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;

```

In the figure shown, the four subplots provide the details of the results of the QPSK process used in the equalization for this example.

### Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.pbufdaf`.

Input Argument	Description
<code>l</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>L</code> defaults to 10.
<code>step</code>	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. <code>step</code> defaults to 1.
<code>leakage</code>	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. <code>leakage</code> defaults to 1 — no leakage.
<code>delta</code>	Initial common value of all of the FFT input signal powers. Its initial value should be positive. <code>delta</code> defaults to 1.

Input Argument	Description
<code>lambda</code>	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. <code>lambda</code> should lie in the range (0,1]. <code>lambda</code> defaults to 0.9.
<code>blocklen</code>	Block length for the coefficient updates. This must be a positive integer such that $(1/\text{blocklen})$ is also an integer. For faster execution, <code>blocklen</code> should be a power of two. <code>blocklen</code> defaults to two.
<code>offset</code>	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. <code>offset</code> defaults to zero.
<code>coeffs</code>	Initial time-domain coefficients of the adaptive filter. It should be a vector of length 1. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
<code>states</code>	Specifies the filter initial conditions. <code>states</code> defaults to a zero vector of length 1.

## Properties

Since your `adaptfilt.pbufdaf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.pbufdaf` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

<b>Name</b>	<b>Range</b>	<b>Description</b>
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. AvgFactor should lie in the range (0,1]. AvgFactor defaults to 0.9. Called lambda as an input argument.
BlockLength		Block length for the coefficient updates. This must be a positive integer such that (1/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.

# adaptfilt.pbufdaf

---

Name	Range	Description
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. <code>Leakage</code> defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. <code>voffset</code> defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Name	Range	Description
Power	2*1 element vector	A vector of 2*1 elements, each initialized with the value <code>delta</code> from the input arguments. As you filter data, <code>Power</code> gets updated by the filter process.
StepSize	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. <code>step</code> defaults to 1.

## Examples

Demonstrating Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. To perform the equalization, this example runs for 1000 iterations.

```
D = 16;          % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7];    % Denominator coefficients of channel
ntr= 1000;       % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
del = 1; % Initial FFT input powers
mu = 0.1; % Step size
lam = 0.9; % Averaging factor
N = 8; % Block size
ha = adaptfilt.pbufdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
```

```
legend('Desired','Output','Error');  
xlabel('Time Index'); ylabel('Signal Value');  
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);  
title('Received Signal Scatter Plot'); axis('square');  
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;  
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);  
title('Equalized Signal Scatter Plot'); axis('square');  
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

You can compare this algorithm to another, such as the `pbfdaf` version. Use the same example of QPSK adaptation. The following figure shows the results.

# adaptfilt.qrdls1

---

**Purpose** QR-decomposition-based least-squares lattice adaptive filter

**Syntax** `ha = adaptfilt.qrdls1(1,lambda,delta,coeffs,states)`

**Description** `ha = adaptfilt.qrdls1(1,lambda,delta,coeffs,states)` returns a QR-decomposition-based least squares lattice adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.qrdls1`.

Input Argument	Description
<code>1</code>	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. <code>L</code> defaults to 10.
<code>lambda</code>	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range $(0, 1]$ . <code>lambda</code> defaults to 1. <code>lambda = 1</code> denotes infinite memory while adapting to find the new filter.
<code>delta</code>	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. <code>delta</code> defaults to 1.
<code>coeffs</code>	Vector of initial joint process filter coefficients. It must be a length <code>1</code> vector. <code>coeffs</code> defaults to a length <code>1</code> vector of all zeros.
<code>states</code>	Vector of the angle normalized backward prediction error states of the adaptive filter

## Properties

Since your `adaptfilt.qrdls1` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.qrdls1` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPrediction		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length <code>1</code> vector where <code>1</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>1</code> vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range $(0, 1]$ . It defaults to <code>1</code> . Setting <code>forgetting factor = 1</code> denotes infinite memory while adapting to find the new filter. Note that this is the <code>lambda</code> input argument.

Name	Range	Description
FwdPrediction		Returns the predicted samples generated during adaptation in the forward direction. Refer to [2] in the bibliography for details about linear prediction.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. <code>delta</code> defaults to one.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to <code>false</code> .
States	Vector of elements, data type double	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to <code>1 - 1</code>

## Examples

Implement Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. To see the results of

the equalization process in this example, look at the figure that follows the example code.

```

D = 16; % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr= 1000; % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
lam = 0.995; % Forgetting factor
del = 1; % Soft-constrained initialization factor
ha = adaptfilt.qrdsls(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;

```

## Purpose

FIR adaptive filter that uses QR-decomposition-based RLS

## Syntax

`ha = adaptfilt.qdr1s(1,lambda,sqrtcov,coeffs,states)`

## Description

`ha = adaptfilt.qdr1s(1,lambda,sqrtcov,coeffs,states)` constructs an FIR QR-decomposition-based recursive-least squares (RLS) adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.qdr1s`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>1</code> defaults to 10.
<code>lambda</code>	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. <code>lambda</code> defaults to 1.
<code>sqrtcov</code>	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
<code>coeffs</code>	Vector of initial filter coefficients. It must be a length <code>1</code> vector. <code>coeffs</code> defaults to length <code>1</code> vector whose elements are zeros.
<code>states</code>	Vector of initial filter states. It must be a length <code>1-1</code> vector. <code>states</code> defaults to a length <code>1-1</code> vector of zeros.

## Properties

Since your `adaptfilt.qdr1s` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.qdr1s` objects. To

show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of length $l$	Vector containing the initial filter coefficients. It must be a length $l$ vector where $l$ is the number of filter coefficients. <code>coeffs</code> defaults to length $l$ vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range $(0, 1]$ . It defaults to 1. Setting <code>forgetting factor = 1</code> denotes infinite memory while adapting to find the new filter. Note that this is the <code>lambda</code> input argument.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
SqrtCov	Square matrix with each dimension equal to the filter length 1	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
States	Vector of elements	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + projectord - 2).

## Examples

System Identification of a 32-coefficient FIR filter (500 iterations).

```

x = randn(1,500);      % Input to the filter
b = fir1(31,0.5);     % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(.1)*eye(32); % Initial sqrt correlation matrix

```

# adaptfilt.qrdrls

```
lam = 0.99; % RLS forgetting factor
ha = adaptfilt.qrdrls(32, lam, G0);
[y, e] = filter(ha, x, d);
subplot(2,1,1); plot(1:500, [d; y; e]);
title('System Identification of an FIR Filter');
legend('Desired', 'Output', 'Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.', ha.Coefficients.']);
legend('Actual', 'Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

Using this variant of the RLS algorithm successfully identifies the unknown FIR filter, as shown here.

## See Also

[adaptfilt.rls](#) | [adaptfilt.hrls](#) | [adaptfilt.hswrls](#) | [adaptfilt.swrls](#)

**Purpose** Recursive least-squares FIR adaptive filter

**Syntax** `ha = adaptfilt.rls(1,lambda,invcov,coeffs,states)`

**Description** `ha = adaptfilt.rls(1,lambda,invcov,coeffs,states)` constructs an FIR direct form RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

**Input Arguments**

Entries in the following table describe the input arguments for `adaptfilt.rls`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
lambda	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. lambda defaults to 1.
invcov	Inverse of the input signal covariance matrix. For best performance, you should initialize this matrix to be a positive definite matrix.
coeffs	Vector of initial filter coefficients. it must be a length 1 vector. coeffs defaults to length 1 vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

**Properties**

Since your `adaptfilt.rls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are

also input arguments for creating `adaptfilt.rls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
Coefficients	Vector containing <code>l</code> elements	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps. Remember that filter length is filter order + 1.
ForgettingFactor	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting <code>forgetting factor = 1</code> denotes infinite memory while adapting to find the new filter. Note that this is the <code>lambda</code> input argument.
InvCov	Matrix of size <code>l</code> -by- <code>l</code>	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.

Name	Range	Description
KalmanGain	Vector of size (1,1)	Empty when you construct the object, this gets populated after you run the filter.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. Defaults to false.
States	Double array	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .

## Examples

System Identification of a 32-coefficient FIR filter over 500 adaptation iterations.

```
x = randn(1,500); % Input to the filter
b = fir1(31,0.5); % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n; % Desired signal
P0 = 10*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99; % RLS forgetting factor
ha = adaptfilt.rls(32,lam,P0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
```

```
subplot(2,1,2); stem([b.',ha.Coefficients.']);  
legend('Actual','Estimated');  
xlabel('Coefficient #'); ylabel('Coefficient value'); grid on;
```

In this example of adaptive filtering using the RLS algorithm to update the filter coefficients for each iteration, the figure shown reveals the fidelity of the derived filter after adaptation.

**See Also**

[adaptfilt.hr1s](#) | [adaptfilt.hswr1s](#) | [adaptfilt.qdr1s](#)

**Purpose** Sign-data FIR adaptive filter

**Syntax** `ha = adaptfilt.sd(1,step,leakage,coeffs,states)`

**Description** `ha = adaptfilt.sd(1,step,leakage,coeffs,states)` constructs an FIR sign-data adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

**Input Arguments**

Entries in the following table describe the input arguments for `adaptfilt.sd`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
step	SD step size. It must be a nonnegative scalar. step defaults to 0.1
leakage	Your SD leakage factor. It must be a scalar between 0 and 1. When leakage is less than one, <code>adaptfilt.sd</code> implements a leaky SD algorithm. When you omit the leakage property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
coeffs	Vector of initial filter coefficients. it must be a length 1 vector. coeffs defaults to length 1 vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

## Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for `sign-data` objects, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-data	Defines the adaptive filter algorithm the object uses during adaptation.
Coefficients	<code>zeros(1,1)</code>	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need <code>l</code> entries in <code>coefficients</code> .
FilterLength	10	Reports the length of the filter, the number of coefficients or taps.
Leakage	0	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to 0.

Property	Default Value	Description
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	zeros(1-1,1)	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 - 1).
StepSize	0.1	Sets the SD algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

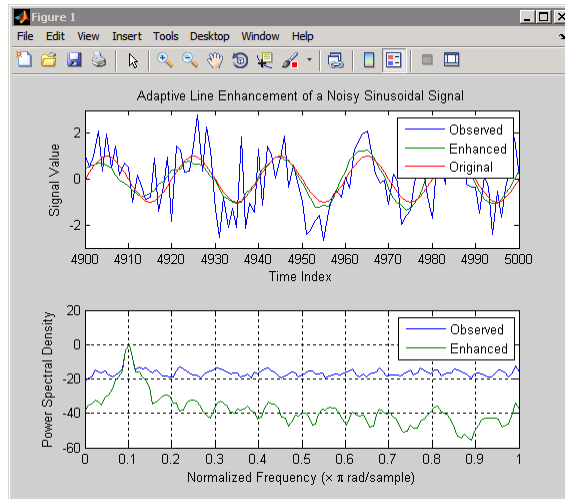

## Examples

Adaptive line enhancement using a 32-coefficient FIR filter to perform the enhancement. This example runs for 5000 iterations, as you see in property iter.

```
d = 1; % Number of samples of delay
ntr= 5000; % Number of iterations
v = sin(2*pi*0.05*[1:ntr+d]); % Sinusoidal signal
n = randn(1,ntr+d); % Noise signal
```

```
x = v(1:ntr)+n(1:ntr);           % Input signal
d = v(1+d:ntr+d)+n(1+d:ntr+d); % Desired signal
mu = 0.0001;                     % Sign-data step size.
ha = adaptfilt.sd(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of a Noisy Sinusoidal Signal');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
[pxx,om] = pwelch(x(ntr-1000:ntr));
pyy = pwelch(y(ntr-1000:ntr));
subplot(2,1,2);
plot(om/pi,10*log10([pxx/max(pxx),pyy/max(pyy)]));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

Each of the variants — sign-data, sign-error, and sign-sign — uses the same example. You can compare the results by viewing the figure shown for each adaptive filter method — `adaptfilt.sd`, `adaptfilt.se`, and `adaptfilt.ss`.

### Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.se`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
step	SE step size. It must be a nonnegative scalar. You can use <code>maxstep</code> to determine a reasonable range of step size values for the signals being processed. <code>step</code> defaults to 0.1
leakage	Your SE leakage factor. It must be a scalar between 0 and 1. When <code>leakage</code> is less than one, <code>adaptfilt.se</code> implements a leaky SE algorithm. When you omit the <code>leakage</code> property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.

Input Argument	Description
coeffs	Vector of initial filter coefficients. it must be a length <code>l</code> vector. <code>coeffs</code> defaults to length <code>l</code> vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length <code>l-1</code> vector. <code>states</code> defaults to a length <code>l-1</code> vector of zeros.

## Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for the sign-error SD object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-error	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	<code>zeros(1,1)</code>	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps

Property	Default Value	Description
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to one if omitted.
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	zeros(1-1,1)	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 -1).
StepSize	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Use `inspect(ha)` to view or change the object properties graphically using the MATLAB Property Inspector.

## Examples

Adaptive line enhancement using a 32-coefficient FIR filter running over 5000 iterations.

```
d = 1; % Number of samples of delay
ntr= 5000; % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d)); % Sinusoidal signal
n = randn(1,ntr+d); % Noise signal
x = v(1:ntr)+n(1:ntr); % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d); % Desired signal
mu = 0.0001; % Sign-error step size
ha = adaptfilt.se(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
HWelch = spectrum.welch;
InputPsd = psd(HWelch,x(ntr-1000:ntr));
OutputPsd = psd(HWelch,y(ntr-1000:ntr));
CompPsdEst = [InputPsd.Data/max(InputPsd.Data), OutputPsd.Data/max(OutputPsd.Data)];
subplot(2,1,2); plot(InputPsd.Frequencies/pi,10*log10(CompPsdEst));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

Compare the figure shown here to the ones for `adaptfilt.sd` and `adaptfilt.ss` to see how the variants perform on the same example.

[adaptfilt.sd](#) | [adaptfilt.ss](#) | [adaptfilt.lms](#)

**Purpose** FIR adaptive filter that uses sign-sign algorithm

**Syntax** `ha = adaptfilt.ss(1,step,leakage,coeffs,states)`

**Description** `ha = adaptfilt.ss(1,step,leakage,coeffs,states)` constructs an FIR sign-error adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

**Input Arguments**

Entries in the following table describe the input arguments for `adaptfilt.ss`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
step	SS step size. It must be a nonnegative scalar. step defaults to 0.1.
leakage	Your SS leakage factor. It must be a scalar between 0 and 1. When leakage is less than one, <code>adaptfilt.lms</code> implements a leaky SS algorithm. When you omit the leakage property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
coeffs	Vector of initial filter coefficients. it must be a length 1 vector. coeffs defaults to length 1 vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length 1 -1 vector. states defaults to a length 1-1 vector of zeros.

`adaptfilt.ss` can be called for a block of data, when `x` and `d` are vectors, or in “sample by sample mode” using a For-loop with the method `filter`:

```
for n = 1:length(x)
    ha = adaptfilt.ss(25,0.9);
    [y(n),e(n)] = filter(ha,(x(n),d(n),s));
end
```

## Properties

In the syntax for creating the `adaptfilt` object, most of the input options are properties of the object you create. This table lists the properties for sign-sign objects, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-sign	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	<code>zeros(1,1)</code>	Vector containing the initial filter coefficients. It must be a length 1 vector where 1 is the number of filter coefficients. <code>coeffs</code> defaults to length 1 vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps

Property	Default Value	Description
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. 1 is the default value.
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	zeros(1-1,1)	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1-1).
StepSize	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

## Examples

Demonstrating adaptive line enhancement using a 32-coefficient FIR filter provides a good introduction to the sign-sign algorithm.

```
d = 1; % Number of samples of delay
ntr= 5000; % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d)); % Sinusoidal signal
n = randn(1,ntr+d); % Noise signal
x = v(1:ntr)+n(1:ntr); % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d); % Desired signal
mu = 0.0001; % Sign-error step size
ha = adaptfilt.ss(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
[InputPsd,wi] = pwelch(x(ntr-1000:ntr));
[OutputPsd,wo] = pwelch(y(ntr-1000:ntr));
CompPsdEst = [InputPsd/max(InputPsd), OutputPsd/max(OutputPsd)];
subplot(2,1,2); plot(wi/pi,10*log10(CompPsdEst));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

This example is the same as the ones used for the sign-data and sign-error examples. Comparing the figures shown for each of the others lets you assess the performance of each for the same task.

# adaptfilt.swftf

---

**Purpose** FIR adaptive filter that uses sliding window fast transversal least squares

**Syntax** `ha = adaptfilt.swftf(1,delta,blocklen,gamma,gstates, dstates,...coeffs,states)`

**Description** `ha = adaptfilt.swftf(1,delta,blocklen,gamma,gstates, dstates,...coeffs,states)` constructs a sliding window fast transversal least squares adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.swftf`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>1</code> defaults to 10.
<code>delta</code>	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to maintain stability. <code>delta</code> defaults to 1.
<code>blocklen</code>	Block length of the sliding window. This must be an integer at least as large as the filter length <code>1</code> , which is the default value.
<code>gamma</code>	Conversion factor. <code>gamma</code> defaults to the matrix $[1 \ -1]$ that specifies soft-constrained initialization.
<code>gstates</code>	States of the Kalman gain updates. <code>gstates</code> defaults to a zero vector of length $(1 + \text{blocklen} - 1)$ .

Input Argument	Description
dstates	Desired signal states of the adaptive filter. <code>dstates</code> defaults to a zero vector of length equal to $(\text{blocklen} - 1)$ . For a default object, <code>dstates</code> is $(1-1)$ .
coeffs	Vector of initial filter coefficients. It must be a length <code>l</code> vector. <code>coeffs</code> defaults to length <code>l</code> vector of all zeros.
states	Vector of initial filter states. <code>states</code> defaults to a zero vector of length equal to $(l + \text{blocklen} - 2)$ .

## Properties

Since your `adaptfilt.swftf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.swftf` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPredictions		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
BlockLength		Block length of the sliding window. This must be an integer at least as large as the filter length <code>l</code> , which is the default value.

Name	Range	Description
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length <code>l</code> vector where <code>l</code> is the number of filter coefficients. <code>coeffs</code> defaults to length <code>l</code> vector of zeros when you do not provide the argument for input.
ConversionFactor		Conversion factor. Called <code>gamma</code> when it is an input argument, it defaults to the matrix <code>[1 -1]</code> that specifies soft-constrained initialization.
DesiredSignal States		Desired signal states of the adaptive filter. <code>dstates</code> defaults to a zero vector with length equal to <code>(blocklen - 1)</code> .
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
FwdPrediction		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. <code>delta</code> defaults to one.

Name	Range	Description
KalmanGain		Empty when you construct the object, this gets populated after you run the filter.
KalmanGainStates		Contains the states of the Kalman gains for the adaptive algorithm. Initialized to a vector of double data type entries.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + projectord - 2).

### Examples

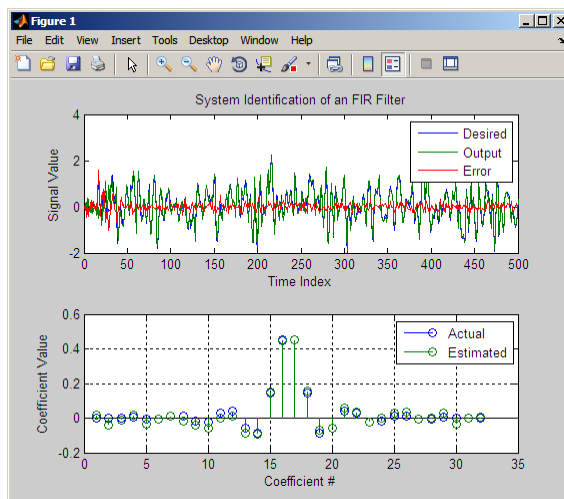

Over 500 iterations, perform a system identification of a 32-coefficient FIR filter.

```
x = randn(1,500); % Input to the filter
b = fir1(31,0.5); % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n; % Desired signal
L = 32; % Adaptive filter length
```

# adaptfilt.swftf

```
del = 0.1;           % Soft-constrained initialization factor
N = 64;             % block length
ha = adaptfilt.swftf(L,del,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.'ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value'); grid on;
```

Review the figure for the results of the example. When you evaluate the example you should get the same results, within the differences in the random noise signal you use.

# adaptfilt.swrls

---

**Purpose** FIR adaptive filter that uses window recursive least squares (RLS)

**Syntax** `ha = adaptfilt.swrls(1,lambda,invcov,swblocklen,  
dstates,...coeffs,states)`

**Description** `ha = adaptfilt.swrls(1,lambda,invcov,swblocklen,  
dstates,...coeffs,states)` constructs an FIR sliding window RLS  
adaptive filter `ha`.

For information on how to run data through your adaptive filter object,  
see the Adaptive Filter Syntaxes section of the reference page for  
filter.

## Input Arguments

Entries in the following table describe the input arguments for  
`adaptfilt.swrls`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. <code>1</code> defaults to 10.
<code>lambda</code>	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. <code>lambda</code> defaults to 1.
<code>invcov</code>	Inverse of the input signal covariance matrix. You should initialize <code>invcov</code> to a positive definite matrix.
<code>swblocklen</code>	Block length of the sliding window. This integer must be at least as large as the filter length. <code>swblocklen</code> defaults to 16.
<code>dstates</code>	Desired signal states of the adaptive filter. <code>dstates</code> defaults to a zero vector with length equal to $(swblocklen - 1)$ .

Input Argument	Description
coeffs	Vector of initial filter coefficients. It must be a length 1 vector. coeffs defaults to length 1 vector of all zeros.
states	Vector of initial filter states. states defaults to a zero vector of length equal to $(1 + \text{swblocklen} - 2)$ .

## Properties

Since your `adaptfilt.swrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.swrls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Any vector of 1 elements	Vector containing the initial filter coefficients. It must be a length 1 vector where 1 is the number of filter coefficients. coeffs defaults to length 1 vector of zeros when you do not provide the argument for input.
DesiredSignalStates	Vector	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to $(\text{swblocklen} - 1)$ .

Name	Range	Description
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.
InvCov	Matrix	Square matrix with each dimension equal to the filter length l.
KalmanGain	Vector with dimensions (1,1)	Empty when you construct the object, this gets populated after you run the filter.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. Defaults to false.

Name	Range	Description
States	Vector of elements, data type double	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 + \text{swblocklen} - 2)$
SwBlockLength	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. <code>swblocklen</code> defaults to 16.

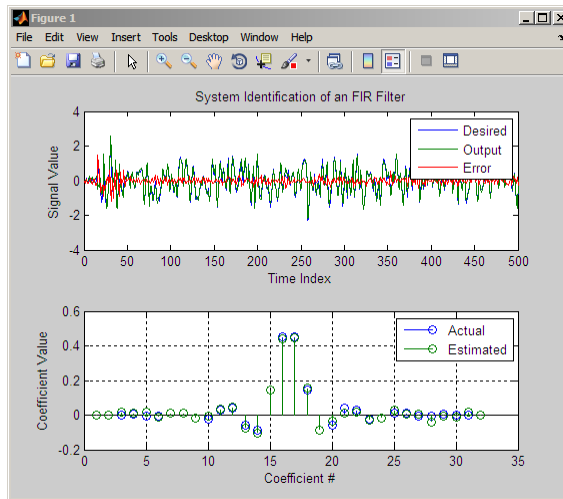

## Examples

System Identification of a 32-coefficient FIR filter. Use 500 iterations to adapt to the unknown filter. After the example code, you see a figure that plots the results of the running the code.

```
x = randn(1,500);      % Input to the filter
b = fir1(31,0.5);     % FIR system to be identified
n = 0.1*randn(1,500); % Observation noise signal
d = filter(b,1,x)+n;  % Desired signal
P0 = 10*eye(32);     % Initial correlation matrix inverse
lam = 0.99;          % RLS forgetting factor
N = 64;              % Block length
ha = adaptfilt.swrls(32,lam,P0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
    title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value'); grid on;
```

In the figure you see clearly that the adaptive filter process successfully identified the coefficients of the unknown FIR filter. You knew it

had to or many things that you take for granted, such as modems on computers, would not work.

## See Also

[adaptfilt.rls](#) | [adaptfilt.qrdrls](#) | [adaptfilt.hswrls](#)

## Purpose

Adaptive filter that uses discrete cosine transform

## Syntax

```
ha = adaptfilt.tdafdct(1,step,leakage,offset,delta,lambda,
coeffs,states)
```

## Description

`ha = adaptfilt.tdafdct(1,step,leakage,offset,delta,lambda,coeffs,states)` constructs a transform-domain adaptive filter `ha` object that uses the discrete cosine transform to perform filter adaptation.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.tdafdct`.

Input Argument	Description
1	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. 1 defaults to 10.
step	Adaptive filter step size. It must be a nonnegative scalar. You can use <code>maxstep</code> to determine a reasonable range of step size values for the signals being processed. <code>step</code> defaults to 0.
leakage	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDCT algorithm. <code>leakage</code> defaults to 1 — no leakage.

<b>Input Argument</b>	<b>Description</b>
<code>offset</code>	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. <code>offset</code> defaults to zero.
<code>delta</code>	Initial common value of all of the transform domain powers. Its initial value should be positive. <code>delta</code> defaults to 5.
<code>lambda</code>	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. <code>lambda</code> should lie between zero and one. For default filter objects, <code>lambda</code> equals $(1 - \text{step})$ .
<code>coeffs</code>	Initial time domain coefficients of the adaptive filter. Set it to be a length <code>l</code> vector. <code>coeffs</code> defaults to a zero vector of length <code>l</code> .
<code>states</code>	Initial conditions of the adaptive filter. <code>states</code> defaults to a zero vector with length equal to $(l - 1)$ .

## Properties

Since your `adaptfilt.tdafdct` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.tdafdct` objects. To show you the properties that apply, this table lists and describes each property for the transform domain filter object.

<b>Name</b>	<b>Range</b>	<b>Description</b>
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor		Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor should lie between zero and one. For default filter objects, AvgFactor equals (1 - step). lambda is the input argument that represent AvgFactor.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector where 1 is the number of filter coefficients. coeffs defaults to length 1 vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. leakage defaults to 1 — no leakage.

Name	Range	Description
Offset		Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. <code>offset</code> defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to <code>false</code> .
Power	2*1 element vector	A vector of 2*1 elements, each initialized with the value <code>delta</code> from the input arguments. As you filter data, <code>Power</code> gets updated by the filter process.

Name	Range	Description
States	Vector of elements, data type double	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .
StepSize	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. You can use <code>maxstep</code> to determine a reasonable range of step size values for the signals being processed. <code>step</code> defaults to 0.

For checking the values of properties for an adaptive filter object, use `get(ha)` or enter the object name, without a trailing semicolon, at the MATLAB prompt.

## Examples

Using 1000 iterations, perform a Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

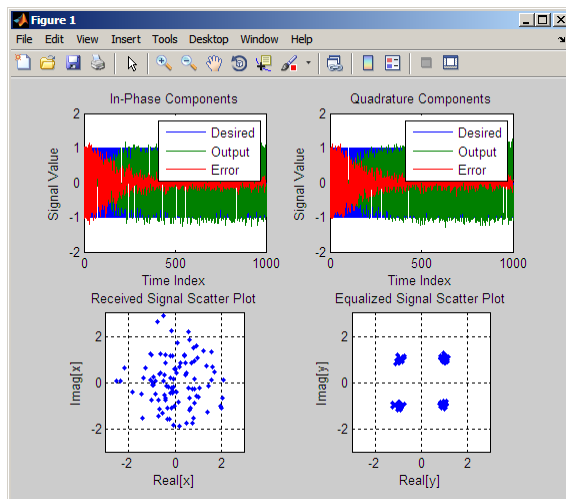

```
D = 16; % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr= 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); %QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
L = 32; % filter length
mu = 0.01; % Step size
ha = adaptfilt.tdafdct(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1);
plot(1:ntr,real([d;y;e])); title('In-Phase Components');
```

```

legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square'); xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); grid on;
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');

```

Compare the plots shown in this figure to those in the other time domain filter variations. The comparison should help you select and understand how the variants differ.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.tdafdft`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>1</code> defaults to 10.
<code>step</code>	Adaptive filter step size. It must be a nonnegative scalar. You can use <code>maxstep</code> to determine a reasonable range of step size values for the signals being processed. <code>step</code> defaults to 0.
<code>leakage</code>	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. <code>leakage</code> defaults to 1 — no leakage.

<b>Input Argument</b>	<b>Description</b>
<code>offset</code>	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. <code>offset</code> defaults to zero.
<code>delta</code>	Initial common value of all of the transform domain powers. Its initial value should be positive. <code>delta</code> defaults to 5.
<code>lambda</code>	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. <code>lambda</code> should lie between zero and one. For default filter objects, LAMBDA equals (1 - step).
<code>coeffs</code>	Initial time domain coefficients of the adaptive filter. Set it to be a length 1 vector. <code>coeffs</code> defaults to a zero vector of length 1.
<code>states</code>	Initial conditions of the adaptive filter. <code>states</code> defaults to a zero vector with length equal to (1 - 1).

## Properties

Since your `adaptfilt.tdafdf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.tdafdf` objects. To show you the properties that apply, this table lists and describes each property for the transform domain filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor should lie between zero and one. For default filter objects, AvgFactor equals (1 - step). lambda is the input argument that represent AvgFactor.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector where 1 is the number of filter coefficients. coeffs defaults to length 1 vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. leakage defaults to 1 — no leakage.

Name	Range	Description
Offset		Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. <code>offset</code> defaults to zero.
PersistentMemory	false or true	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to <code>false</code> .
Power	2*1 element vector	A vector of 2*1 elements, each initialized with the value <code>delta</code> from the input arguments. As you filter data, <code>Power</code> gets updated by the filter process.
States	Vector of elements, data type double	Vector of the adaptive filter states. <code>states</code> defaults to a vector of zeros which has length equal to $(1 + \text{projectord} - 2)$ .
StepSize	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. <code>step</code> defaults to 0.

## Examples

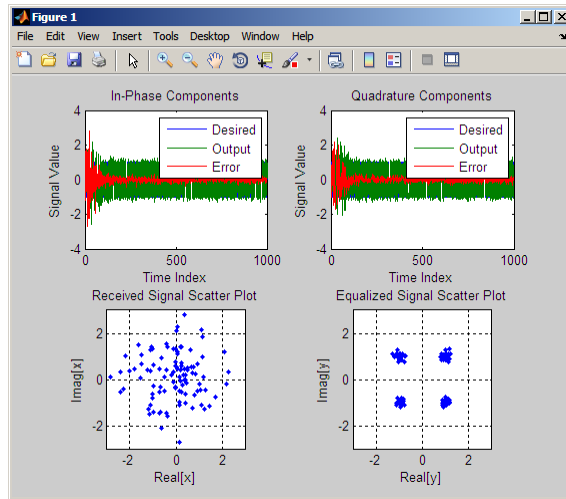

Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter (1000 iterations).

```
D = 16; % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr= 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
L = 32; % filter length
mu = 0.01; % Step size
ha = adaptfilt.tdafdft(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square'); xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

All of the time domain adaptive filter reference pages use this QPSK example. By comparing the results for each variation you get an idea of the differences in the way each one performs.

This figure demonstrates the results of running the example code shown.

**Purpose** FIR adaptive filter that uses unconstrained frequency-domain with quantized step size normalization

**Syntax** `ha = adaptfilt.ufdaf(1,step,leakage,delta,lambda,blocklen,offset,coeffs,states)`

**Description** `ha = adaptfilt.ufdaf(1,step,leakage,delta,lambda,blocklen,offset,coeffs,states)`

constructs an unconstrained frequency-domain FIR adaptive filter `ha` with quantized step size normalization.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

## Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ufdaf`.

Input Argument	Description
<code>1</code>	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. <code>1</code> defaults to 10.
<code>step</code>	Adaptive filter step size. It must be a nonnegative scalar. <code>step</code> defaults to 0.
<code>leakage</code>	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. <code>leakage</code> defaults to 1 — no leakage.
<code>delta</code>	Initial common value of all of the FFT input signal powers. the initial value of <code>delta</code> should be positive, and it defaults to 1.

<b>Input Argument</b>	<b>Description</b>
<code>lambda</code>	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. <code>lambda</code> should lie in the range (0,1]. For default UFDAF filter objects, <code>lambda</code> defaults to 0.9.
<code>blocklen</code>	Block length for the coefficient updates. This must be a positive integer. For faster execution, ( <code>blocklen - 1</code> ) should be a power of two. <code>blocklen</code> defaults to 1.
<code>offset</code>	Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.
<code>coeffs</code>	Initial time-domain coefficients of the adaptive filter. It should be a length 1 vector. The filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by <code>blocklen</code> .
<code>states</code>	Adaptive filter states. <code>states</code> defaults to a zero vector with length equal to 1.

## Properties

Since your `adaptfilt.ufdaf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.ufdaf` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. AvgFactor should lie in the range (0,1]. For default UFDAF filter objects, AvgFactor defaults to 0.9. Note that AvgFactor and lambda are the same thing — lambda is an input argument and AvgFactor a property of the object.
BlockLength		Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen + 1) should be a power of two. blocklen defaults to 1.
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

<b>Name</b>	<b>Range</b>	<b>Description</b>
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. Leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Name	Range	Description
Power	2*1 element vector	A vector of 2*1 elements, each initialized with the value <code>delta</code> from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Adaptive filter step size. It must be a nonnegative scalar. You can use <code>maxstep</code> to determine a reasonable range of step size values for the signals being processed. <code>step</code> defaults to 0.

## Examples

Show an example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. For fidelity, use 1024 iterations. The figure that follows the code provides the information you need to assess the performance of the equalization process.

```
D = 16; % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr= 1024; % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));
r = filter(b,a,s)+n;% Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
del = 1; %Initial FFT input powers
mu = 0.1; % Step size
lam = 0.9; % Averaging factor
ha = adaptfilt.ufdaf(32,mu,1,del,lam);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:1000,real([d(1:1000);y(1:1000);e(1:1000)]));
```

```

title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;

```

# allpassbpc2bpc

---

**Purpose** Allpass filter for complex bandpass transformation

**Syntax** [AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)

**Description** [AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the first-order allpass mapping filter for performing a complex bandpass to complex bandpass frequency transformation. This transformation effectively places two features of an original filter, located at frequencies  $W_{o1}$  and  $W_{o2}$ , at the required target frequency locations  $W_{t1}$  and  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle. This is very attractive for adaptive systems.

## Examples

Design the allpass mapping filter changing the complex bandpass filter with the band edges at  $W_{o1}=0.2$  and  $W_{o2}=0.4$  to the new band edges of  $W_{t1}=0.3$  and  $W_{t2}=0.6$ . Find the frequency response of the allpass mapping filter:

```
Wo = [0.2, 0.4]; Wt = [0.3, 0.6];
[AllpassNum, AllpassDen] = allpassbpc2bpc(Wo, Wt);
[ha, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, angle(ha)/pi, Wt, Wo, 'ro'); title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency values to be transformed from the prototype filter
<i>Wt</i>	Desired frequency locations in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

# allpasslp2bp

---

**Purpose** Allpass filter for lowpass to bandpass transformation

**Syntax** [AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)

**Description** [AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the second-order allpass mapping filter for performing a real lowpass to real bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the “DC mobility,” which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and repositioned at two distinct desired frequencies.

**Examples** Design the allpass mapping filter changing the lowpass filter with cutoff frequency at  $W_o=0.5$  to the real-valued bandpass filter with cutoff frequencies at  $W_{t1}0.25$  and  $W_{t2}=0.375$ .

Compute the frequency response and plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```

Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');

```

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency locations in the transformed target filter

Variable	Description
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

**Purpose**

Allpass filter for lowpass to bandstop transformation

**Syntax**

[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)

**Description**

[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the second-order allpass mapping filter for performing a real lowpass to real bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

**Examples**

Design the allpass filter changing the lowpass filter with cutoff frequency at  $W_o=0.5$  to the real bandstop filter with cutoff frequencies at  $W_{t1}=0.25$  and  $W_{t2}=0.375$ :

```
Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bs(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In the figure, you find the mapping filter function as determined by the example. Note the response is normalized to  $\pi$ :

## Arguments

Variable	Description
$W_o$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency locations in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

# allpasslp2hp

---

**Purpose** Allpass filter for lowpass to highpass transformation

**Syntax** [AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt)

**Description** [AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the first-order allpass mapping filter for performing a real lowpass to real highpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency,  $W_o$ , at the required target frequency location,  $W_t$ , at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by using the lowpass to highpass transformation.

**Examples** Design the allpass filter changing the lowpass filter to the highpass filter with its cutoff frequency moved from  $W_o=0.5$  to  $W_t=0.25$ .

Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;  
[AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt);
```

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt');
ylabel('Old Frequency, Wo');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

**Purpose** Allpass filter for lowpass to lowpass transformation

**Syntax** [AllpassNum, AllpassDen] = allpasslp2lp(Wo, Wt)

**Description** [AllpassNum, AllpassDen] = allpasslp2lp(Wo, Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the first-order allpass mapping filter for performing a real lowpass to real lowpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency  $W_o$ , at the required target frequency location,  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband and so on.

Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by applying the lowpass to lowpass transformation.

## Examples

Design the allpass filter changing the lowpass filter cutoff frequency originally at  $W_o=0.5$  to  $W_t=0.25$ . Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2lp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
```

```
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

As shown in the figure, `allpass2lp` generates a mapping function that converts your prototype lowpass filter to a target lowpass filter with different passband specifications.

## Arguments

Variable	Description
$W_o$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency location in the transformed target filter

Variable	Description
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

**Purpose**

Allpass filter for lowpass to M-band transformation

**Syntax**

```
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)
```

**Description**

[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the Mth-order allpass mapping filter for performing a real lowpass to real multipassband frequency transformation. Parameter M is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ . By default the DC feature is kept at its original location.

[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass) allows you to specify an additional parameter, Pass, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without redesigning them. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of  $W_0=0.5$  into a real multiband filter with band edges of  $W_t=[1:2:9]/10$  precisely defined. Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_0(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [1:2:9]/10;  
[AllpassNum, AllpassDen] = allpasslp2mb(Wo, Wt);  
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');  
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');  
title('Mapping Function Wo(Wt)');  
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

**Arguments**

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency locations in the transformed target filter
<i>Pass</i>	Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

# allpasslp2mbc

---

**Purpose** Allpass filter for lowpass to complex M-band transformation

**Syntax** [AllpassNum, AllpassDen] = allpasslp2mbc(Wo, Wt)

**Description** [AllpassNum, AllpassDen] = allpasslp2mbc(Wo, Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the Mth-order allpass mapping filter for performing a real lowpass to complex multipassband frequency transformation. Parameter M is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need to design them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

**Examples** Design the allpass filter changing the real lowpass filter with the cutoff frequency of  $W_o=0.5$  into a complex multiband filter with band edges of  $W_t=[-3+1:2:9]/10$  precisely defined:

```
Wo = 0.5; Wt = [-3+1:2:9]/10;  
[AllpassNum, AllpassDen] = allpasslp2mbc(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, angle(h)/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In this example, the resulting mapping function converts real filters to multiband complex filters.

# allpasslp2mbc

---

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

**Purpose**

Allpass filter for lowpass to complex N-point transformation

**Syntax**

[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)

**Description**

[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the Nth-order allpass mapping filter, where N is the allpass filter order, for performing a real lowpass to complex multipoint frequency transformation. Parameter N also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places N features of the, original filter located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

**Examples**

Design the allpass filter moving four features of an original complex filter given in  $W_o$  to the new independent frequency locations  $W_t$ . Please

# allpasslp2xc

---

note that the transformation creates N replicas of an original filter around the unit circle, where N is the order of the allpass mapping filter:

```
Wo = [-0.2, 0.3, -0.7, 0.4]; Wt = [0.3, 0.5, 0.7, 0.9];  
[AllpassNum, AllpassDen] = allpasslp2xc(Wo, Wt);  
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency values to be transformed from the prototype filter
<i>Wt</i>	Desired frequency locations in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

**Purpose** Allpass filter for integer upsample transformation

**Syntax** [AllpassNum,AllpassDen] = allpassrateup(N)

**Description** [AllpassNum,AllpassDen] = allpassrateup(N) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the Nth-order allpass mapping filter for performing the rateup frequency transformation, which creates N equal replicas of the prototype filter frequency response.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

**Examples** Design the allpass filter creating the effect of upsampling the digital filter four times:

Choose any feature from an original filter, say at  $W_o=0.2$ :

```
N = 4;
Wo = 0.2; Wt = Wo/N + 2*[0:N-1]/N;
[AllpassNum, AllpassDen] = allpassrateup(N);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

## Arguments

Variable	Description
<i>N</i>	Frequency replication ratio (upsampling ratio)
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

# allpassshift

---

**Purpose** Allpass filter for real shift transformation

**Syntax** [AllpassNum,AllpassDen] = allpassshift(Wo,Wt)

**Description** [AllpassNum,AllpassDen] = allpassshift(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the second-order allpass mapping filter for performing a real frequency shift transformation. This transformation places one selected feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ . This transformation implements the “DC mobility,” which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be moved to a different frequency by applying a shift transformation. In such a way you can avoid designing the filter from the beginning.

**Examples** Design the allpass filter precisely shifting one feature of the lowpass filter originally at  $W_o=0.5$  to the new frequencies of  $W_t=0.25$ :

```
Wo = 0.5; Wt = 0.25;  
[AllpassNum, AllpassDen] = allpassshift(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');  
title('Mapping Function Wo(Wt)');  
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

# allpassshift

---

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`iirshift` | `zpkshift`

**Purpose**

Allpass filter for complex shift transformation

**Syntax**

```
[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt)
[AllpassNum,AllpassDen] = allpassshiftc(0,0.5)
[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5)
```

**Description**

[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt) returns the numerator, AllpassNum, and denominator, AllpassDen, vectors of the allpass mapping filter for performing a complex frequency shift of the frequency response of the digital filter by an arbitrary amount.

[AllpassNum,AllpassDen] = allpassshiftc(0,0.5) calculates the allpass filter for doing the Hilbert transformation, a 90 degree counterclockwise rotation of an original filter in the frequency domain.

[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5) calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

**Examples**

Design the allpass filter precisely rotating the whole filter by the amount defined by the location of the selected feature from an original filter,  $W_o=0.5$ , and its required position in the target filter,  $W_t=0.25$ :

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshiftc(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

**Arguments**

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter

# allpassshiftc

---

Variable	Description
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

**Purpose** Automatic dynamic range scaling

**Syntax** `autoscale(hd,x)`  
`hnew = autoscale(hd,x)`

**Description** `autoscale(hd,x)` provides dynamic range scaling for each node of the filter `hd`. This method runs signal `x` through `hd` in floating-point to simulate filtering. `autoscale` uses the maximum and minimum data obtained from that simulation at each filter node to set fraction lengths to cover the simulation full range and maximize the precision. Word lengths are not changed during autoscaling.

`hnew = autoscale(hd,x)` If you request an output, `autoscale` returns a new filter with the scaled fraction lengths. The original filter is not changed.

For introductory demonstrations of the automatic scale process, refer to the following demos in the toolbox:

- Fixed-Point Scaling of an Elliptic IIR Filter
- Floating-Point to Fixed-Point Conversion of IIR Filters
- Floating-Point to Fixed-Point Conversion of FIR Filters

**Examples** Demonstrate dynamic range scaling in a lattice ARMA filter:

```
hd = design(fdesign.bandpass,'ellip');  
hd = convert(hd,'latticearma');  
hd.arithmetic = 'fixed';  
rng(4); x = rand(100,10); % Training input data.  
hd(2) = autoscale(hd,x);  
hfvtool(hd,'Analysis','magesestimate','Showreference','off');  
legend(hfvtool, 'Before Autoscaling', 'After Autoscaling')
```

# autoscale

**See Also** [qreport](#)

**Purpose** Generate block from multirate or multistage filter

**Syntax** `block(hm)`  
`block(hm, 'propertyname1', propertyvalue1, 'propertyname2', propertyvalue2, ...)`

**Description** `block(hm)` generates a DSP System Toolbox block equivalent to `hm`.  
`block(hm, 'propertyname1', propertyvalue1, 'propertyname2', propertyvalue2, ...)` generates a DSP System Toolbox block using the options specified in the property name/property value pairs. The valid properties and their values are

Property Name	Property Values	Description and Values
Destination	'current' (default), 'new', or <i>Subsystemname</i> .	Determine which Simulink model gets the block. Enter 'current', 'new', or specify the name of an existing subsystem with <i>Subsystemname</i> . 'current' adds the block to your current Simulink model. Specifying 'new' opens a new model and adds the block. Specifying <i>Subsystemname</i> opens a new model and adds the block. If you provide the name of a subsystem in <i>Subsystemname</i> , <code>block</code> adds the new block to your specified subsystem.
Blockname	'filter' (default)	Specify the name of the generated block. The name appears below the block in the model. When you do not specify a block name, the default is <code>filter</code> .

# block

Property Name	Property Values	Description and Values
OverwriteBlock	'off' (default), or 'on'.	Tell block whether to overwrite an existing block of the same name, or create a new block. 'off' is the default setting—block does not overwrite existing blocks with matching names. Switching from 'off' to 'on' directs block to overwrite existing blocks.
MapStates	'off' (default), or 'on'.	Specify whether to apply the current filter states to the new block. This lets you save states from a filter object you may have used or configured in a specific way. The default setting of 'off' means the states are not transferred to the block. Choosing 'on' preserves the current filter states in the block.
Link20bj	'off' (default), or 'on'.	Specify how to set the <b>Coefficient source</b> in the block mask. The default setting is 'off' and the <b>Coefficient source</b> is set to <b>Dialog parameters</b> . Setting Link20bj to 'on' sets the <b>Coefficient source</b> to <b>Discrete-time filter object (DFILT)</b> . The Link20bj and MapCoeffstoPorts cannot be simultaneously 'on'.

Property Name	Property Values	Description and Values
MapCoeffstoPorts	'on' (default) or 'off'	Specify whether to map the coefficients of the filter to the ports of the block. The Link2Obj and MapCoeffstoPorts cannot be simultaneously 'on'. See mfilt for a list of supported filter objects.
CoeffNames	{ 'Num' } (default FIR) { 'Num', 'Den' } (default direct form IIR) { 'Num', 'Den', 'g' } (default IIR SOS), { 'K' } (default form lattice)	Specify the coefficient variable names as string variables in a cell array. MapCoeffstoPorts must be set to 'on' for this property to apply.
InputProcessing	'columns as channels' (default), 'elements as channels', or 'inherited'	Specify sample-based (elements as channels) or frame-based (columns as channels) processing. The Inherited (this choice will be removed - see release notes) option will be removed in a future release.
RateOption	'enforce single rate' (default) or 'allow multirate'	Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when InputProcessing is 'columns as channels'.

## Using block to Realize Fixed-Point Multirate Filters

When the source filter `hm` is fixed-point, the input word and fraction lengths for the block are derived from the block input signal. The realization process issues a warning and ignores the input word and input fraction lengths that are part of the source filter object, choosing to inherit the settings from the input data. Other fixed-point properties map directly to settings for word and fraction length in the realized block.

### Examples

Two examples of using `block` demonstrate the syntax capabilities. Both examples start from an `mfilt` object with interpolation factor of three. In the first example, use `block` with the default syntax, letting the function determine the block name and configuration.

```
hm = mfilt.firdecim(3);
```

Now use the default syntax to create a block.

```
block(hm);
```

In this second example, define the block name to meet your needs by using the property name/property value pair input arguments.

```
block(hm, 'blockname', 'firdecim');
```

The figure below shows the blocks in a Simulink model. When you try these examples, you see that the second block writes over the first block location. You can avoid this by moving the first block before you generate the second, always naming your block with the `blockname` property, or setting the `Destination` property to `new` which puts the filter block in a new Simulink model.

# butter

---

**Purpose** Butterworth IIR filter design using specification object

**Syntax** `hd = design(d, 'butter')`  
`hd = design(d, 'butter', designoption, value...)`

**Description** `hd = design(d, 'butter')` designs a Butterworth IIR digital filter using the specifications supplied in the object `d`.

`hd = design(d, 'butter', designoption, value...)` returns a Butterworth IIR filter where you specify a design option and value.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d, 'method')
```

For complete help about using `butter`, refer to the command line help system. For example, to get specific information about using `butter` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d, 'butter')
```

**Examples** Construct a default lowpass filter specification object and design a Butterworth filter:

```
d = fdesign.lowpass;  
hd = design(d, 'butter', 'matchexactly', 'stopband');
```

Construct a highpass filter specification object and design a Butterworth filter:

```
%Order 8 and 3 dB frequency 0.6*pi radians/sample  
d = fdesign.highpass('N,F3dB',8,.6);  
hd = design(d, 'butter');  
fvtool(hd)
```

**Purpose** Convert coupled allpass filter to transfer function form

**Syntax**  
[b,a]=ca2tf(d1,d2)  
[b,a]=ca2tf(d1,d2,beta)  
[b,a,bp]=ca2tf(d1,d2)  
[b,a,bp]=ca2tf(d1,d2,beta)

**Description** [b,a]=ca2tf(d1,d2) returns the vector of coefficients b and the vector of coefficients a corresponding to the numerator and the denominator of the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2} [H1(z) + H2(z)]$$

d1 and d2 are real vectors corresponding to the denominators of the allpass filters H1(z) and H2(z).

[b,a]=ca2tf(d1,d2,beta) where d1, d2 and beta are complex, returns the vector of coefficients b and the vector of coefficients a corresponding to the numerator and the denominator of the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2} [ -(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z) ]$$

[b,a,bp]=ca2tf(d1,d2), where d1 and d2 are real, returns the vector bp of real coefficients corresponding to the numerator of the power complementary filter G(z)

$$G(z) = Bp(z) / A(z) = \frac{1}{2} [H1(z) - H2(z)]$$

[b,a,bp]=ca2tf(d1,d2,beta), where d1, d2 and beta are complex, returns the vector of coefficients bp of real or complex coefficients that correspond to the numerator of the power complementary filter G(z)

$$G(z) = Bp(z) / A(z) = \frac{1}{2_j} [ -(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z) ]$$

## Examples

Create a filter, convert the filter to coupled allpass form, and convert the result back to the original structure (create the power complementary filter as well).

```
[b,a]=cheby1(10,.5,.4);
[d1,d2,beta]=tf2ca(b,a);           % tf2ca returns the %
                                   % denominators of the %
                                   % allpasses.

[num,den,numpc]=ca2tf(d1,         % Reconstruct the original
d2,beta);                          % filter plus the power %
                                   % complementary one.

[h,w,s]=freqz(num,den);
hpc = freqz(numpc,den);
s.plot = 'mag';
s.yunits = 'sq';
freqzplot([h hpc],w,s);           % Plot the mag response of
                                   % the % original filter and
                                   % the % power complementary
                                   % one.
```

# cheby1

---

**Purpose** Chebyshev Type I filter using specification object

**Syntax**

```
hd = design(d, 'cheby1')  
hd = design(d, 'cheby1', designoption, value, designoption,  
value, ...)
```

**Description** `hd = design(d, 'cheby1')` designs a type I Chebyshev IIR digital filter using the specifications supplied in the object `d`. Depending on the filter specification object, `cheby1` may or may not be a valid design. Use `designmethods` with the filter specification object to determine if a Chebyshev type I filter design is possible.

`hd = design(d, 'cheby1', designoption, value, designoption, value, ...)` returns a type I Chebyshev IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d, 'method')
```

For complete help about using `cheby1`, refer to the command line help system. For example, to get specific information about using `cheby1` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d, 'cheby1')
```

**Examples** These examples use filter specification objects to construct Chebyshev type I filters. In the first example, you use the `matchexactly` option to ensure the performance of the filter in the passband.

```
d = fdesign.lowpass; designopts(d, 'cheby1');  
hd = design(d, 'cheby1', 'matchexactly', 'passband');
```

Specify the filter order, passband edge frequency, and the passband ripple to get the filter exactly as required.

```
d = fdesign.highpass('n,fp,ap',7,20,.4,50);  
hd = design(d,'cheby1');
```

Use `fvtool` to view the resulting filter.

```
fvtool(hd)
```

By design, `cheby1` returns filters that use second-order sections (SOS). For many applications, and for most fixed-point applications, SOS filters are particularly well-suited.

## See Also

# cheby2

---

**Purpose** Chebyshev Type II filter using specification object

**Syntax**

```
hd = design(d, 'cheby2')  
hd = design(d, 'cheby2', designoption, value, designoption,  
value, ...)
```

**Description**

`hd = design(d, 'cheby2')` designs a Chebyshev II IIR digital filter using the specifications supplied in the object `d`.

`hd = design(d, 'cheby2', designoption, value, designoption, value, ...)` returns a Chebyshev II IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d, 'method')
```

For complete help about using `cheby1`, refer to the command line help system. For example, to get specific information about using `cheby2` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d, 'cheby2')
```

**Examples**

These examples use filter specification objects to construct Chebyshev type I filters. In the first example, you use the `matchexactly` option to ensure the performance of the filter in the passband.

```
d = fdesign.lowpass;  
hd = design(d, 'cheby2', 'matchexactly', 'passband');
```

`cheby2` also designs highpass, bandpass, and bandstop filters. Here is a highpass filter where you specify the filter order, the stopband edge frequency, and the stopband attenuation to get the filter exactly as required.

```
d = fdesign.highpass('n,fst,ast', 5, 20, 55, 50);
```

```
hd=design(d, 'cheby2');
```

The Filter Visualization Tool shows the highpass filter meets the specifications.

```
fvtool(hd)
```

By design, `cheby2` returns filters that use second-order sections. For many applications, and for most fixed-point applications, SOS filters are particularly well-suited for use.

`butter` | `cheby1` | `ellip`

**Purpose** Convert coupled allpass lattice to transfer function form

**Syntax**  
[b,a] = cl2tf(k1,k2)  
[b,a] = cl2tf(k1,k2,beta)  
[b,a,bp] = cl2tf(k1,k2)  
[b,a,bp] = cl2tf(k1,k2,beta)

**Description** [b,a] = cl2tf(k1,k2) returns the numerator and denominator vectors of coefficients b and a corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2} [H1(z) + H2(z)]$$

where  $H1(z)$  and  $H2(z)$  are the transfer functions of the allpass filters determined by  $k1$  and  $k2$ , and  $k1$  and  $k2$  are real vectors of reflection coefficients corresponding to allpass lattice structures.

[b,a] = cl2tf(k1,k2,beta) where  $k1$ ,  $k2$  and  $\beta$  are complex, returns the numerator and denominator vectors of coefficients b and a corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2} [ -(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z) ]$$

[b,a,bp] = cl2tf(k1,k2) where  $k1$  and  $k2$  are real, returns the vector bp of real coefficients corresponding to the numerator of the power complementary filter  $G(z)$

$$G(z) = Bp(z) / A(z) = \frac{1}{2} [H1(z) - H2(z)]$$

[b,a,bp] = cl2tf(k1,k2,beta) where  $k1$ ,  $k2$  and  $\beta$  are complex, returns the vector of coefficients bp of possibly complex coefficients corresponding to the numerator of the power complementary filter  $G(z)$

$$G(z) = Bp(z) / A(z) = \frac{1}{2^j} [ -(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z) ]$$

## Examples

```
[b,a]=cheby1(10,.5,.4); %TF2CL returns the reflection coeffs
[k1,k2,beta]=tf2cl(b,a); % Reconstruct the original filter
% plus the power complementary one.
[num,den,numpc]=cl2tf(k1,k2,beta);
[h,w]=freqz(num,den); hpc = freqz(numpc,den);
% and the power complementary one.
subplot(211);
plot(w./pi,20*log10(abs(h)), 'k'); hold on; grid on;
plot(w./pi,20*log10(abs(hpc)), 'b');
xlabel('Normalized Frequency (x \pi radians/sample)');
ylabel('dB');
legend('Original Filter', 'Power Complementary Filter', ...
      'Location', 'best');
subplot(212);
plot(w./pi,unwrap(angle(h)), 'k'); hold on; grid on;
xlabel('Normalized Frequency (x \pi radians/sample)');
ylabel('Phase (radians)');
plot(w./pi,unwrap(angle(hpc)), 'b');
```

<b>Purpose</b>	Coefficients for filters
<b>Syntax</b>	<pre>s = coeffs(ha) s = coeffs(hd) s = coeffs(hm) s = coeffs(hs) s = coeffs(hs,Name,Value)</pre>
<b>Description</b>	<p><code>s = coeffs(ha)</code> returns a structure containing the coefficients of the adaptive filter <code>ha</code>.</p> <p><code>s = coeffs(hd)</code> returns a structure containing the coefficients of the discrete-time filter <code>hd</code>.</p> <p><code>s = coeffs(hm)</code> returns a structure containing the coefficients of the multirate filter <code>hm</code>.</p> <p><code>s = coeffs(hs)</code> returns filter coefficients for the filter System object <code>hs</code>.</p> <p><code>s = coeffs(hs,Name,Value)</code> returns filter coefficients for the filter System object <code>hs</code> with additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Input Arguments</b>	<p><b>ha</b> Adaptive <code>adaptfilt</code> filter object.</p> <p><b>hd</b> Discrete-time <code>dfilt</code> filter object.</p> <p><b>hm</b> Multirate <code>mfilt</code> filter object. CIC-based filters do not have coefficients, so the function does not support CIC filter structures such as <code>mfilt.cicdecim</code>.</p> <p><b>hs</b></p>

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.FIRDecimator`
- `dsp.FIRRateConverter`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Arithmetic'**

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Output Arguments

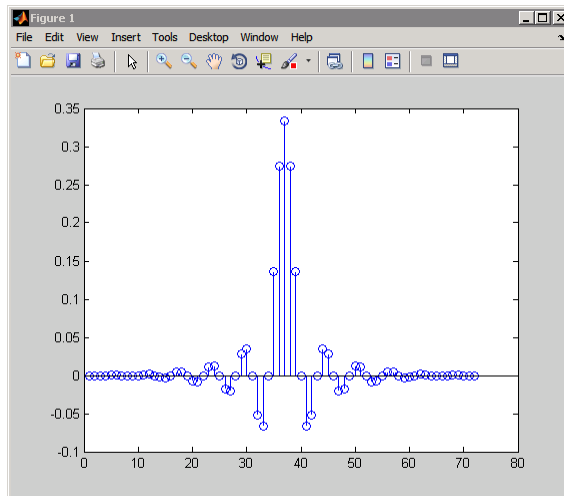

**s**

Structure with a single field, `Numerator`, containing filter coefficients. For adaptive filters, `s` contains the instantaneous frequency response available at the time you use the function.

## Examples

`coeffs` works the same way for all filters. This example uses a multirate filter `hm` to demonstrate the function.

```
hm=mfilt.firdecim(3);  
s=coeffs(hm);  
stem(s.Numerator)
```

The filter coefficients may be extracted by typing `s.Numerator` at the command prompt.

`zerophase` | `zplane`

# coeread

---

**Purpose** Read Xilinx COE file

**Syntax** `hd = coeread(filename)`

**Description** `hd = coeread(filename)` extracts the Distributed Arithmetic FIR filter coefficients defined in the XILINX CORE Generator .COE file specified by `filename`. It returns a `dfilt` object, the fixed-point filter `hd`. If you do not provide the file type extension `.coe` with the `filename`, the function assumes the `.coe` extension.

**See Also** `coewrite` | `dfilt` | `dfilt.dffir`

**Purpose** Write Xilinx COE file

**Syntax**

```
coewrite(hd)
coewrite(hd,radix)
coewrite(...,filename)
```

**Description** `coewrite(hd)` writes a XILINX Distributed Arithmetic FIR filter coefficient .COE file which can be loaded into the XILINX CORE Generator. The coefficients are extracted from the fixed-point `dfilt` object `hd`. Your fixed-point filter must be a direct form FIR structure `dfilt` object with one section and whose `Arithmetic` property is set to `fixed`. You cannot export single-precision, double-precision, or floating-point filters as .coe files, nor multiple-section filters. To enable you to provide a name for the file, `coewrite` displays a dialog box where you fill in the file name. If you do not specify the name of the output file, the default file name is `untitled.coe`.

`coewrite(hd,radix)` indicates the radix (number base) used to specify the FIR filter coefficients. Valid `radix` values are 2 for binary, 10 for decimal, and 16 for hexadecimal (default).

`coewrite(...,filename)` writes a XILINX.COE file to `filename`. If you omit the file extension, `coewrite` adds the .coe extension to the name of the file.

The `coewrite` function always generates the XILINX.COE file in your current folder. To use this function, you must have write permission in your current folder.

**Examples** `coewrite` generates an ASCII text file that contains the filter coefficients in a format the XILINX CORE Generator can read and load. In this example, you create a 30th-order fixed-point filter and generate the .coe file that includes the filter coefficients as well as associated information about the filter.

```
b = firceqip(30,0.4,[0.05 0.03]); hq = dfilt.dffir(b);
set(hq,'arithmetic','fixed'); coewrite(hq,10,'mycoefile');
```

## coewrite

---

The `coewrite` function generates the output file, `mycoefile.coe`, in your current folder. The `.coe` file contains the radix, coefficient width, and filter coefficients. The file reports the filter coefficients in column-major order. The radix, coefficient width, and filter coefficients are the minimum set of data needed in a `.coe` file.

`coeread` | `dfilt` | `dfilt.dffir`

## Purpose

Constrain coefficient wordlength

## Syntax

```
Hq = constraincoeffwl(Hd,wordlength)
Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)
Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',
    NSFlag)
Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)
Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)
```

## Description

`Hq = constraincoeffwl(Hd,wordlength)` returns a fixed-point filter `Hq` meeting the design specifications of the single-stage or multistage FIR filter object `Hd` with a wordlength of at most `wordlength` bits. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same `wordlength` is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `Hd` must be generated using `fdesign` and `design`. `constraincoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

`Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use. `Hq` is first filter among the trials to meet the specifications in `Hd` with a wordlength of at most `wordlength`.

`Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the constraint of the wordlength. By default `NSFlag` is true. Setting `NSFlag` to false constrains the wordlength without using noise-shaping.

`Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)` specifies the passband ripple tolerance in dB. `'Apasstol'` defaults to `1e-4`.

`Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. `'Astoptol'` defaults to `1e-2`

# constraincoeffwl

You must have the Fixed-Point Designer software installed to use this function.

## Examples

Design fixed-point filter with a wordlength of at most 11 bits:

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',.4,.5,1,60);  
Hd = design(Hf,'equiripple'); % 43 coefficients  
Hq = constraincoeffwl(Hd,11); % 45 11-bit coefficients  
hfvt = fvtool(Hd,Hq,'showreference','off');  
legend(hfvt,'Floating-point Filter','Fixed-point Filter');
```

## Tutorials

- “Fixed-Point Data Types”

<b>Purpose</b>	Convert filter structure of discrete-time or multirate filter
<b>Syntax</b>	<pre>hq = convert(hq,newstruct) hm = convert(hm,newstruct)</pre>
<b>Description</b>	<p><b>Discrete-Time Filters</b></p> <p>hq = convert(hq,newstruct) returns a quantized filter whose structure has been transformed to the filter structure specified by string newstruct. You can enter any one of the following quantized filter structures:</p> <ul style="list-style-type: none"><li>• 'antisymmetricfir': Antisymmetric finite impulse response (FIR)</li><li>• 'df1': Direct form I</li><li>• 'df1t': Direct form I transposed</li><li>• 'df1sos': Direct-Form I, Second-Order Sections</li><li>• 'df1tsos': Direct-Form I Transposed, Second-Order Sections</li><li>• 'df2': Direct form II</li><li>• 'df2t': Direct form II transposed. Default filter structure</li><li>• 'df2sos': Direct-Form II, Second-Order Sections</li><li>• 'df2tsos': Direct-Form II Transposed, Second-Order Sections</li><li>• 'dffir': FIR</li><li>• 'dffirt': Direct form FIR transposed</li><li>• 'latcallpass': Lattice allpass</li><li>• 'latticeca': Lattice coupled-allpass</li><li>• 'latticecapc': Lattice coupled-allpass power-complementary</li><li>• 'latticear': Lattice autoregressive (AR)</li><li>• 'latticemamax': Lattice moving average (MA) maximum phase</li><li>• 'latticemamin': Lattice moving average (MA) minimum phase</li></ul>

## convert

---

- 'latticearma': Lattice ARMA
- 'statespace': Single-input/single-output state-space
- 'symmetricfir': Symmetric FIR. Even and odd forms

All filters can be converted to the following structures:

- 'df1': Direct form I
- 'df1t': Direct form I transposed
- 'df1sos': Direct-Form I, Second-Order Sections
- 'df1tsos': Direct-Form I Transposed, Second-Order Sections
- 'df2': Direct form II
- 'df2t': Direct form II transposed. Default filter structure
- 'df2sos': Direct-Form II, Second-Order Sections
- 'df2tsos': Direct-Form II Transposed, Second-Order Sections
- 'statespace': Single-input/single-output state-space
- 'symmetricfir': Symmetric FIR. Even and odd forms

For the following filter classes, you can specify other conversions as well:

- Minimum phase FIR filters can be converted to `latticeamin`
- Maximum phase FIR filters can be converted to `latticeamax`
- Allpass filters can be converted to `latcallpass`

`convert` generates an error when you specify a conversion that is not possible.

### **Multirate Filters**

`hm = convert(hm,newstruct)` returns a multirate filter whose structure has been transformed to the filter structure specified by string `newstruct`. You can enter any one of the following multirate filter structures, defined by the strings shown, for `newstruct`:

### **Cascaded Integrator-Comb Structure**

- `cicdecim` — CIC-based decimator
- `cicinterp` — CIC-based interpolator

### FIR Structures

- `firdecim` — FIR decimator
- `firtdecim` — transposed FIR decimator
- `firfracdecim` — FIR fractional decimator
- `firinterp` — FIR interpolator
- `firfracinterp` — FIR fractional interpolator
- `firsrc` — FIR sample rate change filter
- `firholdinterp` — FIR interpolator that uses hold interpolation between input samples
- `firlinearinterp` — FIR interpolator that uses linear interpolation between input samples
- `fftfirinterp` — FFT-based FIR interpolator

You cannot convert between the FIR and CIC structures.

## Examples

```
[b,a]=ellip(5,3,40,.7); hq = dfilt.df2t(b,a);  
hq2 = convert(hq,'df1');
```

For an example of changing the structure of a multirate filter, try the following conversion from a CIC interpolator to a CIC interpolator with zero latency.

```
hm = mfilt.cicinterp(2,2,3,8,8);
```

---

**Note** The above example will generate a warning:

Warning: Using reference filter for structure conversion.  
Fixed-point attributes will not be converted.

Since CIC interpolators only use fixed-point arithmetic, the user may disregard this warning. The fixed-point structure will not be lost on conversion.

---

## See Also

`mfilt` | `dfilt`

**Purpose**

Estimate cost of discrete-time or multirate filter

**Syntax**

```
c = cost(hd)
c = cost(hm)
c = cost(hs)
c = cost(hs,Name,Value)
```

**Description**

`c = cost(hd)` returns a cost estimate `c` for the discrete-time filter `hd`.  
`c = cost(hm)` return a cost estimate `c` for the multirate filter `hm`.  
`c = cost(hs)` returns a cost estimate `c` for the filter System object `hs`.  
`c = cost(hs,Name,Value)` returns a cost estimate `c` for the filter System object `hs` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments****hd**

Discrete-time `dfilt` filter object.

**hm**

Multirate `mfilt` filter object.

**hs**

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`
- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

#### 'Arithmetic'

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the **CoefficientDataType** property and whether the System object is locked or unlocked.

#### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <b>CustomCoefficientsDataType</b> property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

**c**

Cost estimate. **c** has the following fields.

## cost

---

Estimated Value	Field Name	Description
Number of Multiplications	nmult	Number of multiplications during the filter run. nmult ignores multiplications by -1, 0, and 1 in the total multiple.
Number of Additions	nadd	Number of additions during the filter run.
Number of States	nstates	Number of states the filter uses.
Multiplications per Input Sample	multperinputsample	Number of multiplication operations performed for each input sample
Additions per Input Sample	addperinputsample	Number of addition operations performed for each input sample

### Examples

These examples show you the cost method applied to `dfilt` and `mfilt` objects.

```
hd = design(fdesign.lowpass);  
c = cost(hd);
```

When you are using a multirate filter object, `cost` works the same way.

```
d = fdesign.decimator(4,'cic');  
hm = design(d,'multisection');
```

### See Also

`qreport`

**Purpose**

Vector of SOS filters for cumulative sections

**Syntax**

```
h = cumsec(hd)
h = cumsec(hd,indices)
h = cumsec(hd,indices,secondary)
cumsec(hd,...)
h = cumsec(hs)
h = cumsec(hs,Name,Value)
```

**Description**

`h = cumsec(hd)` returns a vector `h` of SOS filter objects with the cumulative sections. Each element in `h` is a filter with the structure of the original filter. The first element is the first filter section of `hd`. The second element of `h` is a filter that represents the combination of the first and second sections of `hd`. The third element of `h` is a filter which combines sections 1, 2, and 3 of `hd`. This pattern continues until the final element of `h` contains all the sections of `hd` and should be identical to `hd`.

`h = cumsec(hd,indices)` returns a vector `h` of SOS filter objects whose indices into the original filter are in the vector `indices`.

`h = cumsec(hd,indices,secondary)` uses the secondary scaling points `secondary` in the sections to determine where the sections should be split.

`cumsec(hd,...)` uses FVTool to plot the magnitude response of the cumulative sections.

`h = cumsec(hs)` returns the cumulative sections of the `dsp.BiquadFilter` filter System object `hs`. You can also use the optional input arguments `indices` and `secondary` with this syntax. You can also omit the output argument `h` to use FVTool to plot the magnitude response of the cumulative sections.

`h = cumsec(hs,Name,Value)` returns the cumulative sections of the filter System object `hs` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **hd**

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsosfilter` object.

### **hs**

`dsp.BiquadFilter` filter System object.

### **indices**

Filter indices. Use `indices` to specify the filter sections `cumsec` uses to compute the cumulative responses.

### **secondary**

This option applies only when `hd` is a `df2sos` and `df1tsos` filter. For these second-order section structures, the secondary scaling points refer to the scaling locations between the recursive and the nonrecursive parts of the section (the "middle" of the section). Argument `secondary` accepts either `true` or `false`. By default, `secondary` is `false`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Arithmetic'**

`'double'` | `'single'` | `'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Examples

To demonstrate how cumsec works, this example plots the relative responses of the sections of a sixth-order filter SOS filter with three sections. Each curve adds one more section to form the filter response.

```
hs = fdesign.lowpass('n,fc',6,.4); hd = butter(hs);
h = cumsec(hd); hfvt = fvtool(h);
legend(hfvt,'First Section','First Two Sections','Overall Filter');
```

scale | scalecheck

**Purpose** Undo filter coefficient and gain changes caused by `normalize`

**Syntax** `denormalize(hq)`

**Description** `denormalize(hq)` reverses the coefficient changes you make when you use `normalize` with `hq`. The filter coefficients do not change if you call `denormalize(hq)` before you use `normalize(hq)`. Calling `denormalize` more than once on a filter does not change the coefficients after the first `denormalize` call.

**Examples** Make a quantized filter `hq` and normalize the filter coefficients. After normalizing the coefficients, restore them to their original values by reversing the effects of the `normalize` function.

```
d=fdesign.highpass('n,F3dB',14,0.45);
hd =design(d,'butter');
hd.arithmetic='fixed';
normalize(hd)
NormSOSMatrix = hd.sosMatrix;
denormalize(hd)
eqSOSMatrices = isequal(NormSOSMatrix,hd.sosMatrix);
% returns a 0
```

**See Also** `normalize`

# design

---

**Purpose** Apply design method to filter specification object

**Syntax**

```
H = design(D)
H = design(D,METHOD)
H = design(D,METHOD,PARAM1,VALUE1,PARAM2,VALUE2,...)
H = design(D,METHOD,OPTS)
Hs = design(D,...,'SystemObject',sysobjflag)
```

**Description** H = design(D) uses the filter specifications object D to generate a filter H. When you do not provide a design method as an input argument, design uses a default design method. Use designmethods(D,'default') to see the default design method for your filter specifications object.

H = design(D,METHOD) forces the design method specified by the string METHOD. METHOD must be one of the strings returned by designmethods. Use designmethods(D,'default') to determine which algorithm is used by default.

The design method you provide as the designmethod input argument must be one of the methods returned by

designmethods(d)

To help you design filters more quickly, the input argument METHOD accepts a variety of special keywords that force design to behave in different ways. The following table presents the keywords you can use for METHOD and how design responds to the keyword.

Designmethod Keyword	Description of the design Response
'FIR'	Forces design to produce an FIR filter. When no FIR design method exists for object D, design returns an error.
'IIR'	Forces design to produce an IIR filter. When no IIR design method exists for object D, design returns an error.

Designmethod Keyword	Description of the design Response
'ALLFIR'	Produces filters from every applicable FIR design method for the specifications in D, one filter for each design method. As a result, <code>design</code> returns multiple filters in the output object.
'ALLIIR'	Produces filters from every applicable IIR design method for the specifications in D, one filter for each design method. As a result, <code>design</code> returns multiple filters in the output object.
'ALL'	Designs filters using all applicable design methods for the specifications object D. As a result, <code>design</code> returns multiple filters, one for each design method. <code>design</code> uses the design methods in the order that <code>designmethods(D)</code> returns them.

Keywords are not case sensitive

When `design` returns multiple filters in the output object, use indexing to see the individual filters. For example, to see the third filter in H, enter

```
H(3)
```

`H = design(D,METHOD,PARAM1,VALUE1,PARAM2,VALUE2,...)` specifies design-method options. Use `help(D,METHOD)` for complete information on which design-method-specific options are available. You can also use `designopts(D,METHOD)` for a less-detailed listing of the design-method-specific options.

`H = design(D,METHOD,OPTS)` specifies design-method options using the structure `OPTS`. `OPTS` is usually obtained from `designopts` and then specified as an input to `design`. Use `help(D,METHOD)` for more information on optional inputs.

`Hs = design(D,...,'SystemObject',sysobjflag)` uses the filter specifications object D to generate a filter System object `Hs` when

`sysobjflag` is true. To generate System objects, you must have the DSP System Toolbox product installed. When `sysobjflag` is false, the function generates a `dfilt` or `mfilt` object `H`, as described previously. Design methods and design options for filter System objects are not necessarily the same as those for `dfilt` and `mfilt` objects. To check design methods for System objects, use `designmethods` with the `'SystemObject'`, `sysobjflag` syntax.

If you are specifying design-method-specific options using `OPTS`, you can also set `OPTS.SystemObject` to true instead of calling `design` with the `'SystemObject'`, `sysobjflag` syntax.

## Examples

Design an FIR equiripple lowpass filter. The passband edge frequency is  $0.2\pi$  radians/sample, and the stopband edge frequency is  $0.25\pi$  radians/sample. The passband ripple is 0.5 dB, and the stopband attenuation is 40 dB.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,0.5,40);
H = design(D); % Uses the default equiripple method.
```

If you have the DSP System Toolbox software installed, you can design a minimum-phase FIR equiripple filter. Design a minimum-phase filter and compare the pole-zero plots of the original and minimum-phase designs.

```
Hmin = design(D,'equiripple','MinPhase',true);
hfvt = fvtool([H Hmin],'analysis','polezero');
legend(hfvt,'Original Design','Minimum Phase Design');
```

Design a Butterworth lowpass filter. The passband edge frequency is  $0.2\pi$  radians/sample, and the stopband edge frequency is  $0.25\pi$  radians/sample. The passband ripple is 0.5 dB, and the stopband attenuation is 40 dB. Obtain help on the design options specific to the Butterworth design method. Design the filter with the `"MatchExactly"` option set to `'Passband'`.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,0.5,40);
% Query design-method-specific options
```

```
help(D,'butter')
% Match passband exactly
H = design(D,'butter','MatchExactly','passband');
```

If you have the DSP System Toolbox software, you can specify the  $P$ -th norm scaling on the second-order sections. Use L-infinity norm scaling in the time domain.

```
H = design(D,'butter','MatchExactly','passband','SOSScaleNorm','linf');
```

If you have the DSP System Toolbox software, you can create a filter System object.

```
Hs = design(D,'SystemObject',true);
```

# designmethods

---

<b>Purpose</b>	Methods available for designing filter from specification object
<b>Syntax</b>	<pre>M = designmethods(D) M = designmethods(D,'default') M = designmethods(D,TYPE) M = designmethods(D,'full') Ms = designmethods(D,...,'SystemObject',<i>sysobjflag</i>)</pre>
<b>Description</b>	<p>M = designmethods(D) returns the available design methods for the filter specification object, D, and the current value of the Specification property.</p> <p>M = designmethods(D,'default') returns the default design method for the filter specification object D and the current value of the Specification property.</p> <p>M = designmethods(D,TYPE) returns either the TYPE design methods that apply to D. TYPE can be either 'FIR' or 'IIR'.</p> <p>M = designmethods(D,'full') returns the full name for each of the available design methods. For example, designmethods with the 'full' argument returns Butterworth for the butter method.</p> <p>Ms = designmethods(D,...,'SystemObject',<i>sysobjflag</i>) returns the available design methods for designing filter System objects when <i>sysobjflag</i> is true. To use System objects, you must have the DSP System Toolbox product installed. When <i>sysobjflag</i> is false, the function checks methods for creating <i>dfilt</i> and <i>mfilt</i> objects, as described previously. Design methods and design options for filter System objects are not necessarily the same as those for <i>dfilt</i> and <i>mfilt</i> objects.</p>
<b>Examples</b>	<p>Construct a lowpass filter specification object and determine the valid design methods. Obtain detailed command line help on the Chebyshev type I design method.</p> <pre>D =fdesign.lowpass('Fp,Fst,Ap,Ast',500,600,0.5,60,1e4); M = designmethods(D) help(D,M{2})</pre>

The last line of the example is equivalent to `help(D, 'cheby1')`.

If you have DSP System Toolbox software installed, use the `'SystemObject'`, *sysobjflag* syntax to return design methods for a filter System object:

```
Ms = designmethods(D, 'SystemObject', true);
```

### See Also

[design](#) | [designopts](#) | [fdesign](#)

# designopts

---

**Purpose** Valid input arguments and values for specification object and method

**Syntax** `OPTS = designopts(D,METHOD)`

**Description** `OPTS = designopts(D,METHOD)` returns a structure array with the default design parameters used by the design method `METHOD`. `METHOD` must be one of the strings returned by `designmethods`.

Use `help(D,METHOD)` to get a description of the design parameters.

If you have DSP System Toolbox software installed, `OPTS` has the `SystemObject` property if at least one of the structures available for that design method is supported by System objects. However, not all structures for that design method are supported by System objects.

## Examples

Create a lowpass filter with a numerator and denominator order of 10 and a 3-dB frequency of  $0.2\pi$  radians/sample. Obtain the default design parameters for a Butterworth design, and test whether the filter structure is a direct-form II biquad.

```
D = fdesign.lowpass('Nb,Na,F3dB',10,10,0.2);
OPTS = designopts(D,'butter');
if (OPTS.FilterStructure == 'df2sos')
    fprintf('The default filter structure is Direct-Form II\n');
    fprintf('with second-order sections.\n');
end
```

If you have DSP System Toolbox software installed, `OPTS` has the `SystemObject` property.

## See Also

`design` | `designmethods` | `fdesign` | `validstructures`

**Purpose** Discrete-time filter

**Syntax**

```
hd = dfilt.structure(input1,...)
hd = [dfilt.structure(input1,...), dfilt.structure(input1,
...),...]
hd = design(d,'designmethod')
```

**Description** `hd = dfilt.structure(input1,...)` returns a discrete-time filter, `hd`, of type *structure*. Each structure takes one or more inputs. When you specify a `dfilt.structure` with no inputs, a default filter is created.

---

**Note** You must use a *structure* with `dfilt`.

---

`hd = [dfilt.structure(input1,...), dfilt.structure(input1,...),...]` returns a vector containing `dfilt` filters.

### Structures

Structures for `dfilt.structure` specify the type of filter structure. Available types of structures for `dfilt` are shown below.

<b>dfilt.structure</b>	<b>Description</b>	<b>Coefficient Mapping Support in realizemdl</b>
<code>dfilt.allpass</code>	Allpass filter	Supported
<code>dfilt.cascadeallpass</code>	Cascade of allpass filter sections	Supported
<code>dfilt.cascadewdfallpass</code>	Cascade of allpass wave digital filters	Supported
<code>dfilt.delay</code>	Delay	Not supported
<code>dfilt.df1</code>	Direct-form I	Supported
<code>dfilt.df1sos</code>	Direct-form I, second-order sections	Supported

<b>dfilt.structure</b>	<b>Description</b>	<b>Coefficient Mapping Support in realizedmdl</b>
dfilt.df1t	Direct-form I transposed	Supported
dfilt.df1tsos	Direct-form I transposed, second-order sections	Supported
dfilt.df2	Direct-form II	Supported
dfilt.df2sos	Direct-form II, second-order sections	Supported
dfilt.df2t	Direct-form II transposed	Supported
dfilt.df2tsos	Direct-form II transposed, second-order sections	Supported
dfilt.dffir	Direct-form FIR	Supported
dfilt.dffirt	Direct-form FIR transposed	Supported
dfilt.dfsymfir	Direct-form symmetric FIR	Supported
dfilt.dfasymfir	Direct-form antisymmetric FIR	Supported
dfilt.farrowfd	Generic fractional delay Farrow filter	Supported
dfilt.farrowlinearfd	Linear fractional delay Farrow filter	Not supported
dfilt.fftfir	Overlap-add FIR	Not supported
dfilt.latticeallpass	Lattice allpass	Supported
dfilt.latticear	Lattice autoregressive (AR)	Supported
dfilt.latticearma	Lattice autoregressive moving-average (ARMA)	Supported
dfilt.latticemamax	Lattice moving-average (MA) for maximum phase	Supported
dfilt.latticemamin	Lattice moving-average (MA) for minimum phase	Supported

<b>dfilt.structure</b>	<b>Description</b>	<b>Coefficient Mapping Support in realizemdl</b>
<code>dfilt.calattice</code>	Coupled, allpass lattice	Supported
<code>dfilt.calatticepc</code>	Coupled, allpass lattice with power complementary output	Supported
<code>dfilt.statespace</code>	State-space	Supported
<code>dfilt.scalar</code>	Scalar gain object	Supported
<code>dfilt.wdfallpass</code>	Allpass wave digital filter object	Supported
<code>dfilt.cascade</code>	Filters arranged in series	Supported
<code>dfilt.parallel</code>	Filters arranged in parallel	Supported

For more information on each structure, refer to its reference page.

`hd = design(d, 'designmethod')` returns the `dfilt` object `hd` resulting from the filter specification object `d` and the design method you specify in *designmethod*. When you omit the *designmethod* argument, `design` uses the default design method to construct a filter from the object `d`.

With this syntax, you design filters by:

- 1** Specifying the filter specifications, such as the response shape (perhaps `highpass`) and details (passband edges and attenuation).
- 2** Selecting a method (such as `equiripple`) to design the filter.
- 3** Applying the method to the specifications object with `design(d, 'designmethod')`.

Using the specification-based technique can be more effective than the coefficient-based filter design techniques.

### **Design Methods for Design Syntax**

When you use the `hd = design(d, 'designmethod')` syntax, you have a range of design methods available depending on `d`, the filter

specification object. The next table lists all of the design methods in the toolbox.

<b>Design Method String</b>	<b>Filter Design Result</b>
butter	Butterworth IIR
cheby1	Chebyshev Type I IIR
cheby2	Chebyshev Type II IIR
ellip	Elliptic IIR
equiripple	Equiripple with the same ripple in the pass and stopbands
firls	Least-squares FIR
fregsamp	Frequency-Sampled FIR
ifir	Interpolated FIR
iirlpnorm	Least Pth norm IIR
iirls	Least-Squares IIR
kaiserwin	Kaiser-windowed FIR
lagrange	Fractional delay filter
multistage	Multistage FIR
window	Windowed FIR

As the specifications object `d` changes, the available methods for designing filters from `d` also change. For instance, if `d` is a lowpass filter with the default specification `'Fp,Fst,Ap,Ast'`, the applicable methods are:

```
% Create an object to design a lowpass filter.
d=fdesign.lowpass;
designmethods(d) % What design methods apply to object d?
```

---

If you change the specification string to 'N,F3dB', the available design methods change:

```
d=fdesign.lowpass('N,F3dB');  
designmethods(d)
```

## Analysis Methods

Methods provide ways of performing functions directly on your `dfilt` object without having to specify the filter parameters again. You can apply these methods directly on the variable you assigned to your `dfilt` object.

For example, if you create a `dfilt` object, `hd`, you can check whether it has linear phase with `islinphase(hd)`, view its frequency response plot with `fvtool(hd)`, or obtain its frequency response values with `h = freqz(hd)`. You can use all of the methods described here in this way.

---

**Note** If your variable `hd` is a 1-D array of `dfilt` filters, the method is applied to each object in the array. Only `freqz`, `grpdelay`, `impz`, `is*`, `order`, and `stepz` methods can be applied to arrays. The `zplane` method can be applied to an array only if `zplane` is used without outputs.

---

Some of the methods listed here have the same name as functions in Signal Processing Toolbox software. They behave similarly.

<b>Method</b>	<b>Description</b>
<code>addstage</code>	Adds a stage to a <code>cascade</code> or <code>parallel</code> object, where a stage is a separate, modular filter. Refer to <code>dfilt.cascade</code> and <code>dfilt.parallel</code> .
<code>block</code>	<p><code>block(hd)</code> creates a block of the <code>dfilt</code> object. The <code>block</code> method can specify these properties and values:</p> <p>'Destination' indicates where to place the block. 'Current' places the block in the current Simulink model. 'New' creates a new model. Default value is 'Current'.</p> <p>'Blockname' assigns the entered string to the block name. Default name is 'Filter'.</p> <p>'OverwriteBlock' indicates whether to overwrite the block generated by the <code>block</code> method ('on') and defined by <code>Blockname</code>. Default is 'off'.</p> <p>'MapStates' specifies initial conditions in the block ('on'). Default is 'off'. Refer to "Using Filter States" in Signal Processing Toolbox documentation.</p>
<code>cascade</code>	Returns the series combination of two <code>dfilt</code> objects. Refer to <code>dfilt.cascade</code> .
<code>coeffs</code>	Returns the filter coefficients in a structure containing fields that use the same property names as those in the original <code>dfilt</code> .
<code>convert</code>	Converts a <code>dfilt</code> object from one filter structure, to another filter structure.

Method	Description
<code>fcfwrite</code>	<p>Writes a filter coefficient ASCII file. The file can contain a single filter or a vector of objects. The file can contain multirate filters (<code>mfilt</code>) or adaptive filters (<code>adaptfilt</code>). The default file name is <code>untitled.fcf</code>.</p> <p><code>fcfwrite(hd,filename)</code> writes to a disk file named <code>filename</code> in the current working folder. The <code>.fcf</code> extension is added automatically.</p> <p><code>fcfwrite(...,fmt)</code> writes the coefficients in the format <code>fmt</code>, where valid <code>fmt</code> strings are:</p> <ul style="list-style-type: none"> <li>'hex' for hexadecimal</li> <li>'dec' for decimal</li> <li>'bin' for binary representation</li> </ul>
<code>fftcoeffs</code>	Returns the frequency-domain coefficients used when filtering with a <code>dfilt.fftfir</code>
<code>filter</code>	Performs filtering using the <code>dfilt</code> object.
<code>firtype</code>	Returns the type (1-4) of a linear phase FIR filter.
<code>freqz</code>	Plots the frequency response in <code>fvtool</code> . Unlike the <code>freqz</code> function, this <code>dfilt</code> <code>freqz</code> method has a default length of 8192.
<code>grpdelay</code>	Plots the group delay in <code>fvtool</code> .
<code>impz</code>	Plots the impulse response in <code>fvtool</code> .
<code>impzlength</code>	Returns the length of the impulse response.
<code>info</code>	Displays <code>dfilt</code> information, such as filter structure, length, stability, linear phase, and, when appropriate, lattice and ladder length.

<b>Method</b>	<b>Description</b>
<code>isallpass</code>	Returns a logical 1 (i.e., true) if the <code>dfilt</code> object in an allpass filter or a logical 0 (i.e., false) if it is not.
<code>iscascade</code>	Returns a logical 1 if the <code>dfilt</code> object is cascaded or a logical 0 if it is not.
<code>isfir</code>	Returns a logical 1 if the <code>dfilt</code> object has finite impulse response (FIR) or a logical 0 if it does not.
<code>islinphase</code>	Returns a logical 1 if the <code>dfilt</code> object is linear phase or a logical 0 if it is not.
<code>ismaxphase</code>	Returns a logical 1 if the <code>dfilt</code> object is maximum-phase or a logical 0 if it is not.
<code>isminphase</code>	Returns a logical 1 if the <code>dfilt</code> object is minimum-phase or a logical 0 if it is not.
<code>isparallel</code>	Returns a logical 1 if the <code>dfilt</code> object has parallel stages or a logical 0 if it does not.
<code>isreal</code>	Returns a logical 1 if the <code>dfilt</code> object has real-valued coefficients or a logical 0 if it does not.
<code>isscalar</code>	Returns a logical 1 if the <code>dfilt</code> object is a scalar or a logical 0 if it is not scalar.
<code>issos</code>	Returns a logical 1 if the <code>dfilt</code> object has second-order sections or a logical 0 if it does not.
<code>isstable</code>	Returns a logical 1 if the <code>dfilt</code> object is stable or a logical 0 if it are not.

Method	Description
nsections	Returns the number of sections in a second-order sections filter. If a multistage filter contains stages with multiple sections, using nsections returns the total number of sections in all the stages (a stage with a single section returns 1).
nstages	Returns the number of stages of the filter, where a stage is a separate, modular filter.
nstates	Returns the number of states for an object.
order	Returns the filter order. If <code>hd</code> is a single-stage filter, the order is given by the number of delays needed for a minimum realization of the filter. If <code>hd</code> has multiple stages, the order is given by the number of delays needed for a minimum realization of the overall filter.
parallel	Returns the parallel combination of two <code>dfilt</code> filters. Refer to <code>dfilt.parallel</code> .
phasez	Plots the phase response in <code>fvtool</code> .
realizemdl	<p>(Available only with Simulink.)</p> <p><code>realizemdl(hd)</code> creates a Simulink model containing a subsystem block realization of your <code>dfilt</code>.</p> <p><code>realizemdl(hd,p1,v1,p2,v2,...)</code> creates the block using the properties <code>p1</code>, <code>p2</code>,... and values <code>v1</code>, <code>v2</code>,... specified.</p> <p>The following properties are available:</p> <p>'Blockname' specifies the name of the block. The default value is 'Filter'.</p> <p>'Destination' specifies whether to add the block to a current Simulink model or create a</p>

Method	Description
	<p>new model. Valid values are 'Current' and 'New'.</p> <p>'OverwriteBlock' specifies whether to overwrite an existing block that was created by <code>realizemdl</code> or create a new block. Valid values are 'on' and 'off'. Only blocks created by <code>realizemdl</code> are overwritten.</p> <p>The following properties optimize the block structure. Specifying 'on' turns the optimization on and 'off' creates the block without optimization. The default for each block is 'off'.</p> <p>'OptimizeZeros' removes zero-gain blocks.</p> <p>'OptimizeOnes' replaces unity-gain blocks with a direct connection.</p> <p>'OptimizeNegOnes' replaces negative unity-gain blocks with a sign change at the nearest summation block.</p> <p>'OptimizeDelayChains' replaces delay chains made up of <math>n</math> unit delays with a single delay by <math>n</math>.</p>
removestage	Removes a stage from a cascade or parallel <code>dfilt</code> . Refer to <code>dfilt.cascade</code> and <code>dfilt.parallel</code> .
setstage	Overwrites a stage of a cascade or parallel <code>dfilt</code> . Refer to <code>dfilt.cascade</code> and <code>dfilt.parallel</code> .

Method	Description
sos	<p>Converts the <code>dfilt</code> to a second-order sections <code>dfilt</code>. If <code>hd</code> has a single section, the returned filter has the same class.</p> <p><code>sos(hd, flag)</code> specifies the ordering of the second-order sections. If <code>flag='UP'</code>, the first row contains the poles closest to the origin, and the last row contains the poles closest to the unit circle. If <code>flag='down'</code>, the sections are ordered in the opposite direction. The zeros are always paired with the poles closest to them.</p> <p><code>sos(hd, flag, scale)</code> specifies the scaling of the gain and the numerator coefficients of all second-order sections. <code>scale</code> can be <code>'none'</code>, <code>'inf'</code> (infinity-norm), or <code>'two'</code> (2-norm). Using infinity-norm scaling with up ordering minimizes the probability of overflow in the realization. Using 2-norm scaling with down ordering minimizes the peak roundoff noise.</p>
ss	<p>Converts the <code>dfilt</code> to state-space. To see the separate <code>A, B, C, D</code> matrices for the state-space model, use <code>[A, B, C, D]=ss(hd)</code>.</p>
stepz	<p>Plots the step response in <code>fvtool</code></p> <p><code>stepz(hd, n)</code> computes the first <code>n</code> samples of the step response.</p> <p><code>stepz(hd, n, Fs)</code> separates the time samples by <math>T = 1/Fs</math>, where <code>Fs</code> is assumed to be in hertz.</p>
sysobj	<p>Converts the <code>dfilt</code> to a filter System object. See the reference page for a list of supported objects.</p>

Method	Description
tf	Converts the <code>dfilt</code> to a transfer function.
zerophase	Plots the zero-phase response in <code>fvtool</code> .
zpk	Converts the <code>dfilt</code> to zeros-pole-gain form.
zplane	Plots a pole-zero plot in <code>fvtool</code> .

## Viewing Properties

As with any object, use `get` to view a `dfilt` properties. To see a specific property, use

```
get(hd, 'property')
```

To see all properties for an object, use

```
get(hd)
```

---

**Note** `dfilt` objects include an arithmetic property. You can change the internal arithmetic of the filter from double-precision to single-precision using: `hd.arithmetic = 'single'`.

If you have Fixed-Point Designer software, you can change the arithmetic property to fixed-point using: `hd.arithmetic = 'fixed'`

---

## Changing Properties

To set specific properties, use

```
set(hd, 'property1', value, 'property2', value, ...)
```

You must use single quotation marks around the property name. Use single quotation marks around the value argument when the value is a string, such as `specifyall` or `fixed`.

## Copying an Object

To create a copy of an object, use the `copy` method.

```
h2 = copy(hd)
```

---

**Note** Using the syntax `H2 = hd` copies only the object handle and does not create a new, independent object.

---

## Converting Between Filter Structures

To change the filter structure of a `dfilt` object `hd`, use

```
hd2 = convert(hd, 'structure_string');
```

where `structure_string` is any valid structure name in single quotation marks. If `hd` is a cascade or parallel structure, each stage is converted to the new structure.

## Using Filter States

Two properties control the filter states:

- `states` — Stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions. For `df1`, `df1t`, `df1sos` and `df1tsos` structures, `states` returns a `filtstates` object.
- `PersistentMemory` — Controls whether filter states are saved. The default value is `'false'`, which causes the initial conditions to be reset to zero before filtering and turns off the display of states information. Setting `PersistentMemory` to `'true'` allows the filter to use your initial conditions or to reuse the final conditions from a previous filtering operation as the initial conditions of the next filtering operation. The `true` setting also displays information about the filter states.

---

**Note** If you set the `states` and want to use them for filtering, you must set `PersistentMemory` to `'true'` before you use the filter.

---

## Examples

Create a direct-form I filter, and use a method to see if it is stable.

```
[b,a] = butter(8,0.25);  
hd = dfilt.df1(b,a);  
isstable(hd)
```

If a `dfilt`'s numerator values do not fit on a single line, a description of the vector is displayed. To see the specific numerator values for this example, use

```
B = get(hd,'numerator');  
% or  
B1 = hd.numerator;
```

Create an array containing two `dfilt` objects, apply a method and verify that the method acts on both objects. Use a method to test whether the objects are FIR objects.

```
b = fir1(5,.5);  
hd = dfilt.dfir(b);           % Create an FIR filter object  
[b,a] = butter(5,.5);       % Create IIR filter  
hd(2) = dfilt.df2t(b,a);    % Create DF2T object and place  
                             % in the second column of hd.  
  
[h,w] = freqz(hd);  
test_fir = isfir(hd)  
% hd(1) is FIR and hd(2) is not.
```

Refer to the reference pages for each structure for more examples.

```

**Purpose** Allpass filter

**Syntax** `hd = dfilt.allpass(c)`

**Description** `hd = dfilt.allpass(c)` constructs an allpass filter with the minimum number of multipliers from the elements in vector `c`. To be valid, `c` must contain one, two, three, or four real elements. The number of elements in `c` determines the order of the filter. For example, `c` with two elements creates a second-order filter and `c` with four elements creates a fourth-order filter.

The transfer function for the allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

given the coefficients in `c`.

To construct a cascade of allpass filter objects, use `dfilt.cascadeallpass`. For more information about creating cascades of allpass filters, refer to `dfilt.cascadeallpass`.

## Properties

The following table provides a list of all the properties associated with an allpass `dfilt` object.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.

# dfilt.allpass

---

Property Name	Brief Description
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Examples

This example constructs and displays the information about a second-order allpass filter that uses the minimum number of multipliers.

```
c = [1.5, 0.7];  
% Create a second-order dfilt object.  
hd = dfilt.allpass(c);
```

## See Also

`dfilt` | `dfilt.cascadeallpass` | `dfilt.cascadewdfallpass` | `dfilt.latticeallpass` | `mfilt.iirdecim` | `mfilt.iirinterp`

**Purpose** Coupled-allpass, lattice filter

**Syntax**  
`hd = dfilt.calattice(k1,k2,beta)`  
`hd = dfilt.calattice`

**Description** `hd = dfilt.calattice(k1,k2,beta)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, which is two allpass, lattice filter structures coupled together. The lattice coefficients for each structure are vectors `k1` and `k2`. Input argument `beta` is shown in the diagram below.

`hd = dfilt.calattice` returns a default, discrete-time coupled-allpass, lattice filter object, `hd`. The default values are `k1 = k2 = []`, which is the default value for `dfilt.latticeallpass`, and `beta = 1`. This filter passes the input through to the output unchanged.

## Examples

Specify a third-order lattice coupled-allpass filter structure for a `dfilt` filter, `hd` with the following code.

```
k1 = [0.9511 + 1j*0.3088; 0.7511 + 1j*0.1158];  
k2 = 0.7502 - 1j*0.1218;  
beta = 0.1385 + 1j*0.9904;  
hd = dfilt.calattice(k1,k2,beta);
```

The `Allpass1` and `Allpass2` properties store vectors of coefficients.

## See Also

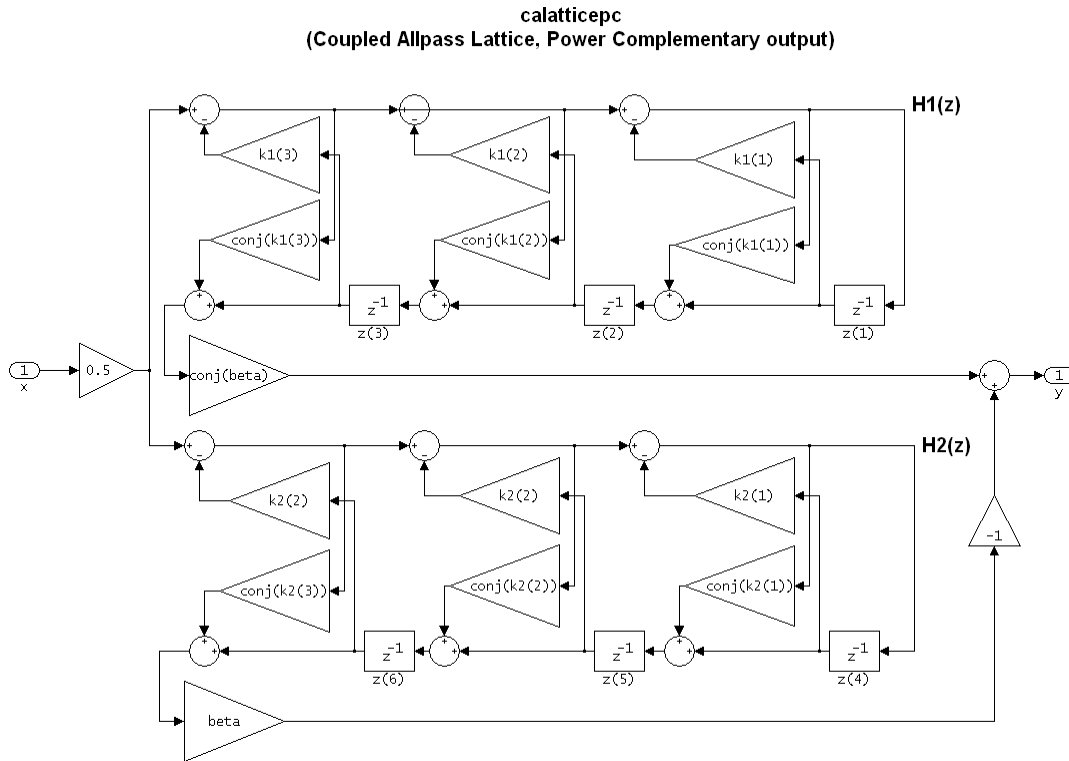

`dfilt.calatticepc` | `dfilt` | `dfilt.latticeallpass` |  
`dfilt.latticear` | `dfilt.latticearma` | `dfilt.latticemax` |  
`dfilt.latticemin`

**Purpose** Coupled-allpass, power-complementary lattice filter

**Syntax** `hd = dfilt.calatticepc(k1,k2)`  
`hd = dfilt.calatticepc`

**Description** `hd = dfilt.calatticepc(k1,k2)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. This object is two allpass lattice filter structures coupled together to produce complementary output. The lattice coefficients for each structure are vectors, `k1` and `k2`, respectively. `beta` is shown in the following diagram.

`hd = dfilt.calatticepc` returns a default, discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. The default values are `k1 = k2 = []`, which is the default value for the `dfilt.latticeallpass`. The default for `beta = 1`. This filter passes the input through to the output unchanged.

## Examples

Specify a third-order lattice coupled-allpass power complementary filter structure for a filter  $h_d$  with the following code. You see from the returned properties that `Allpass1` and `Allpass2` contain vectors of coefficients for the constituent filters.

```
k1 = [0.9511 + 0.3088i; 0.7511 + 0.1158i];
k2 = 0.7502 - 0.1218i;
beta = 0.1385 + 0.9904i;
hd = dfilt.calatticepc(k1,k2,beta);
```

To see the coefficients for `Allpass1`, check the property values.

```
get(hd, 'Allpass1')
```

# dfilt.cascade

**Purpose** Cascade of discrete-time filters

**Syntax** Refer to `dfilt.cascade` in Signal Processing Toolbox documentation for more information.

**Description** `hd = dfilt.cascade(filterobject1,filterobject2,...)` returns a discrete-time filter object `hd` of type `cascade`, which is a serial interconnection of two or more filter objects `filterobject1`, `filterobject2`, and so on. `dfilt.cascade` accepts any combination of `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

You can use the standard notation to cascade one or more filters:

```
cascade(hd1,hd2,...)
```

where `hd1`, `hd2`, and so on can be mixed types, such as `dfilt` objects and `mfilt` objects.

`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the cascade must be the same arithmetic format — `double`, `single`, or `fixed`. `hd`, the filter object returned, inherits the format of the cascaded filters.

**Examples** Cascade a lowpass filter and a highpass filter to produce a bandpass filter.

```
[b1,a1]=butter(8,0.6); % Lowpass
[b2,a2]=butter(8,0.4,'high'); % Highpass
h1=dfilt.df2t(b1,a1);
h2=dfilt.df2t(b2,a2);
hcas=dfilt.cascade(h1,h2); % Bandpass with passband 0.4-0.6
% View stage 1 with hcas.Stage(1)
```

**See Also** `dfilt` | `dfilt.parallel` | `dfilt.scalar`

## Purpose

Cascade of allpass discrete-time filters

## Syntax

```
hd = dfilt.cascadeallpass(c1,c2,...)
```

## Description

`hd = dfilt.cascadeallpass(c1,c2,...)` constructs a cascade of allpass filters, each of which uses the minimum number of multipliers, given the filter coefficients provided in `c1`, `c2`, and so on.

Each vector `c` represents one section in the cascade filter. `c` vectors must contain one, two, three, or four elements as the filter coefficients for each section. As a result of the design algorithm, each section is a `dfilt.allpass` structure whose coefficients are given in the matching `c` vector, such as the `c1` vector contains the coefficients for the first stage.

States for each section are shared between sections.

Vectors `c` do not have to be the same length. You can combine various length vectors in the input arguments. For example, you can cascade fourth-order sections with second-order sections, or first-order sections.

For more information about the vectors `ci` and about the transfer function of each section, refer to `dfilt.allpass`.

Generally, you do not construct these allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadeallpass` to design an IIR filter.

## Properties

In the next table, the row entries are the filter properties and a brief description of each property.

# dfilt.cascadeallpass

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Examples

Two examples show how `dfilt.cascadeallpass` works in very different applications — designing a halfband IIR filter and constructing an allpass cascade of `dfilt` objects.

First, design the IIR halfband filter using cascaded allpass filters. Each branch of the parallel cascade construction is a `cascadeallpass` filter object.

```
tw = 100; % Transition width of filter to be designed, 100 Hz.  
ast = 80; % Stopband attenuation of filter to be designed, 80dB.  
fs = 2000; % Sampling frequency of signal to be filtered.  
% Store halfband design specs in the specifications object d.  
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual filter design. `hd` contains two `dfilt.cascadeallpass` objects.

```
hd = design(d,'ellip','filterstructure','cascadeallpass');  
% Get summary information about one dfilt.cascadeallpass stage.  
StageInfo = hd.Stage(1).Stage(1);
```

This second example constructs a `dfilt.cascadeallpass` filter object directly given allpass coefficients for the input vectors.

```
section1 = 0.8;  
section2 = [1.2,0.7];  
section3 = [1.3,0.9];  
hd = dfilt.cascadeallpass(section1,section2,section3);  
% Get information about the filter  
% return informatio in character array  
S = info(hd);
```

# dfilt.cascadewdfallpass

---

**Purpose** Cascade allpass WDF filters to construct allpass WDF

**Syntax** `hd = dfilt.cascadewdfallpass(c1,c2,...)`

**Description** `hd = dfilt.cascadewdfallpass(c1,c2,...)` constructs a cascade of allpass wave digital filters given the allpass coefficients in the vectors `c1`, `c2`, and so on.

Each `c` vector contains the coefficients for one section of the cascaded filter. `C` vectors must have one, two, or four elements (coefficients). Three element vectors are not supported.

When the `c` vector has four elements, the first and third elements of the vector must be 0. Each section of the cascade is an allpass wave digital filter, from `dfilt.wdfallpass`, with the coefficients given by the corresponding `c` vector. That is, the first section has coefficients from vector `c1`, the second section coefficients come from `c2`, and on until all of the `c` vectors are used.

You can mix the lengths of the `c` vectors. They do not need to be the same length. For example, you can cascade several fourth-order sections (`length(c) = 4`) with first or second-order sections.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

Generally, you do not construct these WDF allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadewdfallpass` to design an IIR filter.

For more information about the `c` vectors and the transfer function for the allpass filters, refer to `dfilt.wdfallpass`.

**Properties** In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass wave digital filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Examples

To demonstrate two approaches to using `dfilt.cascadewdfallpass` to design a filter, these examples show both direct construction and construction as part of another filter.

The first design shown creates an IIR halfband filter that uses lattice wave digital filters. Each branch of the parallel connection in the lattice is an allpass cascade wave digital filter.

```
tw = 100; % Transition width of filter, 100 Hz.  
ast = 80; % Stopband attenuation of filter, 80 dB.  
fs = 2000; % Sampling frequency of signal to filter.  
% Store halfband specs.  
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

# dfilt.cascadewdfallpass

Now perform the actual halfband design process. `hd` contains two `dfilt.cascadewdfallpass` filters.

```
hd = design(d,'ellip','filterstructure','cascadewdfallpass');  
% Summary info on dfilt.cascadewdfallpass.  
StageSummary = hd.stage(1).stage(2);
```

This example demonstrates direct construction of a `dfilt.cascadewdfallpass` filter with allpass coefficients.

```
section1 = 0.8;  
section2 = [1.5,0.7];  
section3 = [1.8,0.9];  
hd = dfilt.cascadewdfallpass(section1,section2,section3);
```

**See Also**      `dfilt` | `dfilt.wdfallpass`

# dfilt.delay

---

**Purpose** Delay filter

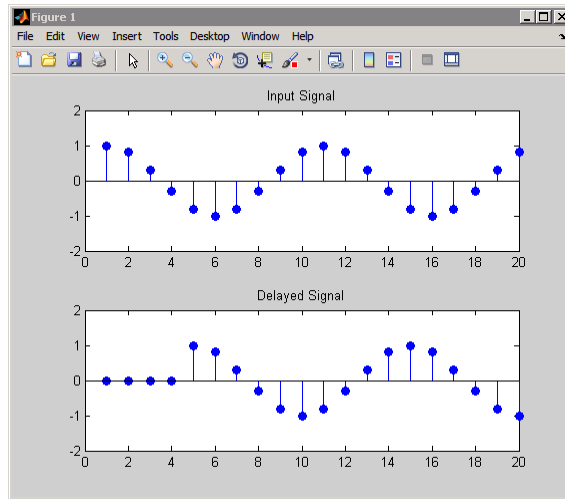

**Syntax**  
`Hd = dfilt.delay`  
`Hd = dfilt.delay(latency)`

**Description** `Hd = dfilt.delay` returns a discrete-time filter, `Hd`, of type `delay`, which adds a single delay to any signal filtered with `Hd`. The filtered signal has its values shifted by one sample.

`Hd = dfilt.delay(latency)` returns a discrete-time filter, `Hd`, of type `delay`, which adds the number of delay units specified in `latency` to any signal filtered with `Hd`. The filtered signal has its values shifted by the `latency` number of samples. The values that appear before the shifted signal are the filter states.

**Examples** Create a delay filter with a latency of 4 and filter a simple signal to view the impact of applying a delay.

```
h = dfilt.delay(4);  
Fs = 1000;  
t = 0:1/Fs:1;  
sig = cos(2*pi*100*t);  
y = filter(h,sig);  
subplot(211);  
stem(sig,'markerfacecolor',[0 0 1]);  
axis([0 20 -2 2]);  
title('Input Signal');  
subplot(212);  
stem(y,'markerfacecolor',[0 0 1]);  
axis([0 20 -2 2]);  
title('Delayed Signal');
```

**See Also** [dfilt](#)

# dfilt.df1

---

**Purpose** Discrete-time, direct-form I filter

**Syntax** Refer to `dfilt.df1` in Signal Processing Toolbox documentation.

**Description** `hd = dfilt.df1` returns a default discrete-time, direct-form I filter object that uses double-precision arithmetic. By default, the numerator and denominator coefficients `b` and `a` are set to 1. With these coefficients the filter passes the input to the output without changes.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “`Arithmetic`” on page 5-19.

---

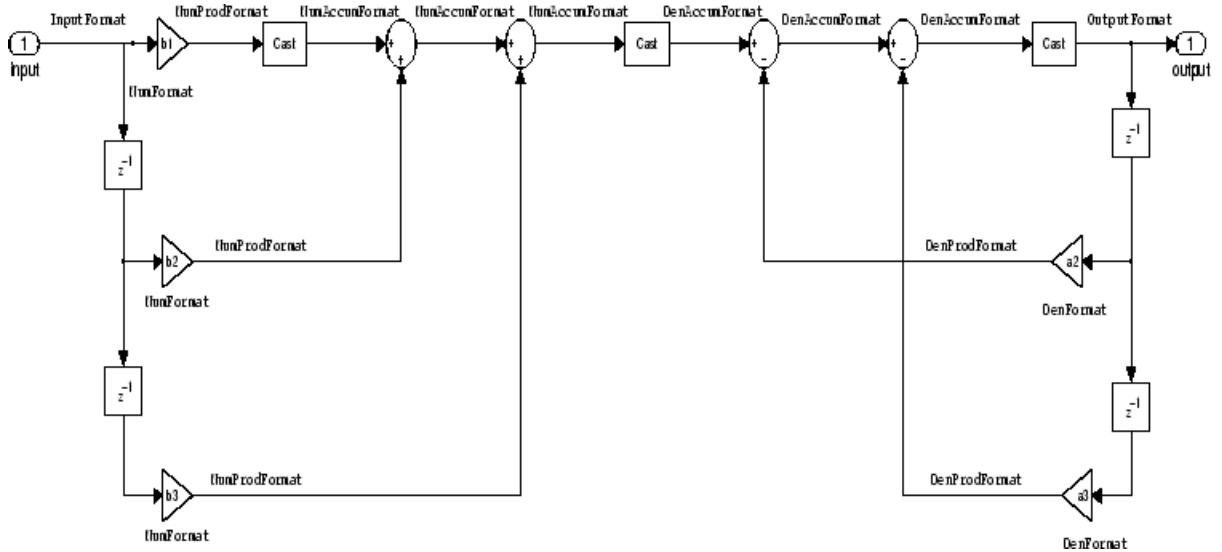

**Note** `a(1)`, the leading denominator coefficient, cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

## Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented by `dfilt.df1`. To help you see how the filter processes the coefficients, input, output, and states of the filter, as well as numerical operations, the figure includes the locations of the arithmetic and data type format elements within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFormat	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFormat	CoeffWordLength	DenFracLength	CoeffAutoScale , SignedDenominator
DenProdFormat	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFormat	InputWordLength	InputFracLength	None
NumAccumFormat	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFormat	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFormat	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFormat	OutputWordLength	OutputFracLength	OutputMode

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFormat, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFormat refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with df1 implementations of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use `get(hd)` where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

<b>Property Name</b>	<b>Brief Description</b>
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length the filter algorithm uses to interpret the results of product operations involving denominator coefficients. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to <code>false</code> .
Denominator	Stores the denominator coefficients for the IIR filter.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.

<b>Property Name</b>	<b>Brief Description</b>
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>

# dfilt.df1

---

Property Name	Brief Description
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Examples

Specify a second-order direct-form I structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df1(b,a);  
% Convert hd to fixed-point filter  
set(hd,'arithmetic','fixed')
```

## See Also

`dfilt` | `dfilt.df1t` | `dfilt.df2` | `dfilt.df2t`

**Purpose**

Discrete-time, SOS direct-form I filter

**Syntax**

Refer to `dfilt.df1sos` in Signal Processing Toolbox documentation.

**Description**

`hd = dfilt.df1sos(s)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 5-19.

`hd = dfilt.df1sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, and so on.

`hd = dfilt.df1sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. When you do not specify `g`, all gains default to one.

`hd = dfilt.df1sos` returns a default, discrete-time, second-order section, direct-form I filter object, `hd`. This filter passes the input through to the output unchanged.

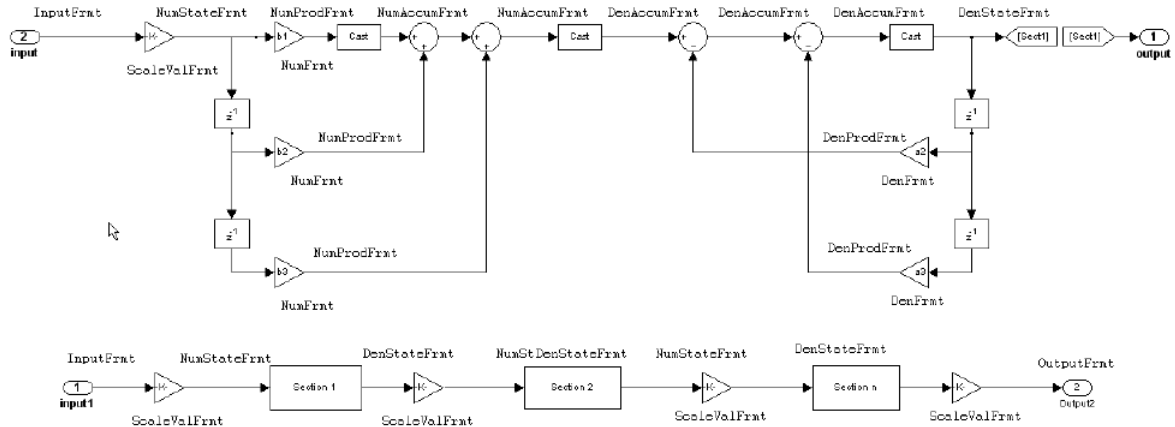

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

## Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented in second-order sections by `dfilt.df1sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFrmt` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Similarly consider `NumFrmt`, which refers to the word and fraction lengths

(CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValueFracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with

product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with SOS implementation of direct-form I `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output

Property Name	Brief Description
	from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>AccumWordLength</code>	Sets the word length used to store data in the accumulator/buffer.
<code>Arithmetic</code>	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
<code>CastBeforeSum</code>	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
<code>CoeffAutoScale</code>	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
<code>CoeffWordLength</code>	Specifies the word length to apply to filter coefficients.
<code>DenAccumFracLength</code>	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>DenFracLength</code>	Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .

Property Name	Brief Description
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
DenStateWordLength	Specifies the word length used to represent the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumStateFracLength	Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.

Property Name	Brief Description
NumWordFracLength	Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	Determines the word length applied for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
ScaleValueFracLength	<p>Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable <code>AutoScaleMode</code> by setting it to <code>false</code>.</p>

Property Name	Brief Description
ScaleValues	Scaling for the filter objects in SOS filters.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type <code>double</code> to represent the coefficients.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a fixed-point, second-order section, direct-form I `dfilt` object with the following code:

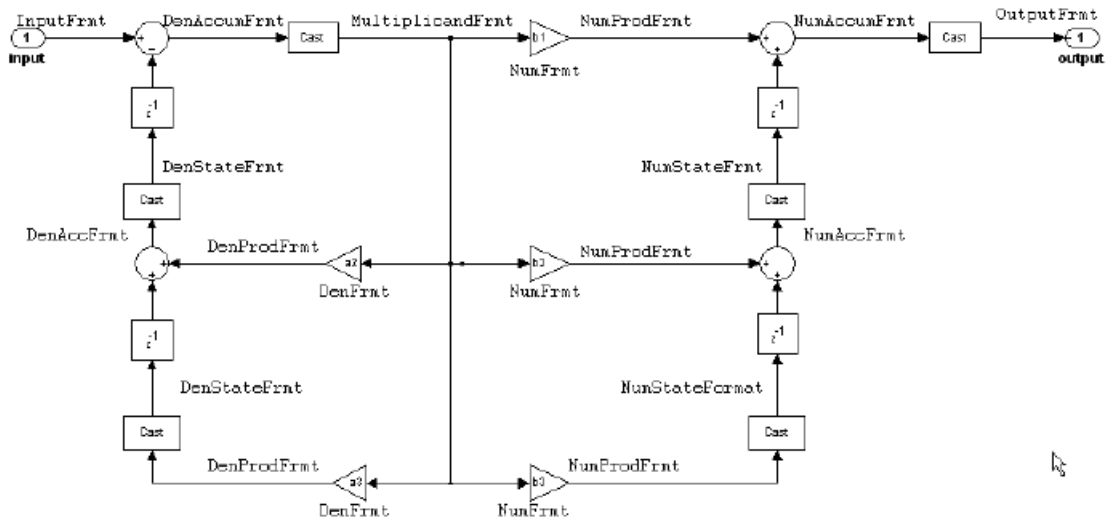

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df1sos(b,a);  
% Convert to fixed-point filter  
hd.arithmetic = 'fixed';
```

<b>Purpose</b>	Discrete-time, direct-form I transposed filter
<b>Syntax</b>	Refer to <code>dfilt.df1t</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>hd = dfilt.df1t(b,a)</code> returns a discrete-time, direct-form I transposed filter object <code>hd</code>, with numerator coefficients <code>b</code> and denominator coefficients <code>a</code>.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to “<code>Arithmetic</code>” on page 5-19.</p> <p><code>hd = dfilt.df1t</code> returns a default, discrete-time, direct-form I transposed filter object <code>hd</code>, with <code>b=1</code> and <code>a=1</code>. This filter passes the input through to the output unchanged.</p> <hr/> <p><b>Note</b> The leading coefficient of the denominator <code>a(1)</code> cannot be 0. To allow you to change the arithmetic setting to <code>fixed</code> or <code>single</code>, <code>a(1)</code> must be equal to 1.</p> <hr/>
<b>Fixed-Point Filter Structure</b>	The following figure shows the signal flow for the transposed direct-form I filter implemented by <code>dfilt.df1t</code> . To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, , Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
Multiplicandfrmt	Multiplicand-WordLength	Multiplicand-FracLength	CastBeforeSum
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWord- Length	NumStateFrac- Length	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From

reviewing the table, you see that the `DenProdFrmt` refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with `df1t` implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>AccumWordLength</code>	Sets the word length used to store data in the accumulator/buffer.

Property Name	Brief Description
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
Denominator	Holds the denominator coefficients for the filter.

<b>Property Name</b>	<b>Brief Description</b>
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
MultiplicandFracLength	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
MultiplicandWordLength	Sets the word length applied to the values input to a multiply operation (the multiplicands).
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.

Property Name	Brief Description
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
NumStateFracLength	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"><li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li><li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li></ul>

Property Name	Brief Description
	<ul style="list-style-type: none"><li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li></ul>
<code>OutputWordLength</code>	Determines the word length used for the output data.
<code>OverflowMode</code>	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
<code>ProductMode</code>	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul>

Property Name	Brief Description
	The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateAutoScale	Setting autoscaling for filter states to <code>true</code> reduces the possibility of overflows occurring during fixed-point operations. Set to <code>false</code> , <code>StateAutoScale</code> lets the filter select the fraction length to limit the overflow potential.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a second-order direct-form I transposed filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df1t(b,a);  
% Convert filter to single-precision arithmetic  
set(hd,'arithmetic','single')
```

## See Also

---

<b>Purpose</b>	Discrete-time, SOS direct-form I transposed filter
<b>Syntax</b>	Refer to <code>dfilt.df1tsos</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>hd = dfilt.df1tsos(s)</code> returns a discrete-time, second-order section, direct-form I, transposed filter object <code>hd</code>, with coefficients given in the <code>s</code> matrix.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to .</p> <p><code>hd = dfilt.df1tsos(b1,a1,b2,a2,...)</code> returns a discrete-time, second-order section, direct-form I, transposed filter object <code>hd</code>, with coefficients for the first section given in the <code>b1</code> and <code>a1</code> vectors, for the second section given in the <code>b2</code> and <code>a2</code> vectors, etc.</p> <p><code>hd = dfilt.df1tsos(...,g)</code> includes a gain vector <code>g</code>. The elements of <code>g</code> are the gains for each section. The maximum length of <code>g</code> is the number of sections plus one. If <code>g</code> is not specified, all gains default to one.</p> <p><code>hd = dfilt.df1tsos</code> returns a default, discrete-time, second-order section, direct-form I, transposed filter object, <code>hd</code>. This filter passes the input through to the output unchanged.</p>

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

## Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I transposed filter implemented using second-order sections by `dfilt.df1tsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
MultiplicandFrmt	Multiplicand-WordLength	Multiplicand-FracLength	CastBeforeSum
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValue-FracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with SOS implementation of transposed direct-form I `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.

<b>Property Name</b>	<b>Brief Description</b>
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.

Property Name	Brief Description
InputWordLength	Specifies the word length applied to interpret input data.
MultiplicandFracLength	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
MultiplicandWordLength	Sets the word length applied to the values input to a multiply operation (the multiplicands)
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
NumStateFracLength	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.

Property Name	Brief Description
NumStateWordLength	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"><li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li><li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li><li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li></ul>

Property Name	Brief Description
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <b>FullPrecision</b> ), or whether to keep the most significant bit ( <b>KeepMSB</b> ) or least significant bit ( <b>KeepLSB</b> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <b>ProductMode</b> to <b>SpecifyPrecision</b> .

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li></ul>

Property Name	Brief Description
	<ul style="list-style-type: none"> <li>• round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.
ScaleValues	Scaling for the filter objects in SOS filters.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Property Name	Brief Description
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/sectiondatatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

With the following code, this example specifies a second-order section, direct-form I transposed `dfilt` object for a filter. Then convert the filter to fixed-point operation.

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df1tsos(b,a);  
set(hd,'arithmetic','fixed')
```

**See Also**

[dfilt](#) | [dfilt.df1sos](#) | [dfilt.df2sos](#) | [dfilt.df2tsos](#)

**Purpose** Discrete-time, direct-form II filter

**Syntax** Refer to `dfilt.df2` in Signal Processing Toolbox documentation.

**Description** `hd = dfilt.df2(b,a)` returns a discrete-time, direct-form II filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “`Arithmetic`” on page 5-19.

`hd = dfilt.df2` returns a default, discrete-time, direct-form II filter object `hd`, with `b = 1` and `a = 1`. This filter passes the input through to the output unchanged.

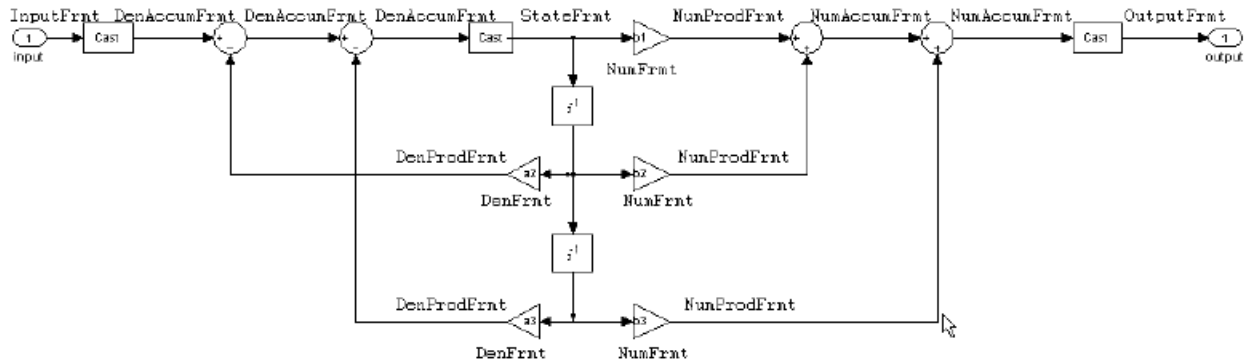

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

## Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II filter implemented by `dfilt.df2`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFrmt` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFrmt`, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
StateFrmt	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the df2 implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any dfilt object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.

<b>Property Name</b>	<b>Brief Description</b>
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
Denominator	Holds the denominator coefficients for IIR filters.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .

<b>Property Name</b>	<b>Brief Description</b>
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.

Property Name	Brief Description
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"><li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li><li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li><li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li></ul>
OutputWordLength	<p>Determines the word length used for the output data.</p>
OverflowMode	<p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.</p>

Property Name	Brief Description
ProductMode	<p>Determines how the filter handles the output of product operations. Choose from full precision (<code>FullPrecision</code>), or whether to keep the most significant bit (<code>KeepMSB</code>) or least significant bit (<code>KeepLSB</code>) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code>.</p>
PersistentMemory	<p>Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.</p>
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative</li></ul>

Property Name	Brief Description
	numbers, and toward positive infinity for positive numbers.  The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a second-order direct-form II filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df2(b,a);  
% Change filter to fixed-point  
set(hd,'arithmetic','fixed')
```

## See Also

`dfilt` | `dfilt.df1` | `dfilt.df1t` | `dfilt.df2t`

**Purpose**

Discrete-time, SOS, direct-form II filter

**Syntax**

Refer to `dfilt.df2sos` in Signal Processing Toolbox documentation.

**Description**

`hd = dfilt.df2sos(s)` returns a discrete-time, second-order section, direct-form II filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 5-19.

`hd = dfilt.df2sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II object, `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

`hd = dfilt.df2sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df2sos` returns a default, discrete-time, second-order section, direct-form II filter object, `hd`. This filter passes the input through to the output unchanged.

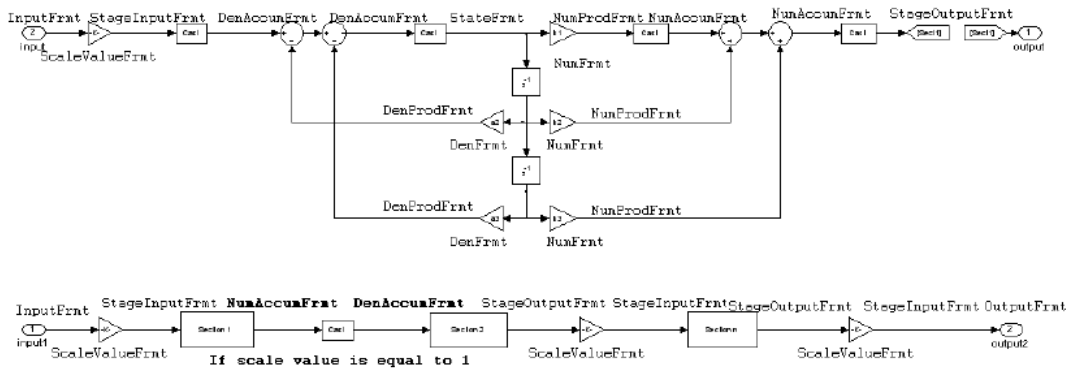

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

## Fixed-Point Filter Structure

The figure below shows the signal flow for the direct-form II filter implemented with second-order sections by `dfilt.df2sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFrmt` label refers to the word length and fraction length used to interpret the data input to the filter. The `frmt` properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFrmt`, which refers to the word and fraction lengths

(CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, sosMatrix
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength, sosMatrix
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, sosMatrix
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmat	CoeffWordLength	ScaleValue-FracLength	CoeffAutoScale, ScaleValues
SectionInputFormt	SectionInput-WordLength	SectionInput-FracLength	SectionInput-AutoScale
SectionOutputFrmt	SectionOutput-WordLength	SectionOutput-FracLength	SectionOutput-AutoScale
StateFrmt	StateWordLength	StateFracLength	CastBeforeSum, States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with second-order section implementation of direct-form II `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.

Property Name	Brief Description
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.

Property Name	Brief Description
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
ScaleValueFracLength	<p>Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable <code>AutoScaleMode</code> by setting it to <code>false</code>.</p>

Property Name	Brief Description
ScaleValues	Scaling for the filter objects in SOS filters.
SectionInputAutoScale	Tells the filter whether to set the stage input data format to minimize the occurrence of overflow conditions.
SectionInputFracLength	Lets you set the fraction length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionInputWordLength	Lets you set the word length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionOutputAutoScale	Tells the filter whether to set the section output data format to minimize the occurrence of overflow conditions.
SectionOutputFracLength	Lets you set the fraction length for section outputs in SOS filters, if you set SectionOutputAutoScale to off.
SectionOutputWordLength	Lets you set the word length for section outputs in SOS filters, if you set SectionOutputAutoScale to false.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.

Property Name	Brief Description
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a second-order section, direct-form II `dfilt` object for a Butterworth filter converted to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2sos(s,g);
% Convert filter to fixed-point
hd.arithmetic='fixed';
```

## See Also

`dfilt` | `dfilt.df1sos` | `dfilt.df1tsos` | `dfilt.df2tsos`

<b>Purpose</b>	Discrete-time, direct-form II transposed filter
<b>Syntax</b>	Refer to <code>dfilt.df2t</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>hd = dfilt.df2t(b,a)</code> returns a discrete-time, direct-form II transposed filter object <code>hd</code>, with numerator coefficients <code>b</code> and denominator coefficients <code>a</code>.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to “Arithmetic” on page 5-19.</p> <p><code>hd = dfilt.df2t</code> returns a default, discrete-time, direct-form II transposed filter object <code>hd</code>, with <code>b = 1</code> and <code>a = 1</code>. This filter passes the input through to the output unchanged.</p>

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

## Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II transposed filter implemented by `dfilt.df2t`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt.” In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The

format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFrmt`, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	None
StateFrmt	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `DenProdFrmt`, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the `DenProdFrmt` refers to the

properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with `df2t` implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>AccumWordLength</code>	Sets the word length used to store data in the accumulator/buffer.

<b>Property Name</b>	<b>Brief Description</b>
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
Denominator	Holds the denominator coefficients for IIR filters.

Property Name	Brief Description
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data.
OutputWordLength	Determines the word length used for the output data.

<b>Property Name</b>	<b>Brief Description</b>
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	<p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>

Property Name	Brief Description
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Create a fixed-point filter by specifying a second-order direct-form II transposed filter structure for a `dfilt` object, and then converting the double-precision arithmetic setting to fixed-point.

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df2t(b,a);  
% Convert filter to fixed-point  
set(hd,'arithmetic','fixed')
```

## See Also

`dfilt` | `dfilt.df1` | `dfilt.df1t` | `dfilt.df2`

<b>Purpose</b>	Discrete-time, SOS direct-form II transposed filter
<b>Syntax</b>	Refer to <code>dfilt.df2tsos</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>hd = dfilt.df2tsos(s)</code> returns a discrete-time, second-order section, direct-form II, transposed filter object <code>hd</code>, with coefficients given in the matrix <code>s</code>.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to “Arithmetic” on page 5-19.</p> <p><code>hd = dfilt.df2tsos(b1,a1,b2,a2,...)</code> returns a discrete-time, second-order section, direct-form II, transposed filter object <code>hd</code>, with coefficients for the first section given in the <code>b1</code> and <code>a1</code> vectors, for the second section given in the <code>b2</code> and <code>a2</code> vectors, etc.</p> <p><code>hd = dfilt.df2tsos(...,g)</code> includes a gain vector <code>g</code>. The elements of <code>g</code> are the gains for each section. The maximum length of <code>g</code> is the number of sections plus one. If <code>g</code> is not specified, all gains default to one.</p> <p><code>hd = dfilt.df2tsos</code> returns a default, discrete-time, second-order section, direct-form II, transposed filter object, <code>hd</code>. This filter passes the input through to the output unchanged.</p>

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

## Fixed-Point Filter Structure

The figure below shows the signal flow for the second-order section transposed direct-form II filter implemented by `dfilt.df2tsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, SignedNumerator

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValueFracLength	CoeffAutoScale, ScaleValues
SectionInputFrmt	SectionInput-WordLength	SectionInput-FracLength	
SectionOutputFrmt	SectionOutput-WordLength	SectionOutput-FracLength	
StateFrmt	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with second-order section implementation of transposed direct-form II dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

<b>Property Name</b>	<b>Brief Description</b>
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .

Property Name	Brief Description
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
ScaleValueFracLength	<p>Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable <code>AutoScaleMode</code> by setting it to <code>false</code>.</p>
ScaleValues	<p>Scaling for the filter objects in SOS filters.</p>
Signed	<p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>

Property Name	Brief Description
SosMatrix	Holds the filter coefficients as property values — you use <code>set</code> and <code>get</code> to modify them. Displays the matrix in the format [sections x coefficients/section data type].
SectionInputFracLength	Lets you set the fraction length for section inputs in SOS filters, if you set <code>SectionInputAutoScale</code> to <code>false</code> .
SectionInputWordLength	Lets you set the word length for section inputs in SOS filters, if you set <code>SectionInputAutoScale</code> to <code>false</code> .
SectionOutputFracLength	Lets you set the fraction length for section outputs in SOS filters, if you set <code>SectionOutputAutoScale</code> to <code>off</code> .
SectionOutputWordLength	Lets you set the word length for section outputs in SOS filters, if you set <code>SectionOutputAutoScale</code> to <code>false</code> .
StateAutoScale	Setting autoscaling for filter states to <code>true</code> reduces the possibility of overflows occurring during fixed-point operations. Set to <code>false</code> , <code>StateAutoScale</code> lets the filter select the fraction length to limit the overflow potential.
StateFracLength	When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Construct a second-order section Butterworth filter for fixed-point filtering. Start by specifying a Butterworth filter, and then convert the filter to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
```

```
[s,g] = zp2sos(z,p,k);  
hd = dfilt.df2tsos(s,g);  
% convert filter to fixed-point  
hd.arithmetic='fixed';
```

# dfilt.dfasymfir

---

<b>Purpose</b>	Discrete-time, direct-form antisymmetric FIR filter
<b>Syntax</b>	Refer to <code>dfilt.dfasymfir</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>hd = dfilt.dfasymfir(b)</code> returns a discrete-time, direct-form, antisymmetric FIR filter object <code>hd</code>, with numerator coefficients <code>b</code>.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to “<code>Arithmetic</code>” on page 5-19.</p> <p><code>hd = dfilt.dfasymfir</code> returns a default, discrete-time, direct-form, antisymmetric FIR filter object <code>hd</code>, with <code>b=1</code>. This filter passes the input through to the output unchanged.</p>

---

**Note** Only the coefficients in the first half of vector `b` are used because `dfilt.dfasymfir` assumes the coefficients in the second half are antisymmetric to those in the first half. For example, in the figure coefficients,  $b(4) = -b(3)$ ,  $b(5) = -b(2)$ , and  $b(6) = -b(1)$ .

---

## Fixed-Point Filter Structure

The following figure shows the signal flow for the odd-order antisymmetric FIR filter implemented by `dfilt.dfasymfir`. The even-order filter uses similar flow. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
AccumFormat	AccumWordLength	AccumFracLength	None
InputFormat	InputWordLength	InputFracLength	None
NumFormat	CoeffWordLength	NumFracLength	CoeffAutoScale, , Signed, Numerator
OutputFormat	OutputWordLength	OutputFracLength	None
ProductFormat	ProductWordLength	ProductFracLength	None
TapSumFormat	InputWordLength	InputFracLength	InputFormat

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with an antisymmetric FIR implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [27]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[33]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

## dfilt.dfasymfir

Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data. Also controls TapSumFracLength.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data. Also determines TapSumWordLength.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [27]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [33]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). <ul style="list-style-type: none"> <li>• <b>ceil</b> - Round toward positive infinity.</li> <li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <b>fix</b> - Round toward zero.</li> </ul>

Name	Values	Description
		<ul style="list-style-type: none"><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	<code>fi</code> object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

## Examples

### Odd Order

Specify a fifth-order direct-form antisymmetric FIR filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];  
hd = dfilt.dfasymfir(b);
```

## Even Order

Specify a fourth-order direct-form antisymmetric FIR filter structure for `dfilt` object `hd`, with the following code:

```
b = [-0.01 0.1 0.0 -0.1 0.01];  
hd = dfilt.dfasymfir(b);  
hd.arithmetic='fixed';  
FilterCoefs = get(hd,'numerator');  
% or equivalently  
FilterCoefs = hd.numerator;
```

## See Also

[dfilt](#) | [dfilt.dffir](#) | [dfilt.dffirt](#) | [dfilt.dfsymfir](#)

**Purpose** Discrete-time, direct-form FIR filter

**Syntax** Refer to `dfilt.dffir` in Signal Processing Toolbox documentation.

**Description** `hd = dfilt.dffir(b)` returns a discrete-time, direct-form finite impulse response (FIR) filter object `hd`, with numerator coefficients `b`.  
Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

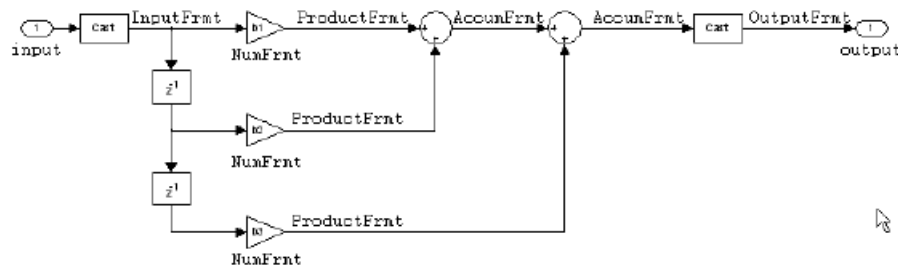

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “`Arithmetic`” on page 5-19.

`hd = dfilt.dffir` returns a default, discrete-time, direct-form FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form FIR filter implemented by `dfilt.dffir`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFrmt` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFrmt`, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFrmt	AccumWordLength	AccumFracLength	None
InputFrmt	InputWordLength	InputFracLength	None
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
OutputFrmt	OutputWordLength	OutputFracLength	None
ProductFrmt	ProductWordLength	ProductFracLength	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `ProductFrmt`, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `ProductFrmt` refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with direct-form FIR implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[34]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.

Name	Values	Description
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Name	Values	Description
ProductFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [32]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <b>ceil</b> - Round toward positive infinity.</li> <li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <b>fix</b> - Round toward zero.</li> <li>• <b>floor</b> - Round toward negative infinity.</li> <li>• <b>nearest</b> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <b>round</b> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. # dfilt.dffir

Name	Values	Description
		and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

## Examples

Specify a second-order direct-form FIR filter structure for a `dfilt` object `hd`, with the following code that constructs the filter in double-precision format and then converts the filter to fixed-point operation:

```
b = [0.05 0.9 0.05];  
hd = dfilt.dffir(b);  
% Create fixed-point filter  
hd.arithmetic='fixed';  
% Change FilterInternals property to  
% SpecifyPrecision enabling other properties  
hd.FilterInternals='SpecifyPrecision';
```

<b>Purpose</b>	Discrete-time, direct-form FIR transposed filter
<b>Syntax</b>	Refer to <code>dfilt.dffirt</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>hd = dfilt.dffirt(b)</code> returns a discrete-time, direct-form FIR transposed filter object <code>hd</code>, with numerator coefficients <code>b</code>.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to “Arithmetic” on page 5-19.</p> <p><code>hd = dfilt.dffirt</code> returns a default, discrete-time, direct-form FIR transposed filter object <code>hd</code>, with <code>b = 1</code>. This filter passes the input through to the output unchanged.</p>
<b>Fixed-Point Filter Structure</b>	<p>The following figure shows the signal flow for the transposed direct-form FIR filter implemented by <code>dfilt.dffirt</code>. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.</p>

# dfilt.dffirt

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
AccumFormat	AccumWordLength	AccumFracLength	None
InputFormat	InputWordLength	InputFracLength	None
NumFormat	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
OutputFormat	OutputWordLength	OutputFracLength	None
ProductFormat	ProductWordLength	ProductFracLength	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the transposed direct-form FIR implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[34]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [30]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [34]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

Name	Values	Description
OverflowMode	saturate, [wrap]	<p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.</p>
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <b>ceil</b> - Round toward positive infinity.</li><li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <b>fix</b> - Round toward zero.</li><li>• <b>floor</b> - Round toward negative infinity.</li><li>• <b>nearest</b> - Round toward nearest. Ties round toward positive infinity.</li><li>• <b>round</b> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul>

Name	Values	Description
		The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

### Examples

Specify a second-order direct-form FIR transposed filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.05 0.9 0.05];
hd = dfilt.dffirt(b);
set(hd, 'arithmetic', 'fixed')
```

### See Also

`dfilt` | `dfilt.dffir` | `dfilt.dfasymfir` | `dfilt.dfsymfir`

# dfilt.dfsymfir

---

<b>Purpose</b>	Discrete-time, direct-form symmetric FIR filter
<b>Syntax</b>	Refer to <code>dfilt.dfsymfir</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>hd = dfilt.dfsymfir(b)</code> returns a discrete-time, direct-form symmetric FIR filter object <code>hd</code>, with numerator coefficients <code>b</code>.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to “Arithmetic” on page 5-19.</p> <p><code>hd = dfilt.dfsymfir</code> returns a default, discrete-time, direct-form symmetric FIR filter object <code>hd</code>, with <code>b=1</code>. This filter passes the input through to the output unchanged.</p>

---

**Note** Only the coefficients in the first half of vector `b` are used because `dfilt.dfsymfir` assumes the coefficients in the second half are symmetric to those in the first half. In the following figure, for example,  $b(3) = 0$ ,  $b(4) = b(2)$  and  $b(5) = b(1)$ .

---

<b>Fixed-Point Filter Structure</b>	In the following figure you see the signal flow diagram for the symmetric FIR filter that <code>dfilt.dfsymfir</code> implements.
-------------------------------------	---

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
AccumFrmt	AccumWordLength	AccumFracLength	None
InputFrmt	InputWordLength	InputFracLength	None
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
OutputFrmt	OutputWordLength	OutputFracLength	None
ProductFrmt	ProductWordLength	ProductFracLength	None
TapSumFrmt	InputWordLength	InputFracLength	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFrmt, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFrmt refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the symmetric FIR implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

## Examples

### Odd Order

Specify a fifth-order direct-form symmetric FIR filter structure for a `dfilt` object `hd`, with the following code:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd = dfilt.dfsymfir(b);
% Create fixed-point filter
set(hd,'arithmetic','fixed')
% Change FilterInternals property to
% SpecifyPrecision
hd.Filterinternals='SpecifyPrecision';
```

### Even Order

Specify a fourth-order, fixed-point, direct-form symmetric FIR filter structure for a `dfilt` object `hd`, with the following code:

```
b = [-0.01 0.1 0.8 0.1 -0.01];
hd = dfilt.dfsymfir(b);
set(hd,'arithmetic','fixed');
```

## See Also

`dfilt` | `dfilt.dfasymfir` | `dfilt.dffir` | `dfilt.dffirt`

# dfilt.farrowfd

---

**Purpose** Fractional Delay Farrow filter

**Syntax** Hd = dfilt.farrowfd(D, COEFFS)

**Description** Hd = dfilt.farrowfd(D, COEFFS)  
Constructs a discrete-time fractional delay Farrow filter with COEFFS coefficients and D delay.

**Examples** Farrow filters can be designed with the dfilt.farrowfd filter designer.

```
coeffs = [-1/6 1/2 -1/3 0;1/2 -1 -1/2 1;  
-1/2 1/2 1 0;1/6 0 -1/6 0];  
Hd = dfilt.farrowfd(0.5, coeffs);
```

Design a cubic fractional delay filter with the Lagrange method.

```
fdelay = .2; % Fractional delay  
d = fdesign.fracdelay(fdelay,'N',3);  
Hd = design(d, 'lagrange', 'FilterStructure', 'farrowfd');  
fvtool(Hd, 'Analysis', 'grpdelay');
```

For more information about fractional delay filter implementations, see the “Fractional Delay Filters Using Farrow Structures” example, `farrowdemo`.

## How To

- `dfilt`

# dfilt.farrowlinearfd

---

**Purpose** Farrow Linear Fractional Delay filter

**Syntax** Hd = DFILT.FARROWLINEARFD(D)

**Description** Hd = DFILT.FARROWLINEARFD(D)  
Constructs a discrete-time linear fractional delay Farrow filter with the delay D.

**Examples** Farrow linear fractional delay filter with 1/2 sample delay:

```
Hd = dfilt.farrowlinearfd(0.5);  
n = cos(pi/10*(0:159));  
y = filter(Hd,x);  
stem(x(1:40));  
axis([0 40 -2 2]);  
hold on;  
stem(y(1:40),'color',[1 0 0],'markerfacecolor',[1 0 0]);  
legend('Original Signal','Filtered Signal','Location','best');
```

For more information about fractional delay filter implementations, see the “Fractional Delay Filters Using Farrow Structures” example, `farrowdemo`.

**How To** • `dfilt`

---

<b>Purpose</b>	Discrete-time, overlap-add, FIR filter
<b>Syntax</b>	<pre>Hd = dfilt.fftfir(b,len) Hd = dfilt.fftfir(b) Hd = dfilt.fftfir</pre>
<b>Description</b>	<p>This object uses the overlap-add method of block FIR filtering, which is very efficient for streaming data.</p> <p><code>Hd = dfilt.fftfir(b,len)</code> returns a discrete-time, FFT, FIR filter, <code>Hd</code>, with numerator coefficients, <code>b</code> and block length, <code>len</code>. The block length is the number of input points to use for each overlap-add computation.</p> <p><code>Hd = dfilt.fftfir(b)</code> returns a discrete-time, FFT, FIR filter, <code>Hd</code>, with numerator coefficients, <code>b</code> and block length, <code>len=100</code>.</p> <p><code>Hd = dfilt.fftfir</code> returns a default, discrete-time, FFT, FIR filter, <code>Hd</code>, with the numerator <code>b=1</code> and block length, <code>len=100</code>. This filter passes the input through to the output unchanged.</p>

---

**Note** When you use a `dfilt.fftfir` object to filter, the input signal length must be an integer multiple of the object's block length, `len`. The resulting number of FFT points = (filter length + the block length - 1). The filter is most efficient if the number of FFT points is a power of 2.

---

The `fftfir` uses an overlap-add block processing algorithm, which is represented as follows,

where  $len$  is the block length and  $M$  is the length of the numerator-1,  $(length(b) - 1)$ , which is also the number of states. The output of each convolution is a block that is longer than the input block by a tail of  $(length(b) - 1)$  samples. These tails overlap the next block and are added to it. The states reported by `dfilt.fftfir` are the tails of the final convolution.

## Examples

Create an FFT FIR discrete-time filter with coefficients from a 30<sup>th</sup> order lowpass equiripple design:

```
b = firpm(30,[0 .1 .2 .5]*2,[1 1 0 0]);  
Hd = dfilt.fftfir(b);  
% To obtain frequency domain coefficients  
% used in filtering  
Coeffs = fftcoeffs(Hd);
```

<b>Purpose</b>	Discrete-time, lattice allpass filter
<b>Syntax</b>	Refer to <code>dfilt.latticeallpass</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>hd = dfilt.latticeallpass(k)</code> returns a discrete-time, lattice allpass filter object <code>hd</code>, with lattice coefficients, <code>k</code>.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to “Arithmetic” on page 5-19.</p> <p><code>hd = dfilt.latticeallpass</code> returns a default, discrete-time, lattice allpass filter object <code>hd</code>, with <code>k=[]</code>. This filter passes the input through to the output unchanged.</p>
<b>Fixed-Point Filter Structure</b>	<p>The following figure shows the signal flow for the allpass lattice filter implemented by <code>dfilt.latticeallpass</code>. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.</p>

# dfilt.latticeallpass

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the allpass lattice implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
<code>AccumFracLength</code>	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>AccumWordLength</code>	Sets the word length used to store data in the accumulator/buffer.
<code>Arithmetic</code>	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
<code>CastBeforeSum</code>	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

<b>Property Name</b>	<b>Brief Description</b>
<code>CoeffAutoScale</code>	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> property value to specify the precision used.
<code>CoeffWordLength</code>	Specifies the word length to apply to filter coefficients.
<code>FilterStructure</code>	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
<code>InputFracLength</code>	Specifies the fraction length the filter uses to interpret input data.
<code>InputWordLength</code>	Specifies the word length applied to interpret input data.
<code>Lattice</code>	Any lattice structure coefficients. No default value.
<code>LatticeFracLength</code>	Sets the fraction length applied to the lattice coefficients.
<code>OutputFracLength</code>	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .

Property Name	Brief Description
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"><li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li><li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li><li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li></ul>
OutputWordLength	<p>Determines the word length used for the output data.</p>
OverflowMode	<p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.</p>
ProductFracLength	<p>For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <b>ProductMode</b> to <b>SpecifyPrecision</b>.</p>

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> </ul>

Property Name	Brief Description
	<ul style="list-style-type: none"><li>• nearest - Round toward nearest. Ties round toward positive infinity.</li><li>• round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a third-order lattice allpass filter structure for a `dfilt` object `hd`, with the following code:

```
k = [.66 .7 .44];  
hd=dfilt.latticeallpass(k);  
% convert to fixed-point arithmetic  
hd.arithmetic = 'fixed';
```

## See Also

```
dfilt | dfilt.latticear | dfilt.latticearma |  
dfilt.latticemamax | dfilt.latticemamin
```

**Purpose** Discrete-time, lattice, autoregressive filter

**Syntax** Refer to `dfilt.latticear` in Signal Processing Toolbox documentation.

**Description** `hd = dfilt.latticear(k)` returns a discrete-time, lattice autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd, 'arithmetic', 'single');
```

- To change to fixed-point filtering, enter

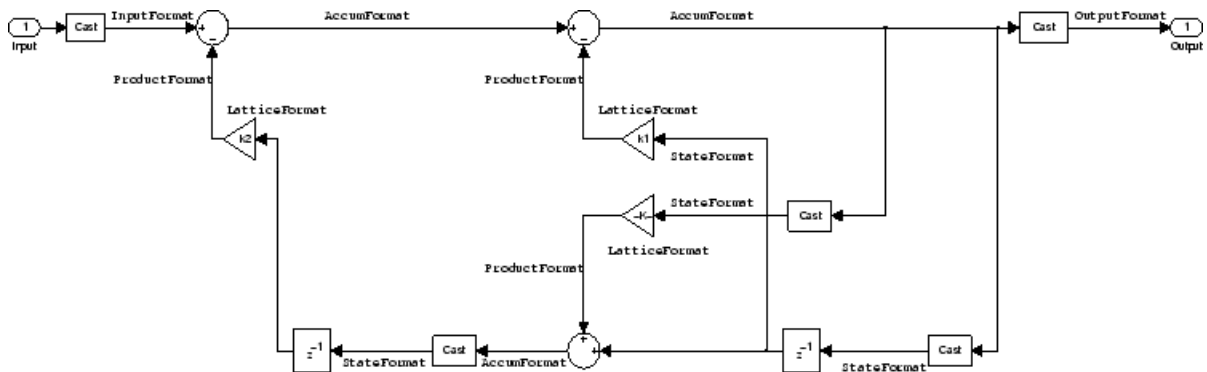

```
set(hd, 'arithmetic', 'fixed');
```

For more information about the property `Arithmetic`, refer to “`Arithmetic`” on page 5-19.

`hd = dfilt.latticear` returns a default, discrete-time, lattice autoregressive filter object `hd`, with `k=[]`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticear`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the autoregressive lattice implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

---

For further information about the properties of this filter or any dfilt object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

<b>Property Name</b>	<b>Brief Description</b>
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .

Property Name	Brief Description
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	<p>Determines the word length used for the output data.</p>
OverflowMode	<p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.</p>
ProductFracLength	<p>For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <b>ProductMode</b> to <b>SpecifyPrecision</b>.</p>

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <b>FullPrecision</b> ), or whether to keep the most significant bit ( <b>KeepMSB</b> ) or least significant bit ( <b>KeepLSB</b> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <b>ProductMode</b> to <b>SpecifyPrecision</b> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <b>ProductMode</b> to <b>SpecifyPrecision</b> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <b>False</b> is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). <ul style="list-style-type: none"><li>• <b>ceil</b> - Round toward positive infinity.</li><li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <b>fix</b> - Round toward zero.</li><li>• <b>floor</b> - Round toward negative infinity.</li></ul>

Property Name	Brief Description
	<ul style="list-style-type: none"> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a third-order lattice autoregressive filter structure for a `dfilt` object, `hd`, with the following code that creates a fixed-point filter.

## dfilt.latticear

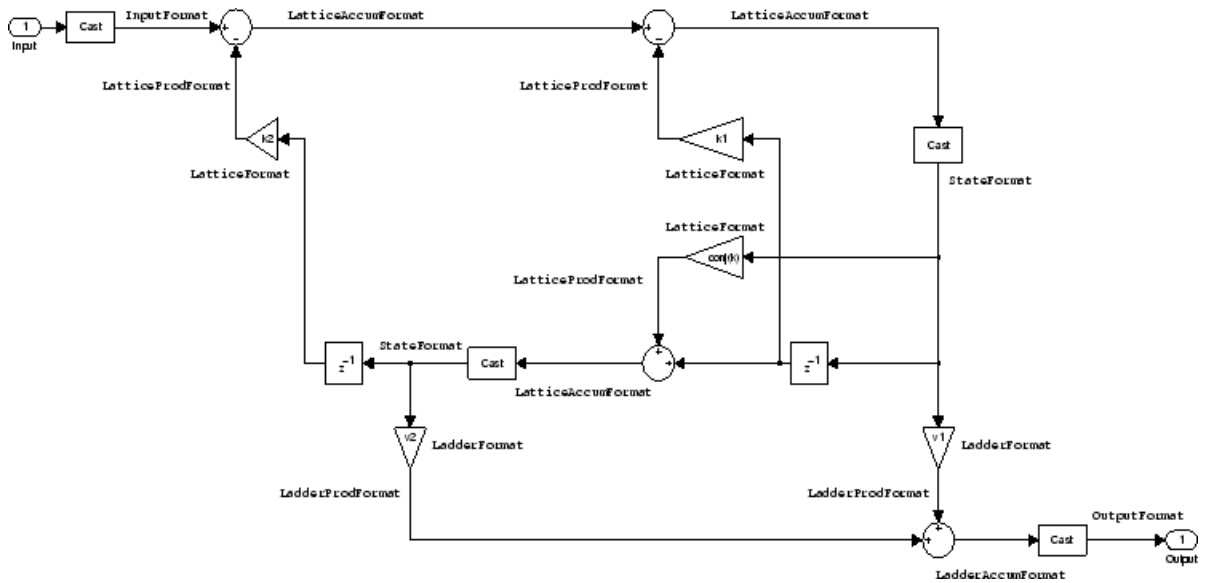

---

```
k = [.66 .7 .44];  
hd1=dfilt.latticear(k);  
hd1.arithmetic='fixed';  
specifyall(hd1);
```

<b>Purpose</b>	Discrete-time, lattice, autoregressive, moving-average filter
<b>Syntax</b>	Refer to <code>dfilt.latticearma</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>hd = dfilt.latticearma(k)</code> returns a discrete-time, lattice moving-average autoregressive filter object <code>hd</code>, with lattice coefficients, <code>k</code>.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to “Arithmetic” on page 5-19.</p> <p><code>hd</code> <code>dfilt.latticearma</code> returns a default, discrete-time, lattice moving-average, autoregressive filter object <code>hd</code>, with <code>k = []</code>. This filter passes the input through to the output unchanged.</p>
<b>Fixed-Point Filter Structure</b>	<p>The following figure shows the signal flow for the autoregressive lattice filter implemented by <code>dfilt.latticearma</code>. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.</p>

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFormat` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFormat`, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
InputFormat	InputWordLength	InputFracLength	None
LadderAccumFormat	AccumWordLength	LadderAccumFracLength	AccumMode
LadderFormat	CoeffWordLength	LadderFracLength	CoeffAutoScale
LadderProdFormat	ProductWordLength	LadderProdFracLength	ProductMode
LatticeAccumFormat	AccumWordLength	LatticeAccum-FracLength	AccumMode
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
LatticeProdFormat	ProductWordLength	LatticeProdFracLength	ProductMode
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label LatticeProdFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that lattice coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the LatticeProdFormat refers to the properties ProductWordLength, LatticeProdFracLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the autoregressive moving-average lattice implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .

Property Name	Brief Description
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Ladder	Stores the ladder coefficients for lattice ARMA ( <code>dfilt.latticearma</code> ) filters.

Property Name	Brief Description
LadderAccumFracLength	Sets the fraction length used to interpret the output from sum operations that include the ladder coefficients. You can change this property value after you set AccumMode to SpecifyPrecision.
LadderFracLength	Determines the precision used to represent the ladder coefficients in ARMA lattice filters.
Lattice	Stores the lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"><li>• AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li><li>• BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li><li>• SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.</li></ul>

Property Name	Brief Description
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic.</p>

Property Name	Brief Description
	Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

**See Also**

dfilt | dfilt.latticeallpass | dfilt.latticear |  
dfilt.latticemamin | dfilt.latticemamin

# dfilt.latticemamax

---

**Purpose** Discrete-time, lattice, moving-average filter with maximum phase

**Syntax** Refer to `dfilt.latticemamax` in Signal Processing Toolbox documentation.

**Description** `hd = dfilt.latticemamax(k)` returns a discrete-time, lattice, moving-average filter object `hd`, with lattice coefficients `k`.  
Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 5-19.

---

**Note** When the `k` coefficients define a maximum phase filter, the resulting filter in this structure is maximum phase. When your coefficients do not define a maximum phase filter, placing them in this structure does not produce a maximum phase filter.

---

`hd = dfilt.latticemamax` returns a default discrete-time, lattice, moving-average filter object `hd`, with `k = []`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the maximum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamax`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical

operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the maximum phase, moving average lattice implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
<code>AccumFracLength</code>	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>AccumWordLength</code>	Sets the word length used to store data in the accumulator/buffer.
<code>Arithmetic</code>	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
<code>CastBeforeSum</code>	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

Property Name	Brief Description
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .

Property Name	Brief Description
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	<p>Determines the word length used for the output data.</p>
OverflowMode	<p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.</p>
ProductFracLength	<p>For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <b>ProductMode</b> to <b>SpecifyPrecision</b>.</p>

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <b>FullPrecision</b> ), or whether to keep the most significant bit ( <b>KeepMSB</b> ) or least significant bit ( <b>KeepLSB</b> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <b>ProductMode</b> to <b>SpecifyPrecision</b> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <b>ProductMode</b> to <b>SpecifyPrecision</b> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <b>False</b> is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). <ul style="list-style-type: none"><li>• <b>ceil</b> - Round toward positive infinity.</li><li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <b>fix</b> - Round toward zero.</li><li>• <b>floor</b> - Round toward negative infinity.</li></ul>

Property Name	Brief Description
	<ul style="list-style-type: none"> <li>• nearest - Round toward nearest. Ties round toward positive infinity.</li> <li>• round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a fourth-order lattice, moving-average, maximum phase filter structure for a `dfilt` object, `hd`, with the following code:

## dfilt.latticemamax

---

```

### See Also

[dfilt](#) | [dfilt.latticeallpass](#) | [dfilt.latticear](#) |  
[dfilt.latticearma](#) | [dfilt.latticemamin](#)

**Purpose** Discrete-time, lattice, moving-average filter with minimum phase

**Syntax** Refer to `dfilt.latticemamin` in Signal Processing Toolbox documentation.

**Description** `hd = dfilt.latticemamin(k)` returns a discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 5-19.

---

**Note** When the `k` coefficients define a minimum phase filter, the resulting filter in this structure is minimum phase. When your coefficients do not define a minimum phase filter, placing them in this structure does not produce a minimum phase filter.

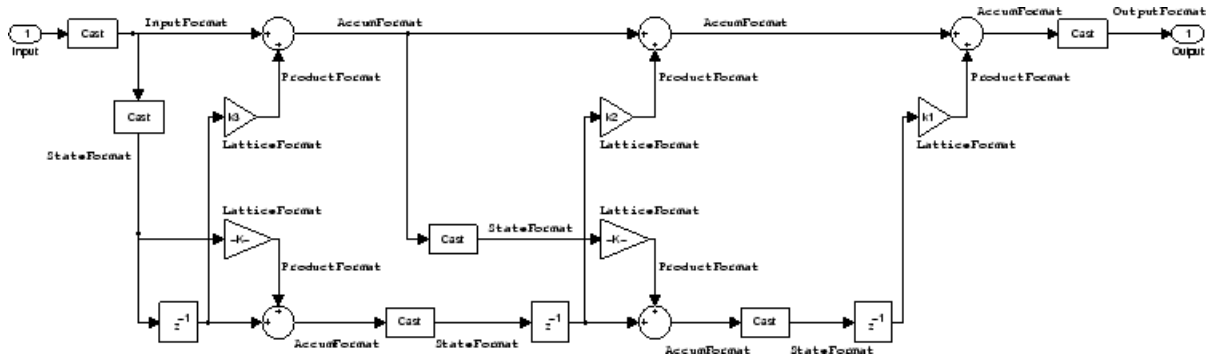

---

`hd = dfilt.latticemamin` returns a default discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the minimum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamin`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical

operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the minimum phase, moving average lattice implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
<code>AccumFracLength</code>	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>AccumWordLength</code>	Sets the word length used to store data in the accumulator/buffer.
<code>Arithmetic</code>	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
<code>CastBeforeSum</code>	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

Property Name	Brief Description
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .

Property Name	Brief Description
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"><li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li><li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li><li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li></ul>
OutputWordLength	<p>Determines the word length used for the output data.</p>
OverflowMode	<p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.</p>
ProductFracLength	<p>For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <b>ProductMode</b> to <b>SpecifyPrecision</b>.</p>

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> </ul>

Property Name	Brief Description
	<ul style="list-style-type: none"><li>• nearest - Round toward nearest. Ties round toward positive infinity.</li><li>• round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a third-order lattice, moving-average, minimum phase, filter structure for a `dfilt` object, `hd`, with the following code:

```
k = [.66 .7 .44];  
hd = dfilt.latticemamin(k);
```

```
dfilt | dfilt.latticeallpass | dfilt.latticear |  
dfilt.latticearma | dfilt.latticemamax
```

# dfilt.parallel

**Purpose** Discrete-time, parallel structure filter

**Syntax** Refer to `dfilt.parallel` in Signal Processing Toolbox documentation.

**Description** `hd = dfilt.parallel(hd1,hd2,...)` returns a discrete-time filter object `hd`, which is a structure of two or more `dfilt` filter objects, `hd1`, `hd2`, and so on arranged in parallel.

You can also use the standard notation to combine filters into a parallel structure.

`parallel(hd1,hd2,...)`

In this syntax, `hd1`, `hd2`, and so on can be a mix of `dfilt` objects, `mfilt` objects, and `adaptfilt` objects.

`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the parallel structure must be the same arithmetic format — double, single, or fixed. `hd`, the filter returned, inherits the format of the individual filters.

**See Also** `dfilt` | `dfilt.cascade` | `parallel` | `dfilt.cascade` | `dfilt.parallel`

---

<b>Purpose</b>	Discrete-time, scalar filter
<b>Syntax</b>	Refer to <code>dfilt.scalar</code> in Signal Processing Toolbox documentation.
<b>Description</b>	<p><code>dfilt.scalar(g)</code> returns a discrete-time, scalar filter object with gain <code>g</code>, where <code>g</code> is a scalar.</p> <p>Make this filter a fixed-point or single-precision filter by changing the value of the <code>Arithmetic</code> property for the filter <code>hd</code> as follows:</p> <ul style="list-style-type: none"><li>• To change to single-precision filtering, enter <pre>set(hd,'arithmetic','single');</pre></li><li>• To change to fixed-point filtering, enter <pre>set(hd,'arithmetic','fixed');</pre></li></ul> <p>For more information about the property <code>Arithmetic</code>, refer to “Arithmetic” on page 5-19.</p> <p><code>dfilt.scalar</code> returns a default, discrete-time scalar gain filter object <code>hd</code>, with gain 1.</p>

## Properties

In this table you see the properties associated with the scalar implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 5-2.

Property Name	Brief Description
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>CoeffFracLength</code> property to specify the precision used.
CoeffFracLength	Set the fraction length the filter uses to interpret coefficients. <code>CoeffFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
Gain	Returns the gain for the scalar filter. Scalar filters do not alter the input data except by adding gain.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.

Property Name	Brief Description
InputWordLength	Specifies the word length applied to interpret input data.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"><li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li><li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li><li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li></ul>
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

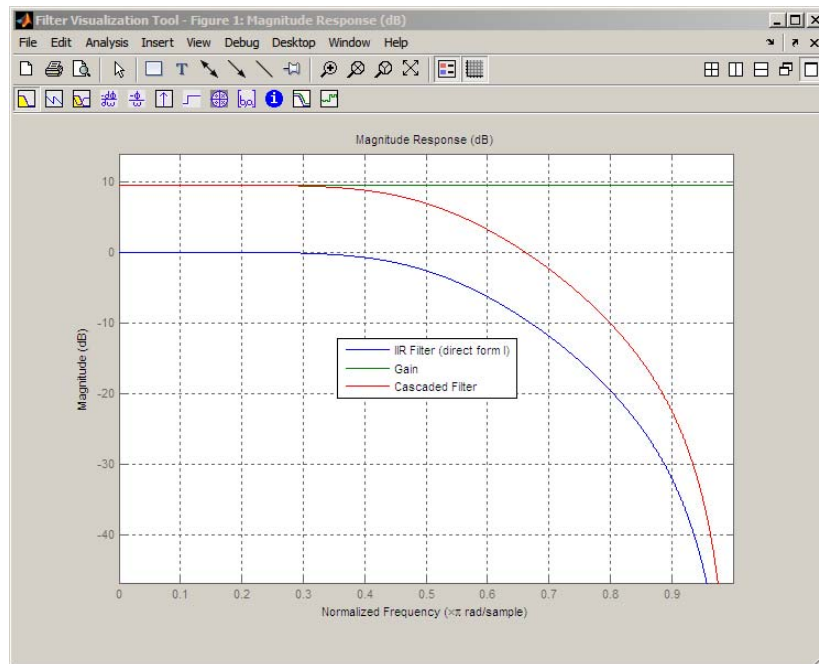

Property Name	Brief Description
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"><li>• <code>ceil</code> - Round toward positive infinity.</li><li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li><li>• <code>fix</code> - Round toward zero.</li><li>• <code>floor</code> - Round toward negative infinity.</li><li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li><li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li></ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>

Property Name	Brief Description
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Examples

Create a direct-form I filter object `hd_filt` and a scalar object with a gain of 3 `hd_gain` and cascade them together.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd_filt = dfilt.df1(b,a);
hd_gain = dfilt.scalar(3);
hd_cascade=cascade(hd_gain,hd_filt);
fvtool_handle = fvtool(hd_filt,hd_gain,hd_cascade);
legend(fvtool_handle,'IIR Filter (direct form I)',...
'Gain','Cascaded Filter');
```

To view the stages of the cascaded filter, use

```
hd.Stage(1)
```

and

```
hd.Stage(2)
```

## See Also

```
dfilt | dfilt.cascade
```

**Purpose** Wave digital allpass filter

**Syntax** `hd = dfilt.wdfallpass(c)`

**Description** `hd = dfilt.wdfallpass(c)` constructs an allpass wave digital filter structure given the allpass coefficients in vector `c`.

Vector `c` must have, one, two, or four elements (filter coefficients). Filters with three coefficients are not supported. When you use `c` with four coefficients, the first and third coefficients must be 0.

Given the coefficients in `c`, the transfer function for the wave digital allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

Internally, the allpass coefficients are converted to wave digital filters for filtering. Note that `dfilt.wdfallpass` allows only stable filters. Also note that the leading coefficient in the denominator, a 1, does not need to be included in vector `c`.

Use the constructor `dfilt.cascadewdfallpass` to cascade `wdfallpass` filters.

To compare these filters to other similar filters, `dfilt.wdfallpass` and `dfilt.cascadewdfallpass` filters have the same number of multipliers as the non-wave digital filters `dfilt.allpass` and `dfilt.cascadeallpass`. However, the wave digital filters use fewer states and they may require more adders in the filter structure.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

**Properties** In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass wave digital filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Filter Structure

When you change the order of the wave digital filters in the cascade, the filter structure changes as well.

As shown in this example, `realizemd1` lets you see the filter structure used for your filter, if you have Simulink installed.

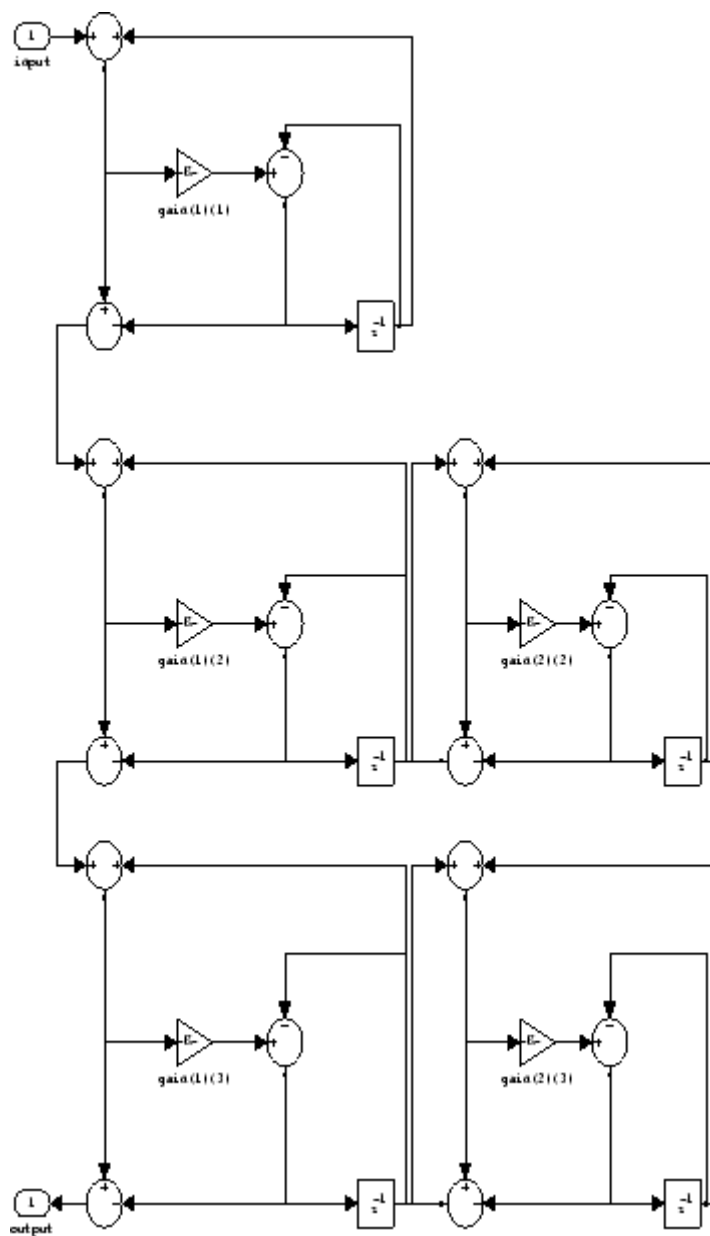

```
section11=0.8;  
section12=[1.5,0.7];  
section13=[1.8,0.9];  
hd1=dfilt.cascadewdfallpass(section11,section12,section13);
```

```
section21=[0.8,0.4];  
section22=[0,1.5,0,0.7];
```

```
section23=[0,1.8,0,0.9];  
hd2=dfilt.cascadewdfallpass(section21,section22,section23);  
% If you have Simulink  
realizemdl(hd2)
```

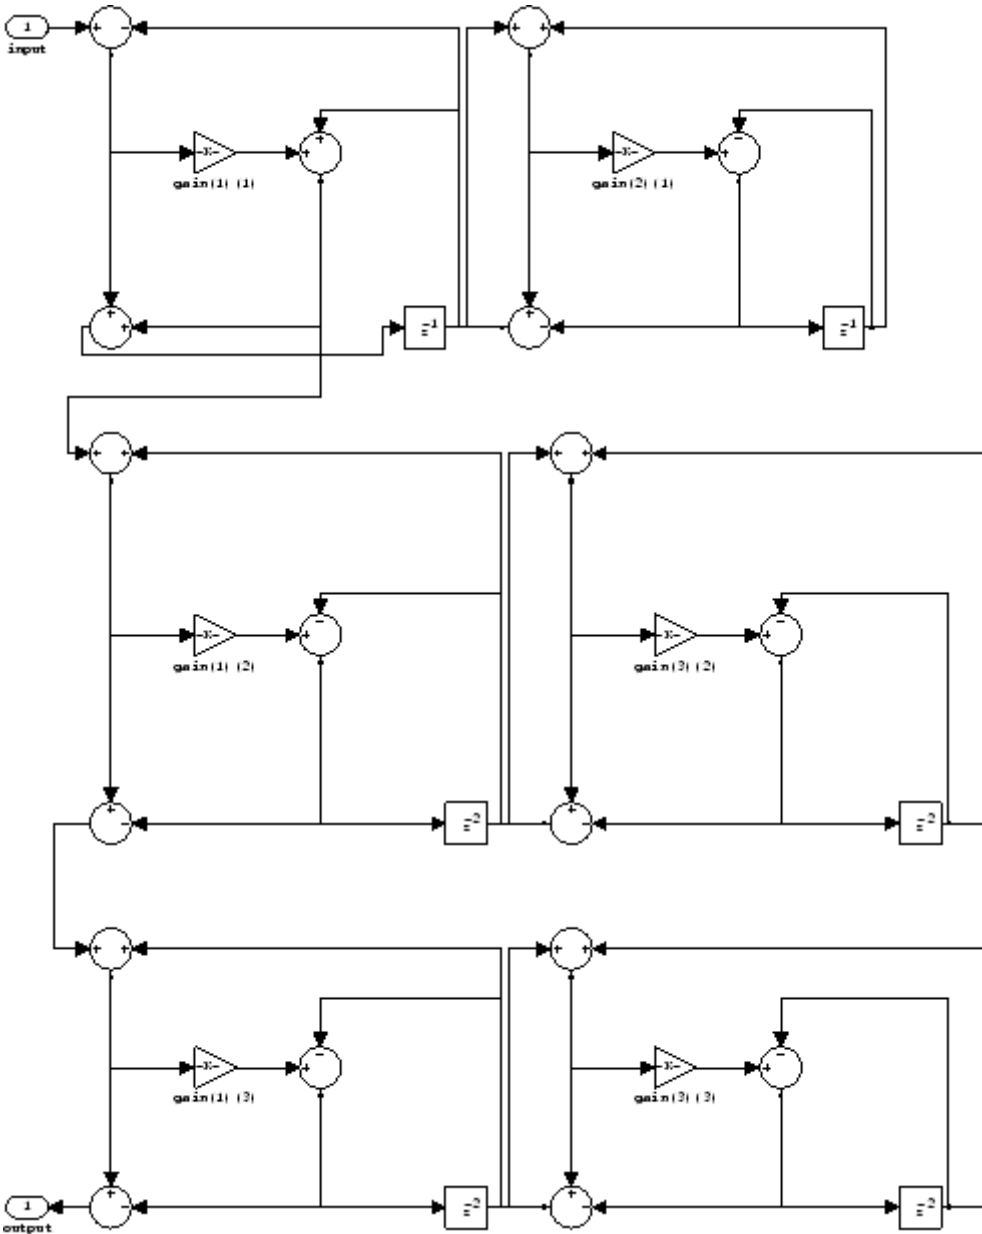

hd1 has this filter structure with three sections.

# dfilt.wdfallpass

The filter structure for `hd2` is somewhat different, with the different orders and interconnections between the three sections.

# dfilt.wdfallpass

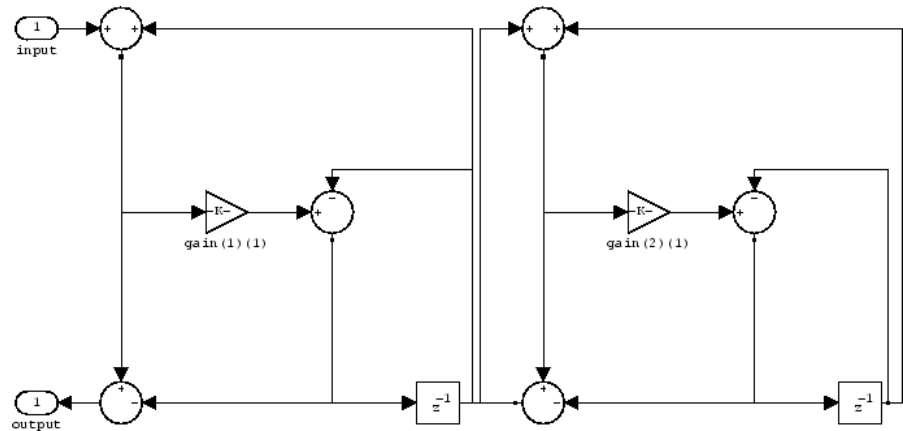

**Examples**

Construct a second-order wave digital allpass filter with two coefficients. Note that to use `realizemdl`, you must have Simulink.

```
c = [1.5,0.7];
hd = dfilt.wdfallpass(c);
```

With Simulink installed, `realizemdl` returns this structure for `hd`.

**See Also**

`dfilt` | `dfilt.allpass` | `dfilt.latticeallpass` |  
`dfilt.cascadewdfallpass` | `dfilt.cascadeallpass` |  
`mfilt.iirdecim` | `mfilt.iirinterp`

# disp

---

**Purpose** Filter properties and values

**Syntax** `disp(hd)`  
`disp(ha)`  
`disp(hm)`

**Description** Similar to omitting the closing semicolon from an expression on the command line, except that `disp` does not display the variable name. `disp` lists the property names and property values for any filter object, such as a `dfilt` object or `adaptfilt` object.

The following examples illustrate the default display for an adaptive filter `ha` and a multirate filter `hm`.

```
ha=adaptfilt.rls;
fprintf('Displaying properties for default RLS adaptive filter:\n');
fprintf('\n');
disp(ha)
pause(2);
hm=mfilt.cicdecim(6);
fprintf('Displaying properties for cascaded integrator-comb decimator\n');
fprintf('with a decimation factor of 6:\n');
fprintf('\n');
disp(hm)
```

**See Also** `set`

**Purpose**

Cast fixed-point filter to use double-precision arithmetic

**Syntax**

```
hd = double(h)
```

**Description**

`hd = double(h)` returns a new filter `hd` that has the same structure and coefficients as `h`, but whose arithmetic property is set to `double` to use double-precision arithmetic for filtering. `double(h)` is not the same as the `reffilter(h)` function:

- `hd`, the filter returned by `double` has the quantized coefficients of `h` represented in double-precision floating-point format
- The reference filter returned by `reffilter` has double-precision, floating-point coefficients that have not been quantized.

You might find `double(h)` useful to isolate the effects of quantizing the coefficients of a filter by using `double` to create a filter `hd` that operates in double-precision but uses the quantized filter coefficients.

**Examples**

Use the same filter, once with fixed-point arithmetic and once with floating-point, to compare fixed-point filtering with double-precision floating-point filtering.

```
h = dfilt.dffir(firgr(27,[0 .4 .6 1],...  
[1 1 0 0])); % Lowpass filter.  
% Set h to use fixed-point arithmetic to filter.  
% Quantize the coeffs.  
h.arithmetic = 'fixed';  
% Cast h to double-precision  
hd = double(h);  
% Set up an input signal.  
n = 0:99; x = sin(0.7*pi*n(:));  
y = filter(h,x); % Fixed-point output.  
yd = filter(hd,x); % Floating-point output.  
FixedFloatNormDiff=norm(yd-double(y),inf);
```

**See Also**

`reffilter`

# dsp.util.getLogLogsArray

---

**Purpose** Return logged signal as MATLAB array

**Syntax**

```
Array = dsp.util.getLogLogsArray(LogObject,Format2D,  
    'SignalPath',PATH)  
Array = dsp.util.getLogLogsArray(LogObject,Format2D,  
    'SignalName',NAME)
```

**Description**

Array =  
dsp.util.getLogLogsArray(LogObject,Format2D,'SignalPath',PATH)  
returns a MATLAB array that contains a signal in LogObject. You must specify the PATH to the signal in LogObject using the Name, Value pair argument.

Array =  
dsp.util.getLogLogsArray(LogObject,Format2D,'SignalName',NAME)  
returns a MATLAB array that contains a signal in LogObject. You must specify the NAME of the signal in LogObject using the Name, Value pair argument.

## Input Arguments

### LogObject

Specify the name of the object that contains your logged signals. Valid classes for LogObject depend on the syntax you use:

- When you specify PATH as a dsp.util.SignalPath object, LogObject can be either a Simulink.SimulationData.Dataset or Simulink.SimulationData.Signal object.
- When you specify PATH as the full path to a block in a Simulink model, LogObject must be a Simulink.SimulationData.Dataset object.
- When you specify the NAME of a signal in LogObject, LogObject can be an object of class timeseries, Simulink.SimulationData.Dataset, or Simulink.SimulationData.Signal.

### Format2D

Specify a logical value to determine whether the function formats 3-D logged signals as a 2-D or 3-D MATLAB array. When you set this property to `true`, the function uses the following formula to format the 3-D logged signal into a 2-D MATLAB array:

```
dim = size(signal);  
ntimes = dim(1)*dim(3);  
Array = reshape(permute(signal,[1 3 2]),[ntimes dim(2)]);
```

When you set this property to `false`, the function returns the logged signal without any reformatting.

## PATH

Specify the path to the logged signal in `LogObject`. You can specify the path using a `dsp.util.SignalPath` object, or you can provide the full path to a block in your Simulink model. To get the full path to a block in your Simulink model, use the `gcb` command.

## NAME

Specify the name of the signal in `LogObject`.

## Output Arguments

### Array

The output `Array` is a MATLAB array that contains the specified logged signal. When the input is a 3-D logged signal, the dimensions of `Array` depend on the value you specify for `Format2D`:

- When `Format2D` is `true`, `Array` is a 2-D MATLAB array.
- When `Format2D` is `false`, `Array` is a 3-D MATLAB array.

When the input is not a 3-D signal, the dimensions of the output `Array` match those of the input.

# dsp.util.getLogArrays

---

## Examples

---

**Note** To run the following examples, you must first load `ex_logout.mat` which contains a `Simulink.SimulationData.Dataset` object. Alternatively, you can open and simulate the `ex_log_utils` Simulink model. Doing so will log signals and generate the necessary `ex_logout` object.

---

### Extract a unique signal named **Signal3x4** from `ex_logout`.

```
dsp.util.getLogArrays(ex_logout, true, 'SignalName', 'Signal3x4')
```

### Extract a unique signal named **Signal3x4** from `ex_logout` as a **3-D** array.

```
dsp.util.getLogArrays(ex_logout, false, 'SignalName', 'Signal3x4')
```

### Find and extract a specific signal from multiple signals that have the same name.

Because `ex_logout` contains multiple signals named `Signal2x4`, you must use the `dsp.util.getSignalPath` function to find the paths to each of those signals.

```
paths = dsp.util.getSignalPath(ex_logout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogArrays function and provide the 'SignalPath' name-value
% pair argument.
dsp.util.getLogArrays(ex_logout, true, 'SignalPath', paths(2))
```

### Find and extract a signal from a bus.

Use the `dsp.util.getSignalPath` function to get paths to all the signals in the bus named `Bus1`.

```
buspaths = dsp.util.getSignalPath(ex_logout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to t
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus
% Now that you have the path to the signal, call dsp.util.getLogsArray
% using the 'SignalPath' name-value pair argument.
dsp.util.getLogsArray(ex_logout, true, 'SignalPath', buspaths(1))
```

## See Also

```
dsp.util.getSignalPath | dsp.util.SignalPath
| Simulink.SimulationData.BlockPath
| Simulink.SimulationData.Dataset |
Simulink.SimulationData.Signal | timeseries
```

## How To

- “Export Signal Data Using Signal Logging”
- “Configure a Signal for Signal Logging”
- “Specify the Signal Logging Data Format”

# dsp.util.getSignalPath

---

**Purpose** Paths to logged signals

**Syntax** Path = dsp.util.getSignalPath(LogObject, SignalName)

**Description** Path = dsp.util.getSignalPath(LogObject, SignalName) returns all paths to signals in LogObject with name SignalName. The output Path is a dsp.util.SignalPath object or an array of dsp.util.SignalPath objects.

**Tips**

- To return the path to an unnamed signal in LogObject, set SignalName to the empty string (' ').

**Input Arguments**

**LogObject**  
Specify the name of the object that contains your logged signals. LogObject must be a Simulink.SimulationData.Dataset or Simulink.SimulationData.Signal object.

**SignalName**  
Specify the name of a logged signal in LogObject.

**Output Arguments**

**Path**  
The output Path contains the path to all signals named SignalName in LogObject.

- If LogObject contains a unique signal with name SignalName, the function returns a single dsp.util.SignalPath object.
- If LogObject contains more than one signal with the specified name, the function returns an array of dsp.util.SignalPath objects.

## Examples

---

**Note** To run the following examples, you must first load `ex_logstdout.mat` which contains a `Simulink.SimulationData.Dataset` object. Alternatively, you can open and simulate the `ex_log_utils` Simulink model. Doing so will log signals and generate the necessary `ex_logstdout` object.

---

### Find and extract a specific signal from multiple signals that have the same name.

Because `ex_logstdout` contains multiple signals named `Signal2x4`, you must use the `dsp.util.getSignalPath` function to find the paths to each of those signals.

```
paths = dsp.util.getSignalPath(ex_logstdout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogArray function and provide the 'SignalPath' name-value
% pair argument.
dsp.util.getLogArray(ex_logstdout, true, 'SignalPath', paths(2))
```

### Find and extract a signal from a bus.

Use the `dsp.util.getSignalPath` function to get paths to all the signals in the bus named `Bus1`.

```
buspaths = dsp.util.getSignalPath(ex_logstdout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to t
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus'
% Now that you have the path to the signal, call dsp.util.getLogArray
% using the 'SignalPath' name-value pair argument.
dsp.util.getLogArray(ex_logstdout, true, 'SignalPath', buspaths(1))
```

# dsp.util.getSignalPath
