- The `transpose` function that is overloaded for `timeseries` objects does not transpose the data. Instead, this function changes whether the first or the last dimension of the data aligns with the time vector. To transpose the data, transpose the `Data` property of the time series. For example, you can use the syntax `transpose(ts.Data)` or `(ts.Data).'`. The value of the `Data` property must be a 2-D array.
- Consider a time series with 10 samples with the property `IsTimeFirst = True`. When you transpose this time series, the data size changes from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

  The following table summarizes how the size for timeseries data (up to three dimensions) display before and after transposing.

  Data Size Before and After Transposing

Size of Original Data	Size of Transposed Data
N-by-1	1-by-1-by-N
N-by-M	M-by-1-by-N
N-by-M-by-L	M-by-L-by-N

Input Arguments

ts

The `timeseries` object that you want to transpose.

Output Arguments

ts1

The `timeseries` object that is the result of transposing the original `timeseries` object.

Examples

Suppose that a `timeseries` object, `ts`, has `ts.Data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is `true`, which means that the first dimension of the data aligns with the time vector. `transpose(ts)` modifies the `timeseries` object, such that the last dimension of the data now aligns with the time vector. This permutes the data, such that the size of `ts.Data` becomes 3-by-2-by-10.

See Also

`timeseries` | `transpose`

timeseries.std

Purpose

Standard deviation of `timeseries` data

Syntax

```
ts_std = std(ts)
ts_std = std(ts,Name,Value)
```

Description

`ts_std = std(ts)` returns the standard deviation of the `timeseries` data.

`ts_std = std(ts,Name,Value)` specifies additional options specified with one or more `Name,Value` pair arguments.

Input Arguments

ts

The `timeseries` object for which you want the standard deviation of the data.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'MissingData'

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

'Weighting'

A string specifying one of two possible values, `none` or `time`. When you specify `time`, larger time values correspond to larger weights.

Output Arguments

ts_std

The standard deviation of `ts.Data` values as follows:

- When `ts.Data` is a vector, `ts_std` is the standard deviation of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_std` is the standard deviation of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `std` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

The following example finds the standard deviation for a `timeseries` object. MATLAB calculates the standard deviation for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:

load count.dat

% Create a timeseries object with 24 time values:

count_ts = timeseries(count,1:24,'Name','CountPerSecond');

% Calculate the standard deviation of each data column for this
% timeseries object:

std(count_ts)
```

MATLAB returns:

```
25.3703   41.4057   68.0281
```

Algorithms

MATLAB determines weighting by:

1. Attaching a weighting to each time value, depending on its order, as follows:
   - First time point — The duration of the first time interval `(t(2) - t(1))`.
   - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval `((t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2)`.
   - Last time point — The duration of the last time interval `((t(end) - t(end - 1))`.
2. Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

   Note If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

   ---

3. Multiplying the data for each time by its normalized weighting.

`iqr` | `max` | `mean` | `median` | `min` | `sum` | `timeseries` | `var`

Purpose

Sum of `timeseries` data

Syntax

```
ts_sm = sum(ts)
ts_sm = sum(ts,Name,Value)
```

Description

`ts_sm = sum(ts)` returns the sum of the `timeseries` data.

`ts_sm = sum(ts,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments.

Input Arguments

ts

The `timeseries` object for which you want the sum of the data.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'MissingData'

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

'Weighting'

A string specifying one of two possible values, `none` or `time`. When you specify `time`, larger time values correspond to larger weights.

Output Arguments

ts_sm

The sum of the `timeseries` data, as follows:

- When `ts.Data` is a vector, ts_sm is the sum of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then ts_sm is a row vector containing the sum of each column of `ts.Data`.

When `ts.Data` is a N-dimensional array, `sum` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

Calculate the sum of each data column for a `timeseries` object:

```
% Load a 24-by-3 data array:

load count.dat

% Create a timeseries object with 24 time values:

count_ts = timeseries(count,1:24,'Name','CountPerSecond');

% Calculate the sum of each data column for this timeseries object:

sum(count_ts)
```

MATLAB returns:

```
768        1117        1574
```

Algorithms

MATLAB determines weighting by:

1. Attaching a weighting to each time value, depending on its order, as follows:
   - First time point — The duration of the first time interval `(t(2) - t(1))`.
   - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval `((t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2)`.
   - Last time point — The duration of the last time interval `((t(end) - t(end - 1))`.
2. Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

   Note If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

3. Multiplying the data for each time by its normalized weighting.

`iqr` | `max` | `mean` | `median` | `min` | `std` | `timeseries` | `var`

timeseries.var

Purpose

Variance of `timeseries` data

Syntax

```
ts_var = var(ts)
ts_var = var(ts,Name,Value)
```

Description

`ts_var = var(ts)` returns the variance of `ts.data`.

`ts_var = var(ts,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ts

The `timeseries` object for which you want the variance of the data.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'MissingData'

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

'Weighting'

A string specifying one of two possible values, none or time. When you specify time, larger time values correspond to larger weights.

Output Arguments

ts_var

The variance of ts.data, as follows:

- When ts.Data is a vector, then ts_var is the variance of ts.Data values.
- When ts.Data is a matrix, and IsTimeFirst is true, and the first dimension of ts is aligned with time, then ts_var is a row vector containing the variance of each column of ts.Data.

When ts.Data is an N-dimensional array, var always operates along the first nonsingleton dimension of ts.Data.

Examples

The following example calculates the variance values of a multivariate timeseries object. MATLAB calculates the variance independently for each data column in the timeseries object.

Load a 24-by-3 data array. Then create a timeseries object with 24 time values.

```
load count.dat
count_ts = timeseries(count,[1:24],'Name','CountPerSecond');
```

Calculate the variance of each data column.

```
var(count_ts)
```

MATLAB returns:

```
1.0e+03 *
  0.6437    1.7144    4.6278
```

Algorithms

MATLAB determines weighting by:

1. Attaching a weighting to each time value, depending on its order, as follows:
   - First time point — The duration of the first time interval `(t(2) - t(1))`.
   - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval `((t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2)`.
   - Last time point — The duration of the last time interval `((t(end) - t(end - 1))`.
2. Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

   Note If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

   ---

3. Multiplying the data for each time by its normalized weighting.

Purpose

Triangulation in 2-D or 3-D

Description

Use `triangulation` to create an in-memory representation of any 2-D or 3-D triangulation data that is in matrix format, such as the matrix output from the `delaunay` function or other software tools. When your data is represented using `triangulation`, you can perform topological and geometric queries, which you can use to develop geometric algorithms. For example, you can find the triangles or tetrahedra attached to a vertex, those that share an edge, their circumcenters, and other features.

Construction

`TR = triangulation(T,P)` creates a 2-D or 3-D triangulation representation using the triangulation connectivity list, `T`, and the points in matrix `P`.

`TR = triangulation(T,x,y)` creates a 2-D triangulation representation with the point coordinates specified as column vectors, `x` and `y`.

`TR = triangulation(T,x,y,z)` creates a 3-D triangulation representation with the point coordinates specified as column vectors, `x`, `y`, and `z`.

Input Arguments

T

Triangulation connectivity list, specified as an `m`-by-`n` matrix, where `m` is the number of triangles or tetrahedra, and `n` is the number of vertices per triangle or tetrahedron. Each element in `T` is a “Vertex ID” on page 1-4317. Each row of `T` contains the vertex IDs that define a triangle or tetrahedron.

P

Points, specified as a matrix whose columns are the `x`, `y`, (and possibly `z`) coordinates of the triangulation points. The row numbers of `P` are the vertex IDs in the triangulation.

x

x-coordinates vector, specified as a column vector containing the *x*-coordinates of the triangulation points.

y

y-coordinates vector, specified as a column vector containing the *y*-coordinates of the triangulation points.

z

z-coordinates vector, specified as a column vector containing the *z*-coordinates of the triangulation points.

Properties

Points

Points in the triangulation, represented as a matrix containing the following information:

- Each row in `TR.Points` contains the coordinates of a vertex.
- Each row number of `TR.Points` is a vertex ID.

ConnectivityList

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each element in `TR.ConnectivityList` is a vertex ID.
- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `TR.ConnectivityList` is a "Triangle or Tetrahedron ID" on page 1-4317.

Methods

barycentricToCartesian	Converts point coordinates from barycentric to Cartesian
cartesianToBarycentric	Converts point coordinates from Cartesian to barycentric

circumcenter	Circumcenter of triangle or tetrahedron
edgeAttachments	Triangles or tetrahedra attached to specified edge
edges	Triangulation edges
faceNormal	Triangulation face normal
featureEdges	Triangulation sharp edges
freeBoundary	Triangulation facets referenced by only one triangle or tetrahedron
incenter	Incenter of triangle or tetrahedron
isConnected	Test if two vertices are connected by edge
neighbors	Neighbors to specified triangle or tetrahedron
size	Size of triangulation connectivity list
vertexAttachments	Triangles or tetrahedra attached to specified vertex
vertexNormal	Triangulation vertex normal

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

2-D Triangulation

Define the points in the triangulation.

```
P = [ 2.5    8.0
      6.5    8.0
      2.5    5.0
      6.5    5.0
      1.0    6.5
      8.0    6.5];
```

Define the triangles. This is the triangulation connectivity list.

```
T = [5  3  1;
     3  2  1;
     3  4  2;
     4  6  2];
```

Create the triangulation representation.

```
TR = triangulation(T,P)
```

```
TR =

  triangulation with properties:

              Points: [6x2 double]
    ConnectivityList: [4x3 double]
```

Examine the coordinates of the vertices of the first triangle.

```
TR.Points(TR.ConnectivityList(1,:),:)
```

```
ans =

    1.0000    6.5000
```

```
    2.5000    5.0000
    2.5000    8.0000
```

See Also

`delaunayTriangulation` |

triangulation.barycentricToCartesian

Purpose

Converts point coordinates from barycentric to Cartesian

Syntax

```
PC = barycentricToCartesian(TR,ti,B)
```

Description

`PC = barycentricToCartesian(TR,ti,B)` returns the Cartesian coordinates of the points in `B`. Each row, `B(j,:)`, contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, `ti(j)`. The point, `PC(j,:)`, is the `j`th point represented in Cartesian coordinates.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

ti

Triangle or tetrahedron IDs, specified as a column vector.

B

Barycentric coordinates, specified as a matrix. Each row, `B(j,:)`, contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, `ti(j)`.

Output Arguments

PC

Cartesian coordinates, returned as a matrix. The point, `PC(j,:)`, is the `j`th point represented in Cartesian coordinates.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

Barycentric Coordinates Converted to Cartesian Coordinates

Create a triangulation from a set of points, `P`, and triangulation connectivity list, `T`.

```
P = [ 2.5    8.0
      6.5    8.0
      2.5    5.0
      6.5    5.0
      1.0    6.5
      8.0    6.5];

T = [5  3  1;
     3  2  1;
     3  4  2;
     4  6  2];

TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Specify the barycentric coordinates of the second point in the triangle.

```
B = [0 1 0];
```

Convert the point to Cartesian coordinates.

```
PC = barycentricToCartesian(TR,ti,B)
```

```
PC =

    2.5000    5.0000
```

Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(DT);
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
axis equal;
```

Create a new triangulation which is a deformed version of `DT` .

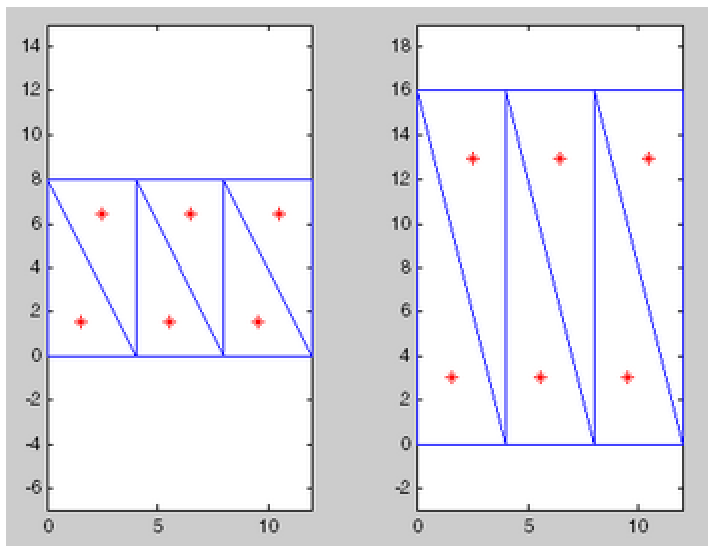
```
ti = DT.ConnectivityList;
y = [0 0 0 0 16 16 16 16]';
TR = triangulation(ti,x,y);
```

Compute the barycentric coordinates for the incenters of `DT`, and use them to compute the Cartesian coordinates of the analogous points in `TR`.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(TR);
hold on;
plot(xc(:,1),xc(:,2),'*r');
hold off;
axis equal;
```



See Also

`cartesianToBarycentric` | `delaunayTriangulation` |

triangulation.cartesianToBarycentric

Purpose

Converts point coordinates from Cartesian to barycentric

Syntax

```
B = cartesianToBarycentric(TR,ti,PC)
```

Description

`B = cartesianToBarycentric(TR,ti,PC)` returns the barycentric coordinates of the points in `PC`. Each row, `PC(j,:)`, contains the Cartesian coordinates of a point you want to convert. `B(j,:)` are the barycentric coordinates of the point, `PC(j,:)`, with respect to triangle or tetrahedron, `ti(j)`.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

ti

Triangle or tetrahedron IDs, specified as a column vector.

PC

Cartesian coordinates, specified as a matrix. Each row, `PC(j,:)`, contains the Cartesian coordinates of a point with respect to triangle or tetrahedron, `ti(j)`.

Output Arguments

B

Barycentric coordinates, returned as a matrix. `B(j,:)` are the barycentric coordinates of `PC(j,:)` with respect to `ti(j)`.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

Cartesian Coordinates Coverted to Barycentric Coordinates

Create a triangulation from a set of points, `P`, and triangulation connectivity list, `T`.

```
P = [ 2.5    8.0
      6.5    8.0
      2.5    5.0
      6.5    5.0
      1.0    6.5
      8.0    6.5];

T = [5  3  1;
     3  2  1;
     3  4  2;
     4  6  2];

TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Get the coordinates of the third vertex in the first triangle.

```
PC = TR.Points(TR.ConnectivityList(1,3),:)

PC =

    2.5000    8.0000
```

Convert the point to barycentric coordinates.

```
B = cartesianToBarycentric(TR,ti,PC)

B =

     0     0     1
```

Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

```
x = [0 4 8 12 0 4 8 12]';
```

```
y = [0 0 0 0 8 8 8 8]';
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(DT);
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
axis equal;
```

Create a new triangulation which is a deformed version of `DT` .

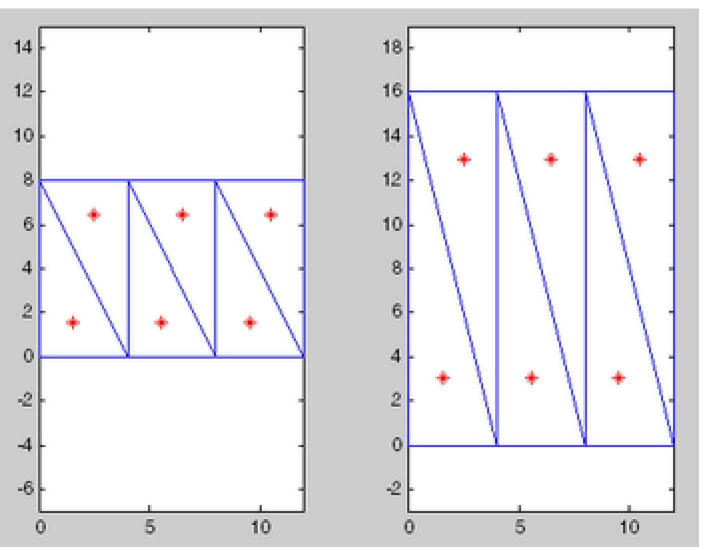
```
ti = DT.ConnectivityList;
y = [0 0 0 0 16 16 16 16]';
TR = triangulation(ti,x,y);
```

Compute the barycentric coordinates for the incenters of `DT`, and use them to compute the Cartesian coordinates of the analogous points in `TR`.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(TR);
hold on;
plot(xc(:,1),xc(:,2),'*r');
hold off;
axis equal;
```



See Also

`barycentricToCartesian` | `delaunayTriangulation` |

triangulation.circumcenter

Purpose

Circumcenter of triangle or tetrahedron

Syntax

```
CC = circumcenter(TR,ti)
[CC,r] = circumcenter(TR,ti)
CC = circumcenter(TR)
[CC,r] = circumcenter(TR)
```

Description

`CC = circumcenter(TR,ti)` returns the coordinates of the circumcenter of each triangle or tetrahedron specified in `ti`.

`[CC,r] = circumcenter(TR,ti)` also returns the corresponding radii of the circumscribed circles or spheres.

`CC = circumcenter(TR)` returns the circumcenters of all triangles or tetrahedra in the triangulation.

`[CC,r] = circumcenter(TR)` also returns the corresponding radii of the circumscribed circles or spheres for the entire triangulation.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

ti

Triangle or tetrahedron IDs, specified as a column vector.

Output Arguments

CC

Circumcenters, returned as a matrix. Each row, `CC(j,:)`, contains the coordinates of the circumcenter of `ti(j)`.

r

Radii of the circumscribed circles or spheres, returned as a vector. The radius at `r(j)` corresponds to the circle or sphere circumscribing `ti(j)`.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

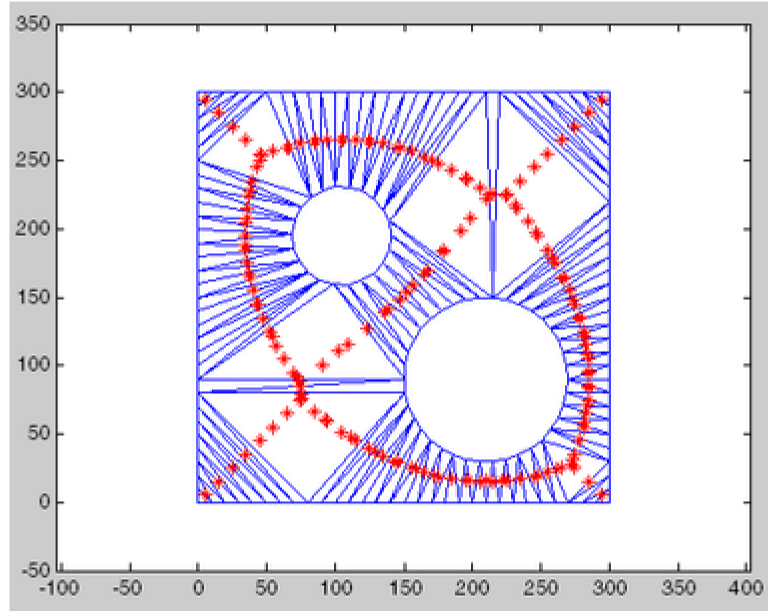
Circumcenters in 2-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Compute the circumcenters.

```
CC = circumcenter(TR);
triplot(TR)
axis([-50 350 -50 350]);
axis equal;
hold on;
plot(CC(:,1),CC(:,2),'*r');
hold off;
```



The circumcenters represent points on the medial axis of the polygon.

Circumcenters in 3-D Delaunay Triangulation

Create the Delaunay triangulation using a random set of points, `P`.

```
P = gallery('uniformdata',10,3,0);
DT = delaunayTriangulation(P);
```

Calculate the circumcenters of the first five tetrahedra in `DT`.

```
CC = circumcenter(DT,[1:5]')
```

```
CC =

    0.9626    0.3892    0.0928
    6.3458    0.2377    3.1814
    0.4820    0.9064    0.5176
```

```
   -1.2993    1.8384   -1.2185
   -0.1595    1.0852   -0.2536
```

See Also

`incenter` | `delaunayTriangulation` |

triangulation.edgeAttachments

Purpose

Triangles or tetrahedra attached to specified edge

Syntax

```
ti = edgeAttachments(TR,vstart,vend)
ti = edgeAttachments(TR,E)
```

Description

`ti = edgeAttachments(TR,vstart,vend)` returns the triangles or tetrahedra attached to the specified edges. To specify the edges, use the vectors, `vstart` and `vend`. These vectors contain the "Vertex ID" on page 1-4333 at the start and end of each edge.

`ti = edgeAttachments(TR,E)` specifies the starting and ending vertices of each edge in a 2-column matrix, `E`.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

vstart

IDs of starting vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the start of an edge.

vend

IDs of ending vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the end of an edge.

E

IDs of the edge vertices, specified as a 2-column matrix of vertex IDs. Each row of `E` corresponds to an edge and contains two IDs:

- `E(j,1)` is the ID of the vertex at the start of an edge.
- `E(j,2)` is the ID of the vertex at end of the edge.

Output Arguments

ti

IDs of the triangles or tetrahedra attached to the edges, returned as an `m`-by-`1` cell array. Each cell in `ti` contains the IDs of the

attached triangles or tetrahedra. The attachments to the edge located between the vertices, `vstart(j)` and `vend(j)`, or `E(j,:)`, are returned in `ti{j}`. The attachments are returned in a cell array because the number of triangles or tetrahedra associated with each edge can vary.

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

Edge Attachments in 3-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load tetmesh
TR = triangulation(tet,X);
```

Define the starting and ending vertices of the edges.

```
vstart = [15; 21];
vend = [936; 716];
```

Find the edge attachments.

```
ti = edgeAttachments(TR,vstart,vend);
```

Examine the attachments to the first edge.

```
ti{1}
```

```
ans =

     927     2060     3438     3423     2583     4690
```

Edge Attachments in 2-D Delaunay Triangulation

Create a Delaunay triangulation.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to edge (1,5).

```
ti = edgeAttachments(DT,1,5);

triangulation.edges

Purpose

Triangulation edges

Syntax

```
E = edges(TR)
```

Description

`E = edges(TR)` returns the triangulation edges as a matrix of vertex IDs. The vertices referenced in `E` indicate the beginning and end of each edge.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

Output Arguments

E

Edge vertex IDs, returned as a 2-column matrix. Each row of `E` corresponds to an edge and contains two IDs:

- `E(j,1)` is the ID of the vertex at the start of the edge.
- `E(j,2)` is the ID of the vertex at end of the edge.

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Edges in a 2-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Find the edges in the triangulation.

```
E = edges(TR);
```

List the first five edges.

```
E(1:5,:)

ans =

     1     2
     1   118
     1   119
     1   120
     2     3
```

Edges in a 2-D Delaunay Triangulation

Create 2-D Delaunay triangulation from a set of 10 random points.

```
X = gallery('uniformdata',[10, 2],0);
DT = delaunayTriangulation(X);
```

Find the edges in the triangulation.

```
E = edges(DT)

E =

     1     3
     1     4
     1     5
     1     6
     1     9
     2     4
     2     5
     2     6
     2     7
     2     8
     2    10
     3     4
     3     7
     3    10
     4     6
     4    10
```

```
     5     6
     5     8
     5     9
     6     9
     7     8
     7    10
```

See Also

`edgeAttachments` | `delaunayTriangulation` |

triangulation.faceNormal

Purpose

Triangulation face normal

Syntax

```
FN = faceNormal(TR,ti)
FN = faceNormal(TR)
```

Description

`FN = faceNormal(TR,ti)` returns the unit normal vector to each triangle specified by `ti`. The `faceNormal` function supports only 2-D triangulations.

`FN = faceNormal(TR)` returns the unit normal vectors to all triangles.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

ti

Triangle IDs, specified as a column vector.

Output Arguments

FN

Face normals, returned as a matrix. Each row, `FN(j,:)`, is the unit normal vector to triangle `ti(j)`.

If you do not specify `ti`, then `faceNormal` returns the unit normal information for the entire triangulation. In this case, the normal associated with `TR.ConnectivityList(j,:)` is `FN(j,:)`.

Definitions

Triangle ID

A row number of the matrix, `TR.ConnectivityList`. You use this ID to refer a specific triangle.

Examples

Plot Unit Normals to Facets on a Spherical Surface

Create a set of random points on a spherical surface.

```
theta = gallery('uniformdata',[100,1],0)*2*pi;
phi = gallery('uniformdata',[100,1],1)*pi;
```

```
x = cos(theta).*sin(phi);
y = sin(theta).*sin(phi);
z = cos(phi);
```

Triangulate the points with `delaunayTriangulation`.

```
DT = delaunayTriangulation(x,y,z);
```

Find the free boundary facets and use them to create a triangulation representation for plotting.

```
[T,Xb] = freeBoundary(DT);
TR = triangulation(T,Xb);
```

Plot the triangulation.

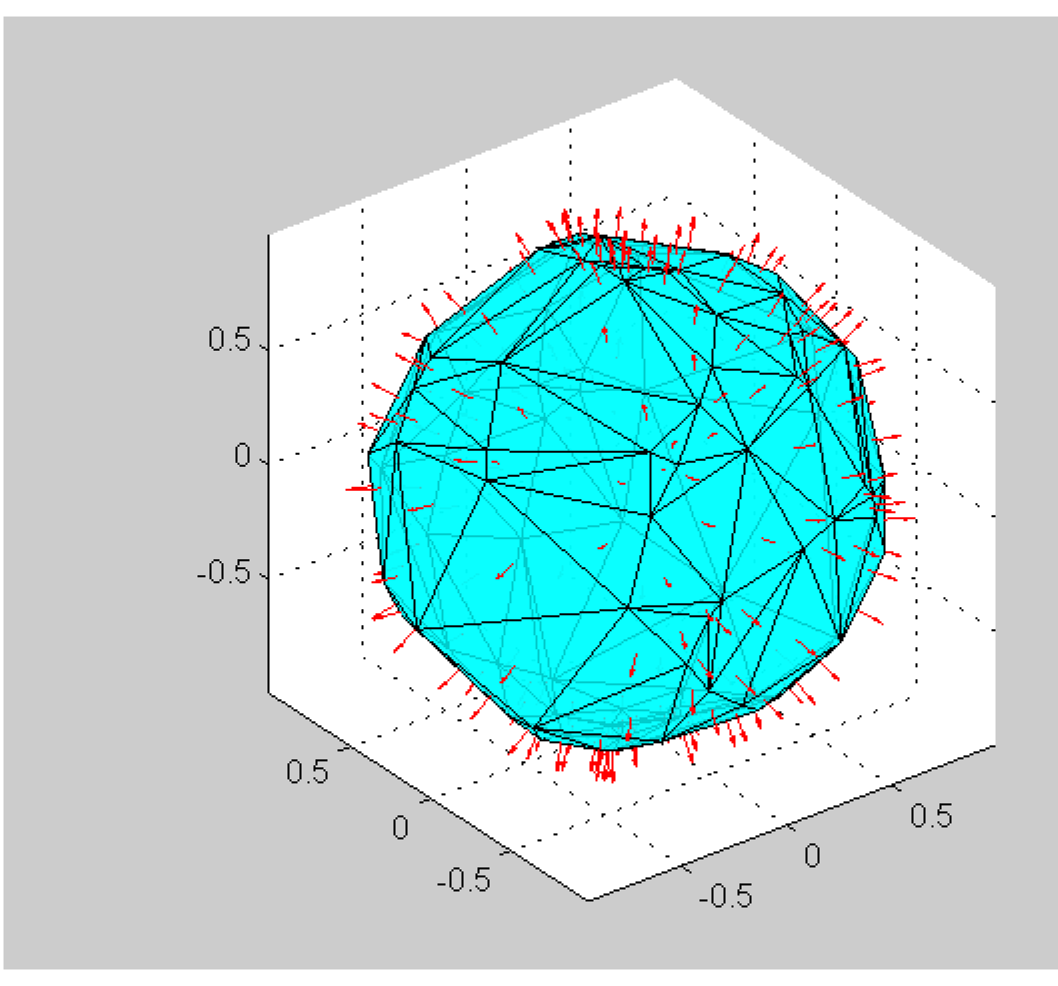
```
figure
trisurf(T,Xb(:,1),Xb(:,2),Xb(:,3), ...
     'FaceColor', 'cyan', 'faceAlpha', 0.8);
axis equal;
hold on;
```

Calulate the incenters and face normals.

```
P = incenter(TR);
fn = faceNormal(TR);
```

Display the normal vectors on the surface.

```
quiver3(P(:,1),P(:,2),P(:,3), ...
     fn(:,1),fn(:,2),fn(:,3),0.5, 'color','r');
hold off;
```



See Also `freeBoundary` | `delaunayTriangulation` |

Purpose

Triangulation sharp edges

Syntax

```
FE = featureEdges(TR,filterangle)
```

Description

`FE = featureEdges(TR,filterangle)` returns the feature edges in a 2-D triangulation.

Use this method to extract the sharp edges in the surface mesh for display purposes. A feature edge is an edge that has any of the following attributes:

- The edge is shared by only one triangle.
- The edge is shared by more than two triangles.
- The edge is shared by a pair of triangles with angular deviation greater than the `filterangle`.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

filterangle

Filter angle, specified as a scalar value in the range $[0,\pi]$. `featureEdges` returns adjacent triangles that have a dihedral angle that deviates from π by an angle greater than `filterangle`.

Output Arguments

FE

Feature edge vertex IDs, returned as a two-column matrix. Each row of `FE` corresponds to a feature edge and contains two IDs:

- `FE(j,1)` is the ID of the vertex at the start of the edge.
- `FE(j,2)` is the ID of the vertex at end of the edge.

triangulation.featureEdges

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Feature Edges Shown on a Surface

Use `featureEdges` to find the feature edges of a surface and display them on a plot.

Create a surface triangulation.

```
x = [0 0 0 0 0 3 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
DT = delaunayTriangulation(x,y);
T = DT(:,:);
```

Elevate the 2-D mesh to create a surface.

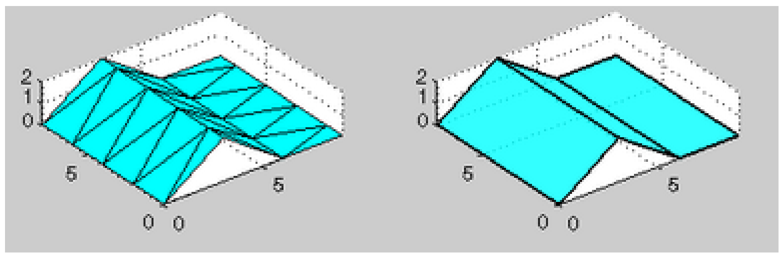
```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(T,x,y,z,'FaceColor','cyan');
axis equal;
```

Compute the feature edges using a filter angle of `pi/6`.

```
TR = triangulation(T,x,y,z);
fe = featureEdges(TR,pi/6)';
subplot(1,2,2);
trisurf(TR,'FaceColor','cyan','EdgeColor',...
'none','FaceAlpha',0.8);
axis equal;
```

Add the feature edges to the plot.

```
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth',1.5);
hold off;
```



See Also

edges | delaunayTriangulation |

triangulation.freeBoundary

Purpose

Triangulation facets referenced by only one triangle or tetrahedron

Syntax

```
FBtri = freeBoundary(TR)
[FBtri,FBpoints] = freeBoundary(TR)
```

Description

`FBtri = freeBoundary(TR)` returns the free boundary facets of `TR.ConnectivityList`. A facet in `TR` is on the free boundary if it is referenced by only one triangle or tetrahedron.

`[FBtri,FBpoints] = freeBoundary(TR)` also returns a matrix containing the vertices of the free boundary facets.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

Output Arguments

FBtri

Triangulation connectivity list, returned as a matrix that contains the following information:

- Each row in `FBtri` represents a facet on the free boundary.
- Each element is a "Vertex ID" on page 1-4345.

The vertex IDs in `FBtri` reference a specific matrix, depending on the syntax you choose:

- If you call `freeBoundary` with one output argument, then the elements of `FBtri` are row numbers of `TR.Points`.
- If you call `freeBoundary` with two output arguments, then the elements of `FBtri` are row numbers of `FBpoints`.

FBpoints

Free boundary points, returned as a matrix containing the coordinates of the vertices of the free boundary facets. Each row of `FBpoints` contains coordinates of a vertex.

Definitions

Vertex ID

A row number of the matrix, `TR.Points` or `FBpoints`. Use this ID to refer a specific vertex in the triangulation.

Examples

Surface of 3-D Triangulation

Use `freeBoundary` to extract the facets of a 3-D triangulation that cover the surface of an object.

Load a 3-D triangulation.

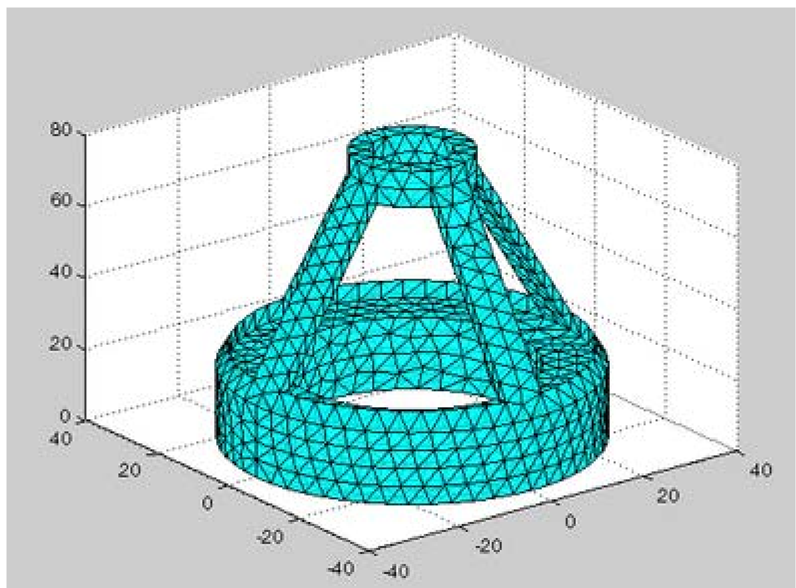
```
load tetmesh;
TR = triangulation(tet,X);
```

Compute the boundary triangulation.

```
[FBtri,FBpoints] = freeBoundary(TR);
```

Plot the boundary triangulation.

```
trisurf(FBtri,FBpoints(:,1),FBpoints(:,2),FBpoints(:,3), ...
       'FaceColor','cyan','FaceAlpha', 0.8);
```



Free Boundary of 2-D Delaunay Triangulation

Use `freeBoundary` when you want to highlight the outer edges of a 2-D Delaunay triangulation.

Create a triangulation from a random set of points.

```
x = gallery('uniformdata',[20,1],0);
y = gallery('uniformdata',[20,1],1);
DT = delaunayTriangulation(x,y);
```

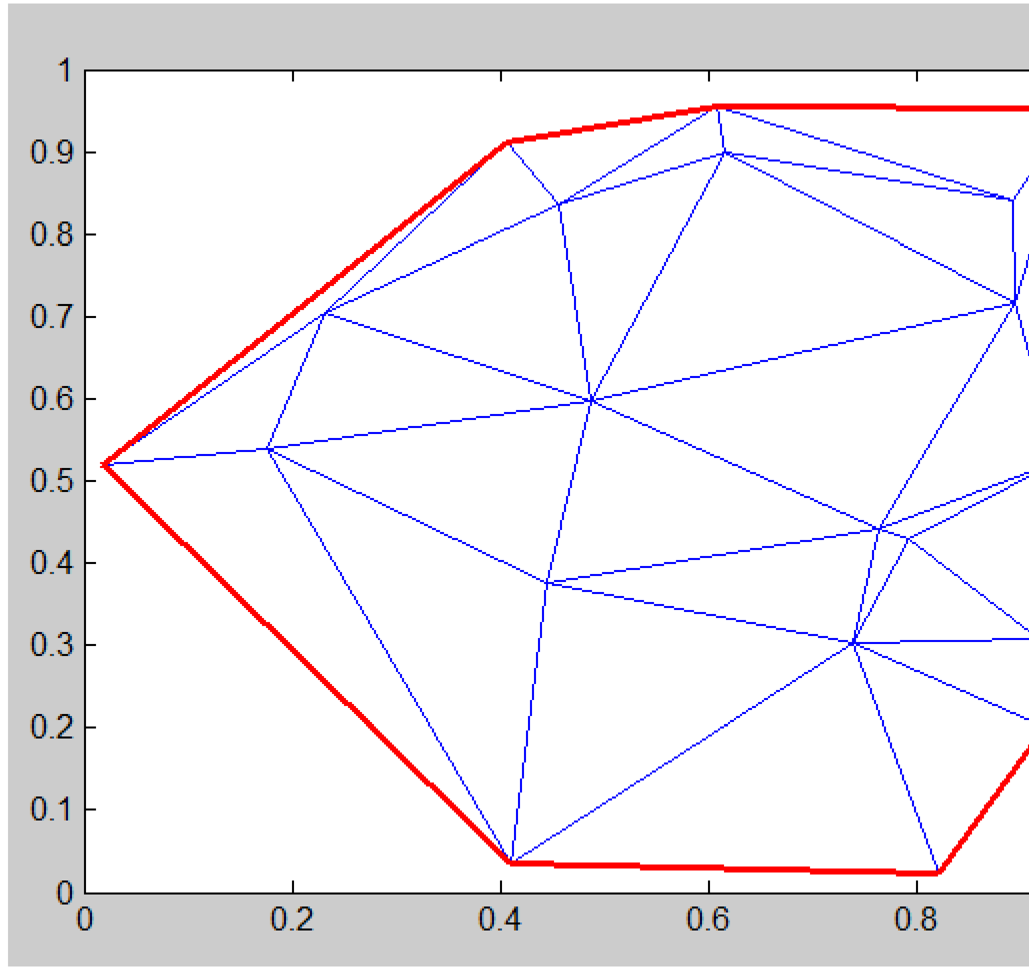
Find the free boundary edges.

```
fe = freeBoundary(DT)';
```

Plot the mesh and highlight the free boundary edges in red.

```
triplot(DT);
hold on;
```

```
plot(x(fe),y(fe),'-r','LineWidth',2) ;
hold off;
```



See Also

featureEdges | faceNormal | delaunayTriangulation |

triangulation.incenter

Purpose

Incenter of triangle or tetrahedron

Syntax

```
IC = incenter(TR,ti)
[IC,r] = incenter(TR,ti)
```

Description

`IC = incenter(TR,ti)` returns the coordinates of the incenter of each triangle or tetrahedron specified by `ti`.

`[IC,r] = incenter(TR,ti)` also returns the radii of the inscribed circles or spheres.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

ti

Triangle or tetrahedron IDs, specified as a column vector.

Output Arguments

IC

Incenters, returned as a matrix. Each row of `IC` contains the coordinates of an incenter. For example, `IC(j,:)` is the incenter of `ti(j)`.

r

Radii of the inscribed circles or spheres, returned as a vector. `r(j)` is the radius of the inscribed circle or sphere whose center is `IC(j,:)`.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

Find Incenters in 3-D Triangulation

Load a 3-D triangulation.

```
load tetmesh
```

Calculate the incenters of the first five tetrahedra.

```
TR = triangulation(tet,X);
IC = incenter(TR,[1:5]')

IC =

   -6.1083  -31.0234    8.1439
   -2.1439  -31.0283    5.8742
   -1.9555  -31.9463    7.4112
   -4.3019  -30.8460   10.5169
   -3.1596  -29.3642    6.1851
```

Find Incenters in 2-D Delaunay Triangulation

Create the Delaunay triangulation.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
DT = delaunayTriangulation(x,y);
```

Calculate incenters of the triangles

```
IC = incenter(DT)

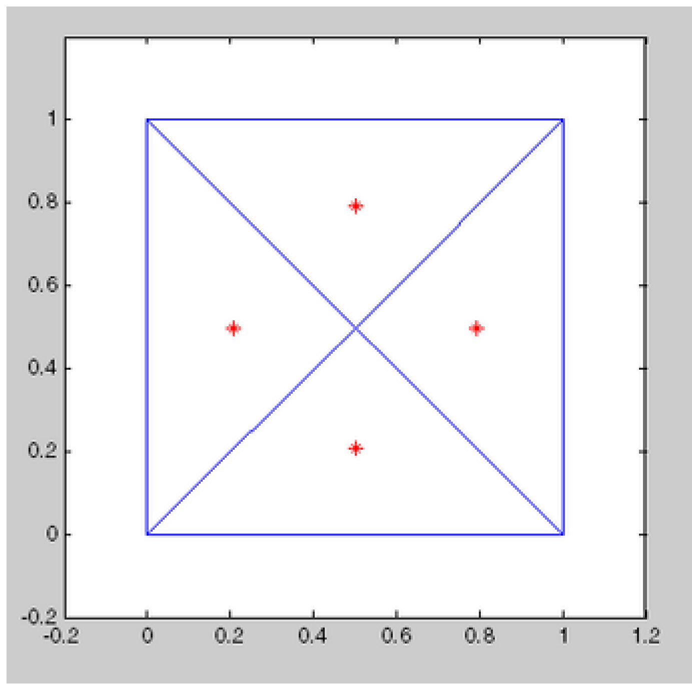
IC =

    0.2071    0.5000
    0.5000    0.7929
    0.7929    0.5000
    0.5000    0.2071
```

Plot the triangles and incenters.

```
triplot(DT);
axis equal;
```

```
axis([-0.2 1.2 -0.2 1.2]);
hold on;
plot(IC(:,1),IC(:,2),'*r');
hold off;
```



See Also

`circumcenter` | `delaunayTriangulation` |

Purpose

Test if two vertices are connected by edge

Syntax

```
tf = isConnected(TR,vstart,vend)
tf = isConnected(TR,E)
```

Description

`tf = isConnected(TR,vstart,vend)` returns a `logical` array of `true` or `false` values that indicate whether the specified pairs of vertices are connected by an edge. Element `tf(j)` is `true` when the vertices, `vstart(j)` and `vend(j)`, are connected by an edge.

`tf = isConnected(TR,E)` specifies the edge start and end indices in matrix `E`. Element `tf(j)` is `true` when the vertices, `E(j,1)` and `E(j,2)`, are connected by an edge.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

vstart

IDs of start vertices, specified as a column vector. Each vertex ID refers to a vertex at the start of an edge.

vend

IDs of end vertices, specified as a column vector. Each vertex ID refers to a vertex at the end of an edge.

E

IDs of the edge vertices, specified as a two-column matrix. Each row of `E` corresponds to a candidate edge and contains two IDs:

- `E(j,1)` is the ID of the vertex at the start of a candidate edge.
- `E(j,2)` is the ID of the vertex at end of the edge.

Output Arguments

tf

Logical values, returned as a column vector. Element `tf(j)` is `true` when either of the following are true:

- The vertices, `vstart(j)` and `vend(j)`, are connected by an edge.
- The vertices, `E(j,1)` and `E(j,2)`, are connected by an edge.

Otherwise, `tf(j)` is false.

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Determine Whether Vertices are connected by an Edge in 2-D

Load a 2-D triangulation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Determine whether vertices `3` and `117` are connected by an edge.

```
isConnected(TR,3,117)
```

```
ans =

     1
```

The vertices are connected by an edge.

Determine whether vertices `3` and `164` are connected by an edge.

```
isConnected(TR,3,164)
```

```
ans =
```

```
     0
```

The vertices are not connected by an edge.

Determine Whether Vertices are connected by an Edge in 3-D

```
X = gallery('uniformdata',[10,3],0);
DT = delaunayTriangulation(X);
```

Determine whether vertices 2 and 7 are connected by an edge.

```
E = [2 7];
isConnected(DT,E)
```

```
ans =

     1
```

The vertices are connected by an edge.

See Also

edges | edgeAttachments | delaunayTriangulation |

triangulation.neighbors

Purpose

Neighbors to specified triangle or tetrahedron

Syntax

```
N = neighbors(TR,ti)
N = neighbors(TR)
```

Description

`N = neighbors(TR,ti)` returns the neighbors of the triangles or tetrahedra specified in `ti`.

`N = neighbors(TR)` returns the neighbors of all the triangles or tetrahedra.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

ti

Triangle or tetrahedron IDs, specified as a column vector.

Output Arguments

TN

IDs of the neighboring triangles or tetrahedra, returned as a matrix. The elements in `TN(i,:)` are the neighbors associated with `ti(i)`.

By convention, `TN(i,j)` is the neighbor opposite the `j`th vertex of `ti(i)`. If a triangle or tetrahedron has one or more boundary facets, the nonexistent neighbors are represented as `NaN` values in `TN`.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Query Neighbors in 2-D Delaunay Triangulation

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[10,1],0);
y = gallery('uniformdata',[10,1],1);
DT = delaunayTriangulation(x,y);
```

Find the neighbors of the first triangle.

```
TN = neighbors(DT,1)

TN =

   NaN     4     5
```

The first triangle has a boundary edge and two neighbors.

Examine the vertex IDs of the first neighbor, `TN(2)`.

```
DT.ConnectivityList(TN(2),:)

ans =

     2     4     7
```

Query Neighbors in 3-D Triangulation

Create the Delaunay triangulation.

```
load tetmesh
TR = triangulation(tet,X);
```

Find the neighbors to each triangle in the triangulation.

```
TN = neighbors(TR);
```

Find the neighbors of the fifth tetrahedron.

```
TN(5,:)
```

```
ans =

        2360        1539           2        1851
```

Examine the vertex IDs of the first neighbor, `TN(1)`.

```
TR.ConnectivityList(TN(1),:)
```

```
ans =

        1093         891         893         858
```

See Also

`edgeAttachments` | `delaunayTriangulation` |

Purpose

Size of triangulation connectivity list

Syntax

```
sz = size(TR)
```

Description

`sz = size(TR)` returns the size the triangulation connectivity list.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

Output Arguments

sz

Size of connectivity list, returned as a two-element row vector. The first element, `sz(1)` is the number of triangles or tetrahedra in the triangulation, and `sz(2)` is the number of vertices per triangle or tetrahedron.

Examples

Size of 2-D Triangulation

Create a triangulation.

```
P = [ 2.5    8.0
      6.5    8.0
      2.5    5.0
      6.5    5.0
      1.0    6.5
      8.0    6.5];

T = [5  3  1;
     3  2  1;
     3  4  2;
     4  6  2];

TR = triangulation(T,P);
```

Get the size of the connectivity list.

triangulation.size

```
size(TR)

ans =

     4     3
```

The triangulation has 4 triangles, and each triangle has 3 vertices.

See Also

`sizedelaunayTriangulation` |

triangulation.vertexAttachments

Purpose

Triangles or tetrahedra attached to specified vertex

Syntax

```
ti = vertexAttachments(TR,vi)
ti = vertexAttachments(TR)
```

Description

`ti = vertexAttachments(TR,vi)` returns the triangles or tetrahedra attached to the specified vertices, `vi`.

`ti = vertexAttachments(TR)` returns the triangles or tetrahedra attached to every vertex in the triangulation.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

vi

Query vertices, specified as a column vector of vertex IDs.

Output Arguments

ti

IDs of the triangles or tetrahedra attached to the vertices, returned as an `m`-by-`1` cell array. Each cell in `ti` contains the IDs of the attached triangles or tetrahedra. `ti{j}` contains the attachments to the vertex, `vi(j)`. The attachments are returned in a cell array because the number of triangles or tetrahedra associated with each vertex can vary.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Attachments to Specific Vertex in 2-D Delaunay Triangulation

Locate and plot the attachments to a specific vertex.

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20,1],0);
y = gallery('uniformdata',[20,1],1);
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to the fifth vertex.

```
ti = vertexAttachments(DT,5);
ti{:}
```

```
ans =

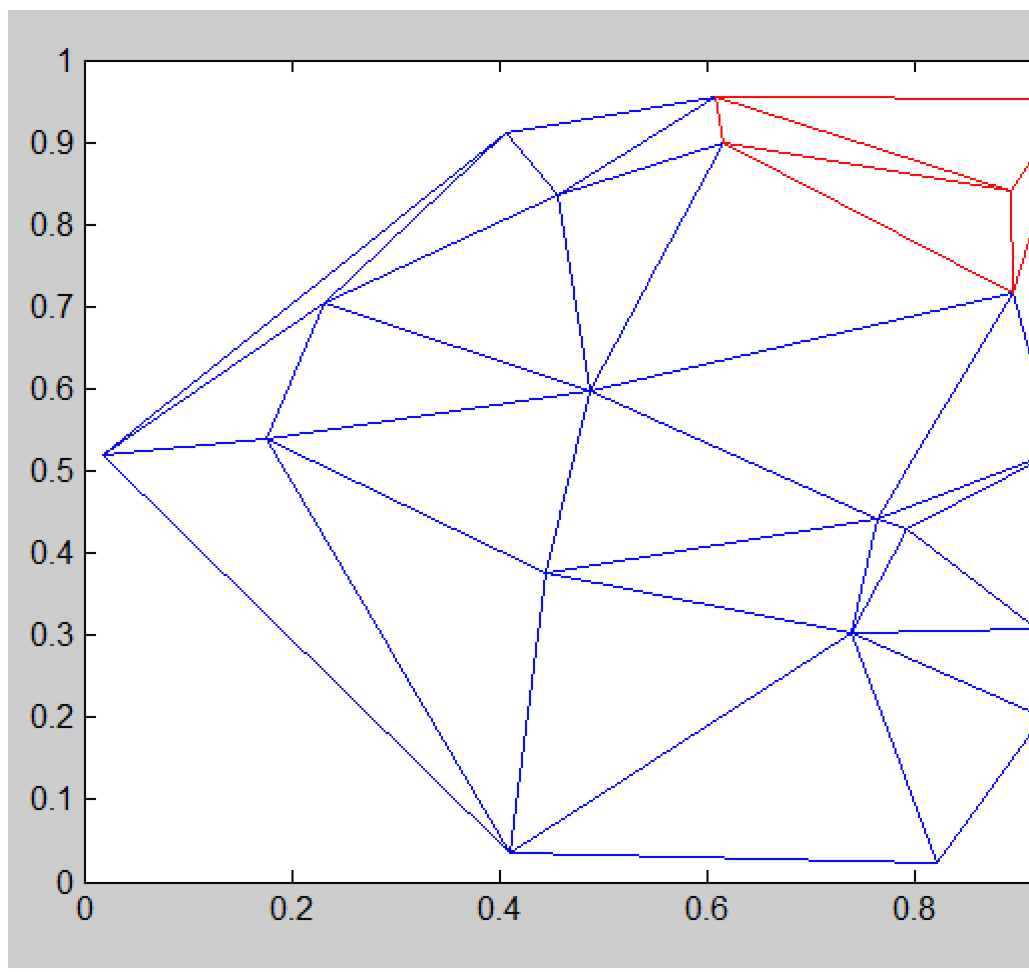
    18    23    21    22
```

Plot the triangulation.

```
triplot(DT);
hold on;
```

Plot the triangles attached to vertex 5 (in red).

```
triplot(DT(ti{:},:),x,y,'Color','r');
hold off;
```



See Also

`edgeAttachments` | `delaunayTriangulation` |

triangulation.vertexNormal

Purpose Triangulation vertex normal

Syntax

```
VN = vertexNormal(TR,vi)
VN = vertexNormal(TR)
```

Description

`VN = vertexNormal(TR,vi)` returns the unit normal vector to each of the specified vertices in `vi`.

`VN = vertexNormal(TR)` returns the normal information for all vertices in the triangulation.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

vi

IDs of vertices to query, specified as a column vector. Each element in `vi` is a “Vertex ID” on page 1-4362.

Output Arguments

VN

Vertex normals, returned a matrix. Each row, `VN(j,:)`, is the unit normal vector at the vertex `vi(j)`. The vector at `VN(j,:)` is the average unit normal of the faces attached to vertex `vi(j)`.

If you do not specify `vi`, then `vertexNormal` returns the unit normal information for all vertices in the triangulation. In this case, the normal associated with `TR.Points(j,:)` is `VN(j,:)`.

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Unit Normal Vectors to the Surface of a Cube

Create a 3-D triangulation representing the volume of a cube.

```
[X,Y,Z] = meshgrid(1:4);
X = X(:);
Y = Y(:);
Z = Z(:);
dt = delaunayTriangulation(X,Y,Z);
```

Find the surfaces of the cube and isolate them in a 2-D triangulation.

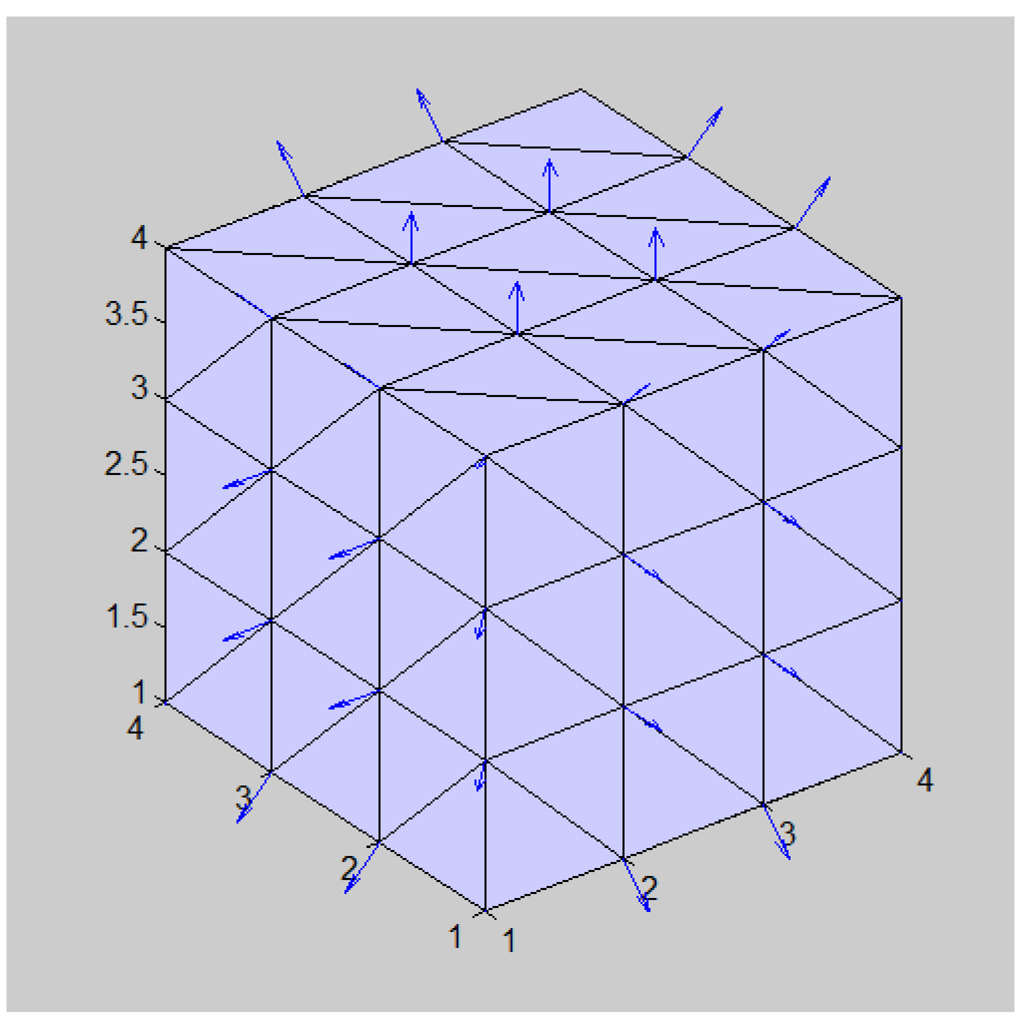
```
[Tfb,Xfb] = freeBoundary(dt);
TR = triangulation(Tfb,Xfb);
```

Find the unit normal vectors to the triangles on the surface of the cube.

```
vn = vertexNormal(TR);
```

Plot the results.

```
trisurf(TR,'FaceColor', [0.8 0.8 1.0]);
axis equal
hold on
quiver3(Xfb(:,1),Xfb(:,2),Xfb(:,3),...
     vn(:,1),vn(:,2),vn(:,3),0.5,'color','b');
hold off
```



See Also `freeBoundary` | `delaunayTriangulation` |

Purpose

Real part of complex number

Syntax

```
X = real(Z)
```

Description

`X = real(Z)` returns the real part of the elements of the complex array `Z`.

Examples

`real(2+3*i)` is `2`.

See Also

`abs` | `angle` | `conj` | `i` | `j` | `imag`

reallog

Purpose

Natural logarithm for nonnegative real arrays

Syntax

```
Y = reallog(X)
```

Description

`Y = reallog(X)` returns the natural logarithm of each element in array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

Examples

```
M = magic(4)

M =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1

reallog(M)

ans =
    2.7726    0.6931    1.0986    2.5649
    1.6094    2.3979    2.3026    2.0794
    2.1972    1.9459    1.7918    2.4849
    1.3863    2.6391    2.7081         0
```

See Also

`log` | `realpow` | `realsqrt`

Purpose

Largest positive floating-point number

Syntax

```
n = realmax
```

Description

`n = realmax` returns the largest finite floating-point number in IEEE double precision.

`realmax('double')` is the same as `realmax` with no arguments.

`realmax('single')` returns the largest finite floating-point number in IEEE single precision.

Examples

Find the value of the constant `realmax`:

```
ndouble = realmax
nsingle = realmax('single')
```

```
ndouble =

  1.7977e+308

nsingle =

  3.4028e+38
```

See Also

`eps` | `realmin` | `intmax`

Tutorials

- “Floating-Point Numbers”

realmin

Purpose

Smallest positive normalized floating-point number

Syntax

```
n = realmin
realmin('double')
realmin('single')
```

Description

`n = realmin` returns the smallest positive normalized floating-point number in IEEE double precision.

`realmin('double')` is the same as `realmin` with no arguments.

`realmin('single')` returns the smallest positive normalized floating-point number in IEEE single precision.

Examples

Find the value of the constant `realmin`:

```
ndouble = realmin
nsingle = realmin('single')
```

```
ndouble =

  2.2251e-308

nsingle =

  1.1755e-38
```

See Also

`eps` | `realmax` | `intmin`

Tutorials

- "Floating-Point Numbers"

Purpose Array power for real-only output

Syntax

```
Z = realpow(X,Y)
```

Description

`Z = realpow(X,Y)` raises each element of array `X` to the power of its corresponding element in array `Y`. Arrays `X` and `Y` must be the same size. The range of `realpow` is the set of all real numbers, i.e., all elements of the output array `Z` must be real.

Examples

```
X = -2*ones(3,3)

X =
     -2     -2     -2

    -2    -8    64
```

See Also

`reallog` | `realsqrt` | `Arithmetic Operator .^`

realsqrt

Purpose

Square root for nonnegative real arrays

Syntax

```
Y = realsqrt(X)
```

Description

`Y = realsqrt(X)` returns the square root of each element of array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

Examples

```
M = magic(4)

M =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1

realsqrt(M)

ans =
    4.0000    1.4142    1.7321    3.6056
    2.2361    3.3166    3.1623    2.8284
    3.0000    2.6458    2.4495    3.4641
    2.0000    3.7417    3.8730    1.0000
```

See Also

`reallog` | `realpow` | `sqrt` | `sqrtm`

Purpose

Record data and event information to file

Syntax

```
record(obj)
record(obj,'switch')
```

Description

`record(obj)` toggles the recording state for the serial port object, `obj`.

`record(obj,'switch')` initiates or terminates recording for `obj`. *`switch`* can be `on` or `off`. If *`switch`* is `on`, recording is initiated. If *`switch`* is `off`, recording is terminated.

Tips

Before you can record information to disk, `obj` must be connected to the device with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to record information while `obj` is not connected to the device. Each serial port object must record information to a separate file. Recording is automatically terminated when `obj` is disconnected from the device with `fclose`.

The `RecordName` and `RecordMode` properties are read-only while `obj` is recording, and must be configured before using `record`.

For a detailed description of the record file format and the properties associated with recording data and event information to a file, refer to Debugging: Recording Information to Disk.

Examples

This example creates the serial port object `s` on a Windows platform. It connects `s` to the device, configures `s` to record information to a file, writes and reads text data, and then disconnects `s` from the device.

```
s = serial('COM1');
fopen(s)
s.RecordDetail = 'verbose';
s.RecordName = 'MySerialFile.txt';
record(s,'on')
fprintf(s,'*IDN?')
out = fscanf(s);
record(s,'off')
```

```
fclose(s)
```

See Also

fclose | fopen | RecordDetail | RecordMode | RecordName | RecordStatus | Status

Purpose

Record audio to `audiorecorder` object

Syntax

```
record(recorderObj)
record(recorderObj, length)
```

Description

`record(`*`recorderObj`*`)` records audio from an input device, such as a microphone connected to your system. *`recorderObj`* is an `audiorecorder` object that defines the sample rate, bit depth, and other properties of the recording.

`record(`*`recorderObj`*`, `*`length`*`)` records for the number of seconds specified by *`length`*.

Examples

Record 5 seconds of your speech with a microphone:

```
myVoice = audiorecorder;

% Define callbacks to show when
% recording starts and completes.
myVoice.StartFcn = 'disp(''Start speaking.'')';
myVoice.StopFcn = 'disp(''End of recording.'')';

record(myVoice, 5);
```

To listen to the recording, call the `play` method:

```
play(myVoice);
```

`audiorecorder` | `getaudiodata` | `recordblocking`

How To

- “Record Audio”
- “Recording or Playing Audio within a Function”

audiorecorder.recordblocking

Purpose

Record audio to `audiorecorder` object, holding control until recording completes

Syntax

`recordblocking(*recorderObj*, *length*)`

Description

`recordblocking(*recorderObj*, *length*)` records audio from an input device, such as a microphone connected to your system, for the number of seconds specified by *`length`*. The `recordblocking` method does not return control until recording completes. *`recorderObj`* is an `audiorecorder` object that defines the sample rate, bit depth, and other properties of the recording.

Examples

Record 5 seconds of your speech with a microphone, and play it back:

```
myVoice = audiorecorder;

disp('Start speaking.');
recordblocking(myVoice, 5);
disp('End of recording. Playing back ...');

play(myVoice);
```

`audiorecorder` | `getaudiodata` | `record`

How To

- "Record Audio"

Purpose

Create 2-D rectangle object

Syntax

```
rectangle
rectangle('Position',[x,y,w,h])
rectangle('Curvature',[x,y])
rectangle('PropertyName',propertyvalue,...)
h = rectangle(...)
```

Properties

For a list of properties, see Rectangle Properties.

Description

`rectangle` draws a rectangle with `Position [0,0,1,1]` and `Curvature [0,0]` (i.e., no curvature).

`rectangle('Position',[x,y,w,h])` draws the rectangle from the point `x`,`y` and having a width of `w` and a height of `h`. Specify values in axes data units.

Note that, to display a rectangle in the specified proportions, you need to set the axes data aspect ratio so that one unit is of equal length along both the x and y axes. You can do this with the command `axis equal` or `daspect([1,1,1])`.

`rectangle('Curvature',[x,y])` specifies the curvature of the rectangle sides, enabling it to vary from a rectangle to an ellipse. The horizontal curvature `x` is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature `y` is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of `x` and `y` can range from `0` (no curvature) to `1` (maximum curvature). A value of `[0,0]` creates a rectangle with square sides. A value of `[1,1]` creates an ellipse. If you specify only one value for `Curvature`, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension.

`rectangle('PropertyName',propertyvalue,...)` draws the rectangle using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see Rectangle Properties.

`h = rectangle(...)` returns the handle of the rectangle object created.

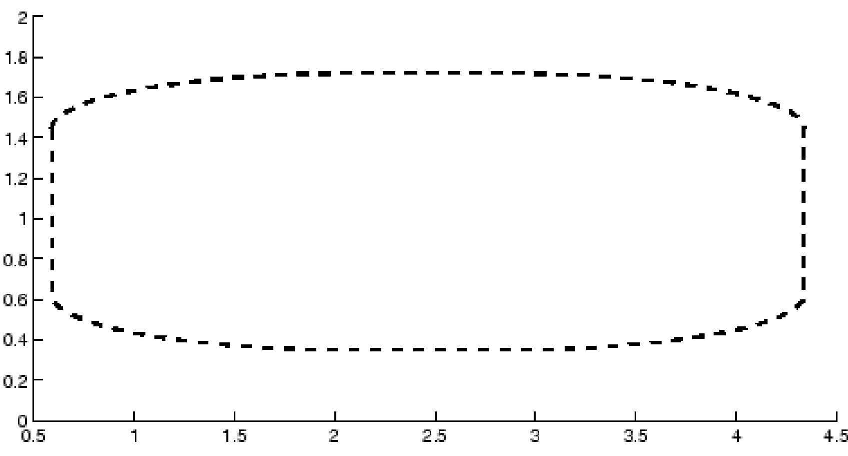
Tips

Rectangle objects are 2-D and can be drawn in an axes only if the view is `[0 90]` (i.e., `view(2)`). Rectangles are children of axes and are defined in coordinates of the axes data.

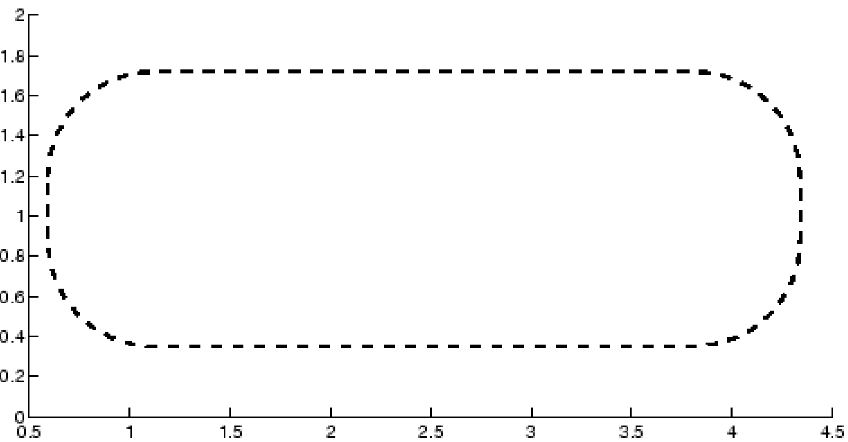
Examples

This example sets the data aspect ratio to `[1,1,1]` so that the rectangle is displayed in the specified proportions (`daspect`). Note that the horizontal and vertical curvature can be different. Also, note the effects of using a single value for `Curvature`.

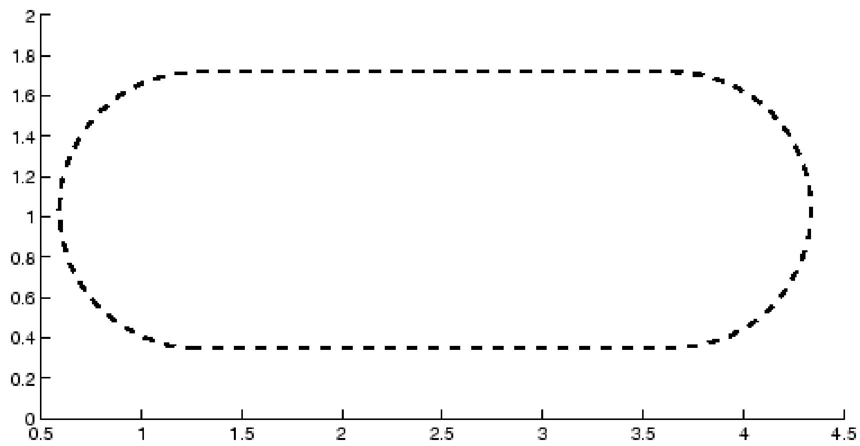
```
rectangle('Position',[0.59,0.35,3.75,1.37],...
          'Curvature',[0.8,0.4],...
         'LineWidth',2,'LineStyle','--')
daspect([1,1,1])
```



Specifying a single value of `[0.4]` for `Curvature` produces



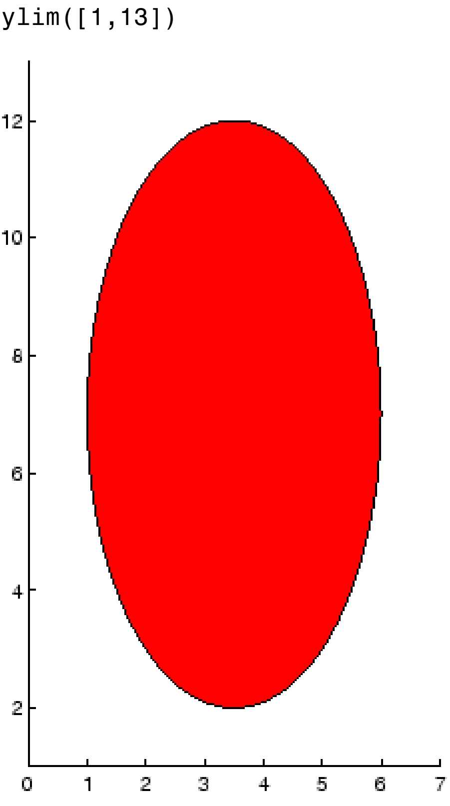
A `Curvature` of `[1]` produces a rectangle with the shortest side completely round:



This example creates an ellipse and colors the face red.

```
rectangle('Position',[1,2,5,10],'Curvature',[1,1],...
          'FaceColor','r')
daspect([1,1,1])
xlim([0,7])
```

```
ylim([1,13])
```



Setting Default Properties

You can set default rectangle properties on the axes, figure, and `root object` levels:

```
set(0,'DefaultRectangleProperty',PropertyValue...)
set(gcf,'DefaultRectangleProperty',PropertyValue...)
set(gca,'DefaultRectangleProperty',PropertyValue...)
```

where *`Property`* is the name of the rectangle property whose default value you want to set and `PropertyValue` is the value you are specifying. Use `set` and `get` to access the surface properties.

`line` | `patch` | `annotation` | Rectangle Properties

Rectangle Properties

Purpose

Define rectangle properties

Creating Rectangle Objects

Use `rectangle` to create rectangle objects.

Modifying Properties

You can set and query graphics object properties in two ways:

- "The Property Editor" is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see "Setting Default Property Values".

See "Core Graphics Objects" for general information about this type of object.

Rectangle Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Annotation`

`hg.Annotation` object (read-only)

Handle of `Annotation` *object.* The `Annotation` property enables you to specify whether this rectangle object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the rectangle object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Represent this rectangle object in a legend (default)
`off`	Do not include this rectangle object in a legend
`children`	Same as `on` because rectangle objects do not have children

Setting the IconDisplayStyle property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','off')
```

Using the IconDisplayStyle property

See "Controlling Legends" for more information and examples.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Button press callback function. Executes whenever you press a mouse button while the pointer is over the rectangle object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
   sel_typ = get(gcbf,'SelectionType')
   switch sel_typ
      case 'normal'
         disp('User clicked left-mouse button')
         set(src,'Selected','on')
      case 'extend'
         disp('User did a shift-click')
         set(src,'Selected','on')
      case 'alt'
         disp('User did a control-click')
         set(src,'Selected','on')
         set(src,'SelectionHighlight','off')
   end
end
```

Suppose `h` is the handle of a rectangle object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h,'ButtonDownFcn',@button_down)
```

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`Children`
: vector of handles

  The empty matrix; rectangle objects have no children.

`Clipping`
: `{on} | off`

Clipping mode. MATLAB clips rectangles to the axes plot box by default. If you set `Clipping` to `off`, rectangles are displayed outside the axes plot box. This can occur if you create a rectangle, set `hold` to `on`, freeze axis scaling (`axis` set to `manual`), and then create a larger rectangle.

`CreateFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Executes when MATLAB creates a rectangle object. You must define this property as a default value for rectangles or in a call to the `rectangle` function to create a new rectangle object. For example, the statement:

```
set(0,'DefaultRectangleCreateFcn',@rect_create)
```

defines a default value for the rectangle `CreateFcn` property on the root level that sets the axes `DataAspectRatio` whenever you create a rectangle object. The callback function must be on your MATLAB path when you execute the above statement.

```
function rect_create(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
  axh = get(src,'Parent');
  set(axh,'DataAspectRatio',[1,1,1]))
end
```

MATLAB executes this function after setting all rectangle properties. Setting this property on an existing rectangle object has no effect. The function must define at least two input arguments (handle of object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function

and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`Curvature`

one- or two-element vector `[x,y]`

Amount of horizontal and vertical curvature. Specifies the curvature of the rectangle sides, which enables the shape of the rectangle to vary from rectangular to ellipsoidal. The horizontal curvature `x` is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature `y` is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of `x` and `y` can range from `0` (no curvature) to `1` (maximum curvature). A value of `[0,0]` creates a rectangle with square sides. A value of `[1,1]` creates an ellipse. If you specify only one value for `Curvature`, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Delete rectangle callback function. Executes when you delete the rectangle object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
```

```
   obj_tp = get(src,'Type');
   disp([obj_tp, ' object deleted'])
   disp('Its user data is:')
   disp(get(src,'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DisplayName`
string

String used by legend. The `legend` function uses the `DisplayName` property to label the rectangle object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EdgeColor`
`{ColorSpec} | none`

Color of the rectangle edges. Specifies the color of the rectangle edges as a color or specifies that no edges be drawn.

`EraseMode`
`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase rectangle objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the rectangle when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the rectangle by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath the rectangle.

However, the rectangle's color depends on the color of whatever is beneath it on the display.

- `background` — Erase the rectangle by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is `none`. This damages objects that are behind the erased rectangle, but rectangles are always properly colored.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceColor`
`ColorSpec | {none}`

Color of rectangle face. Specifies the color of the rectangle face, which is not colored by default.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.

- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the Root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

`HitTest`

`{on} | off`

Selectable by mouse click. Determines if the rectangle can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the

rectangle. If `HitTest` is `off`, clicking the rectangle selects the object below it (which might be the axes containing it).

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`

`{-} | -- | : | -. | none`

Line style of rectangle edge.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

`LineWidth`

size in points

Width of the rectangle edge line. Specify this value in points. 1 point = $^1/_{72}$ inch. The default value is `0.5` points.

`Parent`
handle of axes, hggroup, or hgtransform

Parent of rectangle object. Contains the handle of the rectangle object's parent. The parent of a rectangle object is the axes, hggroup, or hgtransform object that contains it.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Position`
four-element vector `[x,y,width,height]`

Location and size of rectangle. Specifies the location and size of the rectangle in the data units of the axes. The point defined by `x`, `y` specifies one corner of the rectangle, and `width` and `height` define the size in units along the *x*- and *y*-axes respectively.

`Selected`
`on | off`

Is object selected? When this property is `on` MATLAB displays selection handles if the `SelectionHighlight` property is also `on`. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing handles at each vertex. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`Tag`
string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

`Type`
string (read-only)

Class of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For rectangle objects, `Type` is always '`rectangle`'.

`UIContextMenu`
handle of uicontextmenu object

Associate a context menu with the rectangle. Assign this property the handle of a uicontextmenu object created in the same figure as the rectangle. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the rectangle.

`UserData`
matrix

User-specified data. Data you want to associate with the rectangle object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Rectangle visibility. By default, all rectangles are visible. When set to `off`, the rectangle is not visible, but still exists, and you can `get` and `set` its properties.

See Also

`rectangle`

Purpose

Rectangle intersection area

Syntax

```
area = rectint(A,B)
```

Description

`area = rectint(A,B)` returns the area of intersection of the rectangles specified by position vectors `A` and `B`.

If `A` and `B` each specify one rectangle, the output `area` is a scalar.

`A` and `B` can also be matrices, where each row is a position vector. `area` is then a matrix giving the intersection of all rectangles specified by `A` with all the rectangles specified by `B`. That is, if `A` is `n`-by-`4` and `B` is `m`-by-`4`, then `area` is an `n`-by-`m` matrix where `area(i,j)` is the intersection area of the rectangles specified by the `i`th row of `A` and the `j`th row of `B`.

Note A position vector is a four-element vector `[x,y,width,height]`, where the point defined by `x` and `y` specifies one corner of the rectangle, and `width` and `height` define the size in units along the x and y axes respectively.

See Also

`polyarea`

Purpose

Set option to move deleted files to recycle folder

Syntax

```
recycle
stat = recycle
previousStat = recycle state
previousStat = recycle('state')
```

Description

`recycle` displays the current state, `on` or `off`, for recycling files you remove using the `delete` function. When the value is `on`, deleted files move to a different location. The location varies by platform—see "Deleting Files and Folders Using Functions". When the value is `off`, the `delete` function permanently removes the files. For details, see the Tips section.

`stat = recycle` returns the current state for recycling files to the character array `stat`.

`previousStat = recycle` *`state`* sets the recycle option for MATLAB to the specified state, either `on` or `off`. The `previousStat` value is the recycle state before running the statement.

`previousStat = recycle('state')` is the function form of the syntax.

Tips

The preference for **Deleting files** sets the state of the `recycle` function at startup. When you change the preference, it changes the state of `recycle`. When you change the state of `recycle`, it does not change the preference. Use `recycle` to override the behavior of the preference. For example, regardless of the setting for the **Deleting files** preference, to remove `thisfile.m` permanently, run:

```
recycle('off')
delete('thisfile.m')
```

After setting the `recycle` state to `off`, all files you delete using the `delete` function are deleted permanently until you do one of the following:

- Run `recycle('on')`

- Restart MATLAB. Upon startup, MATLAB sets the state for `recycle` to match the **Deleting files** preference.

Examples

Start from a state where file recycling is off. Verify the current recycle state:

```
recycle
ans =
   off
```

Turn file recycling on. Delete a file and move it to the recycle bin or temporary folder:

```
recycle on;
delete myfile.txt
```

`delete` | `dir` | `ls` | `rmdir`

How To

- “General Preferences”

Purpose

Reduce number of patch faces

Syntax

```
nfv = reducepatch(p,r)
nfv = reducepatch(fv,r)
nfv = reducepatch(p) or nfv = reducepatch(fv)
reducepatch(...,'fast')
reducepatch(...,'verbose')
nfv = reducepatch(f,v,r)
[nf,nv] = reducepatch(...)
```

Description

`reducepatch(p,r)` reduces the number of faces of the patch identified by handle `p`, while attempting to preserve the overall shape of the original object. The MATLAB software interprets the reduction factor `r` in one of two ways depending on its value:

- If `r` is less than 1, `r` is interpreted as a fraction of the original number of faces. For example, if you specify `r` as 0.2, then the number of faces is reduced to 20% of the number in the original patch.
- If `r` is greater than or equal to 1, then `r` is the target number of faces. For example, if you specify `r` as 400, then the number of faces is reduced until there are 400 faces remaining.

`nfv = reducepatch(p,r)` returns the reduced set of faces and vertices but does not set the `Faces` and `Vertices` properties of patch `p`. The struct `nfv` contains the faces and vertices after reduction.

`nfv = reducepatch(fv,r)` performs the reduction on the faces and vertices in the struct `fv`.

`nfv = reducepatch(p) or nfv = reducepatch(fv)` uses a reduction value of `0.5`.

`reducepatch(...,'fast')` assumes the vertices are unique and does not compute shared vertices.

`reducepatch(...,'verbose')` prints progress messages to the command window as the computation progresses.

`nfv = reducepatch(f,v,r)` performs the reduction on the faces in `f` and the vertices in `v`.

`[nf,nv] = reducepatch(...)` returns the faces and vertices in the arrays `nf` and `nv`.

Tips

If the patch contains nonshared vertices, MATLAB computes shared vertices before reducing the number of faces. If the faces of the patch are not triangles, MATLAB triangulates the faces before reduction. The faces returned are always defined as triangles.

The number of output triangles may not be exactly the number specified with the reduction factor argument (`r`), particularly if the faces of the original patch are not triangles.

Examples

This example illustrates the effect of reducing the number of faces to only 15% of the original value.

```
[x,y,z,v] = flow;
p = patch(isosurface(x,y,z,v,-3));
set(p,'facecolor','w','EdgeColor','b');
daspect([1,1,1])
view(3)
figure;
h = axes;
p2 = copyobj(p,h);
reducepatch(p2,0.15)
daspect([1,1,1])
view(3)
```

`isosurface` | `isocaps` | `isonormals` | `smooth3` | `subvolume` | `reducevolume`

How To

- Vector Field Displayed with Cone Plots

Purpose

Reduce number of elements in volume data set

Syntax

```
[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])
[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])
nv = reducevolume(...)
```

Description

`[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])` reduces the number of elements in the volume by retaining every `Rx`th element in the x direction, every `Ry`th element in the y direction, and every `Rz`th element in the z direction. If a scalar `R` is used to indicate the amount or reduction instead of a three-element vector, the MATLAB software assumes the reduction to be `[R R R]`.

The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The reduced volume is returned in `nv`, and the coordinates of the reduced volume are returned in `nx`, `ny`, and `nz`.

`[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p] = size(V)`.

`nv = reducevolume(...)` returns only the reduced volume.

Examples

This example uses a data set that is a collection of MRI slices of a human skull. This data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then reduced (`reducevolume`) so that what remains is every fourth element in the x and y directions and every element in the z direction.
- The reduced data is smoothed (`smooth3`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with an interpolated face color draws the end caps (`FaceColor`) `isocaps`).
- The view of the object is set (`view`, `axis`, `daspect`).

- A 100-element grayscale colormap provides coloring for the end caps (colormap).
- Adding a light to the right of the camera illuminates the object (camlight, lighting).

```
load mri
D = squeeze(D);
[x,y,z,D] = reducevolume(D,[4,4,1]);
D = smooth3(D);
p1 = patch(isosurface(x,y,z,D, 5,'verbose'),...
    'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
    'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight; lighting gouraud
```

refresh

Purpose Redraw current figure

Syntax

```
refresh
refresh(h)
```

Description

`refresh` erases and redraws the current figure.

`refresh(h)` redraws the figure identified by `h`.

refreshdata

Purpose

Refresh data in graph when data source is specified

Syntax

```
refreshdata
refreshdata(figure_handle)
refreshdata(object_handles)
refreshdata(object_handles,'workspace')
```

Description

`refreshdata` evaluates any data source properties (`XDataSource`, `YDataSource`, or `ZDataSource`) on all objects in graphs in the current figure. If the specified data source has changed, the MATLAB software updates the graph to reflect this change.

Note The variable assigned to the data source property must be in the base workspace or you must specify the *`workspace`* option as `'caller'`.

`refreshdata(figure_handle)` refreshes the data of the objects in the specified figure.

`refreshdata(object_handles)` refreshes the data of the objects specified in `object_handles` or the children of those objects. Therefore, `object_handles` can contain figure, axes, or plot object handles.

`refreshdata(object_handles,'`*`workspace`*`')` enables you to specify whether the data source properties are evaluated in the base workspace or the workspace of the function in which `refreshdata` was called. *`workspace`* is a string that can be

- `base` — Evaluate the data source properties in the base workspace.
- `caller` — Evaluate the data source properties in the workspace of the function that called refreshdata.

Tips

The Linked Plots feature (see documentation for `linkdata`) sets up data sources for graphs and synchronizes them with the workspace variables they display. When you use this feature, you do not also need to call

`refreshdata`, as it is essentially automatically triggered every time a data source changes.

If you are not using the Linked Plots feature, you need to set the `XDataSource`, `YDataSource`, and/or `ZDataSource` properties of a graph in order to use `refreshdata`. You can do that programmatically, as shown in the examples below, or use the Property Editor, one of the plotting tools. In the Property Editor, select the graph (e.g., a lineseries object) and type in (or select from the drop-down choices) the name(s) of the workspace variable(s) from which you want the plot to refresh, in the fields labelled **X Data Source**, **Y Data Source**, and/or **Z Data Source**. The call to `refreshdata` causes the graph to update.

Examples

Plot a sine wave, identify data sources, and then modify its `YDataSource`:

```
x = 0:.1:8;
y = sin(x);
h = plot(x,y)
set(h,'YDataSource','y')
set(h,'XDataSource','x')
y = sin(x.^3);
refreshdata
```

Create a surface plot, identify a `ZDataSource` for it, and change the data to a different size.

```
Z = peaks(5);
h = surf(Z)
set(h,'ZDataSource','Z')
pause(3)
Z = peaks(25);
refreshdata
```

How To

- plot objects
- "Updating Plot Object Axis and Color Data"

Purpose

Match regular expression (case sensitive)

Syntax

```
startIndex = regexp(str,expression)
[startIndex,endIndex] = regexp(str,expression)

out = regexp(str,expression,outkey)
[out1,...,outN] =
regexp(str,expression,outkey1,...,outkeyN)

___= regexp(___,option1,...,optionM)
```

Description

`startIndex = regexp(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexp(str,expression)` returns the starting and ending indices of all matches.

`out = regexp(str,expression,outkey)` returns the output specified by `outkey`. For example, if `outkey` is `'match'`, then `regexp` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] = regexp(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify `'match'`,`'tokens'`, then `regexp` returns substrings that match the entire expression and tokens that match parts of the expression.

`___= regexp(___,option1,...,optionM)` modifies the search using the specified option flags. For example, specify `'ignorecase'` to perform a case-insensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

Input Arguments

str - Input text

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If `str` and `expression` are both cell arrays, they must have the same dimensions.

Data Types

`char` | `cell`

expression - Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in `str`.

The following tables describe the elements of regular expressions.

Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
`.`	Any single character, including white space	`'..ain'` matches sequences of five consecutive characters that end with `'ain'`.
[$c_1c_2c_3$]	Any character contained within the brackets	`'[rp]ain'` matches `'rain'` or `'pain'`.
[^$c_1c_2c_3$]	Any character not contained within the brackets	`'[^rp]ain'` matches all four-letter sequences that end in `'ain'`, except `'rain'` and `'pain'`. For example, it matches `'gain'`, `'lain'`, or `'vain'`.

Metacharacter	Description	Example
[c_1-c_2]	Any character in the range of c_1 through c_2	'[A-G]' matches a single character in the range of A through G.
\w	Any alphabetic, numeric, or underscore character. For English character sets, \w is equivalent to [a-zA-Z_0-9]	'\w*' identifies a word.
\W	Any character that is not alphabetic, numeric, or underscore. For English character sets, \W is equivalent to [^a-zA-Z_0-9]	'\W*' identifies a substring that is not a word.
\s	Any white-space character; equivalent to [\f\n\r\t\v]	'\w*n\s' matches words that end with the letter n, followed by a white-space character.
\S	Any non-white-space character; equivalent to [^ \f\n\r\t\v]	'\d\S' matches a numeric digit followed by any non-white-space character.
\d	Any numeric digit; equivalent to [0-9]	'\d*' matches any number of consecutive digits.
\D	Any nondigit character; equivalent to [^0-9]	'\w*\D\>' matches words that do not end with a numeric digit.
\oN or \o{N}	Character of octal value N	'\o{40}' matches the space character, defined by octal 40.
\xN or \x{N}	Character of hexadecimal value N	'\x2C' matches the comma character, defined by hex 2C.

Character Representation

Operator	Description
\a	Alarm (beep)
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab
\v	Vertical tab
char	Any character with special meaning in regular expressions that you want to match literally (for example, use \\ to match a single backslash)

Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
expr*	0 or more times consecutively.	'\w*' matches a word of any length.
expr?	0 times or 1 time.	'\w*(\.m)?' matches words that optionally end with the extension .m.
expr+	1 or more times consecutively.	'<img src="\w+\.gif">' matches an <img> HTML tag when the file name contains one or more characters.
expr{m,n}	At least m times, but no more than n times consecutively. {0,1} is equivalent to ?.	'\S{4,8}' matches between four and eight non-white-space characters.

Quantifier	Matches the expression when it occurs...	Example
expr{m,}	At least m times consecutively. {0,} and {1,} are equivalent to * and +, respectively.	'<a href="\w{1,}\.html">' matches an <a> HTML tag when the file name contains one or more characters.
expr{n}	Exactly n times consecutively. Equivalent to {n,n}.	'\d{4}' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. *q* represents any of the quantifiers in the previous table.

Mode	Description	Example
expr*q*	Greedy expression: match as many characters as possible.	Given the string '<tr><td> text </td>', the expression '</?t.*>' matches all characters between <tr and /td>: '<tr><td> text </td>'
expr*q*?	Lazy expression: match as few characters as necessary.	Given the string '<tr><td> text </td>', the expression '</?t.*?>' ends each match at the first occurrence of the closing bracket (>): '<tr>' '<td>' '</td>'
expr*q*+	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string '<tr><td> text </td>', the expression '</?t.*+>' does not return any matches, because the closing bracket is captured using .*, and is not rescanned.

Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

<table>
<tr><th>Grouping Operator</th><th>Description</th><th>Example</th></tr>
<tr><td>(expr)</td><td>Group elements of the expression and capture tokens.</td><td>'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.</td></tr>
<tr><td>(?:expr)</td><td>Group, but do not capture tokens.</td><td>'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.

Without grouping, '[aeiou][^aeiou]{2}'matches a vowel followed by two nonvowels.</td></tr>
<tr><td>(?>expr)</td><td>Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.</td><td>'A(?>.*)Z' does not match 'AtoZ', although 'A(?:.*)Z' does. Using the atomic group, Z is captured using .* and is not rescanned.</td></tr>
<tr><td>(expr1|expr2)</td><td>Match expression expr1 or expression expr2.

If there is a match with expr1, then expr2 is ignored.

You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.</td><td>'(let|tel)\w+' matches words in a string that start with let or tel.</td></tr>
</table>

Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
`^expr`	Beginning of the input string.	`'^M\w*'` matches a word starting with `M` at the beginning of the string.
`expr$`	End of the input string.	`'\w*m$'` matches words ending with `m` at the end of the string.
`\<expr`	Beginning of a word.	`'\<n\w*'` matches any words starting with `n`.
`expr\>`	End of a word.	`'\w*e\>'` matches any words ending with `e`.

Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
`expr(?=test)`	Look ahead for characters that match `test`.	`'\w*(?=ing)'` matches strings that are followed by `ing`, such as `'Fly'` and `'fall'` in the input string `'Flying, not falling.'`
`expr(?!test)`	Look ahead for characters that do not match `test`.	`'i(?!ng)'` matches instances of the letter `i` that are not followed by `ng`.

Lookaround Assertion	Description	Example
`(?<=test)expr`	Look behind for characters that match `test`..	`'(?<=re)\w*'` matches strings that follow `'re'`, such as `'new'`, `'use'`, and `'cycle'` in the input string `'renew, reuse, recycle'`
`(?<!test)expr`	Look behind for characters that do not match `test`.	`'(?<!\d)(\d)(?!\d)'` matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical `AND`.

Operation	Description	Example
`(?=test)expr`	Match both `test` and `expr`.	`'(?=[a-z])[^aeiou]'` matches consonants.
`(?!test)expr`	Match `expr` and do not match `test`.	`'(?![aeiou])[a-z]'` matches consonants.

Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical `OR`, and `if` or `if/else` conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

<table>
<tr><th>Conditional Operator</th><th>Description</th><th>Example</th></tr>
<tr><td>expr1|expr2</td><td>Match expression expr1 or expression expr2.

If there is a match with expr1, then expr2 is ignored.</td><td>'(let|tel)\w+' matches words in a string that start with let or tel.</td></tr>
<tr><td>(?(cond)expr)</td><td>If condition cond is true, then match expr.</td><td>'(?(?@ispc)[A-Z]:\\)' matches a drive name, such as C:\, when run on a Windows system.</td></tr>
<tr><td>(?(cond)expr1|expr2)</td><td>If condition cond is true, then match expr1. Otherwise, match expr2.</td><td>'Mr(s?)\..*?(?(1)her|his) \w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.</td></tr>
</table>

Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
(expr)	Capture in a token the characters that match the enclosed expression.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
\N	Match the Nth token.	'<(\w+).*>.*</\1>' captures tokens for HTML tags, such

<table>
<tr><th>Ordinal Token Operator</th><th>Description</th><th>Example</th></tr>
<tr><td></td><td></td><td>as 'title' from the string '<title>Some text</title>'.</td></tr>
<tr><td>(?(N)expr1|expr2)</td><td>If the Nth token is found, then match expr1. Otherwise, match expr2.</td><td>'Mr(s?)\..*?(?(1)her|his) \w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.</td></tr>
</table>

<table>
<tr><th>Named Token Operator</th><th>Description</th><th>Example</th></tr>
<tr><td>(?<name>expr)</td><td>Capture in a named token the characters that match the enclosed expression.</td><td>'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.</td></tr>
<tr><td>\k<name></td><td>Match the token referred to by name.</td><td>'<(?<tag>\w+).*>.*</\k<tag>>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.</td></tr>
<tr><td>(?(name)expr1|expr2)</td><td>If the named token is found, then match expr1. Otherwise, match expr2.</td><td>'Mr(?<sex>s?)\..*?(?(sex)her|his) \w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.</td></tr>
</table>

Note If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern `'(and(y|rew))'`, MATLAB creates a token for `'andrew'` but not for `'y'` or `'rew'`.

Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
`(??expr)`	Parse `expr` and include the resulting string in the match expression. When parsed, `expr` must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of `expr`, and one for the complete match.	`'^(\d+)((??\\w{$1}))'` determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching `'5XXXXX'` captures tokens for `'5'` and `'XXXXX'`.
`(??@cmd)`	Execute the MATLAB command represented by `cmd`, and include the string returned by the command in the match expression.	`'(.{2,}).?(??@fliplr($1))'` finds palindromes that are at least four characters long, such as `'abba'`.
`(?@cmd)`	Execute the MATLAB command represented by `cmd`, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	`'\w*?(\w)(?@disp($1))\1\w*'` matches words that include double letters (such as `pp`), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
$& or $0	Portion of the input string that is currently a match
$`	Portion of the input string that precedes the current match
$'	Portion of the input string that follows the current match (use $'' to represent the string $')
$N	Nth token
$<name>	Named token
${cmd}	String returned when MATLAB executes the command, cmd

Comments

Characters	Description	Example
(?#comment)	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	'(?# Initial digit)\<\d\w+' includes a comment, and matches words that begin with a number.

Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
(?-i)	Match letter case (default for regexp and regexprep).
(?i)	Do not match letter case (default for regexpi).
(?s)	Match dot (.) in the pattern string with any character (default).
(?-s)	Match dot in the pattern with any character that is not a newline character.
(?-m)	Match the ^ and $ metacharacters at the beginning and end of a string (default).
(?m)	Match the ^ and $ metacharacters at the beginning and end of a line.
(?-x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use '\ ' and '\#' to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (:), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

Data Types
char | cell

outkey - Keyword that indicates which outputs to return

'start' | 'end' | 'tokenExtents' | 'match' | 'tokens' | 'names' | 'split'

Keyword that indicates which outputs to return, specified as one of the following strings.

Output Keyword	Returns
'start'	Starting indices of all matches, startIndex
'end'	Ending indices of all matches, endIndex
'tokenExtents'	Starting and ending indices of all tokens
'match'	Text of each substring that matches the pattern in expression
'tokens'	Text of each captured token in str
'names'	Name and text of each named token
'split'	Text of nonmatching substrings of str

Data Types
char

option - Search option

'once' | 'warnings' | 'ignorecase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors'

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

Default	Override	Description
'all'	'once'	Match the expression as many times as possible (default), or only once.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.

Default	Override	Description
'matchcase'	'ignorecase'	Match letter case (default), or ignore case.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (`\n`).
'stringanchors'	'lineanchors'	Apply `^` and `$` metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With `freespacing`, use `'\ '` and `'\#'` to match space and # characters.

Data Types
`char`

Output Arguments

startIndex - Starting index of each match
row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

endIndex - Ending index of each match
row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

out - Information about matches

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for `outkey`, as follows.

<table>
<tr><th>Output Keyword</th><th>Output Description</th><th>Output Type and Dimensions</th></tr>
<tr><td>'start'</td><td>Starting indices of matches</td><td rowspan="2">For both 'start' and 'end':
• If str and expression are both strings, the output is a row vector (or, if there are no matches, an empty array).
• If str or expression is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
• If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</td></tr>
<tr><td>'end'</td><td>Ending indices of matches</td></tr>
</table>

Output Keyword	Output Description	Output Type and Dimensions
'tokenExtents'	Starting and ending indices of all tokens	By default, when returning all matches: • If str and expression are both strings, the output is a 1-by-n-cell array, where n is the number of matches. Each cell contains an m-by-2 numeric array of indices, where m is the number of tokens in the match. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array, where each inner cell contains an m-by-2 numeric array. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the 'once' option to return only one match, the output is either an m-by-2 numeric array or a cell array with the same dimensions as str and/or expression. If a token is expected at a particular index N, but is not found, then MATLAB returns extents for that token of [N,N-1].

Output Keyword	Output Description	Output Type and Dimensions
`'match'`	Text of each substring that matches the pattern in `expression`	By default, when returning all matches: • If `str` and `expression` are both strings, the output is a 1-by-`n`-cell array of strings, where `n` is the number of matches. • If `str` or `expression` is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array of strings. • If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is either a string or a cell array of strings with the same dimensions as `str` and `expression`.
`'tokens'`	Text of each captured token in `str`	By default, when returning all matches: • If `str` and `expression` are both strings, the output is a 1-by-`n`-cell array, where `n` is the number of matches. Each cell contains a 1-by-`m` cell array of strings, where `m` is the number of tokens in the match. • If `str` or `expression` is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array, where each inner cell contains a 1-by-`m` cell array of strings.

Output Keyword	Output Description	Output Type and Dimensions
		• If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is a 1-by-`m` cell array of strings or a cell array that has the same dimensions as `str` and/or `expression`. If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, `''`.
`'names'`	Name and text of each named token	For all matches: • If `str` and `expression` are both strings, the output is a 1-by-`n` structure array, where `n` is the number of matches. The structure field names correspond to the token names. • If `str` or `expression` is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` structure array. • If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.
`'split'`	Text of nonmatching substrings of `str`	For all matches: • If `str` and `expression` are both strings, the output is a 1-by-`n`-cell array of strings, where `n` is the number of nonmatching strings.

Output Keyword	Output Description	Output Type and Dimensions
		• If `str` or `expression` is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array of strings. • If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

Examples

Find Patterns in Single Strings

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car coat court CUT ct CAT-scan';
expression = 'c[aeiou]+t';
startIndex = regexp(str,expression)
```

```
startIndex =
     5    17
```

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the `+` operator.
- `t` must be the last character, with no characters between the bracketed pattern and the `t`.

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression. The matching word `cat`

starts at index 5, and `coat` starts at index 17. The words `CUT` and `CAT` do not match because they are uppercase.

Find Patterns in Multiple Strings

Find the location of capital letters and spaces within strings in a cell array.

```
str = {'Madrid, Spain','Romeo and Juliet','MATLAB is great'};
capExpr = '[A-Z]';
spaceExpr = '\s';

capStartIndex = regexp(str,capExpr);
spaceStartIndex = regexp(str,spaceExpr);
```

`capStartIndex` and `spaceStartIndex` are cell arrays because the input `str` is a cell array.

View the indices for the capital letters.

```
celldisp(capStartIndex)
```

```
capStartIndex{1} =
     1     9

capStartIndex{2} =
     1    11

capStartIndex{3} =
     1     2     3     4     5     6
```

View the indices for the spaces.

```
celldisp(spaceStartIndex)
```

```
spaceStartIndex{1} =
     8

spaceStartIndex{2} =
```

```
     6    10

spaceStartIndex{3} =
     7    10
```

Return Substrings Using 'match' Keyword

Capture words within a string that contain the letter `x`.

```
str = 'EXTRA! The regexp function helps you relax.';
expression = '\w*x\w*';
matchStr = regexp(str,expression,'match')
```

```
matchStr =
    'regexp'    'relax'
```

The regular expression `'\w*x\w*'` specifies that the string:

- Begins with any number of alphanumeric or underscore characters, `\w*`.
- Contains the lowercase letter `x`.
- Ends with any number of alphanumeric or underscore characters after the `x`, including none, as indicated by `\w*`.

Split String at Delimiter Using 'split' Keyword

Split a string into several substrings, where each substring is delimited by a `^` character.

```
str = ['Split ^this string into ^several pieces'];
expression = '\^';
splitStr = regexp(str,expression,'split')
```

```
splitStr =
    'Split '    'this string into '    'several pieces'
```

Because the carat symbol has special meaning in regular expressions, precede it with the escape character, a backslash (`\`). To split a string

at other delimiters, such as a semicolon, you do not need to include the backslash.

Return Both Matching and Nonmatching Substrings

Capture parts of a string that match a regular expression using the `'match'` keyword, and the remaining parts that do not match using the `'split'` keyword.

```
str = 'She sells sea shells by the seashore.';
expression = '[Ss]h.';
[match,noMatch] = regexp(str,expression,'match','split')
```

```
match = 
    'She'    'she'    'sho'

noMatch = 
    ''    ' sells sea '    'lls by the sea'    're.'
```

The regular expression `'[Ss]h.'` specifies that:

- `S` or `s` is the first character.
- `h` is the second character.
- The third character can be anything, including a space, as indicated by the dot (`.`).

When the first (or last) character in a string matches a regular expression, the first (or last) return value from the `'split'` keyword is an empty string.

Optionally, reassemble the original string from the substrings.

```
combinedStr = strjoin(noMatch,match)
```

```
combinedStr =
She sells sea shells by the seashore.
```

Capture Substrings of Matches Using Ordinal Tokens

Find the names of HTML tags by defining a token within a regular expression. Tokens are indicated with parentheses, ().

```
str = '<title>My Title</title><p>Here is some text.</p>';
expression = '<(\w+).*>.*</\1>';
[tokens,matches] = regexp(str,expression,'tokens','match');
```

The regular expression <(\w+).*>.*</\1> specifies this pattern:

- <(\w+) finds an opening angle bracket followed by one or more alphanumeric or underscore characters. Enclosing \w+ in parentheses captures the name of the HTML tag in a token.
- .*> finds any number of additional characters, such as HTML attributes, and a closing angle bracket.
- </\1> finds the end tag corresponding to the first token (indicated by \1). The end tag has the form <*tagname*>.

View the tokens and matching substrings.

```
celldisp(tokens)
```

```
tokens{1}{1} =
   title

tokens{2}{1} =
   p
```

```
celldisp(matches)
```

```
matches{1} =
   <title>My Title</title>

matches{2} =
   <p>Here is some text.</p>
```

Capture Substrings of Matches Using Named Tokens

Parse dates that can appear with either the day or the month first, in these forms: `mm/dd/yyyy` or `dd-mm-yyyy`. Use named tokens to identify each part of the date.

```
str = '01/11/2000  20-02-2020  03/30/2000  16-04-2020';
expression = ['(?<month>\d+)/(?<day>\d+)/(?<year>\d+)|'...
              '(?<day>\d+)-(?<month>\d+)-(?<year>\d+)'];
tokenNames = regexp(str,expression,'names');
```

The regular expression specifies this pattern:

- `(?<name>\d+)` finds one or more numeric digits and assigns the result to the token indicated by *`name`*.
- `|` is the logical `or` operator, which indicates that there are two possible patterns for dates. In the first pattern, slashes (`/`) separate the tokens. In the second pattern, hyphens (`-`) separate the tokens.

View the named tokens.

```
for k = 1:length(tokenNames)
   disp(tokenNames(k))
end
```

```
    month: '01'
      day: '11'
     year: '2000'

    month: '02'
      day: '20'
     year: '2020'

    month: '03'
      day: '30'
     year: '2000'

    month: '04'
```

```
      day: '16'
     year: '2020'
```

Perform Case-Insensitive Matches

Find both uppercase and lowercase instances of a word.

By default, `regexp` performs case-sensitive matching.

```
str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexp(str,expression,'match')
```

```
matchStr =
    'lowercase'
```

The regular expression specifies that the string:

- Begins with any number of alphanumeric or underscore characters, `\w*`.
- Ends with the literal text `case`.

The `regexpi` function uses the same syntax as `regexp`, but performs case-insensitive matching.

```
matchWithRegexpi = regexpi(str,expression,'match')
```

```
matchWithRegexpi =
    'UPPERCASE'    'lowercase'
```

Alternatively, disable case-sensitive matching for `regexp` using the `'ignorecase'` option.

```
matchWithIgnorecase = regexp(str,expression,'match','ignorecase')
```

```
matchWithIgnorecase =
    'UPPERCASE'    'lowercase'
```

For multiple expressions, disable case-sensitive matching for selected expressions using the `(?i)` search flag.

```
expression = {'(?-i)\w*case';...
              '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)
```

```
matchStr{1}{1} =
   lowercase

matchStr{2}{1} =
   UPPERCASE

matchStr{2}{2} =
   lowercase
```

Parse Strings with Newline Characters

Create a string that contains a newline, `\n`, and parse the string using a regular expression.

```
str = sprintf('abc\n de');
expression = '.*';
matchStr = regexp(str,expression,'match')
```

```
matchStr =
   [1x7 char]
```

By default, the dot (`.`) matches every character, including the newline, and returns a single match that is equivalent to the original string.

Exclude newline characters from the match using the `'dotexceptnewline'` option. This returns separate matches for each line of text.

```
matchStrNoNewline = regexp(str,expression,'match','dotexceptnewline')
```

```
matchStrNoNewline =
    'abc'    ' de'
```

Find the first or last character of each line using the ^ or $ metacharacters and the 'lineanchors' option.

```
expression = '.$';
lastInLine = regexp(str,expression,'match','lineanchors')
```

```
lastInLine =
    'c'    'e'
```

Definitions

Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form dd-mmm-yyyy, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';
expression = '(\d+)-(\w+)-(\d+)';

mydate = regexp(str,expression,'tokens');
mydate{:}
```

```
ans =
    '01'    'April'    '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';

mydate = regexp(str,expression,'names')
```

```
mydate =
      day: '01'
    month: 'Apr'
     year: '2020'
```

For more information, see “Tokens in Regular Expressions”.

Algorithms

MATLAB parses each input string from left to right, attempting to match the text in the string with the first element of the regular expression. During this process, MATLAB skips over any text that does not match.

When MATLAB finds the first match, it continues parsing the string to match the second piece of the expression, and so on.

Tips

- Use `strfind` to find an exact character match within a string. Use `regexp` to look for a pattern of characters.

See Also

`regexpi | regexprep | regexptranslate | strfind | strjoin | strsplit | strrep`

Concepts

- “Lookahead Assertions in Regular Expressions”
- “Dynamic Regular Expressions”

Purpose

Match regular expression (case insensitive)

Syntax

```
startIndex = regexpi(str,expression)
[startIndex,endIndex] = regexpi(str,expression)

out = regexpi(str,expression,outkey)
[out1,...,outN] =
regexpi(str,expression,outkey1,...,outkeyN)

___= regexpi(___,option1,...,optionM)
```

Description

`startIndex = regexpi(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression, without regard to letter case. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexpi(str,expression)` returns the starting and ending indices of all matches.

`out = regexpi(str,expression,outkey)` returns the output specified by `outkey`. For example, if `outkey` is `'match'`, then `regexpi` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] =`
`regexpi(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify `'match'`,`'tokens'`, then `regexpi` returns substrings that match the entire expression and tokens that match parts of the expression.

`___= regexpi(___,option1,...,optionM)` modifies the search using the specified option flags. For example, specify `'matchcase'` to perform a case-sensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

Input Arguments

str - Input text

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If `str` and `expression` are both cell arrays, they must have the same dimensions.

Data Types

`char | cell`

expression - Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in `str`.

The following tables describe the elements of regular expressions.

Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
`.`	Any single character, including white space	`'..ain'` matches sequences of five consecutive characters that end with `'ain'`.
[$c_1c_2c_3$]	Any character contained within the brackets	`'[rp]ain'` matches `'rain'` or `'pain'`.
[^$c_1c_2c_3$]	Any character not contained within the brackets	`'[^rp]ain'` matches all four-letter sequences that end in `'ain'`, except `'rain'` and `'pain'`. For example, it matches `'gain'`, `'lain'`, or `'vain'`.

Metacharacter	Description	Example
[c_1-c_2]	Any character in the range of c_1 through c_2	'[A-G]' matches a single character in the range of A through G.
\w	Any alphabetic, numeric, or underscore character. For English character sets, \w is equivalent to [a-zA-Z_0-9]	'\w*' identifies a word.
\W	Any character that is not alphabetic, numeric, or underscore. For English character sets, \W is equivalent to [^a-zA-Z_0-9]	'\W*' identifies a substring that is not a word.
\s	Any white-space character; equivalent to [\f\n\r\t\v]	'\w*n\s' matches words that end with the letter n, followed by a white-space character.
\S	Any non-white-space character; equivalent to [^ \f\n\r\t\v]	'\d\S' matches a numeric digit followed by any non-white-space character.
\d	Any numeric digit; equivalent to [0-9]	'\d*' matches any number of consecutive digits.
\D	Any nondigit character; equivalent to [^0-9]	'\w*\D\>' matches words that do not end with a numeric digit.
\oN or \o{N}	Character of octal value N	'\o{40}' matches the space character, defined by octal 40.
\xN or \x{N}	Character of hexadecimal value N	'\x2C' matches the comma character, defined by hex 2C.

Character Representation

Operator	Description
\a	Alarm (beep)
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab
\v	Vertical tab
char	Any character with special meaning in regular expressions that you want to match literally (for example, use \\ to match a single backslash)

Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
expr*	0 or more times consecutively.	'\w*' matches a word of any length.
expr?	0 times or 1 time.	'\w*(\.m)?' matches words that optionally end with the extension .m.
expr+	1 or more times consecutively.	'<img src="\w+\.gif">' matches an <img> HTML tag when the file name contains one or more characters.
expr{m,n}	At least m times, but no more than n times consecutively. {0,1} is equivalent to ?.	'\S{4,8}' matches between four and eight non-white-space characters.

Quantifier	Matches the expression when it occurs...	Example
expr{m,}	At least m times consecutively. {0,} and {1,} are equivalent to * and +, respectively.	'<a href="\w{1,}\.html">' matches an <a> HTML tag when the file name contains one or more characters.
expr{n}	Exactly n times consecutively. Equivalent to {n,n}.	'\d{4}' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. *q* represents any of the quantifiers in the previous table.

Mode	Description	Example
expr*q*	Greedy expression: match as many characters as possible.	Given the string '<tr><td> text </td>', the expression '</?t.*>' matches all characters between <tr and /td>: '<tr><td> text </td>'
expr*q*?	Lazy expression: match as few characters as necessary.	Given the string '<tr><td> text </td>', the expression '</?t.*?>' ends each match at the first occurrence of the closing bracket (>): '<tr>' '<td>' '</td>'
expr*q*+	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string '<tr><td> text </td>', the expression '</?t.*+>' does not return any matches, because the closing bracket is captured using .*, and is not rescanned.

Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

<table>
<tr><th>Grouping Operator</th><th>Description</th><th>Example</th></tr>
<tr><td>(expr)</td><td>Group elements of the expression and capture tokens.</td><td>'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.</td></tr>
<tr><td>(?:expr)</td><td>Group, but do not capture tokens.</td><td>'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.

Without grouping, '[aeiou][^aeiou]{2}'matches a vowel followed by two nonvowels.</td></tr>
<tr><td>(?>expr)</td><td>Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.</td><td>'A(?>.*)Z' does not match 'AtoZ', although 'A(?:.*)Z' does. Using the atomic group, Z is captured using .* and is not rescanned.</td></tr>
<tr><td>(expr1|expr2)</td><td>Match expression expr1 or expression expr2.

If there is a match with expr1, then expr2 is ignored.

You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.</td><td>'(let|tel)\w+' matches words in a string that start with let or tel.</td></tr>
</table>

Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
`^expr`	Beginning of the input string.	`'^M\w*'` matches a word starting with `M` at the beginning of the string.
`expr$`	End of the input string.	`'\w*m$'` matches words ending with `m` at the end of the string.
`\<expr`	Beginning of a word.	`'\<n\w*'` matches any words starting with `n`.
`expr\>`	End of a word.	`'\w*e\>'` matches any words ending with `e`.

Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
`expr(?=test)`	Look ahead for characters that match `test`.	`'\w*(?=ing)'` matches strings that are followed by `ing`, such as `'Fly'` and `'fall'` in the input string `'Flying, not falling.'`
`expr(?!test)`	Look ahead for characters that do not match `test`.	`'i(?!ng)'` matches instances of the letter `i` that are not followed by `ng`.

Lookaround Assertion	Description	Example
`(?<=test)expr`	Look behind for characters that match `test`..	`'(?<=re)\w*'` matches strings that follow `'re'`, such as `'new'`, `'use'`, and `'cycle'` in the input string `'renew, reuse, recycle'`
`(?<!test)expr`	Look behind for characters that do not match `test`.	`'(?<!\d)(\d)(?!\d)'` matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical `AND`.

Operation	Description	Example
`(?=test)expr`	Match both `test` and `expr`.	`'(?=[a-z])[^aeiou]'` matches consonants.
`(?!test)expr`	Match `expr` and do not match `test`.	`'(?![aeiou])[a-z]'` matches consonants.

Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical `OR`, and `if` or `if/else` conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

<table>
<tr><th>Conditional Operator</th><th>Description</th><th>Example</th></tr>
<tr><td>expr1|expr2</td><td>Match expression expr1 or expression expr2.

If there is a match with expr1, then expr2 is ignored.</td><td>'(let|tel)\w+' matches words in a string that start with let or tel.</td></tr>
<tr><td>(?(cond)expr)</td><td>If condition cond is true, then match expr.</td><td>'(?(?@ispc)[A-Z]:\\)' matches a drive name, such as C:\, when run on a Windows system.</td></tr>
<tr><td>(?(cond)expr1|expr2)</td><td>If condition cond is true, then match expr1. Otherwise, match expr2.</td><td>'Mr(s?)\..*?(?(1)her|his) \w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.</td></tr>
</table>

Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
(expr)	Capture in a token the characters that match the enclosed expression.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
\N	Match the Nth token.	'<(\w+).*>.*</\1>' captures tokens for HTML tags, such

<table>
<tr><th>Ordinal Token Operator</th><th>Description</th><th>Example</th></tr>
<tr><td></td><td></td><td>as 'title' from the string '<title>Some text</title>'.</td></tr>
<tr><td>(?(N)expr1|expr2)</td><td>If the Nth token is found, then match expr1. Otherwise, match expr2.</td><td>'Mr(s?)\..*?(?(1)her|his) \w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.</td></tr>
</table>

<table>
<tr><th>Named Token Operator</th><th>Description</th><th>Example</th></tr>
<tr><td>(?<name>expr)</td><td>Capture in a named token the characters that match the enclosed expression.</td><td>'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.</td></tr>
<tr><td>\k<name></td><td>Match the token referred to by name.</td><td>'<(?<tag>\w+).*>.*</\k<tag>>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.</td></tr>
<tr><td>(?(name)expr1|expr2)</td><td>If the named token is found, then match expr1. Otherwise, match expr2.</td><td>'Mr(?<sex>s?)\..*?(?(sex)her|his) \w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.</td></tr>
</table>

Note If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern `'(and(y|rew))'`, MATLAB creates a token for `'andrew'` but not for `'y'` or `'rew'`.

Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
`(??expr)`	Parse `expr` and include the resulting string in the match expression. When parsed, `expr` must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of `expr`, and one for the complete match.	`'^(\d+)((??\\w{$1}))'` determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching `'5XXXXX'` captures tokens for `'5'` and `'XXXXX'`.
`(??@cmd)`	Execute the MATLAB command represented by `cmd`, and include the string returned by the command in the match expression.	`'(.{2,}).?(??@fliplr($1))'` finds palindromes that are at least four characters long, such as `'abba'`.
`(?@cmd)`	Execute the MATLAB command represented by `cmd`, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	`'\w*?(\w)(?@disp($1))\1\w*'` matches words that include double letters (such as `pp`), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
$& or $0	Portion of the input string that is currently a match
$`	Portion of the input string that precedes the current match
$'	Portion of the input string that follows the current match (use $'' to represent the string $')
$N	Nth token
$<name>	Named token
${cmd}	String returned when MATLAB executes the command, cmd

Comments

Characters	Description	Example
(?#comment)	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	'(?# Initial digit)\<\d\w+' includes a comment, and matches words that begin with a number.

Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
`(?-i)`	Match letter case (default for `regexp` and `regexprep`).
`(?i)`	Do not match letter case (default for `regexpi`).
`(?s)`	Match dot (`.`) in the pattern string with any character (default).
`(?-s)`	Match dot in the pattern with any character that is not a newline character.
`(?-m)`	Match the `^` and `$` metacharacters at the beginning and end of a string (default).
`(?m)`	Match the `^` and `$` metacharacters at the beginning and end of a line.
`(?-x)`	Include space characters and comments when matching (default).
`(?x)`	Ignore space characters and comments when matching. Use `'\  '` and `'\#'` to match space and `#` characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (`:`), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

Data Types
`char | cell`

outkey - Keyword that indicates which outputs to return
'start' | 'end' | 'tokenExtents' | 'match' | 'tokens' | 'names' | 'split'

Keyword that indicates which outputs to return, specified as one of the following strings.

Output Keyword	Returns
'start'	Starting indices of all matches, startIndex
'end'	Ending indices of all matches, endIndex
'tokenExtents'	Starting and ending indices of all tokens
'match'	Text of each substring that matches the pattern in expression
'tokens'	Text of each captured token in str
'names'	Name and text of each named token
'split'	Text of nonmatching substrings of str

Data Types
char

option - Search option
'once' | 'warnings' | 'matchcase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors'

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

Default	Override	Description
'all'	'once'	Match the expression as many times as possible (default), or only once.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.

Default	Override	Description
'ignorecase'	'matchcase'	Ignore letter case (default), or match case.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (\n).
'stringanchors'	'lineanchors'	Apply ^ and $ metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With freespacing, use '\ ' and '\#' to match space and # characters.

Data Types
char

Output Arguments

startIndex - Starting index of each match
row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If str and expression are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If str or expression is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

endIndex - Ending index of each match
row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

out - Information about matches

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for `outkey`, as follows.

<table>
<tr><th>Output Keyword</th><th>Output Description</th><th>Output Type and Dimensions</th></tr>
<tr><td>'start'</td><td>Starting indices of matches</td><td rowspan="2">For both 'start' and 'end':
• If str and expression are both strings, the output is a row vector (or, if there are no matches, an empty array).
• If str or expression is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
• If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</td></tr>
<tr><td>'end'</td><td>Ending indices of matches</td></tr>
</table>

Output Keyword	Output Description	Output Type and Dimensions
`'tokenExtents'`	Starting and ending indices of all tokens	By default, when returning all matches: • If `str` and `expression` are both strings, the output is a 1-by-`n`-cell array, where `n` is the number of matches. Each cell contains an `m`-by-2 numeric array of indices, where `m` is the number of tokens in the match. • If `str` or `expression` is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array, where each inner cell contains an `m`-by-2 numeric array. • If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is either an `m`-by-2 numeric array or a cell array with the same dimensions as `str` and/or `expression`. If a token is expected at a particular index `N`, but is not found, then MATLAB returns extents for that token of `[N,N-1]`.

<table>
<tr><th>Output Keyword</th><th>Output Description</th><th>Output Type and Dimensions</th></tr>
<tr><td>'match'</td><td>Text of each substring that matches the pattern in expression</td><td>By default, when returning all matches:
• If str and expression are both strings, the output is a 1-by-n-cell array of strings, where n is the number of matches.
• If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array of strings.
• If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.
When you specify the 'once' option to return only one match, the output is either a string or a cell array of strings with the same dimensions as str and expression.</td></tr>
<tr><td>'tokens'</td><td>Text of each captured token in str</td><td>By default, when returning all matches:
• If str and expression are both strings, the output is a 1-by-n-cell array, where n is the number of matches. Each cell contains a 1-by-m cell array of strings, where m is the number of tokens in the match.
• If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array, where each inner cell contains a 1-by-m cell array of strings.</td></tr>
</table>

Output Keyword	Output Description	Output Type and Dimensions
		• If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is a 1-by-`m` cell array of strings or a cell array that has the same dimensions as `str` and/or `expression`. If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, `''`.
`'names'`	Name and text of each named token	For all matches: • If `str` and `expression` are both strings, the output is a 1-by-`n` structure array, where `n` is the number of matches. The structure field names correspond to the token names. • If `str` or `expression` is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` structure array. • If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.
`'split'`	Text of nonmatching substrings of `str`	For all matches: • If `str` and `expression` are both strings, the output is a 1-by-`n`-cell array of strings, where `n` is the number of nonmatching strings.

Output Keyword	Output Description	Output Type and Dimensions
		• If `str` or `expression` is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array of strings. • If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

Examples

Pattern Matching

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car COAT court cut ct CAT-scan';
expression = 'c[aeiou]+t';
startIndex = regexpi(str,expression)

startIndex =
     5    17    28    35
```

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression.

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the + operator.

- t must be the last character, with no characters between the bracketed pattern and the t.

Case-Sensitive Match

Match letter case in all or part of an expression.

By default, regexpi performs case-insensitive matching.

```
str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexpi(str,expression,'match')

matchStr =
    'UPPERCASE'    'lowercase'
```

Use the regexp function with the same syntax as regexpi to perform case-sensitive matching.

```
matchWithRegexp = regexp(str,expression,'match')

matchWithRegexp =
    'lowercase'
```

To disable case-sensitive matching for regexp, use the 'ignorecase' option.

```
matchWithIgnorecase = regexp(str,expression,'match','ignorecase')

matchWithIgnorecase =
    'UPPERCASE'    'lowercase'
```

For multiple expressions, enable and disable case-insensitive matching for selected expressions using the (?i) and (?-i) search flags.

```
expression = {'(?-i)\w*case';...
              '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)
```

```
matchStr{1}{1} =
   lowercase

matchStr{2}{1} =
   UPPERCASE

matchStr{2}{2} =
   lowercase
```

Definitions

Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form `dd-mmm-yyyy`, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';
expression = '(\d+)-(\w+)-(\d+)';

mydate = regexp(str,expression,'tokens');
mydate{:}

ans =
    '01'    'April'    '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';

mydate = regexp(str,expression,'names')

mydate =
      day: '01'
    month: 'Apr'
     year: '2020'
```

For more information, see “Tokens in Regular Expressions”.

Concepts

- “Lookahead Assertions in Regular Expressions”
- “Dynamic Regular Expressions”

regexprep

Purpose

Replace string using regular expression

Syntax

```
newStr = regexprep(str,expression,replace)
newStr =
regexprep(str,expression,replace,option1,...optionM)
```

Description

`newStr = regexprep(str,expression,replace)` replaces the text in `str` that matches `expression` with the text described by `replace`. The `regexprep` function returns the updated text in `newStr`.

- If `str` is a string, then `newStr` is also a string, even when `expression` or `replace` is a cell array of strings. When `expression` is a cell array, `regexprep` applies the first expression to the string, and then applies each subsequent expression to the preceding result.
- If `str` is a cell array, then `newStr` is a cell array with the same dimensions as `str`. For each element of `str`, the `regexprep` function applies each expression in sequence.
- If there are no matches to `expression`, then `newStr` is equivalent to `str`.

`newStr =`
`regexprep(str,expression,replace,option1,...optionM)` modifies the search using the specified options. For example, specify `'ignorecase'` to perform a case-insensitive match.

Input Arguments

str - Text to update

string | cell array of strings

Text to update, specified as a string or a cell array of strings.

Data Types

`char | cell`

expression - Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in `str`.

The following tables describe the elements of regular expressions.

Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
`.`	Any single character, including white space	`'..ain'` matches sequences of five consecutive characters that end with `'ain'`.
[$c_1c_2c_3$]	Any character contained within the brackets	`'[rp]ain'` matches `'rain'` or `'pain'`.
[^$c_1c_2c_3$]	Any character not contained within the brackets	`'[^rp]ain'` matches all four-letter sequences that end in `'ain'`, except `'rain'` and `'pain'`. For example, it matches `'gain'`, `'lain'`, or `'vain'`.
[c_1-c_2]	Any character in the range of c_1 through c_2	`'[A-G]'` matches a single character in the range of `A` through `G`.
`\w`	Any alphabetic, numeric, or underscore character. For English character sets, `\w` is equivalent to `[a-zA-Z_0-9]`	`'\w*'` identifies a word.
`\W`	Any character that is not alphabetic, numeric, or underscore. For English character sets, `\W` is equivalent to `[^a-zA-Z_0-9]`	`'\W*'` identifies a substring that is not a word.

Metacharacter	Description	Example
\s	Any white-space character; equivalent to [\f\n\r\t\v]	'\w*n\s' matches words that end with the letter n, followed by a white-space character.
\S	Any non-white-space character; equivalent to [^ \f\n\r\t\v]	'\d\S' matches a numeric digit followed by any non-white-space character.
\d	Any numeric digit; equivalent to [0-9]	'\d*' matches any number of consecutive digits.
\D	Any nondigit character; equivalent to [^0-9]	'\w*\D\>' matches words that do not end with a numeric digit.
\oN or \o{N}	Character of octal value N	'\o{40}' matches the space character, defined by octal 40.
\xN or \x{N}	Character of hexadecimal value N	'\x2C' matches the comma character, defined by hex 2C.

Character Representation

Operator	Description
\a	Alarm (beep)
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab
\v	Vertical tab
char	Any character with special meaning in regular expressions that you want to match literally (for example, use \\ to match a single backslash)

Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
expr*	0 or more times consecutively.	'\w*' matches a word of any length.
expr?	0 times or 1 time.	'\w*(\.m)?' matches words that optionally end with the extension .m.
expr+	1 or more times consecutively.	'<img src="\w+\.gif">' matches an <img> HTML tag when the file name contains one or more characters.
expr{m,n}	At least m times, but no more than n times consecutively. {0,1} is equivalent to ?.	'\S{4,8}' matches between four and eight non-white-space characters.
expr{m,}	At least m times consecutively. {0,} and {1,} are equivalent to * and +, respectively.	'<a href="\w{1,}\.html">' matches an <a> HTML tag when the file name contains one or more characters.
expr{n}	Exactly n times consecutively. Equivalent to {n,n}.	'\d{4}' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. *q* represents any of the quantifiers in the previous table.

Mode	Description	Example
expr*q*	Greedy expression: match as many characters as possible.	Given the string '<tr><td> text </td>', the expression '</?t.*>' matches all characters between <tr and /td>: '<tr><td> text </td>'
expr*q*?	Lazy expression: match as few characters as necessary.	Given the string '<tr><td> text </td>', the expression '</?t.*?>' ends each match at the first occurrence of the closing bracket (>): '<tr>' '<td>' '</td>'
expr*q*+	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string '<tr><td> text </td>', the expression '</?t.*+>' does not return any matches, because the closing bracket is captured using .*, and is not rescanned.

Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
(expr)	Group elements of the expression and capture tokens.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
(?:expr)	Group, but do not capture tokens.	'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'. Without grouping, '[aeiou][^aeiou]{2}'matches a vowel followed by two nonvowels.
(?>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?>.*)Z' does not match 'AtoZ', although 'A(?:.*)Z' does. Using the atomic group, Z is captured using .* and is not rescanned.
(expr1|expr2)	Match expression expr1 or expression expr2. If there is a match with expr1, then expr2 is ignored. You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.	'(let|tel)\w+' matches words in a string that start with let or tel.

Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
^expr	Beginning of the input string.	'^M\w*' matches a word starting with M at the beginning of the string.
expr$	End of the input string.	'\w*m$' matches words ending with m at the end of the string.
\<expr	Beginning of a word.	'\<n\w*' matches any words starting with n.
expr\>	End of a word.	'\w*e\>' matches any words ending with e.

Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the test expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
expr(?=test)	Look ahead for characters that match test.	'\w*(?=ing)' matches strings that are followed by ing, such as 'Fly' and 'fall' in the input string 'Flying, not falling.'
expr(?!test)	Look ahead for characters that do not match test.	'i(?!ng)' matches instances of the letter i that are not followed by ng.

Lookaround Assertion	Description	Example
`(?<=test)expr`	Look behind for characters that match `test`..	`'(?<=re)\w*'` matches strings that follow `'re'`, such as `'new'`, `'use'`, and `'cycle'` in the input string `'renew, reuse, recycle'`
`(?<!test)expr`	Look behind for characters that do not match `test`.	`'(?<!\d)(\d)(?!\d)'` matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical `AND`.

Operation	Description	Example
`(?=test)expr`	Match both `test` and `expr`.	`'(?=[a-z])[^aeiou]'` matches consonants.
`(?!test)expr`	Match `expr` and do not match `test`.	`'(?![aeiou])[a-z]'` matches consonants.

Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical `OR`, and `if` or `if/else` conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

<table>
<tr><th>Conditional Operator</th><th>Description</th><th>Example</th></tr>
<tr><td>expr1|expr2</td><td>Match expression expr1 or expression expr2.

If there is a match with expr1, then expr2 is ignored.</td><td>'(let|tel)\w+' matches words in a string that start with let or tel.</td></tr>
<tr><td>(?(cond)expr)</td><td>If condition cond is true, then match expr.</td><td>'(?(?@ispc)[A-Z]:\\)' matches a drive name, such as C:\, when run on a Windows system.</td></tr>
<tr><td>(?(cond)expr1|expr2)</td><td>If condition cond is true, then match expr1. Otherwise, match expr2.</td><td>'Mr(s?)\..*?(?(1)her|his) \w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.</td></tr>
</table>

Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

<table>
<tr><th>Ordinal Token Operator</th><th>Description</th><th>Example</th></tr>
<tr><td>(expr)</td><td>Capture in a token the characters that match the enclosed expression.</td><td>'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.</td></tr>
<tr><td>\N</td><td>Match the Nth token.</td><td>'<(\w+).*>.*</\1>' captures tokens for HTML tags, such</td></tr>
</table>

<table>
<tr><th>Ordinal Token Operator</th><th>Description</th><th>Example</th></tr>
<tr><td></td><td></td><td>as 'title' from the string '<title>Some text</title>'.</td></tr>
<tr><td>(?(N)expr1|expr2)</td><td>If the Nth token is found, then match expr1. Otherwise, match expr2.</td><td>'Mr(s?)\..*?(?(1)her|his) \w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.</td></tr>
</table>

<table>
<tr><th>Named Token Operator</th><th>Description</th><th>Example</th></tr>
<tr><td>(?<name>expr)</td><td>Capture in a named token the characters that match the enclosed expression.</td><td>'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.</td></tr>
<tr><td>\k<name></td><td>Match the token referred to by name.</td><td>'<(?<tag>\w+).*>.*</\k<tag>>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.</td></tr>
<tr><td>(?(name)expr1|expr2)</td><td>If the named token is found, then match expr1. Otherwise, match expr2.</td><td>'Mr(?<sex>s?)\..*?(?(sex)her|his) \w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.</td></tr>
</table>

Note If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern `'(and(y|rew))'`, MATLAB creates a token for `'andrew'` but not for `'y'` or `'rew'`.

Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
`(??expr)`	Parse `expr` and include the resulting string in the match expression. When parsed, `expr` must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of `expr`, and one for the complete match.	`'^(\d+)((??\\w{$1}))'` determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching `'5XXXXX'` captures tokens for `'5'` and `'XXXXX'`.
`(??@cmd)`	Execute the MATLAB command represented by `cmd`, and include the string returned by the command in the match expression.	`'(.{2,}).?(??@fliplr($1))'` finds palindromes that are at least four characters long, such as `'abba'`.
`(?@cmd)`	Execute the MATLAB command represented by `cmd`, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	`'\w*?(\w)(?@disp($1))\1\w*'` matches words that include double letters (such as `pp`), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
$& or $0	Portion of the input string that is currently a match
$`	Portion of the input string that precedes the current match
$'	Portion of the input string that follows the current match (use $'' to represent the string $')
$N	Nth token
$<name>	Named token
${cmd}	String returned when MATLAB executes the command, cmd

Comments

Characters	Description	Example
(?#comment)	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	'(?# Initial digit)\<\d\w+' includes a comment, and matches words that begin with a number.

Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
`(?-i)`	Match letter case (default for `regexp` and `regexprep`).
`(?i)`	Do not match letter case (default for `regexpi`).
`(?s)`	Match dot (`.`) in the pattern string with any character (default).
`(?-s)`	Match dot in the pattern with any character that is not a newline character.
`(?-m)`	Match the `^` and `$` metacharacters at the beginning and end of a string (default).
`(?m)`	Match the `^` and `$` metacharacters at the beginning and end of a line.
`(?-x)`	Include space characters and comments when matching (default).
`(?x)`	Ignore space characters and comments when matching. Use `'\ '` and `'\#'` to match space and `#` characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (`:`), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

Data Types
`char | cell`

replace - Replacement text
string | cell array of strings

Replacement text, specified as a string or a cell array of strings, as follows:

- If `replace` is a single string and `expression` is a cell array of strings, then `regexprep` uses the same replacement text for each expression.
- If `replace` is a cell array of `N` strings and `expression` is a single string, then `regexprep` attempts `N` matches and replacements.
- If both `replace` and `expression` are cell arrays of strings, then they must contain the same number of elements. `regexprep` pairs each `replace` element with its matching element in `expression`.

The replacement text can include regular characters, special characters (such as tabs or new lines), or string operators, as shown in the following tables.

Replacement String Operator	Description
`$&` or `$0`	Portion of the input string that is currently a match
`` $` ``	Portion of the input string that precedes the current match
`$'`	Portion of the input string that follows the current match (use `$''` to represent the string `$'`)
`$N`	`N`th token
`$<name>`	Named token
`${cmd}`	String returned when MATLAB executes the command, `cmd`

Operator	Description
`\a`	Alarm (beep)
`\b`	Backspace
`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab
`\char`	Any character with special meaning in regular expressions that you want to match literally (for example, use `\\` to match a single backslash)

Data Types
`char | cell`

option - Search or replacement option

`'once' | N | 'warnings' | 'ignorecase' | 'preservecase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors'`

Search or replacement option, specified as a string or an integer value, as shown in the following table.

Options come in sets: one option that corresponds to the default behavior, and one or two options that allow you to override the default. Specify only one option from a set. Options can appear in any order.

Default	Override	Description
`'all'`	`'once'`	Match and replace the expression as many times as possible (default), or only once.
	`N`	Replace only the `N`th occurrence of the match, where `N` is an integer value.

Default	Override	Description
'nowarnings'	'warnings'	Suppress warnings (default), or display them.
'matchcase'	'ignorecase'	Match letter case (default), or ignore case while matching and replacing.
	'preservecase'	Ignore case while matching, but preserve the case of corresponding characters in the original string while replacing.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (`\n`).
'stringanchors'	'lineanchors'	Apply `^` and `$` metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With `freespacing`, use `'\ '` and `'\#'` to match space and `#` characters.

Data Types
`char`

Output Arguments

newStr - Updated text

string | cell array of strings

Updated text, returned as a string or a cell array of strings. The data type of `newStr` is the same as the data type of `str`.

Examples

Update a Single String

Replace words that begin with `M`, end with `y`, and have at least one character between them.

```
str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
```

```
replace = 'April';

newStr = regexprep(str,expression,replace)

newStr =

My flowers may bloom in April
```

Include Tokens in Replacement Text

Replace variations of the phrase `'walk up'` by capturing the letters that follow `'walk'` in a token.

```
str = 'I walk up, they walked up, we are walking up.';
expression = 'walk(\w*) up';
replace = 'ascend$1';

newStr = regexprep(str,expression,replace)

newStr =

I ascend, they ascended, we are ascending.
```

Include Dynamic Expression in Replacement Text

Replace lowercase letters at the beginning of sentences with their uppercase equivalents using the `upper` function.

```
str = 'here are two sentences. neither is capitalized.';
expression = '(^|\.)\s*.';
replace = '${upper($0)}';

newStr = regexprep(str,expression,replace)

newStr =

Here are two sentences. Neither is capitalized.
```

The regular expression matches single characters (`.`) that follow the beginning of the string (`^`) or a period (`\.`) and any whitespace (`\s*`).

The `replace` expression calls the `upper` function for the currently matching character (`$0`).

Update Multiple Strings

Replace each occurrence of a double letter in a set of strings with the symbols `'--'`.

```
str = {                                  ...
'Whose woods these are I think I know.' ; ...
'His house is in the village though;'   ; ...
'He will not see me stopping here'      ; ...
'To watch his woods fill up with snow.'};

expression = '(.)\1';
replace = '--';
newStr = regexprep(str,expression,replace)

newStr =

    'Whose w--ds these are I think I know.'
    'His house is in the vi--age though;'
    'He wi-- not s-- me sto--ing here'
    'To watch his w--ds fi-- up with snow.'
```

Preserve Case in Original String

Ignore letter case in the regular expression when finding matches, but mimic the letter case of the original string when updating.

```
str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
replace = 'April';

newStr = regexprep(str,expression,replace,'preservecase')

newStr =

My flowers april bloom in April
```

Replace Zero-Length Matches

Insert text at the beginning of a string using the `'^'` operator, which returns a zero-length match, and the `'emptymatch'` keyword.

```
str = 'abc';
expression = '^';
replace = '__';

newStr = regexprep(str,expression,replace,'emptymatch')

newStr =

__abc
```

Concepts

- "Lookahead Assertions in Regular Expressions"
- "Tokens in Regular Expressions"
- "Dynamic Regular Expressions"

Purpose

Translate string into regular expression

Syntax

```
s2 = regexptranslate(type, s1)
```

Description

`s2 = regexptranslate(type, s1)` translates string `s1` into a regular expression string `s2` that you can then use as input into one of the MATLAB regular expression functions such as `regexp`. The `type` input can be either one of the following strings that define the type of translation to be performed. See "Regular Expressions" in the MATLAB Programming Fundamentals documentation for more information.

Type	Description
`'escape'`	Translate all special characters (e.g., '$', '.', '?', '[') in string `s1` so that they are treated as literal characters when used in the `regexp` and `regexprep` functions. The translation inserts an escape character ('\') before each special character in `s1`. Return the new string in `s2`.
`'wildcard'`	Translate all wildcard and '.' characters in string `s1` so that they are treated as literal wildcards and periods when used in the `regexp` and `regexprep` functions. The translation replaces all instances of '*' with '.*', all instances of '?' with '.', and all instances of '.' with '\.'. Return the new string in `s2`.

Examples

Example 1 — Using the 'escape' Option

Because `regexp` interprets the sequence '\n' as a newline character, it cannot locate the two consecutive characters '\' and 'n' in this string:

```
str = 'The sequence \n generates a new line';
pat = '\n';

regexp(str, pat)
ans =
     []
```

To have regexp interpret the expression expr as the characters '\' and 'n', first translate the expression using regexptranslate:

```
pat2 = regexptranslate('escape', pat)
pat2 =
   \\n

regexp(str, pat2)
ans =
    14
```

Example 2 — Using 'escape' In a Replacement String

Replace the word 'walk' with 'ascend' in this string, treating the characters '$1' as a token designator:

```
str = 'I walk up, they walked up, we are walking up.';
pat = 'walk(\w*) up';

regexprep(str, pat, 'ascend$1')
ans =
   I ascend, they ascended, we are ascending.
```

Make another replacement on the same string, this time treating the '$1' as literal characters:

```
regexprep(str, pat, regexptranslate('escape', 'ascend$1'))
ans =
   I ascend$1, they ascend$1, we are ascend$1.
```

Example 3 — Using the 'wildcard' Option

Given the following string of filenames, pick out just the MAT-files. Use regexptranslate to interpret the '*' wildcard as '\w+' instead of as a regular expression quantifier:

```
files = ['test1.mat, myfile.mat, newfile.txt, ' ...
         'jan30.mat, table3.xls'];
regexp(str, regexptranslate('wildcard', '*.mat'), 'match')
ans =
```

```
   'test1.mat' 'myfile.mat' 'jan30.mat'
```

To see the translation, you can type

```
regexptranslate('wildcard','*.mat')
ans =
   \w+\.mat
```

regexp | regexpi | regexprep

How To

- “Regular Expressions”

Purpose

Associate event handler for COM object event at run time

Syntax

```
h.registerevent(eventhandler)
registerevent(h, eventhandler)
```

Description

`h.registerevent(eventhandler)` registers event handler routines with their corresponding events. The `eventhandler` argument can be either a string that specifies the name of the event handler function, or a function handle that maps to that function. Strings used in the `eventhandler` argument are not case sensitive.

`registerevent(h, eventhandler)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

Examples

Show events in the MATLAB sample control:

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.events
```

MATLAB displays all events associated with the instance of the control (output is formatted):

```
Click = void Click()
DblClick = void DblClick()
MouseDown = void MouseDown(int16 Button, int16 Shift,
  Variant x, Variant y)
Event_Args = void Event_Args(int16 typeshort,
  int32 typelong, double typedouble, string typestring,
  bool typebool)
```

Register all events with the same event handler routine, `sampev`:

```
h.registerevent('sampev');
h.eventlisteners
```

MATLAB displays:

```
ans =
    'Click'         'sampev'
    'DblClick'      'sampev'
    'MouseDown'     'sampev'
    'Event_Args'    'sampev'
```

Register individual events:

```
%Unregister existing events
h.unregisterallevents;
%Register specific events
h.registerevent({'click' 'myclick'; ...
    'dblclick' 'my2click'});
h.eventlisteners
```

MATLAB displays:

```
ans =
    'click'       'myclick'
    'dblclick'    'my2click'
```

Register events using a function handle (`@sampev`) instead of the function name:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200]);
registerevent(h, @sampev);
```

See Also

`events (COM)` | `eventlisteners` | `unregisterevent` | `unregisterallevents` | `isevent`

How To

- "Writing Event Handlers"

rehash

Purpose

Refresh function and file system path caches

Syntax

```
rehash
rehash path
rehash toolbox
rehash pathreset
rehash toolboxreset
rehash toolboxcache
```

Description

`rehash` with no arguments updates the MATLAB list of known files and classes for directories on the search path that are not in *`matlabroot`*`/toolbox`. It compares the timestamps for loaded functions against their timestamps on disk. It clears loaded functions if the files on disk are newer. All of this normally happens each time MATLAB displays the Command Window prompt. Use `rehash` with no arguments only when you run a program file that updates another program file, and the calling file needs to reuse the updated version of the second file before the calling file has finished running.

`rehash` **`path`** performs the same updates as `rehash`, but uses a different technique for detecting the files and directories that require updates. Run `rehash path` only if you receive a warning during MATLAB startup notifying you that MATLAB could not tell if a directory has changed, and you encounter problems with MATLAB not using the most current versions of your program files.

`rehash` **`toolbox`** performs the same updates as rehash path, except it updates the list of known files and classes for *all* directories on the search path, including those in *`matlabroot`*`/toolbox`. Run `rehash toolbox` when you change, add, or remove files in *`matlabroot`*`/toolbox` during a session. Typically, you should not make changes to files and directories in *`matlabroot`*`/toolbox`.

`rehash` **`pathreset`** performs the same updates as `rehash` **`path`**, and also ensures the known files and classes list follows precedence rules for shadowed functions.

`rehash` **`toolboxreset`** performs the same updates as `rehash` **`toolbox`**, and also ensures the known files and classes list follows precedence rules for shadowed functions.

`rehash` **`toolboxcache`** performs the same updates as `rehash` **`toolbox`**, and also updates the cache file. This is the equivalent of clicking the **Update Toolbox Path Cache** button in the General Preferences dialog box.

`addpath` | `clear` | `matlabroot` | `path` | `rmpath`

How To

- "Toolbox Path Caching in MATLAB"
- "What Is the MATLAB Search Path?"

Purpose

Release COM interface

Syntax

```
h.release
release(h)
```

Description

`h.release` releases the interface and all resources used by the interface. You must release the handle when you are done with the interface. A released interface is no longer valid. MATLAB generates an error if you try to use an object that represents that interface.

`release(h)` is an alternate syntax.

Releasing the interface does not delete the control itself (see the `delete` function), since other interfaces on that object might still be active.

COM functions are available on Microsoft Windows systems only.

See Also

`delete (COM)` | `actxcontrol` | `actxserver`

How To

- Releasing Interfaces

Purpose

Equality and sorting of handle objects

Syntax

```
TF = eq(H1,H2)
TF = ne(H1,H2)
TF = lt(H1,H2)
TF = le(H1,H2)
TF = gt(H1,H2)
TF = ge(H1,H2)
```

Description

`TF = eq(H1,H2)`

`TF = ne(H1,H2)`

`TF = lt(H1,H2)`

`TF = le(H1,H2)`

`TF = gt(H1,H2)`

`TF = ge(H1,H2)`

For each pair of input arrays (`H1` and `H2`), a logical array of the same size is returned in which each element is an element-wise equality or comparison test result. These methods perform scalar expansion in the same way as the MATLAB built-in functions. See `relationaloperators` for more information.

You can make the following assumptions about the result of a handle comparison:

- The same two handles always compare as equal and the repeated comparison of any two handles always yields the same result in the same MATLAB session.
- Different handles are always not-equal.
- The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.
- If the input arrays belong to different classes (including the case where one input array belongs to a non-handle class such as `double`) then the comparison is always false.

- If a comparison is made between a handle object and an object of a dominant class, the method of the dominant class is invoked. You should generally test only like objects because a dominant class might not define one of these methods.
- An error occurs if the input arrays are not the same size and neither is scalar.

Use `isequal` when you want to determine if handle objects with different handles have the same data in all object properties.

See Also

`handle` | `meta.class`

Purpose

Remainder after division

Syntax

```
R = rem(X,Y)
```

Description

`R = rem(X,Y)` if `Y ~= 0`, returns `X - n.*Y` where `n = fix(X./Y)`. If `Y` is not an integer and the quotient `X./Y` is within roundoff error of an integer, then `n` is that integer. The inputs `X` and `Y` must be real arrays of the same size, or real scalars.

The following are true by convention:

- `rem(X,0)` is `NaN`
- `rem(X,X)` for `X~=0` is `0`
- `rem(X,Y)` for `X~=Y` and `Y~=0` has the same sign as `X`.

Tips

`mod(X,Y)` for `X~=Y` and `Y~=0` has the same sign as `Y`.

`rem(X,Y)` and `mod(X,Y)` are equal if `X` and `Y` have the same sign, but differ by `Y` if `X` and `Y` have different signs.

The `rem` function returns a result that is between 0 and `sign(X)*abs(Y)`. If `Y` is zero, `rem` returns `NaN`.

See Also

`mod`

containers.Map.remove

Purpose

Remove key-value pairs from `containers.Map` object

Syntax

`remove(mapObj,keySet)`

Description

`remove(mapObj,keySet)` erases all specified keys, and the values associated with them, from `mapObj`. Input `keySet` can be a scalar key or a cell array of keys.

Input Arguments

mapObj

Object of class `containers.Map`.

keySet

Scalar value, string, or cell array that specifies keys in `mapObj` to delete.

Examples

Remove Key-Value Pairs from a Map

Create a map and view the keys and the `Count` property:

```
myKeys = {'a','b','c','d'};
myValues = [1,2,3,4];
mapObj = containers.Map(myKeys,myValues);

mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The initial map contains four key-value pairs:

```
mapKeys =
    'a'    'b'    'c'    'd'

mapCount =
                     4
```

Remove the pairs corresponding to keys `b` and `d`:

```
keySet = {'b','d'};
```

```
remove(mapObj,keySet)

mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The modified map contains two key-value pairs:

```
mapKeys =
    'a'    'c'

mapCount =
                    2
```

See Also

containers.Map | keys | values | isKey

removets

Purpose

Remove `timeseries` objects from `tscollection` object

Syntax

```
tsc = removets(tsc,Name)
```

Description

`tsc = removets(tsc,Name)` removes one or more `timeseries` objects with the name specified in `Name` from the `tscollection` object tsc. `Name` can either be a string or a cell array of strings.

Examples

The following example shows how to remove a time series from a `tscollection`.

1 Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

2 Create a `tscollection` object `tsc`, which includes `ts1` and `ts2`.

```
tsc=tscollection({ts1 ts2});
```

3 To view the members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed

Time vector characteristics

      Start time            1 seconds
      End time              5 seconds

Member Time Series Objects:
```

```
      acceleration
      speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of `ts1` and `ts2`, respectively.

4 Remove `ts2` from `tsc`.

```
tsc=removets(tsc,'speed');
```

5 To view the current members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed

Time vector characteristics

      Start time            1 seconds
      End time              5 seconds

Member Time Series Objects:
      acceleration
```

The remaining member of `tsc` is `acceleration`. The `timeseries` `speed` has been removed.

See Also

`addts` | `tscollection`

FTP.rename

Purpose

Rename file on FTP server

Syntax

`rename(ftpobj,oldname,newname)`

Description

`rename(ftpobj,oldname,newname)` changes the name of the file `oldname` to `newname` in the current folder on an FTP server.

Input Arguments

ftpobj

FTP object created by `ftp`.

oldname

String enclosed in single quotation marks that specifies the original name of the file.

newname

String enclosed in single quotation marks that specifies a new name for the file.

Examples

Suppose that hypothetical FTP server `ftp.testsite.com` contains a file named `testfile.m`. Rename the file to `final.m`:

```
test = ftp('ftp.testsite.com');
rename(test, 'testfile.m', 'final.m');
close(test);
```

See Also

`delete` | `dir` | `ftp` | `mget` | `mput`

Purpose

Replicate and tile array

Syntax

```
B = repmat(A,m,n)
B = repmat(A,[m n])
B = repmat(A,[m n p...])
```

Description

`B = repmat(A,m,n)` creates a large matrix `B` consisting of an `m`-by-`n` tiling of copies of `A`. The size of `B` is `[size(A,1)*m, (size(A,2)*n]`. The statement `repmat(A,n)` creates an `n`-by-`n` tiling.

`B = repmat(A,[m n])` accomplishes the same result as `repmat(A,m,n)`.

`B = repmat(A,[m n p...])` produces a multidimensional array `B` composed of copies of `A`. The size of `B` is `[size(A,1)*m, size(A,2)*n, size(A,3)*p, ...]`.

Tips

`repmat(A,m,n)`, when `A` is a scalar, produces an `m`-by-`n` matrix filled with `A`'s value and having `A`'s `class`. For certain values, you can achieve the same results using other functions, as shown by the following examples:

- `repmat(NaN,m,n)` returns the same result as `NaN(m,n)`.
- `repmat(single(inf),m,n)` is the same as `inf(m,n,'single')`.
- `repmat(int8(0),m,n)` is the same as `zeros(m,n,'int8')`.
- `repmat(uint32(1),m,n)` is the same as `ones(m,n,'uint32')`.
- `repmat(eps,m,n)` is the same as `eps(ones(m,n))`.

Examples

Example 1

In this example, `repmat` replicates 12 copies of the second-order identity matrix, resulting in a “checkerboard” pattern.

```
B = repmat(eye(2),3,4)

B =
     1     0     1     0     1     0     1     0
     0     1     0     1     0     1     0     1
     1     0     1     0     1     0     1     0
```

```
0     1     0     1     0     1     0     1
1     0     1     0     1     0     1     0
0     1     0     1     0     1     0     1
```

The statement `N = repmat(NaN,[2 3])` creates a 2-by-3 matrix of `NaN`s.

Example 2

If you have code that uses `repmat` and also a binary operator or function, you can transform the code to use the `bsxfun` function instead. In certain cases, this can provide a simpler and faster solution.

This example replaces the sum of two repmat operations with a single call to `bsxfun`:

```
x = 1:5; y = (1:10)';

% Replace this code
repmat(x,10,1) + repmat(y,1,5)

% with the following:
bsxfun(@plus, x, y)
```

See Also

`reshape` | `bsxfun` | `NaN` | `Inf` | `ones` | `zeros`

Purpose

Select or interpolate data in `tscollection` using new time vector

Syntax

```
tsc = resample(tsc,Time)
tsc = resample(tsc,Time,interp_method)
tsc = resample(tsc,Time,interp_method,code)
```

Description

`tsc = resample(tsc,Time)` resamples the `tscollection` object tsc on the new Time vector. When `tsc` uses date strings and Time is numeric, Time is treated as numerical specified relative to the `tsc.TimeInfo.StartDate` property and in the same units that tsc uses. The `resample` method uses the default interpolation method for each time series member.

`tsc = resample(tsc,Time,interp_method)` resamples the `tscollection` object tsc using the interpolation method given by the string interp_method. Valid interpolation methods include `'linear'` and `'zoh'` (zero-order hold).

`tsc = resample(tsc,Time,interp_method,code)` resamples the `tscollection` object tsc using the interpolation method given by the string interp_method. The integer code is a user-defined quality code for resampling, applied to all samples.

Examples

The following example shows how to resample a `tscollection` that consists of two `timeseries` members.

1 Create two `timeseries` objects.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

2 Create a `tscollection` `tsc`.

```
tsc=tscollection({ts1 ts2});
```

The time vector of the collection `tsc` is [1:5], which is the same as for `ts1` and `ts2` (individually).

3 Get the interpolation method for `acceleration` by typing

```
tsc.acceleration
```

MATLAB responds with

```
Time Series Object: acceleration

Time vector characteristics

      Length                  5
      Start time              1 seconds
      End time                5 seconds

Data characteristics

      Interpolation method  linear
      Size                  [1  1  5]
      Data type             double
```

4 Set the interpolation method for `speed` to zero-order hold by typing

```
setinterpmethod(tsc.speed,'zoh')
```

MATLAB responds with

```
Time Series Object: acceleration

Time vector characteristics

      Length                  5
      Start time              1 seconds
      End time                5 seconds
```

```
Data characteristics

      Interpolation method  zoh
      Size                  [1  1  5]
      Data type             double
```

5. Resample the time-series collection `tsc` by individually resampling each time-series member of the collection and using its interpolation method.

```
res_tsc=resample(tsc,[1 1.5 3.5 4.5 4.9])
```

See Also

`getinterpmethod` | `setinterpmethod` | `tscollection`

reset

Purpose

Reset graphics object properties to their defaults

Syntax

```
reset(h)
```

Description

`reset(h)` resets all properties having factory defaults on the object identified by `h`. To see the list of factory defaults, use the statement

```
get(0,'factory')
```

If `h` is a `figure`, the MATLAB software does not reset `Position`, `Units`, `WindowStyle`, or `PaperUnits`. If `h` is an `axes`, MATLAB does not reset `Position` and `Units`.

Examples

`reset(gca)` resets the properties of the current axes.

`reset(gcf)` resets the properties of the current figure.

See Also

`cla` | `clf` | `gca` | `gcf` | `hold`

Purpose

Reset random number stream

Class

`RandStream`

Syntax

```
reset(s)
reset(s,seed)
```

Description

`reset(s)` resets the generator for the random stream, `s`, to the internal state corresponding to its seed. This is similar to clearing `s` and recreating it using `RandStream(Type,...)`, except that `reset` does not set the stream's `NormalTransform`, `Antithetic`, and `FullPrecision` properties to their original values.

`reset(s,seed)` resets the generator for the random stream, `s`, to the internal state corresponding to `seed` (the seed value), and it updates the `seed` property of `s`. The value of `seed` must be an integer between 0 and $2^{32} - 1$. Resetting a stream's seed can invalidate independence with other streams.

Note Resetting a stream should be used primarily for reproducing results.

Examples

Example 1

Reset a random number stream to its initial state. This does not create a random number stream, it simply resets the stream:

```
stream = RandStream('twister','Seed',0)

stream =

mt19937ar random stream
             Seed: 0
  NormalTransform: Ziggurat
```

```
reset(stream);
stream.Seed

ans =

           0
```

Example 2

Reset a random number stream using a specific seed:

```
stream = RandStream('twister','Seed',0)

stream =

mt19937ar random stream
             Seed: 0
  NormalTransform: Ziggurat

reset(stream,1);
stream.Seed

ans =

           1
```

See Also

`RandStream` | `RandStream.getGlobalStream`

Purpose

Reshape array

Syntax

```
B = reshape(A,m,n)
B = reshape(A,m,n,p,...)
B = reshape(A,[m n p ...])
B = reshape(A,...,[],...)
B = reshape(A,siz)
```

Description

`B = reshape(A,m,n)` returns the `m`-by-`n` matrix `B` whose elements are taken column-wise from `A`. An error results if `A` does not have `m*n` elements.

`B = reshape(A,m,n,p,...)` or `B = reshape(A,[m n p ...])` returns an n-dimensional array with the same elements as `A` but reshaped to have the size `m`-by-`n`-by-`p`-by-`...`. The product of the specified dimensions, `m*n*p*`..., must be the same as `numel(A)`.

`B = reshape(A,...,[],...)` calculates the length of the dimension represented by the placeholder `[]`, such that the product of the dimensions equals `numel(A)`. The value of `numel(A)` must be evenly divisible by the product of the specified dimensions. You can use only one occurrence of `[]`.

`B = reshape(A,siz)` returns an n-dimensional array with the same elements as `A`, but reshaped to `siz`, a vector representing the dimensions of the reshaped array. The quantity `prod(siz)` must be the same as `numel(A)`.

Examples

Reshape a 3-by-4 matrix into a 2-by-6 matrix.

```
A =
     1     4     7    10
     2     5     8    11
     3     6     9    12

B = reshape(A,2,6)

B =
```

```
     1     3     5     7     9    11
     2     4     6     8    10    12
B = reshape(A,2,[])

B =
     1     3     5     7     9    11
     2     4     6     8    10    12
```

shiftdim | squeeze | circshift | permute | repmat | colon (:)

Purpose

Convert between partial fraction expansion and polynomial coefficients

Syntax

```
[r,p,k] = residue(b,a)
[b,a] = residue(r,p,k)
```

Description

The `residue` function converts a quotient of polynomials to pole-residue representation, and back again.

`[r,p,k] = residue(b,a)` finds the residues, poles, and direct term of a partial fraction expansion of the ratio of two polynomials, $b(s)$ and $a(s)$, of the form

$$\frac{b(s)}{a(s)} = \frac{b_1 s^m + b_2 s^{m-1} + b_3 s^{m-2} + \ldots + b_{m+1}}{a_1 s^n + a_2 s^{n-1} + a_3 s^{n-2} + \ldots + a_{n+1}}$$

where b_j and a_j are the `j`th elements of the input vectors `b` and `a`.

`[b,a] = residue(r,p,k)` converts the partial fraction expansion back to the polynomials with coefficients in `b` and `a`.

Definitions

If there are no multiple roots, then

$$\frac{b(s)}{a(s)} = \frac{r_1}{s - p_1} + \frac{r_2}{s - p_2} + \ldots + \frac{r_n}{s - p_n} + k(s)$$

The number of poles `n` is

```
n = length(a)-1 = length(r) = length(p)
```

The direct term coefficient vector is empty if `length(b) < length(a)`; otherwise

```
length(k) = length(b)-length(a)+1
```

If `p(j) = ...  = p(j+m-1)` is a pole of multiplicity `m`, then the expansion includes terms of the form

$$\frac{r_j}{s-p_j}+\frac{r_{j+1}}{(s-p_j)^2}+\ldots+\frac{r_{j+m-1}}{(s-p_j)^m}$$

Arguments

`b,a`	Vectors that specify the coefficients of the polynomials in descending powers of s
`r`	Column vector of residues
`p`	Column vector of poles
`k`	Row vector of direct terms

Algorithms

It first obtains the poles with `roots`. Next, if the fraction is nonproper, the direct term `k` is found using `deconv`, which performs polynomial long division. Finally, the residues are determined by evaluating the polynomial with individual roots removed. For repeated roots, `resi2` computes the residues at the repeated root locations.

Limitations

Numerically, the partial fraction expansion of a ratio of polynomials represents an ill-posed problem. If the denominator polynomial, $a(s)$, is near a polynomial with multiple roots, then small changes in the data, including roundoff errors, can make arbitrarily large changes in the resulting poles and residues. Problem formulations making use of state-space or zero-pole representations are preferable.

Examples

If the ratio of two polynomials is expressed as

$$\frac{b(s)}{a(s)}=\frac{5s^3+3s^2-2s+7}{-4s^3+8s+3}$$

then

```
b = [ 5 3 -2 7]
a = [-4 0 8 3]
```

and you can calculate the partial fraction expansion as

```
[r, p, k] = residue(b,a)

r =
   -1.4167
   -0.6653
    1.3320

p =
    1.5737
   -1.1644
   -0.4093

k =
   -1.2500
```

Now, convert the partial fraction expansion back to polynomial coefficients.

```
[b,a] = residue(r,p,k)

b =
   -1.2500   -0.7500    0.5000   -1.7500

a =
    1.0000   -0.0000   -2.0000   -0.7500
```

The result can be expressed as

$$\frac{b(s)}{a(s)} = \frac{-1.25s^3 - 0.75s^2 + 0.50s - 1.75}{s^3 - 2.00s - 0.75}.$$

Note that the result is normalized for the leading coefficient in the denominator.

restoredefaultpath

Purpose

Restore default search path

Alternatives

As an alternative to the `restoredefaultpath` function, use the Set Path dialog box.

Syntax

```
restoredefaultpath
restoredefaultpath; matlabrc
```

Description

`restoredefaultpath` sets the search path to include only folders for MathWorks installed products. Use `restoredefaultpath` when you are having problems with the search path.

`restoredefaultpath; matlabrc` sets the search path to include only folders for MathWorks installed products and corrects search path problems encountered during startup.

MATLAB does not support issuing `restoredefaultpath` from a UNC path name. Doing so might result in MATLAB being unable to find files on the search path. If you do issue `restoredefaultpath` from a UNC path name, restore the expected behavior by changing the current folder to an absolute path, and then reissuing `restoredefaultpath`.

`addpath` | `genpath` | `matlabrc` | `rmpath` | `savepath`

How To

- "Path Unsuccessfully Set at Startup"
- "What Is the MATLAB Search Path?"

rethrow

Purpose

Reissue error

Note As of version 7.5, MATLAB supports error handling that is based on the `MException` class. Calling `rethrow` with a structure argument, as described on this page, is now replaced by calling rethrow with an `MException` object, as described on the reference page for `rethrow(MException)`. `rethrow` called with a structure input will be removed in a future version.

Syntax

```
rethrow(errorStruct)
```

Description

`rethrow(errorStruct)` reissues the error specified by `errorStruct`. The currently running function terminates and control returns to the keyboard (or to any enclosing `catch` block). The `errorStruct` argument must be a MATLAB structure containing at least the `message` and `identifier` fields:

Fieldname	Description
`message`	Text of the error message
`identifier`	Message identifier of the error message
`stack`	Information about the error from the program stack

See "Message Identifiers" in the MATLAB documentation for more information on the syntax and usage of message identifiers.

Tips

The `errorStruct` input can contain the field `stack`, identical in format to the output of the `dbstack` command. If the `stack` field is present, the stack of the rethrown error will be set to that value. Otherwise, the stack will be set to the line at which the rethrow occurs.

Examples

`rethrow` is usually used in conjunction with `try`-`catch` statements to reissue an error from a `catch` block after performing `catch`-related operations. For example,

```
try
   do_something
catch
   do_cleanup
   rethrow(previous_error)
end
```

See Also

`rethrow(MException)` | `throw(MException)` | `throwAsCaller(MException)` | `try` | `catch` | `error` | `assert` | `dbstop`

rethrow (MException)

Purpose

Reissue existing exception

Syntax

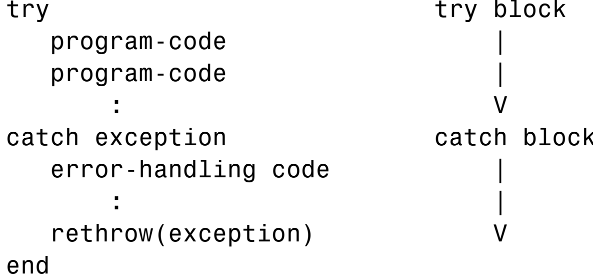
`rethrow(exception)`

Description

`rethrow(exception)` forces an exception (i.e., error report) to be reissued by MATLAB after the error reporting process has been temporarily suspended to diagnose or remedy the problem. MATLAB typically responds to errors by terminating the currently running program. Errors occurring within a try block, however, bypass this mechanism and transfer control of the program to error handling code in the `catch` block instead. This enables you to write your own error handling procedures for parts of your program that require them.

The *exception* input is a scalar object of the `MException` class that contains information about the cause and location of the error.

The code segment below shows the format of a typical `try/catch` statement.



```
try                                 try block
   program-code                          |
   program-code                          |
        :                                V
catch exception                     catch block
   error-handling code                   |
        :                                |
   rethrow(exception)                    V
end
```

An error detected within the `try` block causes MATLAB to enter the corresponding `catch` block. The error record constructed by MATLAB in the process of reporting this error passes to the `catch` command in the statement

```
catch exception
```

Error handling code within the `catch` block uses the information in the error record to address the problem in some predefined manner. The

catch block shown here ends with a rethrow statement which throws the exception returned in the catch statement, and then terminates the function:

```
rethrow(exception)
```

The most significant difference between rethrow and other MATLAB functions that throw exceptions is in how rethrow handles a piece of the exception record called the *stack*. The stack keeps a record of where the error occurred and what functions were called in the process. It is a struct array composed of the following fields, where each element of the array represents an exception:

Fields of the Exception Stack	Description
line	Line number from which the exception was thrown.
name	Name of the function being executed at the time.
file	Name of the file containing that function.

Functions such as error, assert, or throw, create the stack with the location from which they were executed. Calling rethrow, however, preserves information from the original exception. In doing so, rethrow enables you to retrace the path taken to the source of the error.

Tips

There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining techniques to throw an existing exception.

- Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the error function.

- Reissue the original exception by throwing the initial error record unmodified. Use the MException rethrow method to do this.
- Collect additional information on the cause of the error, store it in a new or modified error record, and issue a new exception based on that record. Use the MException addCause and throw methods to do this.
- Make it appear that the error originated in the caller of the currently running function. Use the MException throwAsCaller method to do this.

rethrow can only issue a previously caught exception. Calling rethrow on an exception that was not previously thrown is an error.

Examples

This example shows the difference between using throw and rethrow at the end of a catch block. The combineArrays function vertically concatenates arrays A and B. When the two arrays have rows of unequal length, the function throws an error.

The first time you run the function, comment out the rethrow command at the end of the catch block so that the function calls throw instead:

```
function C = combineArrays(A, B)
try
    catAlongDim1(A, B);              % Line 3
catch exception
    throw(exception)                 % Line 5
    % rethrow(exception)             % Line 6
end

function catAlongDim1(V1, V2)
    C = cat(1, V1, V2);              % Line 10
```

When MATLAB throws the exception, it reports an error on line 5 which is the line that calls throw. In some cases, that might be what you want but, in this case, it does not show the true source of the error.

```
A = 4:3:19;     B = 3:4:19;
combineArrays(A, B)
```

```
Error using combineArrays (line 5)
CAT arguments dimensions are not consistent.
```

Make the following changes to `combineArrays.m` so that you use `rethrow` instead:

```
% throw(exception)                      % Line 5
rethrow(exception)                      % Line 6
```

Run the function again. This time, line 10 is the first line reported which is where the MATLAB concatenation function `cat` was called and the exception originated. The next error reported is on line 3 which is where the call to `catAlongDim1` was called:

```
combineArrays(A, B)

Error using cat
CAT arguments dimensions are not consistent.

Error in combineArrays>catAlongDim1 (line 10)
    C = cat(1, V1, V2);                 % Line 10
Error in combineArrays (line 3)
    catAlongDim1(A, B);                 % Line 3
```

return

Purpose

Return to invoking function

Syntax

```
return
```

Description

`return` causes a normal return to the invoking function or to the keyboard. It also terminates keyboard mode.

Examples

This determinant function uses `return` to handle the special case of an empty matrix:

```
function d = det(A)
%DET det(A) is the determinant of A.
if isempty(A)
    d = 1;
    return
else
    ...
end
```

Purpose

Write modified metadata to existing IFD

Syntax

`tiffobj.rewriteDirectory()`

Description

`tiffobj.rewriteDirectory()` writes modified metadata (tag) data to an existing directory. Use this tag when you want to change the value of a tag in an existing image file directory.

Examples

Open a `Tiff` object for modification and modify the value of a tag. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r');
%  Modify the value of a tag.
t.setTag('Software','MATLAB');
t.rewriteDirectory();
```

References

This method corresponds to the `TIFFRewriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

rgb2hsv

Purpose

Convert RGB colormap to HSV colormap

Syntax

```
cmap = rgb2hsv(M)
hsv_image = rgb2hsv(rgb_image)
```

Description

`cmap = rgb2hsv(M)` converts an RGB colormap `M` to an HSV colormap `cmap`. Both colormaps are *m*-by-3 matrices. The elements of both colormaps are in the range 0 to 1.

The columns of the input matrix `M` represent intensities of red, green, and blue, respectively. The columns of the output matrix `cmap` represent hue, saturation, and value, respectively.

`hsv_image = rgb2hsv(rgb_image)` converts the RGB image to the equivalent HSV image. RGB is an m-by-n-by-3 image array whose three planes contain the red, green, and blue components for the image. HSV is returned as an m-by-n-by-3 image array whose three planes contain the hue, saturation, and value components for the image.

See Also

`brighten` | `colormap` | `hsv2rgb` | `rgbplot`

Purpose

Convert RGB image to indexed image

Syntax

```
[X,map] = rgb2ind(RGB,n)
X = rgb2ind(RGB, map)
[X,map] = rgb2ind(RGB, tol)
[ ___ ] = rgb2ind( ___ ,dither_option)
```

Description

`[X,map] = rgb2ind(RGB,n)` converts the RGB image to an indexed image `X` using minimum variance quantization and dithering. `map` contains at most `n` colors. `n` must be less than or equal to 65,536.

`X = rgb2ind(RGB, map)` converts the RGB image to an indexed image `X` with colormap `map` using the inverse colormap algorithm. `size(map,1)` must be less than or equal to 65,536.

`[X,map] = rgb2ind(RGB, tol)` converts the RGB image to an indexed image `X` using uniform quantization and dithering. `map` contains at most `(floor(1/tol)+1)^3` colors. `tol` must be between 0.0 and 1.0.

`[ ___ ] = rgb2ind( ___ ,dither_option)` enables or disables dithering. `dither_option` is a string that can have one of these values.

`'dither'` (default)	dithers, if necessary, to achieve better color resolution at the expense of spatial resolution.
`'nodither'`	maps each color in the original image to the closest color in the new map. No dithering is performed.

Note The values in the resultant image `X` are indexes into the colormap `map` and should not be used in mathematical processing, such as filtering operations.

Class Support

The input image can be of class `uint8`, `uint16`, `single`, or `double`. If the length of `map` is less than or equal to 256, the output image is of class `uint8`. Otherwise, the output image is of class `uint16`.

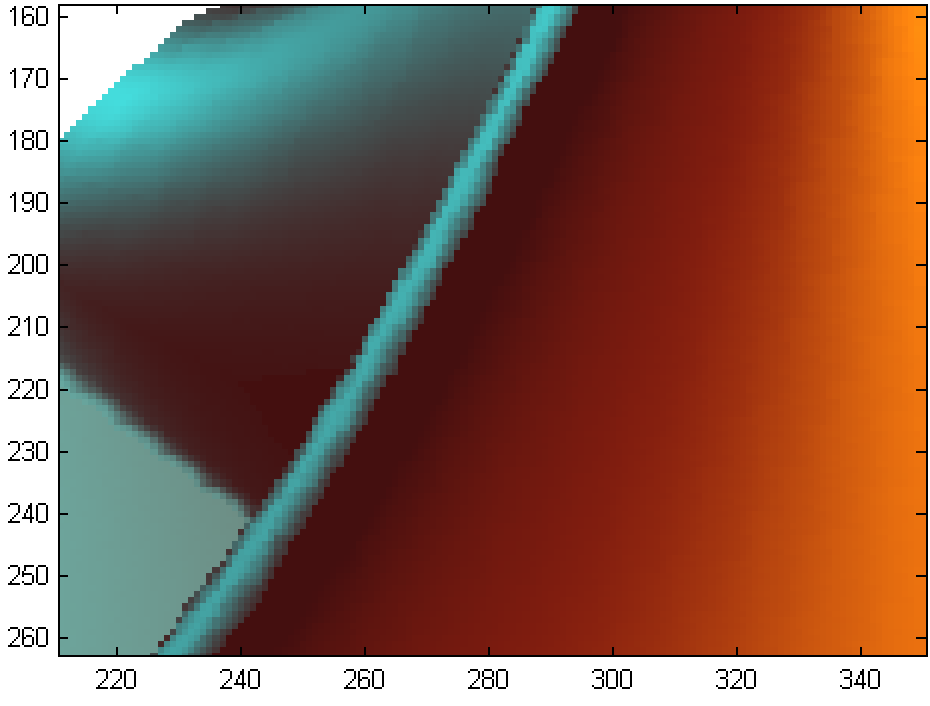
Algorithms

- **Uniform Quantization** — Uniform quantization cuts the RGB color cube into smaller cubes of length tol. [insert material marked "A" on PDF.]
- **Minimum Variance Quantization** — Minimum variance quantization cuts the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number specified, the output colormap is also smaller.
- **Inverse Colormap** — The inverse colormap algorithm quantizes the specified colormap into 32 distinct levels per color component. Then, for each pixel in the input image, the closest color in the quantized colormap is found.

Examples

Read and display a truecolor `uint8` PNG image of the MathWorks logo. Zoom in to see color variation better.

```
imfile = fullfile(matlabroot,...
         'toolbox','matlab','demos','html','logodemo_01.png');
RGB = imread(imfile,'PNG');
figure('Name','RGB Truecolor Image')
imagesc(RGB)
axis image
zoom(4)
```



```
% Convert RGB to an indexed image with 32 colors
[IND,map] = rgb2ind(RGB,32);
figure('Name','Indexed image with 32 Colors')
imagesc(IND)
colormap(map)
axis image
zoom(4)
```

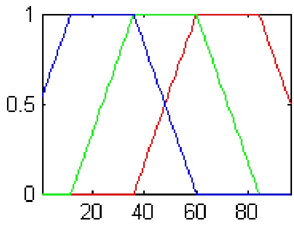
Purpose

Plot colormap



Syntax

```
rgbplot(cmap)
```

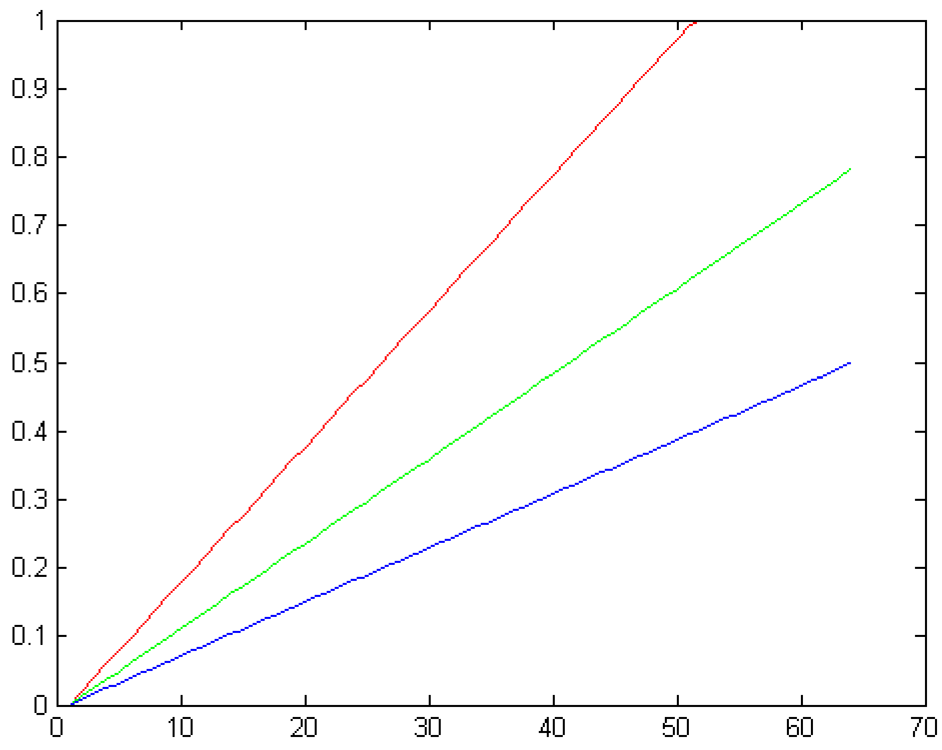
Description

`rgbplot(cmap)` plots the three columns of `cmap`, where `cmap` is an *m*-by-3 colormap matrix. `rgbplot` draws the first column in red, the second in green, and the third in blue.

Examples

Plot the RGB values of the `copper` colormap.

```
rgbplot(copper)
```

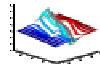


See Also

`colormap`

Purpose

Ribbon plot



Syntax

```
ribbon(Y)
ribbon(X,Y)
ribbon(X,Y,width)
ribbon(axes_handle,...)
h = ribbon(...)
```

Description

`ribbon(Y)` plots the columns of `Y` as three-dimensional ribbons of uniform width using `X = 1:size(Y,1)`. Ribbons advance along the *x*-axis centered on tick marks at unit intervals, three-quarters of a unit in width. Ribbon maps values in `X` to colors in colormap linearly. To change ribbon colors in the graph, change the `colormap`.

`ribbon(X,Y)` plots three dimensional ribbons for data in `Y`, centered at locations specified in `X`. `X` and `Y` are vectors or matrices of the same size. Additionally, `X` can be a row or a column vector, and `Y` a matrix with `length(X)` rows. When `Y` is a matrix, `ribbon` plots each column in `Y` as a ribbon at the corresponding `X` location.

`ribbon(X,Y,width)` specifies the width of the ribbons. The default is `0.75`. If `width = 1`, the ribbons touch, leaving no space between them when viewed down the *z*-axis. If `width > 1`, ribbons overlap and can intersect.

`ribbon(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ribbon(...)` returns a vector of handles to surface graphics objects. `ribbon` returns one handle per strip.

Examples

Create a ribbon plot of the `peaks` function.

```
[x,y] = meshgrid(-3:.5:3,-3:.1:3);
z = peaks(x,y);
```

```
ribbon(y,z)
xlabel('X')
ylabel('Y')
zlabel('Z')
colormap hsv
```

plot | plot3 | surface | waterfall

Purpose

Remove application-defined data

Syntax

```
rmappdata(h,name)
```

Description

`rmappdata(h,name)` removes the application-defined data `name` from the object specified by handle `h`.

Tips

Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

rmdir

Purpose

Remove folder

Syntax

```
rmdir(folderName)
rmdir(folderName,'s')
[status, message, messageid] = rmdir(folderName,'s')
```

Description

`rmdir(folderName)` removes the folder `folderName` from the current folder if `folderName` is empty. If `folderName` is not in the current folder, then specify the relative path or the full path for `folderName`.

`rmdir(folderName,'s')` removes the folder `folderName` and its contents from the current folder. With the `'s'` option, `rmdir` attempts to remove all subfolders and files in `folderName` regardless of their write permissions.

`[status, message, messageid] = rmdir(folderName,'s')` removes the folder `folderName` and its contents from the current folder, returning the status, a message, and the MATLAB message ID.

Tips

- If you specify the `'s'` flag or include a wildcard in the folder name, MATLAB produces an error if it is unable to remove all folders. The error message lists the folder and files that MATLAB could not remove.

Input Arguments

folderName

String specifying the absolute or relative path name of the folder you want to remove.

Default: None

's'

Literal string that directs `rmdir` to remove all subfolders and files in the specified folder, regardless of their write permissions. The result for read-only files follows the practices of the operating system.

Default: `rmdir` does not remove subfolders and files in the specified folder.

Output Arguments

status

Logical scalar indicating the outcome of the `rmdir` operation. The status value is `1` if the operation was successful and `0` if it returned an error.

message

String containing the warning or error message text if the operation is unsuccessful. An empty string, if the operation is successful.

messageid

String containing the warning or error message ID, if the operation is unsuccessful. MATLAB returns an empty string if the operation is successful.

Examples

These examples remove an empty folder, `myfiles`, assuming it is in the current folder:

```
% Remove myfiles from the current folder:

rmdir('myfiles')

% Use the relative path to remove myfiles. Assuming
% the current folder is matlab/work and myfiles is in
% d:/matlab/work/project, type this:

rmdir('project/myfiles')

% Use the full path to remove myfiles, assuming
% the current folder is matlab/work and myfiles is in
% d:/matlab/work/project:

rmdir('d:/matlab/work/project/myfiles')
```

This example removes the `myfiles` folder and its contents, assuming `myfiles` is in the current folder:

```
rmdir('myfiles','s')
```

This example unsuccessfully attempts to remove the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess, id]=rmdir('myfiles')
```

MATLAB returns:

```
stat =
     0

mess =

No directories were removed.

id =

MATLAB:RMDIR:NoDirectoriesRemoved
```

This example successfully removes the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess]=rmdir('myfiles','s')
```

MATLAB returns:

```
stat =
     1

mess =
```

''

Alternatives

Open the Current Folder browser by running `filebrowser`. Then, in the Current Folder browser, right-click the folder name and select **Delete** from the context menu.

FTP.rmdir

Purpose

Remove folder on FTP server

Syntax

```
rmdir(ftpobj,folder)
```

Description

`rmdir(ftpobj,folder)` removes the specified folder from the current folder on an FTP server.

Input Arguments

ftpobj

FTP object created by `ftp`.

folder

String enclosed in single quotation marks that specifies the name of the folder to delete.

Examples

Remove the folder `temp` from the hypothetical FTP server `ftp.testsite.com`:

```
test = ftp('ftp.testsite.com');
rmdir(test, 'temp');
```

See Also

`cd` | `delete` | `dir` | `ftp` | `mkdir`

Purpose

Remove fields from structure

Syntax

```
s = rmfield(s,field)
```

Description

`s = rmfield(s,field)` removes the specified field or fields from structure array `s`. Specify multiple fields using a cell array of strings. The dimensions of `s` remain the same.

Input Arguments

s - Input structure

structure array

Input structure, specified as a structure array.

Data Types
`struct`

field - Field name or names

character array | cell array of strings

Field name or names, specified as a character array or a cell array of strings.

Example: `'f1'`

Example: `{'f1';'f2'}`

Data Types
`char | cell`

Examples

Remove Single Field

Define a scalar structure with fields named `a`, `b`, and `c`.

```
s.a = 1;
s.b = 2;
s.c = 3;
```

Remove field `b`.

```
field = 'b';
```

```
s = rmfield(s,field)
```

```
s =
    a: 1
    c: 3
```

Remove Multiple Fields

Define a scalar structure with fields `first`, `second`, `third`, and `fourth`.

```
S.first = 1;
S.second = 2;
S.third = 3;
S.fourth = 4;
```

Remove fields `first` and `fourth`.

```
fields = {'first','fourth'};
S = rmfield(S,fields)
```

```
S =
    second: 2
     third: 3
```

Purpose Remove folders from search path

Syntax

```
rmpath(folderName)
```

Description `rmpath(folderName)` removes the specified folder from the search path.

Input Arguments

folderName - Name of folder
string

Name of folder to remove from the search path, specified as a string. Use the full path name for `folderName`.

Example: `'c:\matlab\work'`

Example: `'/home/user/matlab'`

Examples

Remove Folder from Search Path

Remove `/usr/local/matlab/mytools` from the search path.

```
rmpath('/usr/local/matlab/mytools')
```

See Also `addpath | savepath | path`

Concepts

- "What Is the MATLAB Search Path?"

rmpref

Purpose

Remove preference

Syntax

```
rmpref('group','pref')
rmpref('group',{'pref1','pref2',...'prefn'})
rmpref('group')
```

Description

`rmpref('group','pref')` removes the preference specified by `group` and `pref`. It is an error to remove a preference that does not exist.

`rmpref('group',{'pref1','pref2',...'prefn'})` removes each preference specified in the cell array of preference names. It is an error if any of the preferences do not exist.

`rmpref('group')` removes all the preferences for the specified `group`. It is an error to remove a group that does not exist.

Examples

```
addpref('mytoolbox','version','1.0')
rmpref('mytoolbox')
```

See Also

`addpref` | `getpref` | `ispref` | `setpref` | `uigetpref` | `uisetpref`

Purpose

Control random number generation

Syntax

```
rng(sd)
rng('shuffle')
rng(sd, generator)
rng('shuffle', generator)
rng('default')
scurr = rng
rng(s)
sprev = rng(...)
```

Description

Note To use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs, see the documentation on "Updating Your Random Number Generator Syntax"

`rng(sd)` seeds the random number generator using the nonnegative integer `sd` so that `rand`, `randi`, and `randn` produce a predictable sequence of numbers.

`rng('shuffle')` seeds the random number generator based on the current time so that `rand`, `randi`, and `randn` produce a different sequence of numbers after each time you call `rng`.

`rng(sd, generator)` and `rng('shuffle', generator)` additionally specify the type of the random number generator used by `rand`, `randi`, and `randn`. The `generator` input is one of:

Generator	Description
`'twister'`	Mersenne Twister
`'combRecursive'`	Combined Multiple Recursive
`'multFibonacci'`	Multiplicative Lagged Fibonacci
`'v5uniform'`	Legacy MATLAB 5.0 uniform generator

Generator	Description
'v5normal'	Legacy MATLAB 5.0 normal generator
'v4'	Legacy MATLAB 4.0 generator

rng('default') puts the settings of the random number generator used by rand, randi, and randn to their default values so that they produce the same random numbers as if you restarted MATLAB. In this release, the default settings are the Mersenne Twister with seed 0.

scurr = rng returns the current settings of the random number generator used by rand, randi, and randn. The settings are returned in a structure scurr with fields 'Type', 'Seed', and 'State'.

rng(s) restores the settings of the random number generator used by rand, randi, and randn back to the values captured previously with a command such as s = rng.

sprev = rng(...) returns the previous settings of the random number generator used by rand, randi, and randn before changing the settings.

Examples

Example 1 — Retrieve and Restore Generator Settings

Save the current generator settings in s:

```
s = rng;
```

Call rand to generate a vector of random values:

```
x = rand(1,5)

x =

    0.8147    0.9058    0.1270    0.9134    0.6324
```

Restore the original generator settings by calling rng. Generate a new set of random values and verify that x and y are equal:

```
rng(s);
y = rand(1,5)
```

```
y =

    0.8147    0.9058    0.1270    0.9134    0.6324
```

Example 2 — Restore Settings for Legacy Generator

Use the legacy generator.

```
sprev = rng(0,'v5uniform')

sprev =
     Type: 'twister'
     Seed: 0
    State: [625x1 uint32]

x = rand

x =

    0.9501
```

Restore the previous settings by calling `rng`:

```
rng(sprev)
```

root object

Purpose

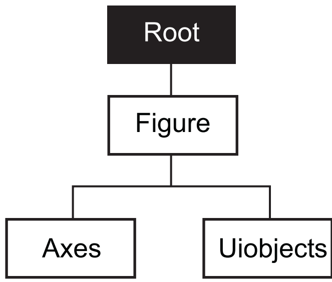
Root

Description

The root is a graphics object that corresponds to the computer screen. There is only one root object and it has no parent. The children of the root object are figures.

The root object exists when you start MATLAB; you never have to create it and you cannot destroy it. Use `set` and `get` to access the root properties.

Object Hierarchy



See Also

`diary` | `echo` | `figure` | `format` | `gcf` | `get` | `set` | Root Properties

Purpose

Root properties

Modifying Properties

You can set and query graphics object properties in two ways:

- Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see "Setting Default Property Values".

Root Properties

This section provides a description of properties. Curly braces `{ }` enclose default values.

`BusyAction`

`cancel | {queue}`

Not used by the root object.

`ButtonDownFcn`

string

Not used by the root object.

`CallbackObject`

handle (read-only)

Handle of current callback's object. Contains the handle of the object whose callback routine is currently executing. If no callback routines are executing, this property contains an empty double array `[ ]`. See also the `gco` command.

`Children`

vector of handles

Handles of child objects. A vector containing the handles of all nonhidden figure objects (see `HandleVisibility` for more

information). You can change the order of the handles and thereby change the sorting order of the figures on the display.

`Clipping`

`{on} | off`

Clipping mode. This property has no effect on the root object.

`CommandWindowSize`

[columns rows]

Current size of command window. Size of the MATLAB command window, in a two-element vector. The first element is the number of columns wide and the second element is the number of rows tall.

For example, a value of `[50,25]` means that 50 characters can display across the Command Window, and 25 lines can display without scrolling.

Enabling the Command Window Display preference **Set matrix display width to eighty columns** forces the returned value for number of columns wide to be 80 regardless of the window width.

`CreateFcn`

The root object does not use this property.

`CurrentFigure`

figure handle

Handle of the current figure, which is the one most recently created, clicked in, or made current with the statement:

```
figure(h) % h is a figure handle
```

which re-sorts the figure to the top of the figures displayed on the screen, or:

```
set(0,'CurrentFigure',h)
```

which does not re-sort the figures. In these statements, `h` is the handle of an existing figure. If there are no figure objects:

```
get(0,'CurrentFigure')
```

returns an empty double array. Note, however, that `gcf` always returns a figure handle. Calling `gcf` creates a new figure if there are no existing figure objects that can become the current figure (for example, figures with hidden handles cannot become the current figure).

`DeleteFcn`
string

This property is not used because you cannot delete the root object.

`Diary`
`on | {off}`

Diary file mode. When this property is `on`, MATLAB maintains a file (whose name is specified by the `DiaryFile` property) that saves a copy of all keyboard input and most of the resulting output. See also the `diary` command.

`DiaryFile`
string

Diary file name. The default name is `diary`. Set this property to the name of the file MATLAB uses write the command-line diary when the `Diary` property is set to on.

`Echo`
`on | {off}`

Script echoing mode. When `Echo` is `on`, MATLAB displays each line of a script file as it executes. See also the `echo` command.

`ErrorMessage`
string

Text of last error message. Contains the last error message issued by MATLAB.

`FixedWidthFontName`
font name

Fixed-width font to use for axes, text, and uicontrols whose `FontName` *is set to* `FixedWidth`. MATLAB uses the font name specified for this property as the value for axes, text, and uicontrol `FontName` properties when their `FontName` property is `FixedWidth`.

Specifying the font name with this property eliminates the need to hardcode font names in MATLAB applications and thereby enables these applications to run without modification in locales where non-ASCII character sets are required. In these cases, MATLAB attempts to set the value of `FixedWidthFontName` to the correct value for a given locale.

MATLAB application developers should not change this property, but should create axes, text, and uicontrols with `FontName` properties set to `FixedWidth` when they want to use a fixed-width font for these objects.

MATLAB end users can set this property if they do not want to use the preselected value. `Courier` is the default in locales that use Latin-based characters.

`Format`
`short | {shortE} | long | longE | bank | hex | + | rat`

Output format mode. Format used to display numbers. See also the `format` command.

- `short` — Fixed-point format with 5 digits
- `shortE` — Floating-point format with 5 digits

- `shortG` — Fixed- or floating-point format displaying as many significant figures as possible with 5 digits
- `long` — Scaled fixed-point format with 15 digits
- `longE` — Floating-point format with 15 digits
- `longG` — Fixed- or floating-point format displaying as many significant figures as possible with 15 digits
- `bank` — Fixed-format of dollars and cents
- `hex` — Hexadecimal format
- `+` — Displays `+` and `-` symbols
- `rat` — Approximation by ratio of small integers

`FormatSpacing`
`compact | {loose}`

Output format spacing (see also `format` command).

- `compact` — Suppress extra line feeds for more compact display.
- `loose` — Display extra line feeds for a more readable display.

`HandleVisibility`
`{on} | callback | off`

This property is not useful on the root object because the handle is always `0`.

`HitTest`
`{on} | off`

This property is not useful on the root object.

`Interruptible`
`{on} | off`

This property is not useful on the root object.

`Language`
string

System environment setting.

`MonitorPositions`
Width and height of monitors, in pixels. Contains information about the size and relative location of monitors connected to your computer. The information returned by the `MonitorPosition` property depends on which computer system you are using.

Windows Systems

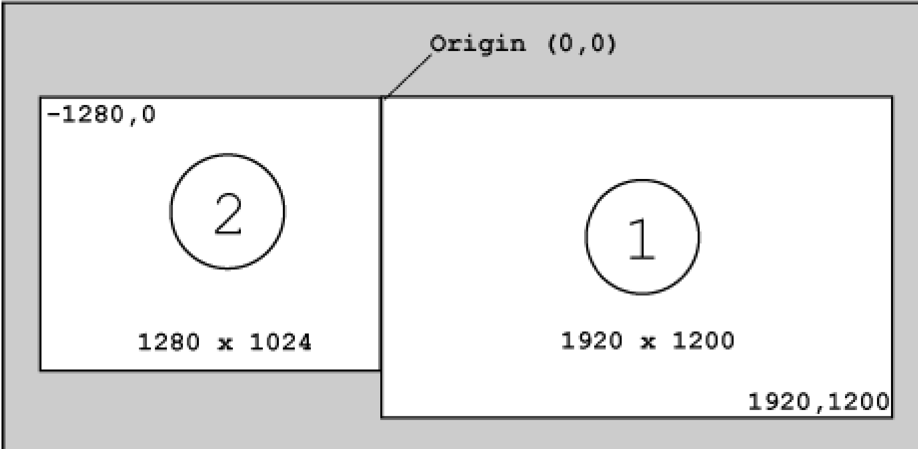
Windows systems define one monitor as device 1, which becomes the reference by which MATLAB determines other monitor positions. The position data is of the form:

```
[xmin2,ymin2,xmax2,ymax2;
 xmin1,ymin1,xmax1,ymax1]
```

The values for minimum and maximum are relative to the origin.

The following picture show the values returned when querying the `MonitorPositions` property on a Windows system having two monitors arranged as shown.

Windows System with Two Monitors



```
get(0,'MonitorPosition')

-1279     1       0       1024
    1     1    1920       1200
```

The `MonitorPositions` property contains an n-by-4 array, with each row representing a monitor position. The first row is the nth monitor and the last row corresponds to device `1`.

The monitor labeled as device `1` in the Windows control panel remains the reference monitor that defines the position of the origin however you reposition the monitors.

Linux Systems

On Linux systems, the upper-left corner of a rectangle enclosing the system monitors forms the origin. The position data is of the form:

```
[xP yP widthP heightP;
 xS yS widthS heightS]
```

Where the values represent the offset from the left (x), the offset from the top (y), and the width and height of the monitor. The `MonitorPositions` property contains an n-by-4 array, with each row representing a monitor position. The first row is the position of the primary monitor.

The following picture show the values returned when querying the `MonitorPositions` property on a Linux system that has two monitors arranged as shown.

Linux System with Two Monitors

```
get(0,'MonitorPosition')

1281     0       1920        1200
   1     503     1280        1024
```

MATLAB on Linux reads control panel settings only at startup. MATLAB does not recognize changes made to the arrangement of monitors during a MATLAB session.

Macintosh Systems

MATLAB on Macintosh systems recognize only the main monitor. The position data is of the form:

```
[x,y,width,height-menuHieght]
```

Where the values are `x = 0`, `y = 0`, monitor width, and monitor height minus the height of the menubar.

The main monitor is determined by which display has the menu bar. The **System Preferences Displays** control panel provides a way to arrange representations of multiple displays, and set one as the main monitor. To make another display the main monitor, drag the representation of the menu bar in the panel from the default display to the other display.

`Parent`

handle

Handle of parent object. This property always contains an empty double array, because the root object has no parent.

`PointerLocation`

`[x,y]`

Current location of pointer. A vector containing the *x*- and *y*-coordinates of the pointer position, measured from the lower left corner of the screen. Move the pointer by changing the values of this property. The `Units` property determines the units of this measurement.

`PointerLocation` always contains the current pointer location, even if the pointer is not in a MATLAB window. A callback

routine querying the `PointerLocation` property can get a value that is different from the location of the pointer when the callback was triggered. This difference results from delays in callback execution caused by competition for system resources.

On Apple Macintosh platforms, you cannot change the pointer location using the `set` command.

`PointerWindow`
handle (read-only)

Handle of window containing the pointer. MATLAB sets this property to the handle of the figure containing the pointer. If the pointer is not in a MATLAB window, the value of this property is `0`. A callback routine querying the `PointerWindow` can get the wrong window handle if you move the pointer to another window before the callback executes. This error results from delays in callback execution caused by competition for system resources.

`RecursionLimit`
integer

Number of nested MATLAB file calls. The limit of the number of nested calls to MATLAB files that MATLAB makes before stopping (or potentially running out of memory). By default the value is set to a large value. Setting this property to a smaller value (something like `150`, for example) should prevent MATLAB from running out of memory and instead causes MATLAB to issue an error when it reaches the limit.

`ScreenDepth`
bits per pixel

Screen depth. The depth of the display bitmap (the number of bits per pixel). The maximum number of simultaneously displayed colors on the current graphics device is 2 raised to this power.

`ScreenDepth` supersedes the `BlackAndWhite` property. To override automatic hardware checking, set this property to `1`. Then MATLAB assumes the display is monochrome. Setting `ScreenDepth` to `1` is useful if MATLAB is running on color hardware but is being displayed on a monochrome terminal. Such a situation can cause MATLAB to determine erroneously that the display is color.

`ScreenPixelsPerInch`
Display resolution

DPI setting for your display. Contains the setting of your display resolution specified in your system preferences.

`ScreenSize`
four-element rectangle vector (read-only)

Screen size. A four-element vector:

```
[left,bottom,width,height]
```

that defines the display size. `left` and `bottom` are `0` for all `Units` except `pixels`, in which case `left` and `bottom` are both `1`. `width` and `height` are the screen dimensions in units specified by the `Units` property.

Determining Screen Size

Note that the screen size in absolute units (for example, inches) is determined by dividing the number of pixels in width and height by the screen DPI (see the `ScreenPixelPerInch` property). This value is approximate and might not represent the actual size of the screen.

Note that the `ScreenSize` property is static. Its values are read-only at MATLAB startup and not updated if system display settings change. Also, the values returned might not represent

the usable screen size for application developers due to the presence of other GUIs, such as the Microsoft Windows task bar.

`Selected`
`on | off`

This property has no effect on the root object.

`SelectionHighlight`
`{on} | off`

This property has no effect on the root object.

`ShowHiddenHandles`
`on | {off}`

Show or hide handles marked as hidden. When set to `on`, this property disables handle hiding and exposes all object handles regardless of the setting of an object's `HandleVisibility` property. When set to `off`, all objects so marked remain hidden within the graphics hierarchy.

`Tag`
string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. While it is not necessary to identify the root object with a tag (since its handle is always `0`), you can use this property to store any string value, which you can later retrieve using `get`.

`Type`
string (read-only)

Class of graphics object. For the root object, `Type` is always the string `root`.

`UIContextMenu`
handle

This property is not used by the root object.

`Units`

`{pixels} | normalized | inches | centimeters | points | characters`

Unit of measurement. Specifies the units MATLAB uses to interpret size and location data contained in the `PointerLocation` and `ScreenSize` properties. All units are measured from the lower left corner of the screen.

- `normalized` — Map the lower left corner of the screen to `(0,0)` and the upper right corner to `(1.0,1.0)`.
- `inches`, `centimeters`, and `points` — Absolute units. 1 point = $^1/_{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your operation, so as not to affect other functions that assume `Units` is set to the default value.

`UserData`

matrix

User-specified data. Data you want to associate with the root object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`

`{on} | off`

Object visibility. This property has no effect on the root object.

See Also

`root object`

Purpose

Polynomial roots

Syntax

```
r = roots(c)
```

Description

`r = roots(c)` returns a column vector whose elements are the roots of the polynomial `c`.

Row vector `c` contains the coefficients of a polynomial, ordered in descending powers. If `c` has `n+1` components, the polynomial it represents is $c_1 s^n + \ldots + c_n s + c_{n+1}$.

Tips

Note the relationship of this function to `p = poly(r)`, which returns a row vector whose elements are the coefficients of the polynomial. For vectors, `roots` and `poly` are inverse functions of each other, up to ordering, scaling, and roundoff error.

Examples

The polynomial $s^3 - 6s^2 - 72s - 27$ is represented in MATLAB software as

```
p = [1 -6 -72 -27]
```

The roots of this polynomial are returned in a column vector by

```
r = roots(p)

r =
    12.1229
    -5.7345
    -0.3884
```

Algorithms

The algorithm simply involves computing the eigenvalues of the companion matrix:

```
A = diag(ones(n-1,1),-1);
A(1,:) = -c(2:n+1)./c(1);
eig(A)
```

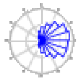
It is possible to prove that the results produced are the exact eigenvalues of a matrix within roundoff error of the companion matrix `A`, but this does not mean that they are the exact roots of a polynomial with coefficients within roundoff error of those in `c`.

See Also

`fzero` | `poly` | `residue`

Purpose

Angle histogram plot



Syntax

```
rose(theta)
rose(theta,x)
rose(theta,nbins)
rose(axes_handle,...)
h = rose(...)
[tout,rout] = rose(...)
```

Description

`rose(theta)` creates an angle histogram, which is a polar plot showing the distribution of values grouped according to their numeric range, showing the distribution of `theta` in 20 angle bins or less. The vector `theta`, expressed in radians, determines the angle of each bin from the origin. The length of each bin reflects the number of elements in `theta` that fall within a group, which ranges from 0 to the greatest number of elements deposited in any one bin.

`rose(theta,x)` uses the vector `x` to specify the number and the locations of bins. `length(x)` is the number of bins and the values of `x` specify the center angle of each bin. For example, if `x` is a five-element vector, `rose` distributes the elements of `theta` in five bins centered at the specified `x` values.

`rose(theta,nbins)` plots `nbins` equally spaced bins in the range `[0, 2*pi]`. The default is `20`.

`rose(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = rose(...)` returns the handles of the line objects used to create the graph.

`[tout,rout] = rose(...)` returns the vectors `tout` and `rout` so `polar(tout,rout)` generates the histogram for the data. This syntax does not generate a plot.

Examples

Load data on sunspot activity over 288 years. Generate a rose histogram of the number of sunspots observed using 12 bins.

```
figure
load sunspot.dat  % Contains a 2-column vector named sunspot
rose(sunspot(:,2),12)
```

How To

- Histograms in Polar Coordinates

Purpose

Classic symmetric eigenvalue test problem

Syntax

```
A = rosser
```

Description

`A = rosser` returns the Rosser matrix. The matrix is 8-by-8 with integer elements. It has:

- A double eigenvalue
- Three nearly equal eigenvalues
- Dominant eigenvalues of opposite sign
- A zero eigenvalue
- A small, nonzero eigenvalue

Examples

```
rosser

ans =

   611   196  -192   407    -8   -52   -49    29
   196   899   113  -192   -71   -43    -8   -44
  -192   113   899   196    61    49     8    52
   407  -192   196   611     8    44    59   -23
    -8   -71    61     8   411  -599   208   208
   -52   -43    49    44  -599   411   208   208
   -49    -8     8    59   208   208    99  -911
    29   -44    52   -23   208   208  -911    99
```

rot90

Purpose

Rotate matrix 90 degrees

Syntax

```
B = rot90(A)
B = rot90(A,k)
```

Description

`B = rot90(A)` rotates matrix `A` counterclockwise by 90 degrees.

`B = rot90(A,k)` rotates matrix `A` counterclockwise by `k*90` degrees, where `k` is an integer.

Examples

The matrix

```
X =
    1    2    3
    4    5    6
    7    8    9
```

rotated by 90 degrees is

```
Y = rot90(X)
Y =
    3    6    9
    2    5    8
    1    4    7
```

See Also

`flipdim` | `fliplr` | `flipud`

Purpose

Rotate object about specified origin and direction

Syntax

```
rotate(h,direction,alpha)
rotate(...,origin)
```

Description

The `rotate` function rotates a graphics object in three-dimensional space.

`rotate(h,direction,alpha)` rotates the graphics object `h` by `alpha` degrees. `direction` is a two- or three-element vector that describes the axis of rotation in conjunction with the origin of the axis of rotation. The default origin of the axis of rotation is the center of the plot box. This point is not necessarily the origin of the axes.

Positive `alpha` is defined as the righthand-rule angle about the direction vector as it extends from the origin of rotation.

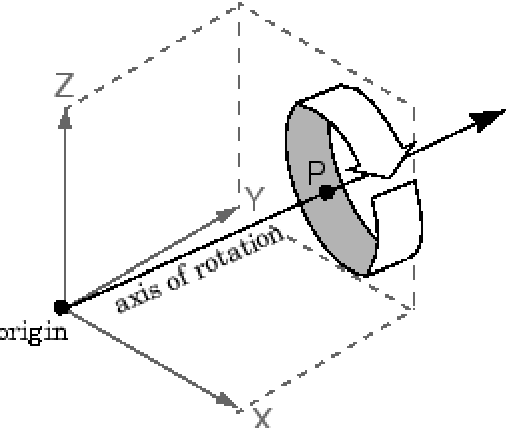
If `h` is an array of handles, all objects must be children of the same axes.

`rotate(...,origin)` specifies the origin of the axis of rotation as a three-element vector $[x_0,y_0,z_0]$.

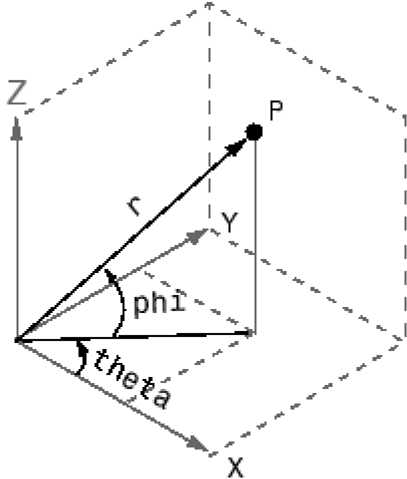
Tips

The rotation transformation modifies the object's data. This technique is different from that used by `view` and `rotate3d`, which modify only the viewpoint.

The axis of rotation is defined by an origin of rotation and a point `P`. Specify `P` as the spherical coordinates `[theta phi]` or as the Cartesian coordinates $[x_p,y_p,z_p]$.



In the two-element form for `direction`, `theta` is the angle in the *x*-*y* plane counterclockwise from the positive *x*-axis. `phi` is the elevation of the direction vector from the *x*-*y* plane.

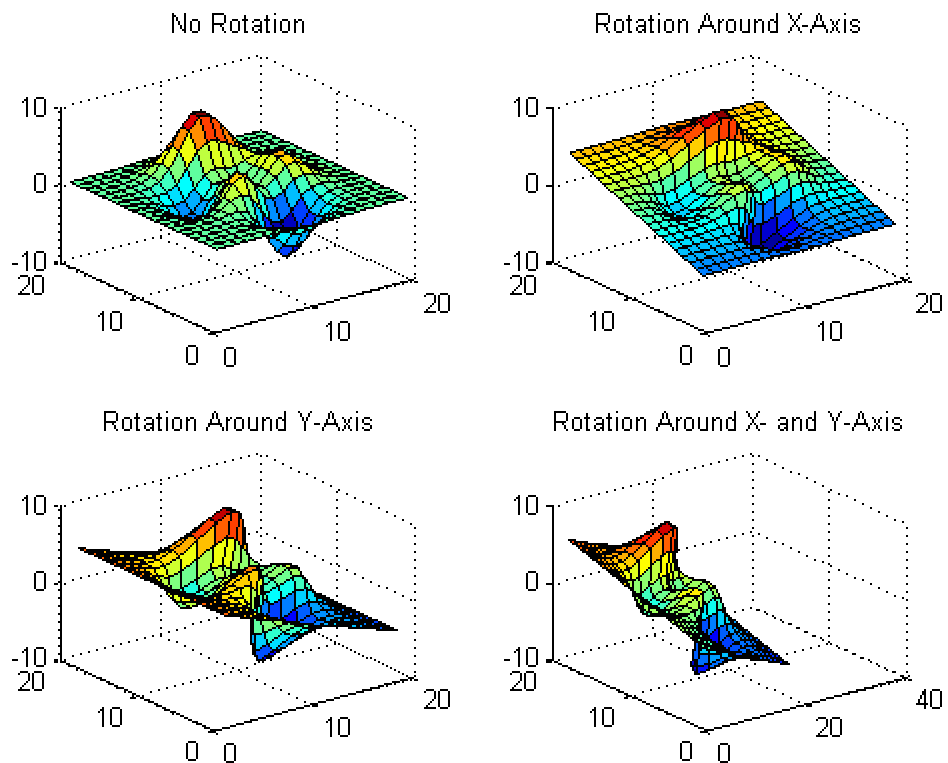


The three-element form for `direction` specifies the axis direction using Cartesian coordinates. The direction vector is the vector from the origin of rotation to `P`.

Examples

Create a 2-by-2 set of surface plots and rotate them around their *x* and *y* axes.

```
figure
sp11 = subplot(2,2,1);
h11 = surf(sp11, peaks(20));
title('No Rotation')
sp12 = subplot(2,2,2);
h12 = surf(sp12, peaks(20));
title('Rotation Around X-Axis')
zdir = [1 0 0];
rotate(h12,zdir,25)
sp21 = subplot(2,2,3);
h21 = surf(sp21, peaks(20));
title('Rotation Around Y-Axis')
zdir = [0 1 0];
rotate(h21,zdir,25)
sp22 = subplot(2,2,4);
h22 = surf(sp22, peaks(20));
title('Rotation Around X- and Y-Axis')
zdir = [1 1 0];
rotate(h22,zdir,25)
```



Tips

`rotate` changes the values of the `Xdata`, `Ydata`, and `Zdata` properties to rotate graphics objects.

See Also

`rotate3d` | `sph2cart` | `view` | `CameraPosition` | `CameraTarget` | `CameraUpVector` | `CameraViewAngle`

Purpose

Rotate 3-D view using mouse

Syntax

```
rotate3d on
rotate3d off
rotate3d
rotate3d(figure_handle,...)
rotate3d(axes_handle,...)
h = rotate3d(figure_handle)
```

Description

`rotate3d on` enables mouse-base rotation on all axes within the current figure.

`rotate3d off` disables interactive axes rotation in the current figure.

`rotate3d` toggles interactive axes rotation in the current figure.

`rotate3d(figure_handle,...)` enables rotation within the specified figure instead of the current figure.

`rotate3d(axes_handle,...)` enables rotation only in the specified axes.

`h = rotate3d(figure_handle)` returns a rotate3d *mode object* for figure figure_handle for you to customize the mode's behavior.

Using Rotate Mode Objects

You access the following properties of rotate mode objects via `get` and modify some of them using `set`.

- `FigureHandle <handle>` — The associated figure handle, a read-only property that cannot be set
- *`Enable`* `'on'|'off'` — Specifies whether this figure mode is currently enabled on the figure
- *`RotateStyle`* `'orbit'|'box'` — Sets the method of rotation

  `'orbit'` rotates the entire axes; `'box'` rotates a plot-box outline of the axes.

Rotate3D Mode Callbacks

You can program the following callbacks for rotate3d mode operations.

- ButtonDownFilter <function_handle> — Function to intercept ButtonDown events

  The application can inhibit the rotate operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to handle callbacks):

  ```
  function [res] = myfunction(obj,event_obj)
  % obj          handle to the object that has been clicked on
  % event_obj    handle to event data object (empty in this release)
  % res [output] logical flag to determine whether the rotate
                 operation should take place or the 'ButtonDownFcn'
                 property of the object should take precedence
  ```

- ActionPreCallback <function_handle> — Function to execute before rotating

  Set this callback to listen to when a rotate operation will start. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

  ```
  function myfunction(obj,event_obj)
  % obj         handle to the figure that has been clicked on
  % event_obj   object containing struct of event data
  ```

  The event data has the following field:

Axes	The handle of the axes that is being panned

- ActionPostCallback <function_handle> — Function to execute after rotating

Set this callback to listen to when a rotate operation has finished. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data (same as the
%              event data of the 'ActionPreCallback' callback)
```

Rotate3D Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesRotate(h,axes)` — Function querying permission to rotate axes

  Calling the function `isAllowAxesRotate` on the rotate3d object, `h`, with a vector of axes handles, `axes`, as input will return a logical array of the same dimension as the axes handle vector which indicate whether a rotate operation is permitted on the axes objects.

- `setAllowAxesRotate(h,axes,flag)` — Function to set permission to pan axes

  Calling the function `setAllowAxesRotate` on the rotate3d object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, will either allow or disallow a rotate operation on the axes objects.

Examples

Example 1

Simple 3-D rotation:

```
surf(peaks);
rotate3d on
% rotate the plot using the mouse pointer.
```

Example 2

Rotate the plot using the "Plot Box" rotate style:

```
surf(peaks);
h = rotate3d;
set(h,'RotateStyle','box','Enable','on');
% Rotate the plot.
```

Example 3

Create two axes as subplots and then prevent one from rotating:

```
ax1 = subplot(1,2,1);
surf(peaks);
h = rotate3d;
ax2 = subplot(1,2,2);
surf(membrane);
setAllowAxesRotate(h,ax2,false);
% rotate the plots.
```

Example 4

Create a buttonDown callback for rotate mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = rotate3d;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse-click on the line
%
function [flag] = mycallback(obj,event_obj)
```

```
% If the tag of the object is 'DoNotIgnore', then return true.
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
   flag = true;
else
   flag = false;
end
```

Example 5

Create callbacks for pre- and post-buttonDown events for rotate3D mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd2
% Listen to rotate events
surf(peaks);
h = rotate3d;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');
%
function myprecallback(obj,evd)
disp('A rotation is about to occur.');
%
function mypostcallback(obj,evd)
newView = round(get(evd.Axes,'View'));
msgbox(sprintf('The new view is [%d %d].',newView));
```

Tips

When enabled, `rotate3d` provides continuous rotation of axes and the objects it contains through mouse movement. A numeric readout appears in the lower left corner of the figure during rotation, showing the current azimuth and elevation of the axes. Releasing the mouse button removes the animated box and the readout. This differs from the `camorbit` function in that while the `rotate3d` tool modifies the `View` property of the axes, the `camorbit` function fixes the aspect ratio

and modifies the `CameraTarget`, `CameraPosition` and `CameraUpVector` properties of the axes. See `Axes Properties` for more information.

You can also enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

You can create a `rotate3d` mode object once and use it to customize the behavior of different axes, as example 3 illustrates. You can also change its callback functions on the fly.

Note **Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure's callbacks, the GUI should some keep track of which interactive mode is active, if any, before attempting to do this.

When you assign different 3-D rotation behaviors to different `subplot` axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse will carry over to the linked axes, regardless of the behavior you previously set for the other axes.

Alternatives

Use the Rotate3D tool on the figure toolbar to enable and disable rotate3D mode on a plot, or select **Rotate 3D** from the figure's **Tools** menu. For details, see "Rotate in 3-D".

See Also

`camorbit` | `pan` | `rotate` | `view` | `zoom` | `Axes Properties`

Purpose

Round to nearest integer

Syntax

```
Y = round(X)
```

Description

`Y = round(X)` rounds the elements of `X` to the nearest integers. Positive elements with a fractional part of 0.5 round up to the nearest positive integer. Negative elements with a fractional part of -0.5 round down to the nearest negative integer. For complex `X`, the imaginary and real parts are rounded independently.

Examples

```
a = [-1.9, -0.2, 3.4, 5.6, 7.0, 2.4+3.6i]

a =
  Columns 1 through 4
  -1.9000            -0.2000             3.4000             5.6000
  Columns 5 through 6
   7.0000             2.4000 + 3.6000i

round(a)

ans =
  Columns 1 through 4
  -2.0000                  0             3.0000             6.0000
  Columns 5 through 6
   7.0000             2.0000 + 4.0000i
```

See Also

`ceil` | `fix` | `floor`

Purpose

Reduced row echelon form

Syntax

```
R = rref(A)
[R,jb] = rref(A)
[R,jb] = rref(A,tol)
```

Description

`R = rref(A)` produces the reduced row echelon form of `A` using Gauss Jordan elimination with partial pivoting. A default tolerance of (`max(size(A))*eps *norm(A,inf)`) tests for negligible column elements.

`[R,jb] = rref(A)` also returns a vector `jb` such that:

- `r = length(jb)` is this algorithm's idea of the rank of `A`.
- `x(jb)` are the pivot variables in a linear system `Ax = b`.
- `A(:,jb)` is a basis for the range of `A`.
- `R(1:r,jb)` is the `r`-by-`r` identity matrix.

`[R,jb] = rref(A,tol)` uses the given tolerance in the rank tests.

Roundoff errors may cause this algorithm to compute a different value for the rank than `rank`, `orth` and `null`.

Examples

Use `rref` on a rank-deficient magic square:

```
A = magic(4), R = rref(A)

A =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1

R =
     1     0     0     1
     0     1     0     3
     0     0     1    -3
```

```
     0     0     0     0
```

See Also

`inv` | `lu` | `rank`

rsf2csf

Purpose

Convert real Schur form to complex Schur form

Syntax

```
[U,T] = rsf2csf(U,T)
```

Description

The *complex Schur form* of a matrix is upper triangular with the eigenvalues of the matrix on the diagonal. The *real Schur form* has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal.

`[U,T] = rsf2csf(U,T)` converts the real Schur form to the complex form.

Arguments `U` and `T` represent the unitary and Schur forms of a matrix `A`, respectively, that satisfy the relationships: `A = U*T*U'` and `U'*U = eye(size(A))`. See `schur` for details.

Examples

Given matrix `A`,

```
 1      1      1      3
 1      2      1      1
 1      1      3      1
-2      1      1      4
```

with the eigenvalues

```
4.8121    1.9202 + 1.4742i    1.9202 + 1.4742i    1.3474
```

Generating the Schur form of `A` and converting to the complex Schur form

```
[u,t] = schur(A);
[U,T] = rsf2csf(u,t)
```

yields a triangular matrix `T` whose diagonal (underlined here for readability) consists of the eigenvalues of `A`.

```
U =
```

```
-0.4916       -0.2756 - 0.4411i    0.2133 + 0.5699i   -0.3428
-0.4980       -0.1012 + 0.2163i   -0.1046 + 0.2093i    0.8001
-0.6751        0.1842 + 0.3860i   -0.1867 - 0.3808i   -0.4260
-0.2337        0.2635 - 0.6481i    0.3134 - 0.5448i    0.2466

T =

4.8121        -0.9697 + 1.0778i   -0.5212 + 2.0051i   -1.0067
     0         1.9202 + 1.4742i    2.3355              0.1117 + 1.6547i
     0              0              1.9202 - 1.4742i    0.8002 + 0.2310i
     0              0                   0              1.3474
```

See Also

schur

Purpose Run MATLAB script

Syntax

```
run(scriptname)
```

Description

`run(scriptname)` runs the MATLAB script specified by `scriptname`.

Input Arguments

scriptname - Full or relative script path

string

Full or relative script path to a MATLAB script, specified as a string. `scriptname` can specify any file type that MATLAB can execute, such as MATLAB script files, Simulink models, or MEX-files.

Tips

- `run` executes scripts not currently on the MATLAB path. However, you should use `cd` or `addpath` to navigate to or to add the appropriate folder, making a script executable by entering its name alone.
- `scriptname` can access any variables in the current workspace.
- `run` changes to the folder that contains the script, executes it, and resets back to the original folder. If the script itself changes folders, then `run` does not revert to the original folder, unless `scriptname` changes to the folder in which this script resides.
- If `scriptname` corresponds to both a `.m` file and a P-file residing in the same folder, then `run` executes the P-file. This occurs even if you specify `scriptname` with a `.m` extension.

Examples

Run Script Not on Current Path

Create a temporary folder and copy an example MATLAB script to it.

```
tmp = tempname;
mkdir(tmp);
runtmp = fullfile(tmp,'buckyball.m');
demodir = fullfile(matlabroot,'toolbox','matlab','demos','buckydem.m');
copyfile(demodir,runtmp);
```

Run the new script.

```
run(runtmp)
```

Concepts

- "Files and Folders that MATLAB Accesses"

Purpose

Save workspace variables to file

Syntax

```
save(filename)
save(filename, variables)
save(filename, '-struct', structName, fieldNames)
save(filename, ..., '-append')
save(filename, ..., format)
save(filename, ..., version)
save filename ...
```

Description

`save(filename)` stores all variables from the current workspace in a MATLAB formatted binary file (MAT-file) called `filename`.

`save(filename, variables)` stores only the specified variables.

`save(filename, '-struct', structName, fieldNames)` stores the fields of the specified scalar structure as individual variables in the file. If you include the optional `fieldNames`, the `save` function stores only the specified fields of the structure. You cannot specify `variables` and the `'-struct'` keyword in the same call to `save`.

`save(filename, ..., '-append')` adds new variables to an existing file. You can specify the `'-append'` option with additional inputs such as `variables`, `'-struct'` , `format`, or `version`.

`save(filename, ..., format)` saves in the specified format: `'-mat'` or `'-ascii'`. You can specify the `format` option with additional inputs such as `variables`, `'-struct'` , `'-append'`, or `version`.

`save(filename, ..., version)` saves to MAT-files in the specified version: `'-v4'`, `'-v6'`, `'-v7'`, or `'-v7.3'`. You can specify the `version` option with additional inputs such as `variables`, `'-struct'` , `'-append'`, or `format`.

`save filename ...` is the command form of the syntax, for convenient saving from the command line. With command syntax, you do not need to enclose input strings in single quotation marks. Separate inputs with spaces instead of commas. Do not use command syntax if inputs such as `filename` are variables. For more information, see “Command

vs. Function Syntax" in the MATLAB Programming Fundamentals documentation.

Input Arguments

filename

Name of a file. If you do not specify *filename*, the `save` function saves to a file named `matlab.mat`.

If *filename* does not include an extension and the value of *format* is `-mat` (the default), MATLAB appends `.mat`. If *filename* does not include a full path, MATLAB saves in the current folder. You must have permission to write to the file.

Default: `'matlab.mat'`

variables

Description of the variables to save. Use one of the following forms:

var1, var2, ...	Save the listed variables. Use the `'*'` wildcard to match patterns. For example, `save('A*')` saves all variables that start with `A`.
`'-regexp'`, *expressions*	Save only the variables that match the specified regular expressions. MATLAB treats all inputs as regular expressions, except the optional *filename*. The *filename* must appear immediately after the `save` command.

Default: all variables

'-struct'

Keyword to request saving the fields of a scalar structure as individual variables in the file. The *structName* input must appear immediately after the `-struct` keyword.

structName

Name of a scalar structure. Required when you use the `'-struct'` keyword.

fieldNames

Description of the fields of a structure to save as individual variables in the file. Use the same forms listed for *variables*. If you use the `'-regexp'` keyword, MATLAB treats all inputs as regular expressions except *filename* and *structName*.

'-append'

Keyword to add data to an existing file. For MAT-files, `-append` adds new variables to the file or replaces the saved values of existing variables with values in the workspace. For ASCII files, `-append` adds data to the end of the file.

format

Specifies the format of the file, regardless of any specified extension. Use one of the following combinations (not case sensitive):

`'-mat'`	Binary MAT-file format (default).
`'-ascii'`	8-digit ASCII format.
`'-ascii', '-tabs'`	Tab-delimited 8-digit ASCII format.
`'-ascii', '-double'`	16-digit ASCII format.
`'-ascii', '-double', '-tabs'`	Tab-delimited 16-digit ASCII format.

For MAT-files, data saved on one machine and loaded on another machine retains as much accuracy and range as the different machine floating-point formats allow.

For ASCII file formats, the `save` function has the following limitations:

- Each variable must be a two-dimensional `double` or character array.
- MATLAB translates characters to their corresponding internal ASCII codes. For example, `'abc'` appears in an ASCII file as:

```
9.7000000e+001   9.8000000e+001   9.9000000e+001
```

- The output includes only the real component of complex numbers.
- MATLAB writes data from each variable sequentially to the file. If you plan to use the `load` function to read the file, all variables must have the same number of columns. The `load` function creates a single variable from the file.

For more flexibility in creating ASCII files, use `dlmwrite` or `fprintf`.

version

Specifies the version of the file. Applies to MAT-files only.

The following table shows the available MAT-file version options and the corresponding supported features.

Option	Can Load in Versions	Supported Features
`'-v7.3'`	7.3 (R2006b) or later	Version 7.0 features plus support for data items greater than or equal to 2 GB on 64-bit systems.
`'-v7'`	7.0 (R14) or later	Version 6 features plus data compression and Unicode character encoding. Unicode encoding enables file sharing between systems that use different default character encoding schemes.

Option	Can Load in Versions	Supported Features
`'-v6'`	5 (R8) or later	Version 4 features plus *N*-dimensional arrays, cell arrays and structures, and variable names greater than 19 characters.
`'-v4'`	all	Two-dimensional `double`, character, and sparse arrays.

If any data items require features that the specified version does not support, MATLAB does not save those items and issues a warning. You cannot specify a version later than your version of MATLAB software.

To view or set the default version for MAT-files, select a **MAT-file save format** option in the General Preferences.

Examples

Save all variables from the workspace in binary MAT-file `test.mat`. Remove the variables from the workspace, and retrieve the data with the `load` function.

```
save test.mat
clear
load test.mat
```

Create a variable `savefile` that stores the name of a file, `pqfile.mat`. Save two variables to the file.

```
savefile = 'pqfile.mat';
p = rand(1, 10);
q = ones(10);
save(savefile, 'p', 'q')
```

Save data to an ASCII file, and view the contents of the file with the `type` function:

```
p = rand(1, 10);
q = ones(10);
save('pqfile.txt', 'p', 'q', '-ASCII')
type pqfile.txt
```

Alternatively, use command syntax for the `save` operation:

```
save pqfile.txt p q -ASCII
```

Save the fields of structure `s1` as individual variables. Check the contents of the file with the `whos` function. Clear the workspace and load the contents of a single field.

```
s1.a = 12.7;
s1.b = {'abc', [4 5; 6 7]};
s1.c = 'Hello!';

save('newstruct.mat', '-struct', 's1');

disp('Contents of newstruct.mat:')
whos('-file', 'newstruct.mat')

clear('s1')
load('newstruct.mat', 'b')
```

Save any variables in the workspace with names that begin with `Mon`, `Tue`, or `Wed` to `mydata.mat`:

```
save('mydata', '-regexp', '^Mon|^Tue|^Wed');
```

`clear` | `hgsave` | `load` | `matfile` | `regexp` | `saveas` | `whos` | `workspace`

How To

- "Save, Load, and Delete Workspace Variables"

- “Write to Delimited Data Files”
- “Supported File Formats”

Purpose

Serialize control object to file

Syntax

```
h.save('filename')
save(h, 'filename')
```

Description

`h.save('filename')` saves the COM control object, `h`, to the file specified in the string, `filename`.

`save(h, 'filename')` is an alternate syntax for the same operation.

Note The COM `save` function is only supported for controls at this time.

Tips

COM functions are available on Microsoft Windows systems only.

Examples

Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.save('mwsample')
```

Now, alter the figure by changing its label and the radius of the circle:

```
h.Label = 'Circle';
h.Radius = 50;
h.Redraw;
```

Using the `load` function, you can restore the control to its original state:

```
h.load('mwsample');
h.get
```

MATLAB displays the original values:

```
ans =
     Label: 'Label'
    Radius: 20
```

See Also

`load (COM)` | `actxcontrol` | `actxserver` | `release` | `delete (COM)`

Purpose

Save serial port objects and variables to file

Syntax

```
save filename
save filename obj1 obj2...
```

Description

`save filename` saves all MATLAB variables to the file `filename`. If an extension is not specified for `filename`, then the `.mat` extension is used.

`save filename obj1 obj2...` saves the serial port objects `obj1 obj2...` to the file `filename`.

Tips

You can use `save` in the functional form as well as the command form shown above. When using the functional form, you must specify the filename and serial port objects as strings. For example. to save the serial port object `s` to the file `MySerial.mat` on a Windows platform

```
s = serial('COM1');
save('MySerial','s')
```

Any data that is associated with the serial port object is not automatically stored in the file. For example, suppose there is data in the input buffer for `obj`. To save that data to a file, you must bring it into the MATLAB workspace using one of the synchronous read functions, and then save to the file using a separate variable name. You can also save data to a text file with the `record` function.

You return objects and variables to the MATLAB workspace with the `load` command. Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

Examples

This example illustrates how to use the command and functional form of `save` on a Windows platform.

```
s = serial('COM1');
set(s,'BaudRate',2400,'StopBits',1)
save MySerial1 s
```

```
set(s,'BytesAvailableFcn',@mycallback)
save('MySerial2','s')
```

See Also

load | record | Status

Purpose

Save figure or Simulink block diagram using specified format

Alternatives

Use **File > Save As** on the figure window menu to access the Save As dialog, in which you can select a graphics format. For details, see "Exporting in a Specific Graphics Format" in the MATLAB Graphics documentation. Sizes of files written to image formats by this GUI and by `saveas` can differ due to disparate resolution settings.

Syntax

```
saveas(h,'filename.ext')
saveas(h,'filename','format')
```

Description

`saveas(h,'filename.ext')` saves the figure or Simulink block diagram with the handle `h` to the file `filename.ext`. The format of the file is determined by the extension, `ext`. Allowable values for `ext` are listed in this table.

You can pass the handle of any Handle Graphics object to `saveas`, which then saves the parent figure to the object you specified should `h` not be a figure handle. This means that `saveas` cannot save a subplot without also saving all subplots in its parent figure.

Text Value	Format
`ai`	Adobe Illustrator '88 Support for this format will be removed in a future release.
`bmp`	Windows bitmap
`emf`	Enhanced metafile
`eps`	EPS Level 1
`fig`	MATLAB figure (invalid for Simulink block diagrams)
`jpg`	JPEG image (invalid for Simulink block diagrams)
`m`	MATLAB file (invalid for Simulink block diagrams)

Text Value	Format
`pbm`	Portable bitmap
`pcx`	Paintbrush 24-bit
`pdf`	Portable Document Format
`pgm`	Portable Graymap
`png`	Portable Network Graphics
`ppm`	Portable Pixmap
`tif`	TIFF image, compressed

`saveas(h,'filename','format')` saves the figure or Simulink block diagram with the handle `h` to the file called `filename` using the specified `format`. The filename can have an extension, but the extension is not used to define the file format. If no extension is specified, the standard extension corresponding to the specified format is automatically appended to the filename.

Allowable values for `format` are the extensions in the table above and the device drivers and graphic formats supported by `print`. The drivers and graphic formats supported by `print` include additional file formats not listed in the table above. When using a `print` device type to specify format for `saveas`, do not prefix it with `-d`.

Tips

You can use `open` to open files saved using `saveas` with an `m` or `fig` extension. Other `saveas` and `print` formats are not supported by `open`. Both the **Save As** and **Export Setup** dialog boxes that you access from a figure's **File** menu use `saveas` with the `format` argument, and support all device and file types listed above.

Note Whenever you specify a format for saving a figure with the **Save As** menu item , that file format is used again the next time you save that figure or a new one. If you do not want to save in the previously-used format, use **Save As** and be sure to set the **Save as type** drop-down menu to the kind of file you want to write. However, saving a figure with the `saveas` function and a format does not change the **Save as type** setting in the GUI.

If you want to control the size or resolution of figures saved in image (bit-mapped) formats, such as `BMP` or `JPG`, use the `print` command and specify dots-per-inch resolution with the `r` switch.

Examples

Example 1: Specify File Extension

Save the current figure that you annotated using the Plot Editor to a file named `pred_prey` using the MATLAB `fig` format. This allows you to open the file `pred_prey.fig` at a later time and continue editing it with the Plot Editor.

```
saveas(gcf,'pred_prey.fig')
```

Example 2: Specify File Format but No Extension

Save the current figure, using a Portable Document format, to the file `logo`. Use the `pdf` extension from the above table to specify the format. The file created is `logo.pdf`.

```
saveas(gcf,'logo', 'pdf')
```

The file created is `logo.pdf`. MATLAB automatically appends the `pdf` extension because no extension was specified.

Example 3: Specify File Format and Extension

Save the current figure to the file `star.eps` using the Level 2 Color PostScript format. If you use `doc print` or `help print`, you can see from

the table for print device types that the device type for this format is `-dpsc2`. The file created is `star.eps`.

```
saveas(gcf,'star.eps', 'psc2')
```

In another example, save the current Simulink block diagram to the file `trans.tiff` using the TIFF format with no compression. From the table for print device types, you can see that the device type for this format is `-dtiffn`. The file created is `trans.tiff`.

```
saveas(gcf,'trans.tiff', 'tiffn')
```

Example 4: Saving a Simulink Diagram

Save a Simulink diagram from command line. The file is saved as `counters.bmp`

```
sldemo_tank
saveas(get_param('sldemo_tank','Handle'),'topmodel.bmp');
```

Using `get_param`, get the `handle` of the model and save using the `saveas` command. The file can be saved in any desired standard image formats.

See Also

`hgsave` | `open` | `print` | `save_system`

Purpose

Modify save process for object

Syntax

```
b = saveobj(a)
```

Description

`b = saveobj(a)` is called by the `save` function if the class of `a` defines a `saveobj` method. `save` writes the returned value, `b`, to the MAT-file.

Define a `loadobj` method to take the appropriate action when loading the object.

If `A` is an array of objects, MATLAB invokes `saveobj` separately for each object saved.

Examples

Call the superclass `saveobj` method from the subclass implementation of `saveobj` with the following syntax:

```
classdef mySub < super
   methods
      function sobj = saveobj(obj)
         % Call superclass saveobj method
         sobj = saveobj@super(obj);
         % Perform subclass save operations
         ...
      end
   ...
   end
...
end
```

See "Saving and Loading Objects from Class Hierarchies".

Update object when saved:

```
function b = saveobj(a)
   % If the object does not have an account number,
   % call method to add account number to AccountNumber property
   if isempty(a.AccountNumber)
      a.AccountNumber = getAccountNumber(a);
```

```
    end
    b = a;
end
```

See "Maintaining Class Compatibility".

Tutorials

- "Control Save and Load"

Purpose

Save current search path

Alternatives

As an alternative to the `savepath` function, use the Set Path dialog box.

Syntax

```
savepath
savepath folderName/pathdef.m
status = savepath...
```

Description

`savepath` updates the MATLAB search path for all users on the system so that the path can be reused in a future session. `savepath` saves the search path to the `pathdef.m` file that MATLAB located at startup, or to the current folder if a `pathdef.m` file exists there. To save the search path programmatically each time you exit MATLAB, use `savepath` in a `finish.m` file.. On a Windows system with User Account Control (UAC) enabled, UAC might prompt you to allow the update operation because it requires administrator-level permission.

`savepath folderName/`**`pathdef.m`** saves the current search path to `pathdef.m` located in `folderName`. Use this form of the syntax if you do not have write access to the current `pathdef.m`. If you do not specify `folderName`, MATLAB saves `pathdef.m` in the current folder. `folderName` can be a relative or absolute path. To use the saved search path automatically in a future session, make `folderName` be the startup folder for MATLAB.

`status = savepath...` returns `0` when `savepath` was successful and `1` when `savepath` failed.

Examples

Save the current search path to `pathdef.m`, located in `I:/my_matlab_files`:

```
savepath I:/my_matlab_files/pathdef.m
```

How To

- "Running a Script When Exiting MATLAB"
- "What Is the MATLAB Search Path?"

Purpose

scatter plot

Syntax

```
scatter(X,Y)
scatter(X,Y,S)
scatter(X,Y,S,C)
scatter( ___ ,'fill')
scatter( ___ ,markertype)
scatter( ___ ,Name,Value)

scatter(axes_handle, ___ )

h = scatter( ___ )
```

Description

`scatter(X,Y)` displays circles at the locations specified by the vectors `X` and `Y`. This type of graph is also known as a bubble plot.

`scatter(X,Y,S)` draws each circle with the size specified by `S`. To plot each circle with equal size, specify `S` as a scalar. To plot each circle with a specific size, specify `S` as a vector with length equal to the length of `X` and `Y`.

`scatter(X,Y,S,C)` draws each circle with the color specified by `C`.

- If `C` is a color string or an RGB row vector, then all circles are plotted with the specified color.
- If `C` is a three column matrix with the number of rows in `C` equal to the length of `X` and `Y`, then each row of `C` specifies an RGB color value for the corresponding circle.
- If `C` is a vector with length equal to the length of `X` and `Y`, then the values in `C` are linearly mapped to the colors in the current colormap.

`scatter( ___ ,'fill')` fills in the circles, using any of the input argument combinations in the previous syntaxes.

`scatter(___,markertype)` specifies the marker type.

`scatter(___,Name,Value)` specifies scattergroup property settings using one or more `Name,Value` pair arguments.

`scatter(axes_handle,___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The `axes_handle` option can precede any of the input argument combinations in the previous syntaxes.

`h = scatter(___)` returns the scattergroup object handle, `h`.

Input Arguments

X - Value of data to display on x-axis

vector

Value of data to display on the *x*-axis, specified as a vector. `X` and `Y` must be vectors of equal length.

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Y - Value of data to display on y-axis

vector

Value of data to display on the *y*-axis, specified as a vector. `X` and `Y` must be vectors of equal length.

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

S - Marker area

36 (default) | scalar | row or column vector | []

Marker area, specified as a scalar, a row or column vector, or `[]`. The values in `S` must be positive. The units for area are points squared.

- If S is a scalar, then scatter plots all markers with the specified area.
- If S is a row or column vector, then each entry in S specifies the area for the corresponding marker. The length of S must equal the length of X and Y, and corresponding entries in X, Y, and S determine the location and area of each marker.
- If S is empty, then the default size of 36 points squared is used.

Example: 50

Example: [36,25,25,17,46]

Data Types
single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

C - Marker color

[0 0 1] (blue) (default) | color string | RGB row vector | three-column matrix of RGB values | vector

Marker color, specified as a color string, an RGB row vector, a three-column matrix of RGB values, or a vector. For an RGB row vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. If you have three points in the scatter plot and want the colors to be indices into the colormap, specify C as a three-element column vector.

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'

RGB Vector	Short Name	Long Name
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'k'`

Example: `[1,2,3,4]`

Example: `reshape([0,1,0,0,0,1,0.5,1,0.2],3,3)`

Data Types
`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char`

markertype - Marker type

`'o'` (default) | string

Marker type, specified as a string. This table lists the supported marker types.

Specifier	Marker Type
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle

Specifier	Marker Type
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

Example: 'p'

Data Types
char

axes_handle - Axes handle

Axes handle, which is the reference to an axes object. Use the gca function to get the handle to the current axes, for example, axes_handle = gca;.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'MarkerFaceColor','red' sets the marker face color to red.

For more information on these settings see scattergroup.

'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar in points. The scalar sets the width size of the marker edge.

Example: `'LineWidth',0.75`

'MarkerEdgeColor' - Marker edge color

`[0 0 1]` (blue) (default) | `'auto'` | `'none'` | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of `'MarkerEdgeColor'` and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'MarkerEdgeColor',[1 .8 .1]`

'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'MarkerFaceColor',[0 .8 1]

Output Arguments

h - Scattergroup object handle

scalar

Scattergroup object handle, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the `scattergroup` object.

Examples

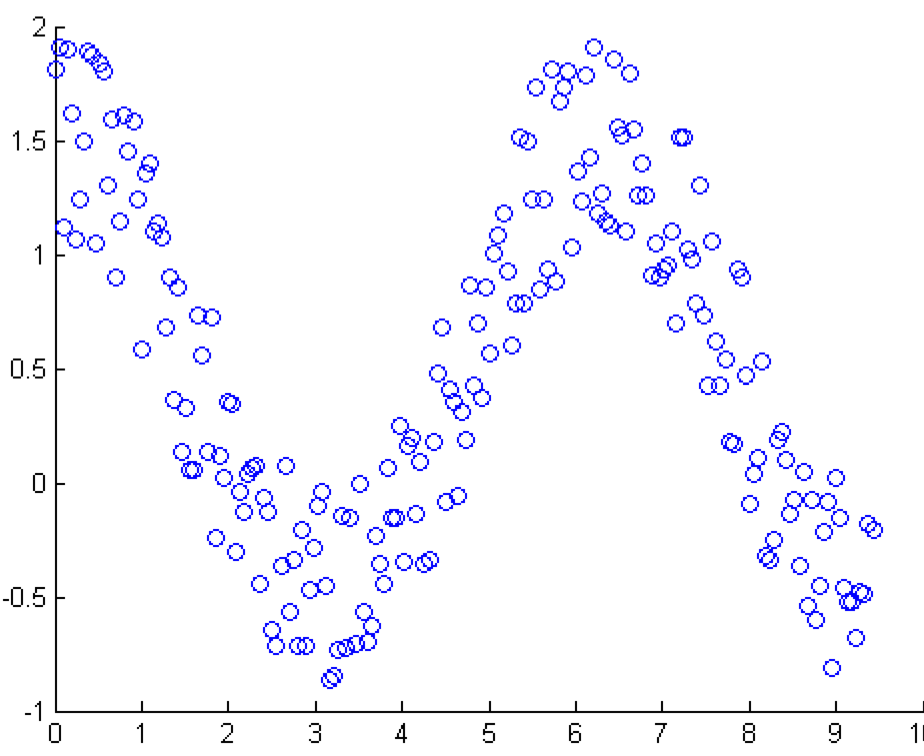
Create Scatter Plot

Set up vector `x` to contain equally spaced values between 0 and 3π. Initialize the random-number generator to make the output of `rand` repeatable, and set up vector `y` to contain cosine values with random noise.

```
x = linspace(0,3*pi,200);
rng(0,'twister');
y = cos(x)+ rand(1,200);
```

Create a scatter plot using the two vector inputs.

```
figure
scatter(x,y)
```



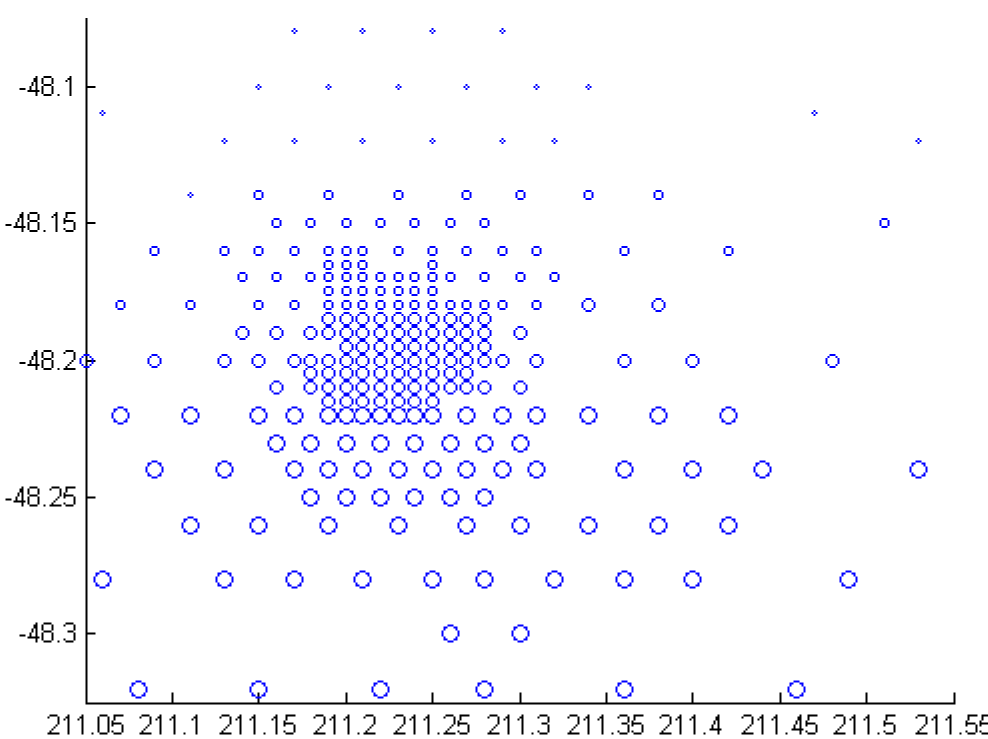
`scatter` plots entries in `x` against corresponding entries in `y`.

Vary Circle Size

Load sample data from `seamount` to get vectors `x` and `y`. Create a scatter plot and vary circle size. Use `zoom` to zoom in on the scatter plot.

```
figure
load seamount
S = linspace(1,50,length(x));
scatter(x,y,S)
```

```
zoom(2)
```



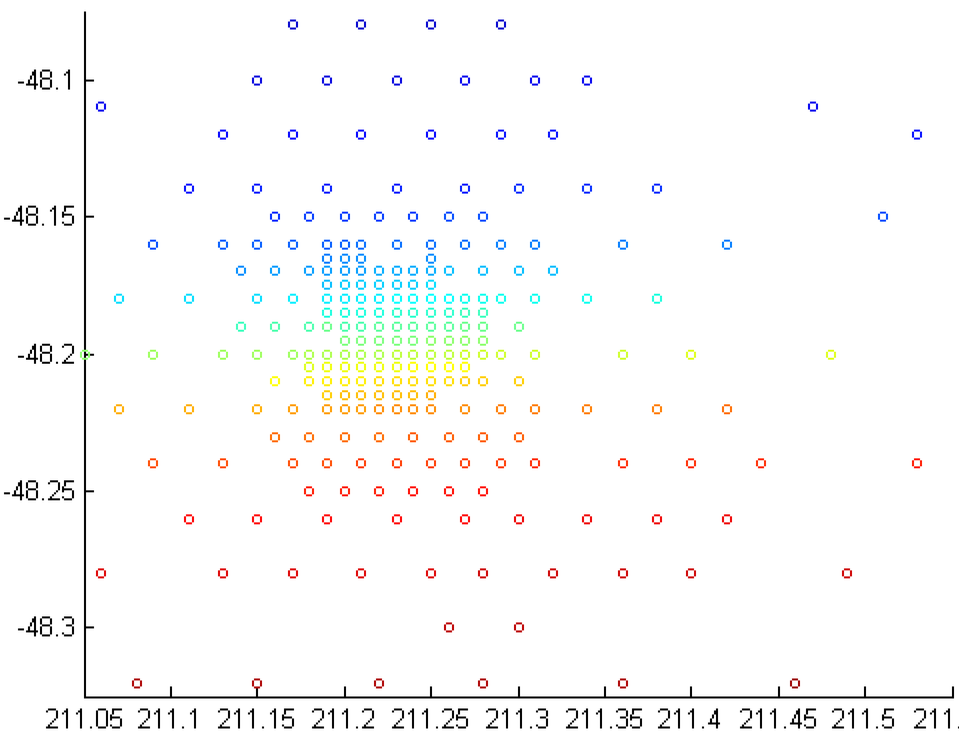
Corresponding entries in X, Y, and S determine the location and size of each marker.

Vary Circle Color

Load sample data from seamount to get vectors x and y. Create a scatter plot and vary the circle color. Use zoom to zoom in on the scatter plot.

```
figure
```

```
load seamount
s = 10;
c = linspace(1,10,length(x));
scatter(x,y,s,c)
zoom(2)
```

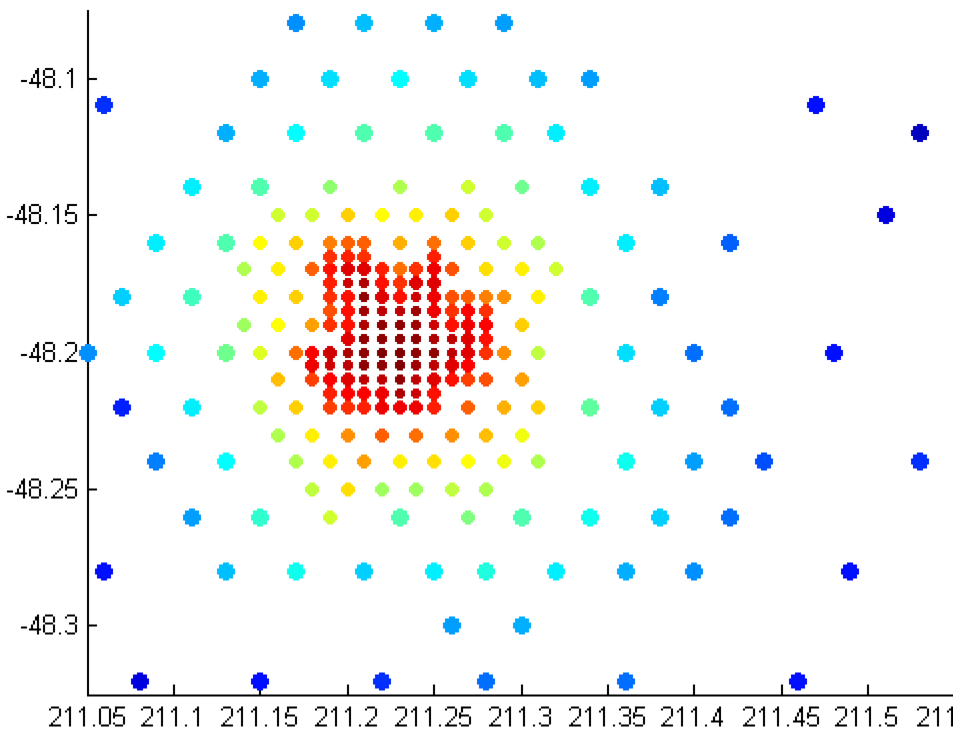


Corresponding entries in `X`, `Y`, and `C` determine the location and color of each marker. Since `S` is a scalar, all markers are plotted with equal size.

Vary Circle Size and Color

Load sample data from `seamount` to get vectors `x`, `y`, and `z`. Create a scatter plot and vary the circle size and color. Fill in the circles and use `zoom` to zoom in on the scatter plot.

```
figure
load seamount
s = sqrt(-z/2);
c = z;
scatter(x,y,s,c,'fill')
zoom(2)
```



Each circle is plotted with a specific size and color determined by the vectors `S` and `C`, respectively.

Specify Marker Symbol

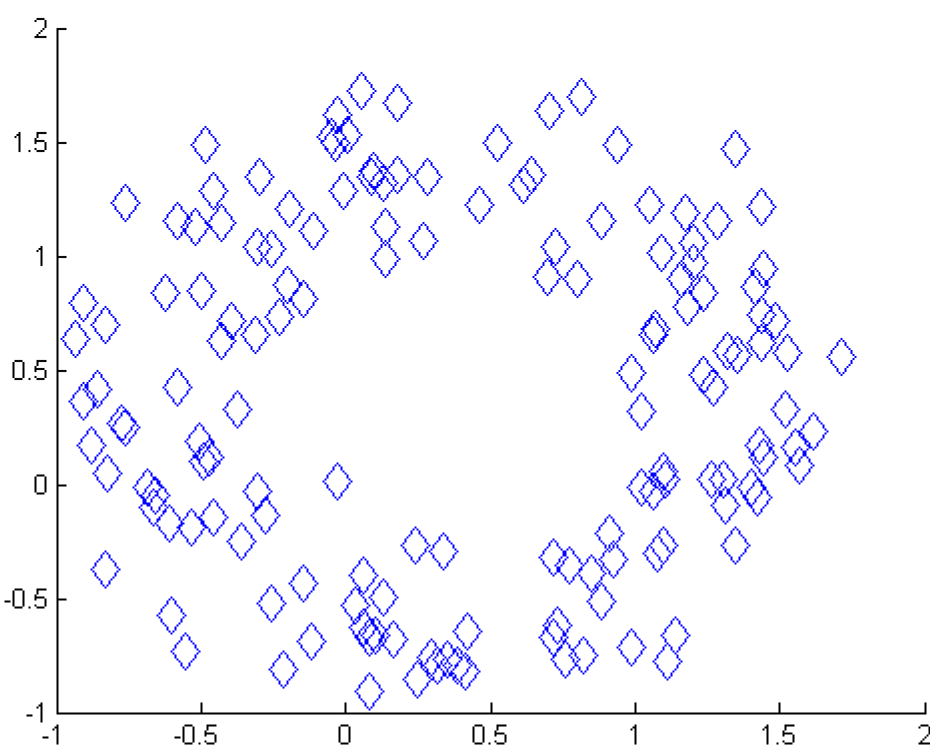
Initialize the random-number generator to make the output of `rand` repeatable. Set up vectors `x` and `y` as sine and cosine values with random noise.

```
rng(0,'twister');
theta = linspace(0,2*pi,150);
```

```
x = sin(theta) + 0.75*rand(1,150);
y = cos(theta) + 0.75*rand(1,150);
```

Create a scatter plot and set the marker type to diamonds with an area of 140 points squared.

```
figure
s = 140;
scatter(x,y,s,'d')
```



To fill in the diamonds, use the 'fill' option.

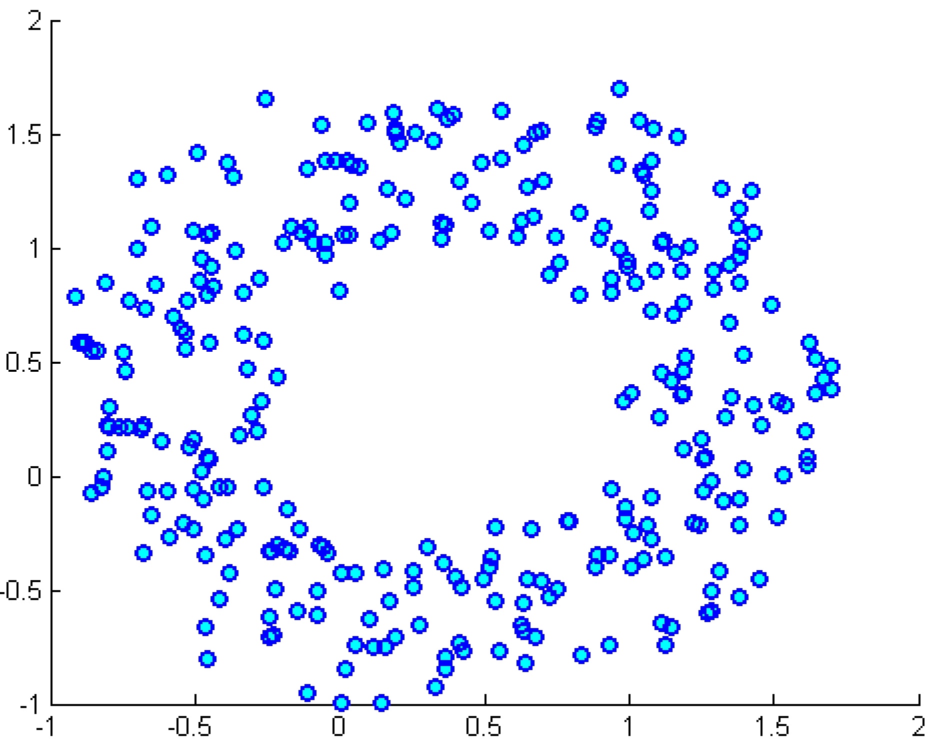
Specify Marker Properties

Initialize the random-number generator to make the output of rand repeatable. Set up vectors x and y as sine and cosine values with random noise.

```
rng(0,'twister');
theta = linspace(0,2*pi,300);
x = sin(theta) + 0.75*rand(1,300);
y = cos(theta) + 0.75*rand(1,300);
```

Create a scatter plot and set the marker size, edge color, face color, and line width.

```
figure
s = 40;
scatter(x,y,s,'MarkerEdgeColor','b','MarkerFaceColor','c','LineWidth',
```



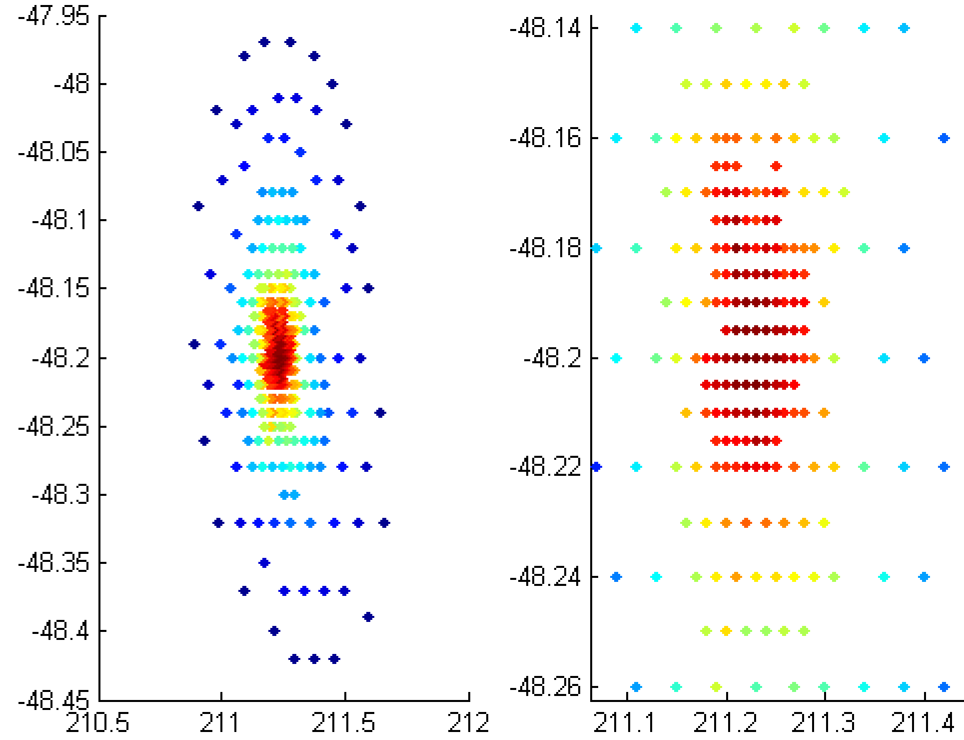
Specify Scatter Plot Axes

Load the sample data from `seamount` to get vectors `x`, `y`, and `z`.

```
load seamount
```

Create a figure with handles to two subplots. Create a scatter plot in the first subplot using the axes handle. In the second subplot, create another scatter plot from the same data sample and use `zoom` to zoom in on the plot.

```
figure
hs(1) = subplot(1,2,1);
hs(2) = subplot(1,2,2);
s = 30;
c = z;
scatter(hs(1),x,y,s,c,'fill','d')
scatter(hs(2),x,y,s,c,'fill','d')
zoom(4)
```



Set Marker Properties Using the Handle

Create a scatter plot and get the scattergroup object handle, h.

```
figure
theta = linspace(0,1,500);
x = exp(theta).*sin(100*theta);
y = exp(theta).*cos(100*theta);
h = scatter(x,y);
```

Use the handle to set the marker edge color, face color, and line width.

```
set(h,'MarkerEdgeColor','b','MarkerFaceColor',[0 .5 .5],'LineWidth',0.6)
```

scatter3 | plot3scattergroup | ColorSpec | LineSpec

scatter3

Purpose

3-D scatter plot

Syntax

```
scatter3(X,Y,Z)
scatter3(X,Y,Z,S)
scatter3(X,Y,Z,S,C)
scatter3( ___ ,'fill')
scatter3( ___ ,markertype)
scatter3( ___ ,Name,Value)

scatter3(axes_handle, ___ )

h = scatter3( ___ )
```

Description

`scatter3(X,Y,Z)` displays circles at the locations specified by the vectors `X`, `Y`, and `Z`.

`scatter3(X,Y,Z,S)` draws each circle with the size specified by `S`. To plot each circle with equal size, specify `S` as a scalar. To plot each circle with a specific size, specify `S` as a vector.

`scatter3(X,Y,Z,S,C)` draws each circle with the color specified by `C`.

- If `C` is a color string or an RGB row vector, then all circles are plotted with the specified color.
- If `C` is a three column matrix with the number of rows in `C` equal to the length of `X`, `Y`, and `Z`, then each row of `C` specifies an RGB color value for the corresponding circle.
- If `C` is a vector with length equal to the length of `X`, `Y`, and `Z`, then the values in `C` are linearly mapped to the colors in the current colormap.

`scatter3( ___ ,'fill')` fills in the circles, using any of the input argument combinations in the previous syntaxes.

`scatter3( ___ ,markertype)` specifies the marker type.

`scatter3(___,Name,Value)` specifies scattergroup property settings using one or more `Name,Value` pair arguments.

`scatter3(axes_handle,___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The `axes_handle` option can precede any of the input argument combinations in the previous syntaxes.

`h = scatter3(___)` returns the scattergroup object handle, `h`.

Input Arguments

X - Value of data to display on x-axis

vector

Value of data to display on the *x*-axis, specified as a vector. `X`, `Y`, and `Z` must be vectors of equal length.

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Y - Value of data to display on y-axis

(default) | vector

Value of data to display on the *y*-axis, specified as a vector. `X`, `Y`, and `Z` must be vectors of equal length.

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Z - Value of data to display on z-axis

(default) | vector

Value of data to display on the *z*-axis, specified as a vector. `X`, `Y`, and `Z` must be vectors of equal length.

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

S - Marker area

36 (default) | scalar | vector | []

Marker area, specified as a scalar, a vector, or []. The values in S must be positive. The units for area are points squared.

- If S is a scalar, then scatter3 plots all markers with the specified area.
- If S is a row or column vector, then each entry in S specifies the area for the corresponding marker. The length of S must equal the length of X, Y and Z. Corresponding entries in X, Y, Z and S determine the location and area of each marker.
- If S is empty, then the default size of 36 points squared is used.

Example: 50

Example: [36,25,25,17,46]

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

C - Marker color

[0 0 1] (blue) (default) | color string | RGB row vector | three-column matrix of RGB values | vector

Marker color, specified as a color string, an RGB row vector, a three-column matrix of RGB values, or a vector. For an RGB row vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. If you have three points in the scatter plot and want the colors to be indices into the colormap, specify C as a three-element column vector.

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'y'

Example: [1,2,3,4]

Example: reshape([0,1,0,0,0,1,0.5,1,0.2],3,3)

Data Types
single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

markertype - Marker type

'o' (default) | string

Marker type, specified as a string. The table below lists the supported marker types.

Specifier	Marker Type
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross

Specifier	Marker Type
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

axes_handle - Axes handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'MarkerFaceColor','red'` sets the marker face color to red.

For more information on these properties see `scattergroup`.

'LineWidth' - Line width

`0.5` (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. The scalar sets the width size in points of the marker edge.

Example: 'LineWidth',0.75

'MarkerEdgeColor' - Marker edge color

[0 0 1] (blue) (default) | 'auto' | 'none' | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'MarkerEdgeColor',[1 .8 .1]`

'MarkerFaceColor' - Marker face color

`'none'` (default) | `'auto'` | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of `'MarkerFaceColor'` and a color value. `MarkerFaceColor` sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'MarkerFaceColor',[0 .8 1]`

Output Arguments

h - Scattergroup object handle

scalar

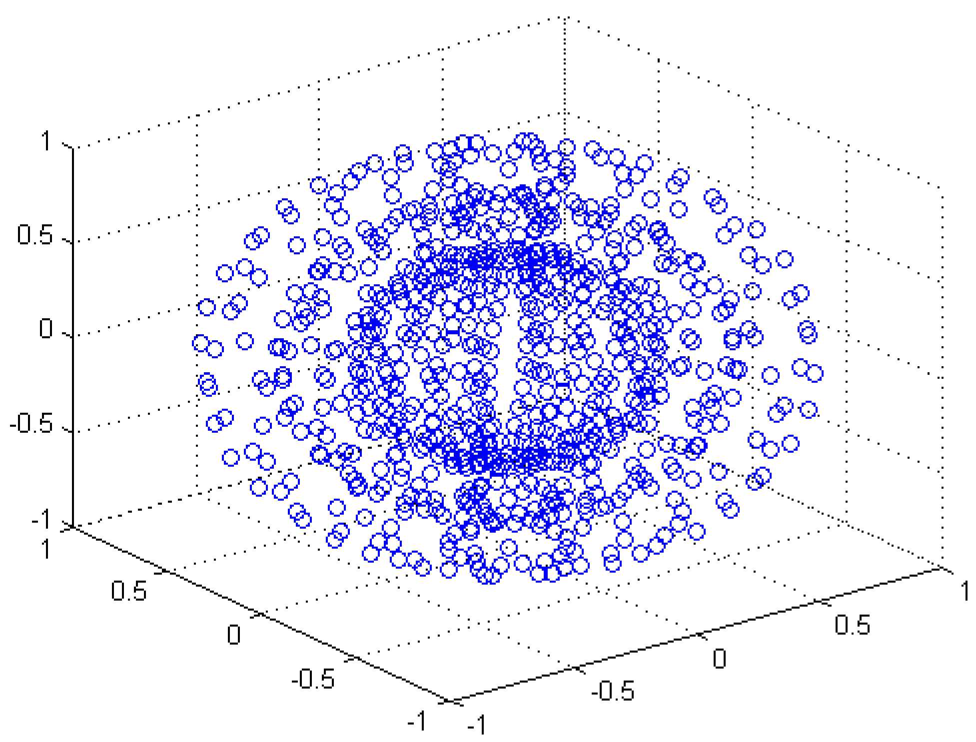
Scattergroup object handle, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the `scattergroup`.

Examples

Create 3-D Scatter Plot

Create a 3-D scatter plot. Use `sphere` to set up vectors `x`, `y`, and `z`.

```
figure
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
scatter3(x,y,z)
```



Vary Marker Size

Use `sphere` to set up vectors `x`, `y`, and `z`.

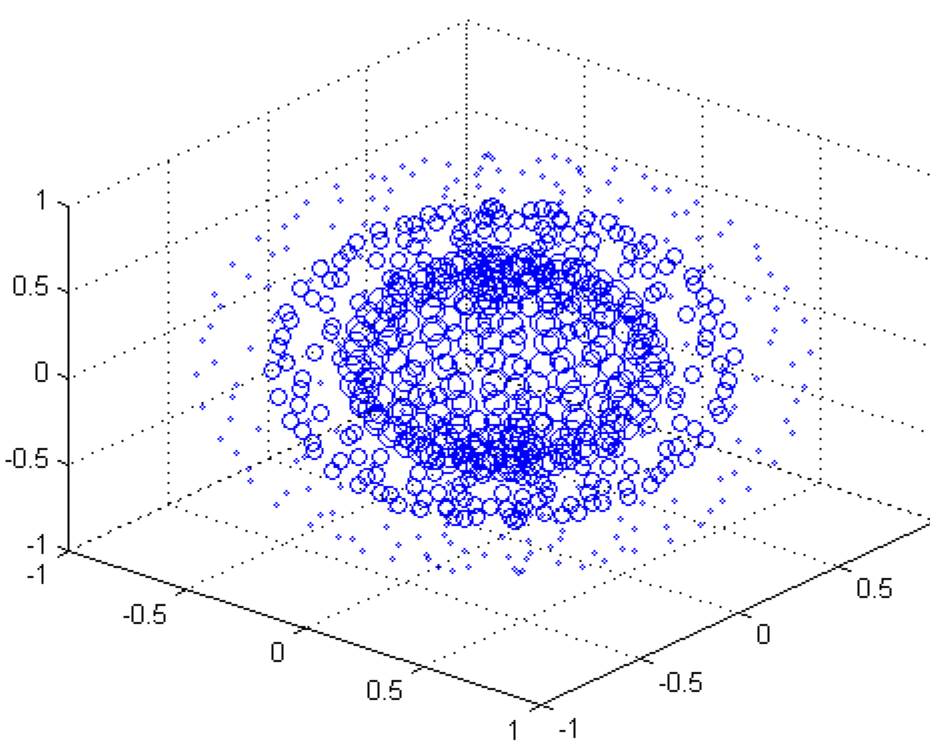
```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Set up vector `s` to specify the marker sizes.

```
S = repmat([100,50,5],numel(X),1);
s = S(:);
```

Create a 3-D scatter plot and use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,s)
view(40,35)
```



Corresponding entries in x, y, z, and s determine the location and size of each marker.

Vary Marker Color

Use sphere to set up vectors x, y, and z.

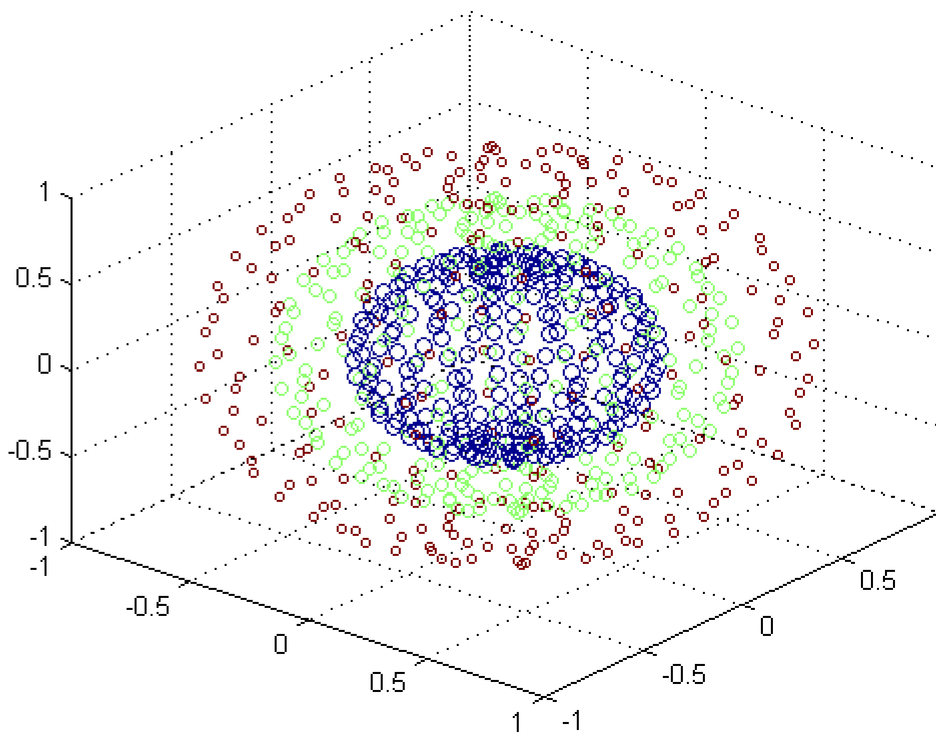
```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Set up vectors s and c to specify the size and color of each marker.

```
S = repmat([50,25,10],numel(X),1);
C = repmat([1,2,3],numel(X),1);
s = S(:);
c = C(:);
```

Create a 3-D scatter plot and use view to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,s,c)
view(40,35)
```



Corresponding entries in x, y, z, and c determine the location and color of each marker.

Fill in Markers

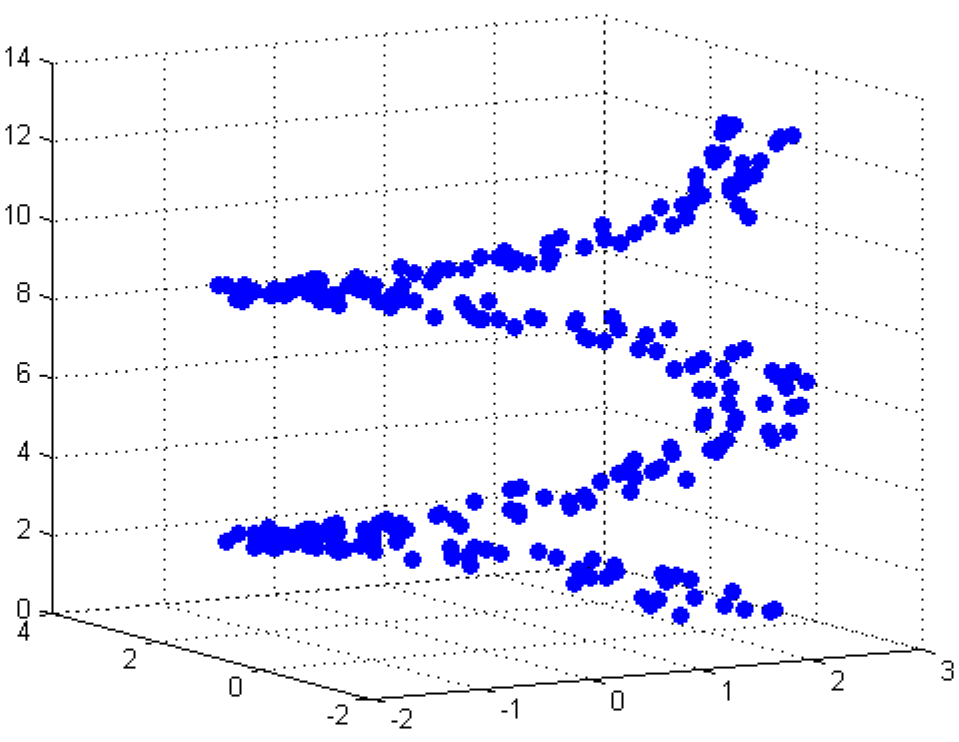
Initialize the random-number generator to make the output of rand repeatable. Set up vectors x and y as cosine and sine values with random noise.

```
rng(0,'twister');
z = linspace(0,4*pi,250);
```

```
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and fill in the markers. Use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,'fill')
view(-30,10)
```



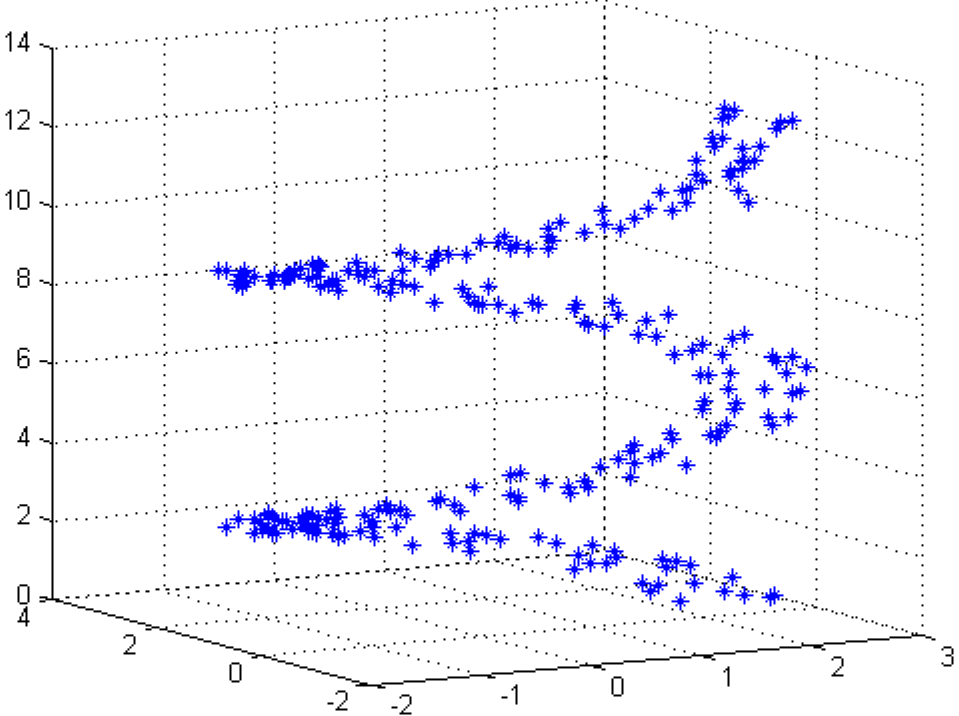
Set Marker Type

Initialize the random-number generator to make the output of `rand` repeatable. Set up vectors `x` and `y` as cosine and sine values with random noise.

```
rng(0,'twister');
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and set the marker type. Use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,'*')
view(-30,10)
```



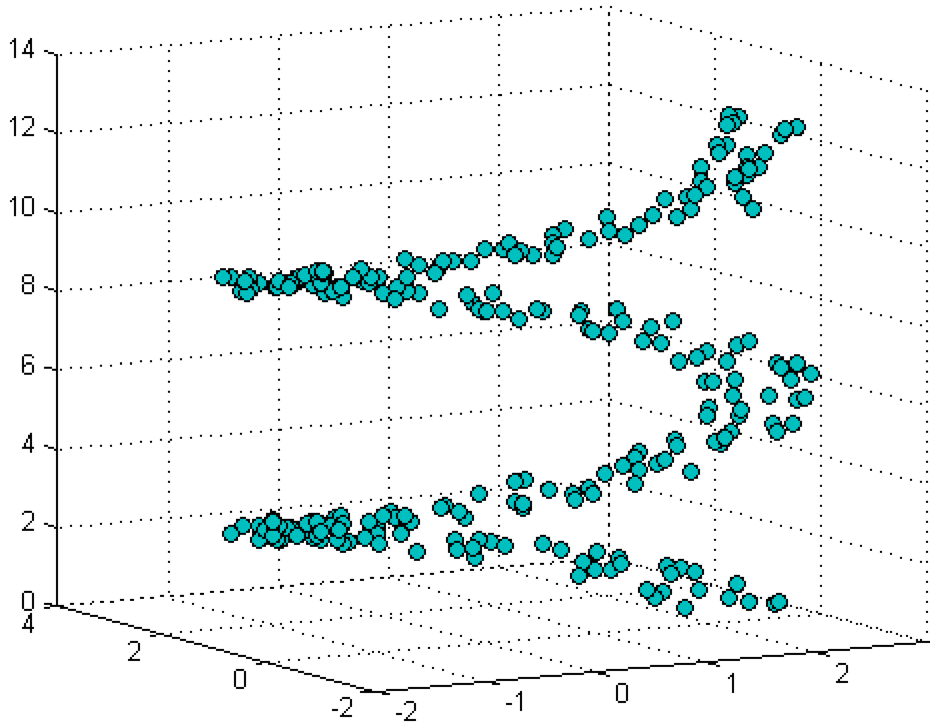
Set Marker Properties

Initialize the random-number generator to make the output of `rand` repeatable. Set up vectors `x` and `y` as cosine and sine values with random noise.

```
rng(0,'twister');
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and set the marker edge color and the marker face color. Use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,'MarkerEdgeColor','k','MarkerFaceColor',[0 .75 .75])
view(-30,10)
```



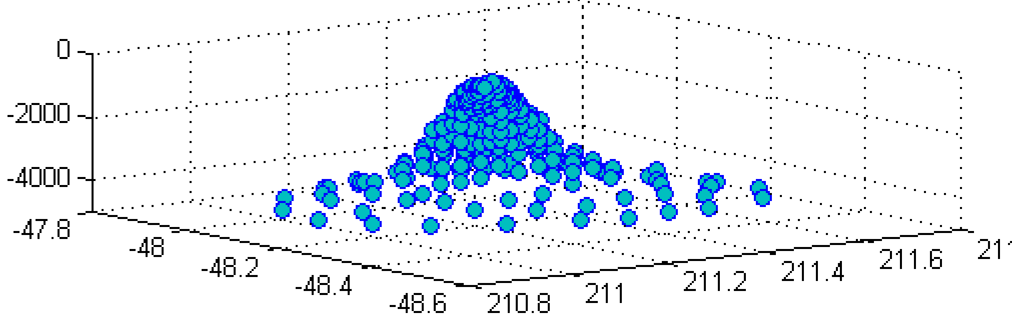
Specify 3-D Scatter Plot Axes

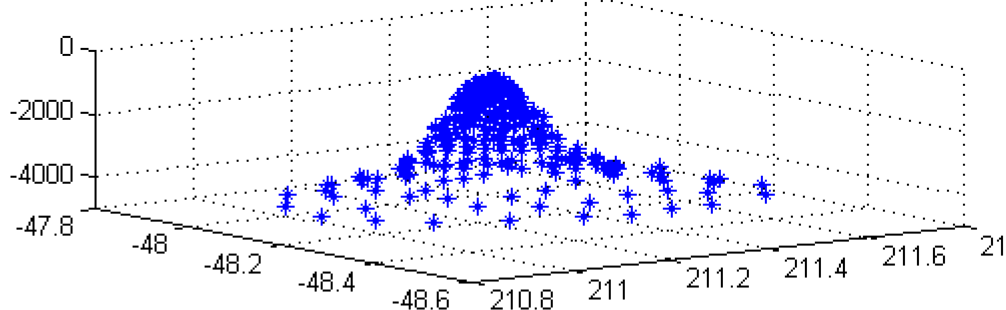
Load the `seamount` data set to get vectors `x`, `y`, and `z`.

```
load seamount
```

Create a figure with handles to two subplots. In each subplot create a 3-D scatter plot and specify the marker properties for each scatter plot.

```
figure
hs(1) = subplot(2,1,1);
hs(2) = subplot(2,1,2);
scatter3(hs(1),x,y,z,'MarkerFaceColor',[0 .75 .75])
scatter3(hs(2),x,y,z,'*')
```





Set Marker Properties Using the Handle

Use `sphere` to set up vectors `x`, `y`, and `z`.

```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Set up vectors `s` and `c` to specify the size and color for each marker.

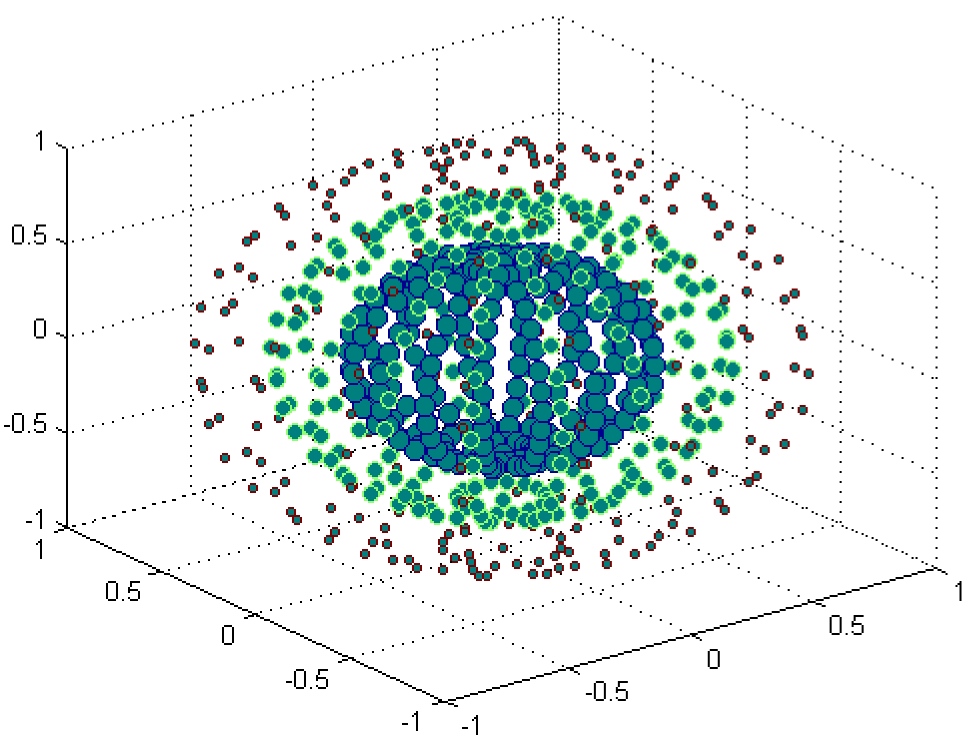
```
S = repmat([70,50,20],numel(X),1);
C = repmat([1,2,3],numel(X),1);
s = S(:);
c = C(:);
```

Create a 3-D scatter plot and get the object handle.

```
figure
h = scatter3(x,y,z,s,c);
```

Use the object handle to set the marker face color.

```
set(h,'MarkerFaceColor',[0 .5 .5])
```



See Also scatter | plot3scattergroup | | ColorSpec | LineSpec

Purpose

Define scattergroup properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default property values for scattergroup objects.

See Plot Objects for information on scattergroup objects.

Scattergroup Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Annotation`

`hg.Annotation` object (read-only)

Control the display of scattergroup objects in legends. Specifies whether this scattergroup object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the scattergroup object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
`on`	Include the scattergroup object in a legend as one entry, but not its children objects
`off`	Do not include the scattergroup or its children in a legend (default)
`children`	Include only the children of the scattergroup as separate entries in the legend

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the IconDisplayStyle Property

See "Controlling Legends" for more information and examples.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

running callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`CData`

vector | `m-by-3` matrix | `ColorSpec`

Color of markers. When `CData` is a vector the same length as `XData` and `YData`, the values in `CData` are linearly mapped to the colors in the current colormap. When `CData` is a `length(XData)`-by-3 matrix, it specifies the colors of the markers as RGB values.

`CDataSource`

string (MATLAB variable)

Link CData to MATLAB variable. Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the `CData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `CData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`Children`

array of graphics object handles

Children of the scattergroup object. An array containing the handle of a patch object parented to the scattergroup object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`

`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`CreateFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y,'CreateFcn',@CallbackFcn)
```

where *`@CallbackFcn`* is a function handle that references the callback function and *`graphicfcn`* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`

string

String used by legend. The `legend` function uses the `DisplayName` property to label the scattergroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EraseMode`

`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`
`{on} | off`

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the markers that compose the scatter plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`
`on | {off}`

Select the object by clicking markers or area of extent. Select plot objects by:

- Clicking scatter markers (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the scatter markers to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the scatter markers).

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineWidth`
size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is `0.5` points.

`Marker`
character (see table)

Marker symbol. Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

Marker Specifiers Table

Specifier	Marker Type
'`+`'	Plus sign
'`o`'	Circle
'`*`'	Asterisk
'`.`'	Point
'`x`'	Cross
'`square`' or '`s`'	Square

Specifier	Marker Type
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'''	Six-pointed star (hexagram)
'none'	No marker (default)

MarkerEdgeColor
ColorSpec | none | {auto}

Marker edge color. The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — Defines color to use.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the CData property.

MarkerFaceColor
ColorSpec | {none} | auto

Fill color for closed-shape markers. The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Makes the interior of the marker transparent, allowing the background to show through.

- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`Parent`
: handle of parent axes, hggroup, or hgtransform

  Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

  See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
: `on | {off}`

  Object selection state. When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
: `{on} | off`

  Object highlighted when selected.

  - `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
  - `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`SizeData`
: square points

  Size of markers in square points. Area of the marker in the scatter graph in units of points. Since there are 72 points to one inch, to

specify a marker that has an area of one square inch you would use a value of `72^2`.

`SizeDataSource`

string (MATLAB variable)

Link SizeData to MATLAB variable. Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the `SizeData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `SizeData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`Tag`

string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an areaseries object and set the `Tag` property.

```
t = area(Y,'Tag','area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

`Type`
string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stemseries objects, `Type` is '`hggroup`'. The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`
handle of uicontextmenu object

Associate context menu with object. Handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

`UserData`
array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Visibility of object and its children.

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

`XData`

array

X-coordinates of scatter markers. The `scatter` function draws individual markers at each *x*-axis location in the `XData` array. The input argument `X` in the `scatter` function calling syntax assigns values to `XData`.

`XDataSource`

MATLAB variable, as a string

Link `XData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h,'XDataSource','xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`

scalar | vector | matrix

Y-coordinates of scatter markers. The `scatter` function draws individual markers at each *y*-axis location in the `YData` array.

The input argument `Y` in the `scatter` function calling syntax assigns values to `YData`.

`YDataSource`

MATLAB variable, as a string

Link `YData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h,'YDataSource','Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`ZData`

vector

Z-coordinates. A vector defining the *z*-coordinates for the graph. `XData` and `YData` must be the same length and have the same number of rows.

`ZDataSource`
MATLAB variable, as a string

Link `ZData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`. The default value is an empty array.

```
set(h,'ZDataSource','zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Purpose Schur decomposition

Syntax

```
T = schur(A)
T = schur(A,flag)
[U,T] = schur(A,...)
```

Description The `schur` command computes the Schur form of a matrix.

`T = schur(A)` returns the Schur matrix `T`.

`T = schur(A,flag)` for real matrix A, returns a Schur matrix `T` in one of two forms depending on the value of `flag`:

`'complex'`	`T` is triangular and is complex if `A` is real and has complex eigenvalues.
`'real'`	`T` has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal. `'real'` is the default when `A` is real.

If `A` is complex, `schur` returns the complex Schur form in matrix `T` and `flag` is ignored. The complex Schur form is upper triangular with the eigenvalues of `A` on the diagonal.

The function `rsf2csf` converts the real Schur form to the complex Schur form.

`[U,T] = schur(A,...)` also returns a unitary matrix `U` so that `A = U*T*U'` and `U'*U = eye(size(A))`.

Examples `H` is a 3-by-3 eigenvalue test matrix:

```
H = [ -149    -50   -154
       537    180    546
       -27     -9    -25 ]
```

Its Schur form is

```
schur(H)
```

```
ans =
     1.0000   -7.1119 -815.8706
          0    2.0000  -55.0236
          0         0    3.0000
```

The eigenvalues, which in this case are 1, 2, and 3, are on the diagonal. The fact that the off-diagonal elements are so large indicates that this matrix has poorly conditioned eigenvalues; small changes in the matrix elements produce relatively large changes in its eigenvalues.

Purpose

Sequence of MATLAB statements in file

Description

A script file is an external file that contains a sequence of MATLAB statements. By typing the filename, you can obtain subsequent MATLAB input from the file. Script files have a filename extension of `.m`.

Scripts are the simplest kind of MATLAB program. They are useful for automating blocks of MATLAB commands, such as computations you have to perform repeatedly from the command line. Scripts can operate on existing data in the workspace, or they can create new data on which to operate. Although scripts do not return output arguments, any variables that they create remain in the workspace, so you can use them in further computations. In addition, scripts can produce graphical output using commands like `plot`.

Scripts can contain any series of MATLAB statements. They require no declarations or begin/end delimiters.

Like any MATLAB program, scripts can contain comments. Any text following a percent sign (`%`) on a given line is comment text. Comments can appear on lines by themselves, or you can append them to the end of any executable line.

Purpose

Scattered data interpolation

Description

Use `scatteredInterpolant` to perform interpolation on a 2-D or 3-D "Scattered Data" on page 1-4658 set. For example, you can pass a set of `(x,y)` points and values, `v`, to `scatteredInterpolant`, and it returns a surface of the form $v = F(x, y)$. This surface always passes through the sample values at the point locations. You can evaluate this surface at any query point, `(xq,yq)`, to produce an interpolated value, `vq`.

Use `scatteredInterpolant` to create the "Interpolant" on page 1-4658, `F`. Then, you can evaluate `F` at specific points using any of the following syntaxes:

- `Vq = F(Pq)` specifies the query points in the matrix `Pq`. Each row in `Pq` contains the coordinates of a query point.
- `Vq = F(Xq,Yq)` and `Vq = F(Xq,Yq,Zq)` specify the query points as two or three matrices of equal size.
- `Vq = F({xq,yq})` and `Vq = F({xq,yq,zq})` specify the query points as "Grid Vectors" on page 1-4658. The interpolated values are returned in `Vq`. Use this syntax to conserve memory when you want to query a large grid of points.

Construction

`F = scatteredInterpolant(x,y,v)` creates an interpolant that fits a surface of the form $v = F(x,y)$. Vectors `x` and `y` specify the `(x,y)` coordinates of the sample points. `v` is a vector that contains the sample values associated with the points, `(x,y)`.

`F = scatteredInterpolant(x,y,z,v)` creates a 3-D interpolant of the form $v = F(x,y,z)$.

`F = scatteredInterpolant(P,v)` specifies the coordinates of the sample points as an array. The rows of `P` contain the (x, y) or (x, y, z) coordinates for the values in `v`.

`F = scatteredInterpolant(___,Method)` specifies a string that describes an interpolation method: `'nearest'`, `'linear'`, or `'natural'`. Specify `Method` as the last input argument in any of the first three syntaxes.

`F = scatteredInterpolant(___,Method,ExtrapolationMethod)` specifies both the interpolation and extrapolation methods as strings. `Method` can be one of three strings: `'nearest'`, `'linear'`, or `'natural'`. Specify `ExtrapolationMethod` as one of the following strings: `'nearest'`, `'linear'`, or `'none'`. Pass `Method` and `ExtrapolationMethod` together as the last two input arguments in any of the first three syntaxes.

`F = scatteredInterpolant()` creates an empty scattered data interpolant. Use `F.Points = P` to initialize `F` with the points in matrix `P`. Use `F.Values = v` to initialize `F` with the values in `v`.

Input Arguments

x

Sample points *x*-coordinates, specified as a vector of the same size as `v`.

y

Sample points *y*-coordinates, specified as a vector of the same size as `v`.

z

Sample points *z*-coordinates, specified as a vector of the same size as `v`.

P

Sample points array, specified as an `m`-by-`n` matrix, where `m` is the number of points and `n` is the dimension of the space where the points reside. Each row of `P` contains the (x, y) or (x, y, z) coordinates of a sample point.

v

Sample values vector, specified as a vector of that defines the values at the sample points.

Method

Interpolation method, specified as one of these strings.

Method String	Description
`'linear'` (default)	Linear interpolation.
`'nearest'`	Nearest neighbor interpolation.
`'natural'`	Natural neighbor interpolation.

ExtrapolationMethod

Extrapolation method, specified as one of these strings.

ExtrapolationMethod String	Description
`'linear'`	Linear extrapolation based on boundary gradients. Default when `Method` is
`'nearest'`	Nearest neighbor extrapolation. This method evaluates to the value of the nearest neighbor on the boundary. Default when `Method = 'nearest'`.
`'none'`	No extrapolation. Any queries outside the convex hull of `F.Points` return `NaN`.

Properties

Points

Array of sample points (locations) for the values in `F.Values`. Each row of `F.Points` contains the (*x*, *y*) or (*x*, *y*, *z*) coordinates of a sample point.

Values

Vector of values associated with each point in `F.Points`.

Method

A string specifying the method used to interpolate the data: `'nearest'`, `'linear'`, or `'natural'`.

ExtrapolationMethod

A string specifying the method used to extrapolate the data: `'nearest'`, `'linear'`, or `'none'`. A value of `'none'` indicates that extrapolation is disabled.

Definitions

Interpolant

Interpolating function that you can evaluate at query locations.

Scattered Data

A set of points that have no structure among their relative locations.

Full Grid

A grid represented as a set of arrays. For example, you can create a full grid using `ndgrid`.

Grid Vectors

A set of vectors that serve as a compact representation of a grid in `ndgrid` format. For example, `[X,Y] = ndgrid(xg,yg)` returns a full grid in the matrices `X` and `Y`. You can represent the same grid using the grid vectors, `xg` and `yg`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Indexing

`scatteredInterpolant` supports index-based editing of the properties of `F`. You can add or remove points in `F.Points` and update the corresponding values in `F.Values`. For example, `F.Points(5,:) = []` removes the fifth point, and `F.Values(5) = []` removes the corresponding value.

Examples

2-D Interpolation

Define 200 random points.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);
x = xy(:,1);
```

```
y = xy(:,2);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

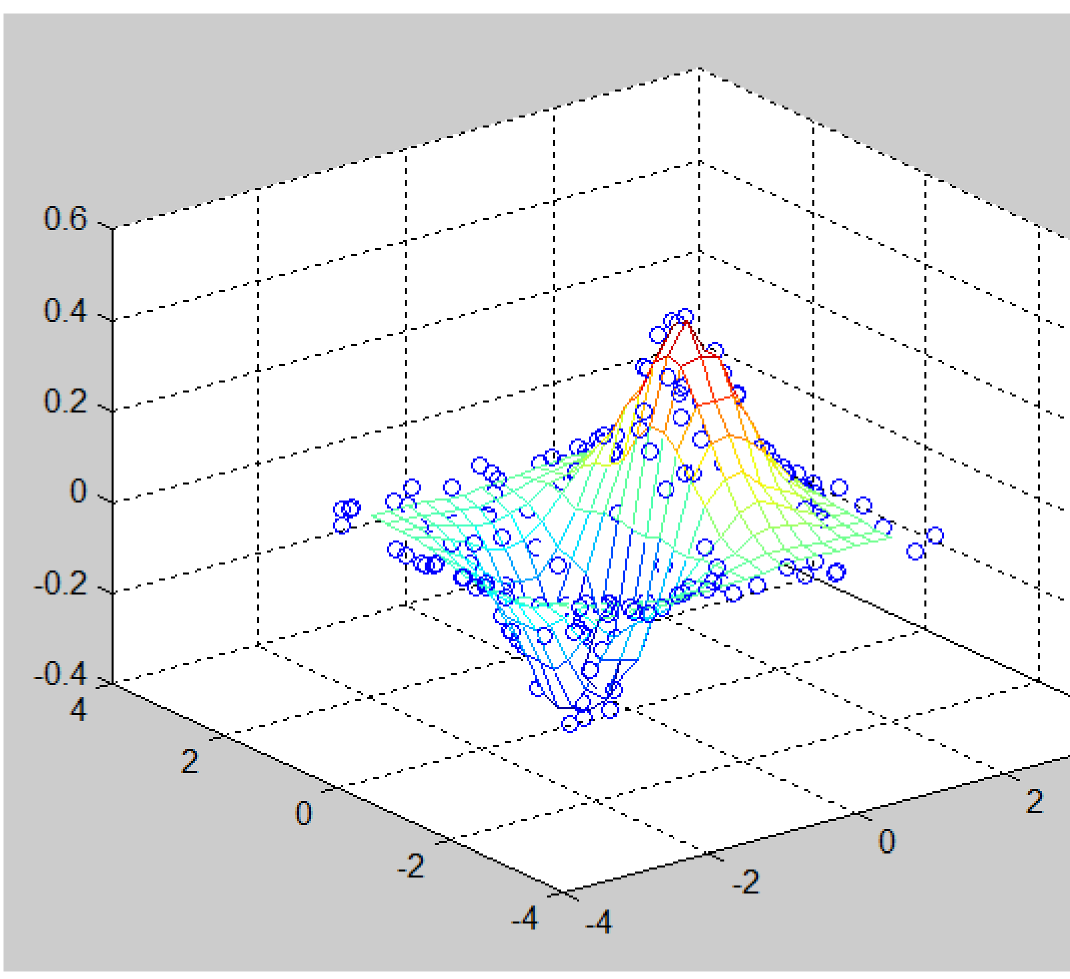
```
F = scatteredInterpolant(x,y,v);
```

Evaluate the interpolant at query locations (*xq*, *yq*).

```
ti = -2:.25:2;
[xq,yq] = meshgrid(ti,ti);
vq = F(xq,yq);
```

Plot the result.

```
figure
mesh(xq,yq,vq);
hold on;
plot3(x,y,v,'o');
hold off;
```



2-D Extrapolation

Query the interpolant at a single point outside the convex hull using nearest neighbor extrapolation.

Define a matrix of 200 random points.

```
P = -2.5 + 5*gallery('uniformdata',[200 2],0);
```

Sample an exponential function. These are the sample values for the interpolant.

```
x = P(:,1);
y = P(:,2);
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant, specifying linear interpolation and nearest neighbor extrapolation.

```
F = scatteredInterpolant(P,v,'linear','nearest')
```

```
F =

  scatteredInterpolant with properties:

                 Points: [200x2 double]
                 Values: [200x1 double]
                 Method: 'linear'
    ExtrapolationMethod: 'nearest'
```

Evaluate the interpolant outside the convex hull.

```
vq = F(3.0,-1.5)
```

```
vq =

    0.0031
```

Disable extrapolation and evaluate F at the same point.

```
F.ExtrapolationMethod = 'none';
vq = F(3.0,-1.5)
```

```
vq =

   NaN
```

Replacement of Sample Values

Replace the elements in the `Values` property when you want to change the values at the sample points. You get immediate results when you evaluate the new interpolant because the original triangulation has not changed.

Create 50 random points.

```
x = -2.5 + 5*gallery('uniformdata',[50 1],0);
y = -2.5 + 5*gallery('uniformdata',[50 1],1);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

```
F = scatteredInterpolant(x,y,v)
```

```
F =

  scatteredInterpolant with properties:

                 Points: [50x2 double]
                 Values: [50x1 double]
                 Method: 'linear'
    ExtrapolationMethod: 'linear'
```

Evaluate the interpolant at `(1.40,1.90)`.

```
F(1.40,1.90)
```

```
ans =

    0.0029
```

Change the interpolant sample values.

```
vnew = x.^2 + y.^2;
F.Values = vnew;
```

Evaluate the interpolant at (1.40,1.90).

```
F(1.40,1.90)
```

```
ans =

    6.1109
```

How To

- Class Attributes
- Property Attributes
- "Interpolating Gridded Data"

Purpose

Secant of argument in radians

Syntax

```
Y = sec(X)
```

Description

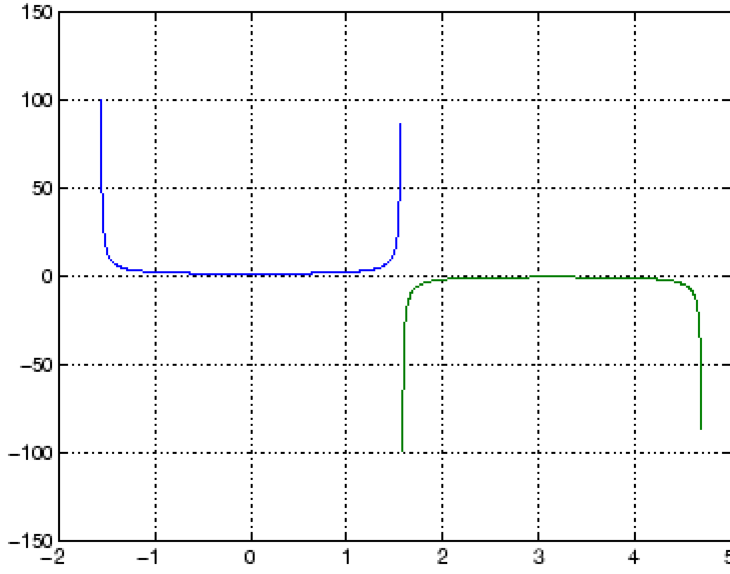
The `sec` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = sec(X)` returns an array the same size as `X` containing the secant of the elements of `X`.

Examples

Graph the secant over the domains $-\pi/2 < x < \pi/2$ and $\pi/2 < x < 3\pi/2$.

```
x1 = -pi/2+0.01:0.01:pi/2-0.01;
x2 = pi/2+0.01:0.01:(3*pi/2)-0.01;
plot(x1,sec(x1),x2,sec(x2)), grid on
```



The expression `sec(pi/2)` does not evaluate as infinite but as the reciprocal of the floating-point accuracy `eps`, because `pi` is a floating-point approximation to the exact value of π.

See Also

secd | sech | asec | asecd | asech

secd

Purpose

Secant of argument in degrees

Syntax

```
Y = secd(X)
```

Description

`Y = secd(X)` returns the secant of the elements of `X`, which are expressed in degrees.

Input Arguments

X - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `secd` operation is element-wise when `X` is nonscalar.

Example:

Data Types
`single | double`
Complex Number Support: Yes

Output Arguments

Y - Secant of angle

scalar value | vector | matrix | N-D array

Secant of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Secant of 90 degrees compared to secant of /2 radians

`secd(90)` is infinite, whereas `sec(pi/2)` is large but finite.

```
secd(90)

ans =

   Inf

sec(pi/2)

ans =
```

```
   1.6331e+16
```

Secant of vector of complex angles, specified in degrees

```
z = [35+i 15+2i 10+3i];
y = secd(z)

y =

   1.2204 + 0.0149i   1.0346 + 0.0097i   1.0140 + 0.0094i
```

See Also

sec | asec | asecd

sech

Purpose

Hyperbolic secant

Syntax

```
Y = sech(X)
```

Description

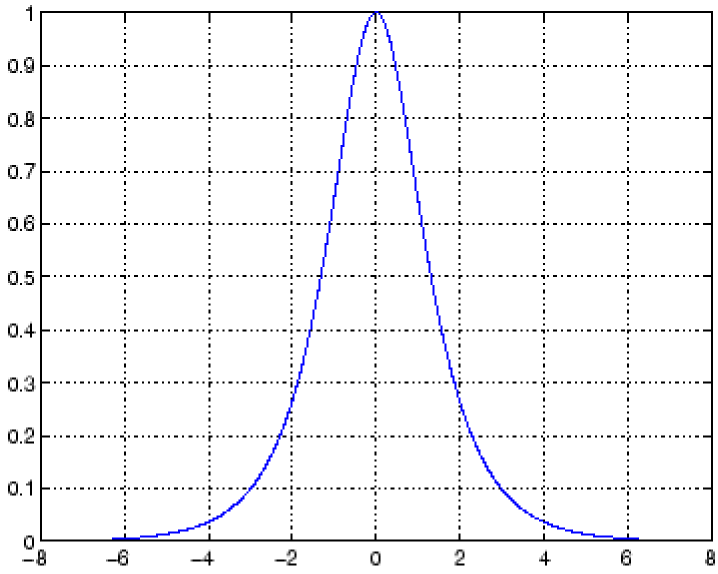
The `sech` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = sech(X)` returns an array the same size as `X` containing the hyperbolic secant of the elements of `X`.

Examples

Graph the hyperbolic secant over the domain $-2\pi \leq x \leq 2\pi$.

```
x = -2*pi:0.01:2*pi;
plot(x,sech(x)), grid on
```



See Also

`asech` | `sec` | `sinh` | `cosh`

Purpose

Select, move, resize, or copy axes and uicontrol graphics objects

Syntax

```
A = selectmoveresize
set(gca,'ButtonDownFcn','selectmoveresize')
```

Description

`selectmoveresize` is useful as the callback routine for axes and uicontrol button down functions. When executed, it selects the object and allows you to move, resize, and copy it.

`A = selectmoveresize` returns a structure array containing

- `A.Type`: a string containing the action type, which can be `Select`, `Move`, `Resize`, or `Copy`
- `A.Handles`: a list of the selected handles, or, for a `Copy`, an m-by-2 matrix containing the original handles in the first column and the new handles in the second column

`set(gca,'ButtonDownFcn','selectmoveresize')` sets the `ButtonDownFcn` property of the current axes to selectmoveresize:

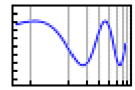
semilogx

Purpose

Semilogarithmic plot



Syntax

```
semilogx(Y)
semilogx(X1,Y1,...)
semilogx(X1,Y1,LineSpec,...)
semilogx(...,'PropertyName',PropertyValue,...)
h = semilogx(...)
```

Description

`semilogx` plot data as logarithmic scales for the *x*-axis.

`semilogx(Y)` creates a plot using a base 10 logarithmic scale for the *x*-axis and a linear scale for the *y*-axis. It plots the columns of `Y` versus their index if `Y` contains real numbers. `semilogx(Y)` is equivalent to `semilogx(real(Y), imag(Y))` if `Y` contains complex numbers. `semilogx` ignores the imaginary component in all other uses of this function.

`semilogx(X1,Y1,...)` plots all `Xn` versus `Yn` pairs. If only `Xn` or `Yn` is a matrix, `semilogx` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`semilogx(X1,Y1,LineSpec,...)` plots all lines defined by the `Xn,Yn,LineSpec` triples. `LineSpec` determines line style, marker symbol, and color of the plotted lines.

`semilogx(...,'PropertyName',PropertyValue,...)` sets property values for all `lineseries properties` graphics objects created by `semilogx`.

`h = semilogx(...)` return a vector of handles to `lineseries` graphics objects, one handle per line.

Tips

If you do not specify a color when plotting more than one line, `semilogx` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix `Xn,Yn` pairs with `Xn,Yn,`*`LineSpec`* triples; for example,

```
semilogx(X1,Y1,X2,Y2,LineSpec,X3,Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

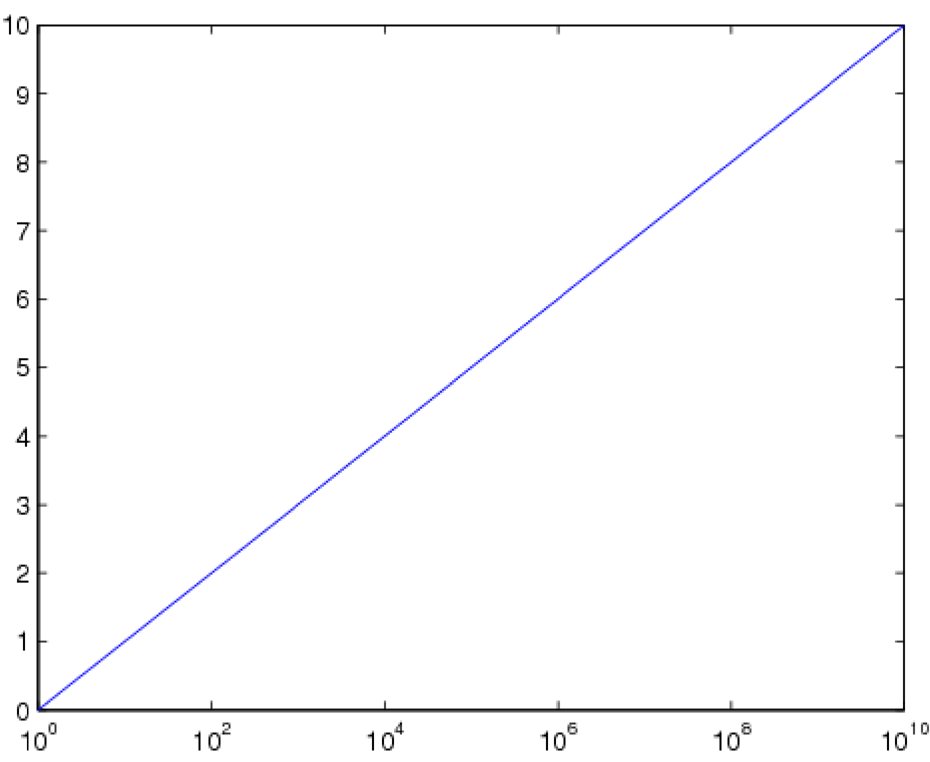
Renderer Support

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure Renderer property for more information on renderers.

Examples

Create a simple `semilogx` plot.

```
x = 0:0.1:10;
semilogx(10.^x,x)
```

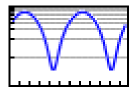


See Also

`line` | `LineSpec` | `loglog` | `plot` | `semilogy`

Purpose

Semilogarithmic plot



Syntax

```
semilogy(Y)
semilogy(X1,Y1,...)
semilogy(X1,Y1,LineSpec,...)
semilogy(...,'PropertyName',PropertyValue,...)
h = semilogy(...)
```

Description

`semilogy` plots data with logarithmic scale for the *y*-axis.

`semilogy(Y)` creates a plot using a base 10 logarithmic scale for the *y*-axis and a linear scale for the *x*-axis. It plots the columns of `Y` versus their index if `Y` contains real numbers. `semilogy(Y)` is equivalent to `semilogy(real(Y), imag(Y))` if `Y` contains complex numbers. `semilogy` ignores the imaginary component in all other uses of this function.

`semilogy(X1,Y1,...)` plots all `Xn` versus `Yn` pairs. If only `Xn` or `Yn` is a matrix, `semilogy` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`semilogy(X1,Y1,LineSpec,...)` plots all lines defined by the `Xn,Yn,LineSpec` triples. `LineSpec` determines line style, marker symbol, and color of the plotted lines.

`semilogy(...,'PropertyName',PropertyValue,...)` sets property values for all `lineseries properties` graphics objects created by `semilogy`.

`h = semilogy(...)` returns a vector of handles to `lineseries` graphics objects, one handle per line.

Tips

If you do not specify a color when plotting more than one line, `semilogy` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix `Xn,Yn` pairs with `Xn,Yn,`*`LineSpec`* triples; for example,

```
semilogy(X1,Y1,X2,Y2,LineSpec,X3,Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

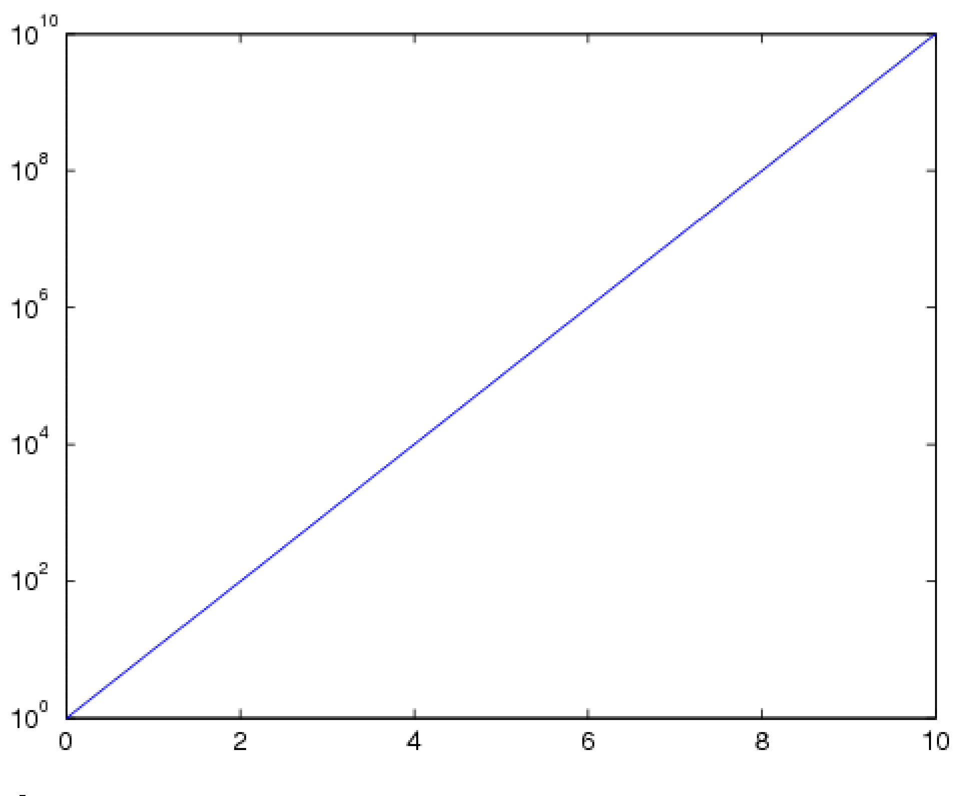
Renderer Support

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure Renderer property for more information on renderers.

Examples

Create a simple `semilogy` plot.

```
x = 0:.1:10;
semilogy(x,10.^x)
```



See Also

line | LineSpec | loglog | plot | semilogx

sendmail

Purpose

Send email message to address list

Syntax

```
sendmail(recipients,subject)
sendmail(recipients,subject,message)
sendmail(recipients,subject,message,attachments)
```

Description

`sendmail(recipients,subject)` sends email to `recipients` with the specified `subject`. The `recipients` input is a string for a single address, or a cell array of strings for multiple addresses.

`sendmail(recipients,subject,message)` includes the specified `message`. If `message` is a string, `sendmail` automatically wraps text at 75 characters. To force a line break in the message text, use `10`, as shown in the Examples. If `message` is a cell array of strings, each cell represents a new line of text.

`sendmail(recipients,subject,message,attachments)` attaches the files listed in the string or cell array `attachments`.

Tips

- The `sendmail` function does not support HTML-formatted messages. However, you can send HTML files as attachments.
- If `sendmail` cannot determine your email address or outgoing SMTP mail server from your system registry, specify those settings using the `setpref` function. For example:

  ```
  setpref('Internet','SMTP_Server','my_server.example.com');
  setpref('Internet','E_mail','my_email@example.com');
  ```

  To identify the SMTP server for the call to `setpref`, check the preferences for your electronic mail application, or consult your email system administrator. If you cannot easily determine the server name, try `'mail'`, which is a common default, such as:

  ```
  setpref('Internet','SMTP_Server','mail');
  ```

- By default, the `sendmail` function does not support email servers that require authentication. To support these servers, change your

system settings and set preferences for the SMTP user name and password, with commands in the following form:

```
props = java.lang.System.getProperties;
props.setProperty('mail.smtp.auth','true');

setpref('Internet','SMTP_Username','myaddress@example.com');
setpref('Internet','SMTP_Password','mypassword');
```

Examples

Send a message with two attachments to a hypothetical email address:

```
sendmail('user@otherdomain.com',...
         'Test subject','Test message',...
         {'folder/attach1.html','attach2.doc'});
```

Send a message with forced line breaks (using 10) to a hypothetical email address:

```
sendmail('user@otherdomain.com','New subject', ...
        ['Line1 of message' 10 'Line2 of message' 10 ...
         'Line3 of message' 10 'Line4 of message']);
```

The resulting message is:

```
Line1 of message
Line2 of message
Line3 of message
Line4 of message
```

Gmail™ servers require authentication and an encrypted connection (SSL) on port 465. Change your system settings to use your Gmail server and send a test message to your Gmail account:

```
% Modify these two lines to reflect
% your account and password.
```

```
myaddress = 'myaddress@gmail.com';
mypassword = 'mypassword';

setpref('Internet','E_mail',myaddress);
setpref('Internet','SMTP_Server','smtp.gmail.com');
setpref('Internet','SMTP_Username',myaddress);
setpref('Internet','SMTP_Password',mypassword);

props = java.lang.System.getProperties;
props.setProperty('mail.smtp.auth','true');
props.setProperty('mail.smtp.socketFactory.class', ...
                  'javax.net.ssl.SSLSocketFactory');
props.setProperty('mail.smtp.socketFactory.port','465');

sendmail(myaddress, 'Gmail Test', 'This is a test message.');
```

Alternatives

On Windows systems with Microsoft Outlook®, you can send email directly through Outlook by accessing the COM server with `actxserver`. For an example, see Solution 1-RTY6J.

How To

- “Specify Proxy Server Settings for Connecting to the Internet”

Purpose

Create serial port object

Syntax

```
obj = serial('port')
obj = serial('port','PropertyName',PropertyValue,...)
```

Description

`obj = serial('port')` creates a serial port object associated with the serial port specified by *`port`*. If *`port`* does not exist, or if it is in use, you will not be able to connect the serial port object to the device.

`Port` object name will depend upon the platform that the serial port is on. `instrhwinfo` ('serial') provides a list of available serial ports. This list is an example of serial constructors on different platforms:

Platform	Serial Port Constructor
Linux and Linux 64	`serial('/dev/ttyS0');`
Mac OS X 64	`serial('/dev/tty.KeySerial1');`
Windows 32 and Windows 64	`serial('com1');`

`obj = serial('port','PropertyName',PropertyValue,...)` creates a serial port object with the specified property names and property values. If an invalid property name or property value is specified, an error is returned and the serial port object is not created.

Tips

When you create a serial port object, these property values are automatically configured:

- The `Type` property is given by `serial`.
- The `Name` property is given by concatenating `Serial` with the port specified in the `serial` function.
- The `Port` property is given by the port specified in the `serial` function.

You can specify the property names and property values using any format supported by the `set` function. For example, you can use property name/property value cell array pairs. Additionally, you can

specify property names without regard to case, and you can make use of property name completion. For example, the following commands are all valid on a Windows platform.

```
s = serial('COM1','BaudRate',4800);
s = serial('COM1','baudrate',4800);
s = serial('COM1','BAUD',4800);
```

Refer to Configuring Property Values for a list of serial port object properties that you can use with `serial`.

Before you can communicate with the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt a read or write operation while the object is not connected to the device. You can connect only one serial port object to a given serial port.

Examples

This example creates the serial port object `s1` associated with the serial port COM1 on a Windows platform.

```
s1 = serial('COM1');
```

The `Type`, `Name`, and `Port` properties are automatically configured.

```
get(s1,{'Type','Name','Port'})
ans =
    'serial'    'Serial-COM1'    'COM1'
```

To specify properties during object creation

```
s2 = serial('COM2','BaudRate',1200,'DataBits',7);
```

See Also

`fclose` | `fopen` | `Name` | `Port` | `Status` | `Type`

Purpose

Send break to device connected to serial port

Syntax

```
serialbreak(obj)
serialbreak(obj,time)
```

Description

`serialbreak(obj)` sends a break of 10 milliseconds to the device connected to the serial port object, `obj`.

`serialbreak(obj,time)` sends a break to the device with a duration, in milliseconds, specified by `time`. Note that the duration of the break might be inaccurate under some operating systems.

Tips

For some devices, the break signal provides a way to clear the hardware buffer.

Before you can send a break to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to send a break while `obj` is not connected to the device.

`serialbreak` is a synchronous function, and blocks the command line until execution is complete.

If you issue `serialbreak` while data is being asynchronously written, an error is returned. In this case, you must call the `stopasync` function or wait for the write operation to complete.

See Also

`fopen` | `stopasync` | `Status`

Purpose

Set Handle Graphics object properties

Syntax

```
set(H,'PropertyName',PropertyValue,...)
set(H,a)
set(H,pn,pv,...)
set(H,pn,MxN_pv)
a = set(h)
pv = set(h,'PropertyName')
```

Description

Note Do not use the `set` function on Java objects as it will cause a memory leak. For more information, see "Accessing Private and Public Data"

`set(H,'PropertyName',PropertyValue,...)` sets the named properties to the specified values on the object(s) identified by `H`. `H` can be a vector of handles, in which case `set` sets the properties' values for all the objects.

`set(H,a)` sets the named properties to the specified values on the object(s) identified by `H`. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties.

`set(H,pn,pv,...)` sets the named properties specified in the cell array `pn` to the corresponding value in the cell array `pv` for all objects identified in `H`.

`set(H,pn,MxN_pv)` sets `n` property values on each of `m` graphics objects, where `m = length(H)` and `n` is equal to the number of property names contained in the cell array `pn`. This allows you to set a given group of properties to different values on each object.

`a = set(h)` returns the user-settable properties and possible values for the object identified by `h`. `a` is a structure array whose field names are the object's property names and whose field values are the possible values of the corresponding properties. If you do not specify an output

argument, the MATLAB software displays the information on the screen. `h` must be scalar.

`pv = set(h,'PropertyName')` returns the possible values for the named property. If the possible values are strings, `set` returns each in a cell of the cell array `pv`. For other properties, `set` returns a statement indicating that `PropertyName` does not have a fixed set of property values. If you do not specify an output argument, MATLAB displays the information on the screen. `h` must be scalar.

Tips

You can use any combination of property name/property value pairs, structure arrays, and cell arrays in one call to `set`.

Setting Property Units

Note that if you are setting both the `FontSize` and the `FontUnits` properties in one function call, you must set the `FontUnits` property first so that the MATLAB software can correctly interpret the specified `FontSize`. The same applies to figure and axes uints — always set the `Units` property before setting properties whose values you want to be interpreted in those units. For example,

```
f = figure('Units','characters',...
        'Position',[30 30 120 35]);
```

Examples

Set the Color property of the current axes to blue.

```
axes;
set(gca,'Color','b')
```

Change all the `lines` in a plot to black.

```
plot(peaks)
set(findobj('Type','line'),'Color','k')
```

You can define a group of properties in a structure to better organize your code. For example, these statements define a structure called `active`, which contains a set of property definitions used for the

`uicontrol` objects in a particular figure. When this figure becomes the current figure, MATLAB changes the colors and enables the controls.

```
active.BackgroundColor = [.7 .7 .7];
active.Enable = 'on';
active.ForegroundColor = [0 0 0];

if gcf == control_fig_handle
 set(findobj(control_fig_handle,'Type','uicontrol'),active)
end
```

You can use cell arrays to set properties to different values on each object. For example, these statements define a cell array to set three properties,

```
PropName(1) = {'BackgroundColor'};
PropName(2) = {'Enable'};
PropName(3) = {'ForegroundColor'};
```

These statements define a cell array containing three values for each of three objects (i.e., a 3-by-3 cell array).

```
PropVal(1,1) = {[.5 .5 .5]};
PropVal(1,2) = {'off'};
PropVal(1,3) = {[.9 .9 .9]};
PropVal(2,1) = {[1 0 0]};
PropVal(2,2) = {'on'};
PropVal(2,3) = {[1 1 1]};
PropVal(3,1) = {[.7 .7 .7]};
PropVal(3,2) = {'on'};
PropVal(3,3) = {[0 0 0]};
```

Now pass the arguments to `set`,

```
set(H,PropName,PropVal)
```

where `length(H) = 3` and each element is the handle to a uicontrol.

Setting Different Values for the Same Property on Multiple Objects

Suppose you want to set the value of the `Tag` property on five line objects, each to a different value. Note how the value cell array needs to be transposed to have the proper shape.

```
h = plot(rand(5));
set(h,{'Tag'},{'line1','line2','line3','line4','line5'}')
```

See Also

`findobj` | `gca` | `gcf` | `gco` | `gcbo` | `get`

audioplayer.set

Purpose

Set property values for `audioplayer` object

Syntax

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

Description

`set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

Tips

The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

Examples

View the list of properties that you can set for an `audioplayer` object:

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj)
```

Set the `Tag` and `UserData` properties of an `audioplayer` object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj, newValues)

% View the values all properties.
get(handelObj)
```

Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for an object called `handelObj` (as created in the Examples):

```
handelObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(handelObj, 'Tag', 'This is my tag.');
```

See Also

`audioplayer` | `get`

audiorecorder.set

Purpose

Set property values for `audiorecorder` object

Syntax

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

Description

`set(obj,Name,Value)` sets the named property to the specified value for the object *`obj`*.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array *`cellOfNames`* to the corresponding values in the cell array *`cellOfValues`*. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array *`structOfProperties`* to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of *`settableProperties`* are the property names.

Tips

The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

Examples

View the list of properties that you can set for an `audiorecorder` object:

```
recorderObj = audiorecorder;
set(recorderObj)
```

Set the `Tag` and `UserData` properties of an `audiorecorder` object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

```
recorderObj = audiorecorder;
set(recorderObj, newValues)

% View the values all properties.
get(recorderObj)
```

Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for an object called `recorderObj` (as created in the Examples):

```
recorderObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(recorderObj, 'Tag', 'This is my tag.');
```

See Also

`audiorecorder` | `get`

set (COM)

Purpose

Set object or interface property to specified value

Syntax

```
h.set('pname',value)
h.set('pname1',value1,'pname2',value2,...)
set(h,...)
```

Description

`h.set('pname',value)` sets the property specified in the string `pname` to the given `value`.

`h.set('pname1',value1,'pname2',value2,...)` sets each property specified in the `pname` strings to the given `value`.

`set(h,...)` is an alternate syntax for the same operation.

For information on how MATLAB converts workspace matrices to COM data types, see "Handling COM Data in MATLAB Software".

Tips

COM functions are available on Microsoft Windows systems only.

Examples

Create an `mwsamp` control and use `set` to change the `Label` and `Radius` properties:

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.1', [0 0 200 200], f);

h.set('Label', 'Click to fire event', 'Radius', 40);
h.invoke('Redraw');
```

Here is another way to do the same thing, only without `set` and `invoke`:

```
h.Label = 'Click to fire event';
h.Radius = 40;
h.Redraw;
```

See Also

`get (COM)` | `inspect` | `isprop` | `addproperty` | `deleteproperty`

Purpose

Assign property values to handle objects derived from `hgsetget` class

Syntax

```
set(H,'PropertyName',value,...)
set(H,pn,pv)
set(H,S)
S = set(h)
```

Description

`set(H,'PropertyName',value,...)` sets the named property to the specified value for the objects in the handle array `H`.

`set(H,pn,pv)` sets the named properties specified in the cell array of strings `pn` to the corresponding values in the cell array `pv` for all objects specified in `H`. The cell array `pn` must be `1`-by-`n` (where `n` is the number of property names), but the cell array `pv` can be `m`-by-`n` where `m` is equal to `length(H)`. `set` updates each object with the associated set of values for the list of property names contained in.

`set(H,S)` sets the properties identified by each field name of `struct` `S` with the values contained in `S`. `S` is a `struct` whose field names are object property names.

`S = set(h)` returns the user-settable properties of scalar `h`. `S` is a `struct` whose field names are the object's property names and whose values are empty cell arrays.

Override the `hgsetget` class `setdisp` method to change how MATLAB displays this information.

How To

- "Implementing a Set/Get Interface for Properties"

VideoReader.set

Purpose

Set property values for video reader object

Syntax

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

Description

`set(obj,Name,Value)` sets the named property to the specified value for the object *obj*.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array *cellOfNames* to the corresponding values in the cell array *cellOfValues*. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array *structOfProperties* to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of *settableProperties* are the property names.

Tips

The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

Examples

View the list of properties that you can set for a video reader object:

```
xyloObj = VideoReader('xylophone.mpg');
set(xyloObj)
```

Set the `Tag` and `UserData` properties of a video reader object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

```
xyloObj = VideoReader('xylophone.mpg');
set(xyloObj, newValues)

% View the values all properties.
get(xyloObj)
```

Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for a reader object called `xyloObj` (as created in the Examples):

```
xyloObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(xyloObj, 'Tag', 'This is my tag.');
```

See Also

`VideoReader` | `get`

set (RandStream)

Purpose

Set random number stream property

Class

`RandStream`

Syntax

```
set(stream,'PropertyName',Value)
set(stream,'Property1',Value1,'Property2',Value2,...)
set(stream,A)
A = set(stream,'Property')
set(stream,'Property')
A = set(stream)
set(stream)
```

Description

`set(stream,'PropertyName',Value)` sets the property `'PropertyName'` of the random stream `stream` to the value `Value`.

`set(stream,'Property1',Value1,'Property2',Value2,...)` sets multiple random stream property values with a single statement.

`set(stream,A)` where `A` is a structure whose field names are property names of the random stream `stream` sets the properties of `stream` named by each field with the values contained in those fields.

`A = set(stream,'Property')` or `set(stream,'Property')` displays possible values for the specified property of `stream`.

`A = set(stream)` or `set(stream)` displays or returns all writable properties of `stream` and their possible values.

See Also

`RandStream` | `get (RandStream)` | `rand` | `randn` | `randi`

Purpose

Configure or display serial port object properties

Syntax

```
set(obj)
props = set(obj)
set(obj,'PropertyName')
props = set(obj,'PropertyName')
set(obj,'PropertyName',PropertyValue,...)
set(obj,PN,PV)
set(obj,S)
```

Description

`set(obj)` displays all configurable properties values for the serial port object, `obj`. If a property has a finite list of possible string values, then these values are also displayed.

`props = set(obj)` returns all configurable properties and their possible values for `obj` to `props`. `props` is a structure whose field names are the property names of `obj`, and whose values are cell arrays of possible property values. If the property does not have a finite set of possible values, then the cell array is empty.

`set(obj,'PropertyName')` displays the valid values for *PropertyName* if it possesses a finite list of string values.

`props = set(obj,'PropertyName')` returns the valid values for *PropertyName* `to props`. `props` is a cell array of possible string values or an empty cell array if *PropertyName* does not have a finite list of possible values.

`set(obj,'PropertyName',PropertyValue,...)` configures multiple property values with a single command.

`set(obj,PN,PV)` configures the properties specified in the cell array of strings `PN` to the corresponding values in the cell array `PV`. `PN` must be a vector. `PV` can be m-by-n where m is equal to the number of serial port objects in `obj` and n is equal to the length of `PN`.

`set(obj,S)` configures the named properties to the specified values for `obj`. `S` is a structure whose field names are serial port object properties, and whose field values are the values of the corresponding properties.

Tips

Refer to Configuring Property Values for a list of serial port object properties that you can configure with `set`.

You can use any combination of property name/property value pairs, structures, and cell arrays in one call to `set`. Additionally, you can specify a property name without regard to case, and you can make use of property name completion. For example, if `s` is a serial port object, then the following commands are all valid.

```
set(s,'BaudRate')
set(s,'baudrate')
set(s,'BAUD')
```

If you use the `help` command to display help for `set`, then you need to supply the pathname shown below.

```
help serial/set
```

Examples

This example illustrates some of the ways you can use `set` to configure or return property values for the serial port object `s`, on a Windows platform.

```
s = serial('COM1');
set(s,'BaudRate',9600,'Parity','even')
set(s,{'StopBits','RecordName'},{2,'sydney.txt'})
set(s,'Parity')
[ {none} | odd | even | mark | space ]
```

See Also

`get`

Purpose

Configure or display timer object properties

Syntax

```
set(obj)
prop_struct = set(obj)
set(obj,'PropertyName')
prop_cell=set(obj,'PropertyName')
set(obj,'PropertyName',PropertyValue,...)
set(obj,S)
set(obj,PN,PV)
```

Description

`set(obj)` displays property names and their possible values for all configurable properties of timer object `obj`. `obj` must be a single timer object.

`prop_struct = set(obj)` returns the property names and their possible values for all configurable properties of timer object `obj`. `obj` must be a single timer object. The return value, `prop_struct`, is a structure whose field names are the property names of `obj`, and whose values are cell arrays of possible property values or empty cell arrays if the property does not have a finite set of possible string values.

`set(obj,'`*`PropertyName`*`')` displays the possible values for the specified property, *`PropertyName`*, of timer object `obj`. `obj` must be a single timer object.

`prop_cell=set(obj,'`*`PropertyName`*`')` returns the possible values for the specified property, *`PropertyName`*, of timer object `obj`. `obj` must be a single timer object. The returned array, `prop_cell`, is a cell array of possible value strings or an empty cell array if the property does not have a finite set of possible string values.

`set(obj,'`*`PropertyName`*`',PropertyValue,...)` configures the property, *`PropertyName`*, to the specified value, `PropertyValue`, for timer object `obj`. You can specify multiple property name/property value pairs in a single statement. `obj` can be a single timer object or a vector of timer objects, in which case `set` configures the property values for all the timer objects specified.

`set(obj,S)` configures the properties of `obj`, with the values specified in `S`, where `S` is a structure whose field names are object property names.

`set(obj,PN,PV)` configures the properties specified in the cell array of strings, `PN`, to the corresponding values in the cell array `PV`, for the timer object `obj`. `PN` must be a vector. If `obj` is an array of timer objects, `PV` can be an M-by-N cell array, where M is equal to the length of timer object array and N is equal to the length of `PN`. In this case, each timer object is updated with a different set of values for the list of property names contained in `PN`.

Note When specifying parameter/value pairs, you can use any mixture of strings, structures, and cell arrays in the same call to `set`.

Examples

Create a timer object.

```
t = timer;
```

Display all configurable properties and their possible values.

```
set(t)
    BusyMode: [ {drop} | queue | error ]
    ErrorFcn: string -or- function handle -or- cell array
    ExecutionMode: [ {singleShot} | fixedSpacing | fixedDelay | fixedRate ]
    Name
    ObjectVisibility: [ {on} | off ]
    Period
    StartDelay
    StartFcn: string -or- function handle -or- cell array
    StopFcn: string -or- function handle -or- cell array
    Tag
    TasksToExecute
    TimerFcn: string -or- function handle -or- cell array
    UserData
```

View the possible values of the `ExecutionMode` property.

```
set(t, 'ExecutionMode')
[ {singleShot} | fixedSpacing | fixedDelay | fixedRate ]
```

Set the value of a specific timer object property.

```
set(t, 'ExecutionMode', 'FixedRate')
```

Set the values of several properties of the timer object.

```
set(t, 'TimerFcn', 'callbk', 'Period', 10)
```

Use a cell array to specify the names of the properties you want to set and another cell array to specify the values of these properties.

```
set(t, {'StartDelay', 'Period'}, {30, 30})
```

See Also

`timer` | `get(timer)`

set (tscollection)

Purpose

Set properties of `tscollection` object

Syntax

```
set(tsc,'Property',Value)
set(tsc,'Property1',Value1,'Property2',Value2,...)
set(tsc,'Property')
```

Description

`set(tsc,'Property',Value)` sets the property `'Property'` of the `tscollection` `tsc` to the value `Value`. The following syntax is equivalent:

```
tsc.Property = Value
```

`set(tsc,'Property1',Value1,'Property2',Value2,...)` sets multiple property values for `tsc` with a single statement.

`set(tsc,'Property')` displays values for the specified property in the time-series collection `tsc`.

`set(tsc)` displays all properties and values of the `tscollection` object `tsc`.

See Also

`get (tscollection)`

setabstime (tscollection)

Purpose

Set times of `tscollection` object as date strings

Syntax

```
tsc = setabstime(tsc,Times)
tsc = setabstime(tsc,Times,format)
```

Description

`tsc = setabstime(tsc,Times)` sets the times in tsc using the date strings Times. Times must be either a cell array of strings, or a `char` array containing valid date or time values in the same date format.

`tsc = setabstime(tsc,Times,format)` specifies the date-string format used in Times explicitly.

Examples

1 Create a `tscollection` object.

```
tsc = tscollection(timeseries(rand(3,1)))
```

2 Set the absolute time vector.

```
tsc = setabstime(tsc,{'12-DEC-2005 12:34:56',...
      '12-DEC-2005 13:34:56','12-DEC-2005 14:34:56'})
```

See Also

`datestr` | `tscollection` | `getabstime (tscollection)`

setappdata

Purpose

Specify application-defined data

Syntax

```
setappdata(h,'name',value)
```

Description

`setappdata(h,'name',value)` sets application-defined data for the object with handle `h`. The application-defined data, which is created if it does not already exist, is assigned the specified `name` and `value`. The `value` can be any type of data.

Tips

Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

See Also

`getappdata` | `isappdata` | `rmappdata`

Purpose

Set default random number stream

Note `RandStream.setDefaultStream` will be removed in a future version. Use `RandStream.setGlobalStream` instead. The shared global stream used by `rand`, `randi`, and `randn`, referred to in former versions of MATLAB as the *default stream* is now referred to as the *global stream*.

Syntax

```
prevstream = RandStream.setDefaultStream(stream)
```

Description

`prevstream = RandStream.setDefaultStream(stream)` returns the current global random number stream, and designates the random number stream `stream` as the new random number stream to be used by the `rand`, `randi`, and `randn` functions.

setdiff

Purpose

Set difference of two arrays

Syntax

```
C = setdiff(A,B)
C = setdiff(A,B,'rows')
[C,ia] = setdiff(A,B)
[C,ia] = setdiff(A,B,'rows')

[C,ia] = setdiff(___,setOrder)
[C,ia] = setdiff(A,B,'legacy')
[C,ia] = setdiff(A,B,'rows','legacy')
```

Description

`C = setdiff(A,B)` returns the values in `A` that are not in `B`. The values of `C` are in sorted order.

`C = setdiff(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns the rows from `A` that are not in `B`. The rows of matrix `C` are in sorted order.

The `'rows'` option does not support cell arrays.

`[C,ia] = setdiff(A,B)` also returns the index vector `ia`, such that `C = A(ia)`.

`[C,ia] = setdiff(A,B,'rows')` also returns the index vector `ia`, such that `C = A(ia,:)`.

`[C,ia] = setdiff(___,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`. If no value is specified, the default is `'sorted'`.

`[C,ia] = setdiff(A,B,'legacy')` and `[C,ia] = setdiff(A,B,'rows','legacy')` preserve the behavior of the `setdiff` function from R2012b and prior releases.

Input Arguments

A,B - Input arrays

vectors | matrices | N-D arrays

Input arrays, specified as vectors, matrices, or N-D arrays whose elements can be any numeric, `logical`, or `char` data type. `A` and `B` also can be cell arrays of strings. Furthermore, `A` and `B` can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option), where the second output of this method is `double` or another built-in numeric class
- `eq`
- `ne`

These objects include heterogeneous arrays derived from the same root class.

`A` and `B` must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.

If you specify the `'rows'` option, `A` and `B` must have the same number of columns.

Data Types
`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell`
Complex Number Support: Yes

setOrder - Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in `C`.

Order Flag	Meaning
`'sorted'`	The values (or rows) in `C` return in sorted order. For example: `C = setdiff([4 1 3 2],[2 1],'sorted')` returns `C = [3 4]`.
`'stable'`	The values (or rows) in `C` return in the same order as in `A`. For example: `C = setdiff([4 1 3 2],[2 1],'stable')` returns `C = [4 3]`.

Data Types
`char`

Output Arguments

`C` - Difference of `A` and `B`

Vector | Matrix

Difference of `A` and `B`, returned as a vector or matrix. The following describes the shape of `C` when the `'legacy'` flag is not specified:

- If the `'rows'` flag is not specified and `A` is a row vector, then `C` is a row vector.
- If the `'rows'` flag is not specified and `A` is not a row vector, then `C` is a column vector.
- If the `'rows'` flag is specified, then `C` is a matrix containing the rows of `A` that are not in `B`.
- If all the values (or rows) of `A` are also in `B`, then `C` is an empty matrix.

The class of `C` is the same as the class of `A`, unless `A` is a character array and `B` is a cell array of strings, in which case `C` is a cell array of strings.

`ia` - Index to `A`

column vector

Index to `A`, returned as a column vector when the `'legacy'` flag is not specified. `ia` identifies the values (or rows) in `A` that are not in `B`. If

there is a repeated value (or row) appearing exclusively in `A`, then `ia` contains the index to the first occurrence of the value (or row).

Examples

Difference of Two Vectors

Define two vectors with values in common.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in `A` that are not in `B`.

```
C = setdiff(A,B)
```

```
C =

     1     3     5
```

Difference of Two Vectors and the Indices to the Different Values

Define two vectors with values in common.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in `A` that are not in `B` as well as the index vector `ia`, such that `C = A(ia)`.

```
[C,ia] = setdiff(A,B)
```

```
C =

     1     3     5

ia =

     4
     1
     5
```

Difference of the Rows in Two Matrices

Define two matrices with rows in common.

```
A = [7 9 7; 0 0 0; 7 9 7; 5 5 5; 1 4 5];
B = [0 0 0; 5 5 5];
```

Find the rows from `A` that are not in `B` as well as the index vector `ia`, such that `C = A(ia,:)`.

```
[C,ia] = setdiff(A,B,'rows')

C =

     1     4     5
     7     9     7

ia =

     5
     1
```

Difference of Two Vectors with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` or `'sorted'` when the order of the values in `C` are important.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
[C,ia] = setdiff(A,B,'stable')

C =

     3     1     5

ia =

     1
```

```
     4
     5
```

Alternatively, you can specify `'sorted'` order.

```
 [C,ia] = setdiff(A,B,'sorted')
```

```
C =

     1     3     5

ia =

     4
     1
     5
```

Difference of Vectors Containing NaNs

Define two vectors containing `NaN`.

```
A = [5 NaN NaN]; B = [5 NaN];
```

Find the set difference of `A` and `B`.

```
C = setdiff(A,B)
```

```
C =

   NaN   NaN
```

`setdiff` treats `NaN` values as distinct.

Cell Array of Strings with Trailing White Space

Create a cell array of strings, `A`.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Find the strings in A that are not in B.

```
[C,ia] = setdiff(A,B)

C =

    'dog'    'fish'

ia =

     1
     3
```

setdiff treats trailing white space in cell arrays of strings as distinct characters.

Difference of Char and Cell Array of Strings

Create a character array, A.

```
A = ['cat';'dog';'fox';'pig'];
class(A)

ans =

char
```

Create a cell array of strings, B.

```
B={'dog','cat','fish','horse'};
class(B)

ans =
```

```
cell
```

Find the strings in A that are not in B.

```
C = setdiff(A,B)
```

```
C =

    'fox'
    'pig'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =

cell
```

Preserve Legacy Behavior of setdiff

Use the 'legacy' flag to preserve the behavior of setdiff from R2012b and prior releases in your code.

Find the difference of A and B with the current behavior.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
[C1,ia1] = setdiff(A,B)
```

```
C1 =

     1     3     5

ia1 =

     4
     1
     5
```

Find the difference of A and B, and preserve the legacy behavior.

```
[C2,ia2] = setdiff(A,B,'legacy')

C2 =

     1     3     5

ia2 =

     7     1     5
```

Purpose

Make specified IFD current IFD

Syntax

`tiffobj.setDirectory(dirNum)`

Description

`tiffobj.setDirectory(dirNum)` sets the image file directory (IFD) specified by `dirNum` as the current IFD. `Tiff` object methods operate on the current IFD. The directory index number is one-based.

Examples

Open a TIFF file and move to an IFD in the file by specifying its index number. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path. The TIFF file should contain multiple images.

```
t = Tiff('myfile.tif','r');
t.setDirectory(2);
```

References

This method corresponds to the `TIFFSetDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

setdisp (hgsetget)

Purpose

Override to change command window display

Syntax

```
setdisp(H)
```

Description

`setdisp(H)` called by `set` when `set` is called with no output arguments and a single input argument that is a handle array. Override this `hgsetget` class method in a subclass to change how property information is displayed in the command window.

See Also

`hgsetget | set (hgsetget)`

How To

- "Implementing a Set/Get Interface for Properties"

Purpose

Set environment variable

Syntax

```
setenv(name,value)
setenv(name)
```

Description

`setenv(name,value)` sets the value of an environment variable belonging to the underlying operating system. Inputs `name` and `value` are both strings. If `name` already exists as an environment variable, then `setenv` replaces its current value with the string given in `value`. If `name` does not exist, `setenv` creates a new environment variable called `name` and assigns `value` to it.

`setenv(name)` is equivalent to `setenv(name, '')` and assigns a null value to the variable `name`. On the Microsoft Windows platform, this is equivalent to undefining the variable. On most UNIX platforms, it is possible to have an environment variable defined as empty.

The maximum number of characters in `name` is 2^{15} - 2 (or 32766). If `name` contains the character =, `setenv` throws an error. The behavior of environment variables with = in the name is not well-defined.

On all platforms, `setenv` passes the `name` and `value` strings to the operating system unchanged. Special characters such as `;`, `/`, `:`, `$`, `%`, etc. are left unexpanded and intact in the variable value.

Values assigned to variables using `setenv` are picked up by any process that is spawned using the MATLAB `system`, `unix`, `dos` or `!` functions. You can retrieve any value set with `setenv` by using `getenv(name)`.

Examples

% Set and retrieve a new value for the environment variable `TEMP`:

```
setenv('TEMP', 'C:\TEMP');
getenv('TEMP')
```

% Append the `Perl\bin` folder to your system `PATH` variable:

```
setenv('PATH', [getenv('PATH') ';D:\Perl\bin']);
```

See Also

`getenv` | `system` | `unix` | `dos` | `!`

setfield

Purpose

Assign values to structure array field

Syntax

```
s = setfield(s,'field',value)
s = setfield(s,{sIndx1,...,sIndxM},'field',{fIndx1,...,
   fIndxN},value)
```

Description

`s = setfield(s,'field',value)`, where `s` is a 1-by-1 structure, sets the contents of the specified field, equivalent to `s.field = value`. If `s` does not contain the specified *field*, the `setfield` function creates the field and assigns the specified value. Pass field references as strings.

`s = setfield(s,{sIndx1,...,sIndxM},'field',{fIndx1,...,fIndxN},value)` sets the contents of the specified field, equivalent to `s(sIndx1,...,sIndxM).field(fIndx1,...,fIndxN) = value`. The `setfield` function supports multiple sets of *field* and *fIndx* inputs. If structure `s` or any of the fields is a nonscalar structure, the *Indx* inputs associated with that input are required. Otherwise, the *Indx* inputs are optional. If you specify a single colon operator for an index input, enclose it in single quotation marks: `':'`.

Tips

- For most cases, add data to a structure array by indexing rather than using the `setfield` function. For more information, see “Access Data in a Structure Array” and “Generate Field Names from Variables”.
- Call `setfield` to simplify references to structure arrays with nested fields, as shown in the Examples section.

Examples

Add values to a structure that contains nested fields:

```
grades = [];
level = 5;
semester = 'Fall';
subject = 'Math';
student = 'John_Doe';
fieldnames = {semester subject student}
newGrades_Doe = [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];
```

```
grades = setfield(grades, {level}, ...
                  fieldnames{:}, {10, 21:30}, ...
                  newGrades_Doe);

% View the new contents.
grades(level).(semester).(subject).(student)(10, 21:30)
```

Using the structure defined in the previous example, remove the tenth row of the specified field:

```
grades = setfield(grades, {level}, fieldnames{:}, {10,':'}, []);
```

See Also

getfield | fieldnames | isfield | orderfields | rmfield

How To

- "Generate Field Names from Variables"
- "Access Data in a Structure Array"

setpixelposition

Purpose

Set component position in pixels

Syntax

```
setpixelposition(handle,position)
setpixelposition(handle,position,recursive)
```

Description

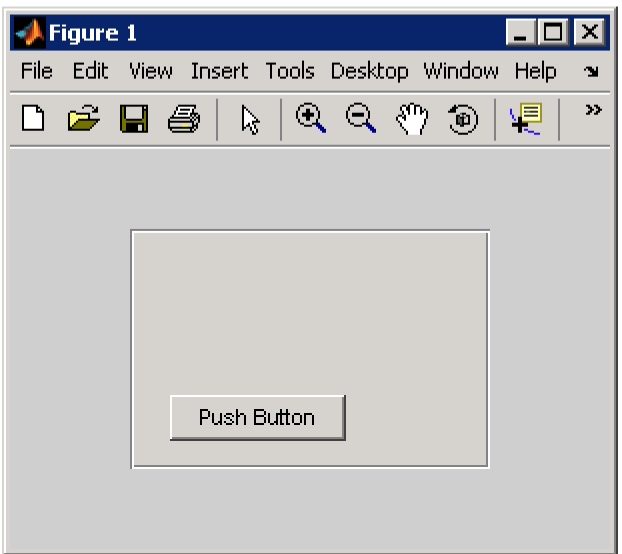
`setpixelposition(handle,position)` sets the position of the component specified by `handle`, to the specified position relative to its parent. `position` is a four-element vector that specifies the location and size of the component: [pixels from left, pixels from bottom, pixels across, pixels high].

`setpixelposition(handle,position,recursive)` sets the position as above. If Boolean `recursive` is true, the position is set relative to the parent figure of `handle`.

Examples

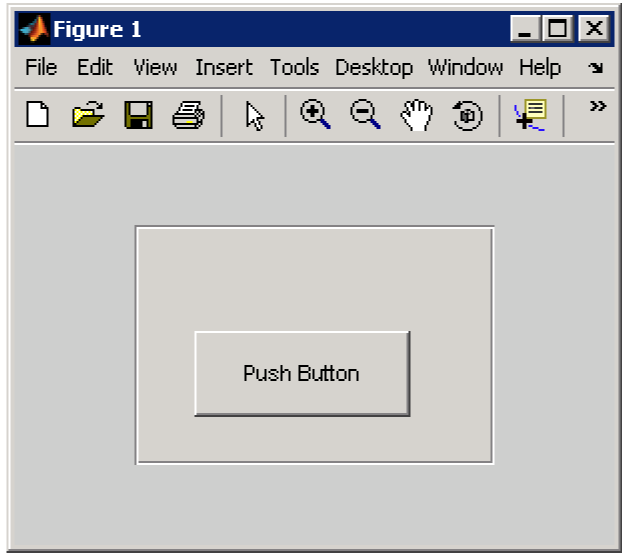
This example first creates a push button within a panel.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton','Units','normalized',...
               'String','Push Button','Position',[.1 .1 .5 .2]);
```



The example then retrieves the position of the push button and changes its position with respect to the panel.

```
pos1 = getpixelposition(h1);
setpixelposition(h1,pos1 + [10 10 25 25]);
```



See Also

getpixelposition | uicontrol | uipanel

Purpose Set preference

Syntax

```
setpref('group','pref',val)
setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,
   valn})
```

Description

`setpref('group','pref',val)` sets the preference specified by `group` and `pref` to the value `val`. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects. Setting a preference that does not yet exist causes it to be created.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g., `'MathWorks_GUIDE_ApplicationPrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,valn})` sets each preference specified in the cell array of names to the corresponding value.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

Use `addpref` to create a preference group called `mytoolbox` and a preference within it called `version`, and then modify the contents of `version` using `setpref`:

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')

ans =
1.0

setpref('mytoolbox','version',{'1.0','beta'})
```

```
getpref('mytoolbox','version')

ans =
    '1.0'    'beta'
```

See Also

addpref | getpref | ispref | rmpref | uigetpref | uisetpref

Purpose

Set string flag

Note `setstr` is not recommended. Use `char` instead.

Description

This MATLAB 4 function has been renamed `char` in MATLAB 5.

Tiff.setSubDirectory

Purpose

Make subIFD specified by byte offset current IFD

Syntax

`tiffobj.setSubDirectory(offset)`

Description

`tiffobj.setSubDirectory(offset)` sets the subimage file directory (subIFD) specified by `offset` the current IFD. The offset value is given in bytes. Use this method when you want to access subIFDs linked through the `SubIFD` tag.

Examples

Open a TIFF file and read the value of the `SubIFD` tag in the current IFD. The `SubIFD` tag contains byte offsets that specify the location of subIFDs in the IFD. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path. The TIFF file should contain subIFDs.

```
t = Tiff('myfile.tif','r');
%
% Read the value of the SubIFD tag to get subdirectory offsets.
offsets = t.getTag('SubIFD');
%
% Set one of the subdirectories (if more than one) as the current directo
t.setSubDirectory(offsets(1));
```

References

This method corresponds to the `TIFFSetSubDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

See Also

`Tiff.setDirectory`

Tutorials

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

Purpose

Set value of tag

Syntax

```
tiffobj.setTag(tagId,tagValue)
tiffobj.setTag(tagStruct)
```

Description

`tiffobj.setTag(tagId,tagValue)` sets the value of the TIFF tag specified by `tagId` to the value specified by `tagValue`. You can specify `tagId` as a character string (`'ImageWidth'`) or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

`tiffobj.setTag(tagStruct)` sets the values of all of the tags with name/value fields in `tagStruct`. The names of fields in `tagstruct` must be the name of TIFF tags.

Note If you are modifying a tag rather than creating it, you must use the `Tiff.rewriteDirectory` method after using the `Tiff.setTag` method.

Examples

Create a structure with fields named after TIFF tags and assign values to the fields. Pass this structure to the `setTag` method to set the values of these tags. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');

tagStruct.ImageWidth = 1600;
tagStruct.ImageLength = 3200;
tagStruct.Photometric = Tiff.Photometric.RGB;
tagStruct.BitsPerSample = 8;
tagStruct.SamplesPerPixel = 3;
tagStruct.TileWidth = 160;
```

```
tagStruct.TileLength = 320;
tagStruct.PlanarConfiguration = Tiff.PlanarConfiguration.Chunky;
tagStruct.Software = 'MATLAB';
t.setTag(tagStruct);
```

References

This method corresponds to the `TIFFSetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

See Also

`Tiff.getTag`

Tutorials

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

Purpose Change name of `timeseries` object in `tscollection`

Syntax

```
tsc = settimeseriesnames(tsc,old,new)
```

Description `tsc = settimeseriesnames(tsc,old,new)` replaces the `old` name of `timeseries` object with the new name in tsc.

See Also `tscollection`

setxor

Purpose

Set exclusive OR of two arrays

Syntax

```
C = setxor(A,B)
C = setxor(A,B,'rows')
[C,ia,ib] = setxor(A,B)
[C,ia,ib] = setxor(A,B,'rows')

[C,ia,ib] = setxor( ___ ,setOrder)

[C,ia,ib] = setxor(A,B,'legacy')

[C,ia,ib] = setxor(A,B,'rows','legacy')
```

Description

`C = setxor(A,B)` returns the values of `A` and `B` that are not in their intersection (the symmetric difference). The values of `C` are in sorted order.

`C = setxor(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns the rows of matrices `A` and `B` that are not in their intersection. The rows of the matrix `C` are in sorted order.

The `'rows'` option does not support cell arrays.

`[C,ia,ib] = setxor(A,B)` also returns index vectors `ia` and `ib`, such that `C` is a sorted combination of the elements `A(ia)` and `B(ib)`.

`[C,ia,ib] = setxor(A,B,'rows')` also returns index vectors `ia` and `ib`, such that `C` is a sorted combination of the rows of `A(ia,:)` and `B(ib,:)`.

`[C,ia,ib] = setxor( ___ ,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A` and `B`. If no value is specified, the default is `'sorted'`.

`[C,ia,ib] = setxor(A,B,'legacy')` and `[C,ia,ib] = setxor(A,B,'rows','legacy')` preserve the behavior of the `setxor` function from R2012b and prior releases.

Input Arguments

A,B - Input arrays

vectors | matrices | N-D arrays

Input arrays, specified as vectors, matrices, or N-D arrays whose elements can be any numeric, `logical`, or `char` data type. `A` and `B` also can be cell arrays of strings. Furthermore, `A` and `B` can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option), where the second output of this method is `double` or another built-in numeric class
- `eq`
- `ne`

These objects include heterogeneous arrays derived from the same root class.

`A` and `B` must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.

If you specify the `'rows'` option, `A` and `B` must have the same number of columns.

Data Types
`double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | cell`
Complex Number Support: Yes

setOrder - Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in `C`.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: `C = setxor([5 1 3],[4 1 2],'sorted')` returns `C = [2 3 4 5]`.
'stable'	The values (or rows) in C return in the same order as in A and B. For example: `C = setxor([5 1 3],[4 1 2],'stable')` returns `C = [5 3 4 2]`.

Data Types
char

Output Arguments

C - Symmetric difference array

vector | matrix

Symmetric difference array, returned as a vector or matrix. The following describes the shape of C when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then C is a column vector unless both A and B are row vectors.
- If the 'rows' flag is not specified and both A and B are row vectors, then C is a row vector.
- If the 'rows' flag is specified, then C is a matrix containing the rows of A and B that are not in the intersection.
- If all the values (or rows) of A are also in B, then C is an empty matrix.

The class of the inputs A and B determines the class of C:

- If the class of A and B are the same, then C is the same class.
- If you combine a char or nondouble numeric class with double, then C is the same class as the nondouble input.
- If you combine a logical class with double, then C is double.

- If you combine a cell array of strings with `char`, then `C` is a cell array of strings.

ia - Index to `A`
column vector

Index to `A`, returned as a column vector when the `'legacy'` flag is not specified. `ia` identifies the values (or rows) in `A` that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in `A`, then `ia` contains the index to the first occurrence of the value (or row).

ib - Index to `B`
column vector

Index to `B`, returned as a column vector when the `'legacy'` flag is not specified. `ib` identifies the values (or rows) in `B` that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in `B`, then `ib` contains the index to the first occurrence of the value (or row).

Examples

Symmetric Difference of Two Vectors

Define two vectors with a value in common.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

Find the values of `A` and `B` that are not in their intersection.

```
C = setxor(A,B)
```

```
C =

     2     3     4     5
```

Symmetric Difference of Two Vectors and the Indices to the Different Values

Define two vectors with a value in common.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

Find the values of `A` and `B` that are not in their intersection as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = setxor(A,B)

C =

     2     3     4     5

ia =

     3
     1

ib =

     3
     1
```

`C` is a sorted combination of the elements `A(ia)` and `B(ib)`.

Symmetric Difference of the Rows in Two Matrices

Define two matrices with rows in common.

```
A = [7 8 9; 7 7 1; 7 7 1; 1 2 3; 4 5 6];
B = [1 2 3; 4 5 6; 7 7 2];
```

Find the rows of `A` and `B` that are not in their intersection as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = setxor(A,B,'rows')

C =
```

```
     7     7     1
     7     7     2
     7     8     9

ia =

     2
     1

ib =

     3
```

`C` is a sorted combination of the rows of `A(ia,:)` and `B(ib,:)`.

Symmetric Difference of Two Vectors in a Specified Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` if you want the values in `C` to have the same order as `A` and `B`.

```
A = [5 1 3 3 3]; B = [4 1 2];
[C,ia,ib] = setxor(A,B,'stable')
```

```
C =

     5     3     4     2

ia =

     1
     3

ib =
```

```
     1
     3
```

Alternatively, you can specify `'sorted'` order.

```
[C,ia,ib] = setxor(A,B,'sorted')
```

```
C =

     2     3     4     5

ia =

     3
     1

ib =

     3
     1
```

Symmetric Difference of Vectors Containing NaNs

Define two vectors containing `NaN`.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Find the symmetric difference of vectors `A` and `B`.

```
C = setxor(A,B)
```

```
C =

   NaN   NaN   NaN   NaN
```

The `setxor` function treats `NaN` values as distinct.

Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Find the strings that are not in the intersection of A and B.

```
[C,ia,ib] = setxor(A,B)

C =

    'dog'    'dog '    'fish'    'fish '

ia =

     1
     3

ib =

     1
     3
```

setxor treats trailing white space in cell arrays of strings as distinct characters.

Symmetric Difference of Vectors of Different Classes and Shapes

Create a column vector character array.

```
A = ['A';'B';'C'], class(A)
```

```
A =

A
B
C

ans =

char
```

Create a row vector containing elements of numeric type `double`.

```
B = [66 67 68], class(B)
```

```
B =

    66    67    68

ans =

double
```

Find the symmetric difference of `A` and `B`.

```
C = setxor(A,B)
```

```
C =

A
D
```

The result is a column vector character array.

```
class(C)
```

```
ans =

char
```

Symmetric Difference of Char and Cell Array of Strings

Create a character array, `A`.

```
A = ['cat';'dog';'fox';'pig'];
class(A)
```

```
ans =

char
```

Create a cell array of strings, `B`.

```
B={'dog','cat','fish','horse'};
class(B)
```

```
ans =

cell
```

Find the strings that are not in the intersection of `A` and `B`.

```
C = setxor(A,B)
```

```
C =

    'fish'
    'fox'
    'horse'
    'pig'
```

The result, `C`, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

Preserve Legacy Behavior of setxor

Use the `'legacy'` flag to preserve the behavior of `setxor` from R2012b and prior releases in your code.

Find the symmetric difference of `A` and `B` with the current behavior.

```
A = [5 1 3 3 3]; B = [4 1 2 2];
[C1,ia1,ib1] = setxor(A,B)

C1 =

     2     3     4     5

ia1 =

     3
     1

ib1 =

     3
     1
```

Find the symmetric difference and preserve the legacy behavior.

```
[C2,ia2,ib2] = setxor(A,B,'legacy')

C2 =

     2     3     4     5

ia2 =
```

```
     5     1

ib2 =

     4     1
```

shading

Purpose

Set color shading properties

Syntax

```
shading flat
shading faceted
shading interp
shading(axes_handle,...)
```

Description

The `shading` function controls the color shading of surface and patch graphics objects.

`shading flat` each mesh line segment and face has a constant color determined by the color value at the endpoint of the segment or the corner of the face that has the smallest index or indices.

`shading faceted` flat shading with superimposed black mesh lines. This is the default shading mode.

`shading interp` varies the color in each line segment and face by interpolating the colormap index or true color value across the line or face.

`shading(axes_handle,...)` applies the shading type to the objects in the axes specified by `axes_handle`, instead of the current axes. Use quoted strings when using a function form. For example:

```
shading(gca,'interp')
```

Examples

Compare a flat, faceted, and interpolated-shaded sphere.

```
subplot(3,1,1)
sphere(16)
axis square
shading flat
title('Flat Shading')

subplot(3,1,2)
sphere(16)
axis square
shading faceted
```

```
title('Faceted Shading')

subplot(3,1,3)
sphere(16)
axis square
shading interp
title('Interpolated Shading')
```

`fill` | `fill3` | `hidden` | `light` | `lighting` | `mesh` | `patch` | `pcolor` | `surf` | patch | surface

shg

Purpose Show most recent graph window

Syntax `shg`

Description `shg` makes the current figure visible and raises it above all other figures on the screen. This is identical to using the command `figure(gcf)`.

See Also `figure` | `gca` | `gcf`

Purpose

Shift dimensions

Syntax

```
B = shiftdim(X,n)
[B,nshifts] = shiftdim(X)
```

Description

`B = shiftdim(X,n)` shifts the dimensions of `X` by `n`. When `n` is positive, `shiftdim` shifts the dimensions to the left and wraps the `n` leading dimensions to the end. When `n` is negative, `shiftdim` shifts the dimensions to the right and pads with singletons.

`[B,nshifts] = shiftdim(X)` returns the array `B` with the same number of elements as `X` but with any leading singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. `nshifts` is the number of dimensions that are removed.

If `X` is a scalar, `shiftdim` has no effect.

Examples

The `shiftdim` command is handy for creating functions that, like `sum` or `diff`, work along the first nonsingleton dimension.

```
a = rand(1,1,3,1,2);
[b,n]  = shiftdim(a); % b is 3-by-1-by-2 and n is 2.
c = shiftdim(b,-n);   % c == a.
d = shiftdim(a,3);    % d is 1-by-2-by-1-by-1-by-3.
```

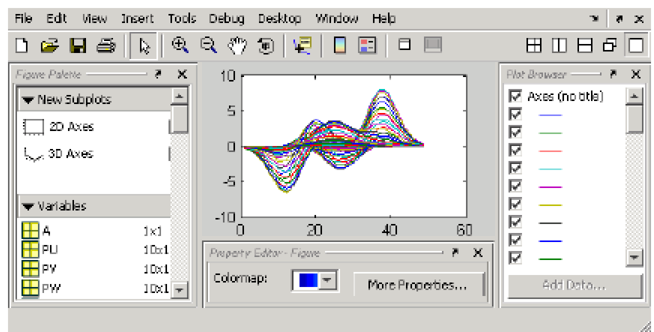
showplottool

Purpose

Show or hide figure plot tool



Syntax

```
showplottool('tool')
showplottool('on','tool')
showplottool('off','tool')
showplottool('toggle','tool')
showplottool(figure_handle,...)
```

Description

`showplottool('tool')` shows the specified plot tool on the current figure. *`tool`* can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

`showplottool('on','tool')` shows the specified plot tool on the current figure.

`showplottool('off','tool')` hides the specified plot tool on the current figure.

`showplottool('toggle','tool')` toggles the visibility of the specified plot tool on the current figure.

`showplottool(figure_handle,...)` operates on the specified figure instead of the current figure.

Note When you dock, undock, resize, or reposition a plotting tool and then close it, it will still be configured as you left it the next time you open it. There is no command to reset plotting tools to their original, default locations.

Alternatives

Click the larger Plotting Tools icon on the figure toolbar to collectively enable plotting tools, and the smaller icon to collectively disable them. Individually select the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see "Plotting Tools — Interactive Plotting".

`figurepalette` | `plotbrowser` | `plottools` | `propertyeditor`

shrinkfaces

Purpose

Reduce size of patch faces

Syntax

```
shrinkfaces(p,sf)
nfv = shrinkfaces(p,sf)
nfv = shrinkfaces(fv,sf)
shrinkfaces(p)
nfv = shrinkfaces(f,v,sf)
[nf,nv] = shrinkfaces(...)
```

Description

`shrinkfaces(p,sf)` shrinks the area of the faces in patch `p` to shrink factor `sf`. A shrink factor of 0.6 shrinks each face to 60% of its original area. If the patch contains shared vertices, the MATLAB software creates nonshared vertices before performing the face-area reduction.

`nfv = shrinkfaces(p,sf)` returns the face and vertex data in the struct `nfv`, but does not set the `Faces` and `Vertices` properties of patch `p`.

`nfv = shrinkfaces(fv,sf)` uses the face and vertex data from the struct `fv`.

`shrinkfaces(p)` and `shrinkfaces(fv)` (without specifying a shrink factor) assume a shrink factor of 0.3.

`nfv = shrinkfaces(f,v,sf)` uses the face and vertex data from the arrays `f` and `v`.

`[nf,nv] = shrinkfaces(...)` returns the face and vertex data in two separate arrays instead of a struct.

Examples

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). Two isosurfaces provide a before and after view of the effects of shrinking the face size.

- First `reducevolume` samples the flow data at every other point and then `isosurface` generates the faces and vertices data.
- The `patch` command accepts the face/vertex struct and draws the first (`p1`) isosurface.

- Use the daspect, view, and axis commands to set up the view and then add a title.
- The shrinkfaces command modifies the face/vertex data and passes it directly to patch.

```
[x,y,z,v] = flow;
[x,y,z,v] = reducevolume(x,y,z,v,2);
fv = isosurface(x,y,z,v,-3);
p1 = patch(fv);
set(p1,'FaceColor','red','EdgeColor',[.5,.5,.5]);
daspect([1 1 1]); view(3); axis tight
title('Original')

figure
p2 = patch(shrinkfaces(fv,.3));
set(p2,'FaceColor','red','EdgeColor',[.5,.5,.5]);
daspect([1 1 1]); view(3); axis tight
title('After Shrinking')
```

sign

Purpose

Signum function

Syntax

```
Y = sign(X)
```

Description

`Y = sign(X)` returns an array `Y` the same size as `X`, where each element of `Y` is:

- `1` if the corresponding element of `X` is greater than zero
- `0` if the corresponding element of `X` equals zero
- `-1` if the corresponding element of `X` is less than zero

For nonzero complex `X`, `sign(X) = X./abs(X)`.

See Also

`abs` | `conj` | `imag` | `real`

Purpose

Sine of argument in radians

Syntax

```
Y = sin(X)
```

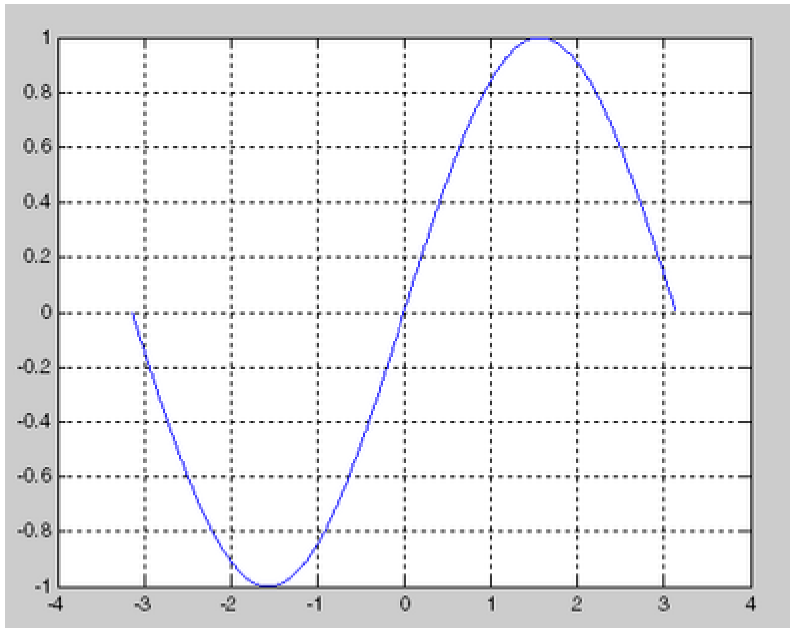
Description

`Y = sin(X)` returns the circular sine of the elements of `X`. The `sin` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the sine function over the domain $-\pi \le x \le \pi$.

```
x = -pi:0.01:pi;
plot(x,sin(x)), grid on
```



See Also

`sind` | `asin` | `asind` | `sinh`

sind

Purpose

Sine of argument in degrees

Syntax

```
Y = sind(X)
```

Description

`Y = sind(X)` returns the sine of the elements in `X`, which are expressed in degrees.

Input Arguments

X - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `sind` operation is element-wise when `X` is nonscalar.

Data Types
`single` | `double`
Complex Number Support: Yes

Output Arguments

Y - Sine of angle

scalar value | vector | matrix | N-D array

Sine of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Sine of 180 degrees compared to sine of radians

```
sind(180)

ans =

     0

sin(pi)

ans =

   1.2246e-16
```

Sine of vector of complex angles, specified in degrees

```
z = [90+i 15+2i 10+3i];
y = sind(z)
```

```
y =

   1.0002          0.2590 + 0.0337i   0.1739 + 0.0516i
```

See Also

sin | asind | asin

Purpose

Convert to single precision

Syntax

```
B = single(A)
```

Description

`B = single(A)` converts the matrix `A` to single precision, returning that value in `B`. `A` can be any numeric object (such as a `double`). If `A` is already single precision, `single` has no effect. Single-precision quantities require less storage than double-precision quantities, but have less precision and a smaller range.

The `single` class is primarily meant to be used to store single-precision values. Hence most operations that manipulate arrays without changing their elements are defined. Examples are `reshape`, `size`, the relational operators, subscripted assignment, and subscripted reference.

You can define your own methods for the `single` class by placing the appropriately named method in an `@single` folder within a folder on your path.

Examples

```
a = magic(4);
b = single(a);

whos
  Name      Size          Bytes  Class

  a         4x4             128  double array
  b         4x4              64  single array
```

See Also

`double`

sinh

Purpose

Hyperbolic sine of argument in radians

Syntax

```
Y = sinh(X)
```

Description

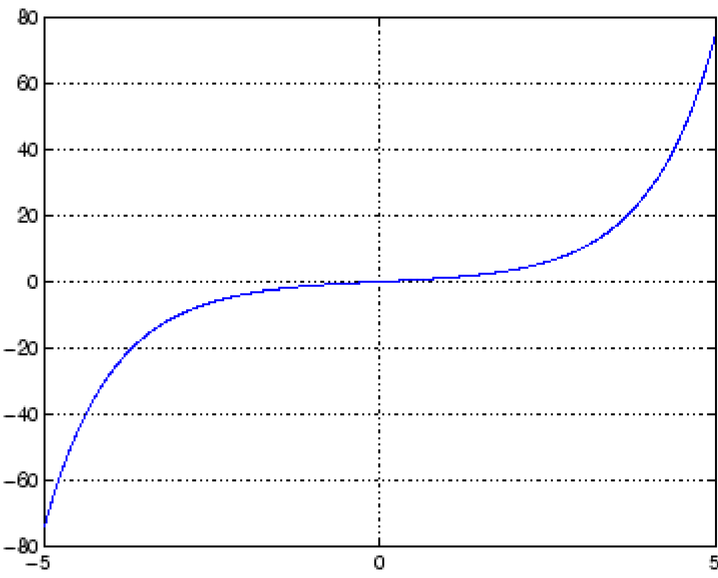
The `sinh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = sinh(X)` returns the hyperbolic sine of the elements of `X`.

Examples

Graph the hyperbolic sine function over the domain $-5 \le x \le 5$.

```
x = -5:0.01:5;
plot(x,sinh(x)), grid on
```



See Also

`sin` | `asinh` | `cosh`

size

Purpose Array dimensions

Syntax

```
d = size(X)
[m,n] = size(X)
m = size(X,dim)
[d1,d2,d3,...,dn] = size(X),
```

Description

`d = size(X)` returns the sizes of each dimension of array `X` in a vector `d` with `ndims(X)` elements. If `X` is a scalar, which MATLAB software regards as a 1-by-1 array, `size(X)` returns the vector `[1 1]`.

`[m,n] = size(X)` returns the size of matrix `X` in separate variables `m` and `n`.

`m = size(X,dim)` returns the size of the dimension of `X` specified by scalar `dim`.

`[d1,d2,d3,...,dn] = size(X)`, for `n` > 1, returns the sizes of the dimensions of the array `X` in the variables d1,d2,d3,...,dn, provided the number of output arguments `n` equals `ndims(X)`. If `n` does not equal `ndims(X)`, the following exceptions hold:

`n < ndims(X)`	`di` equals the size of the `i`th dimension of `X` for `0<i<n`, but `dn` equals the product of the sizes of the remaining dimensions of `X`, that is, dimensions `n` through `ndims(X)`.
`n > ndims(X)`	`size` returns ones in the “extra” variables, that is, those corresponding to `ndims(X)+1` through `n`.

Note For a Java array, `size` returns the length of the Java array as the number of rows. The number of columns is always 1. For a Java array of arrays, the result describes only the top level array.

Examples

Example 1

The size of the second dimension of `rand(2,3,4)` is 3.

```
m = size(rand(2,3,4),2)

m =
     3
```

Here the size is output as a single vector.

```
d = size(rand(2,3,4))

d =
     2     3     4
```

Here the size of each dimension is assigned to a separate variable.

```
[m,n,p] = size(rand(2,3,4))
m =
     2

n =
     3

p =
     4
```

Example 2

If `X = ones(3,4,5)`, then

```
[d1,d2,d3] = size(X)

d1 =        d2 =        d3 =
     3           4           5
```

But when the number of output variables is less than `ndims(X)`:

```
[d1,d2] = size(X)

d1 =        d2 =
     3           20
```

The "extra" dimensions are collapsed into a single product.

If `n > ndims(X)`, the "extra" variables all represent singleton dimensions:

```
[d1,d2,d3,d4,d5,d6] = size(X)

d1 =        d2 =        d3 =
     3           4           5

d4 =        d5 =        d6 =
     1           1           1
```

See Also

`exist` | `length` | `numel` | `whos`

Purpose

Size of `containers.Map` object

Syntax

```
dim = size(mapObj,1)
dimVector = size(mapObj)
[dim1,dim2,...,dimN] = size(mapObj)
```

Description

`dim = size(mapObj,1)` returns a scalar numeric value that indicates the number of key-value pairs in `mapObj`. If you call `size` with a numeric second input argument other than `1`, the `size` method returns the scalar numeric value `1`.

`dimVector = size(mapObj)` returns a two-element vector `[k,1]`, where `k` is the number of key-value pairs in `mapObj`.

`[dim1,dim2,...,dimN] = size(mapObj)` returns `[k,1,...,1]`.

Input Arguments

mapObj

Object of class `containers.Map`.

Output Arguments

dim

Scalar numeric value that indicates the number of key-value pairs in `mapObj`.

dimVector

Two-element numeric vector `[k,1]`, where `k` is the number of key-value pairs in `mapObj`.

[dim1,dim2,...,dimN]

Numeric scalar values. Variable `dim1` equals `k`, where `k` is the number of key-value pairs in `mapObj`. All other outputs equal `1`.

Examples

Determine the Size of a Map

Construct a map and find the number of key-value pairs:

```
myKeys = {'a','b','c'};
myValues = [1,2,3];
```

```
mapObj = containers.Map(myKeys,myValues);
dim = size(mapObj,1)
```

This code returns a scalar numeric value:

```
dim =
     3
```

If you do not specify a second input argument,

```
dimVector = size(mapObj)
```

then the `size` method returns a vector:

```
dimVector =
     3     1
```

See Also

`containers.Map` | `isKey` | `keys` | `length` | `values`

Purpose

Array dimensions

Syntax

```
allDims = size(matObj,variable)
[dim1,...,dimN] = size(matObj,variable)
selectedDim = size(matObj,variable,dim)
```

Description

`allDims = size(matObj,variable)` returns the size of each dimension of the specified variable in the file corresponding to `matObj`. Output `allDims` is a `1`-by-`m` vector, where `m = ndims(variable)`.

`[dim1,...,dimN] = size(matObj,variable)` returns the sizes of each dimension in separate output variables `dim1,...,dimN`.

`selectedDim = size(matObj,variable,dim)` returns the size of the specified dimension.

Tips

- Do not call `size` with the syntax `size(matObj.variable)`. This syntax loads the entire contents of the variable into memory. For very large variables, this load operation results in `Out of Memory` errors.

Input Arguments

matObj

Object created by the `matfile` function.

variable

String enclosed in single quotation marks that specifies the name of a variable in the MAT-file corresponding to `matObj`.

dim

Nonzero positive scalar integer that specifies a dimension of the variable.

Output Arguments

allDims

`1`-by-`m` vector of sizes of the dimensions of the specified variable, where `m = ndims(variable)`.

dim1,...,dimN

Scalar numeric values, where dimK contains the size of the Kth dimension of variable:

- If N < ndims(variable), then dimN, equals the product of the sizes of dimensions N through ndims(variable).
- If N > ndims(variable), the size method returns ones in the output variables corresponding to dimensions ndims(variable)+1 through N.

selectedDim

Scalar numeric value that contains the size of the selected dimension for the specified variable.

Examples

Find the size of the matrix topo in topography.mat without loading any data:

```
matObj = matfile('topography.mat');
[nrows,ncols] = size(matObj,'topo');
```

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable stocks in the example file stocks.mat:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj,'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
    avgs(idx) = mean(matObj.stocks(:,idx));
end
```

Create a three-dimensional array, and call the size method with different numbers of output arguments:

```
matObj = matfile('temp.mat','Writable',true);
matObj.X = rand(2,3,4);

d = size(matObj,'X')
d2 = size(matObj,'X',2)
[m,n] = size(matObj,'X')
[m1,m2,m3,m4] = size(matObj,'X')
```

This code returns

```
d =
     2     3     4

d2 =
     3

m =
     2
n =
    12

m1 =
     2
m2 =
     3
m3 =
     4
m4 =
     1
```

See Also

matfile | whos

size (serial)

Purpose

Size of serial port object array

Syntax

```
d = size(obj)
[m,n] = size(obj)
[m1,m2,m3,...,mn] = size(obj)
m = size(obj,dim)
```

Description

`d = size(obj)` returns the two-element row vector `d` containing the number of rows and columns in the serial port object, `obj`.

`[m,n] = size(obj)` returns the number of rows, `m` and columns, `n` in separate output variables.

`[m1,m2,m3,...,mn] = size(obj)` returns the length of the first `n` dimensions of `obj`.

`m = size(obj,dim)` returns the length of the dimension specified by the scalar `dim`. For example, `size(obj,1)` returns the number of rows.

See Also

`length`

Purpose

(Will be removed) Size of triangulation matrix

Note `size(TriRep)` will be removed in a future release. Use `size(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

`size(TR)`

Description

`size(TR)` provides size information for a triangulation matrix. The matrix is of size `mtri`-by-`nv`, where `mtri` is the number of simplices and `nv` is the number of vertices per simplex (triangle/tetrahedron, etc).

Input Arguments

`TR`	Triangulation matrix

Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

See Also

`size` | `delaunayTriangulation` | `triangulation`

size (tscollection)

Purpose Size of `tscollection` object

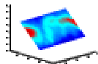
Syntax `size(tsc)`

Description `size(tsc)` returns `[n m]`, where `n` is the length of the time vector and `m` is the number of `tscollection` members.

See Also `length (tscollection)` | `isempty (tscollection)` | `tscollection`

Purpose

Volumetric slice plot



Syntax

```
slice(V,sx,sy,sz)
slice(X,Y,Z,V,sx,sy,sz)
slice(V,XI,YI,ZI)
slice(X,Y,Z,V,XI,YI,ZI)
slice(...,'method')
slice(axes_handle,...)
h = slice(...)
```

Description

`slice` displays orthogonal slice planes through volumetric data.

`slice(V,sx,sy,sz)` draws slices along the *x*, *y*, *z* directions in the volume `V` at the points in the vectors `sx`, `sy`, and `sz`. `V` is an *m*-by-*n*-by-*p* volume array containing data values at the default location `X = 1:n`, `Y = 1:m`, `Z = 1:p`. Each element in the vectors `sx`, `sy`, and `sz` defines a slice plane in the *x*-, *y*-, or *z*-axis direction.

`slice(X,Y,Z,V,sx,sy,sz)` draws slices of the volume `V`. `X`, `Y`, and `Z` are three-dimensional arrays specifying the coordinates for `V`. `X`, `Y`, and `Z` must be monotonic and orthogonally spaced (as if produced by the function `meshgrid`). The color at each point is determined by 3-D interpolation into the volume `V`.

`slice(V,XI,YI,ZI)` draws data in the volume `V` for the slices defined by `XI`, `YI`, and `ZI`. `XI`, `YI`, and `ZI` are matrices that define a surface, and the volume is evaluated at the surface points. `XI`, `YI`, and `ZI` must all be the same size.

`slice(X,Y,Z,V,XI,YI,ZI)` draws slices through the volume `V` along the surface defined by the arrays `XI`, `YI`, `ZI`.

`slice(...,'method')` specifies the interpolation method. `'method'` is `'linear'`, `'cubic'`, or `'nearest'`.

- `linear` specifies trilinear interpolation (the default).

- `cubic` specifies tricubic interpolation.
- `nearest` specifies nearest-neighbor interpolation.

`slice(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes object (`gca`). The axes `clim` property is set to span the finite values of `V`.

`h = slice(...)` returns a vector of handles to surface graphics objects.

Tips

The color drawn at each point is determined by interpolation into the volume `V`.

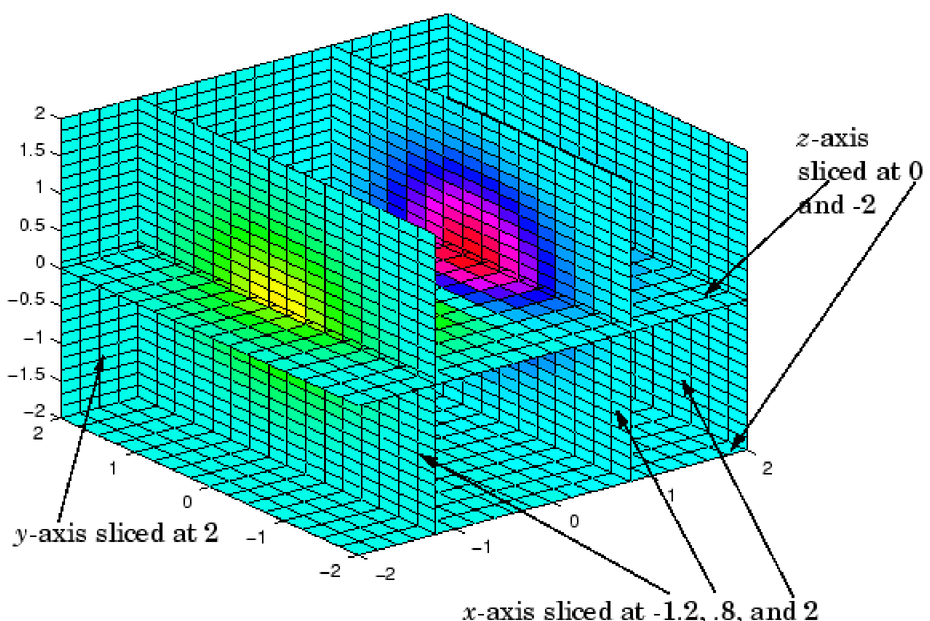
Examples

Visualize the function

$$v = xe^{\left(-x^2 - y^2 - z^2\right)}$$

over the range $-2 \le x \le 2$, $-2 \le y \le 2$, $-2 \le z \le 2$:

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);
v = x.*exp(-x.^2-y.^2-z.^2);
xslice = [-1.2,.8,2]; yslice = 2; zslice = [-2,0];
slice(x,y,z,v,xslice,yslice,zslice)
colormap hsv
```



Slicing At Arbitrary Angles

You can also create slices that are oriented in arbitrary planes. To do this,

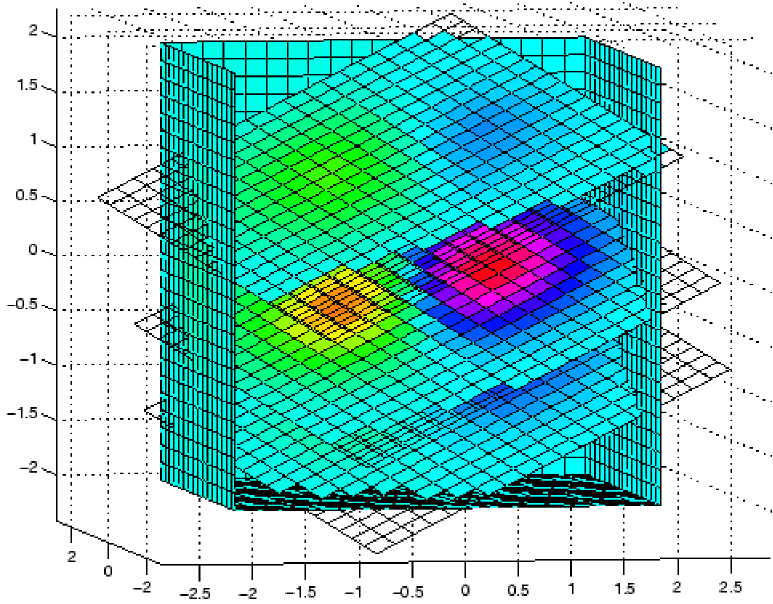
- Create a slice surface in the domain of the volume (`surf`, `linspace`).
- Orient this surface with respect to the axes (`rotate`).
- Get the `XData`, `YData`, and `ZData` of the surface (`get`).
- Use this data to draw the slice plane within the volume.

For example, these statements slice the volume in the first example with a rotated plane. Placing these commands within a `for` loop "passes" the plane through the volume along the *z*-axis.

```
for i = -2:.5:2
 hsp = surf(linspace(-2,2,20),linspace(-2,2,20),zeros(20)+i);
 rotate(hsp,[1,-1,1],30)
```

```
    xd = get(hsp,'XData');
    yd = get(hsp,'YData');
    zd = get(hsp,'ZData');
    delete(hsp)
    slice(x,y,z,v,[-2,2],2,-2) % Draw some volume boundaries
    hold on
    slice(x,y,z,v,xd,yd,zd)
    hold off
    axis tight
    view(-5,10)
    drawnow
end
```

The following picture illustrates three positions of the same slice surface as it passes through the volume.



Slicing with a Nonplanar Surface

You can slice the volume with any surface. This example probes the volume created in the previous example by passing a spherical slice surface through the volume.

```
[xsp,ysp,zsp] = sphere;
slice(x,y,z,v,[-2,2],2,-2)  % Draw some volume boundaries

for i = -3:.2:3
 hsp = surface(xsp+i,ysp,zsp);
 rotate(hsp,[1 0 0],90)
 xd = get(hsp,'XData');
 yd = get(hsp,'YData');
 zd = get(hsp,'ZData');
 delete(hsp)
 hold on
 hslicer = slice(x,y,z,v,xd,yd,zd);
 axis tight
 xlim([-3,3])
 view(-10,35)
 drawnow
 delete(hslicer)
 hold off
end
```

The following picture illustrates three positions of the spherical slice surface as it passes through the volume.

How To

- Exploring Volumes with Slice Planes

Purpose

Smooth 3-D data

Syntax

Description

W = smooth3(V) smooths the input data V and returns the smoothed data in W.

W = smooth3(V,'*filter*') *filter* determines the convolution kernel and can be the strings

- 'gaussian'
- 'box' (default)

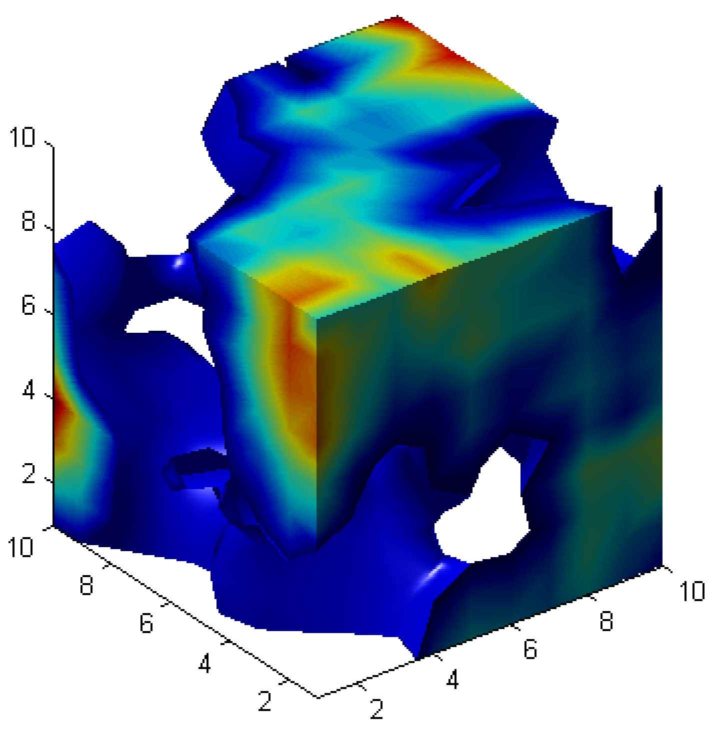
W = smooth3(V,'*filter*',size) sets the size of the convolution kernel (default is [3 3 3]). If size is scalar, then size is interpreted as [size, size, size].

W = smooth3(V,'*filter*',size,sd) sets an attribute of the convolution kernel. When *filter* is gaussian, sd is the standard deviation (default is .65).

Examples

This example smooths some random 3-D data and then creates an isosurface with end caps.

```
rng(9,'twister')
data = rand(10,10,10);
data = smooth3(data,'box',5);
patch(isocaps(data,.5),'FaceColor','interp','EdgeColor','none');
p1 = patch(isosurface(data,.5),'FaceColor','blue','EdgeColor','none');
isonormals(data,p1)
view(3);
axis vis3d tight
camlight left;
lighting phong
```



See Also

isocaps | isonormals | isosurface | patch

How To

- Displaying an Isosurface

Purpose

Force snapshot of image for inclusion in published document

Syntax

```
snapnow
```

Description

The `snapnow` command forces a snapshot of the image or plot that the code has most recently generated for presentation in a published document. The output appears in the published document at the end of the cell that contains the `snapnow` command. When used outside the context of publishing a file, `snapnow` has the same behavior as `drawnow`. That is, if you run a file that contains the `snapnow` command, the MATLAB software interprets it as though it were a `drawnow` command.

Examples

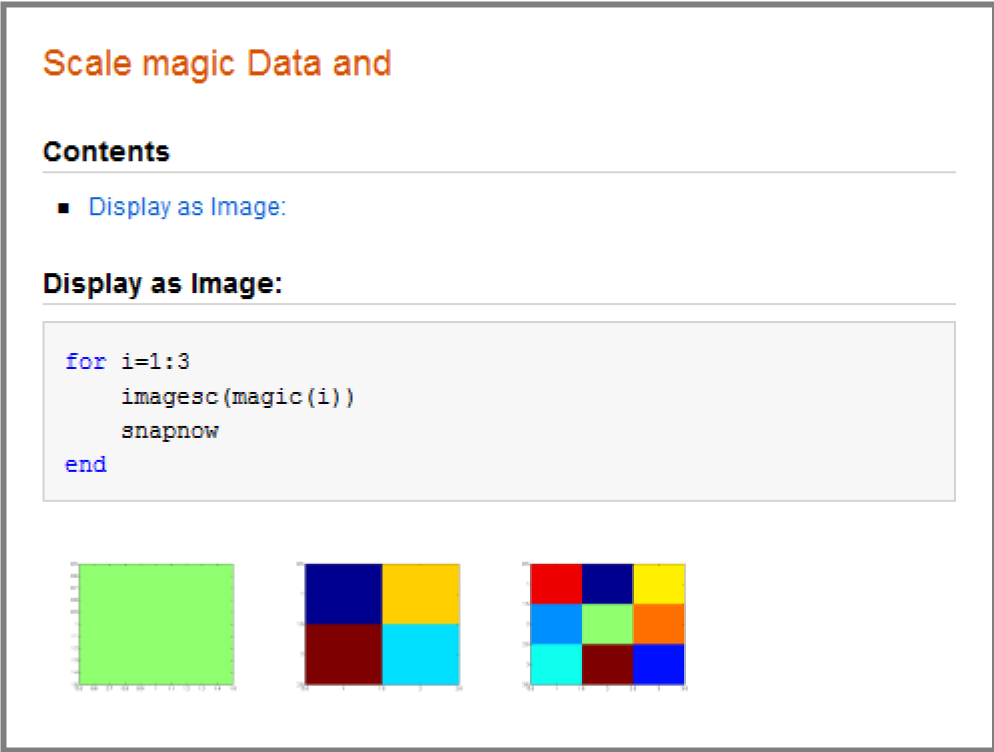
This example demonstrates the difference between publishing code that contains the `snapnow` command and running that code. The first image shows the results of publishing the code and the second image shows the results of running the code.

Suppose you have a file that contains the following code:

```
%% Scale magic Data and
%% Display as Image:

for i=1:3
    imagesc(magic(i))
    snapnow
end
```

When you publish the code to HTML, the published document contains a title, a table of contents, the commented text, the code, and each of the three images produced by the `for` loop. (In the published document shown, the size of the images have been reduced.)



When you run the code, a single Figure window opens and MATLAB updates the image within this window as it evaluates each iteration of the `for` loop. Each successive image replaces the one that preceded it, so that the Figure window appears as follows when the code evaluation completes.

drawnow

Concepts

- "Image Snapshot"

Purpose

Sort array elements in ascending or descending order

Syntax

```
B = sort(A)
B = sort(A,dim)
B = sort(...,mode)
[B,IX] = sort(A,...)
```

Description

`B = sort(A)` sorts the elements along different dimensions of an array, and arranges those elements in ascending order.

If A is a ...	sort(A) ...
Vector	Sorts the elements of `A`.
Matrix	Sorts each column of `A`.
Multidimensional array	Sorts `A` along the first non-singleton dimension, and returns an array of sorted vectors.
Cell array of strings	Sorts the strings in ascending ASCII dictionary order, and returns a vector cell array of strings. The sort is case-sensitive; uppercase letters appear in the output before lowercase. You cannot use the `dim` or `mode` options with a cell array.

Integer, floating-point, logical, and character arrays are permitted. Floating-point arrays can be complex. For elements of `A` with identical values, the order of these elements is preserved in the sorted list. When `A` is complex, the elements are sorted by magnitude, i.e., `abs(A)`, and where magnitudes are equal, further sorted by phase angle, i.e., `angle(A)`, on the interval $[-\pi, \pi]$. If `A` includes any `NaN` elements, `sort` places these at the high end.

`B = sort(A,dim)` sorts the elements along the dimension of `A` specified by a scalar `dim`.

`B = sort(...,mode)` sorts the elements in the specified direction, depending on the value of `mode`.

'ascend'	Ascending order (default)
'descend'	Descending order

[B,IX] = sort(A,...) also returns an array of indices IX, where size(IX) == size(A). If A is a vector, B = A(IX). If A is an m-by-n matrix, then each column of IX is a permutation vector of the corresponding column of A, such that

```
for j = 1:n
    B(:,j) = A(IX(:,j),j);
end
```

If A has repeated elements of equal value, the returned indices preserve the original ordering.

Sorting Complex Entries

If A has complex entries r and s, sort orders them according to the following rule: r appears before s in sort(A) if either of the following hold:

- abs(r) < abs(s)
- abs(r) = abs(s) and angle(r)<angle(s)

  where $-\pi < angle(r) \leq \pi$

For example,

```
v = [1 -1 i -i];
angle(v)

ans =

        0    3.1416    1.5708   -1.5708
sort(v)

ans =

       0 - 1.0000i   1.0000
```

```
      0 + 1.0000i  -1.0000
```

Note `sort` uses a different rule for ordering complex numbers than do the relational operators. See the Relational Operators reference page for more information.

Examples

Example 1

Sort horizontal vector `A`:

```
A = [78 23 10 100 45 5 6];

sort(A)
ans =
     5     6    10    23    45    78   100
```

Example 2

Sort matrix `A` in each dimension:

```
A = [ 3 7 5
      0 4 2 ];

sort(A,1)

ans =
     0     4     2
     3     7     5

sort(A,2)

ans =
     3     5     7
     0     2     4
```

Sort it again, this time returning an array of indices for the result:

```
[B, IX] = sort(A, 2)

B =
     3     5     7
     0     2     4

IX =
     1     3     2
     1     3     2
```

Example 3

Sort each column of matrix A in descending order:

```
A = [ 3  7  5
      6  8  3
      0  4  2 ];

sort(A,1,'descend')

ans =
     6   8   5
     3   7   3
     0   4   2
```

This is equivalent to

```
sort(A,'descend')

ans =
     6   8   5
     3   7   3
     0   4   2
```

sortrows

Purpose

Sort rows in ascending order

Syntax

```
B = sortrows(A)
B = sortrows(A,column)
[B,index] = sortrows(A,...)
```

Description

`B = sortrows(A)` sorts the rows of `A` in ascending order. Argument `A` must be either a matrix or a column vector.

For strings, this is the familiar dictionary sort. When `A` is complex, the elements are sorted by magnitude, and, where magnitudes are equal, further sorted by phase angle on the interval $[-\pi, \pi]$.

`B = sortrows(A,column)` sorts the matrix based on the columns specified in the vector `column`. If an element of `column` is positive, the MATLAB software sorts the corresponding column of matrix `A` in ascending order; if an element of `column` is negative, MATLAB sorts the corresponding column in descending order. For example, `sortrows(A,[2 -3])` sorts the rows of `A` first in ascending order for the second column, and then by descending order for the third column.

`[B,index] = sortrows(A,...)` also returns an index vector `index`.

If `A` is a column vector, then `B = A(index)`. If `A` is an `m`-by-`n` matrix, then `B = A(index,:)`.

Examples

Start with an arbitrary matrix, `A`:

```
A=floor(gallery('uniformdata',[6 7],0)*100);
A(1:4,1)=95;  A(5:6,1)=76;  A(2:4,2)=7;  A(3,3)=73
A =
    95    45    92    41    13     1    84
    95     7    73    89    20    74    52
    95     7    73     5    19    44    20
    95     7    40    35    60    93    67
    76    61    93    81    27    46    83
    76    79    91     0    19    41     1
```

When called with only a single input argument, `sortrows` bases the sort on the first column of the matrix. For any rows that have equal elements in a particular column, (e.g., `A(1:4,1)` for this matrix), sorting is based on the column immediately to the right, (`A(1:4,2)` in this case):

```
B = sortrows(A)
B =
    76    61    93    81    27    46    83
    76    79    91     0    19    41     1
    95     7    40    35    60    93    67
    95     7    73     5    19    44    20
    95     7    73    89    20    74    52
    95    45    92    41    13     1    84
```

When called with two input arguments, `sortrows` bases the sort entirely on the column specified in the second argument. Rows that have equal elements in the specified column, (e.g., `A(2:4,:)`, if sorting matrix `A` by column 2) remain in their original order:

```
C = sortrows(A,2)
C =
    95     7    73    89    20    74    52
    95     7    73     5    19    44    20
    95     7    40    35    60    93    67
    95    45    92    41    13     1    84
    76    61    93    81    27    46    83
    76    79    91     0    19    41     1
```

This example specifies two columns to sort by: columns 1 and 7. This tells `sortrows` to sort by column 1 first, and then for any rows with equal values in column 1, to sort by column 7:

```
D = sortrows(A,[1 7])
D =
    76    79    91     0    19    41     1
    76    61    93    81    27    46    83
    95     7    73     5    19    44    20
    95     7    73    89    20    74    52
```

```
    95     7    40    35    60    93    67
    95    45    92    41    13     1    84
```

Sort the matrix using the values in column 4 this time and in reverse order:

```
E = sortrows(A, -4)
E =
    95     7    73    89    20    74    52
    76    61    93    81    27    46    83
    95    45    92    41    13     1    84
    95     7    40    35    60    93    67
    95     7    73     5    19    44    20
    76    79    91     0    19    41     1
```

See Also

`issorted` | `sort`

Purpose

Convert matrix of signal data to sound

Syntax

```
sound(y)
sound(y,Fs)
sound(y,Fs,nBits)
```

Description

`sound(y)` sends audio signal `y` to the speaker at the default sample rate of 8192 hertz.

`sound(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`sound(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

Input Arguments

y - Audio data

column vector | `m`-by-2 matrix

Audio data, specified as an `m`-by-1 column vector for single-channel (mono) audio, or an `m`-by-2 matrix for stereo playback, where `m` is the number of audio samples. If `y` is an `m`-by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

Data Types
`double`

Fs - Sample rate

8192 (default) | positive number

Sample rate, in hertz, of audio data `y`, specified as a positive number between 80 and 1000000.

Data Types
`single | double`

nBits - Bit depth of sample values

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

Examples

Play Sample Data at Default Sample Rate

Load the example file `gong.mat`, which contains sample data `y` and rate `Fs`, and listen to the audio.

```
load gong.mat;
sound(y);
```

Play Sample Data at Specific Sample Rate

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;
sound(y, 2*Fs);
```

Play Sample Data with Specific Bit Depth

```
load handel.mat;
nBits = 16;
sound(y,Fs,nBits);
```

MATLAB plays the audio with a bit depth of 16 bits per sample, if this is supported on your system.

Tips

- The `sound` function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

Concepts

- "Characteristics of Audio Files"
- "Play Audio"

soundsc

Purpose

Scale data and play as sound

Syntax

```
soundsc(y)
soundsc(y,Fs)
soundsc(y,Fs,nBits)

soundsc( ___ ,yRange)
```

Description

`soundsc(y)` scales the values of audio signal `y` to fit in the range from –1.0 to 1.0, and then sends the data to the speaker at the default sample rate of 8192 hertz. By first scaling the data, `soundsc` plays the audio as loudly as possible without clipping. The mean of the dynamic range of the data is set to zero.

`soundsc(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`soundsc(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

`soundsc( ___ ,yRange)`, where `yRange` is a vector of the form `[low,high]`, linearly scales the values in `y` between `low` and `high` to the full sound range `[-1.0,1.0]`. Values outside `[low,high]` are not clipped. You can use `yRange` with any of the input arguments in the above syntaxes.

Input Arguments

y - Audio data

column vector | m-by-2 matrix

Audio data, specified as an `m`-by-1 column vector for single-channel (mono) audio, or an `m`-by-2 matrix for stereo playback, where `m` is the number of audio samples. If `y` is an `m`-by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

Data Types

`double`

Fs - Sample rate

8192 (default) | positive number

Sample rate, in hertz, of audio data `y`, specified as a positive number between 80 and 1000000.

Data Types
`single | double`

nBits - Bit depth of sample values

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

yRange - Range of audio data to scale

`[min(y),max(y)]` (default) | two-element vector

Range of audio data to scale, specified as a two-element vector of the form `[low,high]`, where `low` and `high` are the lower and upper limits of the range.

Example: `[-0.8,0.8]`

Data Types
`double`

Examples

Play Sample Data at Default Sample Rate

Load the example file gong.mat, which contains sample data `y` and rate `Fs`, and listen to the audio.

```
load gong.mat;
soundsc(y);
```

Play Sample Data at Specific Sample Rate

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;
soundsc(y, 2*Fs);
```

Play Sample Data with Specific Bit Depth

```
load handel.mat;
nBits = 16;
soundsc(y,Fs,nBits);
```

MATLAB plays the scaled audio with a bit depth of 16 bits per sample.

Scale Selected Audio Data

```
load handel.mat;
yRange = [-0.7,0.7];
soundsc(y,yRange);
```

Tips

- The `sound` function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

`audioplayer` | `sound` | `audioread` | `audiowrite`

Purpose

Allocate space for sparse matrix

Syntax

```
S = spalloc(m,n,nzmax)
```

Description

`S = spalloc(m,n,nzmax)` creates an all zero sparse matrix `S` of size `m`-by-`n` with room to hold `nzmax` nonzeros. The matrix can then be generated column by column without requiring repeated storage allocation as the number of nonzeros grows.

`spalloc(m,n,nzmax)` is shorthand for

```
sparse([],[],[],m,n,nzmax)
```

Examples

To generate efficiently a sparse matrix that has an average of at most three nonzero elements per column

```
S = spalloc(n,n,3*n);
for j = 1:n
    S(:,j) = [zeros(n-3,1)' round(rand(3,1))']';end
```

sparse

Purpose

Create sparse matrix

Syntax

```
S = sparse(A)
S = sparse(i,j,s,m,n,nzmax)
S = sparse(i,j,s,m,n)
S = sparse(i,j,s)
S = sparse(m,n)
```

Description

The `sparse` function generates matrices in the MATLAB sparse storage organization.

`S = sparse(A)` converts a full matrix to sparse form by squeezing out any zero elements. If `S` is already sparse, `sparse(S)` returns `S`.

`S = sparse(i,j,s,m,n,nzmax)` uses vectors `i`, `j`, and `s` to generate an `m`-by-`n` sparse matrix such that `S(i(k),j(k)) = s(k)`, with space allocated for `nzmax` nonzeros. Vectors `i`, `j`, and `s` are all the same length. Any elements of `s` that are zero are ignored, along with the corresponding values of `i` and `j`. Any elements of `s` that have duplicate values of `i` and `j` are added together.

Note If any value in `i` or `j` is larger than 2^31-1 for 32-bit platforms, or 2^48-1 on 64-bit platforms, then the sparse matrix cannot be constructed.

To simplify this six-argument call, you can pass scalars for the argument `s` and one of the arguments `i` or `j`—in which case they are expanded so that `i`, `j`, and `s` all have the same length.

`S = sparse(i,j,s,m,n)` uses `nzmax = length(s)`.

`S = sparse(i,j,s)` uses `m = max(i)` and `n = max(j)`. The maxima are computed before any zeros in `s` are removed, so one of the rows of `[i j s]` might be `[m n 0]`.

`S = sparse(m,n)` abbreviates `sparse([],[],[],m,n,0)`. This generates the ultimate sparse matrix, an `m`-by-`n` all zero matrix.

Tips

All of the MATLAB built-in arithmetic, logical, and indexing operations can be applied to sparse matrices, or to mixtures of sparse and full matrices. Operations on sparse matrices return sparse matrices and operations on full matrices return full matrices.

In most cases, operations on mixtures of sparse and full matrices return full matrices. The exceptions include situations where the result of a mixed operation is structurally sparse, for example, `A.*S` is at least as sparse as `S`.

Examples

`S = sparse(1:n,1:n,1)` generates a sparse representation of the `n`-by-`n` identity matrix. The same `S` results from `S = sparse(eye(n,n))`, but this would also temporarily generate a full `n`-by-`n` matrix with most of its elements equal to zero.

`B = sparse(10000,10000,pi)` is probably not very useful, but is legal and works; it sets up a `10000`-by-`10000` matrix with only one nonzero element. Don't try `full(B)`; it requires 800 megabytes of storage.

This dissects and then reassembles a sparse matrix:

```
[i,j,s] = find(S);
[m,n] = size(S);
S = sparse(i,j,s,m,n);
```

So does this, if the last row and column have nonzero entries:

```
[i,j,s] = find(S);
S = sparse(i,j,s);
```

spaugment

Purpose

Form least squares augmented system

Syntax

```
S = spaugment(A,c)
S = spaugment(A)
```

Description

`S = spaugment(A,c)` creates the sparse, square, symmetric indefinite matrix `S = [c*I A; A' 0]`. The matrix `S` is related to the least squares problem

```
min norm(b - A*x)
```

by

```
r = b - A*x
S * [r/c; x] = [b; 0]
```

The optimum value of the residual scaling factor `c`, involves `min(svd(A))` and `norm(r)`, which are usually too expensive to compute.

`S = spaugment(A)` without a specified value of `c`, uses `max(max(abs(A)))/1000`.

Note In previous versions of MATLAB product, the augmented matrix was used by sparse linear equation solvers, \ and /, for nonsquare problems. Now, MATLAB software performs a least squares solve using the `qr` factorization of `A` instead.

See Also

`spparms`

Purpose

Import matrix from sparse matrix external format

Syntax

```
S = spconvert(D)
```

Description

`spconvert` is used to create sparse matrices from a simple sparse format easily produced by non-MATLAB sparse programs. `spconvert` is the second step in the process:

1. Load an ASCII data file containing `[i,j,v]` or `[i,j,re,im]` as rows into a MATLAB variable.
2. Convert that variable into a MATLAB sparse matrix.

`S = spconvert(D)` converts a matrix `D` with rows containing `[i,j,s]` or `[i,j,r,s]` to the corresponding sparse matrix. `D` must have an `nnz` or `nnz+1` row and three or four columns. Three elements per row generate a real matrix and four elements per row generate a complex matrix. A row of the form `[m n 0]` or `[m n 0 0]` anywhere in `D` can be used to specify `size(S)`. If `D` is already sparse, no conversion is done, so `spconvert` can be used after `D` is loaded from either a MAT-file or an ASCII file.

Examples

Suppose the ASCII file `uphill.dat` contains

```
1      1      1.000000000000000
1      2      0.500000000000000
2      2      0.333333333333333
1      3      0.333333333333333
2      3      0.250000000000000
3      3      0.200000000000000
1      4      0.250000000000000
2      4      0.200000000000000
3      4      0.166666666666667
4      4      0.142857142857143
4      4      0.000000000000000
```

Then the statements

```
load uphill.dat
H = spconvert(uphill)

H =
   (1,1)       1.0000
   (1,2)       0.5000
   (2,2)       0.3333
   (1,3)       0.3333
   (2,3)       0.2500
   (3,3)       0.2000
   (1,4)       0.2500
   (2,4)       0.2000
   (3,4)       0.1667
   (4,4)       0.1429
```

recreate `sparse(triu(hilb(4)))`, possibly with roundoff errors. In this case, the last line of the input file is not necessary because the earlier lines already specify that the matrix is at least 4-by-4.

Purpose

Extract and create sparse band and diagonal matrices

Syntax

```
B = spdiags(A)
[B,d] = spdiags(A)
B = spdiags(A,d)
A = spdiags(B,d,A)
A = spdiags(B,d,m,n)
```

Description

The `spdiags` function generalizes the function `diag`. Four different operations, distinguished by the number of input arguments, are possible.

`B = spdiags(A)` extracts all nonzero diagonals from the `m`-by-`n` matrix `A`. `B` is a `min(m,n)`-by-`p` matrix whose columns are the `p` nonzero diagonals of `A`.

`[B,d] = spdiags(A)` returns a vector `d` of length `p`, whose integer components specify the diagonals in `A`.

`B = spdiags(A,d)` extracts the diagonals specified by `d`.

`A = spdiags(B,d,A)` replaces the diagonals specified by `d` with the columns of `B`. The output is sparse.

`A = spdiags(B,d,m,n)` creates an `m`-by-`n` sparse matrix by taking the columns of `B` and placing them along the diagonals specified by `d`.

Note In this syntax, if a column of `B` is longer than the diagonal it is replacing, and `m >= n`, `spdiags` takes elements of super-diagonals from the lower part of the column of `B`, and elements of sub-diagonals from the upper part of the column of `B`. However, if `m < n` , then super-diagonals are from the upper part of the column of `B`, and sub-diagonals from the lower part. (See “Example 5A” on page 1-4805 and “Example 5B” on page 1-4807, below).

Arguments

The `spdiags` function deals with three matrices, in various combinations, as both input and output.

A	An m-by-n matrix, usually (but not necessarily) sparse, with its nonzero or specified elements located on p diagonals.
B	A min(m,n)-by-p matrix, usually (but not necessarily) full, whose columns are the diagonals of A.
d	A vector of length p whose integer components specify the diagonals in A.

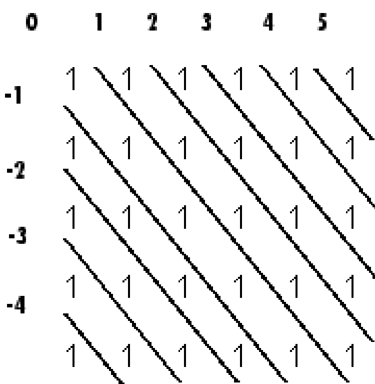
Roughly, A, B, and d are related by

```
for k = 1:p
    B(:,k) = diag(A,d(k))
end
```

Some elements of B, corresponding to positions outside of A, are not defined by these loops. They are not referenced when B is input and are set to zero when B is output.

How the Diagonals of A are Listed in the Vector d

An m-by-n matrix A has m+n-1diagonals. These are specified in the vector d using indices from -m+1 to n-1. For example, if A is 5-by-6, it has 10 diagonals, which are specified in the vector d using the indices -4, -3 , ... 4, 5. The following diagram illustrates this for a vector of all ones.



Examples

Example 1

For the following matrix,

```
A=[0 5 0 10 0 0;...
0 0 6 0 11 0;...
3 0 0 7 0 12;...
1 4 0 0 8 0;...
0 2 5 0 0 9]

A =

     0     5     0    10     0     0
     0     0     6     0    11     0
     3     0     0     7     0    12
     1     4     0     0     8     0
     0     2     5     0     0     9
```

the command

```
[B, d]  =spdiags(A)
```

returns

```
B =

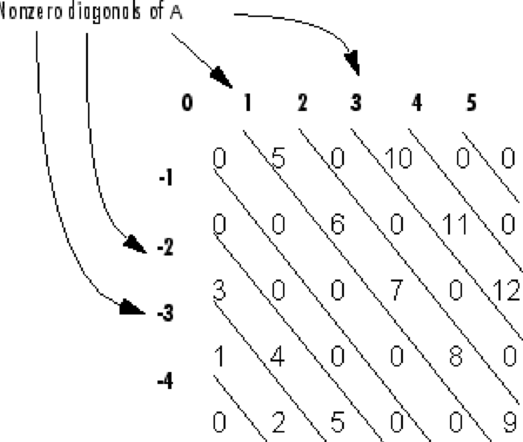
     0     0     5    10
     0     0     6    11
     0     3     7    12
     1     4     8     0
     2     5     9     0

d =

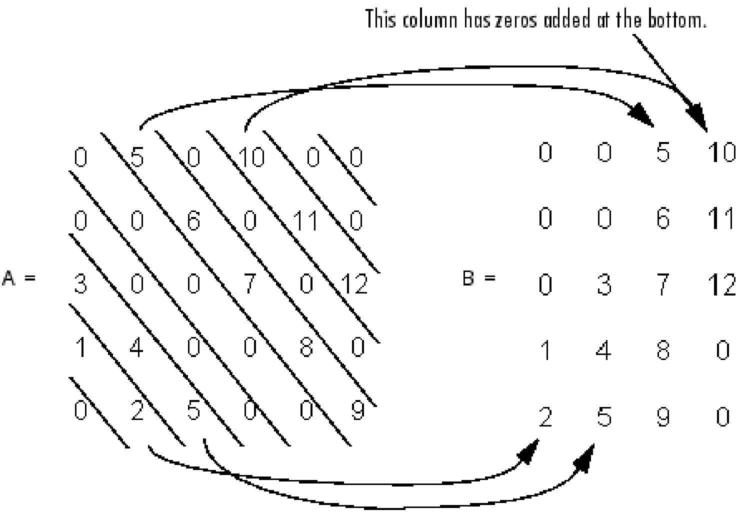
    -3
    -2
     1
```

```
    3
```

The columns of the first output B contain the nonzero diagonals of A. The second output d lists the indices of the nonzero diagonals of A, as shown in the following diagram. See "How the Diagonals of A are Listed in the Vector d" on page 1-4800.



Note that the longest nonzero diagonal in A is contained in column 3 of B. The other nonzero diagonals of A have extra zeros added to their corresponding columns in B, to give all columns of B the same length. For the nonzero diagonals below the main diagonal of A, extra zeros are added at the tops of columns. For the nonzero diagonals above the main diagonal of A, extra zeros are added at the bottoms of columns. This is illustrated by the following diagram.



Example 2

This example generates a sparse tridiagonal representation of the classic second difference operator on `n` points.

```
e = ones(n,1);
A = spdiags([e -2*e e], -1:1, n, n)
```

Turn it into Wilkinson's test matrix (see `gallery`):

```
A = spdiags(abs(-(n-1)/2:(n-1)/2)',0,A)
```

Finally, recover the three diagonals:

```
B = spdiags(A)
```

Example 3

The second example is not square.

```
A = [11    0   13    0
      0   22    0   24
```

```
     0     0    33     0
    41     0     0    44
     0    52     0     0
     0     0    63     0
     0     0     0    74]
```

Here `m =7`, `n = 4`, and `p = 3`.

The statement `[B,d] = spdiags(A)` produces `d = [-3 0 2]'` and

```
B = [41    11     0
     52    22     0
     63    33    13
     74    44    24]
```

Conversely, with the above `B` and `d`, the expression `spdiags(B,d,7,4)` reproduces the original `A`.

Example 4

This example shows how `spdiags` creates the diagonals when the columns of `B` are longer than the diagonals they are replacing.

```
B = repmat((1:6)',[1 7])

B =

     1   1   1   1   1   1   1
     2   2   2   2   2   2   2
     3   3   3   3   3   3   3
     4   4   4   4   4   4   4
     5   5   5   5   5   5   5
     6   6   6   6   6   6   6

d = [-4 -2 -1 0 3 4 5];
A = spdiags(B,d,6,6);
full(A)

ans =
```

```
1  0  0  4  5  6
1  2  0  0  5  6
1  2  3  0  0  6
0  2  3  4  0  0
1  0  3  4  5  0
0  2  0  4  5  6
```

Example 5A

This example illustrates the use of the syntax `A = spdiags(B,d,m,n)`, under three conditions:

- `m` is equal to `n`
- `m` is greater than `n`
- `m` is less than `n`

The command used in this example is

```
A = full(spdiags(B, [-2 0 2], m, n))
```

where `B` is the 5-by-3 matrix shown below. The resulting matrix `A` has dimensions `m`-by-`n`, and has nonzero diagonals at `[-2 0 2]` (a sub-diagonal at `-2`, the main diagonal, and a super-diagonal at `2`).

```
B =
    1     6    11
    2     7    12
    3     8    13
    4     9    14
    5    10    15
```

The first and third columns of matrix `B` are used to create the sub- and super-diagonals of `A` respectively. In all three cases though, these two outer columns of `B` are longer than the resulting diagonals of `A`. Because of this, only a part of the columns is used in `A`.

When `m == n` or `m > n`, `spdiags` takes elements of the super-diagonal in `A` from the lower part of the corresponding column of `B`, and elements

of the sub-diagonal in A from the upper part of the corresponding column of B.

When m < n, spdiags does the opposite, taking elements of the super-diagonal in A from the upper part of the corresponding column of B, and elements of the sub-diagonal in A from the lower part of the corresponding column of B.

Part 1 — m is equal to n.

```
A = full(spdiags(B, [-2 0 2], 5, 5))
 Matrix B                             Matrix A

1     6    11                      6     0    13     0     0
2     7    12                      0     7     0    14     0
3     8    13   == spdiags =>      1     0     8     0    15
4     9    14                      0     2     0     9     0
5    10    15                      0     0     3     0    10
```

A(3,1), A(4,2), and A(5,3) are taken from the upper part of B(:,1).

A(1,3), A(2,4), and A(3,5) are taken from the lower part of B(:,3).

Part 2 — m is greater than n.

```
A = full(spdiags(B, [-2 0 2], 5, 4))
 Matrix B                             Matrix A

1     6    11                      6     0    13     0
2     7    12                      0     7     0    14
3     8    13   == spdiags =>      1     0     8     0
4     9    14                      0     2     0     9
5    10    15                      0     0     3     0
```

Same as in Part A.

Part 3 — m is less than n.

```
A = full(spdiags(B, [-2 0 2], 4, 5))
```

```
 Matrix B                          Matrix A

1    6   11                      6    0   11    0    0
2    7   12                      0    7    0   12    0
3    8   13  == spdiags =>       3    0    8    0   13
4    9   14                      0    4    0    9    0
5   10   15
```

`A(3,1)` and `A(4,2)` are taken from the lower part of `B(:,1)`.

`A(1,3)`, `A(2,4)`, and `A(3,5)` are taken from the upper part of `B(:,3)`.

Example 5B

Extract the diagonals from the first part of this example back into a column format using the command

```
B = spdiags(A)
```

You can see that in each case the original columns are restored (minus those elements that had overflowed the super- and sub-diagonals of matrix A).

Part 1.

```
      Matrix A                               Matrix B

6    0   13    0    0                   1    6    0
0    7    0   14    0                   2    7    0
1    0    8    0   15  == spdiags =>    3    8   13
0    2    0    9    0                   0    9   14
0    0    3    0   10                   0   10   15
```

Part 2.

```
    Matrix A                           Matrix B

6    0   13    0                    1    6    0
0    7    0   14                    2    7    0
1    0    8    0  == spdiags =>     3    8   13
```

```
0     2     0     9                    0    9   14
0     0     3     0
```

Part 3.

```
      Matrix A                              Matrix B

6     0    11     0     0                   0    6   11
0     7     0    12     0                   0    7   12
3     0     8     0    13  == spdiags =>    3    8   13
0     4     0     9     0                   4    9    0
```

See Also

diag | speye

Purpose

Calculate specular reflectance

Syntax

```
R = specular(Nx,Ny,Nz,S,V)
```

Description

`R = specular(Nx,Ny,Nz,S,V)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` and `V` specify the direction to the light source and to the viewer, respectively. You can specify these directions as three vectors`[x,y,z]` or two vectors `[Theta Phi` (in spherical coordinates).

The specular highlight is strongest when the normal vector is in the direction of `(S+V)/2` where `S` is the source direction, and `V` is the view direction.

The surface spread exponent can be specified by including a sixth argument as in `specular(Nx,Ny,Nz,S,V,spread)`.

speye

Purpose

Sparse identity matrix

Syntax

```
S = speye(m,n)
S = speye([m n])
S = speye(n)
S = speye
```

Description

`S = speye(m,n)` and `S = speye([m n])` form an `m`-by-`n` sparse matrix with `1`s on the main diagonal.

`S = speye(n)` abbreviates `speye(n,n)`.

`S = speye` returns the sparse form of the 1-by-1 identity matrix.

Examples

`I = speye(1000)` forms the sparse representation of the 1000-by-1000 identity matrix, which requires only about 16 kilobytes of storage. This is the same final result as `I = sparse(eye(1000,1000))`, but the latter requires eight megabytes for temporary storage for the full representation.

See Also

`spalloc` | `spones` | `spdiags` | `sprand` | `sprandn`

Purpose

Apply function to nonzero sparse matrix elements

Syntax

```
f = spfun(fun,S)
```

Description

The `spfun` function selectively applies a function to only the *nonzero* elements of a sparse matrix `S`, preserving the sparsity pattern of the original matrix (except for underflow or if `fun` returns zero for some nonzero elements of `S`).

`f = spfun(fun,S)` evaluates `fun(S)` on the elements of `S` that are nonzero. `fun` is a function handle.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

Tips

Functions that operate element-by-element, like those in the `elfun` directory, are the most appropriate functions to use with `spfun`.

Examples

Given the 4-by-4 sparse diagonal matrix

```
S = spdiags([1:4]',0,4,4)

S =
   (1,1)        1
   (2,2)        2
   (3,3)        3
   (4,4)        4
```

Because `fun` returns nonzero values for all nonzero element of `S`, `f = spfun(@exp,S)` has the same sparsity pattern as `S.`

```
f =
   (1,1)       2.7183
   (2,2)       7.3891
   (3,3)      20.0855
   (4,4)      54.5982
```

whereas `exp(S)` has `1`s where `S` has `0`s.

```
full(exp(S))

ans =
    2.7183    1.0000    1.0000    1.0000
    1.0000    7.3891    1.0000    1.0000
    1.0000    1.0000   20.0855    1.0000
    1.0000    1.0000    1.0000   54.5982
```

See Also

function_handle

Purpose

Transform spherical coordinates to Cartesian

Syntax

```
[x,y,z] = sph2cart(azimuth,elevation,r)
```

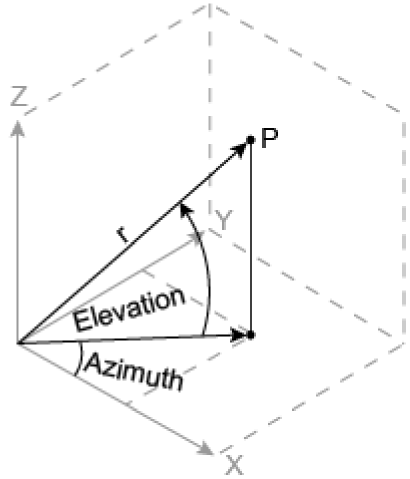
Description

`[x,y,z] = sph2cart(azimuth,elevation,r)` transforms the corresponding elements of spherical coordinate arrays to Cartesian, or *xyz*, coordinates. `azimuth`, `elevation`, and `r` must all be the same size (or any of them can be scalar). `azimuth` and `elevation` are angular displacements in radians from the positive *x*-axis and from the *x*-*y* plane, respectively.

Algorithms

The mapping from spherical coordinates to three-dimensional Cartesian coordinates is

```
x = r .* cos(elevation) .* cos(azimuth)
y = r .* cos(elevation) .* sin(azimuth)
z = r .* sin(elevation)
```



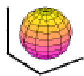
See Also

`cart2pol` | `cart2sph` | `pol2cart`

sphere

Purpose

Generate sphere



Syntax

```
sphere
sphere(n)
[X,Y,Z] = sphere(n)
```

Description

The `sphere` function generates the *x*-, *y*-, and *z*-coordinates of a unit sphere for use with `surf` and `mesh`.

`sphere` generates a sphere consisting of 20-by-20 faces.

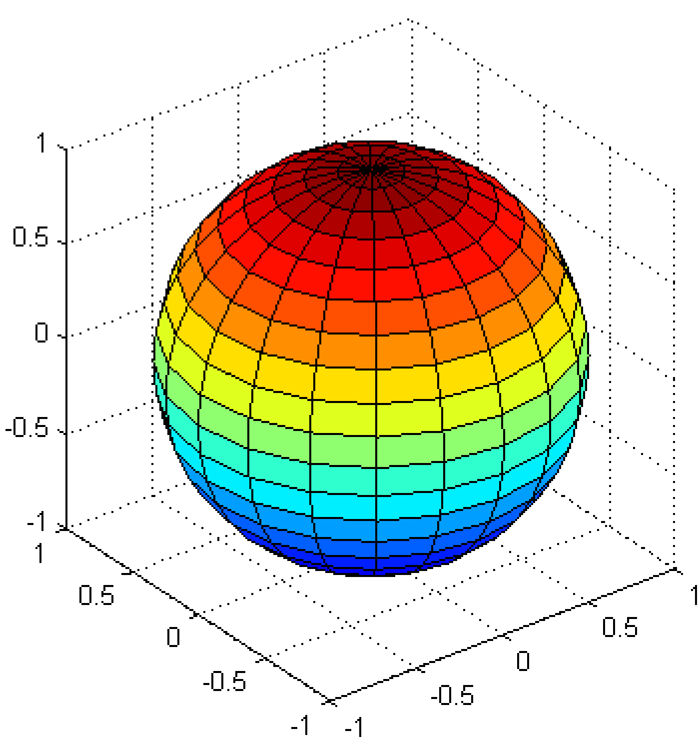
`sphere(n)` draws a `surf` plot of an `n`-by-`n` sphere in the current figure.

`[X,Y,Z] = sphere(n)` returns the coordinates of a sphere in three matrices that are `(n+1)`-by-`(n+1)` in size. You draw the sphere with `surf(X,Y,Z)` or `mesh(X,Y,Z)`.

Examples

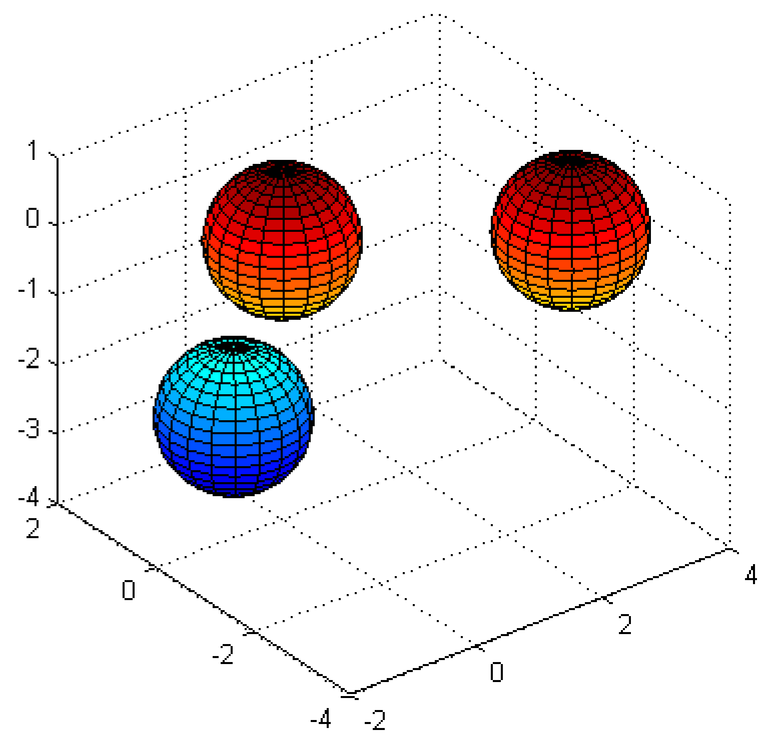
Generate and plot a sphere.

```
figure
sphere
axis equal
```



Plot multiple spheres, translating centers away from the origin:

```
figure
[x,y,z] = sphere;
surf(x,y,z)  % sphere centered at origin
hold on
surf(x+3,y-2,z)  % sphere centered at (3,-2,0)
surf(x,y+1,z-3)  % sphere centered at (0,1,-3)
daspect([1 1 1])
```



See Also

`cylinder` | `axis`

spinmap

Purpose

Spin colormap

Syntax

```
spinmap
spinmap(t)
spinmap(t,inc)
spinmap('inf')
```

Description

The `spinmap` function shifts the colormap RGB values by some incremental value. For example, if the increment equals 1, color 1 becomes color 2, color 2 becomes color 3, etc.

`spinmap` cyclically rotates the colormap for approximately five seconds using an incremental value of 2.

`spinmap(t)` rotates the colormap for approximately 10*t seconds. The amount of time specified by `t` depends on your hardware configuration (e.g., if you are running MATLAB software over a network).

`spinmap(t,inc)` rotates the colormap for approximately 10*t seconds and specifies an increment `inc` by which the colormap shifts. When `inc` is 1, the rotation appears smoother than the default (i.e., 2). Increments greater than 2 are less smooth than the default. A negative increment (e.g., –2) rotates the colormap in a negative direction.

`spinmap('inf')` rotates the colormap for an infinite amount of time. To break the loop, press **Ctrl+C**.

See Also

`colormap` | `colormapeditor`

spline

Purpose

Cubic spline data interpolation

Syntax

```
yy = spline(x,Y,xx)
pp = spline(x,Y)
```

Description

`yy = spline(x,Y,xx)` uses a cubic spline interpolation to find `yy`, the values of the underlying function `Y` at the values of the interpolant `xx`. For the interpolation, the independent variable is assumed to be the final dimension of `Y` with the breakpoints defined by `x`.

The sizes of `xx` and `yy` are related as follows:

- If `Y` is a scalar or vector, `yy` has the same size as `xx`.
- If `Y` is an array that is not a vector,
  - If `xx` is a scalar or vector, `size(yy)` equals `[d1, d2, ..., dk, length(xx)]`.
  - If `xx` is an array of size `[m1,m2,...,mj]`, `size(yy)` equals `[d1,d2,...,dk,m1,m2,...,mj]`.

`pp = spline(x,Y)` returns the piecewise polynomial form of the cubic spline interpolant for later use with `ppval` and the spline utility `unmkpp`. `x` must be a vector. `Y` can be a scalar, a vector, or an array of any dimension, subject to the following conditions:

- If x and Y are vectors of the same size, the not-a-knot end conditions are used.
- If x or Y is a scalar, it is expanded to have the same length as the other and the not-a-knot end conditions are used. (See Exceptions (1) below).
- If Y is a vector that contains two more values than x has entries, the first and last value in Y are used as the endslopes for the cubic spline. (See Exceptions (2) below.)

Exceptions

1. If `Y` is a vector that contains two more values than `x` has entries, the first and last value in `Y` are used as the endslopes for the cubic spline. If `Y` is a vector, this means
   - `f(x) = Y(2:end-1)`
   - `df(min(x)) = Y(1)`
   - `df(max(x)) = Y(end)`
2. If `Y` is a matrix or an `N`-dimensional array with `size(Y,N)` equal to `length(x)+2`, the following hold:
   - `f(x(j))` matches the value `Y(:,...,:,j+1)` for `j=1:length(x)`
   - `Df(min(x))` matches `Y(:,:,...:,1)`
   - `Df(max(x))` matches `Y(:,:,...:,end)`

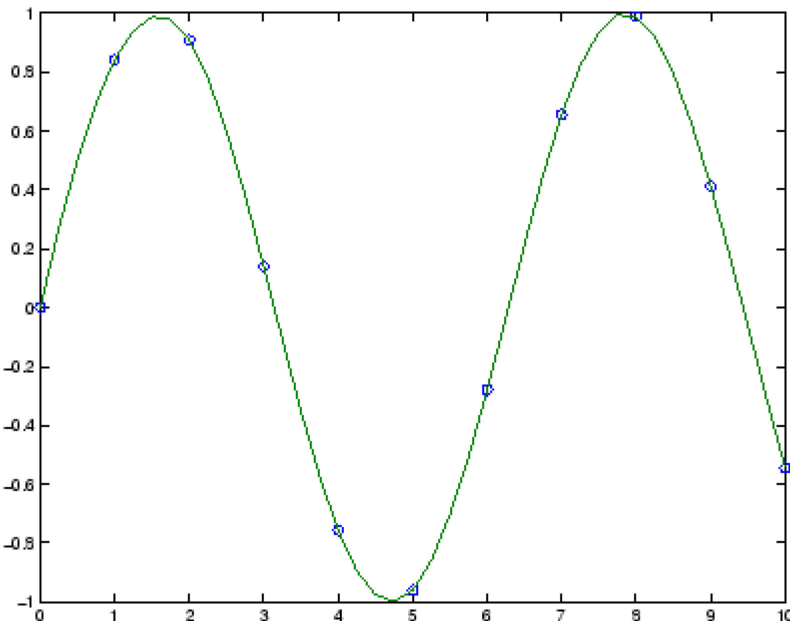
Note You can also perform spline interpolation using the `interp1` function with the command `interp1(x,y,xx,'spline')`. Note that while `spline` performs interpolation on rows of an input matrix, `interp1` performs interpolation on columns of an input matrix.

Examples

Example 1

This generates a sine curve, then samples the spline over a finer mesh.

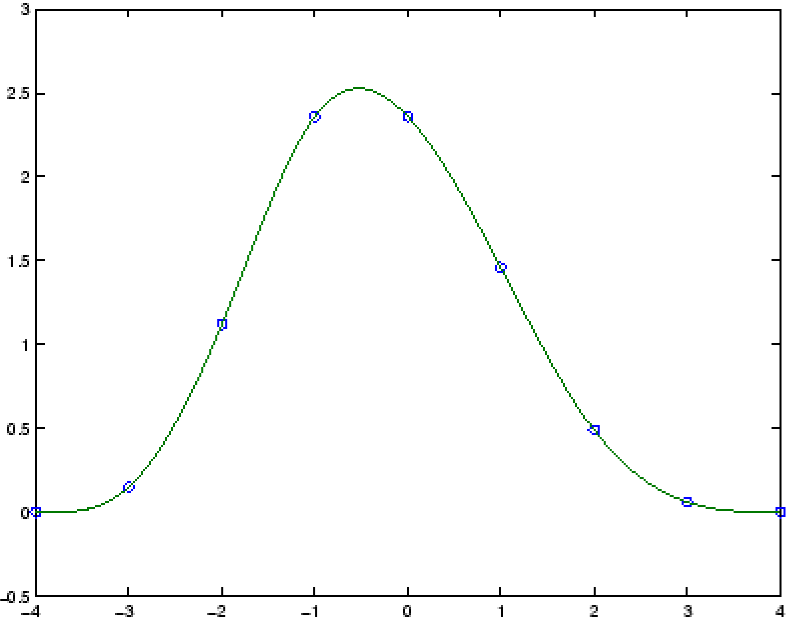
```
x = 0:10;
y = sin(x);
xx = 0:.25:10;
yy = spline(x,y,xx);
plot(x,y,'o',xx,yy)
```



Example 2

This illustrates the use of clamped or complete spline interpolation where end slopes are prescribed. Zero slopes at the ends of an interpolant to the values of a certain distribution are enforced.

```
x = -4:4;
y = [0 .15 1.12 2.36 2.36 1.46 .49 .06 0];
cs = spline(x,[0 y 0]);
xx = linspace(-4,4,101);
plot(x,y,'o',xx,ppval(cs,xx),'-');
```



Example 3

The two vectors

```
t = 1900:10:1990;
p = [ 75.995  91.972  105.711  123.203  131.669 ...
     150.697 179.323  203.212  226.505  249.633 ];
```

represent the census years from 1900 to 1990 and the corresponding United States population in millions of people. The expression

```
spline(t,p,2000)
```

uses the cubic spline to extrapolate and predict the population in the year 2000. The result is

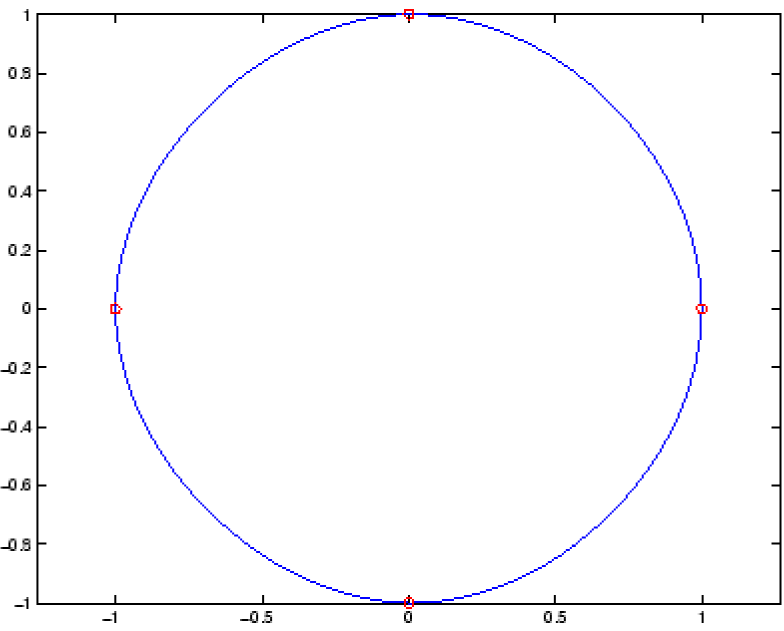
```
ans =
    270.6060
```

Example 4

The statements

```
x = pi*[0:.5:2];
y = [0  1  0 -1  0  1  0;
     1  0  1  0 -1  0  1];
pp = spline(x,y);
yy = ppval(pp, linspace(0,2*pi,101));
plot(yy(1,:),yy(2,:),'-b',y(1,2:5),y(2,2:5),'or'), axis equal
```

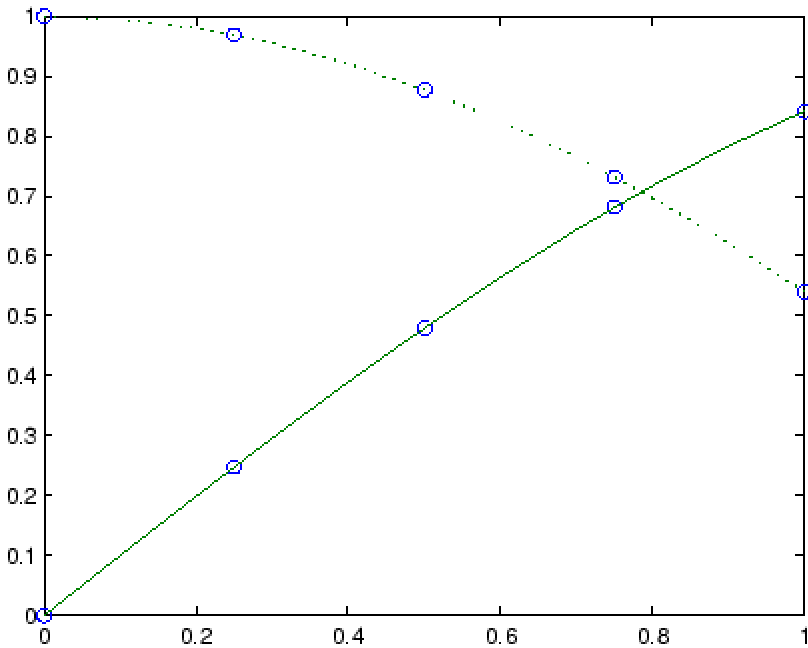
generate the plot of a circle, with the five data points `y(:,2),...,y(:,6)` marked with o's. Note that this `y` contains two more values (i.e., two more columns) than does `x`, hence `y(:,1)` and `y(:,end)` are used as endslopes.



Example 5

The following code generates sine and cosine curves, then samples the splines over a finer mesh.

```
x = 0:.25:1;
Y = [sin(x); cos(x)];
xx = 0:.1:1;
YY = spline(x,Y,xx);
plot(x,Y(1,:),'o',xx,YY(1,:),'-'); hold on;
plot(x,Y(2,:),'o',xx,YY(2,:),':'); hold off;
```



Algorithms

A tridiagonal linear system (with, possibly, several right sides) is being solved for the information needed to describe the coefficients of the various cubic polynomials which make up the interpolating spline. `spline` uses the functions `ppval`, `mkpp`, and `unmkpp`. These routines

form a small suite of functions for working with piecewise polynomials. For access to more advanced features, see the `interp1` reference page, the command-line help for these functions, and the Curve Fitting Toolbox spline functions.

`interp1` | `ppval` | `mkpp` | `pchip` | `unmkpp`

Purpose

Replace nonzero sparse matrix elements with ones

Syntax

`R = spones(S)`

Description

`R = spones(S)` generates a matrix `R` with the same sparsity structure as `S`, but with `1`'s in the nonzero positions.

Examples

`c = sum(spones(S))` is the number of nonzeros in each column.

`r = sum(spones(S'))'` is the number of nonzeros in each row.

`sum(c)` and `sum(r)` are equal, and are equal to `nnz(S)`.

`nnz` | `spalloc` | `spfun`

spparms

Purpose

Set parameters for sparse matrix routines

Syntax

```
spparms('key',value)
spparms
values = spparms
[keys,values] = spparms
spparms(values)
value = spparms('key')
spparms('default')
spparms('tight')
```

Description

`spparms('key',value)` sets one or more of the *tunable* parameters used in the sparse routines. In ordinary use, you should never need to deal with this function.

The meanings of the `key` parameters are

`'spumoni'`	Sparse Monitor flag:
`0`	Produces no diagnostic output, the default
`1`	Produces information about choice of algorithm based on matrix structure, and about storage allocation
`2`	Also produces very detailed information about the sparse matrix algorithms
`'thr_rel'`, `'thr_abs'`	Minimum degree threshold is `thr_rel*mindegree + thr_abs`.
`'exact_d'`	Nonzero to use exact degrees in minimum degree. Zero to use approximate degrees.
`'supernd'`	If positive, minimum degree amalgamates the supernodes every `supernd` stages.
`'rreduce'`	If positive, minimum degree does row reduction every `rreduce` stages.

`'wh_frac'`	Rows with `density > wh_frac` are ignored in `colmmd`.
`'autommd'`	Nonzero to use minimum degree (MMD) orderings with QR-based `\` and `/`.
`'autoamd'`	Nonzero to use `colamd` ordering with the LU-based \ and /, and to use `amd` with Cholesky-based \ and /.
`'piv_tol'`	Pivot tolerance used by the LU-based \ and /.
`'bandden'`	Band density used by `\` and `/` for banded matrices. Band density is defined as (# nonzeros in the band)/(# nonzeros in a full band). If `bandden = 1.0`, never use band solver. If `bandden = 0.0`, always use band solver. Default is `0.5`.
`'umfpack'`	Nonzero to use UMFPACK instead of the v4 LU-based solver in `\` and `/`.
`'sym_tol'`	Symmetric pivot tolerance. See `lu` for more information about the role of the symmetric pivot tolerance.

`spparms`, by itself, prints a description of the current settings.

`values = spparms` returns a vector whose components give the current settings.

`[keys,values] = spparms` returns that vector, and also returns a character matrix whose rows are the keywords for the parameters.

`spparms(values)`, with no output argument, sets all the parameters to the values specified by the argument vector.

`value = spparms('key')` returns the current setting of one parameter.

`spparms('default')` sets all the parameters to their default settings.

`spparms('tight')` sets the minimum degree ordering parameters to their *tight* settings, which can lead to orderings with less fill-in, but which make the ordering functions themselves use more execution time.

The key parameters for `default` and `tight` settings are

	Keyword	Default	Tight
values(1)	'spumoni'	0.0	
values(2)	'thr_rel'	1.1	1.0
values(3)	'thr_abs'	1.0	0.0
values(4)	'exact_d'	0.0	1.0
values(5)	'supernd'	3.0	1.0
values(6)	'rreduce'	3.0	1.0
values(7)	'wh_frac'	0.5	0.5
values(8)	'autommd'	1.0	
values(9)	'autoamd'	1.0	
values(10)	'piv_tol'	0.1	
values(11)	'bandden'	0.5	
values(12)	'umfpack'	1.0	
values(13)	'sym_tol'	0.001

Purpose

Sparse uniformly distributed random matrix

Syntax

```
R = sprand(S)
R = sprand(m,n,density)
R = sprand(m,n,density,rc)
```

Description

`R = sprand(S)` has the same sparsity structure as `S`, but uniformly distributed random entries.

`R = sprand(m,n,density)` is a random, `m`-by-`n`, sparse matrix with approximately `density*m*n` uniformly distributed nonzero entries (`0 <= density <= 1`).

`R = sprand(m,n,density,rc)` also has reciprocal condition number approximately equal to `rc`. `R` is constructed from a sum of matrices of rank one.

If `rc` is a vector of length `lr`, where `lr <= min(m,n)`, then `R` has `rc` as its first `lr` singular values, all others are zero. In this case, `R` is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.

Tips

- `sprand` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

See Also

`sprandn` | `sprandsym`

sprandn

Purpose

Sparse normally distributed random matrix

Syntax

```
R = sprandn(S)
R = sprandn(m,n,density)
R = sprandn(m,n,density,rc)
```

Description

`R = sprandn(S)` has the same sparsity structure as `S`, but normally distributed random entries with mean `0` and variance `1`.

`R = sprandn(m,n,density)` is a random, `m`-by-`n`, sparse matrix with approximately `density*m*n` normally distributed nonzero entries (`(0 <= density <= 1`).

`R = sprandn(m,n,density,rc)` also has reciprocal condition number approximately equal to `rc`. `R` is constructed from a sum of matrices of rank one.

If `rc` is a vector of length `lr`, where `lr <= min(m,n)`, then `R` has `rc` as its first `lr` singular values, all others are zero. In this case, `R` is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.

Tips

- `sprandn` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

See Also

`sprand` | `sprandsym`

Purpose

Sparse symmetric random matrix

Syntax

```
R = sprandsym(S)
R = sprandsym(n,density)
R = sprandsym(n,density,rc)
R = sprandsym(n,density,rc,kind)
R = sprandsym(S,[],rc,3)
```

Description

`R = sprandsym(S)` returns a symmetric random matrix whose lower triangle and diagonal have the same structure as `S`. Its elements are normally distributed, with mean `0` and variance `1`.

`R = sprandsym(n,density)` returns a symmetric random, `n`-by-`n`, sparse matrix with approximately `density*n*n` nonzeros; each entry is the sum of one or more normally distributed random samples, and (`0 <= density <= 1`).

`R = sprandsym(n,density,rc)` returns a matrix with a reciprocal condition number equal to `rc`. The distribution of entries is nonuniform; it is roughly symmetric about 0; all are in [−1,1].

If `rc` is a vector of length `n`, then `R` has eigenvalues `rc`. Thus, if `rc` is a positive (nonnegative) vector then `R` is a positive (nonnegative) definite matrix. In either case, `R` is generated by random Jacobi rotations applied to a diagonal matrix with the given eigenvalues or condition number. It has a great deal of topological and algebraic structure.

`R = sprandsym(n,density,rc,kind)` is positive definite.

- If kind = 1, `R` is generated by random Jacobi rotation of a positive definite diagonal matrix. `R` has the desired condition number exactly.
- If kind = 2, `R` is a shifted sum of outer products. `R` has the desired condition number only approximately, but has less structure.

`R = sprandsym(S,[],rc,3)` has the same structure as the matrix `S` and approximate condition number `1/rc`.

Tips

`sprandsym` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

`sprand` | `sprandn`

Purpose

Structural rank

Syntax

```
r = sprank(A)
```

Description

`r = sprank(A)` is the structural rank of the sparse matrix `A`. For all values of `A`,

```
sprank(A) >= rank(full(A))
```

In exact arithmetic, `sprank(A) == rank(full(sprandn(A)))` with a probability of one.

Examples

```
A = [1    0    2    0
     2    0    4    0 ];

A = sparse(A);

sprank(A)

ans =
     2

rank(full(A))

ans =
     1
```

See Also

`dmperm`

Purpose

Format data into string

Syntax

```
str = sprintf(formatSpec,A1,...,An)
[str,errmsg] = sprintf(formatSpec,A1,...,An)
```

Description

`str = sprintf(formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec` in column order, and returns the results to string `str`.

`[str,errmsg] = sprintf(formatSpec,A1,...,An)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is empty.

Input Arguments

formatSpec - Format of the output fields

string

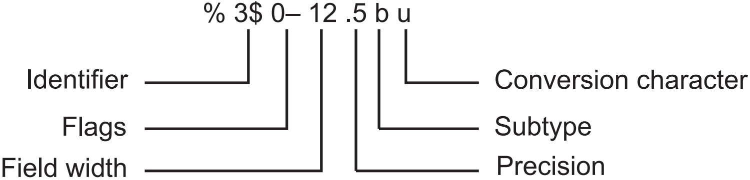
Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

Value Type	Conversion	Details
Integer, signed	`%d` or `%i`	Base 10
Integer, unsigned	`%u`	Base 10
	`%o`	Base 8 (octal)
	`%x`	Base 16 (hexadecimal), lowercase letters `a`–`f`
	`%X`	Same as `%x`, uppercase letters `A`–`F`

Value Type	Conversion	Details
Floating-point number	%f	Fixed-point notation
	%e	Exponential notation, such as 3.141593e+00
	%E	Same as %e, but uppercase, such as 3.141593E+00
	%g	The more compact of %e or %f, with no trailing zeros
	%G	The more compact of %E or %f, with no trailing zeros
	%bx or %bX %bo %bu	Double-precision hexadecimal, octal, or decimal value Example: %bx prints pi as 400921fb54442d18
	%tx or %tX %to %tu	Single-precision hexadecimal, octal, or decimal value Example: %tx prints pi as 40490fdb
Characters	%c	Single character
	%s	String of characters

The string can include optional operators, which appear in the following order (includes spaces for clarity):



Optional operators include:

- Identifier

  Order for processing inputs. Use the syntax *n*$, where *n* represents the position of the value in the input list.

  For example, '%3$s %2$s %1$s %2$s' prints inputs 'A', 'B', 'C' as follows: C B A B.

- Flags

'-'	Left-justify. Example: %-5.2f
'+'	Print sign character (+) for positive values. Example: %+5.2f
' '	Pad to field width with spaces before the value. Example: % 5.2f
'0'	Pad to field width with zeros. Example: %05.2f
'#'	Modify selected numeric conversions: • For %o, %x, or %X, print 0, 0x, or 0X prefix. - For %f, %e, or %E, print decimal point even when precision is 0. - For %g or %G, do not remove trailing zeros or decimal point. Example: %#5.0f

- Field width

  Minimum number of characters to print. Can be a number, or an asterisk (*) to refer to an argument in the input list. For example, the input list ('%12d', intmax) is equivalent to ('%*d', 12, intmax).

- Precision

For `%f`, `%e`, or `%E`:	Number of digits to the right of the decimal point. Example: `'%6.4f'` prints `pi` as `'3.1416'`
For `%g` or `%G`	Number of significant digits. Example: `'%6.4g'` prints `pi` as `' 3.142'`

Can be a number, or an asterisk (`*`) to refer to an argument in the input list. For example, the input list `('%6.4f', pi)` is equivalent to `('%*.*f', 6, 4, pi)`.

The string can also include combinations of the following:

- Literal text to print. To print a single quotation mark, include `''` in `formatSpec`.
- Control characters, including:

`%%`	Percent character
`\\`	Backslash
`\a`	Alarm
`\b`	Backspace
`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab
`\xN`	Character whose ASCII code is the hexadecimal number, *N*
`\N`	Character whose ASCII code is the octal number, *N*

The following limitations apply to conversions:

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses `%e`.
- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, `'%s'` converts `[65 66 67]` to `ABC`.

A1,...,An - Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

Data Types
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: No

Output Arguments

str - Formatted text

string

Formatted text, returned as a string.

errmsg - Error message

string

Error message, returned as a string, when the operation is unsuccessful. Otherwise, `errmsg` is empty.

Tips

- The `sprintf` function is similar to `fprintf`, but `fprintf` prints to a file or to the Command Window.
- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

Examples

Floating-Point Formats

Format a floating-point number using %e, %f, and %g specifiers.

```
A = 1/eps;
str_e = sprintf('%0.5e',A)
str_f = sprintf('%0.5f',A)
str_g = sprintf('%0.5g',A)
```

```
str_e =
4.50360e+15

str_f =
4503599627370496.00000

str_g =
4.5036e+15
```

Literal Text and Array Inputs

Combine literal text with array values to create a string.

```
formatSpec = 'The array is %dx%d.';
A1 = 2;
A2 = 3;
str = sprintf(formatSpec,A1,A2)
```

```
str =
The array is 2x3.
```

Integer Format with Floating-Point Inputs

Explicitly convert double-precision values to integers.

```
str = sprintf('%d',round(pi))
```

```
str =
3
```

Field Width

Specify the minimum width of the printed value.

```
str = sprintf('%025d',[123456])

str =
0000000000000000000123456
```

The 0 flag in the %025d format specifier requests leading zeros in the output.

Position Identifier (n$)

Reorder the input values using the n$ position identifier.

```
A1 = 'X';
A2 = 'Y';
A3 = 'Z';
formatSpec = ' %3$s %2$s %1$s';
str = sprintf(formatSpec,A1,A2,A3)

str =
 Z Y X
```

Cell Array Inputs

Create a string from values in a cell array.

```
C = { 1,   2,   3 ;
     'AA','BB','CC'};

str = sprintf(' %d %s',C{:})

str =
 1 AA 2 BB 3 CC
```

The syntax C{:} creates a comma-separated list of arrays that contain the contents of each cell from C in column order. For example, C{1}==1 and C{2}=='AA'.

Concepts

- "Formatting Strings"

spy

Purpose

Visualize sparsity pattern

Syntax

```
spy(S)
spy(S,markersize)
spy(S,'LineSpec')
spy(S,'LineSpec',markersize)
```

Description

plots the

`spy(S)` sparsity pattern of any matrix `S`.

`spy(S,markersize)`, where `markersize` is an integer, plots the sparsity pattern using markers of the specified point size.

`spy(S,'LineSpec')`, where `LineSpec` is a string, uses the specified plot marker type and color.

`spy(S,'LineSpec',markersize)` uses the specified type, color, and size for the plot markers.

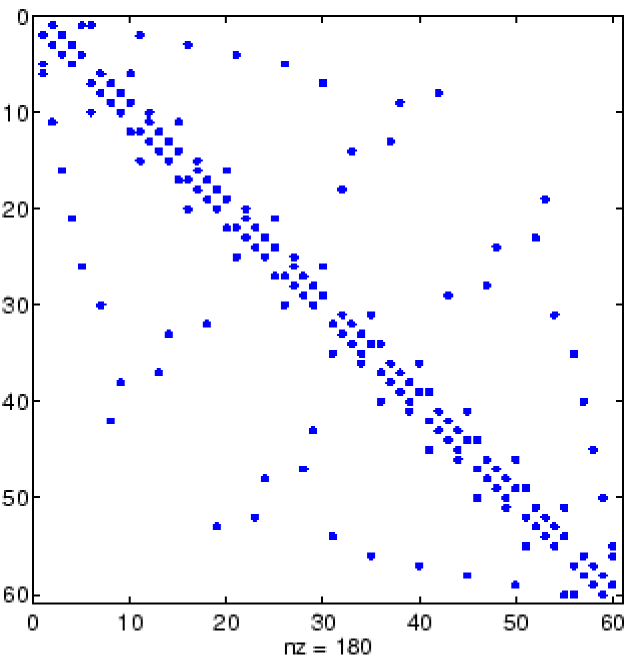
`S` is usually a sparse matrix, but full matrices are acceptable, in which case the locations of the nonzero elements are plotted.

Note `spy` replaces `format +`, which takes much more space to display essentially the same information.

Examples

This example plots the 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster Fuller geodesic dome. This matrix also represents the soccer ball and the carbon-60 molecule.

```
B = bucky;
spy(B)
```



See Also

find | gplot | LineSpec | symamd | symrcm

sqrt

Purpose

Square root

Syntax

```
B = sqrt(X)
```

Description

`B = sqrt(X)` returns the square root of each element of the array `X`. For the elements of `X` that are negative or complex, `sqrt(X)` produces complex results.

Tips

See `sqrtm` for the matrix square root.

Examples

```
sqrt((-2:2)')
ans =
      0 + 1.4142i
      0 + 1.0000i
      0
 1.0000
 1.4142
```

See Also

`nthroot` | `sqrtm` | `realsqrt`

Purpose

Matrix square root

Syntax

```
X = sqrtm(A)
[X, resnorm] = sqrtm(A)
[X, alpha, condest] = sqrtm(A)
```

Description

`X = sqrtm(A)` is the principal square root of the matrix `A`, i.e. `X*X = A`.

`X` is the unique square root for which every eigenvalue has nonnegative real part. If `A` has any eigenvalues with negative real parts then a complex result is produced. If `A` is singular then `A` may not have a square root. A warning is printed if exact singularity is detected.

`[X, resnorm] = sqrtm(A)` does not print any warning, and returns the residual, `norm(A-X^2,'fro')/norm(A,'fro')`.

`[X, alpha, condest] = sqrtm(A)` returns a stability factor `alpha` and an estimate `condest` of the matrix square root condition number of `X`. The residual `norm(A-X^2,'fro')/norm(A,'fro')` is bounded approximately by `n*alpha*eps` and the Frobenius norm relative error in `X` is bounded approximately by `n*alpha*condest*eps`, where `n = max(size(A))`.

Tips

If `A` is real, symmetric and positive definite, or complex, Hermitian and positive definite, then so is the computed matrix square root.

Some matrices, like `A = [0 1; 0 0]`, do not have any square roots, real or complex, and `sqrtm` cannot be expected to produce one.

Examples

Example 1

A matrix representation of the fourth difference operator is

```
A =
     5    -4     1     0     0
    -4     6    -4     1     0
     1    -4     6    -4     1
     0     1    -4     6    -4
     0     0     1    -4     5
```

This matrix is symmetric and positive definite. Its unique positive definite square root, `Y = sqrtm(A)`, is a representation of the second difference operator.

```
 Y =
      2    -1    -0    -0    -0
     -1     2    -1     0    -0
      0    -1     2    -1     0
     -0     0    -1     2    -1
     -0    -0    -0    -1     2
```

Example 2

The matrix

```
A =
     7    10
    15    22
```

has four square roots. Two of them are

```
Y1 =
    1.5667    1.7408
    2.6112    4.1779
```

and

```
Y2 =
     1     2
     3     4
```

The other two are `-Y1` and `-Y2`. All four can be obtained from the eigenvalues and vectors of `A`.

```
[V,D] = eig(A);
D =
    0.1386         0
         0   28.8614
```

The four square roots of the diagonal matrix D result from the four choices of sign in

```
S =
    −0.3723          0
          0    −5.3723
```

All four Ys are of the form

```
Y = V*S/V
```

The `sqrtm` function chooses the two plus signs and produces Y1, even though Y2 is more natural because its entries are integers.

See Also

expm | funm | logm

squeeze

Purpose

Remove singleton dimensions

Syntax

```
B = squeeze(A)
```

Description

`B = squeeze(A)` returns an array `B` with the same elements as `A`, but with all singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. Two-dimensional arrays are unaffected by `squeeze`; if `A` is a row or column vector or a scalar (1-by-1) value, then `B = A`.

Examples

Consider the 2-by-1-by-3 array `Y = rand(2,1,3)`. This array has a singleton column dimension — that is, there's only one column per page.

```
Y =

Y(:,:,1) =       Y(:,:,2) =
       0.5194           0.0346
       0.8310           0.0535

Y(:,:,3) =
       0.5297
       0.6711
```

The command `Z = squeeze(Y)` yields a 2-by-3 matrix:

```
Z =
    0.5194    0.0346    0.5297
    0.8310    0.0535    0.6711
```

Consider the 1-by-1-by-5 array `mat=repmat(1,[1,1,5])`. This array has only one scalar value per page.

```
mat =

mat(:,:,1) =  mat(:,:,2) =

     1         1
```

```
mat(:,:,3) =   mat(:,:,4) =

     1         1

mat(:,:,5) =

     1
```

The command `squeeze(mat)` yields a 5-by-1 matrix:

```
squeeze(mat)

ans =

     1
     1
     1
     1
     1

size(squeeze(mat))

ans =

    5     1
```

See Also

`reshape` | `shiftdim`

Purpose

Convert state-space filter parameters to transfer function form

Syntax

```
[b,a] = ss2tf(A,B,C,D,iu)
```

Description

`ss2tf` converts a state-space representation of a given system to an equivalent transfer function representation.

`[b,a] = ss2tf(A,B,C,D,iu)` returns the transfer function

$$H(s) = \frac{B(s)}{A(s)} = C(sI - A)^{-1}B + D$$

of the system

$$\dot{x} = Ax + Bu$$
$$y = Cx + Du$$

from the `iu`-th input. Vector `a` contains the coefficients of the denominator in descending powers of s. The numerator coefficients are returned in array `b` with as many rows as there are outputs y. `ss2tf` also works with systems in discrete time, in which case it returns the z-transform representation.

The `ss2tf` function is part of the standard MATLAB language.

Purpose

Read formatted data from string

Syntax

```
A = sscanf(str, format)
A = sscanf(str, format, sizeA)
[A, count] = sscanf(...)
[A, count, errmsg] = sscanf(...)
[A, count, errmsg, nextindex] = sscanf(...)
```

Description

`A = sscanf(str, format)` reads data from string `str`, converts it according to the `format`, and returns the results in array `A`. The `sscanf` function reapplies the `format` until either reaching the end of `str` or failing to match the `format`. If `sscanf` cannot match the `format` to the data, it reads only the portion that matches into `A` and stops processing. If `str` is a character array with more than one row, `sscanf` reads the characters in column order.

`A = sscanf(str, format, sizeA)` reads `sizeA` elements into `A`, where `sizeA` can be an integer or can have the form `[m,n]`.

`[A, count] = sscanf(...)` returns the number of elements that `sscanf` successfully reads.

`[A, count, errmsg] = sscanf(...)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is an empty string.

`[A, count, errmsg, nextindex] = sscanf(...)` returns one more than the number of characters scanned in `str`.

Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

Input Arguments

format

String enclosed in single quotation marks that describes each type of element (field). Includes one or more of the following specifiers.

Field Type	Specifier	Details
Integer, signed	`%d`	Base 10
	`%i`	Base determined from the values. Defaults to base 10. If initial digits are `0x` or `0X`, it is base 16. If initial digit is `0`, it is base 8.
	`%ld` or `%li`	64-bit values, base 10, 8, or 16
Integer, unsigned	`%u`	Base 10
	`%o`	Base 8 (octal)
	`%x`	Base 16 (hexadecimal)
	`%lu`, `%lo`, `%lx`	64-bit values, base 10, 8, or 16
Floating-point number	`%f`	Floating-point fields can contain any of the following (not case sensitive): `Inf`, `-Inf`, `NaN`, or `-NaN`.
	`%e`	
	`%g`	
Character string	`%s`	Read series of characters, until find white space.
	`%c`	Read any single character, including white space. (To read multiple characters, specify field length.)
	`%[...]`	Read only characters in the brackets, until the first nonmatching character or white space.

Optionally:

- To skip fields, insert an asterisk (`*`) after the percent sign (`%`). For example, to skip integers, specify `%*d`.

- To specify the maximum width of a field, insert a number. For example, `%10c` reads exactly 10 characters at a time, including white space.
- To skip a specific set of characters, insert the literal characters in the *format*. For example, to read only the floating-point number from `'pi=3.14159'`, specify a *format* of `'pi=%f'`.

sizeA

Dimensions of the output array *A*. Specify in one of the following forms:

`inf`	Read to the end of the input string. (default)
n	Read at most *n* elements.
`[`*m*`,`*n*`]`	Read at most *m*`*`*n* elements in column order. *n* can be `inf`, but *m* cannot.

When the *format* includes `%s`, *A* can contain more than *n* columns. *n* refers to elements, not characters.

str

Character string.

Output Arguments

A

An array. If the *format* includes:

- Only numeric specifiers, *A* is numeric. If *format* includes only 64-bit signed integer specifiers, *A* is of class `int64`. Similarly, if *format* includes only 64-bit unsigned integer specifiers, *A* is of class `uint64`. Otherwise, *A* is of class `double`. If *sizeA* is `inf` or *n*, then *A* is a column vector. If the input contains fewer than *sizeA* elements, MATLAB pads *A* with zeros.
- Only character or string specifiers (`%c` or `%s`), *A* is a character array. If *sizeA* is `inf` or *n*, *A* is a row vector. If the input contains fewer than *sizeA* characters, MATLAB pads *A* with `char(0)`.

- A combination of numeric and character specifiers, *A* is numeric, of class `double`. MATLAB converts each character to its numeric equivalent. This conversion occurs even when the *format* explicitly skips all numeric values (for example, a *format* of `'%*d %s'`).

If MATLAB cannot match the input to the *format*, and the *format* contains both numeric and character specifiers, *A* can be numeric or character. The class of *A* depends on the values MATLAB reads before processing stops.

count

Number of elements `sscanf` reads into *A*.

errmsg

An error message string when `sscanf` cannot open the specified file. Otherwise, an empty string.

nextindex

`sscanf` counts the number of characters `sscanf` reads from *str*, and then adds one.

Examples

Example 1

Read multiple floating-point values from a string:

```
s = '2.7183  3.1416';
A = sscanf(s,'%f')
A =
    2.7183
    3.1416
```

Example 2

Read an octal integer from a string, identified by the `'0'` prefix, using `%i` to preserve the sign:

```
sscanf('-010','%i')
ans =
```

```
-8
```

Example 3

Read numeric values from a two-dimensional character array. By default, `sscanf` reads characters in column order. To preserve the original order of the values, read one row at a time.

```
mixed = ['abc 45 6 ghi'; 'def 7 89 jkl'];

[nrows, ncols] = size(mixed);
for k = 1:nrows
    nums(k,:) = sscanf(mixed(k,:), '%*s %d %d %*s', [1, inf]);
end;

% type the variable name to see the result
nums =
    45     6
     7    89
```

Example 4

`sscanf` finds one match for `%s`

```
[str count] = sscanf('ThisIsOneString', '%s')
str =
    ThisIsOneString
count =
     1
```

`sscanf` finds four matches for `%s`. Because it does not match space characters, there are no spaces in the output string:

```
[str count] = sscanf('These Are Four Strings', '%s')
str =
    TheseAreFourStrings
count =
     4
```

`sscanf` finds five word matches for `%s` and four space character matches for `%c`. Because the `%c` specifier does match a space character, the output string does include spaces:

```
[str count] = sscanf('Five strings and four spaces', '%s%c')
str =
    Five strings and four spaces
count =
    9
```

`sscanf` finds three word matches for `%s` and two numeric matches for `%d`. Because the format specifier has a mixed %d and %s format, sscanf converts all nonnumeric characters to numeric:

```
[str count] = sscanf('5 strings and 4 spaces', '%d%s%s%d%s');
str'
  Columns 1 through 9
     5   115   116   114   105   110   103   115    97
  Columns 10 through 18
   110   100     4   115   112    97    99   101   115
count
count =
     5
```

Example 5

```
[str, count] = sscanf('one two three', '%c')
str =
    one two three
count =
    13

[str, count] = sscanf('one two three', '%13c')
str =
    one two three
count =
     1
```

```
[str, count] = sscanf('one two three', '%s')
str =
    onetwothree
count =
     3

[str, count] = sscanf('one two three', '%1s')
str =
    onetwothree
count =
    11
```

Example 6

```
tempString = '78 F 72 F 64 F 66 F 49 F';

degrees = char(176);
tempNumeric = sscanf(tempString, ['%d' degrees 'F'])'
tempNumeric =
    78    72    64    66    49
```

stairs

Purpose

Stairstep graph

Syntax

```
stairs(Y)
stairs(X,Y)
stairs(___,LineSpec)
stairs(___,Name,Value)

stairs(axes_handle,___)

h = stairs(___)

[xb,yb] = stairs(___)
```

Description

`stairs(Y)` draws a stairstep graph of the elements in `Y`.

- If `Y` is a vector, then the *x*-axis scale ranges from 1 to `length(Y)`.
- If `Y` is a matrix, then `stairs` draws one line per matrix column and the *x*-axis scale ranges from 1 to the number of rows in `Y`.

`stairs(X,Y)` plots the elements in `Y` at the locations specified in `X`. The inputs `X` and `Y` must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

`stairs(___,LineSpec)` specifies a line style, marker symbol, and color. Use this option with any of the input argument combinations in the previous syntaxes.

`stairs(___,Name,Value)` specifies stairseries properties using one or more `Name,Value` pair arguments.

`stairs(axes_handle,___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle`, can precede any of the input argument combinations in the previous syntaxes.

`h = stairs(___)` returns a vector of stairseries object handles in `h`. When multiple stairseries are present, you can make changes to properties of a specific stairseries by specifying a particular handle.

`[xb,yb] = stairs(___)` does not create a plot, but returns matrices `xb` and `yb` of the same size, such that `plot(xb,yb)` plots the stairstep graph.

Input Arguments

Y - Elements to plot

vector or matrix

Elements to plot, specified as a vector or matrix. When `Y` is a vector, `stairs` creates one stairseries. When `Y` is a matrix, `stairs` draws one line per matrix column and creates a separate stairseries for each column.

Data Types

`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`

X - Locations to plot elements in Y

vector or matrix

Locations to plot elements in `Y`, specified as a vector or matrix. When `Y` is a vector, `X` must be a vector of the same size. When `Y` is a matrix, `X` must be a matrix of the same size, or a vector whose length equals the number of rows in `Y`.

Data Types

`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`

LineSpec - Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineSpec`.

Example: `':*r'`

Data Types
`char`

axes_handle - Axes handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Marker','s','MarkerFaceColor','red'` plots the stairstep graph with red square markers.

For more information on stairseries properties see `stairseries`.

'LineStyle' - Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and a line style specifier. This table lists supported line styles.

Specifier	Line Style
'- '	Solid line (default)
'--'	Dashed line
':'	Dotted line

Specifier	Line Style
'-.'	Dash-dot line
'none'	No line

Example: 'LineStyle','-.'

'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar in points.

Example: 'LineWidth',0.75

'Color' - Color

[0 0 1] (blue) (default) | 3-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'Color',[0 1 0]`

Example: `'Color','green'`

'Marker' - Marker symbol

`'none'` (default) | string

Marker symbol, specified as the comma-separated pair consisting of `'Marker'` and a marker specifier. This table lists supported marker symbols.

Specifier	MarkerSymbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

Example: `'Marker','+'`

Example: `'Marker','diamond'`

'MarkerEdgeColor' - Marker edge color

`[0 0 1]` (blue) (default) | `'auto'` | `'none'` | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of `'MarkerEdgeColor'` and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'MarkerEdgeColor',[1 .8 .1]`

'MarkerFaceColor' - Marker face color

`'none'` (default) | `'auto'` | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of `'MarkerFaceColor'` and a color value. `MarkerFaceColor` sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'MarkerFaceColor',[0 .8 1]`

'MarkerSize' - Marker size

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a scalar in points.

Example: 'MarkerSize',7

Output Arguments

h - Stairseries object handle

scalar or column vector

Stairseries object handle, specified as a scalar or column vector. This is a unique identifier, which you can use to query and modify the properties of a specific stairseries.

xb - x values for use with plot

vector or matrix

x values for use with plot, specified as a vector or matrix. xb contains the appropriate values such that plot(xb,yb) creates the stairstep graph.

yb - y values for use with plot

vector or matrix

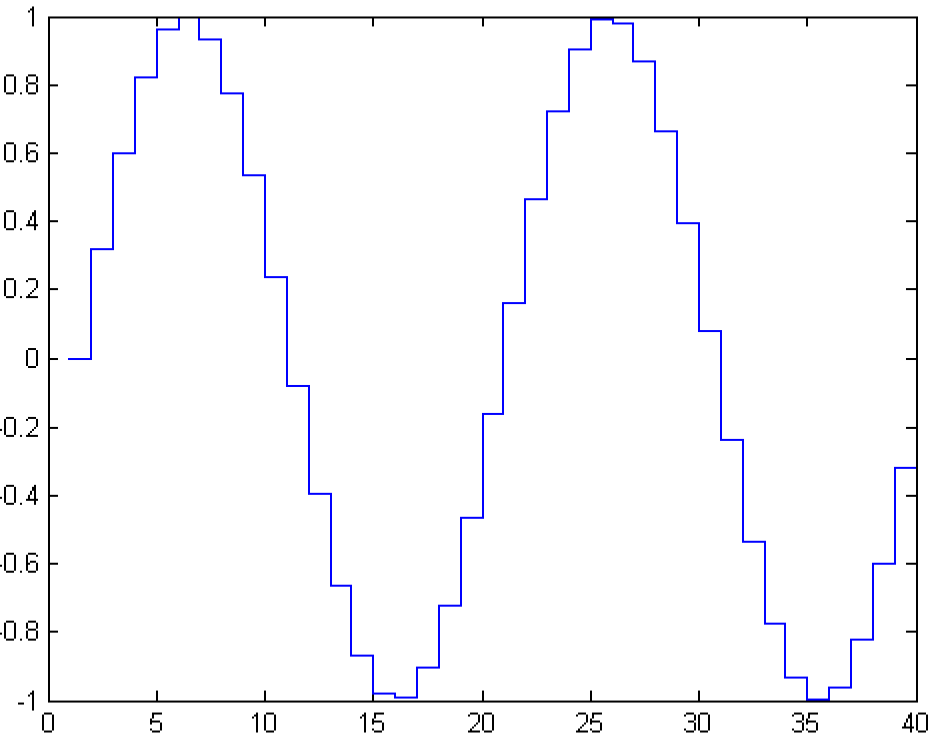
y values for use with plot, specified as a vector or matrix. yb contains the appropriate values such that plot(xb,yb) creates the stairstep graph.

Examples

Plot a Single Data Series

Create a stairstep plot of sine evaluated at 40 equally spaced values between 0 and 4π.

```
figure
X = linspace(0,4*pi,40);
Y = sin(X);
stairs(Y)
```

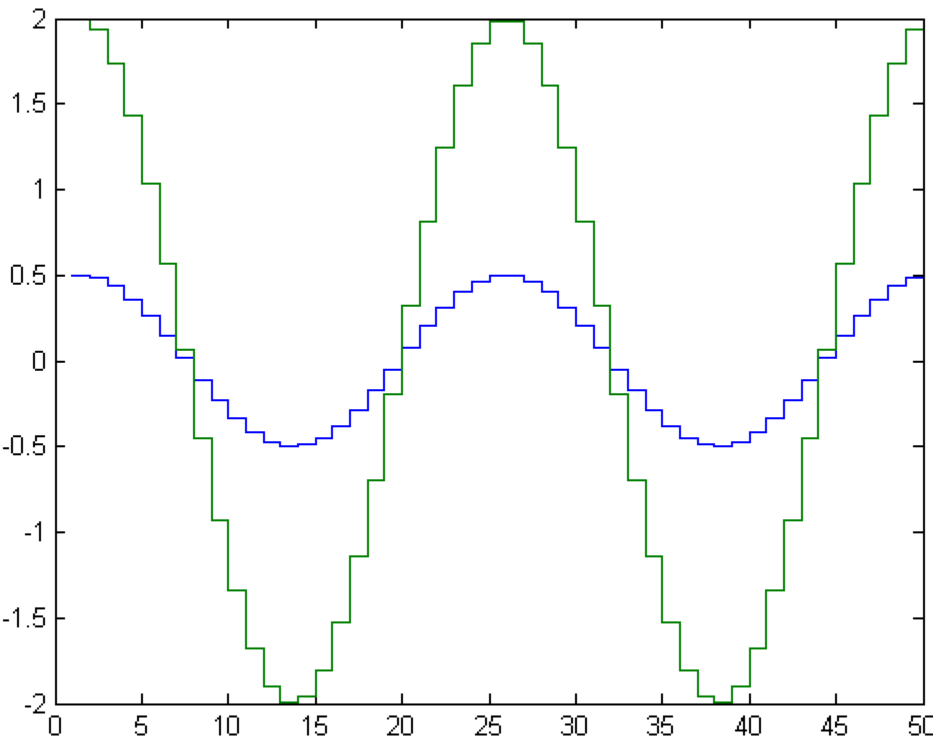


The length of `Y` automatically determines and generates the *x*-axis scale.

Plot Multiple Data Series

Create a stairstep plot of two cosine functions evaluated at 50 equally spaced values between 0 and 4π.

```
figure
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
stairs(Y)
```



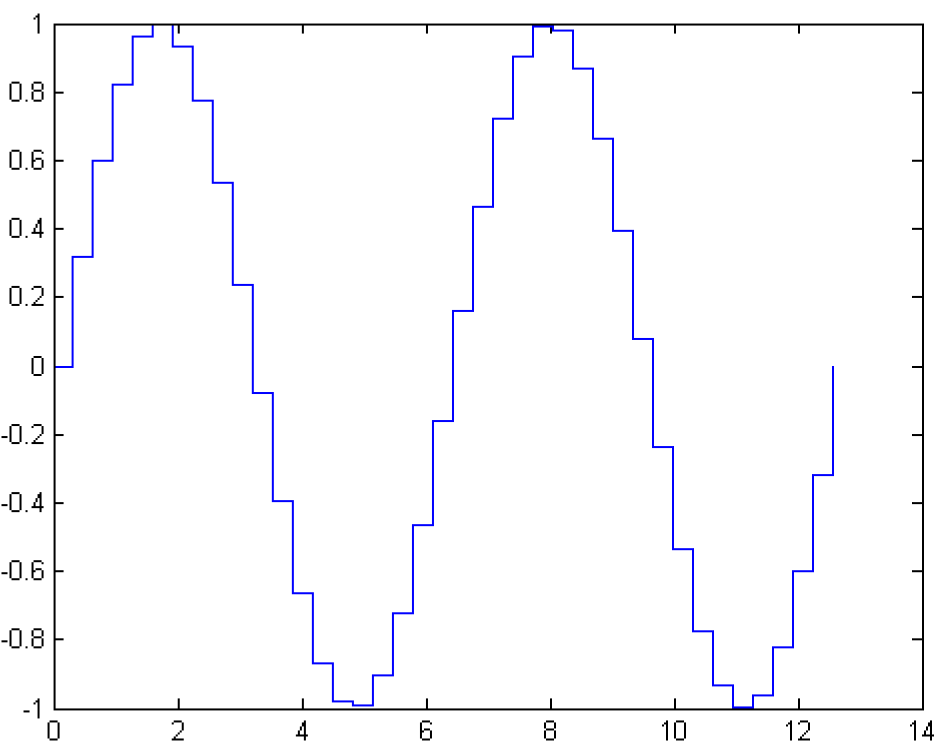
The number of rows in Y automatically determines and generates the *x*-axis scale.

Plot a Single Data Series at Specified *x* Values

Create a stairstep plot of a sine wave evaluated at equally spaced values between 0 and 4π. Specify the set of *x* values for the plot.

```
figure
X = linspace(0,4*pi,40);
Y = sin(X);
```

```
stairs(X,Y)
```



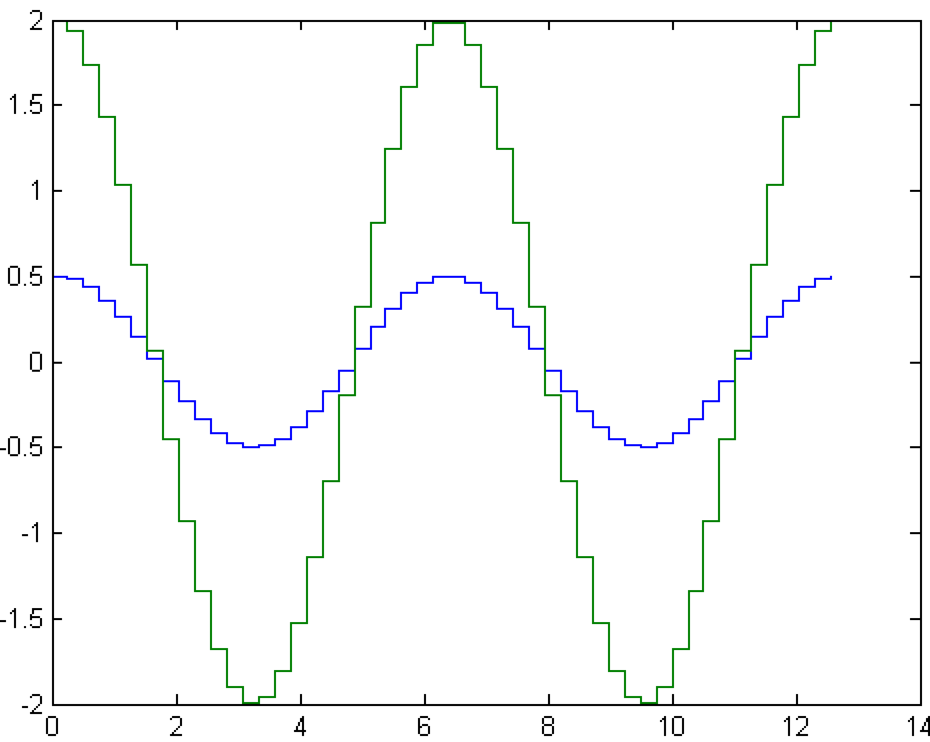
The entries in Y are plotted against the corresponding entries in X.

Plot Multiple Data Series at Specified *x* Values

Create a stairstep plot of two cosine waves evaluated at equally spaced values between 0 and 4π. Specify the set of *x* values for the plot.

```
figure
X = linspace(0,4*pi,50)';
```

```
Y = [0.5*cos(X), 2*cos(X)];
stairs(X,Y)
```

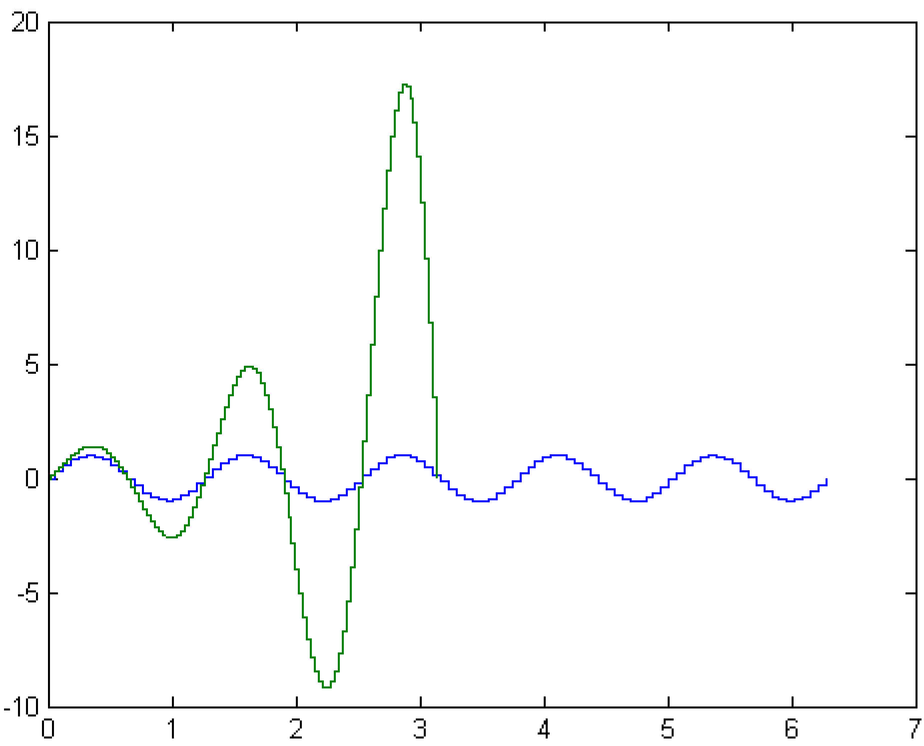


The first vector input, X, determines the *x*-axis positions for both data series.

Plot Multiple Data Series at Unique Sets of *x* Values

Create a stairstep plot of two sine waves evaluated at different values. Specify a unique set of *x* values for plotting each data series.

```
figure
x1 = linspace(0,2*pi)';
x2 = linspace(0,pi)';
X = [x1,x2];
Y = [sin(5*x1),exp(x2).*sin(5*x2)];
stairs(X,Y)
```

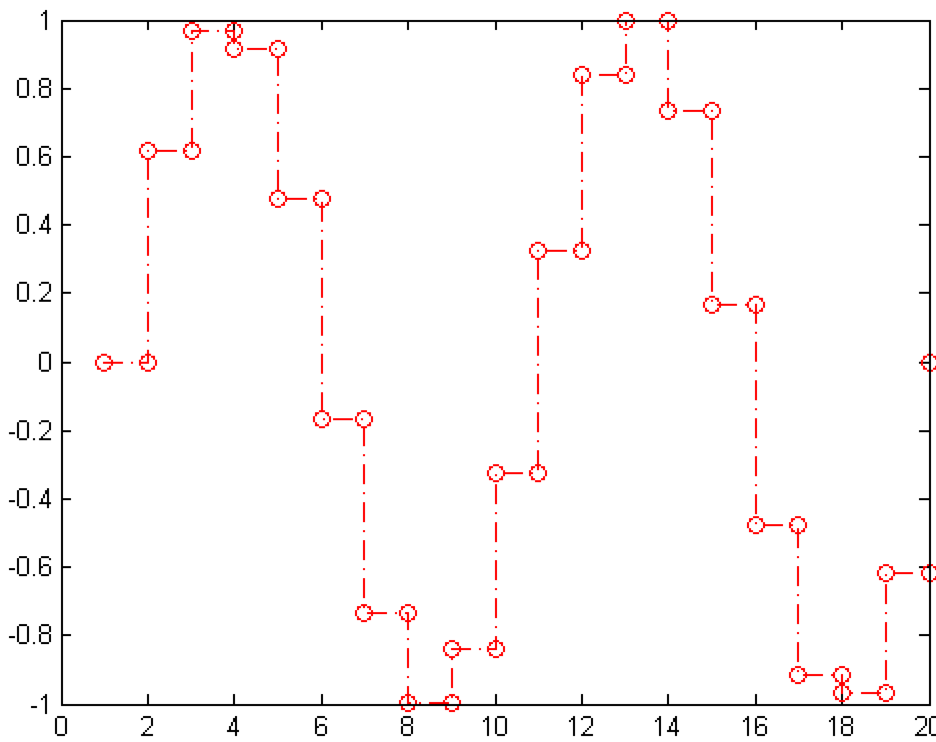


Each column of X is plotted against the corresponding column of Y.

Specify the Line Style, Marker Symbol and Color

Create a stairstep plot and set the line style to a dot-dashed line, the marker symbol to circles, and the color to red.

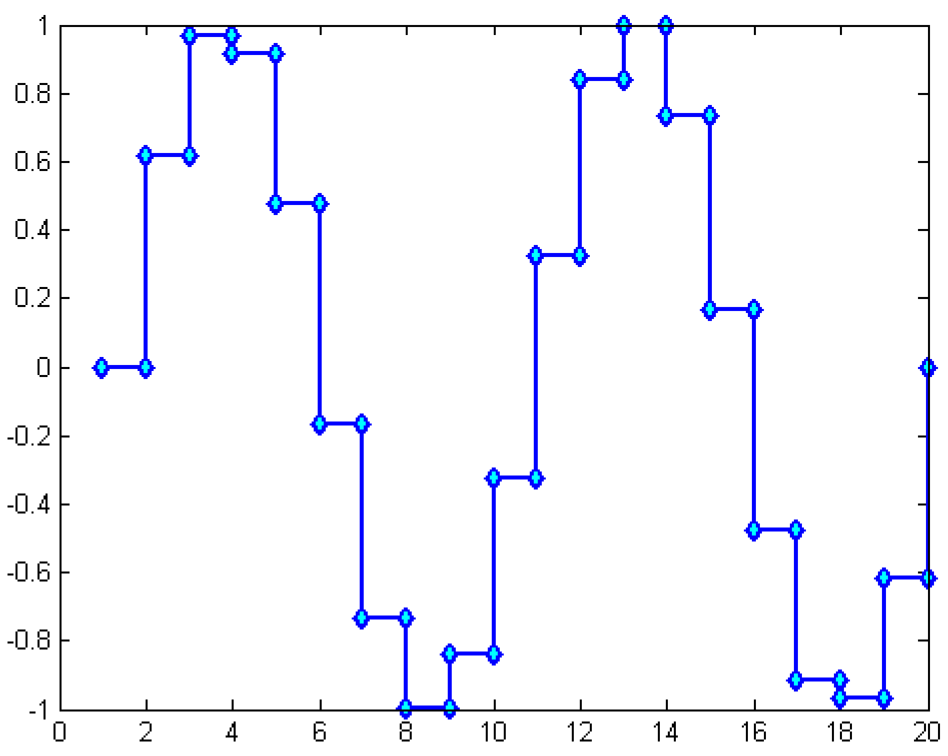
```
figure
X = linspace(0,4*pi,20);
Y = sin(X);
stairs(Y, '-.or')
```



Specify Additional Style Options

Create a stairstep plot and set the line width to 2 points, the marker symbols to diamonds, and the marker face color to cyan using `Name,Value` pair arguments.

```
figure
X = linspace(0,4*pi,20);
Y = sin(X);
stairs(Y,'LineWidth',2,'Marker','d','MarkerFaceColor','c')
```



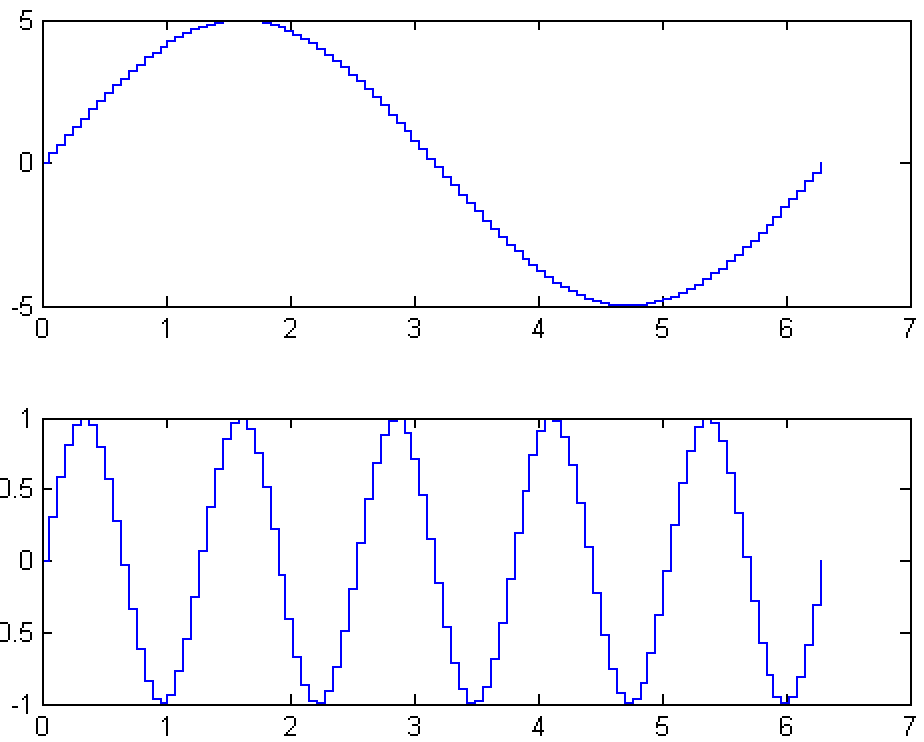
Specify Axes for Stairstep Plots

Create two subplots and return the handles to the axes, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);
```

Create a stairstep plot in each subplot by referring to the axes handles.

```
X = linspace(0,2*pi);
Y1 = 5*sin(X);
Y2 = sin(5*X);
stairs(s(1),X,Y1)
stairs(s(2),X,Y2)
```



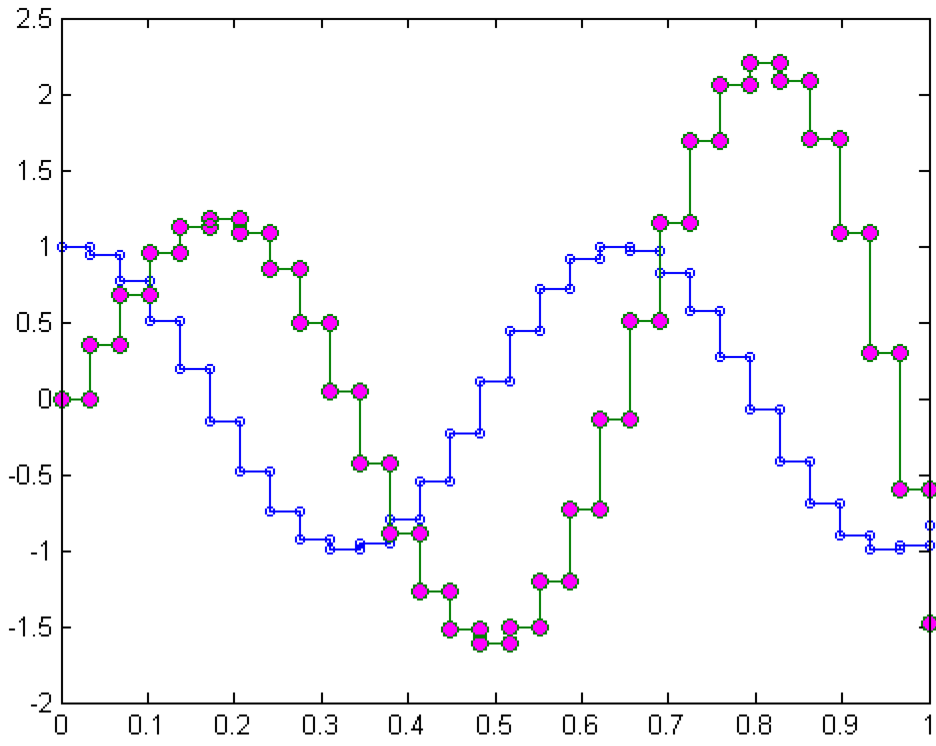
Return Stairseries Handle

Create a stairstep plot of two data series and return the handle to each stairseries.

```
figure
X = linspace(0,1,30)';
Y = [cos(10*X), exp(X).*sin(10*X)];
h = stairs(X,Y);
```

Specify the markers of the first series to small circles and the second series to magenta filled circles by referring to the handles.

```
set(h(1),'Marker','o','MarkerSize',4)
set(h(2),'Marker','o','MarkerFaceColor','m')
```



Create a Stairstep Plot using `plot`

Evaluate two cosine functions at 40 equally spaced values between 0 and 4π and create a stairstep plot using `plot`.

Use `stairs` to get `xb` and `yb`.

```
figure
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
[xb,yb] = stairs(X,Y);
```

`stairs` returns two matrices of the same size, but no plot.

Use `plot` to create the stairstep plot with `xb` and `yb`.

```
plot(xb,yb)
```

Stairseries Properties

Purpose

Define stairseries properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default property values for stairseries objects.

See Plot Objects for information on stairseries objects.

Stairseries Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Annotation`

`hg.Annotation` object (read-only)

Control the display of stairseries objects in legends. Specifies whether this stairseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the stairseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
`on`	Include the stairseries object in a legend as one entry, but not its children objects
`off`	Do not include the stairseries or its children in a legend (default)
`children`	Include only the children of the stairseries as separate entries in the legend

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the IconDisplayStyle Property

See "Controlling Legends" for more information and examples.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

running callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

The expression executes in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`Children`

array of graphics object handles

Children of the stairseries object. An array containing the handles of all line objects parented to the stairseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`

`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`Color`

ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is `[0 0 0]` (`black`).

See the `ColorSpec` reference page for more information on specifying color. See "Adding Arrows and Lines to Graphs".

`CreateFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y,'CreateFcn',@CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`
string

String used by legend. The `legend` function uses the `DisplayName` property to label the stairseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EraseMode`
`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property,

figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`
`{on} | off`

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the stairstep graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`
`on | {off}`

Select the object by clicking lines or area of extent. Select plot objects by:

- Clicking lines (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the lines to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses the stairstep graph).

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

`LineStyle`

`{-} | -- | :  | -.  | none`

Line style of stairseries object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line

Specifier	Line Style
'-.'	Dash-dot line
'none'	No line

Use `LineStyle` `none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is 0.5 points.

`Marker`
character (see table)

Marker symbol. Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond

Specifier	Marker Type
’^’	Upward-pointing triangle
’v’	Downward-pointing triangle
’>’	Right-pointing triangle
’<’	Left-pointing triangle
’pentagram’ or ’p’	Five-pointed star (pentagram)
’hexagram’ or ’h''’	Six-pointed star (hexagram)
’none’	No marker (default)

MarkerEdgeColor
ColorSpec | none | {auto}

Marker edge color. The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the Color property.

MarkerFaceColor
ColorSpec | {none} | auto

Fill color for closed-shape markers. The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Makes the interior of the marker transparent, allowing the background to show through.
- auto — Sets the fill color to the axes Color property. If the axes Color property is none, sets the fill color to the figure Color.

`MarkerSize`
scalar

Marker size. Size of the marker in points. The default value is `6`.

Note MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

`Parent`
handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Object selection state. When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Object highlighted when selected.

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.

- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`Tag`
string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an areaseries object and set the `Tag` property.

```
t = area(Y,'Tag','area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

`Type`
string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stairseries objects, `Type` is '`hggroup`'. The following statement finds all the hggroup objects in the current axes object.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`
handle of uicontextmenu object

Associate context menu with object. Handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu`

function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

`UserData`
array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Visibility of object and its children.

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

`XData`
array

X-axis location of stairs. The `stairs` function uses `XData` to label the *x*-axis. `XData` can be either a matrix equal in size to `YData` or a vector equal in length to the number of rows in `YData`. That is, `length(XData) == size(YData,1)`.

If you do not specify `XData` (which the input argument `X`), the `stairs` function uses the indices of `YData` to create the stairstep graph. See the `XDataMode` property for related information.

`XDataMode`
`{auto} | manual`

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the `X` input

argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

`XDataSource`

MATLAB variable, as a string

Link `XData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h,'XDataSource','xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`

scalar | vector | matrix

Stairs plot data. `YData` contains the data plotted in the stairstep graph. Each value in `YData` is represented by a marker in the stairstep graph. If `YData` is a matrix, the `stairs` function creates a line for each column in the matrix.

The input argument `Y` in the `stairs` function calling syntax assigns values to `YData`.

`YDataSource`

MATLAB variable, as a string

Link `YData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h,'YDataSource','Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Purpose

Start timer(s) running

Syntax

```
start(obj)
```

Description

`start(obj)` starts the timer running, represented by the timer object, `obj`. If `obj` is an array of timer objects, `start` starts all the timers. Use the `timer` function to create a timer object.

`start` sets the `Running` property of the timer object, `obj`, to `'on'`, initiates `TimerFcn` callbacks, and executes the `StartFcn` callback.

The timer stops running if one of the following conditions apply:

- The first `TimerFcn` callback completes, if `ExecutionMode` is `'singleShot'`.
- The number of `TimerFcn` callbacks specified in `TasksToExecute` have been executed.
- The `stop(obj)` command is issued.
- An error occurred while executing a `TimerFcn` callback.

See Also

`timer` | `stop`

Purpose

Start timer(s) running at specified time

Syntax

```
startat(obj,time)
startat(obj,S)
startat(obj,S,pivotyear)
startat(obj,Y,M,D)
startat(obj,[Y,M,D])
startat(obj,Y,M,D,H,MI,S)
startat(obj,[Y,M,D,H,MI,S])
```

Description

`startat(obj,time)` starts the timer represented by timer object `obj`running at the time specified by the serial date number `time`. If `obj` is an array of timer objects, `startat` starts all the timers running at the specified time. To create a timer object, use the `timer` function. You can set the starting *`time`* to any serial date number less than or equal to 25 days from the current date.

`startat` sets the `Running` property of the timer object, `obj`, to `'on'`, initiates `TimerFcn` callbacks, and executes the `StartFcn` callback.

The serial date number, `time`, indicates the number of days that have elapsed since 1-Jan-0000 (starting at 1). See `datenum` for additional information about serial date numbers.

`startat(obj,S)` starts the timer running at the time specified by the date string `S`. The date string must use date format 0, 1, 2, 6, 13, 14, 15, 16, or 23, as defined by the `datestr` function. Date strings with two-character years are interpreted to be within the 100 years centered on the current year.

`startat(obj,S,pivotyear)` uses the specified pivot year as the starting year of the 100-year range in which a two-character year resides. The default pivot year is the current year minus 50 years.

`startat(obj,Y,M,D)` `startat(obj,[Y,M,D])` start the timer at the year (`Y`), month (`M`), and day (`D`) specified. `Y`, `M`, and `D` must be arrays of the same size (or they can be a scalar).

`startat(obj,Y,M,D,H,MI,S)` `startat(obj,[Y,M,D,H,MI,S])` start the timer at the year (`Y`), month (`M`), day (`D`), hour (`H`), minute (`MI`), and

second (S) specified. Y, M, D, H, MI, and S must be arrays of the same size (or they can be a scalar). Values outside the normal range of each array are automatically carried to the next unit (for example, month values greater than 12 are carried to years). Month values less than 1 are set to be 1; all other units can wrap and have valid negative values.

The timer stops running if one of the following conditions apply:

- The number of TimerFcn callbacks specified in TasksToExecute have been executed.
- The stop(obj) command is issued.
- An error occurred while executing a TimerFcn callback.

Examples

This example uses a timer object to execute a function at a specified time.

```
t1=timer('TimerFcn','disp(''it is 10 o''''clock'')');
startat(t1,'10:00:00');
```

This example uses a timer to display a message when an hour has elapsed.

```
t2=timer('TimerFcn','disp(''It has been an hour now.'')');
startat(t2,now+1/24);
```

datenum | datestr | now | timer | start | stop

Purpose

Startup file for user-defined options

Syntax

```
startup
```

Description

`startup` executes commands of your choosing when the MATLAB program starts.

Create a `startup.m` file in your MATLAB startup folder and put in the file any commands you want executed at MATLAB startup. For example, your `startup.m` file might include physical constants, defaults for Handle Graphics properties, engineering conversion factors, or anything else you want predefined in your workspace.

Algorithms

The MATLAB program executes the `matlabrc.m` file when it starts. `matlabrc.m` invokes `startup.m`, if it exists on the MATLAB search path.

You can extend this process to create additional startup files, if needed.

MathWorks does not recommend modifying the `matlabrc.m` file, except perhaps by system administrators in network configurations.

How To

- "Specifying Startup Options in the MATLAB Startup File"
- Preferences

Purpose

Standard deviation

Syntax

```
s = std(X)
s = std(X,flag)
s = std(X,flag,dim)
```

Definitions

There are two common textbook definitions for the standard deviation `s` of a data vector `X`.

$$(1)\ s = \left(\frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})^2 \right)^{\frac{1}{2}}$$

$$(2)\ s = \left(\frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^2 \right)^{\frac{1}{2}},$$

where

$$\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i$$

and n is the number of elements in the sample. The two forms of the equation differ only in $n-1$ versus n in the divisor.

Description

`s = std(X)`, where `X` is a vector, returns the standard deviation using (1) above. The result `s` is the square root of an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples.

If `X` is a matrix, `std(X)` returns a row vector containing the standard deviation of the elements of each column of `X`. If `X` is a multidimensional array, `std(X)` is the standard deviation of the elements along the first nonsingleton dimension of `X`.

`s = std(X,flag)` for `flag = 0`, is the same as `std(X)`. For `flag = 1`, `std(X,1)` returns the standard deviation using (2) above, producing the second moment of the set of values about their mean.

`s = std(X,flag,dim)` computes the standard deviations along the dimension of `X` specified by scalar `dim`. Set `flag` to `0` to normalize `Y` by *n*-1; set `flag` to `1` to normalize by *n*.

The input array, `X`, must be of type `double` or `single` for all syntaxes.

Examples

For matrix `X`

```
X =
      1     5     9
     7    15    22
s = std(X,0,1)
s =
    4.2426    7.0711   9.1924
s = std(X,0,2)
s =
    4.000
    7.5056
```

`corrcoef` | `cov` | `mean` | `median` | `var`

Purpose

Plot discrete sequence data

Syntax

```
stem(Y)
stem(X,Y)
stem(___,'fill')
stem(___,LineSpec)
stem(___,Name,Value)

stem(axes_handle,___)

h = stem(___)
```

Description

`stem(Y)` plots the data sequence, `Y`, as stems that extend from a baseline along the *x*-axis. The data values are indicated by circles terminating each stem.

- If `Y` is a vector, then the *x*-axis scale ranges from 1 to `length(Y)`.
- If `Y` is a matrix, then `stem` plots all elements in a row against the same *x* value, and the *x*-axis scale ranges from 1 to the number of rows in `Y`.

`stem(X,Y)` plots the data sequence, `Y`, at values specified by `X`. The `X` and `Y` inputs must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

- If `X` and `Y` are both vectors, then `stem` plots entries in `Y` against corresponding entries in `X`.
- If `X` is a vector and `Y` is a matrix, then `stem` plots each column of `Y` against the set of values specified by `X`, such that all elements in a row of `Y` are plotted against the same value.
- If `X` and `Y` are both matrices, then `stem` plots columns of `Y` against corresponding columns of `X`.

`stem(___,'fill')` fills the circles. Use this option with any of the input argument combinations in the previous syntaxes.

`stem(___,LineSpec)` specifies the line style, marker symbol, and color.

`stem(___,Name,Value)` specifies stemseries properties using one or more `Name,Value` pair arguments.

`stem(axes_handle,___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle`, can precede any of the input argument combinations in the previous syntaxes.

`h = stem(___)` returns a vector of stemseries object handles in `h`. When multiple stemseries objects are present, you can make changes to properties of a specific stemseries by specifying a particular handle.

Input Arguments

Y - Data sequence to display

vector or matrix

Data sequence to display, specified as a vector or matrix. When `Y` is a vector, `stem` creates one stemseries. When `Y` is a matrix, `stem` creates a separate stemseries for each column.

Data Types

`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`

X - Locations to plot data values in Y

vector or matrix

Locations to plot data values in `Y`, specified as a vector or matrix. When `Y` is a vector, `X` must be a vector of the same size. When `Y` is a matrix, `X` must be a matrix of the same size, or a vector whose length equals the number of rows in `Y`.

Data Types

`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`

LineSpec - Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineSpec`.

Example: `':*r'`

Data Types
`char`

axes_handle - Axes handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'LineStyle',':','MarkerFaceColor','red'` plots the stem as a dotted line and colors the marker face red.

For more information on these properties see `stemseries`.

'LineStyle' - Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and a line style specifier. This table lists supported line styles.

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Example: `'LineStyle','-.'`

'LineWidth' - Line width

`0.5` (default) | scalar

Line width, specified as the comma-separated pair consisting of `'LineWidth'` and a scalar. The scalar sets the width size in points of the stem and marker edge.

Example: `'LineWidth',0.75`

'Color' - Color

`[0 0 1]` (blue) (default) | 3-element RGB vector | string

Color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`.

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'Color',[0 1 0]

Example: 'Color','green'

'Marker' - Marker symbol

'o' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. This table lists supported marker symbols.

Specifier	MarkerSymbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle

Specifier	MarkerSymbol
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

Example: 'Marker','+'

Example: 'Marker','diamond'

'MarkerEdgeColor' - Marker edge color

[0 0 1] (blue) (default) | 'auto' | 'none' | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'MarkerEdgeColor',[1 .8 .1]`

'MarkerFaceColor' - Marker face color

`'none'` (default) | `'auto'` | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of `'MarkerFaceColor'` and a color value. `MarkerFaceColor` sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'MarkerFaceColor',[0 .8 1]`

'MarkerSize' - Marker size

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of `'MarkerSize'` and a scalar in points.

Example: `'MarkerSize',3.75`

Output Arguments

h - Stemseries object handle

scalar or column vector

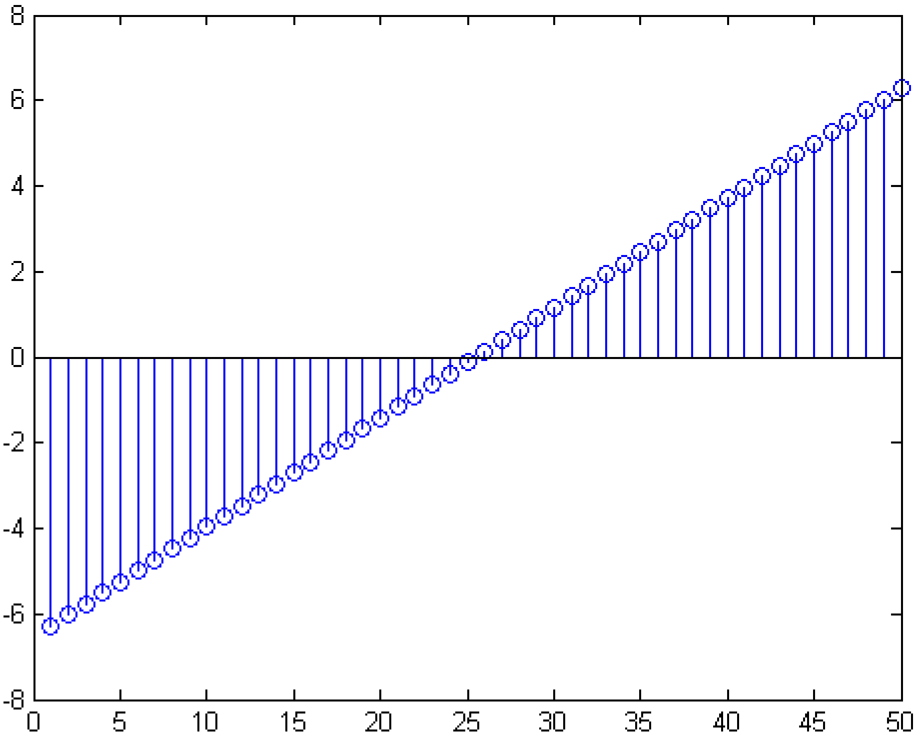
Stemseries object handle, specified as a scalar or column vector. This is a unique identifier, which you can use to query and modify the properties of a specific `stemseries`.

Examples

Plot Single Data Series

Plot 50 data values between -2π and 2π with a vector input.

```
figure
Y = linspace(-2*pi,2*pi,50);
stem(Y)
```



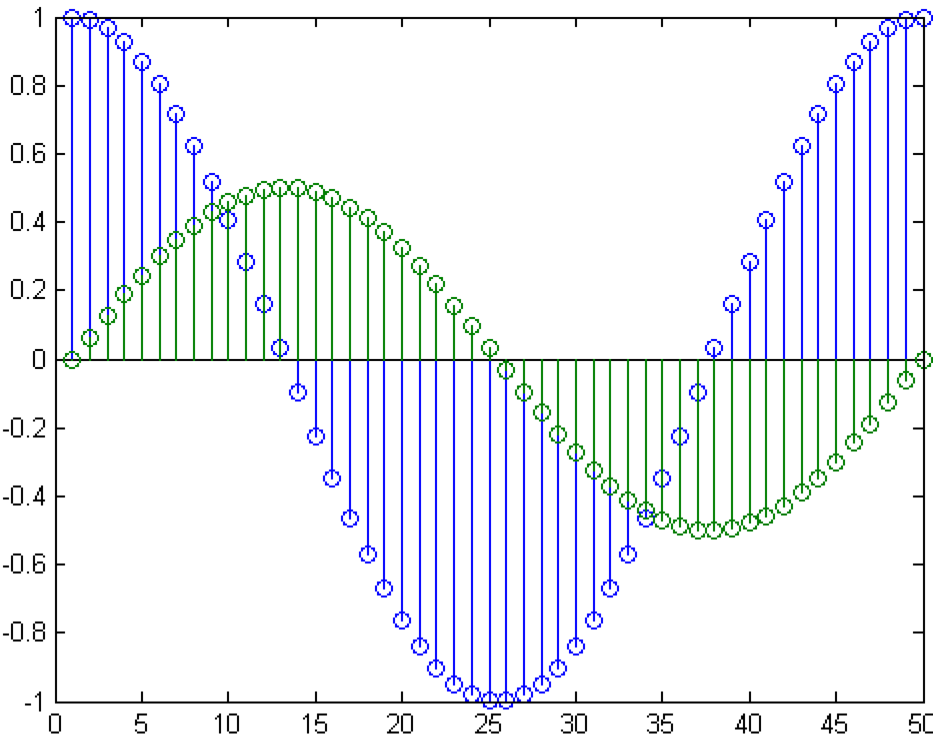
Data values are plotted as stems extending from the baseline and terminating at the data value. The length of `Y` automatically determines the position of each stem on the *x*-axis.

Plot Multiple Data Series

Plot two data series with a two-column matrix input.

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
```

```
stem(Y)
```

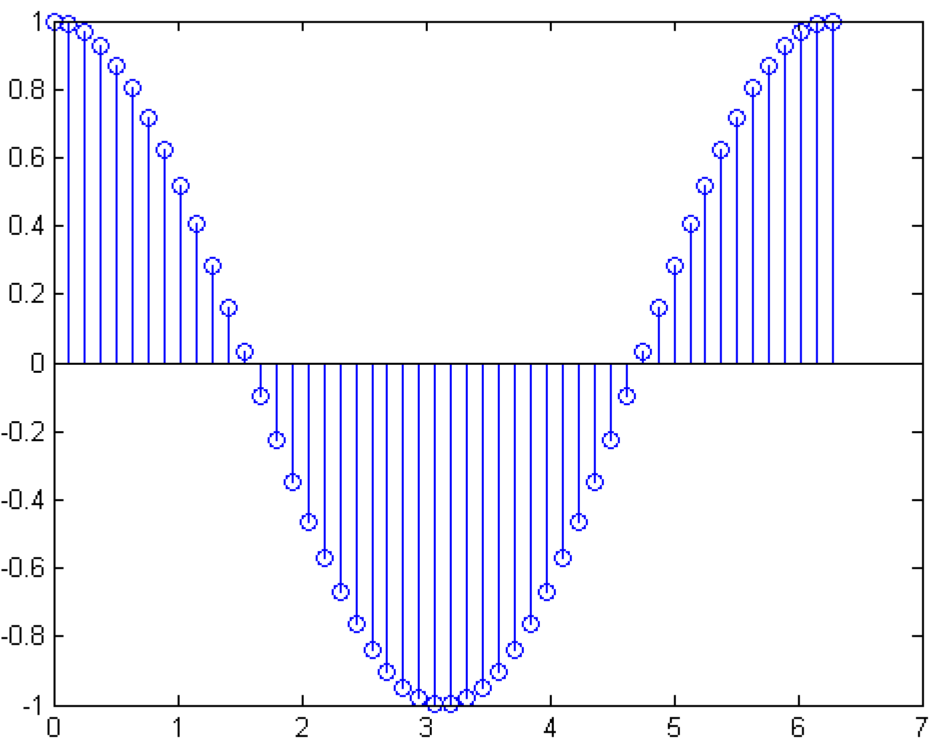


Each column of `Y` is plotted as a separate series, and entries in the same row of `Y` are plotted against the same *x* value. The number of rows in `Y` automatically generates the position of each stem on the *x*-axis.

Plot Single Data Series at Specified *x* values

Plot 50 data values of cosine evaluated between 0 and 2π and specify the set of *x* values for the stem plot.

```
figure
X = linspace(0,2*pi,50)';
Y = cos(X);
stem(X,Y)
```

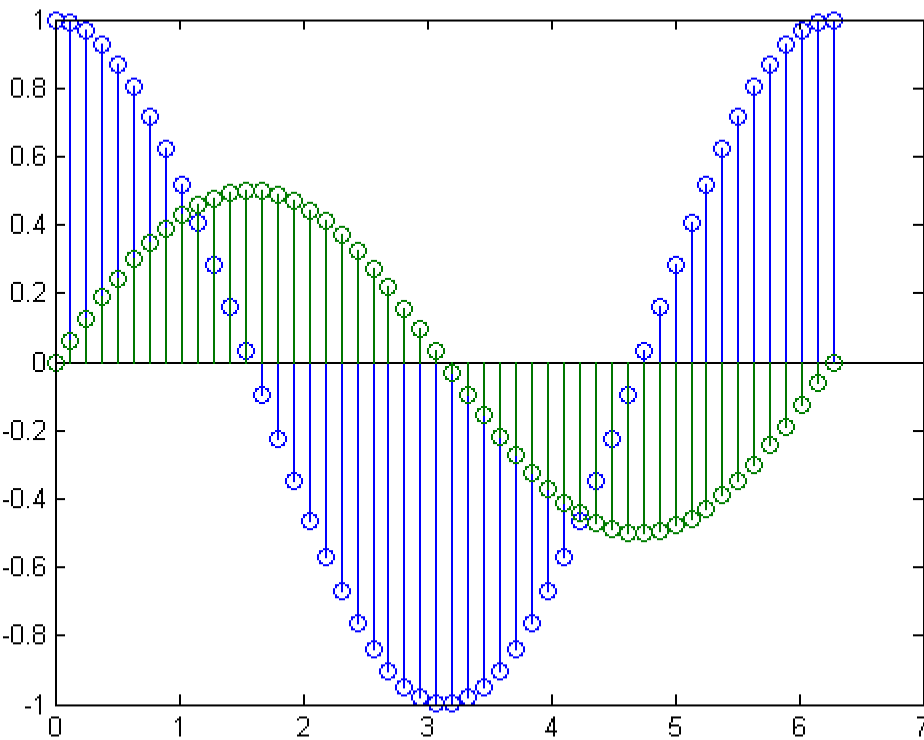


The first vector input determines the position of each stem on the *x*-axis.

Plot Multiple Data Series at Specified *x* values

Plot 50 data values of sine and cosine evaluated between 0 and 2π and specify the set of *x* values for the stem plot.

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
stem(X,Y)
```

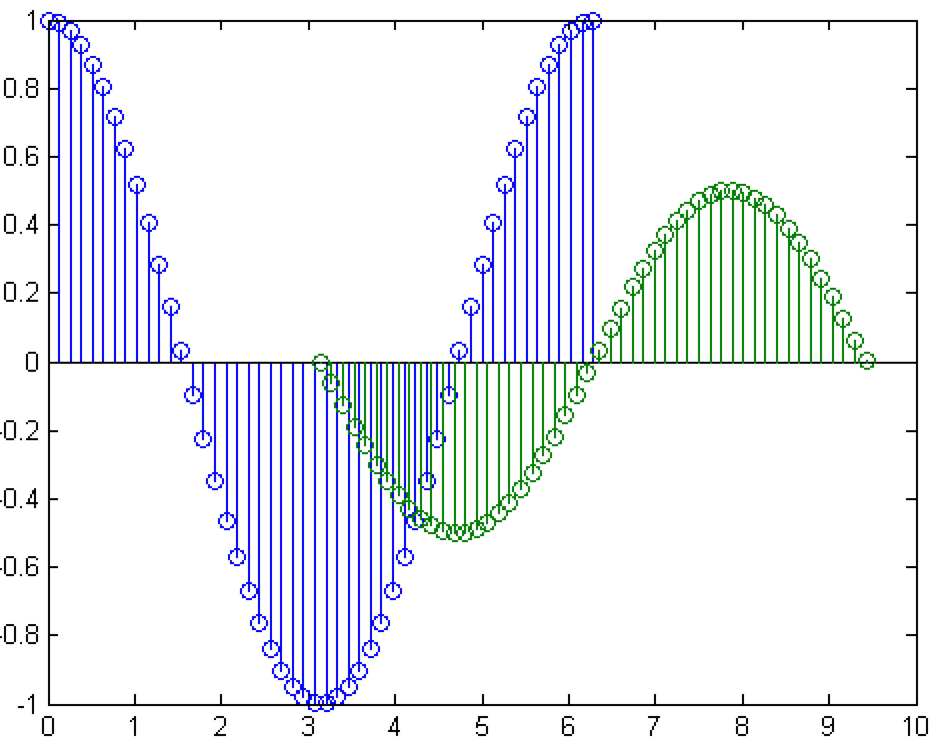


The vector input determines the *x*-axis positions for both data series.

Plot Multiple Data Series at Unique Sets of *x* values

Plot 50 data values of sine and cosine evaluated at different sets of *x* values. Specify the corresponding sets of *x* values for each series.

```
figure
x1 = linspace(0,2*pi,50)';
x2 = linspace(pi,3*pi,50)';
X = [x1, x2];
Y = [cos(x1), 0.5*sin(x2)];
stem(X,Y)
```

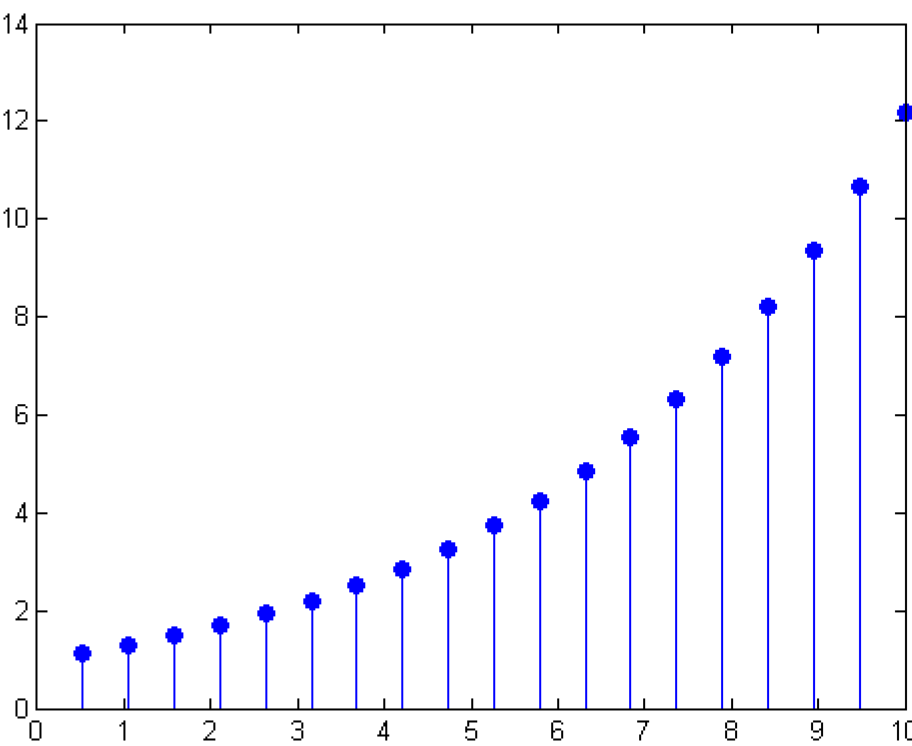


Each column of `X` is plotted against the corresponding column of `Y`.

Fill in Plot Markers

Create a stem plot and fill the circles that terminate each stem.

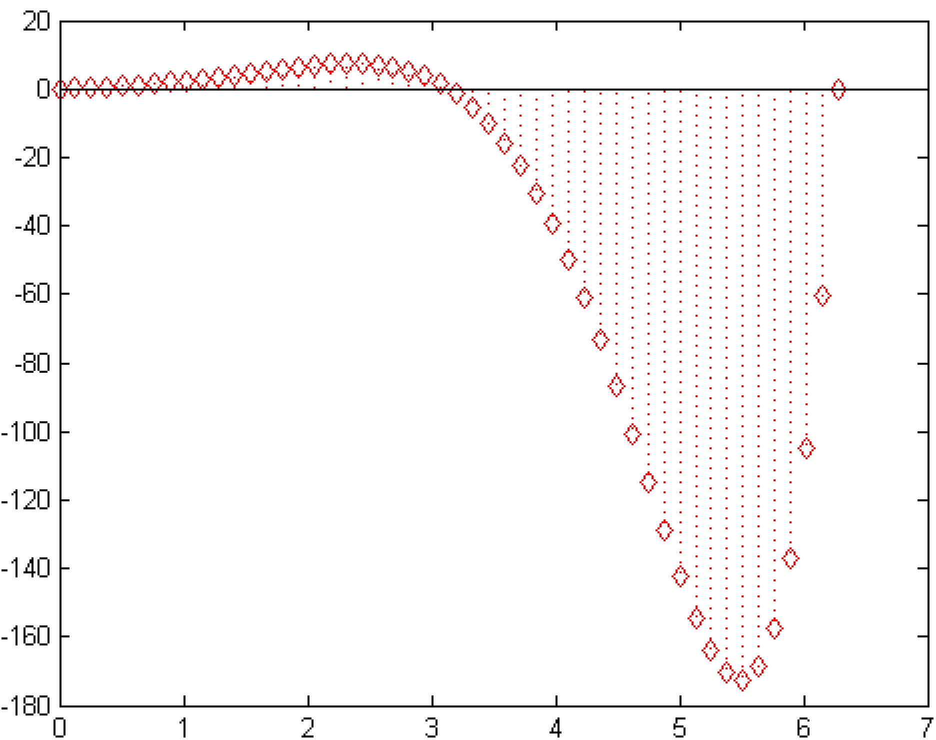
```
figure
X = linspace(0,10,20)';
Y = (exp(0.25*X));
stem(X,Y,'fill')
```



Specify Stem and Marker Options

Create a stem plot and set the line style to a dotted line, the marker symbols to diamonds, and the color to red using the `LineSpec` option.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(X).*sin(X));
stem(X,Y,':diamondr')
```

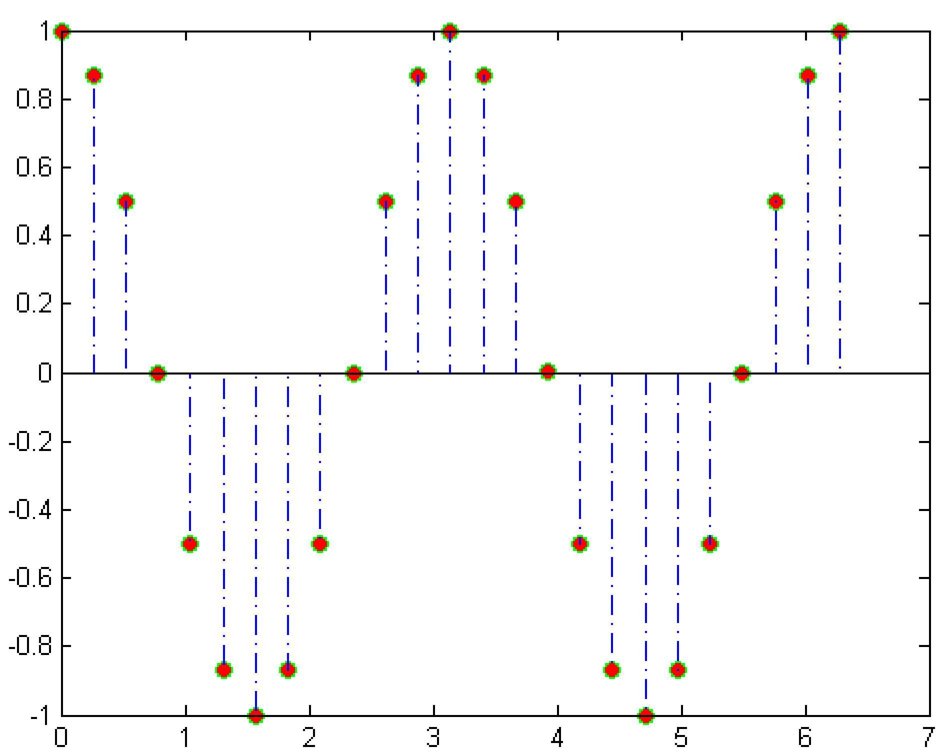


To color the inside of the diamonds, use the `'fill'` option.

Specify Additional Stem and Marker Options

Create a stem plot and set the line style to a dot-dashed line, the marker face color to red, and the marker edge color to green using `Name,Value` pair arguments.

```
figure
X = linspace(0,2*pi,25)';
Y = (cos(2*X));
stem(X,Y,'LineStyle','-.','MarkerFaceColor','red','MarkerEdgeColor','g
```



The stem remains the default color.

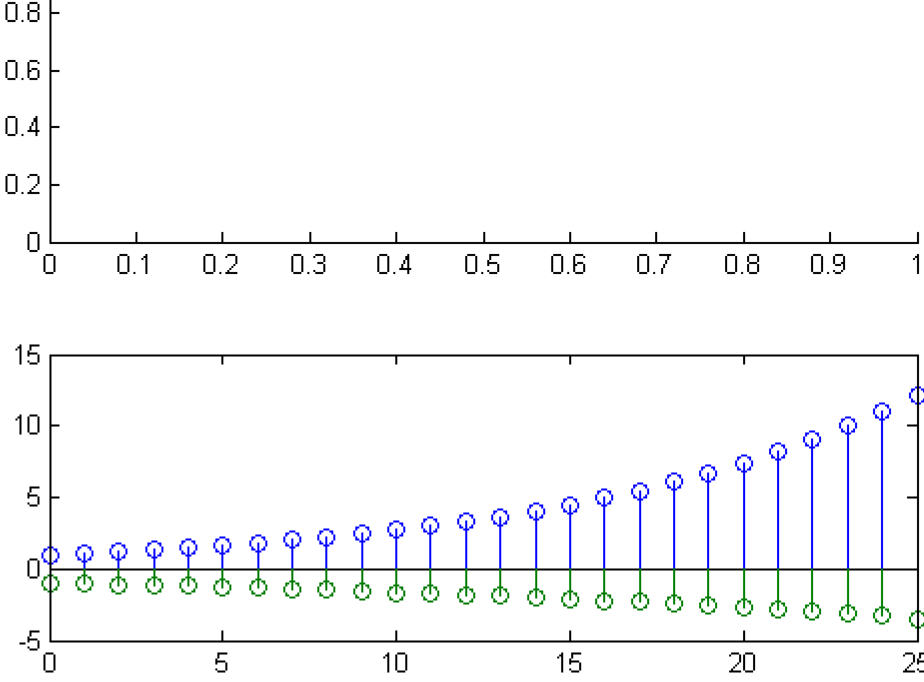
Specify Axes for Stem Plot

Create two subplots and return the handles to each axes, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);
```

Create a stem plot in the lower subplot by referring to the axes handle, `s(2)`.

```
X = 0:25;
Y = [exp(0.1*X); -exp(.05*X)]';
stem(s(2),X,Y)
```



Return Stemseries Handle

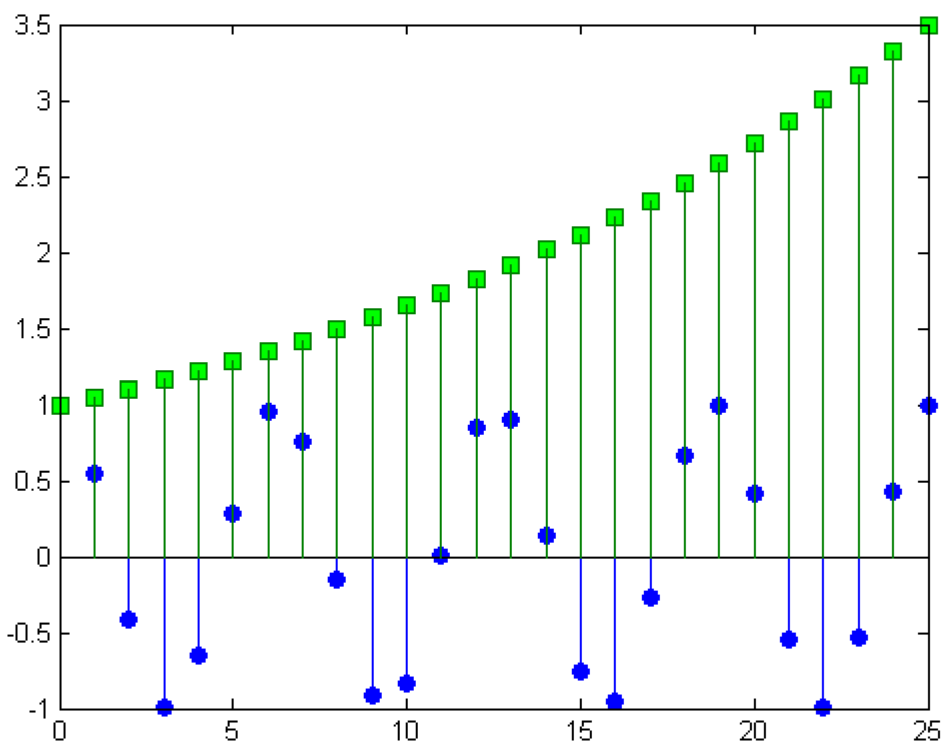
Create a stem plot with multiple series and return the handle to each series.

```
figure
X = 0:25;
Y = [cos(X); exp(0.05*X)]';
h = stem(X,Y);
```

The `stem` function creates two `stemseries` objects, one for each column of data. The output argument, `h`, returns both stemseries handles.

Change the markers of the first series to blue circles and the second series to green squares using the handles.

```
set(h(1),'MarkerFaceColor','blue')
set(h(2),'MarkerFaceColor','green','Marker','square')
```



Adjust Baseline Properties

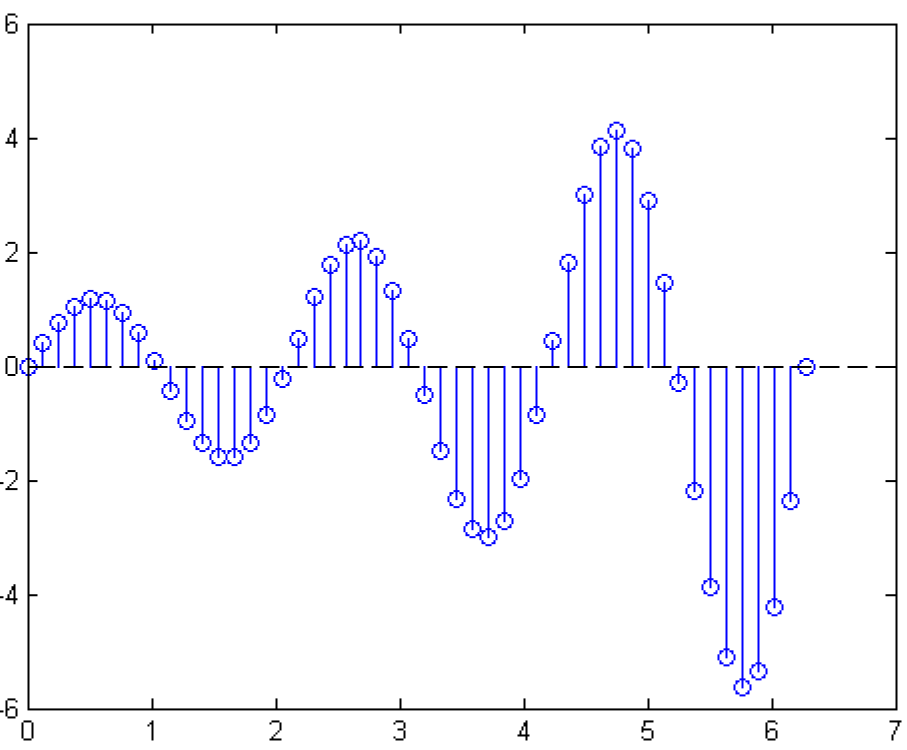
Create a stem plot and change properties of the baseline.

Get the baseline handle.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(0.3*X).*sin(3*X));
h = stem(X,Y);
hbase = get(h,'Baseline');
```

Adjust the color and style of the baseline by specifying a line property and value.

```
set(hbase,'LineStyle','--')
```



Make the baseline invisible by setting the visible property to `'off'`.

```
set(hbase,'Visible','off')
```

Delete the baseline using the delete command.

```
delete(hbase)
```

Change the Baseline Level

Create a stem plot and change the baseline level to 2.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(0.3*X).*sin(3*X));
h = stem(X,Y);
hbase = get(h,'Baseline');
set(hbase,'BaseValue',2)
```

stem3

Purpose

Plot 3-D discrete sequence data

Syntax

```
stem3(Z)
stem3(X,Y,Z)
stem3(___,'fill')
stem3(___,LineSpec)
stem3(___,Name,Value)

stem3(axes_handle,___)

h = stem3(___)
```

Description

`stem3(Z)` plots entries in `Z` as stems extending from the *xy*-plane and terminating with circles at the entry values. The stem locations in the *xy*-plane are automatically generated.

`stem3(X,Y,Z)` plots entries in `Z` as stems extending from the *xy*-plane where `X` and `Y` specify the stem locations in the *xy*-plane. The inputs `X`, `Y`, and `Z` must be vectors or matrices of the same size.

`stem3(___,'fill')` fills the circles. Use this option with any of the input argument combinations in the previous syntaxes.

`stem3(___,LineSpec)` specifies the line style, marker symbol, and color.

`stem3(___,Name,Value)` specifies stemseries properties using one or more `Name,Value` pair arguments.

`stem3(axes_handle,___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle`, can precede any of the input argument combinations in the previous syntaxes.

h = stem3(___) returns the stemseries handle h.

Input Arguments

Z - Data sequence to display

vector or matrix

Data sequence to display, specified as a vector or matrix. stem3 plots each element in Z as a stem extending from the *xy*-plane and terminating at the data value.

- If Z is a row vector, stem3 plots all elements against the same *y* value at equally spaced *x* values.
- If Z is a column vector, stem3 plots all elements against the same *x* value at equally spaced *y* values.
- If Z is a matrix, stem3 plots each row of Z against the same *y* value at equally spaced *x* values.

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

X - Locations to plot values of Z

vector or matrix

Locations to plot values ofZ, specified as a vector or a matrix. Inputs X, Y and Z must be vectors or matrices of the same size.

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Y - Locations to plot values of Z

vector or matrix

Locations to plot values of Z, specified as a vector or a matrix. Inputs X, Y and Z must be vectors or matrices of the same size.

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

LineSpec - Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineSpec`.

Example: `':*r'`

Data Types
`char`

axes_handle - Axes handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'LineStyle',':','MarkerFaceColor','red'` plots the stem as a dotted line and sets the marker face color to red.

For more information on these properties see `stemseries`.

'LineStyle' - Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and a line style specifier. This table lists supported line styles.

Specifier	Line Style
'- '	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-. '	Dash-dot line
'none'	No line

Example: 'LineStyle','-.'

'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. The scalar sets the width size in points of the stem and marker edge.

Example: 'LineWidth',0.75

'Color' - Color

[0 0 1] (blue) (default) | 3-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'Color',[0 1 0]

Example: 'Color','green'

'Marker' - Marker symbol

'o' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. This table lists supported marker symbols.

Specifier	MarkerSymbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle

Specifier	MarkerSymbol
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

Example: 'Marker','+'

Example: 'Marker','diamond'

'MarkerEdgeColor' - Marker edge color

[0 0 1] (blue) (default) | 'auto' | 'none' | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'MarkerEdgeColor',[1 .8 .1]`

'MarkerFaceColor' - Marker face color

`'none'` (default) | `'auto'` | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of `'MarkerFaceColor'` and a color value. `MarkerFaceColor` sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: `'MarkerFaceColor',[0 .8 1]`

'MarkerSize' - Marker size

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of `'MarkerSize'` and a scalar in points.

Example: `'Markersize',12`

Output Arguments

h - Stemseries object handle

scalar

Stemseries object handle, specified as a scalar. This is a unique identifier, which you can use to query and modify the properties of the `stemseries`.

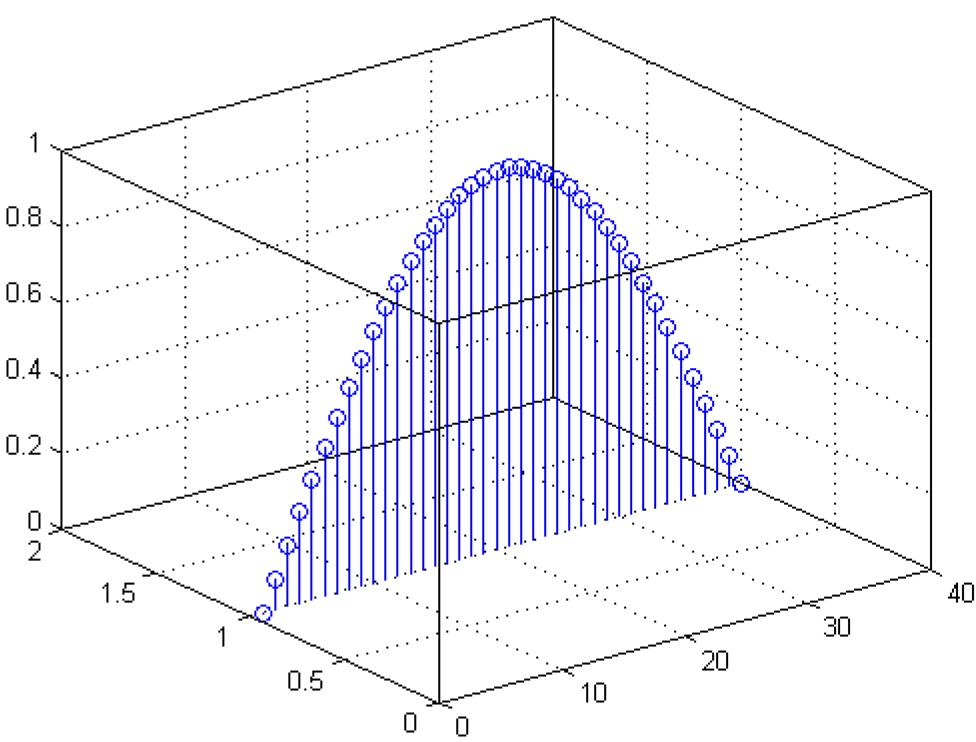
Examples

Row Vector Input

Create a 3-D stem plot of cosine values between -π/2 and π/2 with a row vector input.

```
figure
X = linspace(-pi/2,pi/2,40);
Z = cos(X);
```

```
stem3(Z)
```



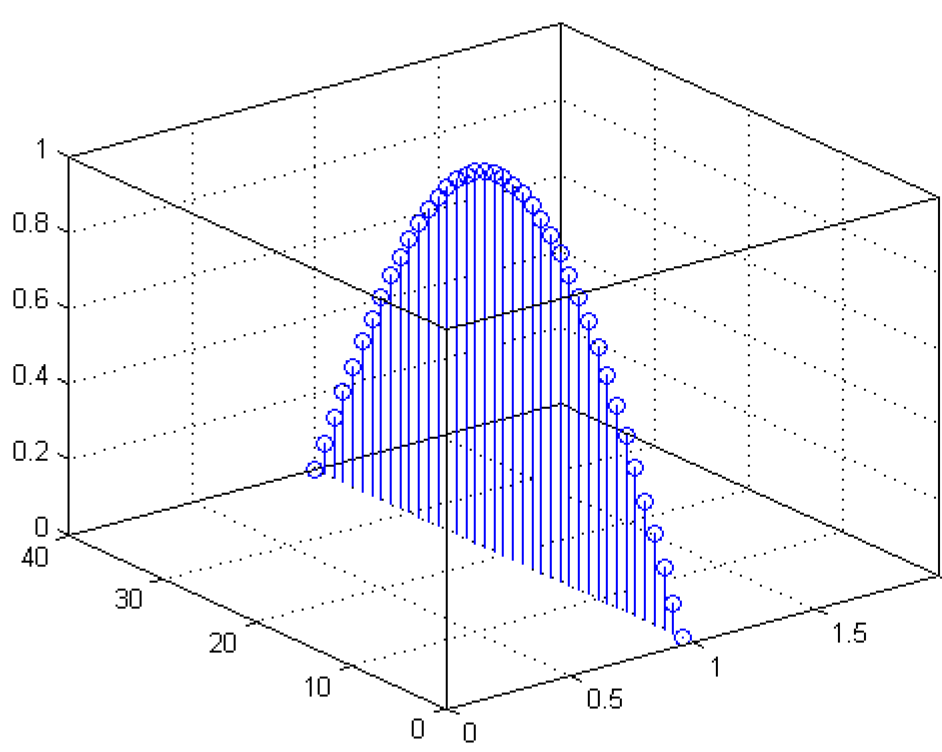
`stem3` plots elements of `Z` against the same *y* value at equally space *x* values.

Column Vector Input

Create a 3-D stem plot of cosine values between -π/2 and π/2 with a column vector input.

```
figure
```

```
X = linspace(-pi/2,pi/2,40)';
Z = cos(X);
stem3(Z)
```

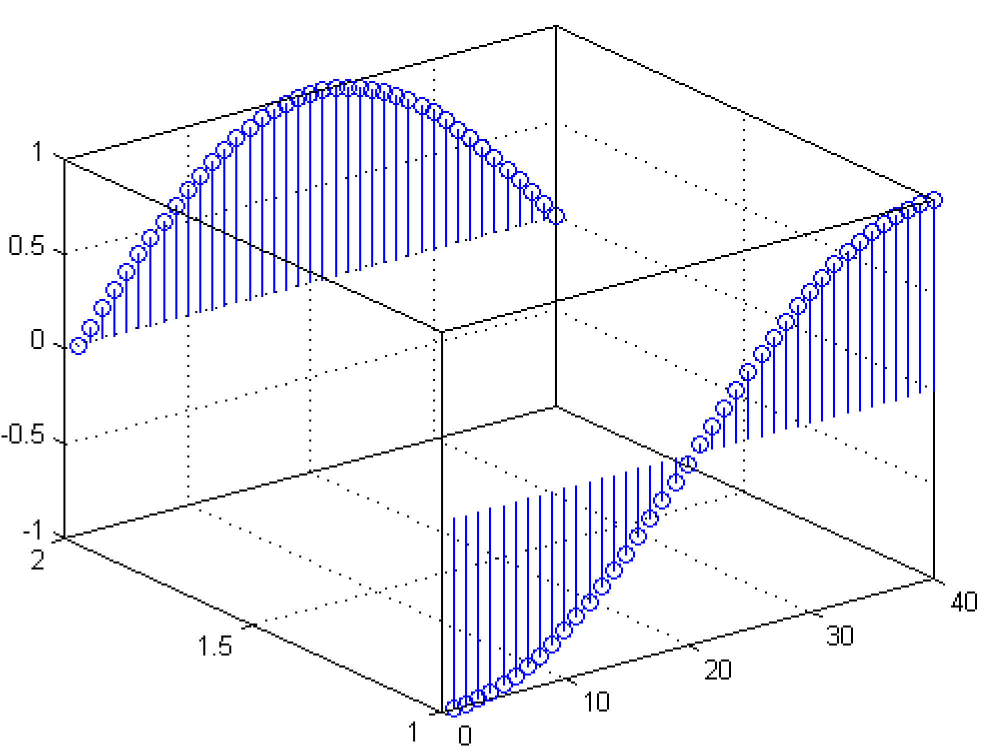


`stem3` plots elements of `Z` against the same *x* value at equally space *y* values.

Matrix Input

Create a 3-D stem plot of sine and cosine values between -π/2 and π/2 with a matrix input.

```
figure
X = linspace(-pi/2,pi/2,40);
Z = [sin(X); cos(X)];
stem3(Z)
```

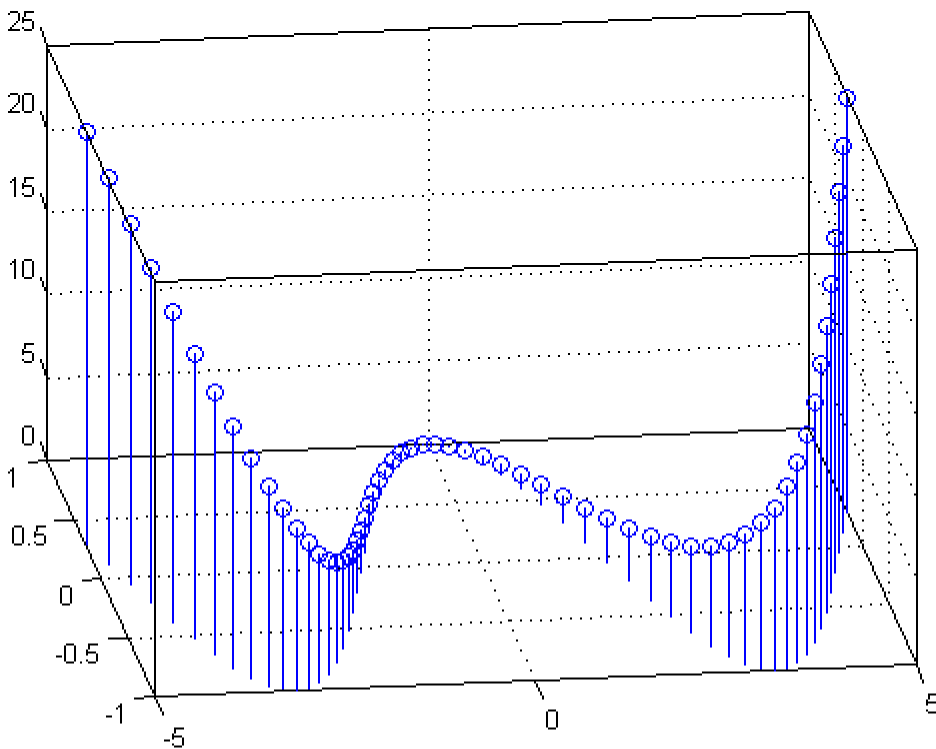


`stem3` plots each row of `Z` against the same *y* value at equally space *x* values.

Specify Stem Locations with Vector Inputs

Create a 3-D stem plot and specify the stem locations along a curve. Use `view` to adjust the angle of the axes in the figure.

```
figure
X = linspace(-5,5,60);
Y = cos(X);
Z = X.^2;
stem3(X,Y,Z)
view(-8,30)
```

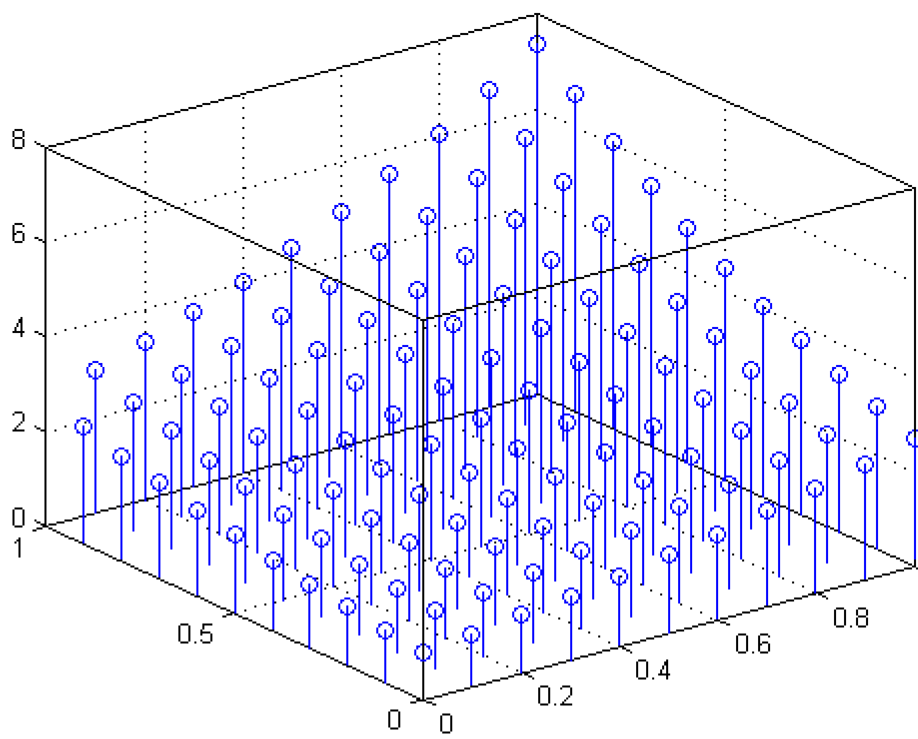


X and Y determine the stem locations. Z determines the marker heights.

Specify Stem Locations with Matrix Inputs

Create a 3-D stem plot with matrix data and specify the stem locations in the *xy*-plane.

```
figure
[X,Y] = meshgrid(0:.1:1);
Z = exp(X+Y);
stem3(X,Y,Z)
```

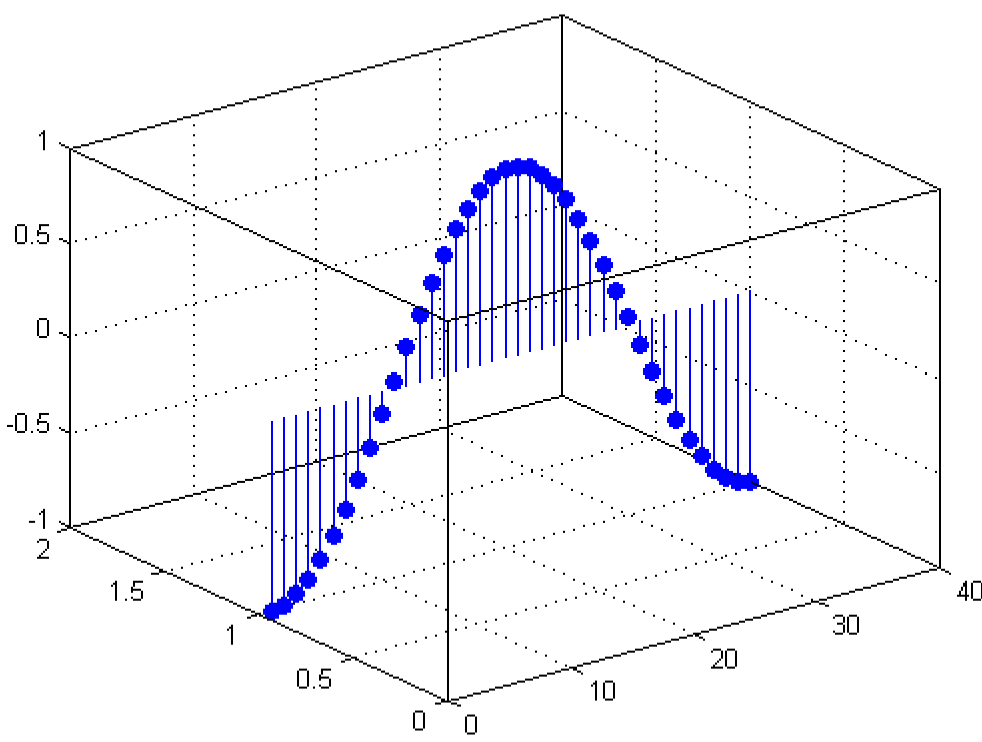


X and Y determine the stem locations. Z determines the marker heights.

Fill in the Circles

Create a 3-D stem plot of cosine values between -π and π. Use 'fill' to fill in the circles.

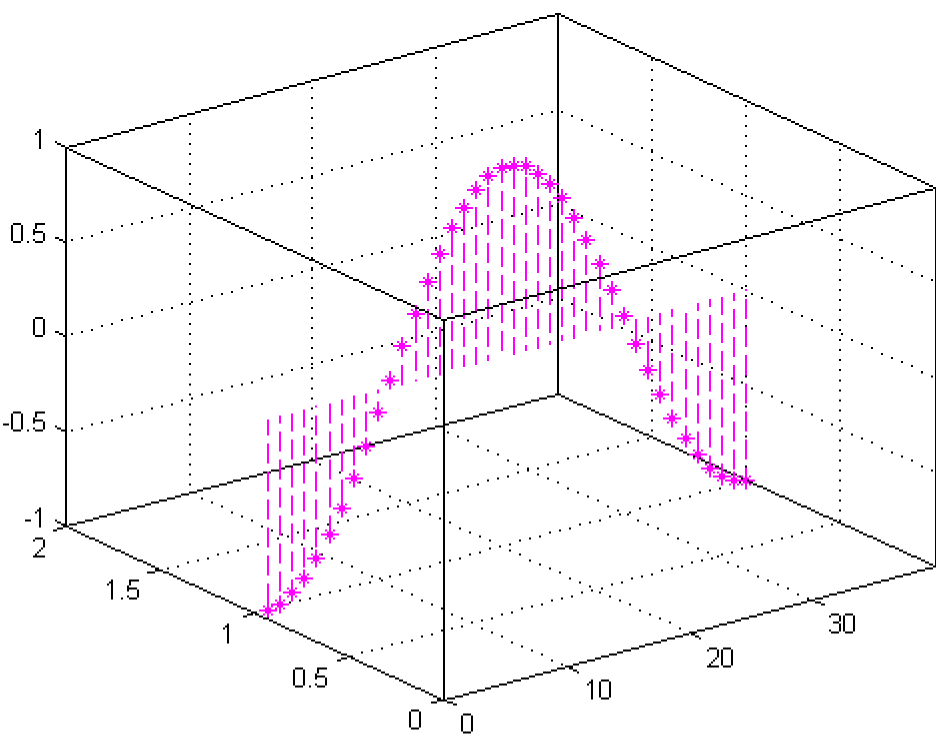
```
figure
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'fill')
```



Line Style, Marker Symbol, and Color Options

Create a 3-D stem plot of cosine values between -π and π. Set the stem to a dashed line style, the marker symbols to stars, and the color to magenta using `LineSpec`.

```
figure
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'--*m')
```



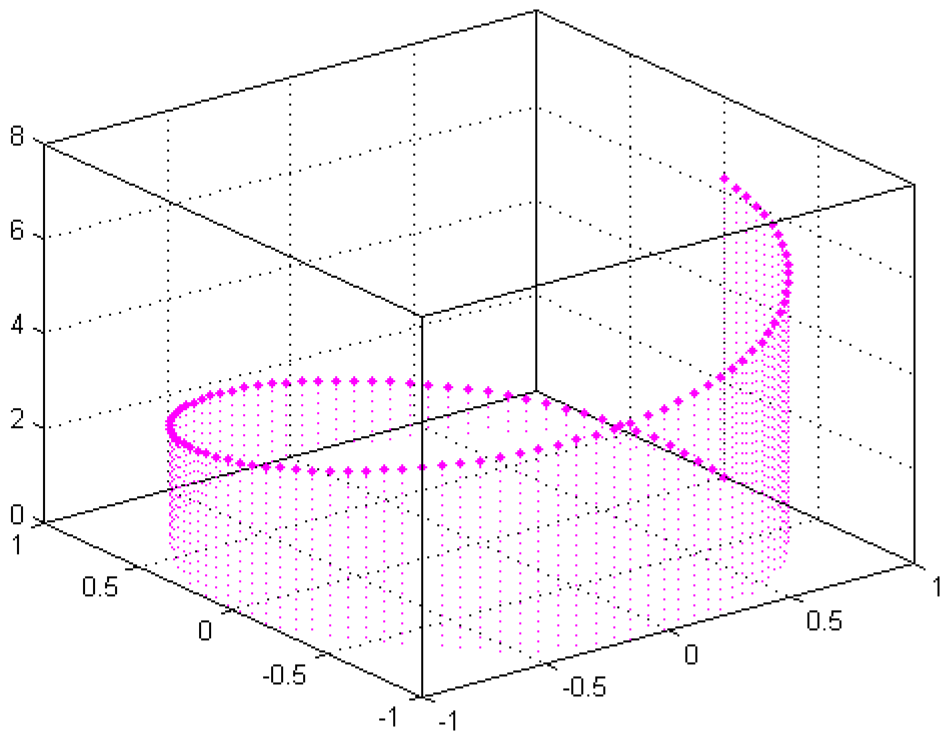
To specify only two of the three `LineSpec` options, omit the third option from the string. For example,`'*m'` sets the marker symbol and the color and leaves the default line style.

Line Style, Marker Symbol, and Color Options

Create a 3-D stem plot and specify the stem locations along a circle. Set the stem to a dashed line style, the marker symbols to stars, and the color to magenta using `LineSpec`.

```
figure
```

```
theta = linspace(0,2*pi);
X = cos(theta);
Y = sin(theta);
Z = theta;
stem3(X,Y,Z,':.m')
```

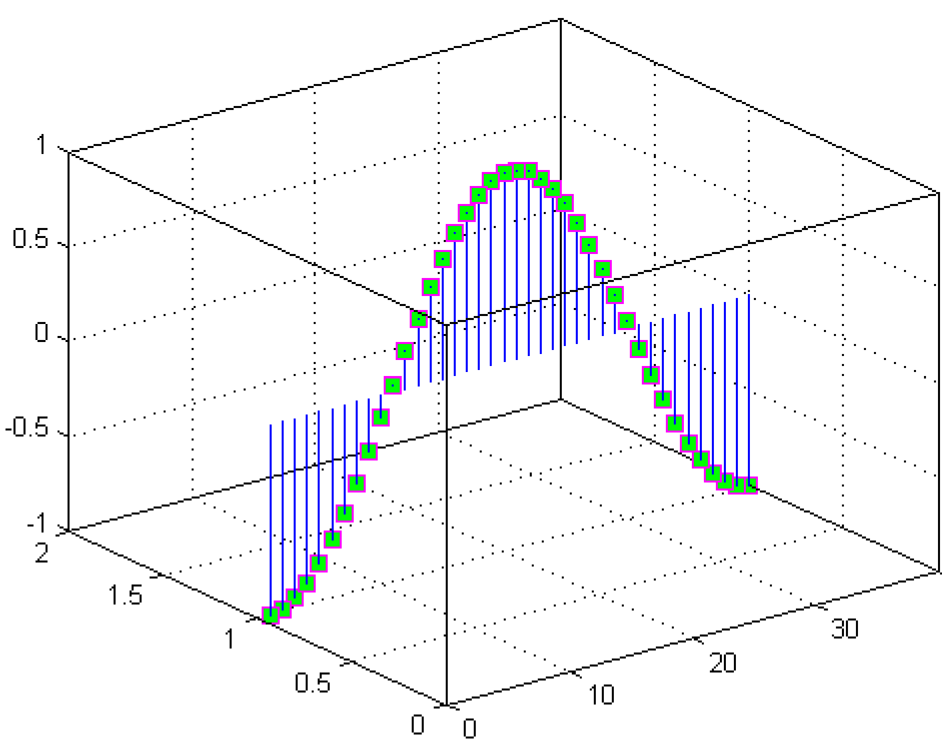


X and Y determine the stem locations. Z determines the marker heights.

Additional Style Options

Create a 3-D stem plot of cosine values between -π and π. Set the marker symbols to squares with green faces and magenta edges.

```
figure
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'Marker','s','MarkerEdgeColor','m','MarkerFaceColor','g')
```



Axes Handles

Specify an axes for the 3-D stem plot.

Create two subplots and return the handles to each axes, `s(1)` and `s(2)`.

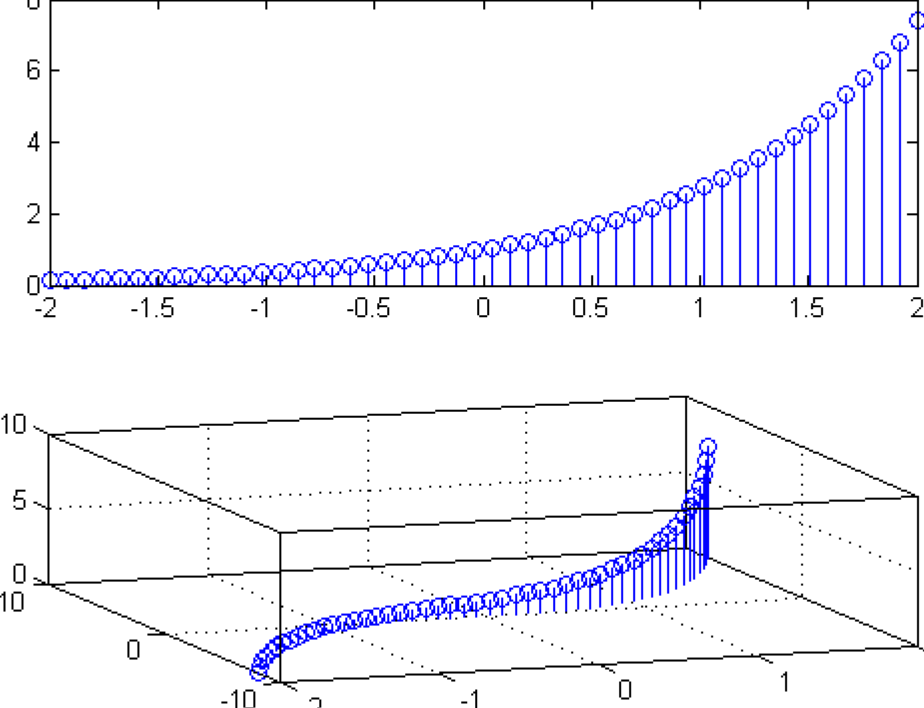
```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);
```

Define vectors `X`, `Y` and `Z`.

```
X = linspace(-2,2,50);
Y = X.^3;
Z = exp(X);
```

Plot a 3-D stem plot in the lower subplot using the axes handle `s(2)`. Adjust the angle of the axes using `view`. For comparison, plot a 2-D stem plot in the upper subplot using `X` and `Z`.

```
stem(s(1),X,Z)
stem3(s(2),X,Y,Z)
view(-20,35)
```



Stemseries Handle

Create a 3-D stem plot and use the stemseries handle to adjust properties of the plot.

Get the handle for the stemseries.

```
figure
X = linspace(0,2);
Y = X.^3;
Z = exp(X).*cos(Y);
```

```
h = stem3(X,Y,Z,'fill');
```

Set the color to magenta and the marker face color to yellow. Use `view` to adjust the angle of the axes in the figure.

```
set(h,'Color','m','MarkerFaceColor','y');
view(-10,35)
```

Stemseries Properties

Purpose

Define stemseries properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or with the property editor (`propertyeditor`).

Note that you cannot define default properties for stemseries objects.

See Plot Objects for information on stemseries objects.

Stemseries Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Annotation`

`hg.Annotation` object (read-only)

Control the display of stemseries objects in legends. Specifies whether this stemseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the stemseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
`on`	Include the stemseries object in a legend as one entry, but not its children objects
`off`	Do not include the stemseries or its children in a legend (default)
`children`	Include only the children of the stemseries as separate entries in the legend

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the IconDisplayStyle Property

See "Controlling Legends" for more information and examples.

`BaseLine`
handle

Handle of the baseline object. Handle of the line object used as the baseline. Set the properties of this line using its handle.

The following example makes the stem plot baseline a dashed, red line:

```
% Create stem plot
stem_handle = stem(randn(10,1));
% Obtain handle of baseline from stemseries object
baseline_handle = get(stem_handle,'BaseLine');
% Set line properties
set(baseline_handle,'LineStyle','--','Color','red')
```

`BaseValue`
y-axis value

Y-axis value where baseline is drawn. Specify the value along the *y*-axis at which the MATLAB software draws the baseline.

`BeingDeleted`
`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`Children`

array of graphics object handles

Children of the stemseries object. An array containing the handles of all line objects parented to the stemseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`

`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`Color`

`ColorSpec`

Color of stem lines. A three-element RGB vector or one of the MATLAB predefined names, specifying the line color. See the `ColorSpec` reference page for more information on specifying color.

For example, the following statement creates a stem plot with red lines.

```
h = stem(randn(10,1),'Color','r');
```

`CreateFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y,'CreateFcn',@CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`

string

String used by legend. The `legend` function uses the `DisplayName` property to label the stemseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EraseMode`
`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

- callback — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- off — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes get, findobj, gca, gcf, gco, newplot, cla, clf, and close.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using callback or off, the object's handle does not appear in its parent's Children property, figures do not appear in the root's CurrentFigure property, objects do not appear in the root's CallbackObject property or in the figure's CurrentObject property, and axes do not appear in their parent's CurrentAxes property.

Overriding Handle Visibility

You can set the root ShowHiddenHandles property to on to make all handles visible regardless of their HandleVisibility settings. This does not affect the values of the HandleVisibility properties. See also findall.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`
`{on} | off`

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the stem plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`
`on | {off}`

Select the object by clicking stem lines or area of extent. Select plot objects by:

- Clicking stem lines (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the stem lines to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the stem lines).

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

`LineStyle`
`{-} | -- | : | -. | none`

Line style of stemseries object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle` `none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is `0.5` points.

`Marker`
character (see table)

Marker symbol. Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'' '	Six-pointed star (hexagram)
'none'	No marker (default)

`MarkerEdgeColor`
`ColorSpec | none | {auto}`

Marker edge color. The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `Color` property.

`MarkerFaceColor`
`ColorSpec | {none} | auto`

Fill color for closed-shape markers. The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`
scalar

Marker size. Size of the marker in points. The default value is `6`.

Note MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

`Parent`
handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
: `on | {off}`

Object selection state. When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
: `{on} | off`

Object highlighted when selected.

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`Tag`
: string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create a stemseries object and set the `Tag` property:

```
Y = linspace(-2*pi,2*pi,10);
t = stem(Y,'Tag','stem1')
```

To access the stemseries object, use `findobj` to find the object's handle. The following statement changes the `MarkerFaceColor` property of the object whose `Tag` is `stem1`.

```
set(findobj('Tag','stem1'),'MarkerFaceColor','red')
```

`Type`

string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stemseries objects, `Type` is '`hggroup`'. The following statement finds all hggroup objects in the current axes object.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`

handle of uicontextmenu object

Associate context menu with object. Handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

`UserData`

array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Visibility of object and its children.

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

`XData`
array

X-axis location of stems. The stem function draws an individual stem at each *x*-axis location in the `XData` array. `XData` can be either a matrix equal in size to `YData` or a vector equal in length to the number of rows in `YData`. That is, `length(XData) == size(YData,1)`. `XData` does not need to be monotonically increasing.

If you do not specify `XData` (which is the input argument `X`), the stem function uses the indices of `YData` to create the stem plot. See the `XDataMode` property for related information.

`XDataMode`
`{auto} | manual`

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the `X` input argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

`XDataSource`
MATLAB variable, as a string

Link `XData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h,'XDataSource','xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`

scalar | vector | matrix

Stem plot data. `YData` contains the data plotted as stems. Each value in `YData` is represented by a marker in the stem plot. If `YData` is a matrix, MATLAB creates a series of stems for each column in the matrix.

The input argument `Y` in the `stem` function calling syntax assigns values to `YData`.

`YDataSource`

MATLAB variable, as a string

Link `YData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h,'YDataSource','Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`ZData`
vector

Z-coordinates. A data defining the stems for 3-D stem graphs. `XData` and `YData` (if specified) must be the same size.

`ZDataSource`
MATLAB variable, as a string

Link `ZData` *to MATLAB variable*. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`. The default value is an empty array.

```
set(h,'ZDataSource','zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable

be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

stop

Purpose

Stop timer(s)

Syntax

```
stop(obj)
```

Description

`stop(obj)` stops the timer, represented by the timer object, `obj`. If obj is an array of timer objects, the `stop` function stops them all. Use the `timer` function to create a timer object.

The `stop` function sets the `Running` property of the timer object, `obj`, to `'off'`, halts further `TimerFcn` callbacks, and executes the `StopFcn` callback.

See Also

`timer` | `start`

Purpose

Stop asynchronous read and write operations

Syntax

```
stopasync(obj)
```

Description

`stopasync(obj)` stops any asynchronous read or write operation that is in progress for the serial port object, `obj`.

Tips

You can write data asynchronously using the `fprintf` or `fwrite` function. You can read data asynchronously using the `readasync` function, or by configuring the `ReadAsyncMode` property to `continuous`. In-progress asynchronous operations are indicated by the `TransferStatus` property.

If `obj` is an array of serial port objects and one of the objects cannot be stopped, the remaining objects in the array are stopped and a warning is returned. After an object stops:

- Its `TransferStatus` property is configured to `idle`.
- Its `ReadAsyncMode` property is configured to `manual`.
- The data in its output buffer is flushed.

Data in the input buffer is not flushed. You can return this data to the MATLAB workspace using any of the synchronous read functions. If you execute the `readasync` function, or configure the `ReadAsyncMode` property to `continuous`, then the new data is appended to the existing data in the input buffer.

See Also

`fprintf` | `fwrite` | `readasync` | `ReadAsyncMode` | `TransferStatus`

str2double

Purpose

Convert string to double-precision value

Syntax

```
X = str2double('str')
X = str2double(C)
```

Description

`X = str2double('str')` converts the string `str`, which should be an ASCII character representation of a real or complex scalar value, to the MATLAB double-precision representation. The string can contain digits, a comma (thousands separator), a decimal point, a leading `+` or `-` sign, an `e` preceding a power of 10 scale factor, and an `i` for a complex unit.

If `str` does not represent a valid scalar value, `str2double` returns `NaN`.

`X = str2double(C)` converts the strings in the cell array of strings `C` to double precision. The matrix `X` returned will be the same size as `C`.

Examples

Here are some valid `str2double` conversions.

```
str2double('123.45e7')
str2double('123 + 45i')
str2double('3.14159')
str2double('2.7i - 3.14')
str2double({'2.71' '3.1415'})
str2double('1,200.34')
```

See Also

`char` | `hex2num` | `num2str` | `str2num` | `cast`

Purpose

Construct function handle from function name string

Syntax

```
str2func('str')
```

Description

`str2func('str')` constructs a function handle `fhandle` for the function named in the string `'str'`. The contents of `str` can be the name of a file that defines a MATLAB function, or the name of an anonymous function.

You can create a function handle `fh` using any of the following four methods:

- Create a handle to a named function:

```
fh = @functionName;
fh = str2func(functionName);
```

- Create a handle to an anonymous function:

```
fh = @(x)functionDef(x);
fh = str2func('@(x)functionDef(x)');
```

You can create an array of function handles from strings by creating the handles individually with `str2func`, and then storing these handles in a cell array.

Tips

Nested functions are not accessible to `str2func`. To construct a function handle for a nested function, you must use the function handle constructor, `@`.

Any variables and their values originally stored in a function handle when it was created are lost if you convert the function handle to a string and back again using the `func2str` and `str2func` functions.

Examples

Example 1

To convert the string, `'sin'`, into a handle for that function, type

```
fh = str2func('sin')
```

```
fh =
    @sin
```

Example 2

If you pass a function name string in a variable, the function that receives the variable can convert the function name to a function handle using `str2func`. The example below passes the variable, `funcname`, to function `makeHandle`, which then creates a function handle. Here is the function:

```
function fh = makeHandle(funcname)
fh = str2func(funcname);
```

This is the code that calls `makeHandle` to construct the function handle:

```
makeHandle('sin')
ans =
    @sin
```

Example 3

To call `str2func` on a cell array of strings, use the `cellfun` function. This returns a cell array of function handles:

```
fh_array = cellfun(@str2func, {'sin' 'cos' 'tan'}, ...
                   'UniformOutput', false);

fh_array{2}(5)
ans =
   0.2837
```

Example 4

In the following example, the `myminbnd` function expects to receive either a function handle or string in the first argument. If you pass a string, `myminbnd` constructs a function handle from it using `str2func`, and then uses that handle in a call to `fminbnd`:

```
function myminbnd(fhandle, lower, upper)
if ischar(fhandle)
```

```
   disp 'converting function string to function handle ...'
   fhandle = str2func(fhandle);
end
fminbnd(fhandle, lower, upper)
```

Whether you call `myminbnd` with a function handle or function name string, the function can handle the argument appropriately:

```
myminbnd('humps', 0.3, 1)
converting function string to function handle ...
ans =
    0.6370
```

Example 5

The `dirByType` function shown here creates an anonymous function called `dirCheck`. What the anonymous function does depends upon the value of the `dirType` argument passed in to the primary function. The example demonstrates one possible use of `str2func` with anonymous functions:

```
function dirByType(dirType)
switch(dirType)
   case 'class', leadchar = '@';
   case 'package', leadchar = '+';
   otherwise disp('ERROR: Unrecognized type'), return;
end

dirfile = @(fs)isdir(fs.name);
dirCheckStr = ['@(fs)strcmp(fs.name(1,1),''', leadchar, ''')'];
dirCheckFun = str2func(dirCheckStr);
s = dir;   filecount = length(s);

for k=1:filecount
   fstruct = s(k);
   if dirfile(fstruct) && dirCheckFun(fstruct)
       fprintf('%s folder: %s\n', dirType, fstruct.name)
   end
end
```

Generate a list of class and package folders:

```
dirByType('class')
class folder: @Point
class folder: @asset
class folder: @bond

dirByType('package')
package folder: +containers
package folder: +event
package folder: +mypkg
```

See Also

`function_handle` | `func2str` | `functions`

Purpose

Form blank-padded character matrix from strings

Note `str2mat` is not recommended. Use `char` instead.

Syntax

```
S = str2mat(T1, T2, T3, ...)
```

Description

`S = str2mat(T1, T2, T3, ...)` forms the matrix `S` containing the text strings `T1, T2, T3, ...` as rows. The function automatically pads each string with blanks in order to form a valid matrix. Each text parameter, `Ti`, can itself be a string matrix. This allows the creation of arbitrarily large string matrices. Empty strings are significant.

Tips

`str2mat` differs from `strvcat` in that empty strings produce blank rows in the output. In `strvcat`, empty strings are ignored.

Examples

```
x = str2mat('36842', '39751', '38453', '90307');

whos x
  Name      Size          Bytes  Class

  x         4x5              40  char array

x(2,3)

ans =

    7
```

See Also

`char`

str2num

Purpose

Convert string to number

Syntax

```
x = str2num('str')
[x, status] = str2num('str')
```

Description

Note `str2num` uses the `eval` function to convert the input argument. Side effects can occur if the string contains calls to functions. Using `str2double` can avoid some of these side effects.

`x = str2num('str')` converts the string `str`, which is an ASCII character representation of a numeric value, to numeric representation. `str2num` also converts string matrices to numeric matrices. If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

The input string can contain one or more numbers separated by spaces, commas, or semicolons, such as '`5`', '`10,11,12`', or '`5,10;15,20`'. In addition to numerical values and delimiters, the input string can also include a decimal point, leading + or - signs, the letter `e` or `d` preceding a power of 10 scale factor, or the letter `i` or `j` indicating a complex or imaginary number.

The following table shows several examples of valid inputs to `str2num`:

String Input	Numeric Output	Output Class
`'500'`	500	1-by-1 scalar `double`
`'500 250 125 67'`	500, 250, 125, 67	1-by-4 row vector of `double`
`'500; 250; 125; 62.5'`	500.0000 250.0000 125.0000 62.5000	4-by-1 column vector of `double`

String Input	Numeric Output	Output Class
'1 23 6 21; 53:56'	1 23 6 21 53 54 55 56	2-by-5 matrix of double
'12e-3 5.9e-3'	0.0120 0.0059	vector of double
'uint16(500)'	500	16–bit unsigned integer

Note str2num does not operate on cell arrays. To convert a cell array of strings to a numeric value, use str2double.

If the input string does not represent a valid number or matrix, str2num(str) returns the empty matrix in x.

[x, status] = str2num('str') returns the status of the conversion in logical status, where status equals logical 1 (true) if the conversion succeeds, and logical 0 (false) otherwise.

Space characters can be significant. For instance, str2num('1+2i') and str2num('1 + 2i') produce x = 1+2i, while str2num('1 +2i') produces x = [1 2i]. You can avoid these problems by using the str2double function.

Examples

Input a character string that contains a single number. The output is a scalar double:

```
A = str2num('500')
A =
   500

class(A)
ans =
   double
```

Repeat this operation, but this time using an unsigned 16–bit integer:

```
A = str2num('uint16(500)')
A =
    500

class(A)
ans =
   uint16
```

Try three different ways of specifying a row vector. Each returns the same answer:

```
str2num('2 4 6 8')              % Separate with spaces.
ans =
     2     4     6     8

str2num('2,4,6,8')              % Separate with commas.
ans =
     2     4     6     8

str2num('[2 4 6 8]')            % Enclose in brackets.
ans =
     2     4     6     8
```

Note that the first two of these commands do not need the MATLAB square bracket operator to create a matrix. The `str2num` function inserts the brackets for you if they are needed.

Use a column vector this time:

```
str2num('2; 4; 6; 8')
ans =
     2
     4
     6
     8
```

And now a 2-by-2 matrix:

```
str2num('2 4; 6 8')
ans =
     2     4
     6     8
```

See Also

`num2str` | `str2double` | `hex2num` | `sscanf` | `sparse` | `char` | `cast` | special characters

Purpose

Concatenate strings horizontally

Syntax

```
combinedStr = strcat(s1, s2, ..., sN)
```

Description

`combinedStr = strcat(s1, s2, ..., sN)` horizontally concatenates strings in arrays `s1`, `s2`, ..., `sN`. Inputs can be combinations of single strings, strings in scalar cells, character arrays with the same number of rows, and same-sized cell arrays of strings. If any input is a cell array, `combinedStr` is a cell array of strings. Otherwise, `combinedStr` is a character array.

Tips

- For character array inputs, `strcat` removes trailing ASCII white-space characters: space, tab, vertical tab, newline, carriage return, and form-feed. To preserve trailing spaces when concatenating character arrays, use horizontal array concatenation, `[s1, s2, ..., sN]`. See the final example in the following section.
- For cell array inputs, `strcat` does not remove trailing white space.
- When combining nonscalar cell arrays and multi-row character arrays, cell arrays must be column vectors with the same number of rows as the character arrays.

Examples

Concatenate two cell arrays:

```
a = {'abcde', 'fghi'};
b = {'jkl',   'mn'};

ab = strcat(a, b)
```

MATLAB returns

```
ab =
    'abcdejkl'    'fghimn'
```

Combine cell arrays `a` and `b` from the previous example with a scalar cell:

```
c = {'Q'};
abc = strcat(a, b, c)
```

MATLAB returns

```
abc =
    'abcdejklQ'    'fghimnQ'
```

Compare the use of `strcat` and horizontal array concatenation with strings that contain trailing spaces:

```
a = 'hello  ';
b = 'goodbye';

using_strcat = strcat(a, b)
using_arrayop = [a, b]      % Equivalent to horzcat(a, b)
```

MATLAB returns

```
using_strcat =
hellogoodbye

using_arrayop =
hello  goodbye
```

cat | vertcat | horzcat | cellstr | strjoin | special character

strcmp

Purpose

Compare strings (case sensitive)

Syntax

```
TF = strcmp(string,string)
TF = strcmp(string,cellstr)
TF = strcmp(cellstr,cellstr)
```

Description

`TF = strcmp(string,string)` compares two strings for equality. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strcmp(string,cellstr)` compares a string with each element of a cell array of strings. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the input arguments is not important.

`TF = strcmp(cellstr,cellstr)` compares each element of one cell array of strings with the same element of the other. The function returns a logical array the same size as either cell array input.

Tips

- The `strcmp` function is intended for comparison of character data. When used to compare numeric data, it returns logical `0`.
- Use `strcmpi` for case-insensitive string comparisons.
- Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
- The value returned by `strcmp` is not the same as the C language convention.
- `strcmp` supports international character sets.

Input Arguments

string

A single character string or n-by-1 array of strings.

cellstr

A cell array of strings.

Output Arguments

TF

When both inputs are character arrays, TF is a scalar logical 1 or 0. This value is logical 1 (true) if the size and content of both arrays are equal, and logical 0 (false) if it is not.

When either or both inputs is a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (true) for those elements of the input arrays that are a match, and logical 0 (false) for those elements that are not.

Examples

Perform a simple comparison of two strings:

```
strcmp('Yes', 'No')
ans =
     0
strcmp('Yes', 'Yes')
ans =
     1
```

Create two cell arrays of strings and call strcmp to compare them:

```
A = {'Handle Graphics', 'Statistics';   ...
     '  Toolboxes', 'MathWorks'};

B = {'Handle Graphics', 'Signal Processing';    ...
     'Toolboxes', 'MATHWORKS'};

match = strcmp(A, B)
match =
     1     0
     0     0
```

The result of comparing the two cell arrays is:

- match{1,1} is 1 because “Handle Graphics” in A{1,1} matches the same text in B{1,1}.

- `match{1,2}` is 0 because "Statistics" in `A{1,2}` does not match "Signal Processing" in `B{1,2}`.
- `match{2,1}` is 0 because " Toolboxes", in `A{2,1}` contains leading space characters that are not in `B{2,1}`.
- `match{2,2}` is 0 because "MathWorks" in `A{2,2}` uses different letter case than "MATHWORKS" in `B{2,2}`, and `strcmp` does a case-sensitive comparison.

The following example has three parts. It compares

- A string to an array of strings.
- A padded string to a cell array of strings.
- An unpadded string to a cell array of strings.

Start by creating the necessary data structures.

1 Cell array of strings –

Create a 3-element cell array of strings:

```
cellarr = { ...
   'There are 10 kinds of people in the world,'; ...
   'those who understand binary math,'; ...
   'and those who don''t.'};
```

2 String array –

From the cell array, create a string array. The string array contains space characters at the end of rows 2 and 3 for the padding needed to make the array rectangular:

```
strarr = char(cellarr)
strarr =
There are 10 kinds of people in the world,
those who understand binary math,
and those who don't.
```

```
%                        Each line ends here   ^
```

3 String vector –

From row 2 of the string array, create a string vector. This string is also padded with spaces at the end:

```
strvec = strarr(2,:)
strvec =
those who understand binary math,
%                     Padded line ends here   ^
```

Begin the comparisons. Start by comparing the string vector with the string array. When comparing character arrays, `strcmp` does not do a row-by-row comparison. It compares *all* of the 1-by-42 `strvec` with *all* of the 3-by-42 `strarr`. Finding them to be different, the answer is `false` and `strcmp` returns logical 0:

```
strcmp(strvec, strarr)
ans =
     0
```

Compare the string vector to the cell array. Even though `strvec` is essentially the same as row 2 of `cellarr`, it is not a match because of the space padding in `strvec`:

```
strcmp(strvec, cellarr)
ans =
     0
     0
     0
```

Remove the space padding from the string vector and compare it to the cell array. `strcmp` compares `strvec` with each row of the `cellarr`, finding a match with the second row of the latter:

```
strcmp(deblank(strvec), cellarr)
ans =
```

```
0
1
0
```

See Also

strncmp | strcmpi | strncmpi | strfind | regexp | regexpi |

Purpose

Compare strings (case insensitive)

Syntax

```
TF = strcmpi(string,string)
TF = strcmpi(string,cellstr)
TF = strcmpi(cellstr,cellstr)
```

Description

`TF = strcmpi(string,string)` compares two strings for equality, ignoring any differences in letter case. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strcmpi(string,cellstr)` compares a string with each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the input arguments is not important.

`TF = strcmpi(cellstr,cellstr)` compares each element of one cell array of strings with the same element of the other, ignoring letter case. The function returns a logical array the same size as the input arrays.

Tips

- The `strcmpi` function is intended for comparison of character data. When used to compare numeric data, it returns logical `0`.
- Use `strcmp` for case-sensitive string comparisons.
- Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
- The value returned by `strcmpi` is not the same as the C language convention.
- `strcmpi` supports international character sets.

Input Arguments

string

A single character string or n-by-1 array of strings.

cellstr

A cell array of strings.

Output Arguments

TF

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (true) if the size and content of both arrays are equal, and logical 0 (false) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (true) for those elements of the input arrays that are a match, and logical 0 (false) for those elements that are not.

Examples

Perform a simple case-insensitive comparison of two strings:

```
strcmpi('Yes', 'No')
ans =
     0
strcmpi('Yes', 'yes')
ans =
     1
```

Create two cell arrays of strings and call strcmpi to compare them:

```
A = {'Handle Graphics', 'Statistics';   ...
     '  Toolboxes', 'MathWorks'};

B = {'Handle Graphics', 'Signal Processing';    ...
     'Toolboxes', 'MATHWORKS'};

match = strcmpi(A, B)
match =
     1     0
     0     1
```

The result of comparing the two cell arrays is:

- match{1,1} is 1 because “Handle Graphics” in A{1,1} matches the same text in B{1,1}.

- `match{1,2}` is 0 because “Statistics” in `A{1,2}` does not match “Signal Processing” in `B{1,2}`.
- `match{2,1}` is 0 because “ Toolboxes”, in `A{2,1}` contains leading space characters that are not in `B{2,1}`.
- `match{2,2}` is 1 because even though “MathWorks” in `A{2,2}` uses different letter case than “MATHWORKS” in `B{2,2}`, `strcmpi` performs the comparison without sensitivity to letter case.

stream2

Purpose

Compute 2-D streamline data

Syntax

```
XY = stream2(x,y,u,v,startx,starty)
XY = stream2(u,v,startx,starty)
XY = stream2(...,options)
```

Description

`XY = stream2(x,y,u,v,startx,starty)` computes streamlines from vector data `u` and `v`.

The arrays `x` and `y`, which define the coordinates for `u` and `v`, must be monotonic, but do not need to be uniformly spaced. `x` and `y` must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XY` contains a cell array of vertex arrays.

`XY = stream2(u,v,startx,starty)` assumes the arrays `x` and `y` are defined as `[x,y] = meshgrid(1:n,1:m)` where `[m,n] = size(u)`.

`XY = stream2(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify a value, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream2`.

Examples

This example draws 2-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx,sy] = meshgrid(80,20:10:50);
streamline(stream2(x(:,:,5),y(:,:,5),u(:,:,5),v(:,:,5),sx,sy));
```

How To

- Specifying Starting Points for Stream Plots

Purpose

Compute 3-D streamline data

Syntax

```
XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)
XYZ = stream3(U,V,W,startx,starty,startz)
XYZ = stream3(...,options)
```

Description

`XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)` computes streamlines from vector data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XYZ` contains a cell array of vertex arrays.

`XYZ = stream3(U,V,W,startx,starty,startz)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:N,1:M,1:P)` where `[M,N,P] = size(U)`.

`XYZ = stream3(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream3`.

Examples

This example draws 3-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamline(stream3(x,y,z,u,v,w,sx,sy,sz))
view(3)
```

`coneplot` | `stream2` | `streamline`

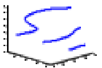
How To

- Specifying Starting Points for Stream Plots

streamline

Purpose

Plot streamlines from 2-D or 3-D vector data



Syntax

```
streamline(X,Y,Z,U,V,W,startx,starty,startz)
streamline(U,V,W,startx,starty,startz)
streamline(XYZ)
streamline(X,Y,U,V,startx,starty)
streamline(U,V,startx,starty)
streamline(XY)
streamline(...,options)
streamline(axes_handle,...)
h = streamline(...)
```

Description

`streamline(X,Y,Z,U,V,W,startx,starty,startz)` draws streamlines from 3-D vector data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, `startz` define the starting positions of the streamlines. The section Specifying Starting Points for Stream Plots provides more information on defining starting points.

`streamline(U,V,W,startx,starty,startz)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:N,1:M,1:P)`, where `[M,N,P] = size(U)`.

`streamline(XYZ)` assumes `XYZ` is a precomputed cell array of vertex arrays (as produced by `stream3`).

`streamline(X,Y,U,V,startx,starty)` draws streamlines from 2-D vector data `U`, `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

startx and starty define the starting positions of the streamlines. The output argument h contains a vector of line handles, one handle for each streamline.

streamline(U,V,startx,starty) assumes the arrays X and Y are defined as [X,Y] = meshgrid(1:N,1:M), where [M,N] = size(U).

streamline(XY) assumes XY is a precomputed cell array of vertex arrays (as produced by stream2).

streamline(...,options) specifies the options used when creating the streamlines. Define options as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 1000

streamline(axes_handle,...) plots into the axes object with the handle axes_handle instead of the into current axes object (gca).

h = streamline(...) returns a vector of line handles, one handle for each streamline.

Examples

This example draws streamlines from data representing air currents over a region of North America. Loading the wind data set creates the variables x, y, z, u, v, and w in the MATLAB workspace.

The plane of streamlines indicates the flow of air from the west to the east (the *x*-direction) beginning at x = 80 (which is close to the minimum value of the x coordinates). The *y*- and *z*-coordinate starting points are multivalued and approximately span the range of

these coordinates. meshgrid generates the starting positions of the streamlines.

```
load wind
[sx,sy,sz] = meshgrid(80,20:10:50,0:5:15);
h = streamline(x,y,z,u,v,w,sx,sy,sz);
set(h,'Color','red')
view(3)
```

coneplot | stream2 | stream3 | streamparticles | meshgrid

How To

- Specifying Starting Points for Stream Plots
- Stream Line Plots of Vector Data

Purpose

Plot stream particles

Syntax

```
streamparticles(vertices)
streamparticles(vertices,n)
streamparticles(...,'PropertyName',PropertyValue,...)
streamparticles(line_handle,...)
h = streamparticles(...)
```

Description

`streamparticles(vertices)` draws stream particles of a vector field. Stream particles are usually represented by markers and can show the position and velocity of a streamline. `vertices` is a cell array of 2-D or 3-D vertices (as if produced by `stream2` or `stream3`).

`streamparticles(vertices,n)` uses `n` to determine how many stream particles to draw. The `ParticleAlignment` property controls how `n` is interpreted.

- If `ParticleAlignment` is set to `off` (the default) and `n` is greater than `1`, approximately `n` particles are drawn evenly spaced over the streamline vertices.

  If `n` is less than or equal to `1`, `n` is interpreted as a fraction of the original stream vertices; for example, if `n` is `0.2`, approximately 20% of the vertices are used.

  `n` determines the upper bound for the number of particles drawn. The actual number of particles can deviate from `n` by as much as a factor of 2.

- If `ParticleAlignment` is `on`, `n` determines the number of particles on the streamline having the most vertices and sets the spacing on the other streamlines to this value. The default value is `n = 1`.

`streamparticles(...,'`*`PropertyName`*`',PropertyValue,...)` controls the stream particles using named properties and specified values. Any unspecified properties have default values. MATLAB ignores the case of property names.

Stream Particle Properties

`Animate` — Stream particle motion [nonnegative integer]

The number of times to animate the stream particles. The default is 0, which does not animate. Inf animates until you enter **Ctrl+C**.

FrameRate — Animation frames per second [nonnegative integer]

This property specifies the number of frames per second for the animation. Inf, the default, draws the animation as fast as possible. Note that the speed of the animation might be limited by the speed of the computer. In such cases, the value of FrameRate cannot necessarily be achieved.

ParticleAlignment — Align particles with streamlines [on | {off}]

Set this property to on to draw particles at the beginning of each streamline. This property controls how streamparticles interprets the argument n (number of stream particles).

Stream particles are line objects. In addition to stream particle properties, you can specify any line object property, such as Marker and EraseMode. streamparticles sets the following line properties when called.

Line Property	Value Set by streamparticles
EraseMode	xor
LineStyle	none
Marker	o
MarkerEdgeColor	none
MarkerFaceColor	red

You can override any of these properties by specifying a property name and value as arguments to streamparticles. For example, this statement uses RGB values to set the MarkerFaceColor to medium gray:

```
streamparticles(vertices,'MarkerFaceColor',[.5 .5 .5])
```

`streamparticles(line_handle,...)` uses the line object identified by `line_handle` to draw the stream particles.

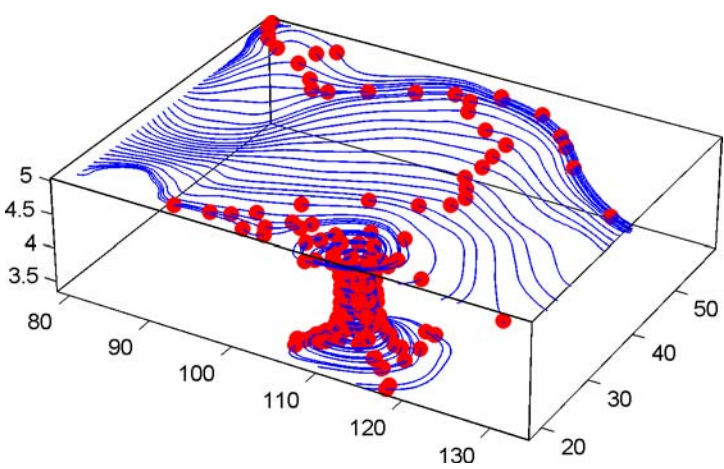
`h = streamparticles(...)` returns a vector of handles to the line objects it creates.

Examples

This example combines streamlines with stream particle animation. The `interpstreamspeed` function determines the vertices along the streamlines where stream particles will be drawn during the animation, thereby controlling the speed of the animation. Setting the axes `DrawMode` property to `fast` provides faster rendering.

```
load wind
[sx sy sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
sl = streamline(verts);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.025);
axis tight; view(30,30); daspect([1 1 .125])
camproj perspective; camva(8)
set(gca,'DrawMode','fast')
box on
streamparticles(iverts,35,'animate',10,'ParticleAlignment','on')
```

The following picture is a static view of the animation.



This example uses the streamlines in the `z = 5` plane to animate the flow along these lines with `streamparticles`.

```
load wind
daspect([1 1 1]); view(2)
[verts averts] = streamslice(x,y,z,u,v,w,[],[],[5]);
sl = streamline([verts averts]);
axis tight off;
set(sl,'Visible','off')
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.05);
set(gca,'DrawMode','fast','Position',[0 0 1 1],'ZLim',[4.9 5.1])
set(gcf,'Color','black')
streamparticles(iverts, 200, ...
    'Animate',100,'FrameRate',40, ...
    'MarkerSize',10,'MarkerFaceColor','yellow')
```

`interpstreamspeed` | `stream3` | `streamline` | `stream2`

How To

- Creating Stream Particle Animations
- Specifying Starting Points for Stream Plots

Purpose

3-D stream ribbon plot from vector volume data

Syntax

```
streamribbon(X,Y,Z,U,V,W,startx,starty,startz)
streamribbon(U,V,W,startx,starty,startz)
streamribbon(vertices,X,Y,Z,cav,speed)
streamribbon(vertices,cav,speed)
streamribbon(vertices,twistangle)
streamribbon(...,width)
streamribbon(axes_handle,...)
h = streamribbon(...)
```

Description

`streamribbon(X,Y,Z,U,V,W,startx,starty,startz)` draws stream ribbons from vector volume data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the stream ribbons at the center of the ribbons. The section Specifying Starting Points for Stream Plots provides more information on defining starting points.

The twist of the ribbons is proportional to the curl of the vector field. The width of the ribbons is calculated automatically.

`streamribbon(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamribbon(vertices,X,Y,Z,cav,speed)` assumes precomputed streamline vertices, curl angular velocity, and flow speed. `vertices` is a

cell array of streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, `cav`, and `speed` are 3-D arrays.

`streamribbon(vertices,cav,speed)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(cav)`.

`streamribbon(vertices,twistangle)` uses the cell array of vectors `twistangle` for the twist of the ribbons (in radians). The size of each corresponding element of `vertices` and `twistangle` must be equal.

`streamribbon(...,width)` sets the width of the ribbons to `width`.

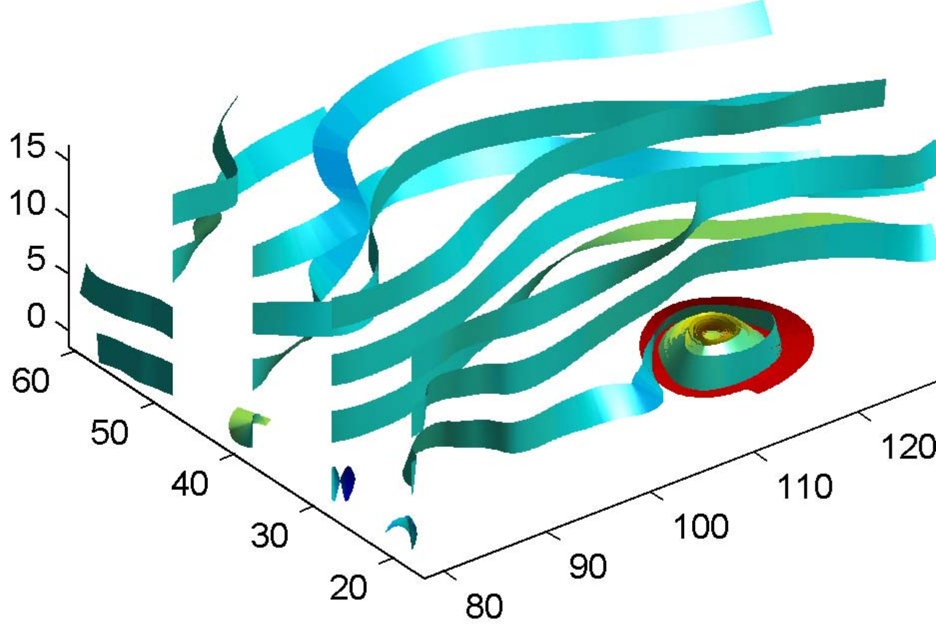
`streamribbon(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamribbon(...)` returns a vector of handles (one per start point) to `surface` objects.

Examples

This example uses stream ribbons to indicate the flow in the `wind` data set. Inputs include the coordinates, vector field components, and starting location for the stream ribbons.

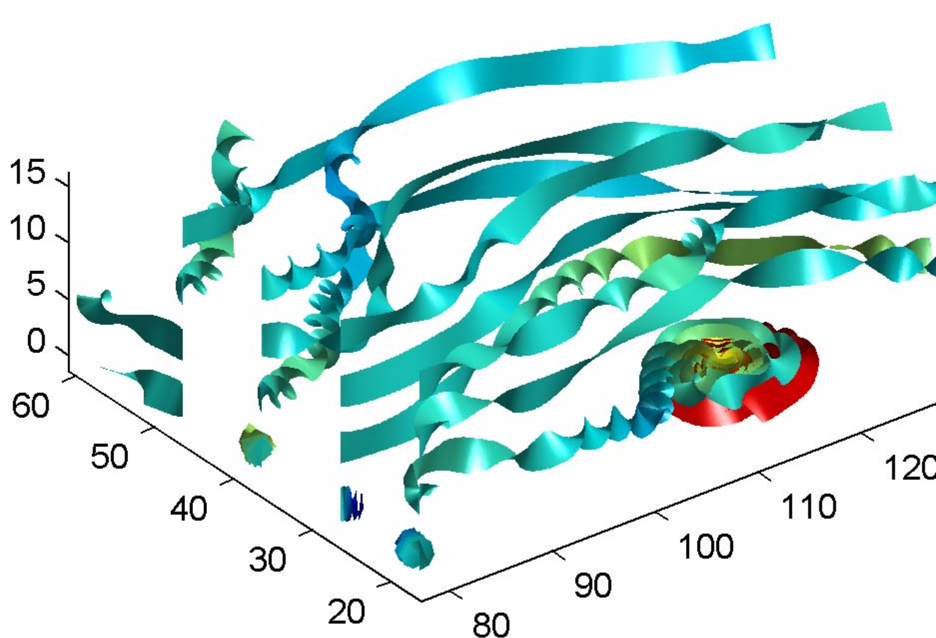
```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
axis tight
shading interp;
view(3);
camlight; lighting gouraud
```



This example uses precalculated vertex data (`stream3`), curl average velocity (`curl`), and speed $\sqrt{u^2 + v^2 + w^2}$. Using precalculated data enables you to use values other than those calculated from the single data source. In this case, the speed is reduced by a factor of 10 compared to the previous example.

```
figure
```

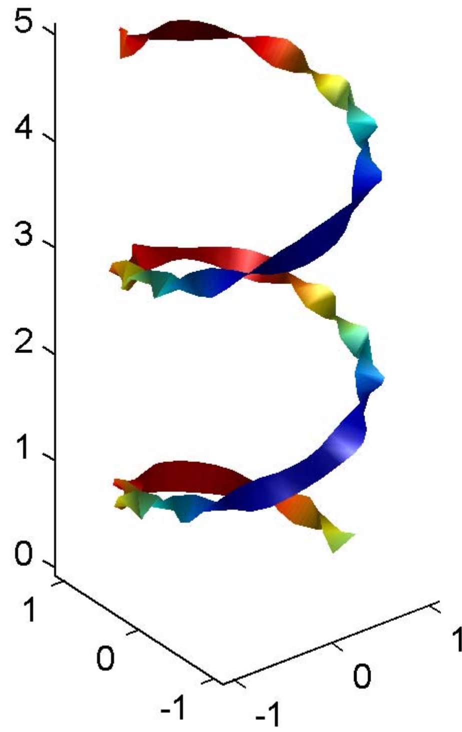
```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
cav = curl(x,y,z,u,v,w);
spd = sqrt(u.^2 + v.^2 + w.^2).*.1;
streamribbon(verts,x,y,z,cav,spd);
% Define viewing and lighting
axis tight
shading interp
view(3)
camlight; lighting gouraud
```



This example specifies a twist angle for the stream ribbon.

```
figure
t = 0:.15:15;
verts = {[cos(t)' sin(t)' (t/3)']};
twistangle = {cos(t)'};
streamribbon(verts,twistangle);
% Define viewing and lighting
```

```
axis tight
shading interp;
view(3);
camlight; lighting gouraud
```



This example combines cone plots (`coneplot`) and stream ribbon plots in one graph.

```
figure
% Define 3-D arrays x, y, z, u, v, w
xmin = -7; xmax = 7;
ymin = -7; ymax = 7;
zmin = -7; zmax = 7;
x = linspace(xmin,xmax,30);
y = linspace(ymin,ymax,20);
z = linspace(zmin,zmax,20);
[x y z] = meshgrid(x,y,z);
u = y; v = -x; w = 0*x+1;
[cx cy cz] = meshgrid(linspace(xmin,xmax,30),...
   linspace(ymin,ymax,30),[-3 4]);
h = coneplot(x,y,z,u,v,w,cx,cy,cz,'quiver');
set(h,'Color','k');

% Plot two sets of streamribbons
[sx sy sz] = meshgrid([-1 0 1],[-1 0 1],-6);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
[sx sy sz] = meshgrid([1:6],[0],-6);
streamribbon(x,y,z,u,v,w,sx,sy,sz);

% Define viewing and lighting
shading interp
view(-30,10) ; axis off tight
camproj perspective; camva(66); camlookat;
camdolly(0,0,.5,'fixtarget')
camlight
```

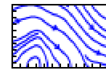
`curl` | `streamtube` | `streamline` | `stream3` | `meshgrid` | `coneplot`

How To

- "Volume Visualization"
- Displaying Curl with Stream Ribbons
- Specifying Starting Points for Stream Plots

Purpose

Plot streamlines in slice planes



Syntax

```
streamslice(X,Y,Z,U,V,W,startx,starty,startz)
streamslice(U,V,W,startx,starty,startz)
streamslice(X,Y,U,V)
streamslice(U,V)
streamslice(...,density)
streamslice(...,'arrowsmode')
streamslice(...,'method')
streamslice(axes_handle,...)
h = streamslice(...)
[vertices arrowvertices] = streamslice(...)
```

Description

`streamslice(X,Y,Z,U,V,W,startx,starty,startz)` draws well-spaced streamlines (with direction arrows) from vector data `U`, `V`, `W` in axis aligned *x*-, *y*-, *z*-planes starting at the points in the vectors `startx`, `starty`, `startz`. (The section Specifying Starting Points for Stream Plots provides more information on defining starting points.)

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`. `U`, `V`, `W` must be m-by-n-by-p volume arrays.

Do not assume that the flow is parallel to the slice plane. For example, in a stream slice at a constant `z`, the `z` component of the vector field `W` is ignored when you are calculating the streamlines for that plane.

Stream slices are useful for determining where to start streamlines, stream tubes, and stream ribbons.

`streamslice(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where [m,n,p] = size(U).

streamslice(X,Y,U,V) draws well-spaced streamlines (with direction arrows) from vector volume data U, V.

The arrays X and Y, which define the coordinates for U and V, must be monotonic, but do not need to be uniformly spaced. X and Y must have the same number of elements, as if produced by meshgrid.

streamslice(U,V) assumes X, Y, and Z are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where [m,n,p] = size(U).

streamslice(...,density) modifies the automatic spacing of the streamlines. density must be greater than 0. The default value is 1; higher values produce more streamlines on each plane. For example, 2 produces approximately twice as many streamlines, while 0.5 produces approximately half as many.

streamslice(...,'*arrowsmode*') determines if direction arrows are present or not. arrowmode can be

- arrows — Draw direction arrows on the streamlines (default).
- noarrows — Do not draw direction arrows.

streamslice(...,'*method*') specifies the interpolation method to use. method can be

- linear — Linear interpolation (default)
- cubic — Cubic interpolation
- nearest — Nearest-neighbor interpolation

See interp3 for more information on interpolation methods.

streamslice(axes_handle,...) plots into the axes object with the handle axes_handle instead of into the current axes object (gca).

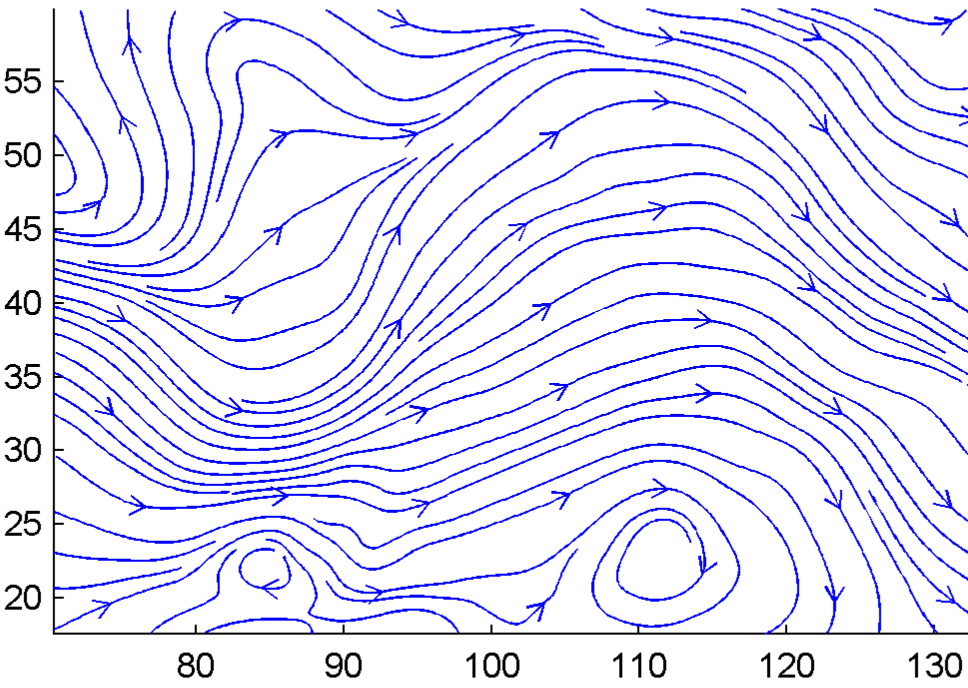
`h = streamslice(...)` returns a vector of handles to the line objects created.

`[vertices arrowvertices] = streamslice(...)` returns two cell arrays of vertices for drawing the streamlines and the arrows. You can pass these values to any of the streamline drawing functions (`streamline`, `streamribbon`, `streamtube`).

Examples

This example creates a stream slice in the `wind` data set at `z = 5`.

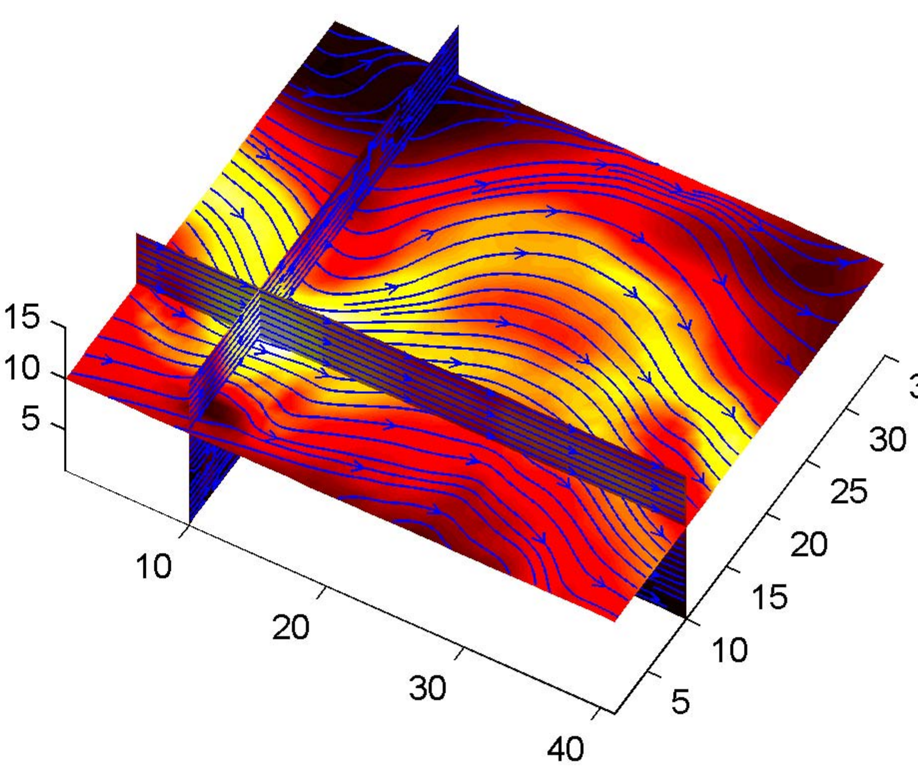
```
figure
load wind
streamslice(x,y,z,u,v,w,[],[],[5])
axis tight
```



This example uses `streamslice` to calculate vertex data for the streamlines and the direction arrows. This data is then used by `streamline` to plot the lines and arrows. Slice planes illustrating with color the wind speed $\sqrt{u^2 + v^2 + w^2}$ are drawn by `slice` in the same planes.

```
figure
```

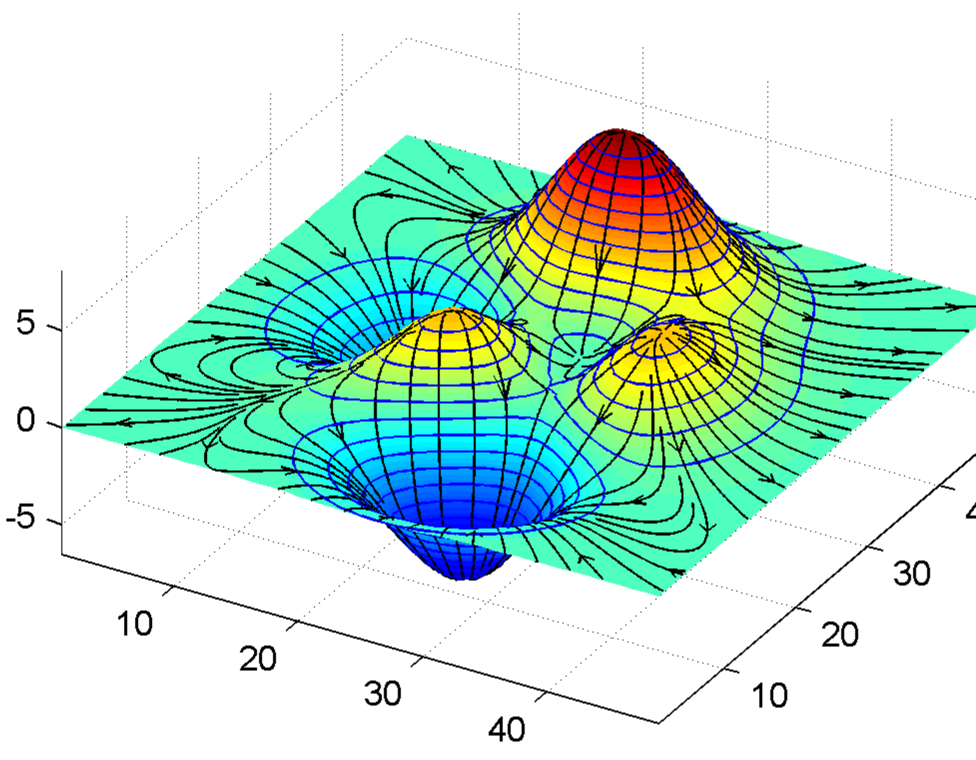
```
load wind
[verts averts] = streamslice(u,v,w,10,10,10);
streamline([verts averts])
spd = sqrt(u.^2 + v.^2 + w.^2);
hold on;
slice(spd,10,10,10);
colormap(hot)
shading interp
view(30,50); axis(volumebounds(spd));
camlight; material([.5 1 0])
```



This example superimposes contour lines on a surface and then uses `streamslice` to draw lines that indicate the gradient of the surface. `interp2` is used to find the points for the lines that lie on the surface.

```
figure
z = peaks;
surf(z)
shading interp
```

```
hold on
[c ch] = contour3(z,20); set(ch,'edgecolor','b')
[u v] = gradient(z);
h = streamslice(-u,-v);
set(h,'color','k')
for i=1:length(h);
 zi = interp2(z,get(h(i),'xdata'),get(h(i),'ydata'));
 set(h(i),'zdata',zi);
end
view(30,50); axis tight
```



See Also

contourslice | slice | streamline | volumebounds | meshgrid | interp3 | interp2 | streamribbon | streamtube

How To

- Specifying Starting Points for Stream Plots

Purpose

Create 3-D stream tube plot

Syntax

```
streamtube(X,Y,Z,U,V,W,startx,starty,startz)
streamtube(U,V,W,startx,starty,startz)
streamtube(vertices,X,Y,Z,divergence)
streamtube(vertices,divergence)
streamtube(vertices,width)
streamtube(vertices)
streamtube(...,[scale n])
streamtube(axes_handle,...)
h = streamtube(...z)
```

Description

`streamtube(X,Y,Z,U,V,W,startx,starty,startz)` draws stream tubes from vector volume data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the streamlines at the center of the tubes. The section Specifying Starting Points for Stream Plots provides more information on defining starting points.

The width of the tubes is proportional to the normalized divergence of the vector field.

`streamtube(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamtube(vertices,X,Y,Z,divergence)` assumes precomputed streamline vertices and divergence. `vertices` is a cell array of

streamline vertices (as produced by stream3). X, Y, Z, and divergence are 3-D arrays.

streamtube(vertices,divergence) assumes X, Y, and Z are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where [m,n,p] = size(divergence).

streamtube(vertices,width) specifies the width of the tubes in the cell array of vectors, width. The size of each corresponding element of vertices and width must be equal. width can also be a scalar, specifying a single value for the width of all stream tubes.

streamtube(vertices) selects the width automatically.

streamtube(...,[scale n]) scales the width of the tubes by scale. The default is scale = 1. When the stream tubes are created, using start points or divergence, specifying scale = 0 suppresses automatic scaling. n is the number of points along the circumference of the tube. The default is n = 20.

streamtube(axes_handle,...) plots into the axes object with the handle axes_handle instead of into the current axes object (gca).

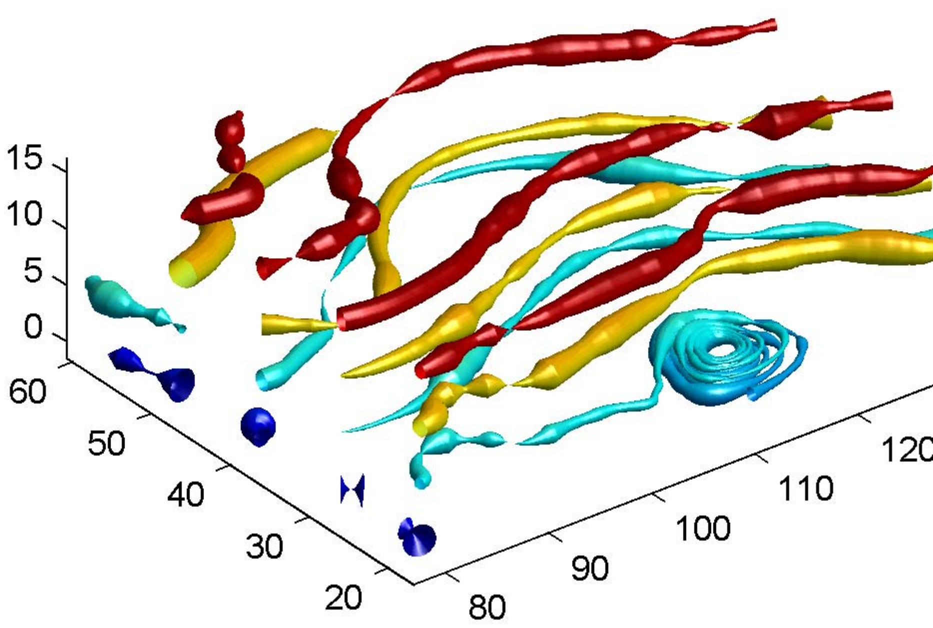
h = streamtube(...z) returns a vector of handles (one per start point) to surface objects used to draw the stream tubes.

Examples

This example uses stream tubes to indicate the flow in the wind data set. Inputs include the coordinates, vector field components, and starting location for the stream tubes.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamtube(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
view(3)
axis tight
```

```
shading interp;
camlight; lighting gouraud
```



This example uses precalculated vertex data (`stream3`) and divergence (`divergence`).

```
figure
load wind
```

```
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
div = divergence(x,y,z,u,v,w);
streamtube(verts,x,y,z,-div);
% Define viewing and lighting
view(3)
axis tight
shading interp
camlight; lighting gouraud
```

How To

- Displaying Divergence with Stream Tubes
- Specifying Starting Points for Stream Plots

strfind

Purpose

Find one string within another

Syntax

```
k = strfind(str, pattern)
k = strfind(cellstr, pattern)
```

Description

`k = strfind(str, pattern)` searches the string `str` for occurrences of a shorter string, `pattern`, and returns the starting index of each such occurrence in the double array `k`. If `pattern` is not found in `str`, or if `pattern` is longer than `str`, then `strfind` returns the empty array `[]`.

`k = strfind(cellstr, pattern)` searches each string in cell array of strings `cellstr` for occurrences of a shorter string, `pattern`, and returns the starting index of each such occurrence in cell array `k`. If `pattern` is not found in a string or if `pattern` is longer then all strings in the cell array, then `strfind` returns the empty array `[]`, for that string in the cell array.

Tips

- The search performed by `strfind` is case sensitive.
- Any leading and trailing blanks in `pattern` or in the strings being searched are explicitly included in the comparison.
- The `strfind` function does not find empty strings (`''`) within a string.

Examples

Use `strfind` to find a two-letter pattern in string `S`:

```
S = 'Find the starting indices of the pattern string';
strfind(S, 'in')
ans =
     2    15    19    45

strfind(S, 'In')
ans =
     []

strfind(S, ' ')
ans =
     5     9    18    26    29    33    41
```

Use `strfind` on a cell array of strings:

```
cstr = {'How much wood would a woodchuck chuck';
        'if a woodchuck could chuck wood?'};

idx = strfind(cstr, 'wood');

idx{:,:}
ans =
    10    23
ans =
     6    28
```

This means that `'wood'` occurs at indices 10 and 23 in the first string and at indices 6 and 28 in the second.

strings

Purpose

String handling

Syntax

```
S = 'Any Characters'
S = [S1 S2 ...]
C = {S1 S2 ...}
S = strcat(S1, S2, ...)
S = char(S1, S2, ...)
S = char(X)
X = double(S)
```

Description

`S = 'Any Characters'` creates a character array, or string. The string is actually a vector that contains the numeric codes for the characters (codes 0 to 127 are ASCII). The length of `S` is the number of characters. A quotation within the string is indicated by two quotation marks.

`S = [S1 S2 ...]` concatenates character arrays `S1`, `S2`, etc. into a new character array, `S`.

`C = {S1 S2 ...}` creates a cell array of strings. Separate each row of the cell array with a semicolon (`;`).

`S = strcat(S1, S2, ...)` horizontally concatenates `S1`, `S2`, etc., which can be character arrays or cell arrays of strings. If the inputs are character arrays, `strcat` removes trailing white space. For more information, see the `strcat` reference page.

`S = char(S1, S2, ...)` vertically concatenates character arrays `S1`, `S2`, etc., padding each input string as needed so that each row contains the same number of characters.

`S = char(X)` converts an array that contains positive integers representing numeric codes into a MATLAB character array.

`X = double(S)` converts the string to its equivalent integer numeric codes.

Tips

- To convert between character arrays and cell arrays of strings, use `char` and `cellstr`. Most string functions support both types.

- To determine whether `S` is a character array or cell array, call `ischar(S)` or `iscellstr(S)`.

Examples

Create a simple string that includes a single quote.

```
msg = 'You''re right!'

msg =
You're right!
```

Create the string `name` using two methods of concatenation.

```
name = ['Thomas' ' R. ' 'Lee']
name = strcat('Thomas',' R.',' Lee')
```

Create a character array of strings.

```
C = char('Hello','Goodbye','Yes','No')

C =
Hello
Goodbye
Yes
No
```

Create a cell array of strings.

```
S = {'Hello' 'Goodbye'; 'Yes' 'No'}

S =
    'Hello'    'Goodbye'
    'Yes'      'No'
```

Concepts

- “Cell Arrays of Strings”

strjoin

Purpose

Join strings in cell array into single string

Syntax

```
str = strjoin(C)
str = strjoin(C,delimiter)
```

Description

`str = strjoin(C)` constructs the string, `str`, by linking each string in the cell array, `C`, with a single space.

`str = strjoin(C,delimiter)` constructs the string, `str`, by linking each string of `C` with the elements in `delimiter`.

Input Arguments

C - Input text

1-by-n cell array of strings

Input text, specified as a 1-by-n cell array of strings. Each element in the cell array must contain a single string in a single row.

Example: `{'The','rain','in','Spain'}`

Data Types
`cell`

delimiter - Delimiting characters

string | 1-by-n cell array of strings

Delimiting characters, specified as a single string or a 1-by-n cell array of strings.

- If `delimiter` is a single string, then `strjoin` forms `str` by inserting `delimiter` between each element of `C`. The `delimiter` input can include any of these escape sequences:

`\\`	Backslash
`\0`	Null
`\a`	Alarm
`\b`	Backspace

`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab

- If `delimiter` is a cell array of strings, then it must contain one fewer element than `C`. Each element in the cell array must contain a single string in a single row. `strjoin` forms `str` by interleaving the elements of `delimiter` and `C`. All characters in `delimiter` are inserted as literal text, and escape sequences are not supported.

Example: `', '`

Example: `{',',' '}`

Data Types
`char | cell`

Examples

Join List of Words with Whitespace

Join individual strings in a cell array of strings, `C`, with a single space.

```
C = {'one','two','three'};
str = strjoin(C)

str =

one two three
```

Join Strings as Comma Separated List

```
C = {'Newton','Gauss','Euclid','Lagrange'};
str = strjoin(C,', ')

str =

Newton, Gauss, Euclid, Lagrange
```

Join Strings with Multiple Different Delimiters

Specify multiple different delimiters in a cell array of strings. The `delimiter` cell array must have one fewer element than `C`.

```
C = {'one','two','three'};
str = strjoin(C,{' + ',' = '})
```

```
str =

one + two = three
```

See Also

strsplit | strcat | cellstr | regexp

Purpose

Justify character array

Syntax

```
T = strjust(S)
T = strjust(S, 'right')
T = strjust(S, 'left')
T = strjust(S, 'center')
```

Description

`T = strjust(S)` or `T = strjust(S, 'right')` returns a right-justified version of the character array `S`.

`T = strjust(S, 'left')` returns a left-justified version of `S`.

`T = strjust(S, 'center')` returns a center-justified version of `S`.

See Also

`deblank` | `strtrim`

strmatch

Purpose

Find possible matches for string

Note `strmatch` is not recommended. Use `strncmp` or `validatestring`, depending on your requirements, instead. `strncmp` returns the numeric index of all array elements that begin with the specified string, whereas `validatestring` returns a single string that represents the best match to the specified string. See Example 2, below.

To find an exact match for a string, use `strcmp`.

Syntax

```
x = strmatch(str, strarray)
x = strmatch(str, strarray, 'exact')
```

Description

`x = strmatch(str, strarray)` looks through the rows of the character array or cell array of strings `strarray` to find strings that begin with the text contained in `str`, and returns the matching row indices. If `strmatch` does not find `str` in `strarray`, `x` is an empty matrix (`[]`). Any trailing space characters in `str` or `strarray` are ignored when matching. `strmatch` is fastest when `strarray` is a character array.

`x = strmatch(str, strarray, 'exact')` compares `str` with each row of `strarray`, looking for an exact match of the entire strings. Any trailing space characters in `str` or `strarray` are ignored when matching.

Examples

Example 1

The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'))
```

returns `x = [1; 3]` since rows 1 and 3 begin with `'max'`. The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'),'exact')
```

returns `x = 1`, since only row 1 matches `'max'` exactly.

Example 2

This example shows how to replace use of the `strmatch` function with `validatestring` or `strncmp`.

To start with, use `strmatch` to return the index of those elements for which there is a match:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = strmatch('max',list)
x =
     1
     3
     4
```

`validatestring` returns the string representing the best match. If multiple or no matches exist, this statement would return an error:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = validatestring('max', list)
x =
   max
```

`strncmp` returns a logical array indicating which strings match the specified string:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = strncmp('max', list, 3)
x =
     1     0     1     1
```

If you prefer that MATLAB return the numeric indices of `list`, use `find` as follows:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = find(strncmp(list, 'max', 3))
```

If your input to `strmatch` is a character matrix, then first convert the matrix to a cell array using `cellstr`. Then, pass the output from `cellstr` to `strncmp` or `validatestring`

See Also

`strcmp` | `strcmpi` | `strncmp` | `strncmpi` | `strfind` | `regexp` | `regexpi` | `regexprep`

Purpose

Compare first `n` characters of strings (case sensitive)

Syntax

```
TF = strncmp(string,string,n)
TF = strncmp(string,cellstr,n)
TF = strncmp(cellstr,cellstr,n)
```

Description

`TF = strncmp(string,string,n)` compares the first `n` characters of two strings for equality. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strncmp(string,cellstr,n)` compares the first `n` characters of a string with the first `n` characters of each element of a cell array of strings. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the first two input arguments is not important.

`TF = strncmp(cellstr,cellstr,n)` compares each element of one cell array of strings with the same element of the other. `strncmp` attempts to match only the first `n` characters of these strings. The function returns a logical array the same size as either input array.

Tips

- The `strncmp` function is intended for comparison of character data. When used to compare numeric data, it returns logical `0`.
- Use `strncmpi` for case-insensitive string comparisons.
- Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
- The value returned by `strncmp` is not the same as the C language convention.
- `strncmp` supports international character sets.

Input Arguments

string

Single character string or n-by-1 array of strings.

cellstr

Cell array of strings.

n

Maximum number of characters to compare. Must be a scalar, integer-valued double.

Output Arguments

TF

When both inputs are character arrays, `TF` is a scalar logical value. This value is logical 1 (`true`) if the size and content of both arrays are equal, and logical 0 (`false`) if they are not.

When either or both inputs are a cell array of strings, `TF` is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (`true`) for those elements of the input arrays that are a match, and logical 0 (`false`) for those elements that are not.

Examples

Before trying the `strncmp` function, use `strcmp` to perform a simple comparison of the two input strings. Because only the first 13 characters are the same, `strcmp` returns logical 0:

```
strcmp('Kansas City, KS', 'Kansas City, MO')
ans =
     0
```

Do the comparison again, but this time using `strncmp` and specifying the number of characters to compare:

```
chars2compare = length('Kansas City, KS') - 2
ans =
    13
strncmp('Kansas City, KS', 'Kansas City, MO', chars2compare)
ans =
     1
```

From a list of 10 MATLAB functions, find those that apply to using a camera:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...
                 'caxis' 'camtarget' 'cast' 'camorbit' ...
                 'callib' 'cart2sph'};

strncmp(function_list, 'cam', 3)
ans =
    0    0    1    0    0    1    0    1    0    0

function_list{strncmp(function_list, 'cam', 3)}
ans =
   camdolly
ans =
   camtarget
ans =
   camorbit
```

Create two 5-by-10 string arrays `str1` and `str2` that are equal, except for the element at row 4, column 3. Using linear indexing, this is element 14:

```
str1 = ['AAAAAAAAAA'; 'BBBBBBBBBB'; 'CCCCCCCCCC'; ...
        'DDDDDDDDDD'; 'EEEEEEEEEE']
str1 =
    AAAAAAAAAA
    BBBBBBBBBB
    CCCCCCCCCC
    DDDDDDDDDD
    EEEEEEEEEE

str2 = str1;
str2(4,3) = '-'
str2 =
    AAAAAAAAAA
```

```
BBBBBBBBBB
CCCCCCCCCC
DD-DDDDDDD
EEEEEEEEEE
```

Because MATLAB compares the arrays in linear order (that is, column by column rather than row by row), `strncmp` finds only the first 13 elements to be the same:

```
str1   A B C D E A B C D E A B C D E
str2   A B C D E A B C D E A B C - E
                                 |
                             element 14

strncmp(str1, str2, 13)
ans =
     1

strncmp(str1, str2, 14)
ans =
     0
```

See Also

`strcmp` | `strncmpi` | `strcmpi` | `strfind` | `regexp` | `regexpi` |

Purpose

Compare first `n` characters of strings (case insensitive)

Syntax

```
TF = strncmpi(string,string,n)
TF = strncmpi(string,cellstr,n)
TF = strncmpi(cellstr,cellstr,n)
```

Description

`TF = strncmpi(string,string,n)` compares the first `n` characters of two strings for equality, ignoring any differences in letter case. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strncmpi(string,cellstr,n)` compares the first `n` characters of a string with the first `n` characters of each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the input arguments is not important.

`TF = strncmpi(cellstr,cellstr,n)` compares each element of one cell array of strings with the same element of the other, ignoring letter case. `strncmpi` attempts to match only the first `n` characters of these strings. The function returns a logical array the same size as either input array.

Tips

- The `strncmpi` function is intended for comparison of character data. When used to compare numeric data, it returns logical `0`.
- Use `strncmp` for case-sensitive string comparisons.
- Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
- The value returned by `strncmpi` is not the same as the C language convention.
- `strncmpi` supports international character sets.

Input Arguments

string

A single character string or n-by-1 array of strings.

cellstr

A cell array of strings.

n

Maximum number of characters to compare. Must be a scalar, integer-valued double.

Output Arguments

TF

When both inputs are character arrays, `TF` is a scalar logical value. This value is logical 1 (`true`) if the size and content of both arrays are equal, and logical 0 (`false`) if they are not.

When either or both inputs are a cell array of strings, `TF` is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (`true`) for those elements of the input arrays that are a match, and logical 0 (`false`) for those elements that are not.

Examples

From a list of 10 MATLAB functions, find those that apply to using a camera. Do the comparison without sensitivity to letter case:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...
                 'caxis' 'Camtarget' 'cast' 'camorbit' ...
                 'callib' 'cart2sph'};

strncmpi(function_list, 'CAM', 3)
ans =
     0     0     1     0     0     1     0     1     0     0

function_list{strncmpi(function_list, 'CAM', 3)}
ans =
   camdolly
ans =
   Camtarget
ans =
   camorbit
```

See Also

`strcmpi` | `strncmp` | `strcmp` | `strfind` | `regexpi` | `regexp` |

strread

Purpose

Read formatted data from string

Note `strread` is not recommended. Use `textscan` instead.

Syntax

```
A = strread('str')
[A, B, ...] = strread('str')
[A, B, ...] = strread('str', 'format')
[A, B, ...] = strread('str', 'format', N)
[A, B, ...] = strread('str', 'format', N, param, value, ...)
```

Description

`A = strread('str')` reads numeric data from input string `str` into a 1-by-`N` vector `A`, where `N` equals the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See "Example 1" on page 1-5042 below.

`[A, B, ...]  = strread('str')` reads numeric data from the string input `str` into scalar output variables `A`, `B`, and so on. The number of output variables must equal the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See "Example 2" on page 1-5043 below.

`[A, B, ...]  = strread('str', 'format')` reads data from `str` into variables `A`, `B`, and so on using the specified `format`. The number of output variables `A`, `B`, etc. must be equal to the number of format specifiers (e.g., `%s` or `%d`) in the `format` argument. You can read all of the data in `str` to a single output variable as long as you use only one format specifier in the command. See "Example 4" on page 1-5043 and "Example 5" on page 1-5044 below.

The table Formats for strread on page 1-5039 lists the valid format specifiers. More information on using formats is available under "Formats" on page 1-5042 in the "Tips" on page 1-5041 section below.

`[A, B, ...]  = strread('str', 'format', N)` reads data from `str` reusing the `format` string `N` times, where `N` is an integer greater than zero. If `N` is -1, `strread` reads the entire string. When `str` contains

only numeric data, you can set `format` to the empty string (`''`). See "Example 3" on page 1-5043 below.

`[A, B, ...]  = strread('str', 'format', N, param, value, ...)` customizes `strread` using `param/value` pairs, as listed in the table Parameters and Values for strread on page 1-5040 below. When `str` contains only numeric data, you can set `format` to the empty string (`''`). The `N` argument is optional and may be omitted entirely. See "Example 7" on page 1-5045 below.

Formats for strread

Format	Action	Output
Literals (ordinary characters)	Ignore the matching characters. For example, in a string that has `Dept` followed by a number (for department number), to skip the `Dept` and read only the number, use `'Dept'` in the `format` string.	None
`%d`	Read a signed integer value.	Double array
`%u`	Read an integer value.	Double array
`%f`	Read a floating-point value.	Double array
`%s`	Read a white-space separated string.	Cell array of strings
`%q`	Read a double quoted string, ignoring the quotes.	Cell array of strings
`%c`	Read characters, including white space.	Character array
`%[...]`	Read the longest string containing characters specified in the brackets.	Cell array of strings

Formats for strread (Continued)

Format	Action	Output
`%[^...]`	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
`%*...`	Ignore the characters following `*`. See “Example 8” on page 1-5045 below.	No output
`%w...`	Read field width specified by `w`. The `%f` format supports `%w.pf`, where `w` is the field width and `p` is the precision.	

Parameters and Values for strread

param	value	Action
`whitespace`	Any from the list below: `\b` Backspace `\n` New line `\r` Carriage return `\t` Horizontal tab `\\` Backslash `%%` Percent sign `''` Single quotation mark	Treats vector of characters, `*`, as white space. Default is `\b\r\n\t`.
`delimiter`	Delimiter character	Specifies delimiter character. Default is one or more whitespace characters.
`expchars`	Exponent characters	Default is `eEdD`.

Parameters and Values for strread (Continued)

param	value	Action
bufsize	Positive integer	Specifies the maximum string length, in bytes. Default is 4095.
commentstyle	matlab	Ignores characters after %.
commentstyle	shell	Ignores characters after #.
commentstyle	c	Ignores characters between /* and */.
commentstyle	c++	Ignores characters after //.
emptyvalue	Value to return for empty numeric fields in delimited files	Default is NaN.

Tips

If you terminate the input string with a newline character (\n), strread returns arrays of equal size by padding arrays of lesser size with the emptyvalue character:

```
[A,B,C] = strread(sprintf('5,7,1,9\n'),'%d%d%d', ...
              'delimiter', ',', 'emptyvalue',NaN)
A =
     5
     9
B =
     7
   NaN
C =
     1
   NaN
```

If you remove the \n from the input string of this example, array A continues to be a 2-by-1 array, but B and C are now 1-by-1.

Delimiters

If your data uses a character other than a space as a delimiter, you must use the strread parameter 'delimiter' to specify the delimiter. For example, if the string str used a semicolon as a delimiter, you would use this command:

```
[names, types, x, y, answer] = strread(str,'%s %s %f ...
    %d %s','delimiter',';')
```

Formats

The format string determines the number and types of return arguments. The number of return arguments must match the number of conversion specifiers in the format string.

The strread function continues reading str until the entire string is read. If there are fewer format specifiers than there are entities in str, strread reapplies the format specifiers, starting over at the beginning. See "Example 5" on page 1-5044 below.

The format string supports a subset of the conversion specifiers and conventions of the C language fscanf routine. White-space characters in the format string are ignored.

Preserving White-Space

If you want to preserve leading and trailing spaces in a string, use the whitespace parameter as shown here:

```
str = '   An  example      of preserving     spaces      ';

strread(str, '%s', 'whitespace', '')
ans =
    '   An  example      of preserving     spaces      '
```

Examples

Example 1

Read numeric data into a 1-by-5 vector:

```
a = strread('0.41 8.24 3.57 6.24 9.27')
a =
    0.4100    8.2400    3.5700    6.2400    9.2700
```

Example 2

Read numeric data into separate scalar variables:

```
[a b c d e] = strread('0.41 8.24 3.57 6.24 9.27')
a =
    0.4100
b =
    8.2400
c =
    3.5700
d =
    6.2400
e =
    9.2700
```

Example 3

Read the only first three numbers in the string, also formatting as floating point:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%4.2f', 3)

a =
    0.4100
    8.2400
    3.5700
```

Example 4

Truncate the data to one decimal digit by specifying format `%3.1f`. The second specifier, `%*1d`, tells `strread` not to read in the remaining decimal digit:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%3.1f %*1d')

a =
```

```
    0.4000
    8.2000
    3.5000
    6.2000
    9.2000
```

Example 5

Read six numbers into two variables, reusing the format specifiers:

```
[a b] = strread('0.41 8.24 3.57 6.24 9.27 3.29', '%f %f')

a =
    0.4100
    3.5700
    9.2700
b =
    8.2400
    6.2400
    3.2900
```

Example 6

Read string and numeric data to two output variables. Ignore commas in the input string:

```
str = 'Section 4, Page 7, Line 26';

[name value] = strread(str, '%s %d,')
name =
    'Section'
    'Page'
    'Line'
value =
     4
     7
    26
```

Example 7

Read the string used in the last example, but this time delimiting with commas instead of spaces:

```
str = 'Section 4, Page 7, Line 26';

[a b c] = strread(str, '%s %s %s', 'delimiter', ',')
a =
    'Section 4'
b =
    'Page 7'
c =
    'Line 26'
```

Example 8

Read selected portions of the input string:

```
str = '<table border=5 width="100%" cellspacing=0>';

[border width space] = strread(str, ...
   '%*s%*s %c %*s "%4s" %*s %c', 'delimiter', '= ')
border =
     5
width =
    '100%'
space =
     0
```

Example 9

Read the string into two vectors, restricting the `Answer` values to `T` and `F`. Also note that two delimiters (comma and space) are used here:

```
str = 'Answer_1: T, Answer_2: F, Answer_3: F';

[a b] = strread(str, '%s %[TF]', 'delimiter', ', ')
a =
    'Answer_1:'
```

```
    'Answer_2:'
    'Answer_3:'
b =
    'T'
    'F'
    'F'
```

`textscan` | `sscanf`

Purpose

Find and replace substring

Syntax

modifiedStr = strrep(*origStr*, *oldSubstr*, *newSubstr*)

Description

modifiedStr = strrep(*origStr*, *oldSubstr*, *newSubstr*) replaces all occurrences of the string *oldSubstr* within string *origStr* with the string *newSubstr*.

Tips

- strrep accepts input combinations of single strings, strings in scalar cells, and same-sized cell arrays of strings. If any inputs are cell arrays, strrep returns a cell array.
- The strrep function does not find empty strings for replacement. That is, when *origStr* and *oldSubstr* both contain the empty string (''), strrep does not replace '' with the contents of *newSubstr*.
- Before replacing strings, strrep finds all instances of *oldSubstr* in *origStr*, like the strfind function. For overlapping patterns, strrep performs multiple replacements. See the final example in the Examples section.

Examples

Replace text in a character array:

```
claim = 'This is a good example.';
new_claim = strrep(claim, 'good', 'great')
```

MATLAB returns:

```
new_claim =
This is a great example.
```

Replace text in a cell array:

```
c_files = {'c:\cookies.m'; ...
           'c:\candy.m';   ...
           'c:\calories.m'};
d_files = strrep(c_files, 'c:', 'd:')
```

MATLAB returns:

```
d_files =
    'd:\cookies.m'
    'd:\candy.m'
    'd:\calories.m'
```

Replace text in a cell array with values in a second cell array:

```
missing_info = {'Start: __'; ...
                'End: __'};

dates = {'01/01/2001'; ...
         '12/12/2002'};

complete = strrep(missing_info, '__', dates)
```

MATLAB returns:

```
complete =
    'Start: 01/01/2001'
    'End: 12/12/2002'
```

Compare the use of `strrep` and `regexprep` to replace a string with a repeated pattern:

```
repeats = 'abc 2 def 22 ghi 222 jkl 2222';
indices = strfind(repeats, '22')

using_strrep = strrep(repeats, '22', '*')
using_regexprep = regexprep(repeats, '22', '*')
```

MATLAB returns:

```
indices =
    11    18    19    26    27    28
```

```
using_strrep =
abc 2 def * ghi ** jkl ***

using_regexprep =
abc 2 def * ghi *2 jkl **
```

See Also

strfind | regexprep

strsplit

Purpose

Split string at specified delimiter

Syntax

```
C = strsplit(str)
C = strsplit(str,delimiter)
C = strsplit(str,delimiter,Name,Value)

[C,matches] = strsplit( ___ )
```

Description

`C = strsplit(str)` splits the string, `str`, at whitespace into the cell array of strings, `C`. A whitespace character is equivalent to any sequence in the set `{' ','\f','\n','\r','\t','\v'}`.

`C = strsplit(str,delimiter)` splits `str` at the delimiters specified by `delimiter`.

`C = strsplit(str,delimiter,Name,Value)` specifies additional delimiter options using one or more name-value pair arguments.

`[C,matches] = strsplit( ___ )` additionally returns a cell array of strings, `matches`, using any of the input arguments in the previous syntaxes. `matches` contains all occurrences of delimiters upon which `strsplit` splits `str`.

Input Arguments

str - Input text

string

Input text, specified as a string.

Data Types

`char`

delimiter - Delimiting characters

string | 1-by-n cell array of strings

Delimiting characters, specified as a single string or a 1-by-n cell array of strings. Strings specified in `delimiter` do not appear in the string fragments of the output `C`.

Specify multiple delimiters in a cell array of strings. Each element of the cell array must contain a single string in a single row. The `strsplit` function splits `str` on the elements of `delimiter` in the order in which they appear in the cell array.

`delimiter` can include the following escape sequences:

`\\`	Backslash
`\0`	Null
`\a`	Alarm
`\b`	Backspace
`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab

Example: `','`

Example: `{'-',','}`

Data Types
`char | cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DelimiterType','RegularExpression'` instructs `strsplit` to treat `delimiter` as a regular expression.

'CollapseDelimiters' - Multiple delimiter handling

`1 (true)` (default) | `0 (false)`

Multiple delimiter handling, specified as the comma-separated pair consisting of `'CollapseDelimiters'` and either `true` or `false`. If `true`, then consecutive delimiters in `str` are treated as one. If `false`, then consecutive delimiters are treated as separate delimiters, resulting in empty string `''` elements between matched delimiters.

Example: `'CollapseDelimiters',true`

'DelimiterType' - Delimiter type

`'Simple'` (default) | `'RegularExpression'`

Delimiter type, specified as the comma-separated pair consisting of `'DelimiterType'` and one of the following strings.

`'Simple'`	Except for escape sequences, `strsplit` treats `delimiter` as a literal string.
`'RegularExpression'`	`strsplit` treats `delimiter` as a regular expression.

In both cases, `delimiter` can include escape sequences.

Output Arguments

C - Parts of original string

cell array of strings

Parts of the original string, returned as a cell array of strings. `C` always contains one more element than `matches` contains. Consequently, if the original string, `str`, ends with a delimiter, then the last cell in `C` contains an empty string.

matches - Identified delimiters

cell array of strings

Identified delimiters, returned as a cell array of strings. `matches` always contains one fewer element than output `C` contains.

Examples

Split String on Whitespace

```
str = 'The rain in Spain.';
C = strsplit(str)

C =

    'The'    'rain'    'in'    'Spain.'
```

`C` is a cell array containing 4 strings.

Split String of Values on Specific Delimiter

Split a string of comma-separated values.

```
data = '1.21, 1.985, 1.955, 2.015, 1.885';
C = strsplit(data,', ')

C =

    '1.21'    '1.985'    '1.955'    '2.015'    '1.885'
```

Split a string of values, `data`, which contains the units `m/s` with an arbitrary number of white-space on either side of the text. The regular expression, `\s*`, matches any white-space character appearing zero or more times.

```
data = '1.21m/s1.985m/s 1.955 m/s2.015 m/s 1.885m/s';
[C,matches] = strsplit(data,'\s*m/s\s*','DelimiterType','RegularExpres

C =

    '1.21'    '1.985'    '1.955'    '2.015'    '1.885'    ''

matches =
```

```
    'm/s'    'm/s '    ' m/s'    ' m/s '    'm/s'
```

In this case, the last string in C is empty. This empty string is the string that follows the last matched delimiter.

Split Path String on File Separator

```
myPath = 'C:\work\matlab';
C = strsplit(myPath,'\')
```

```
C =

    'C:'    'work'    'matlab'
```

Split Text String with Multiple Delimiters

Split a string on `' '` and `'ain'`, treating multiple delimiters as one. Specify multiple delimiters in a cell array of strings.

```
str = 'The rain in Spain stays mainly in the plain.';
[C, matches] = strsplit(str,{' ', 'ain'},'CollapseDelimiters',true)
```

```
C =

    'The'    'r'    'in'    'Sp'    'stays'    'm'    'ly'    'in'    'th

matches =

    ' '    'ain '    ' '    'ain '    ' '    'ain'    ' '    ' '    ' '
```

Split the same string on whitespace and on `'ain'`, using regular expressions and treating multiple delimiters separately.

```
[C, matches] = strsplit(str, {'\s', 'ain'},'CollapseDelimiters',false, ..
                       'DelimiterType','RegularExpression')
```

```
C =
```

```
    'The'    'r'    ''    'in'    'Sp'    ''    'stays'    'm'    'ly

matches =

    ' '    'ain'    ' '    ' '    'ain'    ' '    ' '    'ain'    ' '
```

In this case, `strsplit` treats the two delimiters separately, so empty strings appear in output `C` between the consecutively matched delimiters.

Split Text with Multiple, Overlapping Delimiters

Split text on the strings `', '` and `', and '`.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{', ',', and '})

C =

    'bacon'    'lettuce'    'and tomato'

matches =

    ', '    ', '
```

Because the command lists `', '` first and `', and '` contains `', '`, the `strsplit` function splits `str` on the first delimiter and never proceeds to the second delimiter.

If you reverse the order of delimiters, `', and '` takes priority.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{', and ',', '})

C =

    'bacon'    'lettuce'    'tomato'
```

```
matches =

    ', '    ', and '
```

Split String Into Individual Characters

Split the string, `'abc'`, into individual characters using a regular expression.

The regular expression `'.'` represents any single character (including white space). You can specify this regular expression as a delimiter and extract single characters in the `matches` output. Use the name-value pair `'CollapseDelimiters',false` to treat consecutive characters as individual delimiters so that they appear as separate strings in `matches`. Use ~ in place of `C` to ignore the first output.

```
str = 'abc';
[~, matches] = strsplit(str,'.','DelimiterType', ...
            'RegularExpression','CollapseDelimiters',false)
```

```
matches =

    'a'    'b'    'c'
```

`strsplit` returns individual characters in the second output, `matches`.

`strjoin` | `strfind` | `regexp`

Concepts

- "Regular Expressions"

Purpose

Selected parts of string

Syntax

```
token = strtok(str)
token = strtok(str, delimiter)
[token, remain] = strtok('str', ...)
```

Description

`token = strtok(str)` parses input string `str` from left to right, returning part or all of that string in `token`. Using the white-space character as a delimiter, the `token` output begins at the start of `str`, skipping any delimiters that might appear at the start, and includes all characters up to either the next delimiter or the end of the string. White-space characters include space (ASCII 32), tab (ASCII 9), and carriage return (ASCII 13).

The `str` argument can be a string of characters enclosed in single quotation marks, a cell array of strings each enclosed in single quotation marks, or a variable representing either of the two. If `str` is a cell array of `N` strings, then `token` is a cell array of `N` tokens, with `token{1}` derived from `str{1}`, `token{2}` from `str{2}`, and so on.

`token = strtok(str, delimiter)` is the same as the above syntax except that you specify the delimiting character(s) yourself using the `delimiter` character vector input. White-space characters are not considered to be delimiters when using this syntax unless you include them in the `delimiter` argument. If the `delimiter` input specifies more than one character, MATLAB treats each character as a separate delimiter; it does not treat the multiple characters as a delimiting string. The number and order of characters in the `delimiter` argument is unimportant. Do not use escape sequences as delimiters. For example, use `char(9)` rather than `'\t'` for tab.

`[token, remain] = strtok('str', ...)` returns in `remain` that part of `str`, if any, that follows `token`. If no delimiters are found in the body of the input string, then the entire string (excluding any leading delimiting characters) is returned in `token`, and `remain` is an empty string (`''`). If `str` is a cell array of strings, `token` is a cell array of tokens and `remain` is a cell array of string remainders.

Examples

Example 1

This example uses the default white-space delimiter. Note that space characters at the start of the string are not included in the `token` output, but the space character that follows `token` is included in `remain`:

```
s = '  This is a simple example.';
[token, remain] = strtok(s)

token =
This
remain =
 is a simple example.
```

Example 2

Take a string of HTML code and break it down into segments delimited by the < and > characters. Write a `while` loop to parse the string and print each segment:

```
s = sprintf('%s%s%s%s', ...
'<ul class=continued><li class=continued>', ...
'<pre><a name="13474"></a>token = strtok', ...
'(''str'', delimiter)<a name="13475"></a>', ...
'token = strtok(''str'')');

remain = s;

while true
   [str, remain] = strtok(remain, '<>');
   if isempty(str),  break;  end
   disp(sprintf('%s', str))
end
```

Here is the output:

```
ul class=continued
li class=continued
pre
```

```
a name="13474"
/a
token = strtok('str', delimiter)
a name="13475"
/a
token = strtok('str')
```

Example 3

Using `strtok` on a cell array of strings returns a cell array of strings in `token` and a character array in `remain`:

```
s = {'all in good time'; ...
     'my dog has fleas'; ...
     'leave no stone unturned'};

remain = s;

for k = 1:4
   [token, remain] = strtok(remain);
   token
end
```

Here is the output:

```
token =
    'all'
    'my'
    'leave'
token =
    'in'
    'dog'
    'no'
token =
    'good'
    'has'
    'stone'
token =
```

```
'time'
'fleas'
'unturned'
```

See Also

strfind | strncmp | strcmp | textscan | strsplit

Purpose

Remove leading and trailing white space from string

Syntax

```
S = strtrim(str)
C = strtrim(cstr)
```

Description

`S = strtrim(str)` returns a copy of string `str` with all leading and trailing white-space characters removed. A white-space character is one for which the `isspace` function returns logical `1` (`true`).

`C = strtrim(cstr)` returns a copy of the cell array of strings `cstr` with all leading and trailing white-space characters removed from each string in the cell array.

Examples

Remove the leading white-space characters (spaces and tabs) from `str`:

```
str = sprintf('  \t   Remove    leading white-space')
str =
        Remove    leading white-space

str = strtrim(str)
str =
Remove    leading white-space
```

Remove leading and trailing white-space from the cell array of strings:

```
cstr = {'     Trim leading white-space';
        'Trim trailing white-space     '};

cstr = strtrim(cstr)
cstr =
    'Trim leading white-space'
    'Trim trailing white-space'
```

See Also

`isspace` | `cellstr` | `deblank` | `strjust`

Purpose

Create structure array

Syntax

```
s = struct
s = struct(field,value)
s = struct(field1,value1,...,fieldN,valueN)
s = struct([])

s = struct(obj)
```

Description

`s = struct` creates a scalar (1-by-1) structure with no fields.

`s = struct(field,value)` creates a structure array with the specified field and values.

- If `value` is *not* a cell array, then `s` is a scalar structure, where `s.(field) = value`.
- If `value` is a cell array, then `s` is a structure array with the same dimensions as `value`. Each element of `s` contains the corresponding element of `value`. For example, `s = struct('f',{'a','b'})` returns `s(1).f = 'a'` and `s(2).f = 'b'`.
- If `value` is an empty cell array `{}`, then `s` is an empty (0-by-0) structure.

`s = struct(field1,value1,...,fieldN,valueN)` creates a structure array with multiple fields. Any nonscalar cell arrays in the set `value1,...,valueN` must have the same dimensions.

- If none of the `value` inputs is a cell array, or all are scalar cell arrays, then `s` is a scalar structure.
- If any of the `value` inputs are nonscalar cell arrays, then `s` has the same dimensions as the nonscalar cell arrays. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.
- If any `value` input is an empty cell array, `{}`, then output `s` is an empty (0-by-0) structure.

`s = struct([])` creates an empty (0-by-0) structure with no fields.

`s = struct(obj)` creates a structure with field names and values that correspond to properties of `obj`. MATLAB does not convert `obj`, but rather creates `s` as a new structure. This structure does not retain the class information, so private, protected, and hidden properties become public fields in `s`. The `struct` function issues a warning when you use this syntax.

Input Arguments

field - Field name

string

Field name, specified as a string. Valid field names begin with a letter, and can contain letters, digits, and underscores. The maximum length of a field name is the value that the `namelengthmax` function returns.

value - Values within structure field

cell array | scalar | vector | multidimensional array

Values within structure field, specified as a cell array or as a scalar, vector, or multidimensional array of any other data type.

If none of the `value` inputs is a cell array, or all of the `value` inputs are scalar cell arrays, then output `s` is a scalar structure. Otherwise, `value` inputs that are nonscalar cell arrays must have the same dimensions, and output `s` also has those dimensions. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.

If any `value` input is an empty cell array, `{}`, then output `s` is an empty structure array.

Data Types
`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | cell | function_handle`
Complex Number Support: Yes

obj - Object

any nonfundamental class

Object of any class, except the fundamental data types such as `double` or `char`.

Examples

Structure with One Field

Create a nonscalar structure with one field, `f`.

```
field = 'f';
value = {'some text';
         [10, 20, 30];
         magic(5)};
s = struct(field,value)

s =
3x1 struct array with fields:
    f
```

View the contents each element.

```
s.f

ans =
some text

ans =
    10    20    30

ans =
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

When you access a field of a nonscalar structure, such as `s.f`, MATLAB returns a comma-separated list. In this case, `s.f` is equivalent to `s(1).f, s(2).f, s(3).f`.

Structure with Multiple Fields

Create a nonscalar structure with several fields.

```
field1 = 'f1';  value1 = zeros(1,10);
field2 = 'f2';  value2 = {'a', 'b'};
field3 = 'f3';  value3 = {pi, pi.^2};
field4 = 'f4';  value4 = {'fourth'};

s = struct(field1,value1,field2,value2,field3,value3,field4,value4)

s =
1x2 struct array with fields:
    f1
    f2
    f3
    f4
```

The cell arrays for `value2` and `value3` are 1-by-2, so `s` is also 1-by-2. Because `value1` is a numeric array and not a cell array, both `s(1).f1` and `s(2).f1` have the same contents. Similarly, because the cell array for `value4` has a single element, `s(1).f4` and `s(2).f4` have the same contents.

```
s(1)

ans =
    f1: [0 0 0 0 0 0 0 0 0 0]
    f2: 'a'
    f3: 3.1416
    f4: 'fourth'

s(2)

ans =
    f1: [0 0 0 0 0 0 0 0 0 0]
    f2: 'b'
    f3: 9.8696
    f4: 'fourth'
```

Fields that Contain Cell Arrays

Create a structure with a field that contains a cell array.

```
field = 'mycell';
value = {{'a','b','c'}};
s = struct(field,value)
```

```
s =
    mycell: {'a'  'b'  'c'}
```

Empty Structure Array

Create an empty structure with several fields.

```
s = struct('a',{},'b',{},'c',{})
```

```
s =
0x0 struct array with fields:
    a
    b
    c
```

Nested Structure Array

Create a nested structure: `a` contains field `b`, which in turn contains fields `c` and `d`.

```
a.b = struct('c',{},'d',{})
```

```
a =
    b: [0x0 struct]
```

View the names of the fields of nested structure `a.b`.

```
fieldnames(a.b)
```

```
ans =
    'c'
    'd'
```

struct2cell

Purpose

Convert structure to cell array

Syntax

```
c = struct2cell(s)
```

Description

`c = struct2cell(s)` converts the `m`-by-`n` structure `s` (with `p` fields) into a `p`-by-`m`-by-`n` cell array `c`.

If structure `s` is multidimensional, cell array `c` has size `[p size(s)]`.

Examples

The commands

```
clear s, s.category = 'tree';
s.height = 37.4; s.name = 'birch';
```

create the structure

```
s =
    category: 'tree'
      height: 37.4000
        name: 'birch'
```

Converting the structure to a cell array,

```
c = struct2cell(s)

c =
    'tree'
    [37.4000]
    'birch'
```

`cell2struct` | `cell` | `iscell` | `struct` | `isstruct` | `fieldnames`

How To

- dynamic field names

Purpose

Apply function to each field of scalar structure

Syntax

```
[A1,...,An] = structfun(func,S)
[A1,...,An] = structfun(func,S,Name,Value)
```

Description

`[A1,...,An] = structfun(func,S)` applies the function specified by function handle `func` to each field of scalar structure `S`. Output arrays `A1,...,An`, where `n` is the number of outputs from function `func`, contain the outputs from the function calls.

`[A1,...,An] = structfun(func,S,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

Input Arguments

func

Handle to a function that accepts a single input argument and returns `n` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

S

Scalar structure.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'UniformOutput'

Logical value, as follows:

`true (1)`	Indicates that for all inputs, each output from function `func` is a cell array or a scalar value that is always of the same type. The `structfun` function combines the outputs in arrays `A1,...,An`, where `n` is the number of function outputs. Each output array is of the same type as the individual function outputs.
`false (0)`	Requests that the `structfun` function combine the outputs into scalar structures `A1,...,An`, with the same fields as input structure `S`. The outputs of function `func` can be of any size or type.

Default: `true`

'ErrorHandler'

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

`identifier`	Error identifier.
`message`	Error message text.
`index`	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

Output Arguments

A1,...,An

Arrays that collect the `n` outputs from function `func`.

If `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each input. The class of the corresponding output array is the same as the class of the individual outputs from function `func`.
- Each array `A` is a column vector whose length equals the number of fields in `S`. The `structfun` function applies function `func` to the fields of `S` in the same order as that returned by the `fieldnames` function.

If `UniformOutput` is `false`, each array `A` is a scalar structure with the same fields as input `S`.

Examples

Create a scalar structure, and count the number of characters in each field.

```
s.f1 = 'Sunday';
s.f2 = 'Monday';
s.f3 = 'Tuesday';
s.f4 = 'Wednesday';
s.f5 = 'Thursday';
s.f6 = 'Friday';
s.f7 = 'Saturday';

lengths = structfun(@numel, s)
```

Shorten the text in each field of `s`, created in the previous example. Because the output is nonscalar, set `UniformOutput` to `false`.

```
shortNames = structfun(@(x) ( x(1:3) ), s, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function.

Define and call a custom error handling function.

```
function result = errorfun(errorinfo, field)
```

```
   warning(errorinfo.identifier, errorinfo.message);
   result = NaN;
end

mystruct.f1 = 'text';
myresult = structfun(@(x) x^2, mystruct, 'ErrorHandler', @errorfun)
```

Tutorials

- "Anonymous Functions"

Purpose

Concatenate strings vertically

Note `strvcat` is not recommended. Use `char` instead. Unlike `strvcat`, the `char` function does not ignore empty strings.

Syntax

```
S = strvcat(t1, t2, t3, ...)
S = strvcat(c)
```

Description

`S = strvcat(t1, t2, t3, ...)` forms the character array `S` containing the text strings (or string matrices) `t1,t2,t3,...` as rows. Spaces are appended to each string as necessary to form a valid matrix. Empty arguments are ignored.

`S = strvcat(c)` when `c` is a cell array of strings, passes each element of `c` as an input to `strvcat`. Empty strings in the input are ignored.

Tips

If each text parameter, `ti`, is itself a character array, `strvcat` appends them vertically to create arbitrarily large string matrices.

Examples

The command `strvcat('Hello','Yes')` is the same as `['Hello';'Yes  ']`, except that `strvcat` performs the padding automatically.

```
t1 = 'first'; t2 = 'string'; t3 = 'matrix'; t4 = 'second';

S1 = strvcat(t1, t2, t3)        S2 = strvcat(t4, t2, t3)

S1 =                            S2 =

first                           second
string                          string
matrix                          matrix

S3 = strvcat(S1, S2)

S3 =
```

```
first
string
matrix
second
string
matrix
```

Purpose

Convert subscripts to linear indices

Syntax

```
linearInd = sub2ind(matrixSize, rowSub, colSub)
linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub,
   ...)
```

Description

linearInd = sub2ind(*matrixSize*, *rowSub*, *colSub*) returns the linear index equivalents to the row and column subscripts *rowSub* and *colSub* for a matrix of size *matrixSize*. The *matrixSize* input is a 2-element vector that specifies the number of rows and columns in the matrix as [nRows, nCols]. The *rowSub* and *colSub* inputs are positive, whole number scalars or vectors that specify one or more row-column subscript pairs for the matrix. Example 3 demonstrates the use of vectors for the rowSub and colSub inputs.

linearInd = sub2ind(*arraySize*, *dim1Sub*, *dim2Sub*, *dim3Sub*, ...) returns the linear index equivalents to the specified subscripts for each dimension of an N-dimensional array of size *arraySize*. The *arraySize* input is an n-element vector that specifies the number of dimensions in the array. The *dimNSub* inputs are positive, whole number scalars or vectors that specify one or more row-column subscripts for the matrix.

The *rowSub* and *colSub* inputs must belong to the same class. The *linearInd* output is the same class as the subscript inputs.

If needed, sub2ind assumes that unspecified trailing subscripts are 1. See Example 2, below.

Examples

Example 1

This example converts the subscripts (2, 1, 2) for three-dimensional array A to a single linear index. Start by creating a 3-by-4-by-2 array A:

```
rng(0,'twister');   % Initialize random number generator.
A = rand(3, 4, 2)

A(:,:,1) =
    0.8147    0.9134    0.2785    0.9649
```

```
    0.9058    0.6324    0.5469    0.1576
    0.1270    0.0975    0.9575    0.9706
A(:,:,2) =
    0.9572    0.1419    0.7922    0.0357
    0.4854    0.4218    0.9595    0.8491
    0.8003    0.9157    0.6557    0.9340
```

Find the linear index corresponding to (2, 1, 2):

```
linearInd = sub2ind(size(A), 2, 1, 2)
linearInd =
    14
```

Make sure that these agree:

```
A(2, 1, 2)            A(14)
ans =                 and =
     0.4854               0.4854
```

Example 2

Using the 3-dimensional array `A` defined in the previous example, specify only 2 of the 3 subscript arguments in the call to `sub2ind`. The third subscript argument defaults to 1.

The command

```
linearInd = sub2ind(size(A), 2, 4)
ans =
    11
```

is the same as

```
linearInd = sub2ind(size(A), 2, 4, 1)
ans =
    11
```

Example 3

Using the same 3-dimensional input array A as in Example 1, accomplish the work of five separate sub2ind commands with just one.

Replace the following commands:

```
sub2ind(size(A), 3, 3, 2);
sub2ind(size(A), 2, 4, 1);
sub2ind(size(A), 3, 1, 2);
sub2ind(size(A), 1, 3, 2);
sub2ind(size(A), 2, 4, 1);
```

with a single command:

```
sub2ind(size(A), [3 2 3 1 2], [3 4 1 3 4], [2 1 2 2 1])
ans =
    21    11    15    19    11
```

Verify that these linear indices access the same array elements as their subscripted counterparts:

```
[A(3,3,2),   A(2,4,1),   A(3,1,2),   A(1,3,2),   A(2,4,1)]
ans =
    0.6557    0.1576    0.8003    0.7922    0.1576

A([21, 11, 15, 19, 11])
ans =
    0.6557    0.1576    0.8003    0.7922    0.1576
```

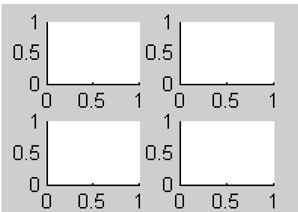
See Also

ind2sub | find | size

subplot

Purpose

Create axes in tiled positions



Syntax

```
subplot(m,n,p)
subplot(m,n,p,'replace')
subplot(m,n,p,'align')
subplot(m,n,P)
subplot(h)
subplot('Position',[left bottom width height])
subplot(...,prop1,value1,prop2,value2,...)
h = subplot(...)
```

Description

`subplot` divides the current figure into a grid that is numbered row-wise. Each block in the grid can contain an axes object which you can manipulate using `Axes Properties`. Subsequent plots are output to the current axes.

`subplot(m,n,p)` breaks the figure window into an `m`-by-`n` grid and creates an axes object in the `p`th location for the current plot, and returns the axes handle. MATLAB numbers the axes along the top row of the figure window, then the second row, etc. For example,

```
subplot(2,1,1), plot(x)
subplot(2,1,2), plot(y)
```

plots *x* on the top half of the window and *y* on the bottom half. The recently created axes becomes the current axes where plot command creates the graph.

`subplot(m,n,p,'replace')` deletes the specified axes object if it already exists and creates a new axes.

`subplot(m,n,p,'align')` places the axes so that the plot boxes are aligned, but does not prevent the labels and ticks from overlapping.

`subplot(m,n,P)`, where `P` is a vector, specifies an axes position that covers all the subplot positions listed in `P`, including those spanned by `P`. For example, `subplot(2,3,[2 5])` creates one axes spanning positions 2 and 5 only (because there are no intervening locations in the grid), while `subplot(2,3,[2 6])` creates one axes spanning positions 2, 3, 5, and 6.

`subplot(h)` makes the axes object with handle `h` the current axes for subsequent plotting commands.

`subplot('Position',[left bottom width height])` creates an axes at the position specified by a four-element vector. The `left`, `bottom`, `width`, and `height` values are normalized coordinates in the range from 0.0 to 1.0.

`subplot(...,prop1,value1,prop2,value2,...)` sets the specified property-value pairs on the subplot axes object. Available property/value pairs are described in `Axes Properties`. To add the subplot to a specific figure or uipanel, pass the handle as the value for the `jParent` property. You cannot specify both a `Parent` and a `Position`; that is, `subplot('Position',[left bottom width height], 'Parent',h)` is not a valid syntax.

`h = subplot(...)` returns the handle to the new `axes` object.

Tips

If a `subplot` specification causes a new axes object to overlap any existing axes, `subplot` deletes the existing axes object and uicontrol objects. However, if the `subplot` specification exactly matches the position of an existing axes object, the matching axes object is not deleted and it becomes the current axes.

`subplot(1,1,1)` or `clf` deletes all axes objects and returns to the default `subplot(1,1,1)` configuration.

You can omit the parentheses and specify `subplot` as

```
subplot mnp
```

where `m` refers to the row, `n` refers to the column, and `p` specifies the grid location.

Be aware when creating subplots from scripts that the `Position` property of subplots is not finalized until either

- A `drawnow` command is issued.
- MATLAB returns to await a user command.

That is, the value obtained for subplot `i` by the command

```
get(h(i),'position')
```

will not be correct until the script refreshes the plot or exits.

Special Case: subplot(111)

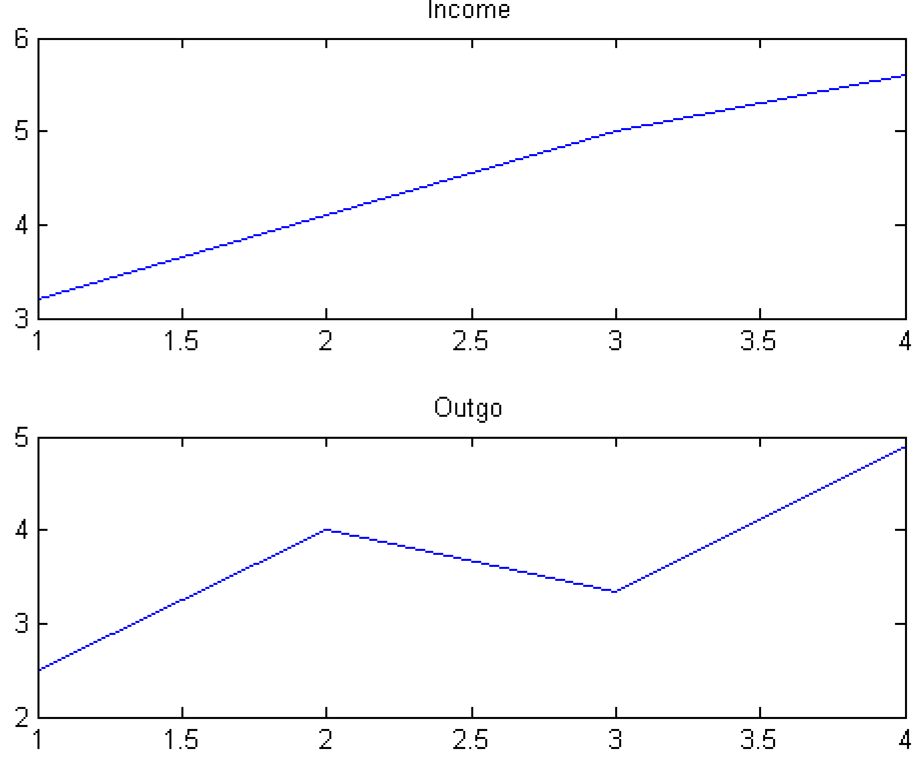
The command `subplot(111)` is not identical in behavior to `subplot(1,1,1)` and exists only for compatibility with previous releases. This syntax does not immediately create an axes object, but instead sets up the figure so that the next graphics command executes a `clf reset` (deleting all figure children) and creates a new axes object in the default position. This syntax does not return a handle, so it is an error to specify a return argument. (MATLAB implements this behavior by setting the figure's `NextPlot` property to `replace`.)

Examples

Upper and Lower Subplots with Titles

To plot `income` in the top half of a figure and `outgo` in the bottom half,

```
income = [3.2,4.1,5.0,5.6];
outgo = [2.5,4.0,3.35,4.9];
subplot(2,1,1); plot(income)
title('Income')
subplot(2,1,2); plot(outgo)
title('Outgo')
```



Subplots in Quadrants

The following illustration shows four subplot regions and indicates the command used to create each.

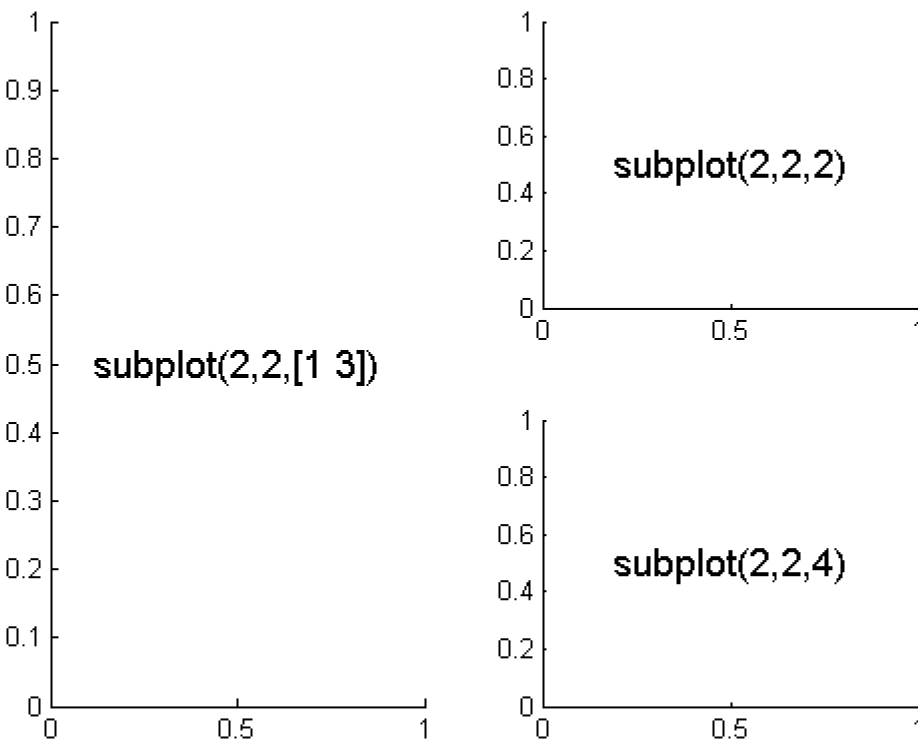
```
figure
subplot(2,2,1)
text(.5,.5,{'subplot(2,2,1)';'or subplot 221'},...
    'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,2)
text(.5,.5,{'subplot(2,2,2)';'or subplot 222'},...
```

```
    'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,3)
text(.5,.5,{'subplot(2,2,3)';'or subplot 223'},...
    'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,4)
text(.5,.5,{'subplot(2,2,4)';'or subplot 224'},...
    'FontSize',14,'HorizontalAlignment','center')
```

Asymmetrical Subplots

The following combinations produce asymmetrical arrangements of subplots.

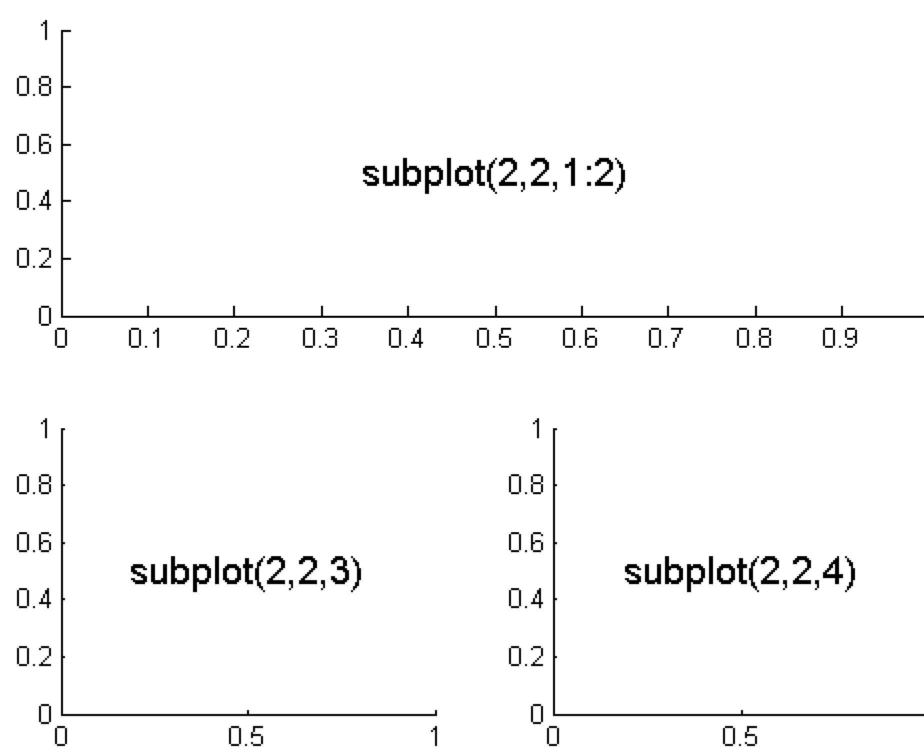
```
figure
subplot(2,2,[1 3])
text(.5,.5,'subplot(2,2,[1 3])',...
    'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,2)
text(.5,.5,'subplot(2,2,2)',...
    'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,4)
text(.5,.5,'subplot(2,2,4)',...
    'FontSize',14,'HorizontalAlignment','center')
```



You can also use the colon operator to specify multiple locations if they are in sequence.

```
figure
subplot(2,2,1:2)
text(.5,.5,'subplot(2,2,1:2)',...
    'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,3)
text(.5,.5,'subplot(2,2,3)',...
    'FontSize',14,'HorizontalAlignment','center')
```

```
subplot(2,2,4)
text(.5,.5,'subplot(2,2,4)',...
    'FontSize',14,'HorizontalAlignment','center')
```



Suppressing Axis Ticks

When you create many subplots in a figure, the axes tickmarks, which are shown by default, can either be obscured or can cause axes to collapse.

- One way to get around this issue is to enlarge the figure to create enough space to properly display the tick labels.
- Another approach is to eliminate the clutter by suppressing xticks and yticks for subplots as data are plotted into them as,

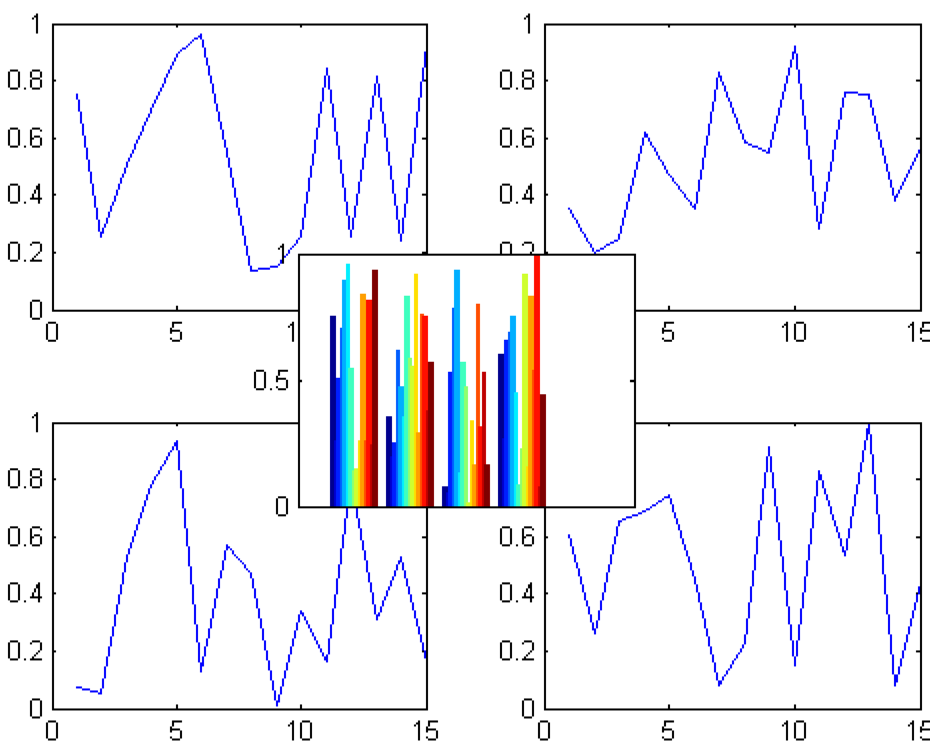
  ```
  h = subplot(10,1,1);
  set(h,'XTick',[],'YTick',[]);
  ```

  If the subplots are stacked, you can then display tick labels for the bottom axis.

Plotting Axes Over Subplots

Place a graph in the center, on top of four other graphs, using the `axes` and `subplot` functions. Data is random; your graphs can differ.

```
figure
y = zeros(4,15);
for k = 1:4
    y(k,:) = rand(1,15);
    subplot(2, 2, k)
    plot(y(k,:));
end
hax = axes('Position', [.35, .35, .3, .3]);
bar(hax,y,'EdgeColor','none')
set(hax,'XTick',[])
```



Alternatives

To add subplots to a figure, click one of the `New Subplot` icons in the Figure Palette, and slide right to select an arrangement of subplots. For details, see Plotting Tools — Interactive Plotting.

How To

- "Displaying Multiple Plots per Figure"

subsasgn

Purpose

Subscripted assignment

Syntax

```
A = subsasgn(A, S, B)
```

Description

`A = subsasgn(A, S, B)` is called by MATLAB for the syntax `A(i) = B`, `A{i} = B`, or `A.i = B` when `A` is an object.

MATLAB uses the built-in `subsasgn` function to interpret indexed assignment statements. Modify the indexed assignment behavior of classes by overloading `subsasgn` in the class.

If `A` is a fundamental class (see "Fundamental MATLAB Classes"), then an indexed reference to `A` calls the built-in `subsasgn` function. It does not call a `subsasgn` method that you have overloaded for that class. Therefore, if `A` is an array of class `double`, and there is an `@double/subsasgn` method on your MATLAB path, the statement `A(I) = B` calls the MATLAB built-in `subsasgn` function.

Tips

Within a class's own methods, MATLAB calls the built-in `subsasgn`, not the class defined `subsasgn`. This behavior enables to use the default `subsasgn` behavior when defining specialized indexing for your class. See "subsref and subsasgn Within Class Methods — Built-In Called" for more information.

Input Arguments

A

Object

S

`struct` array with two fields, `type` and `subs`.

- `type` is a string containing `'()'`, `'{}'`, or `'.'`, where `'()'` specifies integer subscripts, `'{}'` specifies cell array subscripts, and `'.'` specifies subscripted structure fields.
- `subs` is a cell array or string containing the actual subscripts.

B

Assignment value (right-hand side)

Output Arguments

A

Result of evaluating assignment.

Examples

See how MATLAB calls `subsasgn` for the expression:

```
A(1:2,:) = B;
```

The syntax `A(1:2,:)  = B` calls `A = subsasgn(A,S,B)` where `S` is a 1-by-1 structure with `S.type = '()'` and `S.subs = {1:2,':'}`. The string `':'` indicates a colon used as a subscript.

See how MATLAB calls `subsasgn` for the expression:

```
A{1:2} = B;
```

The syntax `A{1:2} = B` calls `A = subsasgn(A,S,B)` where `S.type = '{}'` and `S.subs = {[1 2]}`.

See how MATLAB calls `subsasgn` for the expression:

```
A.field = B;
```

The syntax `A.field = B` calls `A = subsasgn(A,S,B)` where `S.type = '.'` and `S.subs = 'field'`.

See how MATLAB calls `subsasgn` for the expression:

```
A(1,2).name(3:5)=B;
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscripting levels. For instance, `A(1,2).name(3:5)=B` calls `A=subsasgn(A,S,B)` where `S` is a 3-by-1 structure array with the following values:

`S(1).type = '()'`	`S(2).type = '.'`	`S(3).type = '()'`
`S(1).subs = {1,2}`	`S(2).subs = 'name'`	`S(3).subs = {[3 4 5]}`

Algorithms

In the assignment `A(J,K,...)  = B(M,N,...)`, subscripts `J`, `K`, `M`, `N`, and so on, can be scalar, vector, or arrays, when all the following are true:

- The number of subscripts specified for `B`, excluding trailing subscripts equal to 1, does not exceed the value returned by `ndims(B)`.
- The number of nonscalar subscripts specified for `A` equals the number of nonscalar subscripts specified for `B`. For example, `A(5,1:4,1,2) = B(5:8)` is valid because both sides of the equation use one nonscalar subscript.
- The order and length of all nonscalar subscripts specified for `A` matches the order and length of nonscalar subscripts specified for `B`. For example, `A(1:4, 3, 3:9) = B(5:8, 1:7)` is valid because both sides of the equation (ignoring the one scalar subscript `3`) use a 4-element subscript followed by a 7-element subscript.

  See `numel` for information concerning the use of `numel` with regards to the overloaded `subsasgn` function.

See Also

`subsref` | `substruct`

Tutorials

- “Indexed Reference and Assignment”

Purpose

Subscript indexing with object

Syntax

```
ind = subsindex(A)
```

Description

`ind = subsindex(A)` called by MATLAB for the expression `X(A)` when `A` is an object, unless such an expression results in a call to an overloaded `subsref` or `subsasgn` method for `X`. `subsindex` must return the value of the object as a zero-based integer index. (`ind` must contain integer values in the range `0` to `prod(size(X))-1`.) Call `subsindex` directly from an overloaded `subsref` or `subsasgn` method.

MATLAB invokes `subsindex` separately on all the subscripts in an expression, such as `X(A,B)`.

See Also

`subsasgn` | `subsasgn`

Tutorials

- "Using Objects as Indices"

subspace

Purpose

Angle between two subspaces

Syntax

```
theta = subspace(A,B)
```

Description

`theta = subspace(A,B)` finds the angle between two subspaces specified by the columns of `A` and `B`. If `A` and `B` are column vectors of unit length, this is the same as `acos(abs(A'*B))`.

Tips

If the angle between the two subspaces is small, the two spaces are nearly linearly dependent. In a physical experiment described by some observations `A`, and a second realization of the experiment described by `B`, `subspace(A,B)` gives a measure of the amount of new information afforded by the second experiment not associated with statistical errors of fluctuations.

Examples

Consider two subspaces of a Hadamard matrix, whose columns are orthogonal.

```
H = hadamard(8);
A = H(:,2:4);
B = H(:,5:8);
```

Note that matrices `A` and `B` are different sizes — `A` has three columns and `B` four. It is not necessary that two subspaces be the same size in order to find the angle between them. Geometrically, this is the angle between two hyperplanes embedded in a higher dimensional space.

```
theta = subspace(A,B)
theta =
    1.5708
```

That `A` and `B` are orthogonal is shown by the fact that `theta` is equal to $\pi/2$.

```
theta - pi/2
ans =
     0
```

Purpose

Redefine subscripted reference for objects

Syntax

```
B = subsref(A,S)
```

Description

`B = subsref(A,S)` is called by MATLAB for the syntax `A(i)`, `A{i}`, or `A.i` when `A` is an object. `S` is a `struct` array with two fields, `type` and `subs`.

The `type` field is string containing `'()'`, `'{}'`, or `'.'`, where `'()'` specifies integer subscripts, `'{}'` specifies cell array subscripts, and `'.'` specifies subscripted structure fields. The subs field is a cell array or a string containing the actual subscripts.

`B` is the result of the indexed expression.

MATLAB uses the built-in `subsref` function to interpret indexed references to objects. To modify the indexed reference behavior of objects, overload `subsref` in the class.

If `A` is a fundamental class (see "Fundamental MATLAB Classes"), then an indexed reference to `A` calls the built-in `subsref` function. It does not call a `subsref` method that you have overloaded for that class. Therefore, if `A` is an array of class `double`, and there is an `@double/subsref` method on your MATLAB path, the statement `A(I)` calls the MATLAB built-in `subsref` function.

Tips

Within a class's own methods, MATLAB calls the built-in `subsref`, not the class defined `subsref`. This behavior enables to use the default `subsref` behavior when defining specialized indexing for your class. See "subsref and subsasgn Within Class Methods — Built-In Called" for more information.

Examples

See how MATLAB calls `subsref` for the expression:

```
A(1:2,:)
```

The syntax `A(1:2,:)` calls `B = subsref(A,S)` where `S` is a 1-by-1 structure with `S.type='()'` and `S.subs={1:2,':'}`. The string `':'` indicates a colon used as a subscript.

See how MATLAB calls `subsref` for the expression:

```
A{1:2}
```

The syntax `A{1:2}` calls `B = subsref(A,S)` where `S.type='{}'` and `S.subs={[1 2]}`.

See how MATLAB calls `subsref` for the expression:

```
A.field
```

The syntax `A.field` calls `B = subsref(A,S)` where `S.type='.'` and `S.subs='field'`.

See how MATLAB calls `subsref` for the expression:

```
A(1,2).name(3:5)
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscript levels. For instance, `A(1,2).name(3:5)` calls `subsref(A,S)` where `S` is a 3-by-1 structure array with the following values:

`S(1).type='()'`	`S(2).type='.'`	`S(3).type='()'`
`S(1).subs={1,2}`	`S(2).subs='name'`	`S(3).subs={[3 4 5]}`

Tutorials

- “Indexed Reference and Assignment”

Purpose

Create structure argument for subsasgn or subsref

Syntax

```
S = substruct(type1, subs1, type2, subs2, ...)
```

Description

S = substruct(type1, subs1, type2, subs2, ...) creates a structure with the fields required by an overloaded subsref or subsasgn method. Each type string must be one of '.', '()', or '{}'. The corresponding subs argument must be either a field name (for the '.' type) or a cell array containing the index vectors (for the '()' or '{}' types).

Output Arguments

S

struct with these fields:

- type: one of '.', '()', or '{}'
- subs: subscript values (field name or cell array of index vectors)

Examples

Call subsref with arguments equivalent to the syntax:

```
B = A(3,5).field;
```

where A is an object of a class that implements a subsref method

Use substruct to form the input struct, S:

```
S = substruct('()',{3,5},'.','field');
```

Call the class method:

```
B = subsref(A,S);
```

The struct created by substruct in this example contains:

```
S(1)

ans =
```

```
    type: '()'
    subs: {[3]  [5]}

S(2)

ans =

    type: '.'
    subs: 'field'
```

Purpose

Extract subset of volume data set

Syntax

```
[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)
[Nx,Ny,Nz,Nv] = subvolume(V,limits)
Nv = subvolume(...)
```

Description

`[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)` extracts a subset of the volume data set `V` using the specified axis-aligned `limits`. `limits = [xmin,xmax,ymin, ymax,zmin,zmax]` (Any `NaN`s in the limits indicate that the volume should not be cropped along that axis.)

The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The subvolume is returned in `NV` and the coordinates of the subvolume are given in `NX`, `NY`, and `NZ`.

`[Nx,Ny,Nz,Nv] = subvolume(V,limits)` assumes the arrays `X`, `Y`, and `Z` are defined as

```
[X,Y,Z] = meshgrid(1:N,1:M,1:P)
```

where `[M,N,P] = size(V)`.

`Nv = subvolume(...)` returns only the subvolume.

Examples

This example uses a data set that is a collection of MRI slices of a human skull. The data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then a subset of the data is extracted (`subvolume`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with interpolated face color draws the end caps (`FaceColor`, `isocaps`).
- The view of the object is set (`view`, `axis`, `daspect`).
- A 100-element grayscale colormap provides coloring for the end caps (`colormap`).

- Adding lights to the right and left of the camera illuminates the object (`camlight`, `lighting`).

```
load mri
D = squeeze(D);
[x,y,z,D] = subvolume(D,[60,80,nan,80,nan,nan]);
p1 = patch(isosurface(x,y,z,D, 5),...
     'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
     'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight right; camlight left; lighting gouraud
```

Purpose

Sum of array elements

Syntax

```
B = sum(A)
B = sum(A,dim)
B = sum(..., 'double')
B = sum(..., dim,'double')
B = sum(..., 'native')
B = sum(..., dim,'native')
```

Description

`B = sum(A)` returns sums along different dimensions of an array. If `A` is floating point, that is double or single, `B` is accumulated natively, that is in the same class as `A`, and `B` has the same class as `A`. If `A` is not floating point, `B` is accumulated in double and `B` has class double.

If `A` is a vector, `sum(A)` returns the sum of the elements.

If `A` is a matrix, `sum(A)` treats the columns of `A` as vectors, returning a row vector of the sums of each column.

If `A` is a multidimensional array, `sum(A)` treats the values along the first non-singleton dimension as vectors, returning an array of row vectors.

`B = sum(A,dim)` sums along the dimension of `A` specified by scalar `dim`. The `dim` input is an integer value from 1 to `N`, where `N` is the number of dimensions in `A`. Set `dim` to 1 to compute the sum of each column, 2 to sum rows, etc.

`B = sum(..., 'double')` and `B = sum(..., dim,'double')` perform additions in double-precision and return an answer of type `double`, even if `A` has data type `single` or an integer data type. This is the default for integer data types.

`B = sum(..., 'native')` and `B = sum(..., dim,'native')` perform additions in the native data type of `A` and return an answer of the same data type. This is the default for `single` and `double`.

If `A = int8(1:20)` then `sum(A)` accumulates in double and the result is `double(210)` while `sum(A,'native')` accumulates in `int8`, but overflows and saturates to `int8(127)`.

Tips

`sum(diag(A))` is the `trace` of `A`.

Examples

The magic square of order 3 is:

```
M = magic(3)
M =
     8     1     6
     3     5     7
     4     9     2
```

This is called a magic square because the sums of the elements in each column are the same.

```
sum(M)

ans =

    15    15    15
```

The sums of the elements in each row are also the same. You can sum the elements in each row by transposing `M` or by using the `dim` argument.

- Transposing `M`:

  ```
  sum(M')

  ans =

      15    15    15
  ```

- Using the `dim` argument:

  ```
  sum(M,2)

  ans =

      15
      15
      15
  ```

Purpose

Superclass names

Syntax

```
superclasses('ClassName')
superclasses(obj)
s = superclasses(...)
```

Description

`superclasses('ClassName')` displays the names of all visible superclasses of the MATLAB class with the name *ClassName*. Visible classes have a `Hidden` attribute value of `false` (the default).

`superclasses(obj)` `obj` is an instance of a MATLAB class. `obj` can be either a scalar object or an array of objects.

`s = superclasses(...)` returns the superclass names in a cell array of strings.

Examples

Get the name of the `hgsetget` class superclass:

```
superclasses('hgsetget')

Superclasses for class hgsetget:

    handle
```

Tutorials

- "Hierarchies of Classes — Concepts"

superiorto

Purpose

Establish superior class relationship

Syntax

```
superiorto('class1', 'class2', ...)
```

Description

`superiorto('class1', 'class2', ...)` establishes that the class invoking this function in its constructor has higher precedence than the classes in the argument list.

The `superiorto` function establishes a precedence that determines which object method MATLAB calls. Use this function only from a constructor that calls the `class` function to create an object. For classes defined with `classdef` statements, see "Class Precedence".

Examples

Show function dispatching:

`a` is an object of class `class_a`, `b` is an object of class `class_b`, and `c` is an object of class `class_c`. The constructor method for `class_c` contains the statement `superiorto('class_a')`. Then, either of the following two statements:

```
e = fun(a,c);
e = fun(c,a);
```

invokes `class_c/fun`.

If you call a function with two objects having an unspecified relationship, MATLAB considers the two objects to have equal precedence. In this case, MATLAB calls the left-most object method. So `fun(b,c)` calls `class_b/fun`, while `fun(c,b)` calls `class_c/fun`.

Purpose

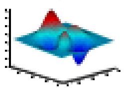
3-D shaded surface plot



Syntax

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(...,'PropertyName',PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

Description

`surf(Z)` creates a three-dimensional shaded surface from the *z* components in matrix `Z`, using `x = 1:n` and `y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a geometrically rectangular grid. `Z` specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of `Z`, a single-valued function defined over a geometrically rectangular grid, and uses matrix `C`, assumed to be the same size as `Z`, to color the surface.

`surf(X,Y,Z)` uses `Z` for the color data and surface height. `X` and `Y` are vectors or matrices defining the `x` and `y` components of a surface. If `X` and `Y` are vectors, `length(X)` = `n` and `length(Y)` = `m`, where `[m,n] = size(Z)`. In this case, the vertices of the surface faces are *(X(j), Y(i), Z(i,j))* triples. To create X and Y matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses `C` to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(...,'PropertyName',PropertyValue)` specifies surface Surfaceplot along with the data.

`surf(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns a handle to a Surfaceplot graphics object.

Tips

`surf` does not accept complex inputs.

Algorithms

Consider a parametric surface parameterized by two independent variables, `i` and `j`, which vary continuously over a rectangle; for example, `1` ≤ `i` ≤ `m` and `1` ≤ `j` ≤ `n`. The three functions `x(i,j)`, `y(i,j)`, and `z(i,j)` specify the surface. When `i` and `j` are integer values, they define a rectangular grid with integer grid points. The functions `x(i,j)`, `y(i,j)`, and `z(i,j)` become three `m`-by-`n` matrices, `X`, `Y`, and `Z`. Surface color is a fourth function, `c(i,j)`, denoted by matrix `C`.

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

```
       i-1,j
         |
i,j-1 - i,j - i,j+1
         |
       i+1,j
```

This underlying rectangular grid induces four-sided patches on the surface. To express this another way, `[X(:) Y(:) Z(:)]` returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of `x` and `y`. Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The `shading` function sets the shading. If the shading is `interp`, `C` must be the same size as `X`, `Y`, and `Z`; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local

coordinates. If the shading is `faceted` (the default) or `flat`, `C(i,j)` specifies the constant color in the surface patch:

```
 (i,j)   -   (i,j+1)
   |   C(i,j)  |
(i+1,j)  -  (i+1,j+1)
```

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surf` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of `XLimMode`, `YLimMode`, and `ZLimMode` axes properties determines the axis labels. You can also set these properties using `axis` function.

The range of `C` or the current setting of the `CLim` and `CLimMode` axes properties determines the color scaling. You can also set the properties using `caxis` function. The scaled color values are indices into the current colormap.

Examples

Color a sphere with the pattern of +1s and -1s in a Hadamard matrix.

```
k = 5;
n = 2^k-1;
[x,y,z] = sphere(n);
c = hadamard(2^k);
surf(x,y,z,c);
colormap([1  1  0; 0  1  1])
axis equal
```

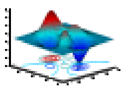
surfc

Purpose

Contour plot under a 3-D shaded surface plot



Syntax

```
surfc(Z)
surfc(Z,C)
surfc(X,Y,Z)
surfc(X,Y,Z,C)
surfc(...,'PropertyName',PropertyValue)
surfc(axes_handles,...)
h = surfc(...)
```

Description

`surfc(Z)` creates a contour plot under the three-dimensional shaded surface from the *z* components in matrix `Z`, using `x = 1:n` and `y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a geometrically rectangular grid. `Z` specifies the color data, as well as surface height, so color is proportional to surface height.

`surfc(Z,C)` plots the height of `Z`, a single-valued function defined over a geometrically rectangular grid, and uses matrix `C`, assumed to be the same size as `Z`, to color the surface.

`surfc(X,Y,Z)` uses `Z` for the color data and surface height. `X` and `Y` are vectors or matrices defining the `x` and `y` components of a surface. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, the vertices of the surface faces are *(X(j), Y(i), Z(i,j))* triples. To create X and Y matrices for arbitrary domains, use the `meshgrid` function.

`surfc(X,Y,Z,C)` uses `C` to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surfc(...,'PropertyName',PropertyValue)` specifies surface Surfaceplot along with the data.

`surfc(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surfc(...)` returns a handle to a Surfaceplot graphics object.

Tips

`surfc` does not accept complex inputs.

Algorithms

Consider a parametric surface parameterized by two independent variables, `i` and `j`, which vary continuously over a rectangle; for example, `1` ≤ `i` ≤ `m` and `1` ≤ `j` ≤ `n`. The three functions `x(i,j)`, `y(i,j)`, and `z(i,j)` specify the surface. When `i` and `j` are integer values, they define a rectangular grid with integer grid points. The functions `x(i,j)`, `y(i,j)`, and `z(i,j)` become three `m`-by-`n` matrices, `X`, `Y`, and `Z`. Surface color is a fourth function, `c(i,j)`, denoted by matrix `C`.

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

```
       i-1,j
         |
i,j-1 - i,j - i,j+1
         |
       i+1,j
```

This underlying rectangular grid induces four-sided patches on the surface. To express this another way, `[X(:) Y(:) Z(:)]` returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of `x` and `y`. Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The `shading` function sets the shading. If the shading is `interp`, `C` must be the same size as `X`, `Y`, and `Z`; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local

coordinates. If the shading is `faceted` (the default) or `flat`, `C(i,j)` specifies the constant color in the surface patch:

```
 (i,j)   -   (i,j+1)
   |   C(i,j)  |
(i+1,j)  -  (i+1,j+1)
```

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surfc` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties (also set by the `axis` function) determines the axis labels.

The range of `C` or the current setting of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function) determines the color scaling. The scaled color values are used as indices into the current colormap.

Examples

Display a surface plot and a contour plot of the `peaks` surface.

```
[X,Y,Z] = peaks(30);
surfc(X,Y,Z)
colormap hsv
```

How To

- Representing a Matrix as a Surface
- Coloring Mesh and Surface Plots

surf2patch

Purpose

Convert surface data to patch data

Syntax

```
fvc = surf2patch(Z)
fvc = surf2patch(Z,C)
fvc = surf2patch(X,Y,Z)
fvc = surf2patch(X,Y,Z,C)
fvc = surf2patch(...,'triangles')
[f,v,c] = surf2patch(...)
```

Description

`fvc = surf2patch(h)`

converts the geometry and color data from the `surface` object identified by the handle `h` into patch format and returns the face, vertex, and color data in the struct `fvc`. You can pass this struct directly to the `patch` command.

`fvc = surf2patch(Z)` calculates the patch data from the surface's `ZData` matrix `Z`.

`fvc = surf2patch(Z,C)` calculates the patch data from the surface's `ZData` and `CData` matrices `Z` and `C`.

`fvc = surf2patch(X,Y,Z)` calculates the patch data from the surface's `XData`, `YData`, and `ZData` matrices `X`, `Y`, and `Z`.

`fvc = surf2patch(X,Y,Z,C)` calculates the patch data from the surface's `XData`, `YData`, `ZData`, and `CData` matrices `X`, `Y`, `Z`, and `C`.

`fvc = surf2patch(...,'triangles')` creates triangular faces instead of the quadrilaterals that compose surfaces.

`[f,v,c] = surf2patch(...)` returns the face, vertex, and color data in the three arrays `f`, `v`, and `c` instead of a struct.

Examples

The first example uses the `sphere` command to generate the `XData`, `YData`, and `ZData` of a surface, which is then converted to a patch. Note that the `ZData` (`z`) is passed to `surf2patch` as both the third and fourth arguments — the third argument is the `ZData` and the fourth argument is taken as the `CData`. This is because the `patch` command does not

automatically use the *z*-coordinate data for the color data, as does the `surface` command.

Also, because `patch` is a low-level command, you must set the `view` to 3-D and `shading` to `faceted` to produce the same results produced by the `surf` command.

```
[x y z] = sphere;
patch(surf2patch(x,y,z,z));
shading faceted; view(3)
```

In the second example `surf2patch` calculates face, vertex, and color data from a surface whose handle has been passed as an argument.

```
s = surf(peaks);
pause
patch(surf2patch(s));
delete(s)
shading faceted; view(3)
```

See Also

`patch` | `reducepatch` | `shrinkfaces` | `surface` | `surf`

surface

Purpose

Create surface object

Syntax

```
surface(Z)
surface(Z,C)
surface(X,Y,Z)
surface(X,Y,Z,C)
surface(x,y,Z)
surface(...'PropertyName',PropertyValue,...)
h = surface(...)
```

Properties

For a list of properties, see `Surface Properties`.

Description

`surface` is the low-level function for creating surface graphics objects. Surfaces are plots of matrix data created using the row and column indices of each element as the *x*- and *y*-coordinates and the value of each element as the *z*-coordinate.

`surface(Z)` plots the surface specified by the matrix `Z`. Here, `Z` is a single-valued function, defined over a geometrically rectangular grid.

`surface(Z,C)` plots the surface specified by `Z` and colors it according to the data in `C` (see "Examples").

`surface(X,Y,Z)` uses `C = Z`, so color is proportional to surface height above the *x*-*y* plane.

`surface(X,Y,Z,C)` plots the parametric surface specified by `X`, `Y`, and `Z`, with color specified by `C`.

`surface(x,y,Z)`, surface(x,y,Z,C) replaces the first two matrix arguments with vectors and must have `length(x) = n` and `length(y) = m` where `[m,n] = size(Z)`. In this case, the vertices of the surface facets are the triples `(x(j),y(i),Z(i,j))`. Note that `x` corresponds to the columns of `Z` and `y` corresponds to the rows of `Z`. For a complete discussion of parametric surfaces, see the `surf` function.

`surface(...'PropertyName',PropertyValue,...)` follows the `X`, `Y`, `Z`, and `C` arguments with property name/property value pairs to specify

additional surface properties. For a description of the properties, see `Surface Properties`.

`h = surface(...)` returns a handle to the created surface object.

Tips

`surface` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds the surface object to the current axes.

If you do not specify separate color data (`C`), MATLAB uses the matrix (`Z`) to determine the coloring of the surface. In this case, color is proportional to values of `Z`. You can specify a separate matrix to color the surface independently of the data defining the area of the surface.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see `set` and `get` for examples of how to specify these data types).

`surface` provides convenience forms that allow you to omit the property name for the `XData`, `YData`, `ZData`, and `CData` properties. For example,

```
surface('XData',X,'YData',Y,'ZData',Z,'CData',C)
```

is equivalent to

```
surface(X,Y,Z,C)
```

When you specify only a single matrix input argument,

```
surface(Z)
```

MATLAB assigns the data properties as if you specified

```
surface('XData',[1:size(Z,2)],...
   'YData',[1:size(Z,1)],...
   'ZData',Z,...
   'CData',Z)
```

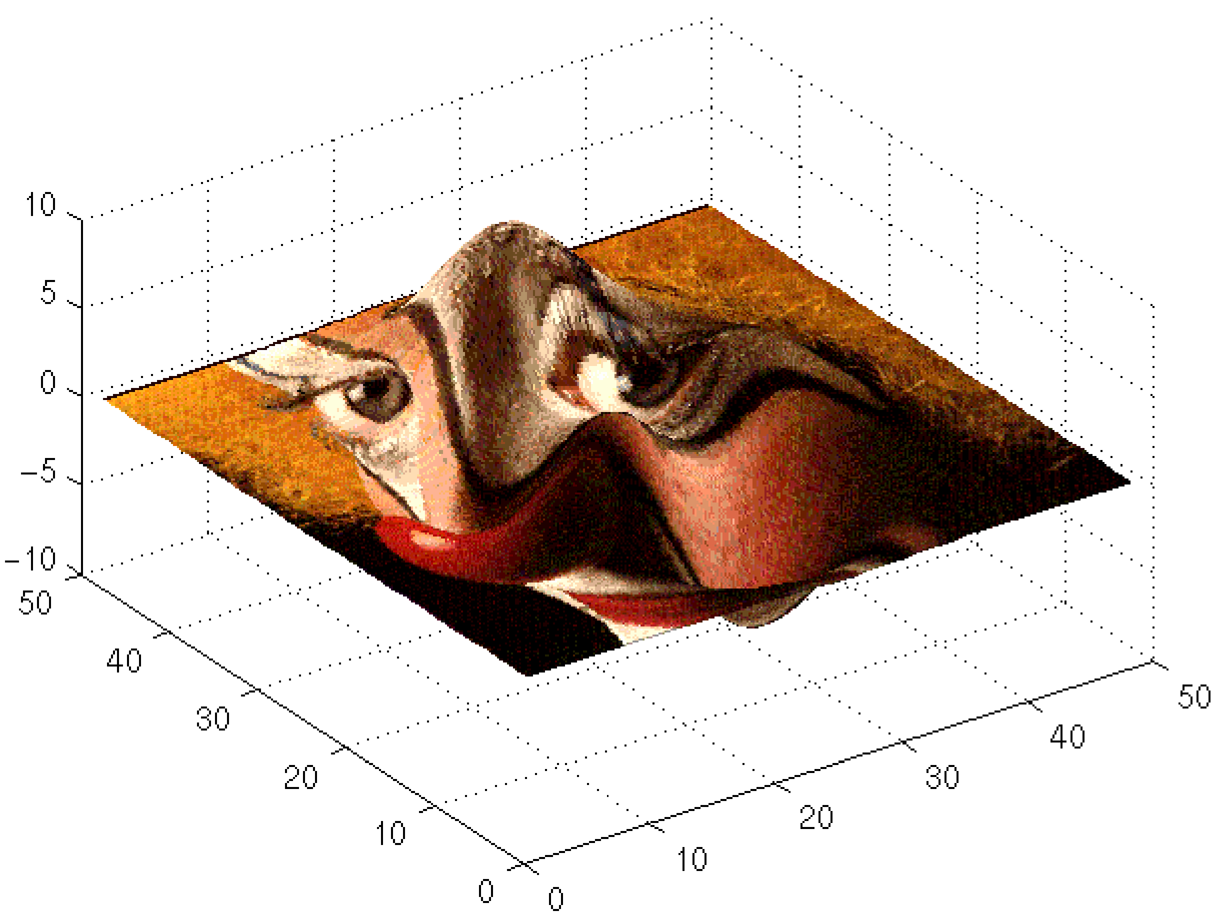
The `axis`, `caxis`, `colormap`, `hold`, `shading`, and `view` commands set graphics properties that affect surfaces. You can also set and query

surface property values after creating them using the `set` and `get` commands.

Examples

This example creates a surface using `peaks` to generate the data, and colors it using the clown image. The `ZData` is a 49-by-49 element matrix, while the `CData` is a 200-by-320 matrix. You must set the surface's `FaceColor` to `texturemap` to use `ZData` and `CData` of different dimensions.

```
load clown
surface(peaks,flipud(X),...
   'FaceColor','texturemap',...
   'EdgeColor','none',...
   'CDataMapping','direct')
colormap(map)
view(-35,45)
```



Note the use of the `surface(Z,C)` convenience form combined with property name/property value pairs.

Since the clown data (`X`) is typically viewed with the `image` command, which MATLAB normally displays with `'ij'` axis numbering and `direct CDataMapping`, this example reverses the data in the vertical direction using `flipud` and sets the `CDataMapping` property to `direct`.

Setting Default Properties

You can set default surface properties on the axes, figure, and `root object` levels:

```
set(0,'DefaultSurfaceProperty',PropertyValue...)
set(gcf,'DefaultSurfaceProperty',PropertyValue...)
set(gca,'DefaultSurfaceProperty',PropertyValue...)
```

where *`Property`* is the name of the surface property whose default value you want to set and `PropertyValue` is the value you are specifying. Use `set` and `get` to access the surface properties.

Tutorials

For examples, see Representing a Matrix as a Surface.

See Also

`ColorSpec` | `patch` | `pcolor` | `surf` | `Surface Properties`

Purpose

Surface properties

Creating Surface Objects

Use `surface` to create surface objects.

Modifying Properties

You can set and query graphics object properties in two ways:

- Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see Setting Default Property Values.

See "Core Graphics Objects" for general information about this type of object.

Surface Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`AlphaData`

`m`-by-`n` matrix of `double` or `uint8`

Transparency data. A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class `double` or `uint8`.

MATLAB software determines the transparency in one of the following ways:

- Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
- Using the elements of `AlphaData` as indices into the current alphamap (`AlphaDataMapping` set to `direct`)

- Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

`AlphaDataMapping`
`none | direct | {scaled}`

Transparency mapping method. Determines how MATLAB interprets indexed alpha data.

- `none` — The transparency values of `AlphaData` are between `0` and `1` or are clamped to this range (the default).
- `scaled` — Transform the `AlphaData` to span the portion of the alphamap indicated by the axes `ALim` property, linearly mapping data values to alpha values.
- `direct` — Use the `AlphaData` as indices directly into the alphamap. When not scaled, the data are usually integer values ranging from `1` to `length(alphamap)`. MATLAB maps values less than `1` to the first alpha value in the alphamap, and values greater than `length(alphamap)` to the last alpha value in the alphamap. Values with a decimal portion are fixed to the nearest lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at `0` (that is, MATLAB maps a value of `0` to the first alpha value in the alphamap).

`AmbientStrength`
scalar >= 0 and <= 1

Strength of ambient light. Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of `light` objects. See the surface `DiffuseStrength` and `SpecularStrength` properties.

`Annotation`

`hg.Annotation` object (read-only)

Handle of `Annotation` object. The `Annotation` property enables you to specify whether this surface object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the surface object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Represent this surface object in a legend (default)
`off`	Do not include this surface object in a legend
`children`	Same as `on` because surface objects do not have children

Setting the IconDisplayStyle property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','off')
```

Using the IconDisplayStyle property

See "Controlling Legends" for more information and examples.

`BackFaceLighting`
`unlit | lit | {reverselit}`

Face lighting control. Determines how faces are lit when their vertex normals point away from the camera.

- `unlit` — Face not lit.
- `lit` — Face lit in normal way.
- `reverselit` — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See "Back Face Lighting" for an example.

`BeingDeleted`
`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`
`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Button press callback function. Executes whenever you press a mouse button while the pointer is over the surface object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).
The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src,evnt)
% src - the object that is the source of the event
```

```
% evnt - empty for this property
   sel_typ = get(gcbf,'SelectionType')
   switch sel_typ
      case 'normal'
         disp('User clicked left-mouse button')
         set(src,'Selected','on')
      case 'extend'
         disp('User did a shift-click')
         set(src,'Selected','on')
      case 'alt'
         disp('User did a control-click')
         set(src,'Selected','on')
         set(src,'SelectionHighlight','off')
   end
end
```

Suppose `h` is the handle of a surface object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h,'ButtonDownFcn',@button_down)
```

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`CData`

matrix (of type `double`)

Vertex colors. Values that specify the color at every point in `ZData`.

Mapping CData to a Colormap

You can specify color as indexed values or true color. Indexed color data specifies a single value for each vertex. These values are either scaled to map linearly into the current colormap (see `caxis`) or interpreted directly as indices into the colormap, depending on the setting of the `CDataMapping` property.

CData as True Color

True color defines an RGB value for each vertex. If the coordinate data (`XData`, for example) are contained in `m`-by-`n` matrices, then `CData` must be an `m`-by-`n`-by-`3` array. The first page contains the red components, the second the green components, and the third the blue components of the colors.

Texturemapping the Surface FaceColor

If you set the `FaceColor` property to `texturemap`, `CData` does not need to be the same size as `ZData`, but must be of type `double` or `uint8`. In this case, MATLAB maps `CData` to conform to the surface defined by `ZData`.

`CDataMapping`
`{scaled} | direct`

Direct or scaled color mapping. Determines how MATLAB interprets indexed color data used to color the surface. (If you use true color specification for `CData`, this property has no effect.)

- `scaled` — Transform the color data to span the portion of the colormap indicated by the axes `CLim` property, linearly mapping data values to colors. See the `caxis` reference page for more information on this mapping.
- `direct` — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to `length(colormap)`. MATLAB maps values less than 1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

`Children`
matrix of handles

Always the empty matrix; surface objects have no children.

Surface Properties

`Clipping`
{on} | off

Clipping to axes rectangle. When `Clipping` is `on`, MATLAB does not display any portion of the surface that is outside the axes rectangle.

`CreateFcn`
function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Executes when MATLAB creates a surface object. You must define this property as a default value for surfaces or set the `CreateFcn` property during object creation.

For example, the following statement creates a surface (assuming `x`, `y`, `z`, and `c` are defined), and executes the function referenced by the function handle `@myCreateFcn`.

```
surface(x,y,z,c,'CreateFcn',@myCreateFcn)
```

MATLAB executes this routine after setting all surface properties. Setting this property on an existing surface object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`
function handle | cell array containing function handle and additional arguments | string (not recommended)

Delete surface callback function. Executes when you delete the surface object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
   obj_tp = get(src,'Type');
   disp([obj_tp, ' object deleted'])
   disp('Its user data is:')
   disp(get(src,'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DiffuseStrength`

scalar >= 0 and <= 1

Intensity of diffuse light. Sets the intensity of the diffuse component of the light falling on the surface. Diffuse light comes from light objects in the axes. Default value is `0.6`.

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

`DisplayName`
string

String used by legend. The `legend` function uses the `DisplayName` property to label the surface object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EdgeAlpha`
{scalar = `1`} | `flat` | `interp`

Transparency of the surface edges.

- scalar — A single non-NaN scalar value between `0` and `1` that controls the transparency of all the edges of the object. `1` (the default) means fully opaque and `0` means completely transparent.

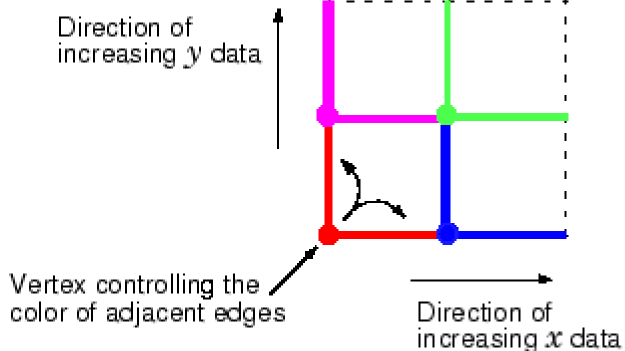
- `flat` — The alpha data (`AlphaData`) value for the first vertex of the face determines the transparency of the edges.
- `interp` — Linear interpolation of the alpha data (`AlphaData`) values at each vertex determines the transparency of the edge.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

`EdgeColor`
`{ColorSpec} | none | flat | interp`

Color of the surface edge. Determines how MATLAB colors the edges of the individual faces that make up the surface.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is `[0 0 0]` (`black`). See `ColorSpec` for more information on specifying color.
- `none` — Edges not drawn.
- `flat` — The `CData` value of the first vertex for a face determines the color of each edge.



- `interp` — Linear interpolation of the `CData` values at the face vertices determines the edge color.

`EdgeLighting`
`{none} | flat | gouraud | phong`

Algorithm used for lighting calculations. Selects the algorithm used to calculate the effect of light objects on surface edges.

- `none` — Lights do not affect the edges of this object.
- `flat` — The effect of light objects is uniform across each edge of the surface.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

`EraseMode`
`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase surface objects. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the surface when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the surface by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the surface does not damage the color of the objects behind it. However, surface color depends on the color of the screen behind it and is correctly colored only when over the axes background `Color`, or the figure background `Color` if the axes `Color` is `none`.
- `background` — Erase the surface by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is set to `none`. This damages objects that are behind the erased object, but surface objects are always properly colored.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceAlpha`
{scalar = `1`} | `flat` | `interp` | `texturemap`

Transparency of the surface faces.

- scalar — A single non-NaN scalar value between `0` and `1` that controls the transparency of all the faces of the object. `1` (the default) means fully opaque and `0` means completely transparent (invisible).

- `flat` — The values of the alpha data (`AlphaData`) determine the transparency for each face. The alpha data at the first vertex determine the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`AlphaData`) at each vertex determines the transparency of each face.
- `texturemap` — Use transparency for the texture map.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `FaceAlpha`.

`FaceColor`
`ColorSpec | none | {flat} | interp | texturemap`

Color of the surface face.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See the `ColorSpec` reference page for more information on specifying color.
- `none` — Do not draw faces. Note that edges are drawn independently of faces.
- `flat` — The values of `CData` determine the color for each face of the surface. The color data at the first vertex determine the color of the entire face.
- `interp` — Bilinear interpolation of the values at each vertex (the `CData`) determines the coloring of each face.
- `texturemap` — Texture map the `CData` to the surface. MATLAB transforms the color data so that it conforms to the surface. (See the texture mapping example.)

`FaceLighting`
`{none} | flat | gouraud | phong`

Algorithm used for lighting calculations. Selects the algorithm used to calculate the effect of `light` objects on the surface.

- `none` — Lights do not affect the faces of this object.
- `flat` — The effect of light objects is uniform across the faces of the surface. Select this choice to view faceted objects.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. This property is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching

the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

`HitTest`
`{on} | off`

Selectable by mouse click. Determines if the surface can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the surface. If `HitTest` is `off`, clicking on the surface selects the object below it (which might be the axes containing it).

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is

the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see "Control Callback Execution and Interruption".

`LineStyle`

`{-} | -- | : | -. | none`

Line style of surface edges.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

`LineWidth`

size in points

Edge line width. The width of the lines in points used to draw surface edges. The default width is `0.5` points. `1` point = $^1/_{72}$ inch.

`Marker`

character (see table)

Marker symbol. Specifies symbols that are displayed at vertices. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

Marker Specifiers Table

Specifier	Marker Type
’+’	Plus sign
’o’	Circle
’*’	Asterisk
’.’	Point
’x’	Cross
’square’ or ’s’	Square
’diamond’ or ’d’	Diamond
’^’	Upward-pointing triangle
’v’	Downward-pointing triangle
’>’	Right-pointing triangle
’<’	Left-pointing triangle
’pentagram’ or ’p’	Five-pointed star (pentagram)
’hexagram’ or ’h''’	Six-pointed star (hexagram)
’none’	No marker (default)

`MarkerEdgeColor`

`none | {auto} | flat | ColorSpec`

Marker edge color. The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `EdgeColor` property.
- `flat` — Uses the `CData` value of the vertex to determine the color of the marker edge.

- `ColorSpec` — Defines color to use.

`MarkerFaceColor`
`{none} | auto | flat | ColorSpec`

Marker face color. The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Uses the axes `Color` for the marker face color.
- `flat` — Uses the `CData` value of the vertex to determine the color of the face.
- `ColorSpec` — Defines a single color to use for all markers on the surface.

`MarkerSize`
scalar

Marker size. Size of the marker in points. The default value is `6`.

Note MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

`MeshStyle`
`{both} | row | column`

Row and column lines. Specifies whether to draw all edge lines or just row or column edge lines.

- `both` — Draws edges for both rows and columns.
- `row` — Draws row edges only.
- `column` — Draws column edges only.

`NormalMode`
`{auto} | manual`

MATLAB generated or user-specified normal vectors.

- `auto` — MATLAB calculates vertex normals based on the coordinate data
- `manual` — If you specify your own vertex normals, MATLAB sets this property to `manual` and does not generate its own data.

See also the `VertexNormals` property.

`Parent`
handle of axes, hggroup, or hgtransform

Parent of surface object. Contains the handle of the surface object's parent. The parent of a surface object is the axes, hggroup, or hgtransform object that contains it.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Is object selected? When this property is `on`, MATLAB displays a dashed bounding box around the surface if the `SelectionHighlight` property is also `on`. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing a dashed bounding box around the surface. When `SelectionHighlight` is `off`, MATLAB does not draw the box.

`SpecularColorReflectance`
scalar in the range `0` to `1`

Color of specularly-reflected light. When this property is `0`, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to `1`, the color of the specularly-reflected light depends only on the color or the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

`SpecularExponent`
scalar >= 1

Harshness of specular reflection. Controls the size of the specular spot. Most materials have exponents in the range of `5` to `20`.

`SpecularStrength`
scalar >= 0 and <= 1

Intensity of specular light. Sets the intensity of the specular component of the light falling on the surface. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the surface object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

`Tag`
string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

`Type`
string (read-only)

Class of the graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For surface objects, `Type` is always '`surface`'.

`UIContextMenu`
handle of uicontextmenu object

Associate a context menu with the surface. Assign this property the handle of a uicontextmenu object created in the same figure as the surface. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the surface.

`UserData`
matrix

User-specified data. Data you want to associate with the surface object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`VertexNormals`
vector | matrix

Surface normal vectors. The vertex normals for the surface. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even if it does not match the coordinate data. This can be useful to produce interesting lighting effects.

`Visible`
`{on} | off`

Surface object visibility. By default, all surfaces are visible. When set to `off`, the surface is not visible, but still exists, and you can query and set its properties.

`XData`
vector | matrix

X-coordinates. The *x*-position of the surface points. If you specify a row vector, `surface` replicates the row internally until it has the same number of columns as `ZData`.

`YData`
vector | matrix

Y-coordinates. The *y*-position of the surface points. If you specify a row vector, `surface` replicates the row internally until it has the same number of rows as `ZData`.

`ZData`
matrix

Z-coordinates. The *z*-position of the surface data points. See the Description section for more information.

See Also

`surface`

Purpose

Define surfaceplot properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

Note that you cannot define default properties for surfaceplot objects.

See Plot Objects for information on surfaceplot objects.

Surfaceplot Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`AlphaData`
: `m-by-n` matrix of `double` or `uint8`

  Transparency data. A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class `double` or `uint8`.

  MATLAB software determines the transparency in one of the following ways:

  - Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
  - Using the elements of `AlphaData` as indices into the current alphamap (`AlphaDataMapping` set to `direct`)
  - Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

`AlphaDataMapping`
: `none | direct | {scaled}`

Transparency mapping method. Determines how MATLAB interprets indexed alpha data. Values for this property are:

- `none` — The transparency values of `AlphaData` are between `0` and `1` or are clamped to this range.
- `scaled` — Transform the `AlphaData` to span the portion of the alphamap indicated by the axes `ALim` property, linearly mapping data values to alpha values (the default).
- `direct` — Use the `AlphaData` as indices directly into the alphamap. When not scaled, the data are usually integer values ranging from `1` to `length(alphamap)`. MATLAB maps values less than `1` to the first alpha value in the alphamap, and values greater than `length(alphamap)` to the last alpha value in the alphamap. Values with a decimal portion are fixed to the nearest, lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at `0` (that is, MATLAB maps a value of `0` to the first alpha value in the alphamap).

`AmbientStrength`

scalar >= 0 and <= 1

Strength of ambient light. Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of `light` objects. See the surfaceplot `DiffuseStrength` and `SpecularStrength` properties.

`Annotation`

`hg.Annotation` object (read-only)

Handle of `Annotation` object. The `Annotation` property enables you to specify whether this surfaceplot object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the surfaceplot object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Represent this surfaceplot object in a legend (default)
`off`	Do not include this surfaceplot object in a legend
`children`	Same as `on` because surfaceplot objects do not have children

Setting the IconDisplayStyle property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','off')
```

Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

`BackFaceLighting`

`unlit | lit | {reverselit}`

Face lighting control. Determines how faces are lit when their vertex normals point away from the camera.

- `unlit` — Face not lit.
- `lit` — Face lit in normal way.
- `reverselit` — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See "Back Face Lighting" for an example.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`
string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`CData`

matrix

Vertex colors. A matrix containing values that specify the color at every point in `ZData`. If you set the `FaceColor` property to `texturemap`, `CData` does not need to be the same size as `ZData`. In this case, MATLAB maps `CData` to conform to the surfaceplot defined by `ZData`.

You can specify color as indexed values or true color. Indexed color data specifies a single value for each vertex. These values are either scaled to map linearly into the current colormap (see `caxis`) or interpreted directly as indices into the colormap, depending on the setting of the `CDataMapping` property. Note that any non-texture data passed as an input argument must be of type `double`.

True color defines an RGB value for each vertex. If the coordinate data (`XData`, for example) are contained in `m`-by-`n` matrices, then `CData` must be an `m`-by-`n`-by-`3` array. The first page contains the red components, the second the green components, and the third the blue components of the colors.

`CDataMapping`

`{scaled} | direct`

Direct or scaled color mapping. Determines how MATLAB interprets indexed color data used to color the surfaceplot. (If you use true color specification for `CData`, this property has no effect.)

- `scaled` — Transform the color data to span the portion of the colormap indicated by the axes `CLim` property, linearly mapping data values to colors. See the `caxis` reference page for more information on this mapping.
- `direct` — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to `length(colormap)`. MATLAB maps values less than

1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

`CDataMode`
`{auto} | manual`

Use automatic or user-specified color data values. If you specify `CData`, MATLAB sets this property to `manual` and uses the `CData` values to color the surfaceplot.

If you set `CDataMode` to `auto` after having specified `CData`, MATLAB resets the color data of the surfaceplot to that defined by `ZData`, overwriting any previous values for `CData`.

`CDataSource`
string (MATLAB variable)

Link CData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `CData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `CData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`Children`
: matrix of handles

  Always the empty matrix; surfaceplot objects have no children.

`Clipping`
: `{on} | off`

  Clipping to axes rectangle. When `Clipping` is `on`, MATLAB does not display any portion of the surfaceplot that is outside the axes rectangle.

`CreateFcn`
: function handle | cell array containing function handle and additional arguments | string (not recommended)

  Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

  You must specify the callback during the creation of the object. For example:

  ```
  graphicfcn(y,'CreateFcn',@CallbackFcn)
  ```

  where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DiffuseStrength`

scalar >= 0 and <= 1

Intensity of diffuse light. Sets the intensity of the diffuse component of the light falling on the surface. Diffuse light comes from light objects in the axes. Default value is `0.6`.

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

`DisplayName`
string

String used by legend. The `legend` function uses the `DisplayName` property to label the surfaceplot object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EdgeAlpha`
{scalar = `1`} | `flat` | `interp`

Transparency of the patch and surface edges.

- scalar — A single non-NaN scalar value between `0` and `1` that controls the transparency of all the edges of the object. `1` (the default) means fully opaque and `0` means completely transparent.

- `flat` — The alpha data (`AlphaData`) value for the first vertex of the face determines the transparency of the edges.
- `interp` — Linear interpolation of the alpha data (`AlphaData`) values at each vertex determines the transparency of the edge.

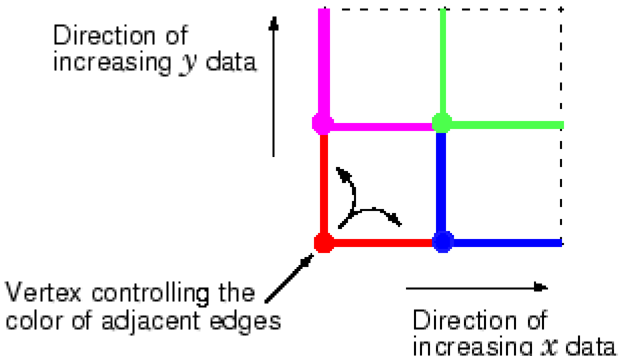
Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

`EdgeColor`
`{ColorSpec} | none | flat | interp`

Color of the surfaceplot edge. This property determines how MATLAB colors the edges of the individual faces that make up the surface:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default `EdgeColor` is black. See `ColorSpec` for more information on specifying color.
- `none` — Edges are not drawn.
- `flat` — The `CData` value of the first vertex for a face determines the color of each edge.



- `interp` — Linear interpolation of the `CData` values at the face vertices determines the edge color.

`EdgeLighting`
`{none} | flat | gouraud | phong`

Algorithm used for lighting calculations. Selects the algorithm used to calculate the effect of light objects on surfaceplot edges.

- `none` — Lights do not affect the edges of this object.
- `flat` — The effect of light objects is uniform across each edge of the surfaceplot.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

`EraseMode`
`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceAlpha`

{scalar = `1`} | `flat` | `interp` | `texturemap`

Transparency of the surfaceplot faces. This property can be any of the following:

- scalar — A single non-NaN scalar value between `0` and `1` that controls the transparency of all the faces of the object. `1` (the default) means fully opaque and `0` means completely transparent (invisible).
- `flat` — The values of the alpha data (`AlphaData`) determine the transparency for each face. The alpha data at the first vertex determine the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`AlphaData`) at each vertex determines the transparency of each face.
- `texturemap` — Use transparency for the texture map.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `FaceAlpha`.

`FaceColor`

`ColorSpec` | `none` | `{flat}` | `interp`

Color of the surfaceplot face. This property can be any of the following:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See `ColorSpec` for more information on specifying color.

- `none` — Do not draw faces. Note that edges are drawn independently of faces.
- `flat` — The values of `CData` determine the color for each face of the surface. The color data at the first vertex determine the color of the entire face.
- `interp` — Bilinear interpolation of the values at each vertex (the `CData`) determines the coloring of each face.
- `texturemap` — Texture map the `CData` to the surface. MATLAB transforms the color data so that it conforms to the surface. (See the texture mapping example for `surface`.)

`FaceLighting`
`{none} | flat | gouraud | phong`

Algorithm used for lighting calculations. This property selects the algorithm used to calculate the effect of light objects on the surface. Choices are

- `none` — Lights do not affect the faces of this object.
- `flat` — The effect of light objects is uniform across the faces of the surface. Select this choice to view faceted objects.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility`

is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`
`{on} | off`

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the surface. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

`LineStyle`

`{-} | -- | :  | -.  | none`

Line style of surfaceplot object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle` `none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
size in points

Width of linear objects and edges of filled areas. Specify in points. `1` point = $^1/_{72}$ inch. The default is `0.5` points.

`Marker`
character (see table)

Marker symbol. Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle

Specifier	Marker Type
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h''	Six-pointed star (hexagram)
'none'	No marker (default)

MarkerEdgeColor
none | {auto} | flat | ColorSpec

Marker edge color. The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the EdgeColor property.
- flat — Uses the CData value of the vertex to determine the color of the marker edge.
- ColorSpec — Defines color to use.

MarkerFaceColor
{none} | auto | flat | ColorSpec

Marker face color. The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Uses the axes `Color` for the marker face color.
- `flat` — Uses the `CData` value of the vertex to determine the color of the face.
- `ColorSpec` — Defines a single color to use for all markers on the surfaceplot.

`MarkerSize`
scalar

Marker size. Size of the marker in points. The default value is `6`.

Note MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

`MeshStyle`
`{both} | row | column`

Row and column lines. Specifies whether to draw all edge lines or just row or column edge lines.

- `both` — Draws edges for both rows and columns.
- `row` — Draws row edges only.
- `column` — Draws column edges only.

`NormalMode`
`{auto} | manual`

MATLAB generated or user-specified normal vectors.

- `auto` — MATLAB calculates vertex normals based on the coordinate data
- `manual` — If you specify your own vertex normals, MATLAB sets this property to `manual` and does not generate its own data.

See also the `VertexNormals` property.

`Parent`
handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Object selection state. When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Selected objects highlighted.

- `on` — MATLAB indicates the selected state by drawing a dashed bounding box around the surface.
- `off` — MATLAB does not draw the bounding box except when in plot edit mode and objects are selected manually.

`SpecularColorReflectance`

scalar in the range `0` to `1`

Color of specularly-reflected light. When this property is `0`, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to `1`, the color of the specularly-reflected light depends only on the color or the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

`SpecularExponent`

scalar >= 1

Harshness of specular reflection. Controls the size of the specular spot. Most materials have exponents in the range of `5` to `20`.

`SpecularStrength`

scalar >= 0 and <= 1

Intensity of specular light. Sets the intensity of the specular component of the light falling on the surfaceplot. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the surfaceplot object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

`Tag`

string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an areaseries object and set the `Tag` property.

```
t = area(Y,'Tag','area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

`Type`
string (read only)

Class of the graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For surfaceplot objects, `Type` is always the string `'surface'`.

`UIContextMenu`
handle of uicontextmenu object

Associate context menu with object. Handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

`UserData`
array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`VertexNormals`
vector | matrix

Surfaceplot normal vectors. Contains the vertex normals for the surfaceplot. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even

if it does not match the coordinate data. This can be useful to produce interesting lighting effects.

Visible
`{on} | off`

Visibility of object and its children.

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

XData
vector | matrix

X-coordinates. The *x*-position of the surfaceplot data points. If you specify a row vector, MATLAB replicates the row internally until it has the same number of columns as `ZData`.

XDataMode
`{auto} | manual`

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the `X` input argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

XDataSource
MATLAB variable, as a string

Link `XData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h,'XDataSource','xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`
vector | matrix

Y-coordinates. The *y*-position of the surfaceplot data points. If you specify a row vector, MATLAB replicates the row internally until it has the same number of rows as `ZData`.

`YDataMode`
{auto} | manual

Use automatic or user-specified y-axis values. If you specify `XData`, MATLAB sets this property to `manual`.

If you set `YDataMode` to `auto` after having specified `YData`, MATLAB resets the *y*-axis ticks and *y*-tick labels to the row indices of the `ZData`, overwriting any previous values for `YData`.

`YDataSource`
MATLAB variable, as a string

Link `YData` *to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h,'YDataSource','Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`ZData`
matrix

Z-coordinates. The *z*-position of the surfaceplot data points. See the Description section for more information.

`ZDataSource`
MATLAB variable, as a string

Link `ZData` *to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`. The default value is an empty array.

```
set(h,'ZDataSource','zdatavariablename')
```

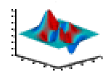
MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's

`ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Purpose

Surface plot with colormap-based lighting



Syntax

```
surfl(Z)
surfl(...,'light')
surfl(...,s)
surfl(X,Y,Z,s,k)
h = surfl(...)
```

Description

The `surfl` function displays a shaded surface based on a combination of ambient, diffuse, and specular lighting models.

`surfl(Z)` and surfl(X,Y,Z) create three-dimensional shaded surfaces using the default direction for the light source and the default lighting coefficients for the shading model. `X`, `Y`, and `Z` are vectors or matrices that define the *x*, *y*, and *z* components of a surface.

`surfl(...,'light')` produces a colored, lighted surface using a MATLAB light object. This produces results different from the default lighting method, `surfl(...,'cdata')`, which changes the color data for the surface to be the reflectance of the surface.

`surfl(...,s)` specifies the direction of the light source. `s` is a two- or three-element vector that specifies the direction from a surface to a light source. `s = [sx sy sz]` or `s = [azimuth elevation]`. The default `s` is 45° counterclockwise from the current view direction.

`surfl(X,Y,Z,s,k)` specifies the reflectance constant. `k` is a four-element vector defining the relative contributions of ambient light, diffuse reflection, specular reflection, and the specular shine coefficient. `k = [ka kd ks shine]` and defaults to `[.55,.6,.4,10]`.

`h = surfl(...)` returns a handle to a surface graphics object.

Tips

surfl does not accept complex inputs.

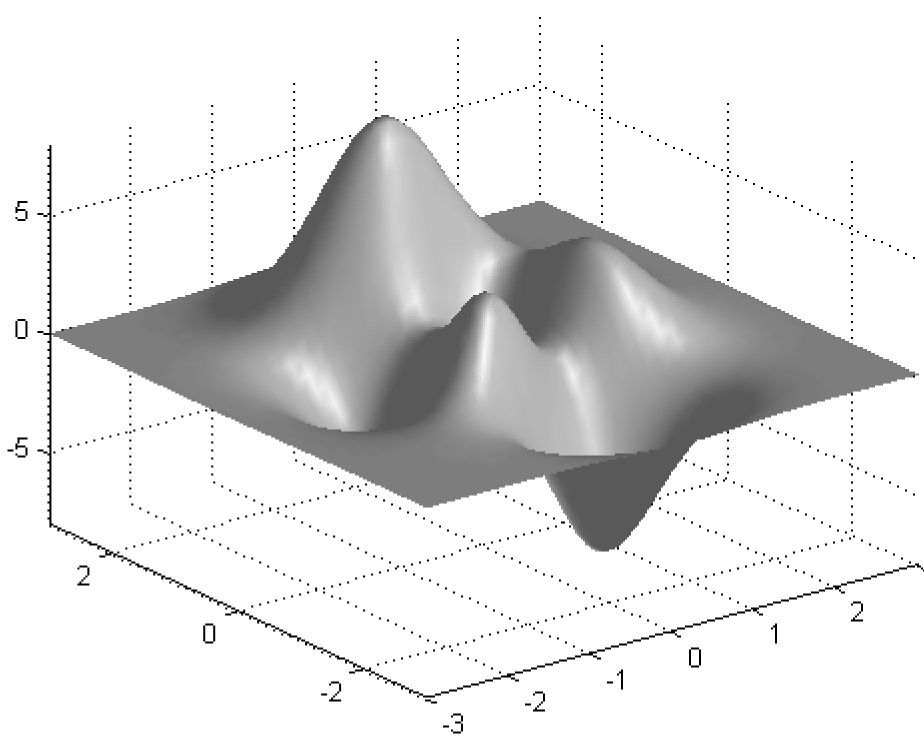
For smoother color transitions, use colormaps that have linear intensity variations (e.g., gray, copper, bone, pink).

The ordering of points in the X, Y, and Z matrices defines the inside and outside of parametric surfaces. If you want the opposite side of the surface to reflect the light source, use surfl(X',Y',Z'). Because of the way surface normal vectors are computed, surfl requires matrices that are at least 3-by-3.

Examples

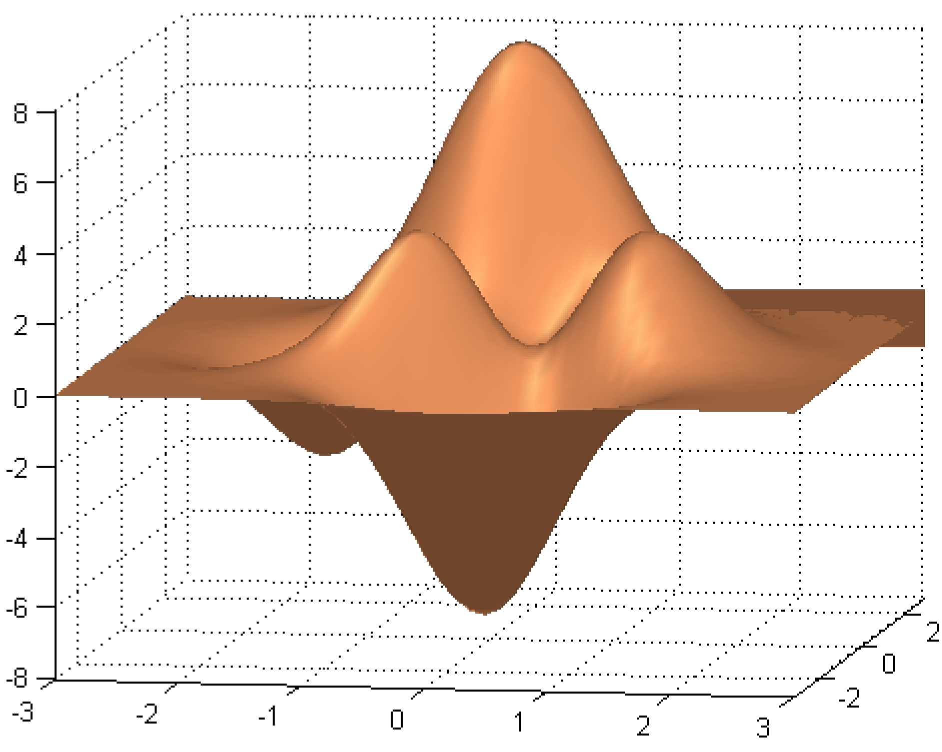
View peaks using colormap-based lighting.

```
[x,y] = meshgrid(-3:1/8:3);
z = peaks(x,y);
surfl(x,y,z);
shading interp
colormap(gray);
axis([-3,3,-3,3,-8,8])
```



To plot a lighted surface from a view direction other than the default,

```
view([10 10])
grid on
hold on
surfl(peaks)
shading interp
colormap copper
hold off
```



See Also colormap | shading | light

Purpose

Compute and display 3-D surface normals

Syntax

```
surfnorm(Z)
surfnorm(X,Y,Z)
surfnorm(axes_handle,___)
surfnorm(___,Name,Value)
[Nx,Ny,Nz] = surfnorm(___)
```

Description

`surfnorm(Z)` plots a surface of the matrix `Z` with `surf` and displays its surface normals as radiating vectors.

`surfnorm(X,Y,Z)` plots a surface and its surface normals from the vectors or matrices `X`, `Y`, and matrix `Z`. `X`, `Y`, and `Z` must be the same size.

`surfnorm(axes_handle,___)` plots into `axes_handle` instead of `gca` and it can include any of the input arguments in previous syntaxes.

`surfnorm(___,Name,Value)` can be used to set the value of the specified `Surface Properties`.

`[Nx,Ny,Nz] = surfnorm(___)` returns the components of the 3-D surface normals for the surface without plotting the surface or surface normals.

Tips

- `surfnorm` does not accept complex inputs.
- Reverse the direction of the normals by calling `surfnorm` with transposed arguments:

  ```
  surfnorm(X',Y',Z')
  ```

- The surface normals represent conditions at vertices and are not normalized. Normals for surface elements that face away from the viewer do not display.
- `surfl` uses `surfnorm` to compute surface normals when calculating the reflectance of a surface.

Input Arguments

Z

2–D array of real numbers representing a surface

X

2–D array of real numbers that defines the *x* component of the surface grid

Y

2–D array of real numbers that defines the *y* component of the surface grid

axes_handle

Handle to the target axes in which to plot the surface

If you do not specify `axes_handle`, MATLAB uses current axes.

Name,Value

Specify optional comma-separated pairs of Name,Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Property names and values of the surface object

See `Surface Properties` for description of property names and values.

Output Arguments

[Nx,Ny,Nz]

x, *y*, and *z* components of the three-dimensional surface normals for the surface

Definitions

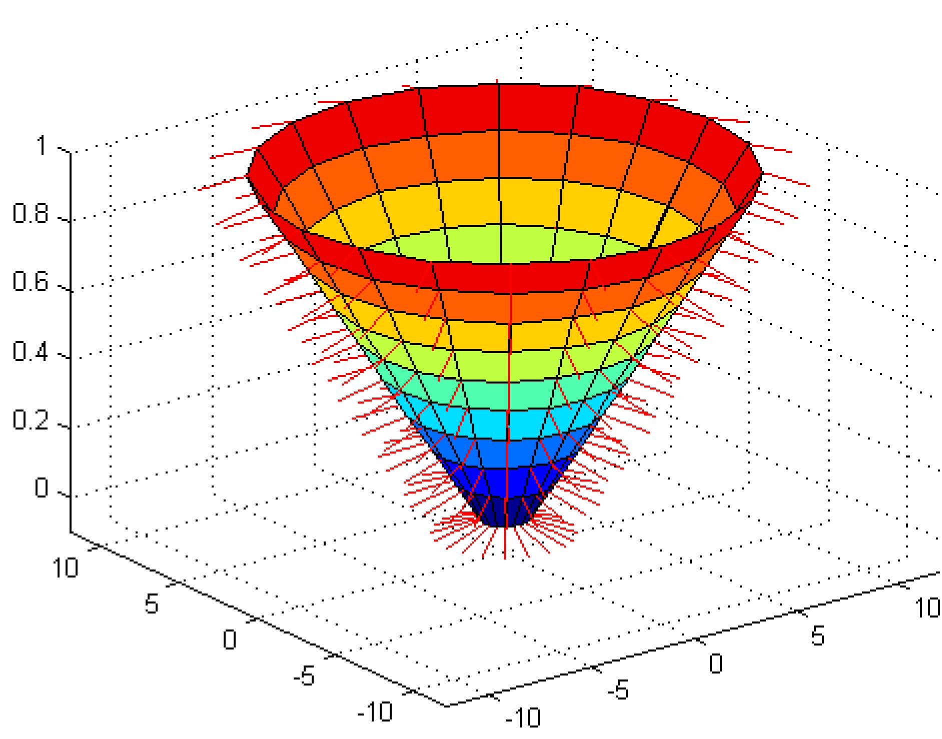
Surface Normal

An imaginary line perpendicular to a flat surface or perpendicular to the tangent plane at a point on a non-flat surface

Examples

Plot the normal vectors for a truncated cone.

```
[x,y,z] = cylinder(1:10);
surfnorm(x,y,z)
axis([-12 12 -12 12 -0.1 1])
```

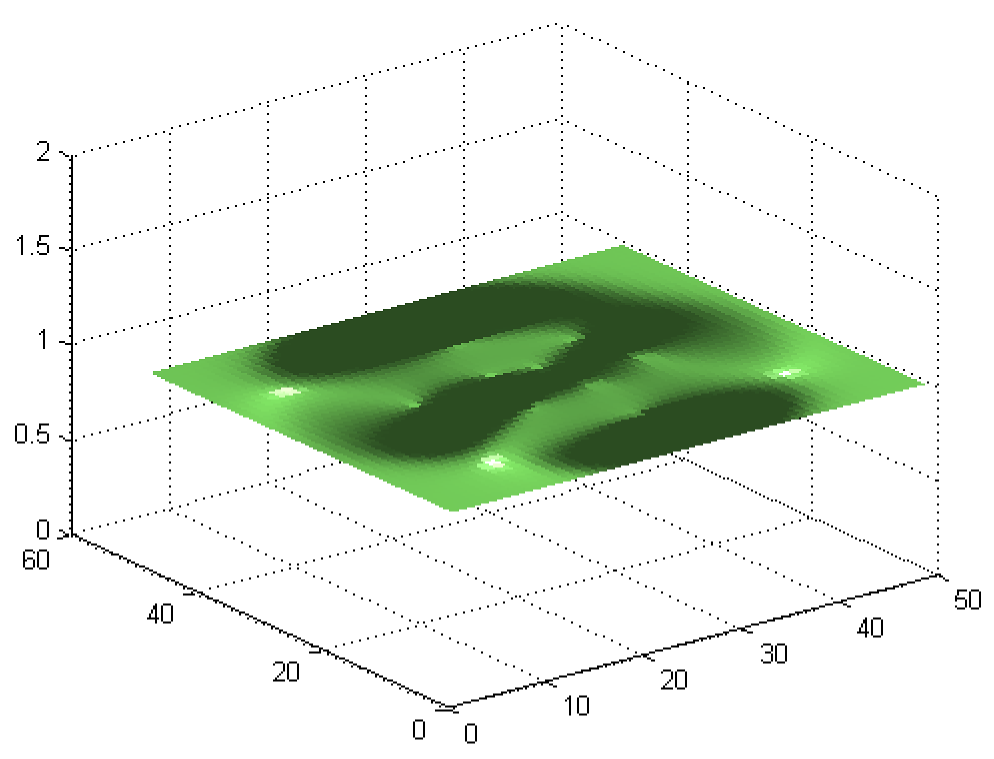


Get normal vectors of an expression representing a surface.

```
[nx, ny, nz] = surfnorm(peaks);
```

You can use these normals in conjunction with `VertexNormals` property and to apply lighting variations to a plain surface as,

```
b = reshape([nx ny nz], 49,49,3);
surf(ones(49), 'VertexNormals', b);%Create a plain surface of size equal
shading interp % remove edge definition from the image
camlight
```



Algorithms

After performing a bicubic fit of the data in the x, y, and z directions, diagonal vectors are computed and crossed to form the normal at each vertex.

Purpose

Singular value decomposition

Syntax

```
s = svd(X)
[U,S,V] = svd(X)
[U,S,V] = svd(X,0)
[U,S,V] = svd(X,'econ')
```

Description

The `svd` command computes the matrix singular value decomposition.

`s = svd(X)` returns a vector of singular values.

`[U,S,V] = svd(X)` produces a diagonal matrix `S` of the same dimension as `X`, with nonnegative diagonal elements in decreasing order, and unitary matrices `U` and `V` so that `X = U*S*V'`.

`[U,S,V] = svd(X,0)` produces the "economy size" decomposition. If `X` is m-by-n with m > n, then `svd` computes only the first `n` columns of `U` and `S` is n-by-n.

`[U,S,V] = svd(X,'econ')` also produces the "economy size" decomposition. If `X` is m-by-n with m >= n, it is equivalent to `svd(X,0)`. For m < n, only the first m columns of `V` are computed and `S` is m-by-m.

Examples

For the matrix

```
X =
     1     2
     3     4
     5     6
     7     8
```

the statement

```
[U,S,V] = svd(X)
```

produces

```
U =
   -0.1525   -0.8226   -0.3945   -0.3800
```

```
    -0.3499   -0.4214    0.2428    0.8007
    -0.5474   -0.0201    0.6979   -0.4614
    -0.7448    0.3812   -0.5462    0.0407

S =
     14.2691         0
           0    0.6268
           0         0
           0         0

V =
    -0.6414     0.7672
    -0.7672    -0.6414
```

The economy size decomposition generated by

```
[U,S,V] = svd(X,0)
```

produces

```
U =
    -0.1525   -0.8226
    -0.3499   -0.4214
    -0.5474   -0.0201
    -0.7448    0.3812
S =
    14.2691         0
          0    0.6268
V =
    -0.6414    0.7672
    -0.7672   -0.6414
```

Diagnostics

If the limit of 75 QR step iterations is exhausted while seeking a singular value, this message appears:

```
Solution will not converge.
```

svds

Purpose

Find singular values and vectors

Syntax

```
s = svds(A)
s = svds(A,k)
s = svds(A,k,sigma)
s = svds(A,k,'L')
s = svds(A,k,sigma,options)
[U,S,V] = svds(A,...)
[U,S,V,flag] = svds(A,...)
```

Description

`s = svds(A)` computes the six largest singular values and associated singular vectors of matrix `A`. If `A` is `m`-by-`n`, `svds(A)` manipulates eigenvalues and vectors returned by `eigs(B)`, where `B = [sparse(m,m) A; A' sparse(n,n)]`, to find a few singular values and vectors of `A`. The positive eigenvalues of the symmetric matrix `B` are the same as the singular values of `A`.

`s = svds(A,k)` computes the `k` largest singular values and associated singular vectors of matrix `A`.

`s = svds(A,k,sigma)` computes the `k` singular values closest to the scalar shift sigma. For example, `s = svds(A,k,0)` computes the `k` smallest singular values and associated singular vectors.

`s = svds(A,k,'L')` computes the `k` largest singular values (the default).

`s = svds(A,k,sigma,options)` sets some parameters (see `eigs`):

Option Structure Fields and Descriptions

Field name	Parameter	Default
`options.tol`	Convergence tolerance: `norm(AV-US,1)<=tol*norm(A,1)`	`1e-10`
`options.maxit`	Maximum number of iterations	`300`
`options.disp`	Number of values displayed each iteration	`0`

svds checks the accuracy of the computed singular vectors. If the vectors they are not accurate enough returns fewer singular values than requested. To obtain the requested number of singular values, try decreasing the error tolerance in the options structure.

[U,S,V] = svds(A,...) returns three output arguments, and if A is m-by-n:

- U is m-by-k with orthonormal columns
- S is k-by-k diagonal
- V is n-by-k with orthonormal columns
- U*S*V' is the closest rank k approximation to A

[U,S,V,flag] = svds(A,...) returns a convergence flag. If eigs converged, then norm(A*V-U*S,1) <= tol*norm(A,1) and flag is 0. If eigs did not converge, then flag is 1.

Note svds is best used to find a few singular values of a large, sparse matrix. To find all the singular values of such a matrix, svd(full(A)) will usually perform better than svds(A,min(size(A))).

Algorithms

svds(A,k) uses eigs to find the k largest magnitude eigenvalues and corresponding eigenvectors of B = [0 A; A' 0].

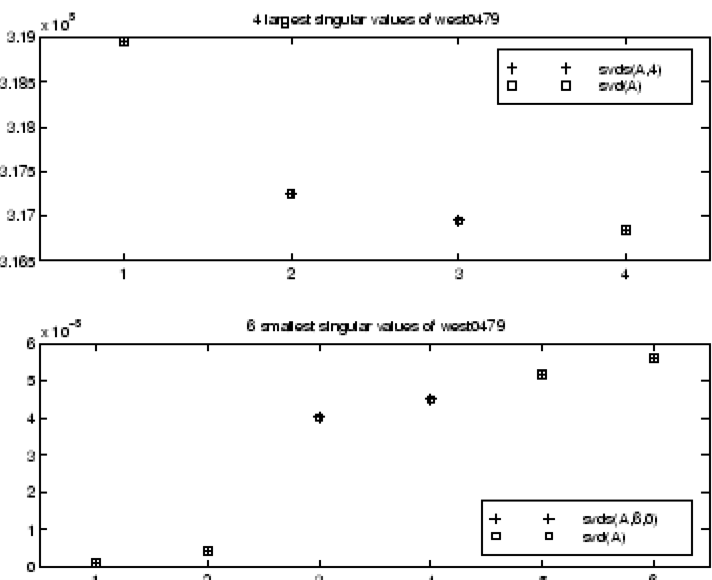
svds(A,k,0) uses eigs to find the 2k smallest magnitude eigenvalues and corresponding eigenvectors of B = [0 A; A' 0], and then selects the k positive eigenvalues and their eigenvectors.

Examples

west0479 is a real 479-by-479 sparse matrix. svd calculates all 479 singular values. svds picks out the largest and smallest singular values.

```
load west0479
s = svd(full(west0479))
sl = svds(west0479,4)
ss = svds(west0479,6,0)
```

These plots show some of the singular values of `west0479` as computed by `svd` and `svds`.



The largest singular value of `west0479` can be computed a few different ways:

```
svds(west0479,1) =
 3.189517598808622e+05
max(svd(full(west0479))) =
 3.18951759880862e+05
norm(full(west0479)) =
 3.189517598808623e+05
```

and estimated:

```
normest(west0479) =
 3.189385666549991e+05
```

`svd` | `eigs`

Purpose

Swap byte ordering

Syntax

```
Y = swapbytes(X)
```

Description

`Y = swapbytes(X)` reverses the byte ordering of each element in array `X`, converting little-endian values to big-endian (and vice versa). The input array must contain all full, noncomplex, numeric elements.

Examples

Example 1

Reverse the byte order for a scalar 32-bit value, changing hexadecimal `12345678` to `78563412`:

```
A = uint32(hex2dec('12345678'));

B = dec2hex(swapbytes(A))
B =
   78563412
```

Example 2

Reverse the byte order for each element of a 1-by-4 matrix:

```
X = uint16([0 1 128 65535])
X =
      0      1    128  65535

Y = swapbytes(X);
Y =
      0    256  32768  65535
```

Examining the output in hexadecimal notation shows the byte swapping:

```
format hex

X, Y
X =
   0000   0001   0080   ffff
```

```
Y =
   0000   0100   8000   ffff
```

Example 3

Create a three-dimensional array A of 16-bit integers and then swap the bytes of each element:

```
format hex

A = uint16(magic(3) * 150);
A(:,:,2) = A * 40;

A
A(:,:,1) =
   04b0   0096   0384
   01c2   02ee   041a
   0258   0546   012c
A(:,:,2) =
   bb80   1770   8ca0
   4650   7530   a410
   5dc0   d2f0   2ee0

swapbytes(A)
ans(:,:,1) =
   b004   9600   8403
   c201   ee02   1a04
   5802   4605   2c01
ans(:,:,2) =
   80bb   7017   a08c
   5046   3075   10a4
   c05d   f0d2   e02e
```

typecast

switch/case/otherwise

Purpose

Switch among several cases based on expression

Syntax

```
switch switch_expression
   case case_expression
      statements
   case case_expression
      statements
    :
   otherwise
      statements
end
```

Description

A `switch` block conditionally executes one set of statements from several choices. Each choice is a `case`.

An evaluated *switch_expression* is a scalar or string. An evaluated *case_expression* is a scalar, a string, or a cell array of scalars or strings. The `switch` block tests each case until one of the cases is `true`. A case is `true` when:

- For numbers, `eq(`*case_expression*`,`*switch_expression*`)`.
- For strings, `strcmp(`*case_expression*`,`*switch_expression*`)`.
- For objects that support the `eq` function, `eq(`*case_expression*`,`*switch_expression*`)`.
- For a cell array *case_expression*, at least one of the elements of the cell array matches *switch_expression*, as defined above for numbers, strings, and objects.

When a case is true, MATLAB executes the corresponding statements, and then exits the `switch` block.

`otherwise` is optional, and executes only when no case is true.

Tips

- Unlike the C language `switch` statement, the MATLAB `switch` does not fall through. If the first `case` statement is `true`, the other `case`

statements do not execute. Do not use a `break` statement within a `switch` block.

- A *`case_expression`* cannot include relational operators such as `<` or `>` to compare against the *`switch_expression`*. To test for inequality, use `if-elseif` statements.
- Because MATLAB executes only one case of any `switch` statement, variables defined within one `case` are not available for other cases. For example, if your current workspace does not contain a variable `x`, only cases that define `x` can use it:

```
switch choice
   case 1
      x = -pi:0.01:pi;
   case 2
      % does not know anything about x
end
```

Examples

Conditionally display different text depending on a value entered at the command line:

```
mynumber = input('Enter a number:');

switch mynumber
    case -1
        disp('negative one');
    case 0
        disp('zero');
    case 1
        disp('positive one');
    otherwise
        disp('other value');
end
```

Decide which plot to create based on the value of the string `plottype`:

```
x = [12, 64, 24];
plottype = 'pie3';

switch plottype
    case 'bar'
        bar(x)
        title('Bar Graph')
    case {'pie','pie3'}
        pie3(x)
        title('Pie Chart')
        legend('First','Second','Third')
    otherwise
        warning('Unexpected plot type. No plot created.');
end
```

In MATLAB `switch` blocks, only the first matching case executes:

```
result = 52;

switch(result)
   case 52
      disp('result is 52')
   case {52, 78}
      disp('result is 52 or 78')
end
```

This code returns

```
result is 52
```

symamd

Purpose

Symmetric approximate minimum degree permutation

Syntax

```
p = symamd(S)
p = symamd(S,knobs)
[p,stats] = symamd(...)
```

Description

`p = symamd(S)` for a symmetric positive definite matrix `S`, returns the permutation vector `p` such that `S(p,p)` tends to have a sparser Cholesky factor than `S`. To find the ordering for `S`, `symamd` constructs a matrix `M` such that `spones(M'*M) = spones (S)`, and then computes `p = colamd(M)`. The `symamd` function may also work well for symmetric indefinite matrices.

`S` must be square; only the strictly lower triangular part is referenced.

`p = symamd(S,knobs)` where `knobs` is a scalar. If `S` is `n`-by-`n`, rows and columns with more than `knobs*n` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs = spparms('wh_frac')`.

`[p,stats] = symamd(...)` produces the optional vector `stats` that provides data about the ordering and the validity of the matrix `S`.

`stats(1)`	Number of dense or empty rows ignored by `symamd`
`stats(2)`	Number of dense or empty columns ignored by `symamd`
`stats(3)`	Number of garbage collections performed on the internal data structure used by `symamd` (roughly of size `8.4*nnz(tril(S,-1)) + 9n` integers)
`stats(4)`	`0` if the matrix is valid, or `1` if invalid
`stats(5)`	Rightmost column index that is unsorted or contains duplicate entries, or `0` if no such column exists
`stats(6)`	Last seen duplicate or out-of-order row index in the column index given by `stats(5)`, or `0` if no such row index exists
`stats(7)`	Number of duplicate and out-of-order row indices

Although, MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `symamd`. For this reason, `symamd` verifies that `S` is valid:

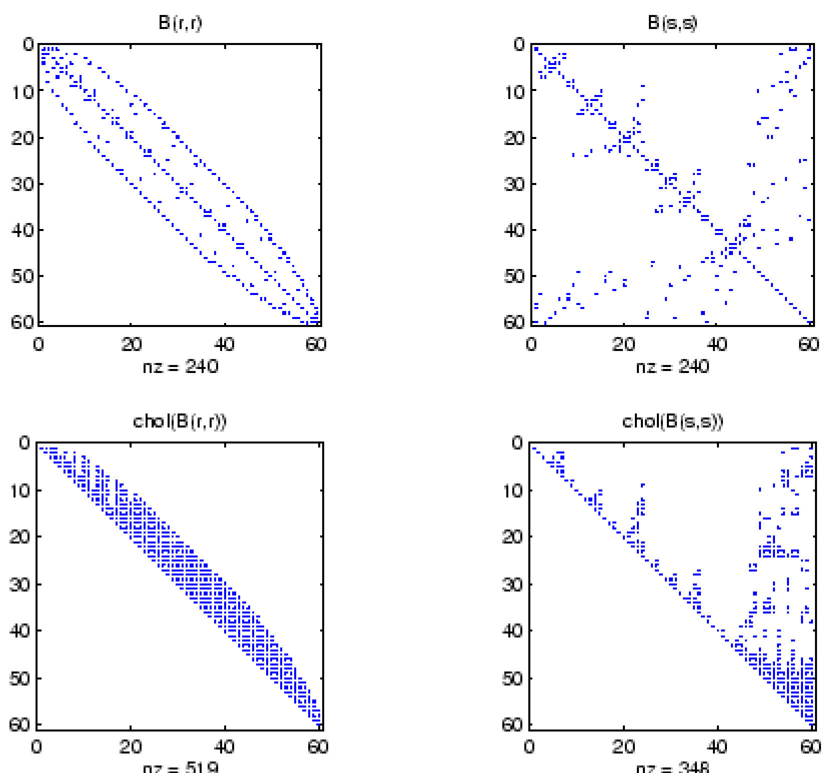
- If a row index appears two or more times in the same column, `symamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `symamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `symamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`).

The ordering is followed by a symmetric elimination tree post-ordering.

Examples

Here is a comparison of reverse Cuthill-McKee and minimum degree on the Bucky ball example mentioned in the `symrcm` reference page.

```
B = bucky+4*speye(60);
r = symrcm(B);
p = symamd(B);
R = B(r,r);
S = B(p,p);
subplot(2,2,1), spy(R,4), title('B(r,r)')
subplot(2,2,2), spy(S,4), title('B(s,s)')
subplot(2,2,3), spy(chol(R),4), title('chol(B(r,r))')
subplot(2,2,4), spy(chol(S),4), title('chol(B(s,s))')
```



Even though this is a very small problem, the behavior of both orderings is typical. RCM produces a matrix with a narrow bandwidth which fills in almost completely during the Cholesky factorization. Minimum degree produces a structure with large blocks of contiguous zeros which do not fill in during the factorization. Consequently, the minimum degree ordering requires less time and storage for the factorization.

References

The authors of the code for `symamd` are Stefan I. Larimore and Timothy A. Davis (`davis@cise.ufl.edu`), University of Florida. The algorithm was developed in collaboration with John Gilbert, Xerox PARC, and Esmond Ng, Oak Ridge National Laboratory.

Sparse Matrix Algorithms Research at the University of Florida:
`http://www.cise.ufl.edu/research/sparse/`

See Also

`colamd` | `colperm` | `spparms` | `symrcm` | `amd`

Purpose

Symbolic factorization analysis

Syntax

```
count = symbfact(A)
count = symbfact(A,'sym')
count = symbfact(A,'col')
count = symbfact(A,'row')
count = symbfact(A,'lo')
[count,h,parent,post,R] = symbfact(...)
[count,h,parent,post,L] = symbfact(A,type,'lower')
```

Description

`count = symbfact(A)` returns the vector of row counts of `R=chol(A)`. `symbfact` should be much faster than `chol(A)`.

`count = symbfact(A,'sym')` is the same as `count = symbfact(A)`.

`count = symbfact(A,'col')` returns row counts of `R=chol(A'*A)` (without forming it explicitly).

`count = symbfact(A,'row')` returns row counts of `R=chol(A*A')`.

`count = symbfact(A,'lo')` is the same as `count = symbfact(A)` and uses `tril(A)`.

`[count,h,parent,post,R] = symbfact(...)` has several optional return values.

The flop count for a subsequent Cholesky factorization is `sum(count.^2)`

Return Value	Description
`h`	Height of the elimination tree
`parent`	The elimination tree itself
`post`	Postordering of the elimination tree
`R`	0-1 matrix having the structure of `chol(A)` for the symmetric case, `chol(A'*A)` for the `'col'` case, or `chol(A*A')` for the `'row'` case.

`symbfact(A)` and `symbfact(A,'sym')` use the upper triangular part of `A (triu(A))` and assume the lower triangular part is the transpose of the upper triangular part. `symbfact(A,'lo')` uses `tril(A)` instead.

`[count,h,parent,post,L] = symbfact(A,type,'lower')` where `type` is one of `'sym'`,`'col'`, `'row'`, or`'lo'` returns a lower triangular symbolic factor `L=R'`. This form is quicker and requires less memory.

symmlq

Purpose

Symmetric LQ method

Syntax

```
x = symmlq(A,b)
symmlq(A,b,tol)
symmlq(A,b,tol,maxit)
symmlq(A,b,tol,maxit,M)
symmlq(A,b,tol,maxit,M1,M2)
symmlq(A,b,tol,maxit,M1,M2,x0)
[x,flag] = symmlq(A,b,...)
[x,flag,relres] = symmlq(A,b,...)
[x,flag,relres,iter] = symmlq(A,b,...)
[x,flag,relres,iter,resvec] = symmlq(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...)
```

Description

`x = symmlq(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be symmetric but need not be positive definite. It should also be large and sparse. The column vector `b` must have length `n`. You can specify `A` as a function handle, `afun`, such that `afun(x)` returns `A*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `symmlq` converges, a message to that effect is displayed. If `symmlq` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`symmlq(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `symmlq` uses the default, `1e-6`.

`symmlq(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `symmlq` uses the default, `min(n,20)`.

`symmlq(A,b,tol,maxit,M)` and `symmlq(A,b,tol,maxit,M1,M2)` use the symmetric positive definite preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(sqrt(M))*A*inv(sqrt(M))*y =`

inv(sqrt(M))*b for y and then return x = in(sqrt(M))*y. If M is []
then symmlq applies no preconditioner. M can be a function handle mfun
such that mfun(x) returns M\x.

symmlq(A,b,tol,maxit,M1,M2,x0) specifies the initial guess. If x0 is
[], then symmlq uses the default, an all-zero vector.

[x,flag] = symmlq(A,b,...) also returns a convergence flag.

Flag	Convergence
0	symmlq converged to the desired tolerance tol within maxit iterations.
1	symmlq iterated maxit times but did not converge.
2	Preconditioner M was ill-conditioned.
3	symmlq stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during symmlq became too small or too large to continue computing.
5	Preconditioner M was not symmetric positive definite.

Whenever flag is not 0, the solution x returned is that with minimal
norm residual computed over all the iterations. No messages are
displayed if the flag output is specified.

[x,flag,relres] = symmlq(A,b,...) also returns the relative
residual norm(b-A*x)/norm(b). If flag is 0, relres <= tol.

[x,flag,relres,iter] = symmlq(A,b,...) also returns the iteration
number at which x was computed, where 0 <= iter <= maxit.

[x,flag,relres,iter,resvec] = symmlq(A,b,...) also returns a
vector of estimates of the symmlq residual norms at each iteration,
including norm(b-A*x0).

[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...) also
returns a vector of estimates of the conjugate gradients residual norms
at each iteration.

Examples

Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50; M1 = spdiags(4*on,0,n,n);

x = symmlq(A,b,tol,maxit,M1);
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

Example 2

This example replaces the matrix `A` in Example 1 with a handle to a matrix-vector product function `afun`. The example is contained in the function `run_symmlq` that:

- Calls `symmlq` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_symmlq` are available to `afun`.

The following shows the code for `run_symmlq`:

```
function x1 = run_symmlq
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = symmlq(@afun,b,tol,maxit,M1);

       function y = afun(x)
          y = 4 * x;
          y(2:n) = y(2:n) - 2 * x(1:n-1);
```

```
            y(1:n-1) = y(1:n-1) - 2 * x(2:n);
        end
end
```

When you enter

```
x1=run_symmlq;
```

MATLAB software displays the message

```
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

Example 3

Use a symmetric indefinite matrix that fails with pcg.

```
A = diag([20:-1:1,-1:-1:-20]);
b = sum(A,2);      % The true solution is the vector of all ones.
x = pcg(A,b);      % Errors out at the first iteration.
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1
```

However, symmlq can handle the indefinite matrix A.

```
x = symmlq(A,b,1e-6,40);
symmlq converged at iteration 39 to a solution with relative
residual 1.3e-007
```

Purpose

Sparse reverse Cuthill-McKee ordering

Syntax

```
r = symrcm(S)
```

Description

`r = symrcm(S)` returns the symmetric reverse Cuthill-McKee ordering of `S`. This is a permutation `r` such that `S(r,r)` tends to have its nonzero elements closer to the diagonal. This is a good preordering for LU or Cholesky factorization of matrices that come from long, skinny problems. The ordering works for both symmetric and nonsymmetric `S`.

For a real, symmetric sparse matrix, `S`, the eigenvalues of `S(r,r)` are the same as those of `S`, but `eig(S(r,r))` probably takes less time to compute than `eig(S)`.

Algorithms

The algorithm first finds a pseudoperipheral vertex of the graph of the matrix. It then generates a level structure by breadth-first search and orders the vertices by decreasing distance from the pseudoperipheral vertex. The implementation is based closely on the SPARSPAK implementation described by George and Liu.

Examples

The statement

```
B = bucky;
```

uses a function in the `demos` toolbox to generate the adjacency graph of a truncated icosahedron. This is better known as a soccer ball, a Buckminster Fuller geodesic dome (hence the name `bucky`), or, more recently, as a 60-atom carbon molecule. There are 60 vertices. The vertices have been ordered by numbering half of them from one hemisphere, pentagon by pentagon; then reflecting into the other hemisphere and gluing the two halves together. With this numbering, the matrix does not have a particularly narrow bandwidth, as the first spy plot shows

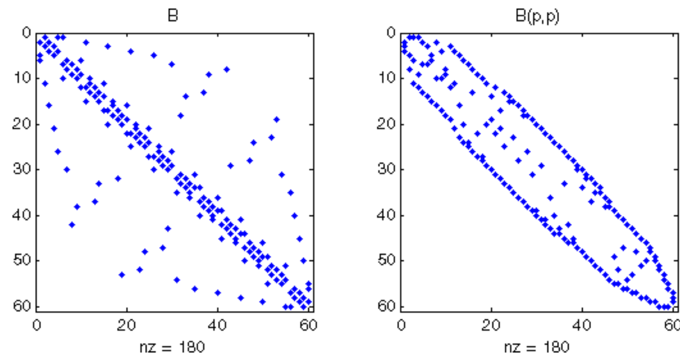
```
subplot(1,2,1),spy(B),title('B')
```

The reverse Cuthill-McKee ordering is obtained with

```
p = symrcm(B);
R = B(p,p);
```

The `spy` plot shows a much narrower bandwidth.

```
subplot(1,2,2),spy(R),title('B(p,p)')
```



This example is continued in the reference pages for `symamd`.

The bandwidth can also be computed with

```
[i,j] = find(B);
bw = max(i-j) + 1;
```

The bandwidths of `B` and `R` are 35 and 12, respectively.

Purpose

Determine symbolic variables in expression

Syntax

```
symvar 'expr'
s = symvar('expr')
```

Description

`symvar 'expr'` searches the expression, `expr`, for identifiers other than `i`, `j`, `pi`, `inf`, `nan`, `eps`, and common functions. `symvar` displays those variables that it finds or, if no such variable exists, displays an empty cell array, `{}`.

`s = symvar('expr')` returns the variables in a cell array of strings, `s`. If no such variable exists, `s` is an empty cell array.

Examples

`symvar` finds variables `beta1` and `x`, but skips `pi` and the `cos` function.

```
symvar 'cos(pi*x - beta1)'

ans =

    'beta1'
    'x'
```

`strfind`

Purpose Two ways to call MATLAB functions

Description You can call MATLAB functions using either *command syntax* or *function syntax*, as described below.

Command Syntax

A function call in this syntax consists of the function name followed by one or more arguments separated by spaces:

```
functionname arg1 arg2 ... argn
```

Command syntax does not allow you to obtain any values that might be returned by the function. Attempting to assign output from the function to a variable using command syntax generates an error. Use function syntax instead.

Examples of command syntax:

```
save mydata.mat x y z
import java.awt.Button java.lang.String
```

Arguments are treated as string literals. See the examples below, under "Argument Passing" on page 1-5207.

Function Syntax

A function call in this syntax consists of the function name followed by one or more arguments separated by commas and enclosed in parentheses:

```
functionname(arg1, arg2, ..., argn)
```

You can assign the output of the function to one or more output values. When assigning to more than one output variable, separate the variables by commas or spaces and enclose them in square brackets (`[]`):

```
[out1,out2,...,outn] = functionname(arg1, arg2, ..., argn)
```

Examples of function syntax:

```
copyfile('srcfile', '..\mytests', 'writable')
[x1,x2,x3,x4] = deal(A{:})
```

Arguments are passed to the function by value. See the examples below, under “Argument Passing” on page 1-5207.

Argument Passing

When calling a function using command syntax, MATLAB passes the arguments as string literals. When using function syntax, arguments are passed by value.

In the following example, assign a value to `A` and then call `disp` on the variable to display the value passed. Calling `disp` with command syntax passes the variable name, `'A'`:

```
A = pi;
disp A
   A
```

while function syntax passes the value assigned to `A`:

```
A = pi;
disp(A)
   3.1416
```

The next example passes two strings to `strcmp` for comparison. Calling the function with command syntax compares the variable names, `'str1'` and `'str2'`:

```
str1 = 'one';    str2 = 'one';
strcmp str1 str2
ans =
     0        (unequal)
```

while function syntax compares the values assigned to the variables, `'one'` and `'one'`:

```
str1 = 'one';    str2 = 'one';
strcmp(str1, str2)
```

```
ans =
     1        (equal)
```

Passing Strings

When using the function syntax to pass a string literal to a function, you must enclose the string in single quotes, ('string'). For example, to create a new folder called myapptests, use

```
mkdir('myapptests')
```

On the other hand, variables that contain strings do not need to be enclosed in quotes:

```
folder = 'myapptests';
mkdir(folder)
```

mlint

How To

- "Check Code for Errors and Warnings"

Purpose

Execute operating system command and return output

Syntax

```
status = system(command)
[status,cmdout] = system(command)
[status,cmdout] = system(command,'-echo')
```

Description

`status = system(command)` calls the operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the `status` variable.

`[status,cmdout] = system(command)` additionally returns the output of the command to `cmdout`. This syntax is most useful for commands that do not require user input, such as `dir`.

`[status,cmdout] = system(command,'-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.

Input Arguments

command - Operating system command

string

Operating system command, specified as a string. The `command` executes in a system shell, which might not be the shell from which you launched MATLAB.

Example: `'dir'`

Example: `'ls'`

Output Arguments

status - Command exit status

0 | nonzero integer

Command exit status, returned as either `0` or a nonzero integer. When the command is successful, `status` is `0`. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (&), then `status` is the exit status upon command launch.
- If `command` does not include the ampersand character (&), then `status` is the exit status upon command completion.

cmdout - Output of operating system command
string

Output of the operating system command, returned as a string.

Examples

Display Windows Operating System Command Status and Output

On a Windows system, display the current folder using the `cd` command.

```
command = 'cd';
[status,cmdout] = system(command)
```

```
status =
     0
cmdout =
C:\matlab\myfiles
```

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the current folder in `cmdout`.

Save UNIX Command Exit Status and Output

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';
[status,cmdout] = unix(command);
status
```

```
status =

     0
```

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

Limitations

- DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `system` with a DOS `command` that relies on the current folder fails. To work around this limitation, change the folder to a mapped drive before calling `system`.

Algorithms

On UNIX, MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the `command` argument (for example, `'notepad &'` on a Windows platform, or `'emacs &'` on UNIX). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

  Note If `command` includes the trailing `&` character, `cmdout` is empty.

- On a UNIX system, the `system` function redirects `stdin` to the invoked command, `command`, by default. This redirection also forwards MATLAB script commands and the keyboard type-ahead buffer to the invoked command while the `system` function executes. This can lead to corrupted output when `system` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

Concepts

- "Running External Commands, Scripts, and Programs"

Purpose

Tangent of argument in radians

Syntax

```
Y = tan(X)
```

Description

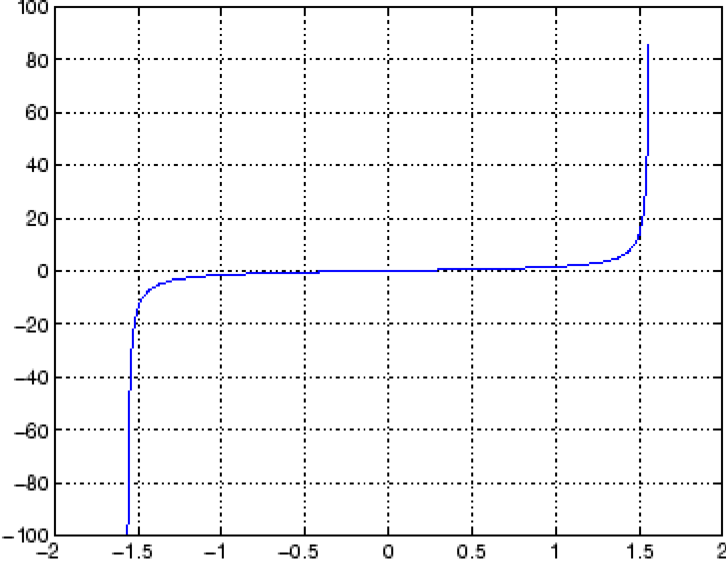
The `tan` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = tan(X)` returns the circular tangent of each element of `X`.

Examples

Graph the tangent function over the domain $-\pi/2 < x < \pi/2$.

```
x = (-pi/2)+0.01:0.01:(pi/2)-0.01;
plot(x,tan(x)), grid on
```



The expression `tan(pi/2)` does not evaluate as infinite but as the reciprocal of the floating point accuracy `eps` since `pi` is only a floating-point approximation to the exact value of π.

See Also

`tand` | `tanh` | `atan` | `atan2` | `atand` | `atan2d`

tand

Purpose Tangent of argument in degrees

Syntax

```
Y = tand(X)
```

Description

`Y = tand(X)` returns the tangent of the elements of `X`, which are expressed in degrees.

Input Arguments

X - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `tand` operation is element-wise when `X` is nonscalar.

Data Types
single | double
Complex Number Support: Yes

Output Arguments

Y - Tangent of angle

scalar value | vector | matrix | N-D array

Tangent of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Tangent of 90 degrees compared to tangent of /2 radians

`tand(90)` is infinite, whereas `tan(pi/2)` is large but finite.

```
tand(90)

ans =

   Inf

tan(pi/2)

ans =

   1.6331e+16
```

Tangent of vector of complex angles, specified in degrees

```
z = [180+i 15+2i 10+3i];
y = tand(z)
```

```
y =

   0 + 0.0175i   0.2676 + 0.0374i   0.1758 + 0.0539i
```

See Also

atand | tan | atan

Purpose

Hyperbolic tangent

Syntax

```
Y = tanh(X)
```

Description

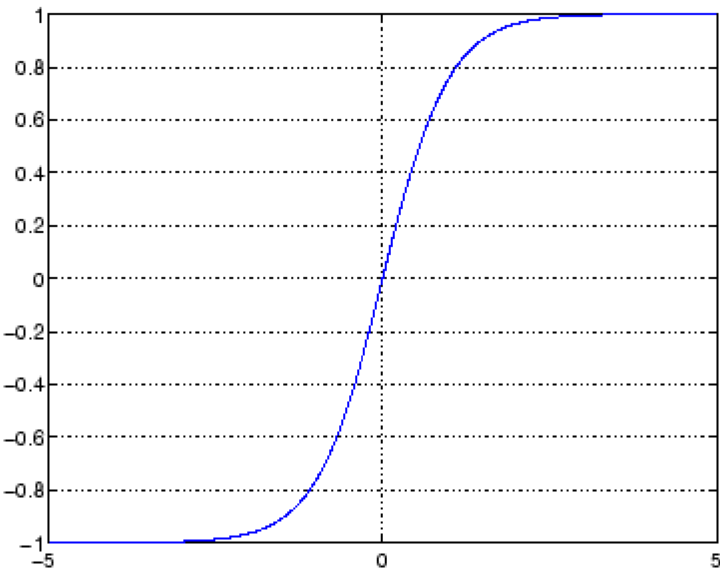
The `tanh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = tanh(X)` returns the hyperbolic tangent of each element of `X`.

Examples

Graph the hyperbolic tangent function over the domain $-5 \le x \le 5$.

```
x = -5:0.01:5;
plot(x,tanh(x)), grid on
```



See Also

`atan` | `atan2` | `tan` | `atanh` | `sinh` | `cosh`

Purpose

Compress files into tar file

Syntax

```
tar(tarfilename,files)
tar(tarfilename,files,rootfolder)
entrynames = tar(...)
```

Description

`tar(tarfilename,files)` creates a tar file named `tarfilename` from the list of files and folders specified in `files`. Folders recursively include all of their content. If `files` includes relative paths, the tar file also contains relative paths. The tar file does not include absolute paths.

`tar(tarfilename,files,rootfolder)` specifies the path for `files` relative to `rootfolder` rather than the current folder. Relative paths in the tar file reflect the relative paths in `files`, and do not include path information from `rootfolder`.

`entrynames = tar(...)` returns a string cell array of the names of the files contained in `tarfilename`. If `files` includes relative paths, `entrynames` also contains relative paths.

Tips

`tar` cannot compress folders larger than 2 GB.

Input Arguments

tarfilename

String specifying the name of the tar file. If `tarfilename` has no extension, MATLAB appends the `.tar` extension. The `tarfilename` extension can end in `.tgz` or `.gz`. In this case, `tarfilename` is gzipped.

files

String or cell array of strings containing the list of files or folders included in `tarfilename`.

Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`,

which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

rootfolder

String specifying the path for *`files`*.

Examples

Tar all files in the current folder to the file `backup.tgz`.

```
tar('backup.tgz','.');
```

See Also

`gzip` | `gunzip` | `untar` | `unzip` | `zip`

Purpose

Name of system's temporary folder

Syntax

```
tmp_folder = tempdir
```

Description

`tmp_folder = tempdir` returns the name of the system's temporary folder, if one exists. This function does not create a new folder.

See Also

`delete` | `recycle` | `tempname`

How To

- "Creating Temporary Files"

tempname

Purpose Unique name for temporary file

Syntax

```
tmp_nam = tempname
```

Description `tmp_nam = tempname` returns a unique string, `tmp_nam`, suitable for use as a temporary filename.

Note The filename that `tempname` generates is not guaranteed to be unique; however, it is likely to be so.

See Also `tempdir`

How To

- “Creating Temporary Files”

Purpose

Tetrahedron mesh plot

Syntax

```
tetramesh(T,X,c)
tetramesh(T,X)
tetramesh(TR)
h = tetramesh(...)
tetramesh(...,'param','value','param','value'...)
```

Description

`tetramesh(T,X,c)` displays the tetrahedrons defined in the `m`-by-4 matrix `T` as mesh. `T` is usually the output of a Delaunay triangulation of a 3-D set of points. A row of `T` contains indices into `X` of the vertices of a tetrahedron. `X` is an `n`-by-3 matrix, representing `n` points in 3 dimension. The tetrahedron colors are defined by the vector `C`, which is used as indices into the current colormap.

`tetramesh(T,X)` uses `C = 1:m` as the color for the `m` tetrahedra. Each tetrahedron has a different color (modulo the number of colors available in the current colormap).

`tetramesh(TR)` displays the tetrahedra in a triangulation representation.

`h = tetramesh(...)` returns a vector of tetrahedron handles. Each element of `h` is a handle to the set of patches forming one tetrahedron. You can use these handles to view a particular tetrahedron by turning the patch `'Visible'` property `'on'` or `'off'`.

`tetramesh(...,'param','value','param','value'...)` allows additional patch property name/property value pairs to be used when displaying the tetrahedrons. For example, the default transparency parameter is set to `0.9`. You can overwrite this value by using the property name/property value pair `('FaceAlpha',value)` where `value` is a number between `0` and `1`. See `Patch Properties` for information about the available properties.

Examples

Generate a 3-D Delaunay triangulation, then use `tetramesh` to visualize the tetrahedrons.

```
d = [-1 1];
```

```
[x,y,z] = meshgrid(d,d,d); % a cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x,y,z] are corners of a cube plus the center.
DT = delaunayTriangulation(x,y,z);
tetramesh(DT);
camorbit(20,0)
```

matlab.unittest.Test

Superclasses

TestSuite

Purpose

Specification of a single test method

Description

The matlab.unittest.Test class holds the information needed for the TestRunner object to be able to run a single Test method of a TestCase class. A scalar Test instance is the fundamental element contained in TestSuite arrays. A simple array of Test instances is a commonly used form of a TestSuite array.

Properties

Name

Name of the Test element.

Attributes:

Dependent	true
GetAccess	public
SetAccess	immutable

Examples

Show Class of a TestSuite Array

Create a suite of Test objects of all test methods in the `BankAccountTest` class.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?BankAccountTest);

whos suite
```

```
  Name       Size             Bytes  Class                    Attributes

  suite      1x5               1636  matlab.unittest.Test
```

Each test is a matlab.unittest.Test object.

Display test method names.

```
{suite.Name}'

ans =

    'BankAccountTest/testConstructor'
    'BankAccountTest/testConstructorNotEnoughInputs'
    'BankAccountTest/testDesposit'
    'BankAccountTest/testWithdraw'
    'BankAccountTest/testNotifyInsufficientFunds'
```

See Also

`matlab.unittest.TestSuite` | `matlab.unittest.TestRunner` |

Concepts

- Property Attributes

matlab.unittest.TestCase

Purpose

Superclass of all `matlab.unittest` test classes

Description

The TestCase class is the means by which a test is written in the `matlab.unittest` framework. It provides the means to write and identify test content, as well as test fixture setup and teardown routines. Creating such a test requires deriving from TestCase to produce a TestCase subclass. Then, subclasses can leverage the metadata attributes to specify tests and test fixtures.

Construction

The matlab.unittest.TestRunner class constructs instances of the TestCase class.

Methods

addTeardown	Dynamically add teardown routine
assertClass	Assert exact class of specified value
assertEmpty	Assert value is empty
assertEqual	Assert value is equal to specified value
assertError	Assert function throws specified exception
assertFail	Produce unconditional assertion failure
assertFalse	Assert value is false
assertGreaterThan	Assert value is greater than specified value
assertGreaterThanOrEqual	Assert value is greater than or equal to specified value
assertInstanceOf	Assert value is object of specified type

assertLength	Assert value has specified length
assertLessThan	Assert value is less than specified value
assertLessThanOrEqual	Assert value is less than or equal to specified value
assertMatches	Assert string matches specified regular expression
assertNotEmpty	Assert value is not empty
assertNotEqual	Assert value is not equal to specified value
assertNotSameHandle	Assert value is not handle to specified instance
assertNumElements	Assert value has specified element count
assertReturnsTrue	Assert function returns true when evaluated
assertSameHandle	Assert two values are handles to same instance
assertSize	Assert value has specified size
assertSubstring	Assert string contains specified string
assertThat	Assert that value meets specified constraint
assertTrue	Assert value is true
assertWarning	Assert function issues specified warning
assertWarningFree	Assert function issues no warnings

assumeClass	Assume exact class of specified value
assumeEmpty	Assume value is empty
assumeEqual	Assume value is equal to specified value
assumeError	Assume function throws specified exception
assumeFail	Produce unconditional assumption failure
assumeFalse	Assume value is false
assumeGreaterThan	Assume value is greater than specified value
assumeGreaterThanOrEqual	Assume value is greater than or equal to specified value
assumeInstanceOf	Assume value is object of specified type
assumeLength	Assume value has specified length
assumeLessThan	Assume value is less than specified value
assumeLessThanOrEqual	Assume value is less than or equal to specified value
assumeMatches	Assume string matches specified regular expression
assumeNotEmpty	Assume value is not empty
assumeNotEqual	Assume value is not equal to specified value
assumeNotSameHandle	Assume value is not handle to specified instance

assumeNumElements	Assume value has specified element count
assumeReturnsTrue	Assume function returns true when evaluated
assumeSameHandle	Assume two values are handles to same instance
assumeSize	Assume value has specified size
assumeSubstring	Assume string contains specified string
assumeThat	Assume value meets specified constraint
assumeTrue	Assume value is true
assumeWarning	Assume function issues specified warning
assumeWarningFree	Assume function issues no warnings
fatalAssertClass	Fatally assert exact class of specified value
fatalAssertEmpty	Fatally assert value is empty
fatalAssertEqual	Fatally assert value is equal to specified value
fatalAssertError	Fatally assert function throws specified exception
fatalAssertFail	Produce unconditional fatal assertion failure
fatalAssertFalse	Fatally assert value is false
fatalAssertGreaterThan	Fatally assert value is greater than specified value

fatalAssertGreaterThanOrEqual	Fatally assert value is greater than or equal to specified value
fatalAssertInstanceOf	Fatally assert value is object of specified type
fatalAssertLength	Fatally assert value has specified length
fatalAssertLessThan	Fatally assert value is less than specified value
fatalAssertLessThanOrEqual	Fatally assert value is less than or equal to specified value
fatalAssertMatches	Fatally assert string matches specified regular expression
fatalAssertNotEmpty	Fatally assert value is not empty
fatalAssertNotEqual	Fatally assert value is not equal to specified value
fatalAssertNotSameHandle	Fatally assert value is not handle to specified instance
fatalAssertNumElements	Fatally assert value has specified element count
fatalAssertReturnsTrue	Fatally assert function returns true when evaluated
fatalAssertSameHandle	Fatally assert two values are handles to same instance
fatalAssertSize	Fatally assert value has specified size
fatalAssertSubstring	Fatally assert string contains specified string
fatalAssertThat	Fatally assert value meets specified constraint
fatalAssertTrue	Fatally assert value is true

fatalAssertWarning	Fatally assert function issues specified warning
fatalAssertWarningFree	Fatally assert function issues no warnings
run	Run `TestCase` test
verifyClass	Verify exact class of specified value
verifyEmpty	Verify value is empty
verifyEqual	Verify value is equal to specified value
verifyError	Verify function throws specified exception
verifyFail	Produce unconditional verification failure
verifyFalse	Verify value is false
verifyGreaterThan	Verify value is greater than specified value
verifyGreaterThanOrEqual	Verify value is greater than or equal to specified value
verifyInstanceOf	Verify value is object of specified type
verifyLength	Verify value has specified length
verifyLessThan	Verify value is less than specified value
verifyLessThanOrEqual	Verify value is less than or equal to specified value
verifyMatches	Verify string matches specified regular expression
verifyNotEmpty	Verify value is not empty

verifyNotEqual	Verify value is not equal to specified value
verifyNotSameHandle	Verify value is not handle to specified instance
verifyNumElements	Verify value has specified element count
verifyReturnsTrue	Verify function returns true when evaluated
verifySameHandle	Verify two values are handles to same instance
verifySize	Verify value has specified size
verifySubstring	Verify string contains specified string
verifyThat	Verify value meets given constraint
verifyTrue	Verify value is true
verifyWarning	Verify function issues specified warning
verifyWarningFree	Verify function issues no warnings

Attributes

Classes that derive from TestCase can define methods blocks which contain `matlab.unittest` framework-specific attributes to specify test content.

`Test`	`Method block to contain test methods.`
`TestMethodSetup`	`Method block to contain setup code.`

`TestMethodTeardown`	Method block to contain teardown code.
`TestClassSetup`	Method block to contain class level setup code.
`TestClassTeardown`	Method block to contain class level teardown code.

Examples

Create Test Case Class

Create a test case class, `FigurePropertiesTest`, with `TestMethodSetup` and `TestMethodTeardown` methods.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase

    properties
        TestFigure
    end

    methods(TestMethodSetup)
        function createFigure(testCase)
            testCase.TestFigure = figure;
        end
    end

    methods(TestMethodTeardown)
        function closeFigure(testCase)
            close(testCase.TestFigure);
        end
    end

    methods(Test)

        function defaultCurrentPoint(testCase)

            cp = get(testCase.TestFigure, 'CurrentPoint');
            testCase.verifyEqual(cp, [0 0], ...
```

```
                'Default current point is incorrect')
        end

        function defaultCurrentObject(testCase)
            import matlab.unittest.constraints.IsEmpty;

            co = get(testCase.TestFigure, 'CurrentObject');
            testCase.verifyThat(co, IsEmpty, ...
                'Default current object should be empty');
        end

    end

end
```

See Also `TestRunner` |

Concepts

- "Method Attributes"

Purpose

Dynamically add teardown routine

Syntax

```
addTeardown(testCase,tearDownFcn)
addTeardown(testCase,tearDownFcn,arg1,...,argN)
```

Description

`addTeardown(testCase,tearDownFcn)` adds the `tearDownFcn` function handle that defines fixture teardown code to the `testCase` instance. The teardown code is executed in the reverse order to which it is added. This is known as LIFO (or Last-In-First-Out).

`addTeardown(testCase,tearDownFcn,arg1,...,argN)`

Input Arguments

testCase

matlab.unittest.TestCase instance

tearDownFcn

Function, specified as a function handle, that defines the fixture teardown code

arg1,...,argN

Input arguments, 1 through N (if any), required by `tearDownFcn`, specified by any type. The argument type is specified by the function argument list.

Examples

Call addTeardown in a TestMethodSetup Method

```
classdef SomeTest < matlab.unittest.TestCase

    methods(TestMethodSetup)
        function createFixture(testCase)
            p = path;
            testCase.addTeardown(@path, p);
            addpath(fullfile(pwd,'testHelpers'));
        end
    end
end
```

matlab.unittest.TestCase.assertClass

Purpose

Assert exact class of specified value

Syntax

```
assertClass(assertable,actual,className)
assertClass(assertable,actual,metaClass)
assertClass( ___ ,diagnostic)
```

Description

`assertClass(assertable,actual,className)` asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`assertClass(assertable,actual,metaClass)` asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. See `assertInstanceOf` to assert inclusion in a class hierarchy.

`assertClass( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- The method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsOfClass;
  assertable.assertThat(actual, IsOfClass(className));
  assertable.assertThat(actual, IsOfClass(metaClass));
  ```

  There exists more functionality when using the `IsOfClass` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

className

Name of class, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyClass`.

See Also

`assertThat` | `assertInstanceOf` |

matlab.unittest.TestCase.assertEmpty

Purpose

Assert value is empty

Syntax

```
assertEmpty(assertable,actual)
assertEmpty(assertable,actual,diagnostic)
```

Description

`assertEmpty(assertable,actual)` asserts that `actual` is an empty MATLAB value.

`assertEmpty(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  assertable.assertThat(actual, IsEmpty());
  ```

  This method is a convenience method. There exists more functionality when using the `IsEmpty` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyEmpty`.

See Also

`assertThat` | `assertNotEmpty` | `isempty`

matlab.unittest.TestCase.assertEqual

Purpose Assert value is equal to specified value

Syntax

```
assertEqual(assertable,actual,expected)
assertEqual( ___ ,Name,Value)
assertEqual( ___ ,diagnostic)
```

Description

`assertEqual(assertable,actual,expected)` asserts that `actual` is strictly equal to `expected`.

`assertEqual( ___ ,Name,Value)` asserts equality with additional options specified by one or more `Name,Value` pair arguments.

`assertEqual( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assertable.assertThat(actual, IsEqualTo(expected));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
    'Within', RelativeTolerance(reltol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

expected

Expected value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'AbsTol'

'RelTol'

matlab.unittest.TestCase.assertEqual

Examples See examples for `verifyEqual`.

See Also `assertThat` | `assertNotEqual` |

Purpose

Assert function throws specified exception

Syntax

```
assertError(assertable,actual,identifier)
assertError(assertable,actual,metaClass)
assertError( ___ ,diagnostic)
```

Description

`assertError(assertable,actual,identifier)` asserts that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`assertError(assertable,actual,metaClass)` asserts that `actual` is a function handle that throws an exception whose type is defined by the meta.class instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the MException class.

`assertError( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Throws;
  assertable.assertThat(actual, Throws(identifier));
  assertable.assertThat(actual, Throws(metaClass));
  ```

  There exists more functionality when using the `Throws` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

identifier

Error identifier, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyError`.

See Also

`assertThat` | `assertWarning` | `MException` | `error`

matlab.unittest.TestCase.assertFail

Purpose

Produce unconditional assertion failure

Syntax

```
assertFail(assertable)
assertFail(assertable,diagnostic)
```

Description

`assertFail(assertable)` produces an unconditional assertion failure when encountered.

`assertFail(assertable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `matlab.unittest.TestCase.verifyFail`.

matlab.unittest.TestCase.assertFalse

Purpose

Assert value is false

Syntax

```
assertFalse(assertable,actual)
assertFalse(assertable,actual,diagnostic)
```

Description

`assertFalse(assertable,actual)` asserts that `actual` is a scalar logical with the value of false.

`assertFalse(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsFalse;
  assertable.assertThat(actual, IsFalse());
  ```

  There exists more functionality when using the `IsFalse` constraint directly via assertThat.
- Unlike assertTrue, this method may create a new constraint for each call. For performance critical uses, consider using assertTrue.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

For examples, see `verifyFalse`.

See Also

`assertThat` | `assertTrue` |

matlab.unittest.TestCase.assertGreaterThan

Purpose

Assert value is greater than specified value

Syntax

```
assertGreaterThan(assertable,actual,floor)
assertGreaterThan(assertable,actual,floor,diagnostic)
```

Description

`assertGreaterThan(assertable,actual,floor)` asserts that all elements of `actual` are greater than all the elements of `floor`.

`assertGreaterThan(assertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThan;
assertable.assertThat(actual, IsGreaterThan(floor));
```

  There exists more functionality when using the `IsGreaterThan` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

floor

Minimum value, exclusive.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyGreaterThan`.

See Also

`assertThat` | `assertGreaterThanOrEqual` | `assertLessThan` | `assertLessThanOrEqual` | `gt`

matlab.unittest.TestCase.assertGreaterThanOrEqual

Purpose

Assert value is greater than or equal to specified value

Syntax

```
assertGreaterThanOrEqual(assertable,actual,floor)
assertGreaterThanOrEqual(assertable,actual,floor,diagnostic)
```

Description

`assertGreaterThanOrEqual(assertable,actual,floor)` asserts that all elements of `actual` are greater than or equal to all the elements of `floor`.

`assertGreaterThanOrEqual(assertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
  assertable.assertThat(actual, IsGreaterThanOrEqualTo(floor));
  ```

  There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

floor

Minimum value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyGreaterThanOrEqual`.

See Also

`assertThat` | `assertGreaterThan` | `assertLessThanOrEqual` | `assertLessThan` | `ge`

matlab.unittest.TestCase.assertInstanceOf

Purpose

Assert value is object of specified type

Syntax

```
assertInstanceOf(assertable,actual,className)
assertInstanceOf(assertable,actual,metaClass)
assertInstanceOf( ___ ,diagnostic)
```

Description

`assertInstanceOf(assertable,actual,className)` asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`assertInstanceOf(assertable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`assertInstanceOf( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  assertable.assertThat(actual, IsInstanceOf(className));
  assertable.assertThat(actual, IsInstanceOf(metaClass));
  ```

  There exists more functionality when using the `IsInstanceOf` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

className

Name of class, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyInstanceOf`.

See Also

`assertThat` | `assertClass` | `isa`

matlab.unittest.TestCase.assertLength

Purpose

Assert value has specified length

Syntax

```
assertLength(assertable,actual,expectedLength)
assertLength(assertable,actual,expectedLength,diagnostic)
```

Description

`assertLength(assertable,actual,expectedLength)` that `actual` is a MATLAB array whose length is `expectedLength`.

`assertLength(assertable,actual,expectedLength,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
assertable.assertThat(actual, HasLength(expectedLength));
```

  There exists more functionality when using the `HasLength` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

expectedLength

The length of an array is defined as the largest dimension of that array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyLength`.

See Also

`assertThat` | `assertSize` | `assertNumElements` | `length`

matlab.unittest.TestCase.assertLessThan

Purpose

Assert value is less than specified value

Syntax

```
assertLessThan(assertable,actual,ceiling)
assertLessThan(assertable,actual,ceiling,diagnostic)
```

Description

`assertLessThan(assertable,actual,ceiling)` asserts that all elements of `actual` are less than all the elements of `ceiling`.

`assertLessThan(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThan;
  assertable.assertThat(actual, IsLessThan(ceiling));
  ```

  There exists more functionality when using the `IsLessThan` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

ceiling

Maximum value, exclusive.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyLessThan`.

See Also

`assertThat` | `assertLessThanOrEqual` | `assertGreaterThan` | `assertGreaterThanOrEqual` | `lt`

matlab.unittest.TestCase.assertLessThanOrEqual

Purpose

Assert value is less than or equal to specified value

Syntax

```
assertLessThanOrEqual(assertable,actual,ceiling)
assertLessThanOrEqual(assertable,actual,ceiling,diagnostic)
```

Description

`assertLessThanOrEqual(assertable,actual,ceiling)` asserts that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`assertLessThanOrEqual(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThanOrEqualTo;
  assertable.assertThat(actual, IsLessThanOrEqualTo(ceiling));
  ```

  There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

ceiling

Maximum value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyLessThanOrEqual`.

See Also

`assertThat` | `assertLessThan` | `assertGreaterThan` | `assertGreaterThanOrEqual` | `le`

matlab.unittest.TestCase.assertMatches

Purpose

Assert string matches specified regular expression

Syntax

```
assertMatches(assertable,actual,expression)
assertMatches(assertable,actual,expression,diagnostic)
```

Description

`assertMatches(assertable,actual,expression)` asserts that `actual` is a string that matches the regular expression defined by `expression`.

`assertMatches(assertable,actual,expression,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Matches;
  assertable.assertThat(actual, Matches(expression));
  ```

  There exists more functionality when using the `Matches` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

expression

The value to match, specified as a regular expression.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyMatches`.

See Also

`assertThat` | `assertSubstring` | `regexp`

matlab.unittest.TestCase.assertNotEmpty

Purpose

Assert value is not empty

Syntax

```
assertNotEmpty(assertable,actual)
assertNotEmpty(assertable,actual,diagnostic)
```

Description

`assertNotEmpty(assertable,actual)` asserts that `actual` is a non-empty MATLAB value.

`assertNotEmpty(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  assertable.assertThat(actual, ~IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNotEmpty`.

See Also

`assertThat` | `assertEmpty` | `isempty`

matlab.unittest.TestCase.assertNotEqual

Purpose

Assert value is not equal to specified value

Syntax

```
assertNotEqual(assertable,actual,notExpected)
assertNotEqual(assertable,actual,notExpected,diagnostic)
```

Description

`assertNotEqual(assertable,actual,notExpected)` asserts that `actual` is not equal to `notExpected`.

`assertNotEqual(assertable,actual,notExpected,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEqualTo;
  assertable.assertThat(actual, ~IsEqualTo(notExpected));
  ```

  There exists more functionality when using the `IsEqualTo` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

notExpected

Value to compare.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNotEqual`.

See Also

`assertThat` | `assertEqual` |

matlab.unittest.TestCase.assertNotSameHandle

Purpose

Assert value is not handle to specified instance

Syntax

```
assertNotSameHandle(assertable,actual,notExpectedHandle)
assertNotSameHandle(assertable,actual,notExpectedHandle,
    diagnostic)
```

Description

`assertNotSameHandle(assertable,actual,notExpectedHandle)` asserts that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`assertNotSameHandle(assertable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  assertable.assertThat(actual, ~IsSameHandleAs(notExpectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

notExpectedHandle

The handle array to compare.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNotSameHandle`.

See Also

`assertThat` | `assertSameHandle` |

matlab.unittest.TestCase.assertNumElements

Purpose

Assert value has specified element count

Syntax

```
assertNumElements(assertable,actual,expectedElementCount)
assertNumElements(assertable,actual,expectedElementCount,
   diagnostic)
```

Description

`assertNumElements(assertable,actual,expectedElementCount)` asserts that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`assertNumElements(assertable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
assertable.assertThat(actual, HasElementCount(expectedElementCount));
```

  There exists more functionality when using the `HasElementCount` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

expectedElementCount

The expected number of elements in the array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNumElements`.

See Also

`assertThat` | `assertSize` | `assertLength` | `numel`

matlab.unittest.TestCase.assertReturnsTrue

Purpose

Assert function returns true when evaluated

Syntax

```
assertReturnsTrue(assertable,actual)
assertReturnsTrue(assertable,actual,diagnostic)
```

Description

`assertReturnsTrue(assertable,actual)` asserts that `actual` is a function handle that returns a scalar logical whose value is true.

`assertReturnsTrue(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using assertTrue because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using assertTrue.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ReturnsTrue;
  assertable.assertThat(actual, ReturnsTrue());
  ```

  There exists more functionality when using the `ReturnsTrue` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The function handle to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyReturnsTrue`.

See Also

`assertThat` | `assertTrue` |

matlab.unittest.TestCase.assertSameHandle

Purpose

Assert two values are handles to same instance

Syntax

```
assertSameHandle(assertable,actual,expectedHandle)
assertSameHandle(assertable,actual,expectedHandle,diagnostic)
```

Description

`assertSameHandle(assertable,actual,expectedHandle)` asserts that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`assertSameHandle(assertable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  assertable.assertThat(actual, IsSameHandleAs(expectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

expectedHandle

The expected handle array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifySameHandle`.

See Also

`assertThat` | `assertNotSameHandle` | `handle`

matlab.unittest.TestCase.assertSize

Purpose

Assert value has specified size

Syntax

```
assertSize(assertable,actual,expectedSize)
assertSize(assertable,actual,expectedSize,diagnostic)
```

Description

`assertSize(assertable,actual,expectedSize)` asserts that `actual` is a MATLAB array whose size is `expectedSize`.

`assertSize(assertable,actual,expectedSize,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasSize;
assertable.assertThat(actual, HasSize(expectedSize));
```

  There exists more functionality when using the `HasSize` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

expectedSize

The expected sizes of each dimension the array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifySize`.

See Also

`assertThat` | `assertLength` | `assertNumElements` | `size`

matlab.unittest.TestCase.assertSubstring

Purpose

Assert string contains specified string

Syntax

```
assertSubstring(assertable,actual,substring)
assertSubstring(assertable,actual,substring,diagnostic)
```

Description

`assertSubstring(assertable,actual,substring)` asserts that `actual` is a string that contains `substring`.

`assertSubstring(assertable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ContainsSubstring;
  assertable.assertThat(actual, ContainsSubstring(substring));
  ```

  There exists more functionality when using the `ContainsSubstring` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

substring

The value to match, specified as a string.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifySubstring`.

See Also

`assertThat` | `assertMatches` | `strfind`

matlab.unittest.TestCase.assertThat

Purpose

Assert that value meets specified constraint

Syntax

```
assertThat(assertable,actual,constraint)
assertThat(assertable,actual,constraint,diagnostic)
```

Description

`assertThat(assertable,actual,constraint)` asserts that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, an assertion failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`assertThat(assertable,actual,constraint,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

constraint

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyThat`.

matlab.unittest.TestCase.assertTrue

Purpose Assert value is true

Syntax

```
assertTrue(assertable,actual)
assertTrue(assertable,actual,diagnostic)
```

Description

`assertTrue(assertable,actual)` asserts that `actual` is a scalar logical with the value of true.

`assertTrue(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and non-zero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsTrue;
  assertable.assertThat(actual, IsTrue());
  ```

  There exists more functionality when using the `IsTrue` constraint directly via assertThat.

  Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as IsEqualTo. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of assertReturnsTrue, which at least shows the display of the function evaluated to generate the failing result.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyTrue`.

See Also

`assertThat` | `assertFalse` | `assertReturnsTrue` |

matlab.unittest.TestCase.assertWarning

Purpose

Assert function issues specified warning

Syntax

```
assertWarning(assertable,actual,warningID)
assertWarning(assertable,actual,warningID,diagnostic)
[output1,...,outputN] = assertWarning( ___ )
```

Description

`assertWarning(assertable,actual,warningID)` asserts that `actual` issues a warning with the identifier `warningID`.

`assertWarning(assertable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assertWarning( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesWarnings;
  assertable.assertThat(actual, IssuesWarnings({warningID}));
  ```

  There exists more functionality when using the `IssuesWarnings` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The function handle to test.

warningID

Warning ID, specified as a string.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Output Arguments

output1,...,outputN

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

Examples

See examples for `verifyWarning`.

See Also

`assertThat` | `assertError` | `assertWarningFree` | `warning`

matlab.unittest.TestCase.assertWarningFree

Purpose

Assert function issues no warnings

Syntax

```
assertWarningFree(assertable,actual)
assertWarningFree(assertable,actual,diagnostic)
[output1,...,outputN] = assertWarningFree( ___ )
```

Description

`assertWarningFree(assertable,actual)` asserts that `actual` is a function handle that issues no warnings.

`assertWarningFree(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assertWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesNoWarnings;
  assertable.assertThat(actual, IssuesNoWarnings());
  ```

  There exists more functionality when using the `IssuesNoWarnings` constraint directly via assertThat.

Input Arguments

assertable

The matlab.unittest.TestCase instance which is used to pass or fail the assertion in conjunction with the test running framework.

actual

The function handle to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Output Arguments

output1,...,outputN

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

Examples

See examples for `verifyWarningFree`.

See Also

`assertThat` | `assertWarning` | `warning`

matlab.unittest.TestCase.assumeClass

Purpose

Assume exact class of specified value

Syntax

```
assumeClass(assumable,actual,className)
assumeClass(assumable,actual,metaClass)
assumeClass(___,diagnostic)
```

Description

`assumeClass(assumable,actual,className)` assumes that `actual` is a MATLAB value whose class is the class specified by `className`.

`assumeClass(assumable,actual,metaClass)` assumes that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. See assumeInstanceOf to assume inclusion in a class hierarchy.

`assumeClass(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- The method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsOfClass;
  assumable.assumeThat(actual, IsOfClass(className));
  assumable.assumeThat(actual, IsOfClass(metaClass));
  ```

  There exists more functionality when using the `IsOfClass` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

className

Name of class, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyClass`.

See Also

`assumeThat` | `assumeInstanceOf` |

matlab.unittest.TestCase.assumeEmpty

Purpose

Assume value is empty

Syntax

```
assumeEmpty(assumable,actual)
assumeEmpty(assumable,actual,diagnostic)
```

Description

`assumeEmpty(assumable,actual)` assumes that `actual` is an empty MATLAB value.

`assumeEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  assumable.assumeThat(actual, IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyEmpty`.

See Also

`assumeThat` | `assumeNotEmpty` | `isempty`

matlab.unittest.TestCase.assumeEqual

Purpose Assume value is equal to specified value

Syntax

```
assumeEqual(assumable,actual,expected)
assumeEqual( ___ ,Name,Value)
assumeEqual( ___ ,diagnostic)
```

Description

`assumeEqual(assumable,actual,expected)` assumes that `actual` is strictly equal to `expected`.

`assumeEqual( ___ ,Name,Value)` assumes equality with additional options specified by one or more `Name,Value` pair arguments.

`assumeEqual( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assumable.assumeThat(actual, IsEqualTo(expected));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
    'Within', RelativeTolerance(reltol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

expected

Expected value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'AbsTol'

'RelTol'

Examples

See examples for `verifyEqual`.

See Also

`assumeThat` | `assumeNotEqual` |

Purpose

Assume function throws specified exception

Syntax

```
assumeError(assumable,actual,identifier)
assumeError(assumable,actual,metaClass)
assumeError( ___ ,diagnostic)
```

Description

`assumeError(assumable,actual,identifier)` assumes that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`assumeError(assumable,actual,metaClass)` assumes that `actual` is a function handle that throws an exception whose type is defined by the meta.class instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the MException class.

`assumeError( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Throws;
  assumable.assumeThat(actual, Throws(identifier));
  assumable.assumeThat(actual, Throws(metaClass));
  ```

  There exists more functionality when using the `Throws` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

identifier

Error identifier, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyError`.

See Also

`assumeThat` | `assumeWarning` | `MException` | `error`

Purpose

Produce unconditional assumption failure

Syntax

```
assumeFail(assumable)
assumeFail(assumable,diagnostic)
```

Description

`assumeFail(assumable)` produces an unconditional assumption failure when encountered.

`assumeFail(assumable,diagnostic)`also displays the diagnostic information in `diagnostic` upon a failure.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `matlab.unittest.TestCase.verifyFail`.

matlab.unittest.TestCase.assumeFalse

Purpose

Assume value is false

Syntax

```
assumeFalse(assumable,actual)
assumeFalse(assumable,actual,diagnostic)
```

Description

`assumeFalse(assumable,actual)` assumes that `actual` is a scalar logical with the value of false.

`assumeFalse(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsFalse;
  assumable.assumeThat(actual, IsFalse());
  ```

  There exists more functionality when using the `IsFalse` constraint directly via assumeThat.
- Unlike assumeTrue, this method may create a new constraint for each call. For performance critical uses, consider using assumeTrue.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

For examples, see `verifyFalse`.

See Also

`assumeThat` | `assumeTrue` |

matlab.unittest.TestCase.assumeGreaterThan

Purpose

Assume value is greater than specified value

Syntax

```
assumeGreaterThan(assumable,actual,floor)
assumeGreaterThan(assumable,actual,floor,diagnostic)
```

Description

`assumeGreaterThan(assumable,actual,floor)` assumes that all elements of `actual` are greater than all the elements of `floor`.

`assumeGreaterThan(assumable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThan;
  assumable.assumeThat(actual, IsGreaterThan(floor));
  ```

  There exists more functionality when using the `IsGreaterThan` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

floor

Minimum value, exclusive.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyGreaterThan`.

See Also

`assumeThat` | `assumeGreaterThanOrEqual` | `assumeLessThanOrEqual` | `assumeLessThan` | `gt`

matlab.unittest.TestCase.assumeGreaterThanOrEqual

Purpose

Assume value is greater than or equal to specified value

Syntax

```
assumeGreaterThanOrEqual(assumable,actual,floor)
assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)
```

Description

`assumeGreaterThanOrEqual(assumable,actual,floor)` assumes that all elements of `actual` are greater than or equal to all the elements of `floor`.

`assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
  assumable.assumeThat(actual, IsGreaterThanOrEqualTo(floor));
  ```

  There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

floor

Minimum value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyGreaterThanOrEqual`.

See Also

`assumeThat` | `assumeGreaterThan` | `assumeLessThanOrEqual` | `assumeLessThan` | `ge`

matlab.unittest.TestCase.assumeInstanceOf

Purpose

Assume value is object of specified type

Syntax

```
assumeInstanceOf(assumable,actual,className)
assumeInstanceOf(assumable,actual,metaClass)
assumeInstanceOf( ___ ,diagnostic)
```

Description

`assumeInstanceOf(assumable,actual,className)` assumes that `actual` is a MATLAB value whose class is the class specified by `className`.

`assumeInstanceOf(assumable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`assumeInstanceOf( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsInstanceOf;
  assumable.assumeThat(actual, IsInstanceOf(className));
  assumable.assumeThat(actual, IsInstanceOf(metaClass));
  ```

  There exists more functionality when using the `IsInstanceOf` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

className

Name of class, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyInstanceOf`.

See Also

`assumeThat` | `assumeClass` | `isa`

matlab.unittest.TestCase.assumeLength

Purpose

Assume value has specified length

Syntax

```
assumeLength(assumable,actual,expectedLength)
assumeLength(assumable,actual,expectedLength,diagnostic)
```

Description

`assumeLength(assumable,actual,expectedLength)` assumes that `actual` is a MATLAB array whose length is `expectedLength`.

`assumeLength(assumable,actual,expectedLength,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasLength;
  assumable.assumeThat(actual, HasLength(expectedLength));
  ```

  There exists more functionality when using the `HasLength` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

expectedLength

The length of an array is defined as the largest dimension of that array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyLength`.

See Also

`assumeThat` | `assumeSize` | `assumeNumElements` | `length`

matlab.unittest.TestCase.assumeLessThan

Purpose

Assume value is less than specified value

Syntax

```
assumeLessThan(assumable,actual,ceiling)
assumeLessThan(assumable,actual,ceiling,diagnostic)
```

Description

`assumeLessThan(assumable,actual,ceiling)` assumes that all elements of `actual` are less than all the elements of `ceiling`.

`assumeLessThan(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThan;
  assumable.assumeThat(actual, IsLessThan(ceiling));
  ```

  There exists more functionality when using the `IsLessThan` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

ceiling

Maximum value, exclusive.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyLessThan`.

See Also

`assumeThat` | `assumeLessThanOrEqual` | `assumeGreaterThan` | `assumeGreaterThanOrEqual` | `lt`

matlab.unittest.TestCase.assumeLessThanOrEqual

Purpose

Assume value is less than or equal to specified value

Syntax

```
assumeLessThanOrEqual(assumable,actual,ceiling)
assumeLessThanOrEqual(assumable,actual,ceiling,diagnostic)
```

Description

`assumeLessThanOrEqual(assumable,actual,ceiling)` assumes that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`assumeLessThanOrEqual(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThanOrEqualTo;
  assumable.assumeThat(actual, IsLessThanOrEqualTo(ceiling));
  ```

  There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

ceiling

Maximum value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyLessThanOrEqual`.

See Also

`assumeThat` | `assumeLessThan` | `assumeGreaterThan` | `assumeGreaterThanOrEqual` | `le`

matlab.unittest.TestCase.assumeMatches

Purpose

Assume string matches specified regular expression

Syntax

```
assumeMatches(assumable,actual,expression)
assumeMatches(assumable,actual,expression,diagnostic)
```

Description

`assumeMatches(assumable,actual,expression)` assumes that `actual` is a string that matches the regular expression defined by `expression`.

`assumeMatches(assumable,actual,expression,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Matches;
  assumable.assumeThat(actual, Matches(expression));
  ```

  There exists more functionality when using the `Matches` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The string to test.

expression

The value to match, specified as a regular expression.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyMatches`.

See Also

`assumeThat` | `assumeSubstring` | `regexp`

matlab.unittest.TestCase.assumeNotEmpty

Purpose

Assume value is not empty

Syntax

```
assumeNotEmpty(assumable,actual)
assumeNotEmpty(assumable,actual,diagnostic)
```

Description

`assumeNotEmpty(assumable,actual)` assumes that `actual` is a non-empty MATLAB value.

`assumeNotEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  assumable.assumeThat(actual, ~IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNotEmpty`.

See Also

`assumeThat` | `assumeEmpty` | `isempty`

matlab.unittest.TestCase.assumeNotEqual

Purpose

Assume value is not equal to specified value

Syntax

```
assumeNotEqual(assumable,actual,notExpected)
assumeNotEqual(assumable,actual,notExpected,diagnostic)
```

Description

`assumeNotEqual(assumable,actual,notExpected)` assumes that `actual` is not equal to `notExpected`.

`assumeNotEqual(assumable,actual,notExpected,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEqualTo;
  assumable.assumeThat(actual, ~IsEqualTo(notExpected));
  ```

  There exists more functionality when using the `IsEqualTo` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

notExpected

Value to compare.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNotEqual`.

See Also

`assumeThat` | `assumeEqual` |

matlab.unittest.TestCase.assumeNotSameHandle

Purpose

Assume value is not handle to specified instance

Syntax

```
assumeNotSameHandle(assumable,actual,notExpectedHandle)
assumeNotSameHandle(assumable,actual,notExpectedHandle,
   diagnostic)
```

Description

`assumeNotSameHandle(assumable,actual,notExpectedHandle)` assumes that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`assumeNotSameHandle(assumable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  assumable.assumeThat(actual, ~IsSameHandleAs(notExpectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

notExpectedHandle

The handle array to compare.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNotSameHandle`.

See Also

`assumeThat` | `assumeSameHandle` |

matlab.unittest.TestCase.assumeNumElements

Purpose

Assume value has specified element count

Syntax

```
assumeNumElements(assumable,actual,expectedElementCount)
assumeNumElements(assumable,actual,expectedElementCount,
   diagnostic)
```

Description

`assumeNumElements(assumable,actual,expectedElementCount)` assumes that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`assumeNumElements(assumable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasElementCount;
  assumable.assumeThat(actual, HasElementCount(expectedElementCount));
  ```

  There exists more functionality when using the `HasElementCount` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

expectedElementCount

The expected number of elements in the array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNumElements`.

See Also

`assumeThat` | `assumeSize` | `assumeLength` | `numel`

matlab.unittest.TestCase.assumeReturnsTrue

Purpose

Assume function returns true when evaluated

Syntax

```
assumeReturnsTrue(assumable,actual)
assumeReturnsTrue(assumable,actual,diagnostic)
```

Description

`assumeReturnsTrue(assumable,actual)` assumes that `actual` is a function handle that returns a scalar logical whose value is true.

`assumeReturnsTrue(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using assumeTrue because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using assumeTrue.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ReturnsTrue;
  assumable.assumeThat(actual, ReturnsTrue());
  ```

  There exists more functionality when using the `ReturnsTrue` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The function handle to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyReturnsTrue`.

See Also

`assumeThat` | `assumeTrue` |

matlab.unittest.TestCase.assumeSameHandle

Purpose

Assume two values are handles to same instance

Syntax

```
assumeSameHandle(assumable,actual,expectedHandle)
assumeSameHandle(assumable,actual,expectedHandle,diagnostic)
```

Description

`assumeSameHandle(assumable,actual,expectedHandle)` assumes that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`assumeSameHandle(assumable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  assumable.assumeThat(actual, IsSameHandleAs(expectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

expectedHandle

The expected handle array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifySameHandle`.

See Also

`assumeThat` | `assumeNotSameHandle` | `handle`

matlab.unittest.TestCase.assumeSize

Purpose

Assume value has specified size

Syntax

```
assumeSize(assumable,actual,expectedSize)
assumeSize(assumable,actual,expectedSize,diagnostic)
```

Description

`assumeSize(assumable,actual,expectedSize)` assumes that `actual` is a MATLAB array whose size is `expectedSize`.

`assumeSize(assumable,actual,expectedSize,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasSize;
assumable.assumeThat(actual, HasSize(expectedSize));
```

  There exists more functionality when using the `HasSize` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

expectedSize

The expected sizes of each dimension the array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifySize`.

See Also

`assumeThat` | `assumeLength` | `assumeNumElements` | `size`

matlab.unittest.TestCase.assumeSubstring

Purpose

Assume string contains specified string

Syntax

```
assumeSubstring(assumable,actual,substring)
assumeSubstring(assumable,actual,substring,diagnostic)
```

Description

`assumeSubstring(assumable,actual,substring)` assumes that `actual` is a string that contains `substring`.

`assumeSubstring(assumable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
assumable.assumeThat(actual, ContainsSubstring(substring));
```

  There exists more functionality when using the `ContainsSubstring` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

substring

The value to match, specified as a string.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifySubstring`.

See Also

`assumeThat` | `assumeMatches` | `strfind`

matlab.unittest.TestCase.assumeThat

Purpose

Assume value meets specified constraint

Syntax

```
assumeThat(assumable,actual,constraint)
assumeThat(assumable,actual,constraint,diagnostic)
```

Description

`assumeThat(assumable,actual,constraint)` assumes that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, an assumption failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`assumeThat(assumable,actual,constraint,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

constraint

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyThat`.

matlab.unittest.TestCase.assumeTrue

Purpose

Assume value is true

Syntax

```
assumeTrue(assumable,actual)
assumeTrue(assumable,actual,diagnostic)
```

Description

`assumeTrue(assumable,actual)` assumes that `actual` is a scalar logical with the value of true.

`assumeTrue(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsTrue;
  assumable.assumeThat(actual, IsTrue());
  ```

  There exists more functionality when using the `IsTrue` constraint directly via assumeThat.

  Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as IsEqualTo. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of assumeReturnsTrue, which at least shows the display of the function evaluated to generate the failing result.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyTrue`.

See Also

`assumeThat` | `assumeFalse` | `assumeReturnsTrue` |

matlab.unittest.TestCase.assumeWarning

Purpose

Assume function issues specified warning

Syntax

```
assumeWarning(assumable,actual,warningID)
assumeWarning(assumable,actual,warningID,diagnostic)
[output1,...,outputN] = assumeWarning( ___ )
```

Description

`assumeWarning(assumable,actual,warningID)` assumes that `actual` issues a warning with the identifier `warningID`.

`assumeWarning(assumable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assumeWarning( ___ )` also return the output arguments `output1,...,outputN` that are produced when invoking `actual`.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesWarnings;
  assumable.assumeThat(actual, IssuesWarnings({warningID}));
  ```

  There exists more functionality when using the `IssuesWarnings` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The function handle to test.

warningID

Warning ID, specified as a string.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Output Arguments

output1,...,outputN

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

Examples

See examples for `verifyWarning`.

See Also

`assumeThat` | `assumeError` | `assumeWarningFree` | `warning`

matlab.unittest.TestCase.assumeWarningFree

Purpose

Assume function issues no warnings

Syntax

```
assumeWarningFree(assumable,actual)
assumeWarningFree(assumable,actual,diagnostic)
[output1,...,outputN] = assumeWarningFree( ___ )
```

Description

`assumeWarningFree(assumable,actual)` assumes that `actual` is a function handle that issues no warnings.

`assumeWarningFree(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assumeWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesNoWarnings;
  assumable.assumeThat(actual, IssuesNoWarnings());
  ```

  There exists more functionality when using the `IssuesNoWarnings` constraint directly via assumeThat.

Input Arguments

assumable

The matlab.unittest.TestCase instance which is used to pass or fail the assumption in conjunction with the test running framework.

actual

The function handle to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Output Arguments

output1,...,outputN

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

Examples

See examples for `verifyWarningFree`.

See Also

`assumeThat` | `assumeWarning` | `warning`

matlab.unittest.TestCase.fatalAssertClass

Purpose

Fatally assert exact class of specified value

Syntax

```
fatalAssertClass(fatalAssertable,actual,className)
fatalAssertClass(fatalAssertable,actual,metaClass)
fatalAssertClass( ___ ,diagnostic)
```

Description

`fatalAssertClass(fatalAssertable,actual,className)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`fatalAssertClass(fatalAssertable,actual,metaClass)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`fatalAssertClass( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- The method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsOfClass;
  fatalAssertable.fatalAssertThat(actual, IsOfClass(className));
  fatalAssertable.fatalAssertThat(actual, IsOfClass(metaClass));
  ```

  There exists more functionality when using the `IsOfClass` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

className

Name of class, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyClass`.

See Also

`fatalAssertThat` | `fatalAssertInstanceOf` |

matlab.unittest.TestCase.fatalAssertEmpty

Purpose

Fatally assert value is empty

Syntax

```
fatalAssertEmpty(fatalAssertable,actual)
fatalAssertEmpty(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertEmpty(fatalAssertable,actual)` fatally asserts that `actual` is an empty MATLAB value.

`fatalAssertEmpty(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  fatalAssertable.fatalAssertThat(actual, IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyEmpty`.

See Also

`fatalAssertThat` | `fatalAssertNotEmpty` | `isempty`

matlab.unittest.TestCase.fatalAssertEqual

Purpose

Fatally assert value is equal to specified value

Syntax

```
fatalAssertEqual(fatalAssertable,actual,expected)
fatalAssertEqual( ___ ,Name,Value)
fatalAssertEqual( ___ ,diagnostic)
```

Description

`fatalAssertEqual(fatalAssertable,actual,expected)` fatally asserts that `actual` is strictly equal to `expected` .

`fatalAssertEqual( ___ ,Name,Value)` fatally asserts equality with additional options specified by one or more `Name,Value` pair arguments.

`fatalAssertEqual( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
fatalAassertable.fatalAssertThat(actual, IsEqualTo(expected, ...
    'Within', RelativeTolerance(reltol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

expected

Expected value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'AbsTol'

'RelTol'

Examples

See examples for `verifyEqual`.

See Also

`fatalAssertThat` | `fatalAssertNotEqual` |

Purpose

Fatally assert function throws specified exception

Syntax

```
fatalAssertError(fatalAssertable,actual,identifier)
fatalAssertError(fatalAssertable,actual,metaClass)
fatalAssertError( ___ ,diagnostic)
```

Description

`fatalAssertError(fatalAssertable,actual,identifier)` fatally asserts that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`fatalAssertError(fatalAssertable,actual,metaClass)` fatally asserts that `actual` is a function handle that throws an exception whose type is defined by the meta.class instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the MException class..

`fatalAssertError( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Throws;
  fatalAssertable.fatalAssertThat(actual, Throws(identifier));
  fatalAssertable.fatalAssertThat(actual, Throws(metaClass));
  ```

  There exists more functionality when using the `Throws` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

identifier

Error identifier, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyError`.

See Also

`fatalAssertThat` | `fatalAssertWarning` | `MException` | `error`

matlab.unittest.TestCase.fatalAssertFail

Purpose

Produce unconditional fatal assertion failure

Syntax

```
fatalAssertFail(fatalAssertable)
fatalAssertFail(fatalAssertable,diagnostic)
```

Description

`fatalAssertFail(fatalAssertable)` produces an unconditional fatal assertion failure when encountered.

`fatalAssertFail(fatalAssertable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `matlab.unittest.TestCase.verifyFail`.

matlab.unittest.TestCase.fatalAssertFalse

Purpose

Fatally assert value is false

Syntax

```
fatalAssertFalse(fatalAssertable,actual)
fatalAssertFalse(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertFalse(fatalAssertable,actual)` fatally asserts that `actual` is a scalar logical with the value of false.

`fatalAssertFalse(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsFalse;
  fatalAssertable.fatalAssertThat(actual, IsFalse());
  ```

  There exists more functionality when using the `IsFalse` constraint directly via fatalAssertThat.
- Unlike fatalAssertTrue, this method may create a new constraint for each call. For performance critical uses, consider using fatalAssertTrue.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyFalse`.

See Also

`fatalAssertThat` | `fatalAssertTrue` |

matlab.unittest.TestCase.fatalAssertGreaterThan

Purpose

Fatally assert value is greater than specified value

Syntax

```
fatalAssertGreaterThan(fatalAssertable,actual,floor)
fatalAssertGreaterThan(fatalAssertable,actual,floor,
    diagnostic)
```

Description

`fatalAssertGreaterThan(fatalAssertable,actual,floor)` fatally asserts that all elements of `actual` are greater than all the elements of `floor`.

`fatalAssertGreaterThan(fatalAssertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  matlab.unittest.constraints.IsGreaterThan;
  fatalAssertable.fatalAssertThat(actual, IsGreaterThan(floor));
  ```

  There exists more functionality when using the `IsGreaterThan` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

floor

Minimum value, exclusive.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyGreaterThan`.

See Also

`fatalAssertThat` | `fatalAssertGreaterThanOrEqual` | `fatalAssertLessThan` | `fatalAssertLessThanOrEqual` | `gt`

matlab.unittest.TestCase.fatalAssertGreaterThanOrEqual

Purpose

Fatally assert value is greater than or equal to specified value

Syntax

```
fatalAssertGreaterThanOrEqual(fatalAssertable,actual,floor)
fatalAssertGreaterThanOrEqual(fatalAssertable,actual,floor,
   diagnostic)
```

Description

`fatalAssertGreaterThanOrEqual(fatalAssertable,actual,floor)` fatally asserts that all elements of `actual` are greater than or equal to all the elements of `floor`.

`fatalAssertGreaterThanOrEqual(fatalAssertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
  fatalAssertable.fatalAssertThat(actual, IsGreaterThanOrEqualTo(floor));
  ```

  There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

floor

Minimum value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyGreaterThanOrEqual`.

See Also

`fatalAssertThat` | `fatalAssertGreaterThan` | `fatalAssertLessThanOrEqual` | `fatalAssertLessThan` | `ge`

matlab.unittest.TestCase.fatalAssertInstanceOf

Purpose

Fatally assert value is object of specified type

Syntax

```
fatalAssertInstanceOf(fatalAssertable,actual,className)
fatalAssertInstanceOf(fatalAssertable,actual,metaClass)
fatalAssertInstanceOf( ___ ,diagnostic)
```

Description

`fatalAssertInstanceOf(fatalAssertable,actual,className)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`fatalAssertInstanceOf(fatalAssertable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`fatalAssertInstanceOf( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;
fatalAssertable.fatalAssertThat(actual, IsInstanceOf(className));
fatalAssertable.fatalAssertThat(actual, IsInstanceOf(metaClass));
```

  There exists more functionality when using the `IsInstanceOf` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

className

Name of class, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyInstanceOf`.

See Also

`fatalAssertThat` | `fatalAssertClass` | `isa`

matlab.unittest.TestCase.fatalAssertLength

Purpose

Fatally assert value has specified length

Syntax

```
fatalAssertLength(fatalAssertable,actual,expectedLength)
fatalAssertLength(fatalAssertable,actual,expectedLength,
   diagnostic)
```

Description

`fatalAssertLength(fatalAssertable,actual,expectedLength)` fatally asserts that `actual` is a MATLAB array whose length is `expectedLength`.

`fatalAssertLength(fatalAssertable,actual,expectedLength,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
fatalAssertable.fatalAssertThat(actual, HasLength(expectedLength));
```

  There exists more functionality when using the `HasLength` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

expectedLength

The length of an array is defined as the largest dimension of that array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyLength`.

See Also

`fatalAssertThat` | `fatalAssertSize` | `fatalAssertNumElements` | `length`

matlab.unittest.TestCase.fatalAssertLessThan

Purpose

Fatally assert value is less than specified value

Syntax

```
fatalAssertLessThan(fatalAssertable,actual,ceiling)
fatalAssertLessThan(fatalAssertable,actual,ceiling,
   diagnostic)
```

Description

`fatalAssertLessThan(fatalAssertable,actual,ceiling)` fatally asserts that all elements of `actual` are less than all the elements of `ceiling`.

`fatalAssertLessThan(fatalAssertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThan;
  assertable.assertThat(actual, IsLessThan(ceiling));
  ```

  There exists more functionality when using the `IsLessThan` constraint directly via assertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

ceiling

Maximum value, exclusive.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyLessThan`.

See Also

`assertThat` | `assertLessThanOrEqual` | `assertGreaterThan` | `assertGreaterThanOrEqual` | `lt`

matlab.unittest.TestCase.fatalAssertLessThanOrEqual

Purpose

Fatally assert value is less than or equal to specified value

Syntax

```
fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling)
fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling,
   diagnostic)
```

Description

`fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling)` fatally asserts that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThanOrEqualTo;
  fatalAssertable.fatalAssertThat(actual, IsLessThanOrEqualTo(ceiling));
  ```

  There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

actual

The value to test.

ceiling

Maximum value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyLessThanOrEqual`.

See Also

`fatalAssertThat` | `fatalAssertLessThan` | `fatalAssertGreaterThan` | `fatalAssertGreaterThanOrEqual` | `le`

matlab.unittest.TestCase.fatalAssertMatches

Purpose

Fatally assert string matches specified regular expression

Syntax

```
fatalAssertMatches(fatalAssertable,actual,expression)
fatalAssertMatches(fatalAssertable,actual,expression,
   diagnostic)
```

Description

`fatalAssertMatches(fatalAssertable,actual,expression)` fatally asserts that `actual` is a string that matches the regular expression defined by `expression`.

`fatalAssertMatches(fatalAssertable,actual,expression,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Matches;
  fatalAssertable.fatalAssertThat(actual, Matches(expression));
  ```

  There exists more functionality when using the `Matches` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

expression

The value to match, specified as a regular expression.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyMatches`.

See Also

`fatalAssertThat` | `fatalAssertSubstring` | `regexp`

matlab.unittest.TestCase.fatalAssertNotEmpty

Purpose

Fatally assert value is not empty

Syntax

```
fatalAssertNotEmpty(fatalAssertable,actual)
fatalAssertNotEmpty(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertNotEmpty(fatalAssertable,actual)` fatally asserts that `actual` is a non-empty MATLAB value.

`fatalAssertNotEmpty(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  fatalAssertable.fatalAssertThat(actual, ~IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNotEmpty`.

See Also

`fatalAssertThat` | `fatalAssertEmpty` | `isempty`

matlab.unittest.TestCase.fatalAssertNotEqual

Purpose

Fatally assert value is not equal to specified value

Syntax

```
fatalAssertNotEqual(fatalAssertable,actual,notExpected)
fatalAssertNotEqual(fatalAssertable,actual,notExpected,
   diagnostic)
```

Description

`fatalAssertNotEqual(fatalAssertable,actual,notExpected)` fatally asserts that `actual` is not equal to `notExpected`.

`fatalAssertNotEqual(fatalAssertable,actual,notExpected,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEqualTo;
  fatalAssertable.fatalAssertThat(actual, ~IsEqualTo(notExpected));
  ```

  There exists more functionality when using the `IsEqualTo` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

notExpected

Value to compare.

Examples

See examples for `verifyNotEqual`.

See Also

`fatalAssertThat` | `fatalAssertEqual` |

matlab.unittest.TestCase.fatalAssertNotSameHandle

Purpose

Fatally assert value is not handle to specified instance

Syntax

```
fatalAssertNotSameHandle(fatalAssertable,actual,
   notExpectedHandle)
fatalAssertNotSameHandle(fatalAssertable,actual,
   notExpectedHandle,diagnostic)
```

Description

`fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle)` fatally asserts that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle,diag` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  fatalAssertable.fatalAssertThat(actual, ~IsSameHandleAs(notExpected
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

notExpectedHandle

The handle array to compare.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNotSameHandle`.

See Also

`fatalAssertThat` | `fatalAssertSameHandle` |

Purpose

Fatally assert value has specified element count

Syntax

```
fatalAssertNumElements(fatalAssertable,actual,
   expectedElementCount)
fatalAssertNumElements(fatalAssertable,actual,
   expectedElementCount,diagnostic)
```

Description

`fatalAssertNumElements(fatalAssertable,actual,expectedElementCount)` fatally asserts that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`fatalAssertNumElements(fatalAssertable,actual,expectedElementCount,dia` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
fatalAssertable.fatalAssertThat(actual, HasElementCount(expectedEler
```

  There exists more functionality when using the `HasElementCount` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

expectedElementCount

The expected number of elements in the array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyNumElements`.

See Also

`fatalAssertThat` | `fatalAssertSize` | `fatalAssertLength` | `numel`

Purpose

Fatally assert function returns true when evaluated

Syntax

```
fatalAssertReturnsTrue(fatalAssertable,actual)
fatalAssertReturnsTrue(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertReturnsTrue(fatalAssertable,actual)` fatally asserts that `actual` is a function handle that returns a scalar logical whose value is true.

`fatalAssertReturnsTrue(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using fatalAssertTrue because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using fatalAssertTrue.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ReturnsTrue;
  fatalAssertable.fatalAssertThat(actual, ReturnsTrue());
  ```

  There exists more functionality when using the `ReturnsTrue` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The function handle to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyReturnsTrue`.

See Also

`fatalAssertThat` | `fatalAssertTrue` |

Purpose

Fatally assert two values are handles to same instance

Syntax

```
fatalAssertSameHandle(fatalAssertable,actual,expectedHandle)
fatalAssertSameHandle(fatalAssertable,actual,expectedHandle,
   diagnostic)
```

Description

`fatalAssertSameHandle(fatalAssertable,actual,expectedHandle)` fatally asserts that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`fatalAssertSameHandle(fatalAssertable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  fatalAssertable.fatalAssertThat(actual, IsSameHandleAs(expectedHandl
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

expectedHandle

The expected handle array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifySameHandle`.

See Also

`fatalAssertThat` | `fatalAssertNotSameHandle` | `handle`

Purpose

Fatally assert value has specified size

Syntax

```
fatalAssertSize(fatalAssertable,actual,expectedSize)
fatalAssertSize(fatalAssertable,actual,expectedSize,
   diagnostic)
```

Description

`fatalAssertSize(fatalAssertable,actual,expectedSize)` fatally asserts that `actual` is a MATLAB array whose size is `expectedSize`.

`fatalAssertSize(fatalAssertable,actual,expectedSize,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasSize;
  fatalAssertable.fatalAssertThat(actual, HasSize(expectedSize));
  ```

  There exists more functionality when using the `HasSize` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

expectedSize

The expected sizes of each dimension the array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifySize`.

See Also

`fatalAssertThat` | `fatalAssertLength` | `fatalAssertNumElements` | `size`

Purpose

Fatally assert string contains specified string

Syntax

```
fatalAssertSubstring(fatalAssertable,actual,substring)
fatalAssertSubstring(fatalAssertable,actual,substring,
   diagnostic)
```

Description

`fatalAssertSubstring(fatalAssertable,actual,substring)` fatally asserts that `actual` is a string that contains `substring`.

`fatalAssertSubstring(fatalAssertable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
fatalAssertable.fatalAssertThat(actual,...
ContainsSubstring(substring));
```

  There exists more functionality when using the `ContainsSubstring` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

substring

The value to match, specified as a string.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifySubstring`.

See Also

`fatalAssertThat` | `fatalAssertMatches` | `strfind`

Purpose

Fatally assert value meets specified constraint

Syntax

```
fatalAssertThat(fatalAssertable,actual,constraint)
fatalAssertThat(fatalAssertable,actual,constraint,diagnostic)
```

Description

`fatalAssertThat(fatalAssertable,actual,constraint)` fatally asserts that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, a fatal assertion failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`fatalAssertThat(fatalAssertable,actual,constraint,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

constraint

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyThat`.

Purpose

Fatally assert value is true

Syntax

```
fatalAssertTrue(fatalAssertable,actual)
fatalAssertTrue(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertTrue(fatalAssertable,actual)` fatally asserts that `actual` is a scalar logical with the value of true.

`fatalAssertTrue(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsTrue;
  fatalAssertable.fatalAssertThat(actual, IsTrue());
  ```

  There exists more functionality when using the `IsTrue` constraint directly via fatalAssertThat.

  However, this method is optimized for performance and does not construct a new `IsTrue` constraint for each call. Sometimes such use can come at the expense of less diagnostic information. Use the fatalAssertReturnsTrue method for a similar approach which may provide better diagnostic information.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

See examples for `verifyTrue`.

See Also

`fatalAssertThat` | `fatalAssertFalse` | `fatalAssertReturnsTrue` |

Purpose

Fatally assert function issues specified warning

Syntax

```
fatalAssertWarning(fatalAssertable,actual,warningID)
fatalAssertWarning(fatalAssertable,actual,warningID,
   diagnostic)
[output1,...,outputN] = fatalAssertWarning( ___ )
```

Description

`fatalAssertWarning(fatalAssertable,actual,warningID)` fatally asserts that `actual` issues a warning with the identifier `warningID`.

`fatalAssertWarning(fatalAssertable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = fatalAssertWarning( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesWarnings;
  fatalAssertable.fatalAssertThat(actual, IssuesWarnings({warningID}))
  ```

  There exists more functionality when using the `IssuesWarnings` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The function handle to test.

warningID

Warning ID, specified as a string.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Output Arguments

output1,...,outputN

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

Examples

See examples for `verifyWarning`.

See Also

`fatalAssertThat` | `fatalAssertError` | `fatalAssertWarningFree` | `warning`

Purpose

Fatally assert function issues no warnings

Syntax

```
fatalAssertWarningFree(fatalAssertable,actual)
fatalAssertWarningFree(fatalAssertable,actual,diagnostic)
[output1,...,outputN] = fatalAssertWarningFree( ___ )
```

Description

`fatalAssertWarningFree(fatalAssertable,actual)` fatally asserts that `actual` is a function handle that issues no warnings.

`fatalAssertWarningFree(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = fatalAssertWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesNoWarnings;
  fatalAssertable.fatalAssertThat(actual, IssuesNoWarnings());
  ```

  There exists more functionality when using the `IssuesNoWarnings` constraint directly via fatalAssertThat.

Input Arguments

fatalAssertable

The matlab.unittest.TestCase instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

actual

The function handle to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Output Arguments

output1,...,outputN

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

Examples

See examples for `verifyWarningFree`.

See Also

`fatalAssertThat` | `fatalAssertWarning` | `warning`

Purpose

Run `TestCase` test

Syntax

```
result = run(testCase)
result = run(testCase,testMethod)
```

Description

`result = run(testCase)` uses `testCase` as a prototype to run a TestSuite array created from all test methods in the class defining `testCase`. This suite is run using a TestRunner object configured for text output.

`result = run(testCase,testMethod)` uses `testCase` as a prototype to run a TestSuite array created from `testMethod`. This test is run using a TestRunner object configured for text output.

This is a convenience method to allow interactive experimentation of TestCase classes in MATLAB, yet running the tests contained in them using a supported TestRunner object.

Input Arguments

testCase

matlab.unittest.TestCase instance

testMethod

Name of desired test method, specified as one of the following:

- string
- `meta.method` instance

The method must correspond to a valid `Test` method of the `testCase` instance.

Output Arguments

result

A matlab.unittest.TestResult object containing the result of the test run.

Examples

Run Test Directly from Test Case

Add the `FigurePropertiesTest.m` test case file to a folder on your MATLAB path.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase

    properties
        TestFigure
    end

    methods(TestMethodSetup)
        function createFigure(testCase)
            %comment
            testCase.TestFigure = figure;
        end
    end

    methods(TestMethodTeardown)
        function closeFigure(testCase)
            close(testCase.TestFigure);
        end
    end

    methods(Test)

        function defaultCurrentPoint(testCase)

            cp = get(testCase.TestFigure, 'CurrentPoint');
            testCase.verifyEqual(cp, [0 0], ...
                'Default current point is incorrect')
        end

        function defaultCurrentObject(testCase)
            import matlab.unittest.constraints.IsEmpty;

            co = get(testCase.TestFigure, 'CurrentObject');
```

```
            testCase.verifyThat(co, IsEmpty, ...
                'Default current object should be empty');
        end

    end

end
```

Create a testcase object.

```
tc = FigurePropertiesTest;
```

Run the tests.

```
tc.run;
```

```
Running FigurePropertiesTest
..
Done FigurePropertiesTest
__________
```

All tests passed.

See Also

matlab.unittest.TestSuite.run | matlab.unittest.TestRunner.run |

matlab.unittest.TestCase.verifyClass

Purpose

Verify exact class of specified value

Syntax

```
verifyClass(verifiable,actual,className)
verifyClass(verifiable,actual,metaClass)
verifyClass(___,diagnostic)
```

Description

`verifyClass(verifiable,actual,className)` verifies that `actual` is a MATLAB value whose class is the class specified by `className`.

`verifyClass(verifiable,actual,metaClass)` verifies that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. Use verifyInstanceOf to verify inclusion in a class hierarchy.

`verifyClass(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- The method is functionally equivalent to the following methods:

  ```
  import matlab.unittest.constraints.IsOfClass;
  verifiable.verifyThat(actual, IsOfClass(className));
  verifiable.verifyThat(actual, IsOfClass(metaClass));
  ```

  There exists more functionality when using the `IsOfClass` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

className

Name of class, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test a Class

These interactive tests verify the class of the number, 5.

Create a TestCase object and the value to test.

```
testCase = matlab.unittest.TestCase;
actvalue = 5;
```

Verify class of `actvalue` is `double`.

```
testCase.verifyClass(actvalue, 'double');
```

```
Interactive verification passed.
```

Verify class of `actvalue` is `char`.

```
testCase.verifyClass(actvalue, 'char');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
```

```
verifyClass failed.
--> The value's class is incorrect.

    Actual Class:
        double
    Expected Class:
        char

Actual Value:
         5
```

Test fails.

Test a Function Handle

These interactive tests verify function handles, specified as a meta.class instance, `?function_handle`.

Create a TestCase object.

```
testCase = matlab.unittest.TestCase;
```

Create a function handle.

```
fh = @sin;
testCase.verifyClass(fh, ?function_handle);
```

```
Interactive verification passed.
```

Test the function name.

```
fh = 'sin';
testCase.verifyClass(fh, ?function_handle);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
```

```
verifyClass failed.
--> The value's class is incorrect.

    Actual Class:
        char
    Expected Class:
        function_handle

Actual Value:
    sin
```

Test fails.

Test a Derived Class

Verify that a derived class is not the same class as its base class.

Create a class, `BaseExample`.

```
classdef BaseExample
end
```

Create a derived class, `DerivedExample`.

```
classdef DerivedExample < BaseExample
end
```

Verify the classes are not equal.

```
testCase.verifyClass(DerivedExample(), ?BaseExample);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyClass failed.
--> The value's class is incorrect.
```

```
    Actual Class:
        DerivedExample
    Expected Class:
        BaseExample

Actual Value:
      DerivedExample with no properties.
```

Test fails.

Test Class of Output Value

Use `verifyClass` to test the `add5` function returns a `double` value.

Function for unit testing:

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.');
end
res = x + 5;
end
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
    methods (Test)
        function testDoubleOut(testCase)
            actOutput = add5(1);
            testCase.verifyClass(actOutput,'double');
        end
        function testNonNumericInput(testCase)
            testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric');
        end
    end
end
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m');

result = run(suite);

Running Add5Test
..
Done Add5Test
__________
```

See Also

verifyThat | verifyInstanceOf |

matlab.unittest.TestCase.verifyEmpty

Purpose

Verify value is empty

Syntax

```
verifyEmpty(verifiable,actual)
verifyEmpty(___,diagnostic)
```

Description

`verifyEmpty(verifiable,actual)` verifies that `actual` is an empty MATLAB value.

`verifyEmpty(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  verifiable.verifyThat(actual, IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test for Empty Strings

Create a TestCase object.

```
testCase = matlab.unittest.TestCase;

testCase.verifyEmpty('');

Interactive verification passed.
```

Test for Empty Arrays

An array with any zero dimension is empty.

```
testCase.verifyEmpty(ones(2, 5, 0, 3));

Interactive verification passed.

testCase.verifyEmpty([2 3], 'Array is not empty.');

Interactive verification failed.

----------------
Test Diagnostic:
----------------
Array is not empty.

---------------------
Framework Diagnostic:
---------------------
verifyEmpty failed.
--> The value must be empty.
--> The value has a size of [1  2].

Actual Value:
         2     3
```

Test failed.

Test for Empty Cell Arrays

Test empty cell array, `{}`.

```
testCase.verifyEmpty({}, 'Cell array is not empty.');
```

```
Interactive verification passed.
```

A cell array of empty arrays is not empty.

```
testCase.verifyEmpty({[], [], []}, 'Cell array is not empty.');
```

```
Interactive verification failed.

----------------
Test Diagnostic:
----------------
Cell array is not empty.

---------------------
Framework Diagnostic:
---------------------
verifyEmpty failed.
--> The value must be empty.
--> The value has a size of [1  3].

Actual Value:
        []    []    []
```

Test failed.

Test for Empty Test Suite

Test for empty object, `emptyTestSuite`.

```
emptyTestSuite = matlab.unittest.TestSuite.emtpy;
testCase.verifyEmpty(emptyTestSuite);
```

```
Interactive verification passed.
```

See Also

verifyThat | matlab.unittest.TestCase.verifyNotEmpty | isempty

matlab.unittest.TestCase.verifyEqual

Purpose

Verify value is equal to specified value

Syntax

```
verifyEqual(verifiable,actual,expected)
verifyEqual(___,Name,Value)
verifyEqual(___,diagnostic)
```

Description

`verifyEqual(verifiable,actual,expected)`) verifies that `actual` is strictly equal to `expected`.

`verifyEqual(___,Name,Value)` verifies equality with additional options specified by one or more `Name,Value` pair arguments.

`verifyEqual(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure

Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
verifiable.verifyThat(actual, IsEqualTo(expected));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
    'Within', RelativeTolerance(reltol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

expected

Expected value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'AbsTol'

'RelTol'

Examples

Comparing Numeric Values

Numeric values are equivalent if they are of the same class with equivalent size, complexity, and sparsity.

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

A value is equal to itself.

```
testCase.verifyEqual(5, 5);
```

```
Interactive verification passed.
```

Values must have equal sizes.

```
testCase.verifyEqual([5 5], 5);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyEqual failed.
--> NumericComparator failed.
    --> Sizes do not match.

    Actual double size:
             1     2
    Expected double size:
             1     1

Actual Value:
         5     5
Expected Value:
         5
```

Test failed.

Test Classes

```
testCase.verifyEqual(int8(5), int16(5));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyEqual failed.
--> NumericComparator failed.
    --> Classes do not match.

    Actual Class:
        int8
    Expected Class:
        int16

Actual Value:
        5
Expected Value:
          5
```

Test failed.

Test Cell Arrays

Each element of a cell array must be equal in value, class, and size.

```
testCase.verifyEqual({'cell', struct, 5}, {'cell', struct, 5});
```

```
Interactive verification passed.
```

Test Numeric Tolerances

```
testCase.verifyEqual(4.95, 5);
```

```
Interactive verification failed.
```

```
----------------
Test Diagnostic:
----------------
4.95 is not equal to 5

---------------------
Framework Diagnostic:
---------------------
verifyEqual failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".

Actual Value:
       4.950000000000000
Expected Value:
          5
```

Test failed.

```
testCase.verifyEqual(1.5, 2, 'AbsTol', 1)
```

```
Interactive verification passed.
```

```
testCase.verifyEqual(1.5, 2, 'RelTol', 0.1, ...
    'Difference between actual and expected exceeds relative tolerance')
```

```
Interactive verification failed.

----------------
Test Diagnostic:
----------------
Difference between actual and expected exceeds relative tolerance

---------------------
Framework Diagnostic:
---------------------
verifyEqual failed.
```

```
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> RelativeTolerance failed.
        --> The value was not within relative tolerance.

            Tolerance Definition:
                abs(expected - actual) <= tolerance .* abs(expected)
            Tolerance Value:
                   0.100000000000000

Actual Value:
       1.500000000000000
Expected Value:
         2
```

Test failed.

verifyThat | verifyNotEqual |

matlab.unittest.TestCase.verifyError

Purpose

Verify function throws specified exception

Syntax

```
verifyError(verifiable,actual,identifier)
verifyError(verifiable,actual,metaClass)
verifyError( ___ ,diagnostic)
```

Description

`verifyError(verifiable,actual,identifier)` verifies that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`verifyError(verifiable,actual,metaClass)` verifies that `actual` is a function handle that throws an exception whose type is defined by the meta.class instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the MException class.

`verifyError( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Throws;
  verifiable.verifyThat(actual, Throws(identifier));
  verifiable.verifyThat(actual, Throws(metaClass));
  ```

  There exists more functionality when using the `Throws` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

identifier

Error identifier, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test for Error IDs

```
% Passing scenarios
%%%%%%%%%%%%%%%%%%%%
testCase.verifyError(@() error('SOME:error:id','Error!'), 'SOME:error:
testCase.verifyError(@testCase.assertFail, ...
    ?matlab.unittest.qualifications.AssertionFailedException);

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%
testCase.verifyError(5, 'some:id', '5 is not a function handle');
testCase.verifyError(@testCase.verifyFail, ...
    ?matlab.unittest.qualifications.AssertionFailedException, ...
    'Verifications dont throw exceptions.');
testCase.verifyError(@() error('SOME:id'), 'OTHER:id', 'Wrong id');
testCase.verifyError(@() error('whoops'), ...
    ?matlab.unittest.qualifications.AssertionFailedException, ...
    'Wrong type of exception thrown');
```

Test Error Condition

Create `testNonNumericInput` to test if function throws expected error message, `add5:InputMustBeNumeric`, for unexpected condition, input is `char`.

Function for unit testing:

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.');
end
res = x + 5;
end
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
    methods (Test)
        function testDoubleOut(testCase)
            actOutput = add5(1);
            testCase.verifyClass(actOutput,'double');
        end
        function testNonNumericInput(testCase)
            testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric');
        end
    end
end
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m');

result = run(suite);
```

```
Running Add5Test
..
Done Add5Test
```

`verifyThat` | `verifyWarning` | `MException` | `error`

matlab.unittest.TestCase.verifyFail

Purpose

Produce unconditional verification failure

Syntax

```
verifyFail(verifiable)
verifyFail(verifiable,diagnostic)
```

Description

`verifyFail(verifiable)` produces an unconditional verification failure when encountered.

`verifyFail(verifiable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

An example of where this method may be used is in a callback function that should not be executed in a given scenario. A test can confirm this does not occur by unconditionally performing a failure if the code path is reached.

Assume a handle class MyHandle with a SomethingHappened event.

```
classdef MyHandle < handle
    events
```

```
        SomethingHappened
    end
end
```

The following is a test method inside a TestCase class.

```
methods(Test)
    function testDisabledListeners(testCase)

        h = MyHandle;

        % Add a listener to a test helper method
        listener = h.addlistener('SomethingHappened', ...
            @testCase.shouldNotGetCalled);

        % Passing scenario (code path is not reached)
        %%%%%%%%%%%%%%%%%%%%
        % Disabled listener should not invoke callbacks
        listener.Enabled = false;
        h.notify('SomethingHappened');

        % Failing scenario (code path is reached)
        %%%%%%%%%%%%%%%%%%%%
        % Enabled listener invoke callback and fail
        listener.Enabled = true;
        h.notify('SomethingHappened');
    end
end
```

matlab.unittest.TestCase.verifyFalse

Purpose

Verify value is false

Syntax

```
verifyFalse(verifiable,actual)
verifyFalse( ___ ,diagnostic)
```

Description

`verifyFalse(verifiable,actual)` verifies that `actual` is a scalar logical with the value of false.

`verifyFalse( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsFalse;
  verifiable.verifyThat(actual, IsFalse());
  ```

  There exists more functionality when using the `IsFalse` constraint directly via verifyThat.
- Unlike verifyTrue, this method may create a new constraint for each call. For performance critical uses, consider using verifyTrue.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test MATLAB Logical Functions

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Test `true`.

```
testCase.verifyFalse(true);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyFalse failed.
--> The value must evaluate to "false".

Actual Value:
         1
```

Test failed.

Test `false`.

```
testCase.verifyFalse(false);
```

```
Interactive verification passed.
```

Test the Value 0

The number `0` is a `double` value, not a logical value.

```
testCase.verifyFalse(0);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyFalse failed.
--> The value must be logical. It is of type "double".

Actual Value:
         0
```

Test failed.

Test Array of Logical Values

To be false, the value must be scalar.

```
testCase.verifyFalse([false false false]);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyFalse failed.
--> The value must be scalar. It has a size of [1  3].

Actual Value:
         0     0     0
```

Test failed.

Test an array of mixed logical values.

```
testCase.verifyFalse([false true false], ...
    'A mixed array of logicals is not the one false value');
```

```
Interactive verification failed.

----------------
Test Diagnostic:
----------------
A mixed array of logicals is not the one false value

---------------------
Framework Diagnostic:
---------------------
verifyFalse failed.
--> The value must be scalar. It has a size of [1  3].

Actual Value:
         0     1     0
```

Test failed.

verifyThat | verifyTrue |

matlab.unittest.TestCase.verifyGreaterThan

Purpose

Verify value is greater than specified value

Syntax

```
verifyGreaterThan(verifiable,actual,floor)
verifyGreaterThan( ___ ,diagnostic)
```

Description

`verifyGreaterThan(verifiable,actual,floor)` verifies that all elements of `actual` are greater than all the elements of `floor`.

`verifyGreaterThan( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  matlab.unittest.constraints.IsGreaterThan;
  verifiable.verifyThat(actual, IsGreaterThan(floor));
  ```

  There exists more functionality when using the `IsGreaterThan` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

floor

Minimum value, exclusive.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Compare Two Numbers

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify 3 is greater than 2.

```
testCase.verifyGreaterThan(3, 2);
```

```
Interactive verification passed.
```

Test if 5 is greater than 9.

```
testCase.verifyGreaterThan(5, 9);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThan failed.
--> The value must be greater than the minimum value.

Actual Value:
         5
Minimum Value (Exclusive):
         9
```

Test failed.

Compare an Array to a Scalar

Test if each element is greater than the `FLOOR` value, `2`.

```
testCase.verifyGreaterThan([5 6 7], 2);
```

```
Interactive verification passed.
```

Test if value `5` is greater than each element in the `FLOOR` array, `[1 2 3]`.

```
testCase.verifyGreaterThan(5, [1 2 3]);
```

```
Interactive verification passed.
```

Test if each element in the matrix is greater than the `FLOOR` value, `4`.

```
testCase.verifyGreaterThan([1 2 3; 4 5 6], 4);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThan failed.
--> Each element must be greater than the minimum value.

    Failing Indices:
             1     2     3     5

Actual Value:
         1     2     3
         4     5     6
Minimum Value (Exclusive):
         4
```

Test failed.

Compare Arrays

Test if each element is greater than each corresponding element of the `FLOOR` array, `[4 -9 0]`.

```
testCase.verifyGreaterThan([5 -3 2], [4 -9 0]);
```

```
Interactive verification passed.
```

Compare an array to itself.

```
testCase.verifyGreaterThan(eye(2), eye(2));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThan failed.
--> Each element must be greater than each corresponding element of th

    Failing Indices:
             1     2     3     4

Actual Value:
         1     0
         0     1
Minimum Value (Exclusive):
         1     0
         0     1
```

Test failed.

`verifyThat` | `verifyGreaterThanOrEqual` | `verifyLessThanOrEqual` | `verifyLessThan` | `gt`

matlab.unittest.TestCase.verifyGreaterThanOrEqual

Purpose

Verify value is greater than or equal to specified value

Syntax

```
verifyGreaterThanOrEqual(verifiable,actual,floor)
verifyGreaterThanOrEqual(___,diagnostic)
```

Description

`verifyGreaterThanOrEqual(verifiable,actual,floor)` that all elements of `actual` are greater than or equal to all the elements of `floor`.

`verifyGreaterThanOrEqual(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
  verifiable.verifyThat(actual, IsGreaterThanOrEqualTo(floor));
  ```

  There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

floor

Minimum value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Compare Two Numbers

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify 3 is greater than 2.

```
testCase.verifyGreaterThanOrEqual(3, 2);
```

```
Interactive verification passed.
```

Verify 3 is greater than or equal to 3.

```
testCase.verifyGreaterThanOrEqual(3, 3);
```

```
Interactive verification passed.
```

Test if 5 is greater than 9.

```
testCase.verifyGreaterThanOrEqual(5, 9);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThanOrEqual failed.
--> The value must be greater than or equal to the minimum value.

Actual Value:
         5
```

```
Minimum Value (Inclusive):
         9
```

Test failed.

Compare an Array to a Scalar

Test if each element is greater than or equal to the `FLOOR` value, `2`.

```
testCase.verifyGreaterThanOrEqual([5 2 7], 2);
```

```
Interactive verification passed.
```

Test if each element in the matrix is greater than or equal to the `FLOOR` value, `4`.

```
testCase.verifyGreaterThanOrEqual([1 2 3; 4 5 6], 4);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThanOrEqual failed.
--> Each element must be greater than or equal to the minimum value.

    Failing Indices:

`verifyThat` | `verifyGreaterThan` | `verifyLessThan` | `verifyLessThanOrEqual` | `ge`

matlab.unittest.TestCase.verifyInstanceOf

Purpose

Verify value is object of specified type

Syntax

```
verifyInstanceOf(verifiable,actual,className)
verifyInstanceOf(verifiable,actual,metaClass)
verifyInstanceOf( ___ ,diagnostic)
```

Description

`verifyInstanceOf(verifiable,actual,className)` verifies that `actual` is a MATLAB value whose class is the class specified by `className`.

`verifyInstanceOf(verifiable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`verifyInstanceOf( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsInstanceOf;
  verifiable.verifyThat(actual, IsInstanceOf(className));
  verifiable.verifyThat(actual, IsInstanceOf(metaClass));
  ```

  There exists more functionality when using the `IsInstanceOf` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

className

Name of class, specified as a string.

metaClass

An instance of meta.class.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test a Class

These interactive tests verify the class of the number, 5.

Create a TestCase object and the value to test.

```
testCase = matlab.unittest.TestCase;
actvalue = 5;
```

Verify `actvalue` is an instance of class `double`.

```
testCase.verifyInstanceOf(actvalue, 'double');
```

```
Interactive verification passed.
```

Verify if `actvalue` is an instance of `char`.

```
testCase.verifyInstanceOf(5, 'char');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyInstanceOf failed.
```

```
--> The value must be an instance of the expected type.

    Actual Class:
        double
    Expected Type:
        char

Actual Value:
         5
```

Test failed.

Test a Function Handle

These tests verify function handles, specified as a meta.class instance, `?function_handle`.

Create a function handle.

```
fh = @sin;
testCase.verifyInstanceOf(fh, ?function_handle);
```

```
Interactive verification passed.
```

Test the function name.

```
fh = 'sin';
testCase.verifyInstanceOf(fh, ?function_handle);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyInstanceOf failed.
--> The value must be an instance of the expected type.

    Actual Class:
        char
```

```
    Expected Type:
        function_handle

Actual Value:
    sin
```

Test failed.

Test a Derived Class

Verify that a derived class is not the same class as its base class.

Create a class, `BaseExample`.

```
classdef BaseExample
end
```

Create a derived class, `DerivedExample`.

```
classdef DerivedExample < BaseExample
end
```

Verify `DerivedExample` is an instance of `BaseExample`.

```
testCase.verifyInstanceOf(DerivedExample(), ?BaseExample);
```

```
Interactive verification passed.
```

Verify `BaseExample` is not an instance of `DerivedExample`.

```
testCase.verifyInstanceOf(BaseExample(), ?DerivedExample);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyInstanceOf failed.
--> The value must be an instance of the expected type.
```

```
    Actual Class:
        BaseExample
    Expected Type:
        DerivedExample

Actual Value:
      BaseExample with no properties.
```

Test failed.

See Also

`verifyThat` | `verifyClass` | `isa`

Purpose

Verify value has specified length

Syntax

```
verifyLength(verifiable,actual,expectedLength)
verifyLength( ___ ,diagnostic)
```

Description

`verifyLength(verifiable,actual,expectedLength)` verifies that `actual` is a MATLAB array whose length is `expectedLength`.

`verifyLength( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
verifiable.verifyThat(actual, HasLength(expectedLength));
```

  There exists more functionality when using the `HasLength` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

expectedLength

The length of an array is defined as the largest dimension of that array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test Array Lengths

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify length of array is the expected value, 5.

```
testCase.verifyLength(ones(2, 5, 3), 5, 'User diagnostic');
```

```
Interactive verification passed.
```

Length of array is not the expected value, 3.

```
testCase.verifyLength([2 3], 3);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLength failed.
--> The array has an incorrect length.

    Actual Length:
             2
    Expected Length:
             3

Actual Array:
         2     3
```

Test failed.

The length of a 2x3 array is `3`.

```
testCase.verifyLength([1 2 3; 4 5 6], 3);
```

```
Interactive verification passed.
```

Verify the length of a 2x3 array is not the number of elements, `6`.

```
testCase.verifyLength([1 2 3; 4 5 6], 6);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLength failed.
--> The array has an incorrect length.

    Actual Length:
             3
    Expected Length:
             6

Actual Array:
         1     2     3
         4     5     6
```

Test failed.

```
testCase.verifyLength(eye(2), 4);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
```

```
verifyLength failed.
--> The array has an incorrect length.

    Actual Length:
             2
    Expected Length:
             4

Actual Array:
         1     0
         0     1
```

Test Cell Array Lengths

```
testCase.verifyLength({'somestring', 'someotherstring'}, 2);
```

```
Interactive verification passed.
```

See Also

verifyThat | verifySize | verifyNumElements | length

Purpose

Verify value is less than specified value

Syntax

```
verifyLessThan(verifiable,actual,ceiling)
verifyLessThan(___,diagnostic)
```

Description

`verifyLessThan(verifiable,actual,ceiling)` verifies that all elements of `actual` are less than all the elements of `ceiling`.

`verifyLessThan(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThan;
  verifiable.verifyThat(actual, IsLessThan(ceiling));
  ```

  There exists more functionality when using the `IsLessThan` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

ceiling

Maximum value, exclusive.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Compare Two Numbers

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify 2 is less than 3.

```
testCase.verifyLessThan(2, 3);
```

```
Interactive verification passed.
```

Test if 9 is less than 5.

```
testCase.verifyLessThan(9, 5);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLessThan failed.
--> The value must be less than the maximum value.

Actual Value:
         9
Maximum Value (Exclusive):
         5
```

Test failed.

Compare an Array to a Scalar

Test if each element is less than the `CEILING` value, `9`.

```
testCase.verifyLessThan([5 6 7], 9);
```

```
Interactive verification passed.
```

Test if each element in the matrix is less than the `CEILING` value, `4`.

```
testCase.verifyLessThan([1 2 3; 4 5 6], 4);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLessThan failed.
--> Each element must be less than the maximum value.

    Failing Indices:
             2     4     6

Actual Value:
         1     2     3
         4     5     6
Maximum Value (Exclusive):
         4
```

Test failed.

Compare Arrays

Test if each element is less than each corresponding element of the `CEILING` array, `[7 -1 8]`.

```
testCase.verifyLessThan([5 -3 2], [7 -1 8]);
```

```
Interactive verification passed.
```

Compare an array to itself.

```
testCase.verifyLessThan(eye(2), eye(2));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLessThan failed.
--> Each element must be less than each corresponding element of the maxi

    Failing Indices:
             1     2     3     4

Actual Value:
         1     0
         0     1
Maximum Value (Exclusive):
         1     0
         0     1
```

Test failed.

See Also

`verifyThat` | `verifyLessThanOrEqual` | `verifyGreaterThan` | `verifyGreaterThanOrEqual` | `lt`

Purpose

Verify value is less than or equal to specified value

Syntax

```
verifyLessThanOrEqual(verifiable,actual,ceiling)
verifyLessThanOrEqual( ___ ,diagnostic)
```

Description

`verifyLessThanOrEqual(verifiable,actual,ceiling)` verifies that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`verifyLessThanOrEqual( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThanOrEqualTo;
  verifiable.verifyThat(actual, IsLessThanOrEqualTo(ceiling));
  ```

  There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

ceiling

Maximum value.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Compare Two Numbers

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify 2 is less than 3.

```
testCase.verifyLessThanOrEqual(2, 3);
```

```
Interactive verification passed.
```

Verify 3 is less than or equal to 3.

```
testCase.verifyLessThanOrEqual(3, 3);
```

```
Interactive verification passed.
```

Test if 9 is less than 5.

```
testCase.verifyLessThanOrEqual(9, 5);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLessThanOrEqual failed.
--> The value must be less than or equal to the maximum value.

Actual Value:
         9
```

```
Maximum Value (Inclusive):
         5
```

Test failed.

Compare an Array to a Scalar

Test if each element is less than or equal to the `CEILING` value, `7`.

```
testCase.verifyLessThanOrEqual([5 2 7], 7);
```

```
Interactive verification passed.
```

Test if each element in the matrix is less than or equal to the `CEILING` value, `4`.

```
testCase.verifyLessThanOrEqual([1 2 3; 4 5 6], 4);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLessThanOrEqual failed.
--> Each element must be less than or equal to the maximum value.

    Failing Indices:
             4     6

Actual Value:
         1     2     3
         4     5     6
Maximum Value (Inclusive):
         4
```

Test failed.

Compare Arrays

Test if each element is less than or equal to each corresponding element of the CEILING array, [5 -3 8].

```
testCase.verifyLessThanOrEqual([5 -3 2], [5 -3 8]);
```

```
Interactive verification passed.
```

Compare an array to itself.

```
testCase.verifyLessThanOrEqual(eye(2), eye(2));
```

```
Interactive verification passed.
```

See Also

verifyThat | verifyLessThan | verifyGreaterThan | verifyGreaterThanOrEqual | le

Purpose

Verify string matches specified regular expression

Syntax

```
verifyMatches(verifiable,actual,expression)
verifyMatches( ___ ,diagnostic)
```

Description

`verifyMatches(verifiable,actual,expression)` that `actual` is a string that matches the regular expression defined by `expression`.

`verifyMatches( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Matches;
  verifiable.verifyThat(actual, Matches(expression));
  ```

  There exists more functionality when using the `Matches` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The string to test.

expression

The value to match, specified as a regular expression.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test for String Matches

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;

testCase.verifyMatches('Some String', 'Some [Ss]tring', ...
    'My result should have matched the expression');

Interactive verification passed.

testCase.verifyMatches('Another string', '(Some |An)other');

Interactive verification passed.

testCase.verifyMatches('Another 3 strings', '^Another \d+ strings?$');

Interactive verification passed.

testCase.verifyMatches('3 more strings', '\d+ strings?');

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyMatches failed.
--> The string did not match the regular expression.

Actual String:
    3 more strings
Regular Expression:
    \d+ strings?
```

Test failed.

`verifyThat` | `verifySubstring` | `regexp`

matlab.unittest.TestCase.verifyNotEmpty

Purpose

Verify value is not empty

Syntax

```
verifyNotEmpty(verifiable,actual)
verifyNotEmpty(___,diagnostic)
```

Description

`verifyNotEmpty(verifiable,actual)` verifies that `actual` is a non-empty MATLAB value.

`verifyNotEmpty(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
verifiable.verifyThat(actual, ~IsEmpty());
```

  There exists more functionality when using the `IsEmpty` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test for Non-Empty Strings

Create a TestCase object.

```
testCase = matlab.unittest.TestCase;

testCase.verifyNotEmpty('');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [0  0].

Actual Value:
         ''
```

Test failed.

Test for Non-Empty Arrays

An array with any zero dimension is empty.

Test array `[2 3]`.

```
testCase.verifyNotEmpty([2 3]);
```

```
Interactive verification passed.
```

Test array with a zero dimension.

```
testCase.verifyNotEmpty(ones(2, 5, 0, 3));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [2  5  0  3].

Actual Value:
       Empty array: 2-by-5-by-0-by-3
```

Test failed.

Test for Non-Empty Cell Arrays

A cell array of empty arrays is not empty.

```
testCase.verifyNotEmpty({[], [], []}, '');
```

```
Interactive verification passed.
```

Test for Non-Empty Test Suite

Test an empty object, `emptyTestSuite`.

```
emptyTestSuite = matlab.unittest.TestSuite.emtpy;
testCase.verifyNotEmpty(emptyTestSuite);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [0  0].

Actual Value:
```

```
0x0 TestCase array with no properties.
```

Test failed.

matlab.unittest.TestCase.verifyNotEqual

Purpose

Verify value is not equal to specified value

Syntax

```
verifyNotEqual(verifiable,actual,notExpected)
verifyNotEqual( ___ ,diagnostic)
```

Description

`verifyNotEqual(verifiable,actual,notExpected)` verifies that `actual` is not equal to `notExpected`.

`verifyNotEqual( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
verifiable.verifyThat(actual, ~IsEqualTo(notExpected));
```

  There exists more functionality when using the `IsEqualTo` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

notExpected

Value to compare.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Compare Numeric Values

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Compare a value to itself.

```
testCase.verifyNotEqual(5, 5);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEqual failed.
--> NumericComparator passed.

Actual Value:
         5
Prohibited Value:
         5
```

Test failed.

Compare different number values.

```
testCase.verifyNotEqual(4.95, 5, '4.95 should be different from 5');
```

```
Interactive verification passed.
```

Values `4.95` and `5` are not equal.

Compare values of different sizes.

```
testCase.verifyNotEqual([5 5], 5, '[5 5] is not equal to 5');
```

```
Interactive verification passed.
```

Values are not equal.

Compare Classes

```
testCase.verifyNotEqual(int8(5), int16(5), 'Classes dont match');
```

```
Interactive verification passed.
```

Compare Cell Arrays

Test a cell array by comparing each element.

```
testCase.verifyNotEqual({'cell', struct, 5}, {'cell', struct, 5});
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEqual failed.
--> CellComparator passed.

Actual Value:
        'cell'    [1x1 struct]    [5]
Prohibited Value:
        'cell'    [1x1 struct]    [5]
```

Test failed.

See Also

verifyThat | verifyEqual |

Purpose

Verify value is not handle to specified instance

Syntax

```
verifyNotSameHandle(verifiable,actual,notExpectedHandle)
verifyNotSameHandle( ___ ,diagnostic)
```

Description

`verifyNotSameHandle(verifiable,actual,notExpectedHandle)` verifies that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`verifyNotSameHandle( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  verifiable.verifyThat(actual, ~IsSameHandleAs(notExpectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

notExpectedHandle

The handle array to compare.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test Handles from Same Class

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Create a handle class, ExampleHandle.

```
classdef ExampleHandle < handle
end
```

Create two handle variables.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Handles point to different objects.

```
testCase.verifyNotSameHandle(h1, h2);
```

```
Interactive verification passed.
```

Show matching handle combinations.

```
testCase.verifyNotSameHandle([h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotSameHandle failed.
```

```
--> The two handles must not refer to the same handle, or should have
different sizes.

Actual Value:
      1x3 ExampleHandle array with no properties.
Handle Object:
      1x3 ExampleHandle array with no properties.
```

Test failed.

The order of the handle arguments matters.

```
testCase.verifyNotSameHandle([h1 h2], [h2 h1]);
```

```
Interactive verification passed.
```

Test a handle with itself.

```
testCase.verifyNotSameHandle(h1, h1);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotSameHandle failed.
--> The two handles must not refer to the same handle, or should have
different sizes.

Actual Value:
      ExampleHandle with no properties.
Handle Object:
      ExampleHandle with no properties.
```

Test failed.

Variables are not same size.

```
testCase.verifyNotSameHandle(h2, [h2 h2]);
```

```
Interactive verification passed.
```

Variables are the same size.

```
testCase.verifyNotSameHandle([h1 h1], [h1 h1]);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotSameHandle failed.
--> The two handles must not refer to the same handle, or should have
different sizes.

Actual Value:
      1x2 ExampleHandle array with no properties.
Handle Object:
      1x2 ExampleHandle array with no properties.
```

Test failed.

See Also

verifySameHandle | verifyThat |

Purpose

Verify value has specified element count

Syntax

```
verifyNumElements(verifiable,actual,expectedElementCount)
verifyNumElements( ___ ,diagnostic)
```

Description

`verifyNumElements(verifiable,actual,expectedElementCount)` verifies that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`verifyNumElements( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasElementCount;
  verifiable.verifyThat(actual, HasElementCount(expectedElementCount)
  ```

  There exists more functionality when using the `HasElementCount` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

expectedElementCount

The expected number of elements in the array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test Matrices

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;

n = 7;
testCase.verifyNumElements(eye(n), n^2);

Interactive verification passed.

testCase.verifyNumElements(3, 1);

Interactive verification passed.

testCase.verifyNumElements([1 2 3; 4 5 6], 5);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNumElements failed.
--> The value did not have the correct number of elements.

    Actual Number of Elements:
             6
    Expected Number of Elements:
             5

Actual Value:
```

```
     1     2     3
     4     5     6
```

Test failed.

Test Cell Array

```
testCase.verifyNumElements({'SomeString', 'SomeOtherString'}, 2);
```

```
Interactive verification passed.
```

Test Structure

```
s.Field1 = 1;
s.Field2 = 2;
testCase.verifyNumElements(s, 2);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNumElements failed.
--> The value did not have the correct number of elements.

    Actual Number of Elements:
             1
    Expected Number of Elements:
             2

Actual Value:
        Field1: 1
        Field2: 2
```

Test failed.

verifyThat | verifySize | verifyLength | numel

matlab.unittest.TestCase.verifyReturnsTrue

Purpose

Verify function returns true when evaluated

Syntax

```
verifyReturnsTrue(verifiable,actual)
verifyReturnsTrue(___,diagnostic)
```

Description

`verifyReturnsTrue(verifiable,actual)` verifies that `actual` is a function handle that returns a scalar logical whose value is true.

`verifyReturnsTrue(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using verifyTrue because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using verifyTrue.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ReturnsTrue;
  verifiable.verifyThat(actual, ReturnsTrue());
  ```

  There exists more functionality when using the `ReturnsTrue` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The function handle to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test if Condition is True

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;

testCase.verifyReturnsTrue(@true);

Interactive verification passed.

testCase.verifyReturnsTrue(@() isequal(1,1));

Interactive verification passed.

testCase.verifyReturnsTrue(@() ~strcmp('a','b'));

Interactive verification passed.

testCase.verifyReturnsTrue(@false);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyReturnsTrue failed.
--> The function handle should have evaluated to "true".
--> Returned value:
             0
```

```
Actual Function Handle:
        @false
```

Test failed.

```
testCase.verifyReturnsTrue(@() strcmp('a',{'a','a'}));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyReturnsTrue failed.
--> The function handle should have returned a scalar. The return value h
--> Returned value:
             1     1

Actual Function Handle:
        @()strcmp('a',{'a','a'})
```

Test failed.

```
testCase.verifyReturnsTrue(@() exist('exist'));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyReturnsTrue failed.
--> The function handle should have returned a logical value. It was of t
--> Returned value:
             5

Actual Function Handle:
        @()exist('exist')
```

Test failed.

See Also

`verifyThat` | `verifyTrue` |

matlab.unittest.TestCase.verifySameHandle

Purpose

Verify two values are handles to same instance

Syntax

```
verifySameHandle(verifiable,actual,expectedHandle)
verifySameHandle( ___ ,diagnostic)
```

Description

`verifySameHandle(verifiable,actual,expectedHandle)` verifies that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`verifySameHandle( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  verifiable.verifyThat(actual, IsSameHandleAs(expectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

expectedHandle

The expected handle array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test Handles from Same Class

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Create a handle class, `ExampleHandle`.

```
classdef ExampleHandle < handle
end
```

Create two handle variables.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Show matching handle combinations.

```
testCase.verifySameHandle(h1, h1);
```

```
Interactive verification passed.
```

```
testCase.verifySameHandle([h1 h1], [h1 h1]);
```

```
Interactive verification passed.
```

```
testCase.verifySameHandle([h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification passed.
```

Handles must point to same object.

```
testCase.verifySameHandle(h1, h2);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySameHandle failed.
--> Values do not refer to the same handle.

Actual Value:
      ExampleHandle with no properties.
Expected Handle Object:
      ExampleHandle with no properties.
```

Test failed.

Size of handle objects must match.

```
testCase.verifySameHandle([h1 h1], h1);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySameHandle failed.
--> Sizes do not match.
     Actual Value Size            : [1  2]
     Expected Handle Object Size : [1  1]

Actual Value:
      1x2 ExampleHandle array with no properties.
Expected Handle Object:
      ExampleHandle with no properties.
```

Test failed.

Order of arguments is important.

```
testCase.verifySameHandle([h1 h2], [h2 h1]);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySameHandle failed.
--> Some elements in the handle array refer to the wrong handle.

Actual Value:
      1x2 ExampleHandle array with no properties.
Expected Handle Object:
      1x2 ExampleHandle array with no properties.
```

Test failed.

matlab.unittest.TestCase.verifySize

Purpose

Verify value has specified size

Syntax

```
verifySize(verifiable,actual,expectedSize)
verifySize( ___ ,diagnostic)
```

Description

`verifySize(verifiable,actual,expectedSize)` verifies that `actual` is a MATLAB array whose size is `expectedSize`.

`verifySize( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasSize;
  verifiable.verifyThat(actual, HasSize(expectedSize));
  ```

  There exists more functionality when using the `HasSize` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

expectedSize

The expected sizes of each dimension the array.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test Arrays

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

```
testCase.verifySize(ones(2, 5, 3), [2 5 3]);
```

```
Interactive verification passed.
```

```
testCase.verifySize([1 2 3; 4 5 6], [2 3]);
```

```
Interactive verification passed.
```

```
testCase.verifySize([2 3], [3 2]);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySize failed.
--> The value had an incorrect size.

    Actual Size:
             1     2
    Expected Size:
             3     2

Actual Value:
         2     3
```

Test failed.

Number of elements is not the same as size.

```
testCase.verifySize([1 2 3; 4 5 6], [6 1]);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySize failed.
--> The value had an incorrect size.

    Actual Size:
             2     3
    Expected Size:
             6     1

Actual Value:
         1     2     3
         4     5     6
```

Test failed.

```
testCase.verifySize(eye(2), [4 1]);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySize failed.
--> The value had an incorrect size.

    Actual Size:
             2     2
    Expected Size:
             4     1
```

```
Actual Value:
         1     0
         0     1
```

Test failed.

Test Cell Array

```
testCase.verifySize({'SomeString', 'SomeOtherString'}, [1 2]);

matlab.unittest.TestCase.verifySubstring

Purpose

Verify string contains specified string

Syntax

```
verifySubstring(verifiable,actual,substring)
verifySubstring( ___ ,diagnostic)
```

Description

`verifySubstring(verifiable,actual,substring)` verifies that `actual` is a string that contains `substring`.

`verifySubstring( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ContainsSubstring;
  verifiable.verifyThat(actual, ContainsSubstring(substring));
  ```

  There exists more functionality when using the `ContainsSubstring` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The string to test.

substring

The value to match, specified as a string.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test for Substrings

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;

testCase.verifySubstring('SomeLongString', 'Long');

Interactive verification passed.
```

Show that case matters.

```
testCase.verifySubstring('SomeLongString', 'lonG');

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySubstring failed.
--> The string must contain the substring.

Actual String:
    SomeLongString
Expected Substring:
    lonG
```

Test failed.

```
testCase.verifySubstring('SomeLongString', 'OtherString');

Interactive verification failed.
```

```
---------------------
Framework Diagnostic:
---------------------
verifySubstring failed.
--> The string must contain the substring.

Actual String:
    SomeLongString
Expected Substring:
    OtherString
```

Test failed.

```
testCase.verifySubstring('SomeLongString', 'SomeLongStringThatIsLonger');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySubstring failed.
--> The string must contain the substring.

Actual String:
    SomeLongString
Expected Substring:
    SomeLongStringThatIsLonger
```

Test failed.

See Also

verifyThat | verifyMatches | strfind

Purpose

Verify value meets given constraint

Syntax

```
verifyThat(verifiable,actual,constraint)
verifyThat( ___ ,diagnostic)
```

Description

`verifyThat(verifiable,actual,constraint)` verifies that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, a verification failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`verifyThat( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

constraint

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test Conditions Using Constraints

```
% Passing scenarios
%%%%%%%%%%%%%%%%%%%%
import matlab.unittest.constraints.IsTrue;
testCase.verifyThat(true, IsTrue);

import matlab.unittest.constraints.IsEqualTo;
testCase.verifyThat(5, IsEqualTo(5), '5 should be equal to 5');

import matlab.unittest.constraints.IsGreaterThan;
import matlab.unittest.constraints.HasNaN;
testCase.verifyThat([5 NaN], IsGreaterThan(10) | HasNaN, ...
    'The value was not greater than 10 or NaN');

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%
import matlab.unittest.constraints.AnyCellOf;
import matlab.unittest.constraints.ContainsSubstring;
testCase.verifyThat( AnyCellOf({'cell','of','strings'}), ...
    ContainsSubstring('char'),'Test description');

import matlab.unittest.constraints.HasSize;
testCase.verifyThat(zeros(10,4,2), HasSize([10,5,2]), ...
    @() disp('A function handle diagnostic.'));

import matlab.unittest.constraints.IsEmpty;
testCase.verifyThat(5, IsEmpty);
```

Purpose

Verify value is true

Syntax

```
verifyTrue(verifiable,actual)
verifyTrue(___,diagnostic)
```

Description

`verifyTrue(verifiable,actual)` verifies that `actual` is a scalar logical with the value of true.

`verifyTrue(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsTrue;
  verifiable.verifyThat(actual, IsTrue());
  ```

  There exists more functionality when using the `IsTrue` constraint directly via verifyThat.

  Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as IsEqualTo. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of verifyReturnsTrue, which at least shows the display of the function evaluated to generate the failing result.
-

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The value to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Examples

Test MATLAB Logical Functions

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Test `true`.

```
testCase.verifyTrue(true);
```

```
Interactive verification passed.
```

Test `false`.

```
testCase.verifyTrue(false);
```

```
Interactive verification failed.
```

```
---------------------
Framework Diagnostic:
---------------------
verifyTrue failed.
--> The value must evaluate to "true".

Actual Value:
         0
```

Test failed.

Test the Value 1

The number `1` is a `double` value, not a logical value.

A double value of `1` is not `true`.

```
testCase.verifyTrue(1);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyTrue failed.
--> The value must be logical. It is of type "double".

Actual Value:
         1
```

Test failed.

Test Array of Logical Values

To be true, the value must be scalar.

```
testCase.verifyTrue([true true true]);
```

```
Interactive verification failed.
```

```
---------------------
Framework Diagnostic:
---------------------
verifyTrue failed.
--> The value must be scalar. It has a size of [1  3].

Actual Value:
         1     1     1
```

Test failed.

Optimized comparison that trades speed for less diagnostics.

```
testCase.verifyTrue(~isempty(strfind('string', 'ring')), ...
    'Could not find expected string');
```

See Also

matlab.unittest.TestCase.verifyWarning

Purpose

Verify function issues specified warning

Syntax

```
verifyWarning(verifiable,actual,warningID)
verifyWarning(___,diagnostic)
[output1,...,outputN] = verifyWarning(___)
```

Description

`verifyWarning(verifiable,actual,warningID)` verifies that `actual` issues a warning with the identifier `warningID`.

`verifyWarning(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = verifyWarning(___)` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesWarnings;
  verifiable.verifyThat(actual, IssuesWarnings({warningID}));
  ```

  There exists more functionality when using the `IssuesWarnings` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The function handle to test.

warningID

Warning ID, specified as a string.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Output Arguments

output1,...,outputN

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

Examples

Test warning Function

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;

testCase.verifyWarning(@() warning('SOME:warning:id','Warning!'), ...
    'SOME:warning:id');

Interactive verification passed.

testCase.verifyWarning(@() warning('SOME:other:id', 'Warning message'),..
    'SOME:warning:id', 'Did not issue specified warning');

Warning: Warning message
> In @()warning('SOME:other:id','Warning message')
  In FunctionHandleConstraint>FunctionHandleConstraint.invoke at 43
  In WarningQualificationConstraint>WarningQualificationConstraint.invoke
  In IssuesWarnings>IssuesWarnings.invoke at 364
  In IssuesWarnings>IssuesWarnings.issuesExpectedWarnings at 411
  In IssuesWarnings>IssuesWarnings.satisfiedBy at 240
```

```
  In QualificationDelegate>QualificationDelegate.qualifyThat at 90
  In QualificationDelegate>QualificationDelegate.qualifyWarning at 196
  In Verifiable>Verifiable.verifyWarning at 701
Interactive verification failed.

----------------
Test Diagnostic:
----------------
Did not issue specified warning

---------------------
Framework Diagnostic:
---------------------
verifyWarning failed.
--> The function handle did not issue a correct warning profile.
    The expected warning profile ignores:
      Set
      Count
      Order
    --> The function handle did not issue the correct warnings.

        Missing Warnings:
             SOME:warning:id

    Actual Warning Profile:
         SOME:other:id
    Expected Warning Profile:
         SOME:warning:id

Evaluated Function:
        @()warning('SOME:other:id','Warning message')
```

Test a Function Without Warnings

Test the `true` function, which does not issue warnings.

```
testCase.verifyWarning(@true, 'SOME:warning:id', ...
```

```
'@true did not issue any warning');

Interactive verification failed.

----------------
Test Diagnostic:
----------------
@true did not issue any warning

---------------------
Framework Diagnostic:
---------------------
verifyWarning failed.
--> The function handle did not issue a correct warning profile.
    The expected warning profile ignores:
      Set
      Count
      Order
    --> The function handle did not issue any warnings.

    Expected Warning Profile:
         SOME:warning:id

Evaluated Function:
        @true
```

Test failed.

Test Function With Output Arguments

Create a `helper` function that generates a warning and returns output.

```
function varargout = helper()
    warning('SOME:warning:id','Warning!');
    varargout = {123, 'abc'};
end
```

Call `helper`.

```
[actualOut1, actualOut2] = testCase.verifyWarning(@helper, ...
    'SOME:warning:id');

Interactive verification passed.
```

See Also

verifyThat | verifyError | verifyWarningFreewarning |

matlab.unittest.TestCase.verifyWarningFree

Purpose

Verify function issues no warnings

Syntax

```
verifyWarningFree(verifiable,actual)
verifyWarningFree( ___ ,diagnostic)
output1,...,outputN = verifyWarningFree( ___ )
```

Description

`verifyWarningFree(verifiable,actual)` verifies that `actual` is a function handle that issues no warnings.

`verifyWarningFree( ___ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`output1,...,outputN = verifyWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesNoWarnings;
  verifiable.verifyThat(actual, IssuesNoWarnings());
  ```

  There exists more functionality when using the `IssuesNoWarnings` constraint directly via verifyThat.

Input Arguments

verifiable

The matlab.unittest.TestCase instance which is used to pass or fail the verification in conjunction with the test running framework.

actual

The function handle to test.

diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see matlab.unittest.diagnostics.Diagnostic.

Output Arguments

output1,...,outputN

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

Examples

Test for Warnings from MATLAB Functions

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Test the `why` function.

```
testCase.verifyWarningFree(@why);
```

```
The bald and not excessively bald and not excessively smart hamster ob
Interactive verification passed.
```

This is a randomly-generated message.

Test the `true` function.

```
testCase.verifyWarningFree(@true);
```

```
Interactive verification passed.
```

Test the `false` function.

```
actualOutputFromFalse = testCase.verifyWarningFree(@false);
```

```
Interactive verification passed.
```

Test a value that is not a function handle.

```
testCase.verifyWarningFree(5,'diagnostic');

Interactive verification failed.

----------------
Test Diagnostic:
----------------
diagnostic

---------------------
Framework Diagnostic:
---------------------
verifyWarningFree failed.
--> The value must be an instance of the expected type.

    Actual Class:
        double
    Expected Type:
        function_handle

Actual Value:
         5
```

Test failed.

Test a function that generates warning.

```
testCase.verifyWarningFree(@() warning('some:id', 'Message'));

verifyThat | verifyWarning | warning

Purpose

Result of running test suite

Description

The matlab.unittest.TestResult class holds the information describing the result of running a test suite using the matlab.unittest framework. The results include information describing whether the test passed, failed, or ran to completion, as well as the duration of each test.

Construction

TestResult arrays are created and returned by the test runner, and are of the same size as the suite which was run.

Properties

Duration

Time elapsed running test.

The `Duration` property indicates the amount of time taken to run a particular test, including the time taken setting up and tearing down any test fixtures.

Fixture setup time is accounted for in the duration of the first test suite array element that uses the fixture. Fixture teardown time is accounted for in the duration of the last test suite array element that uses the fixture.

The total run time for a suite of tests exceeds the sum of the durations for all the elements of the suite because the `Duration` property does not include all the overhead of the TestRunner object, nor any of the time consumed by test runner plugins.

Failed

Logical value showing if test failed.

A TRUE `Failed` property indicates some form of test failure. When `Failed` is FALSE, then no failing conditions were encountered. A failing result can occur with a failure condition either in a test or in setting up and tearing down test fixtures. Failures can occur due to the following:

- Verification failures

- Assertion failures
- Uncaught MExceptions

Fatal assertions are also failing conditions, but in the event of a fatal assertion failure, the entire framework aborts and a TestResult object is never produced.

Incomplete

Logical value showing if test did not run to completion.

A TRUE `Incomplete` property indicates a test did not run to completion. When it is FALSE, then no conditions were encountered that prevented the test from completing. In other words, when FALSE there were no stack disruptions out of the running test content. An incomplete result can occur with a stack disruption in either a test or when setting up and tearing down test fixtures. Incomplete tests can occur due to the following:

- Assertion failures
- Tests filtered through assumption
- Uncaught MExceptions

Fatal assertions are also conditions that prevent the completion of tests, but in the event of a fatal assertion failure the entire framework aborts and a TestResult object is never produced.

Name

The name of the TestSuite object for the result.

The `Name` property is a string that holds the name of the test corresponding to this result.

Passed

Logical value showing if the test passed.

When the `Passed` property is TRUE, then the test completed as expected without any failure. When it is FALSE, then the test did not run to completion and/or encountered a failure condition.

Examples

Use TestResult Object to Identify and Rerun Failed Tests

Add the matlab.unittest.TestSuite class to the current import list.

```
import matlab.unittest.TestSuite;
```

Result display method provides a summary of the results

```
suite = TestSuite.fromClass(?SomeTestClass)
results = run(suite)
```

```
results =

  matlab.unittest.TestResult

  Test Suite Summary:
    12 Passed, 4 Failed, 0 Not Run To Completion.
    5.5091 seconds testing time.
```

Rerun only the failed tests.

```
failedTests = suite([results.Failed]);
failedResults = run(failedTests)
```

```
failedResults =

  matlab.unittest.TestResult

  Test Suite Summary:
    0 Passed, 4 Failed, 0 Not Run To Completion.
    1.2894 seconds testing time.
```

Make the fix and rerun results.

```
newResults = run(failedTests)

newResults =

  matlab.unittest.TestResult

  Test Suite Summary:
    4 Passed, 0 Failed, 0 Not Run To Completion.
    1.1607 seconds testing time.
```

See Also

`TestRunner` | `TestSuite` |

Concepts

- Property Attributes

matlab.unittest.TestRunner

Purpose

Class for running tests in `matlab.unittest` framework

Description

The matlab.unittest.TestRunner class is the fundamental API used to run a suite of tests in the matlab.unittest framework. It runs and operates on TestSuite arrays. Use this class to customize running tests.

The TestRunner class is a sealed class; you cannot derive classes from the TestRunner class.

Construction

To create a simple, silent TestRunner object, call the static withNoPlugins method.

```
runner = matlab.unittest.TestRunner.withNoPlugins
```

To create a TestRunner object to run tests from the MATLAB Command Window , call the static withTextOutput method.

```
runner = matlab.unittest.TestRunner.withTextOutput
```

To create a customized TestRunner object, call the addPlugin method.

```
runner = TestRunner.withNoPlugins;
runner.addPlugin(SomePlugin())
```

Methods

addPlugin	Add plugin to `TestRunner` object
run	Run all tests in `TestSuite` array
withNoPlugins	Create simplest runner possible
withTextOutput	Create `TestRunner` object for command window output

Examples

Create TestRunner Object Configured for Text Output

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;
```

```
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create the TestRunner object and run the suite.

```
runner = TestRunner.withTextOutput;
result = run(runner,suite);
```

See Also

TestSuite | TestResult |

matlab.unittest.TestRunner.addPlugin

Purpose

Add plugin to `TestRunner` object

Syntax

`addPlugin(runner,plugin)`

Description

`addPlugin(runner,plugin)` adds `plugin` to `runner`.

Input Arguments

runner

matlab.unittest.TestRunner object.

plugin

Mechanism provided to customize the manner in which a TestSuite array is run, specified as a TestRunnerPlugin object.

Examples

Run Test with Custom Plugin

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a TestRunner object.

```
runner = TestRunner.withNoPlugins;
```

Add a custom plugin.

```
import matlab.unittest.plugins;
runner.addPlugin(DiagnosticsValidationPlugin);
```

Run the test.

```
result = run(runner,suite);
```

Purpose Run all tests in `TestSuite` array

Syntax

```
result = run(runner,suite)
```

Description

`result = run(runner,suite)` runs the TestSuite array defined by `suite` using the TestRunner object provided in `runner`, and returns the result in `result`.

This method runs all of the appropriate methods of the TestCase class to set up fixtures and run test content. It handles errors and qualification failures and records the information in `result`.

Input Arguments

runner

matlab.unittest.TestRunner object.

suite

Set of tests, specified as a matlab.unittest.TestSuite array.

Output Arguments

result

A matlab.unittest.TestResult object containing the result of the test run. `result` is the same size as `suite` and each element is the result of the corresponding element in `suite`.

Examples

Run All Tests in a Package

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a test suite, and a test runner that displays text.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
runner = TestRunner.withTextOutput;
```

Run the test suite.

```
result = runner.run(suite)
```

See Also

matlab.unittest.TestSuite.run | matlab.unittest.TestCase.run |

Purpose Create simplest runner possible

Syntax

```
runner = matlab.unittest.TestRunner.withNoPlugins
```

Description

`runner = matlab.unittest.TestRunner.withNoPlugins` creates a TestRunner that is guaranteed to have no plugins installed and returns it in `runner`. It is the method one can use to create the simplest runner possible without violating the guarantees a test writer has when writing TestCase classes. This runner is a silent runner, meaning that regardless of passing or failing tests, this runner produces no command window output, although the results returned after running a test suite are accurate.

This method can also be used when it is desirable to have complete control over which plugins are installed and in what order. It is the only method guaranteed to produce the minimal TestRunner with no plugins, so one can create it and add additional plugins as desired.

Output Arguments

runner

matlab.unittest.TestRunner object.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Create a Silent TestRunner Object with no Plugins

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a TestRunner object.

```
runner = TestRunner.withNoPlugins;

% Run the suite silently
result = run(runner,suite)
```

Control Plugins

Using the TestRunner object created in the previous example, control which plugins are installed and in what order they are installed.

Add matlab.unittest class to the current import list.

```
import matlab.unittest.plugins;
```

Add specific plugins.

```
runner.addPlugin(DiagnosticsValidationPlugin);
runner.addPlugin(TestSuiteProgressPlugin);
```

Rerun the tests.

```
result = run(runner,suite)
```

Purpose

Create `TestRunner` object for command window output

Syntax

`runner = matlab.unittest.TestRunner.withTextOutput`

Description

`runner = matlab.unittest.TestRunner.withTextOutput` creates a TestRunner object that is configured for running tests from the MATLAB Command Window and returns it in `runner`. The output produced includes test progress as well as diagnostics in the event of test failures.

Output Arguments

runner

matlab.unittest.TestRunner object.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Display Test Results in Command Window

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a TestRunner object that produced output to the Command Window.

```
runner = TestRunner.withTextOutput;
```

```
% Run the suite
result = run(runner,suite)
```

See Also run |

Purpose

Class for grouping tests to run

Description

The matlab.unittest.TestSuite class is the fundamental interface used to group and run a set of tests in the unit test framework. The matlab.unittest.TestRunner object can only run arrays of TestSuite objects.

Construction

TestSuite arrays are created using static methods of the TestSuite class. These methods may return subclasses of the TestSuite class depending on the method call and context.

Methods

fromClass	Create suite from `TestCase` class
fromFile	Create `TestSuite` array from test file
fromFolder	Create `TestSuite` array from all tests in folder
fromMethod	Create `TestSuite` array from single test method
fromPackage	Create `TestSuite` array from all tests in package
run	Run `TestSuite` array using `TestRunner` object configured for text output

Examples

Create Test Suite of Every Type of Test Set

Add the matlab.unittest.TestSuite class to the current import list.

```
import matlab.unittest.TestSuite;
```

Create test suites using a each method.

```
fileSuite    = TestSuite.fromFile('SomeTestFile.m');
```

```
folderSuite  = TestSuite.fromFolder(pwd);
packageSuite = TestSuite.fromPackage('mypackage.subpackage');
classSuite   = TestSuite.fromClass(?mypackage.MyTestClass);
methodSuite  = TestSuite.fromMethod(?SomeTestClass,'testMethod');
```

Concatenate the suites.

```
largeSuite = [fileSuite, folderSuite, packageSuite, classSuite, methodSui
```

Run the full suite.

```
result = run(largeSuite)
```

See Also

TestRunner | TestResult |

Purpose

Create suite from `TestCase` class

Syntax

```
suite = matlab.unittest.TestSuite.fromClass(testClass)
```

Description

`suite = matlab.unittest.TestSuite.fromClass(testClass)` creates a TestSuite array from all of the `Test` methods contained in `testClass` and returns that array in `suite`.

Tips

- `testClass` must be on the MATLAB path when using this method to create `suite`, as well as when `suite` is run.

Input Arguments

testClass

Class containing test methods, specified as a `meta.class` instance. Use the `?` operator to create a `meta.class` instance. `testClass` must derive from matlab.unittest.TestCase.

Output Arguments

suite

Set of tests, specified as a matlab.unittest.TestSuite array.

Attributes

Static	true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run Tests in a Package Class

Add the matlab.unittest.TestSuite class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?mypackage.MyTestClass);
result = run(suite)
```

Run Tests in a Class Without a Package

Add the matlab.unittest.TestSuite class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?MyTestClass);
result = run(suite)
```

See Also

TestRunner | fromMethod | fromPackage |

Purpose

Create `TestSuite` array from test file

Syntax

```
suite = matlab.unittest.TestSuite.fromFile(file)
```

Description

`suite = matlab.unittest.TestSuite.fromFile(file)` creates a TestSuite array from all of the `Test` methods in `file`.

When the test suite is run, MATLAB changes the current folder to the folder the suite was created from, and adds it to the path for the duration of the test run.

Input Arguments

file

Class file derived from matlab.unittest.TestCase containing test methods, specified as a string.

Output Arguments

suite

Set of tests, specified as a matlab.unittest.TestSuite array.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run Tests in Class File

Function for unit testing:

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.');
end
res = x + 5;
end
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
    methods (Test)
        function testDoubleOut(testCase)
            actOutput = add5(1);
            testCase.verifyClass(actOutput,'double');
        end
        function testNonNumericInput(testCase)
            testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric');
        end
    end
end
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m');

result = run(suite);
```

```
Running Add5Test
..
Done Add5Test
__________
```

See Also

TestRunner | fromFolder |

Purpose

Create `TestSuite` array from all tests in folder

Syntax

```
suite = matlab.unittest.TestSuite.fromFolder(folder)
suite = matlab.unittest.TestSuite.fromFolder(folder,Name,
   Value)
```

Description

`suite = matlab.unittest.TestSuite.fromFolder(folder)` creates a TestSuite array from all of the `Test` methods of all concrete TestCase classes contained in `folder` and returns that array in `suite`. The method is not recursive, returning only those tests directly in the specified folder.

When the test suite is run, MATLAB changes the current folder to the folder the suite was created from, and adds it to the path for the duration of the test run.

`suite = matlab.unittest.TestSuite.fromFolder(folder,Name,Value)` creates a TestSuite array with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

folder

Folder containing test methods, specified as a string. `folder` can be either an absolute or relative path to the desired folder.

Name-Value Pair Arguments

'IncludingSubfolders'

Include test methods from any `folder` subfolders, excluding package, class, and private folders.

Output Arguments

suite

Set of tests, specified as a matlab.unittest.TestSuite array.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run Tests in Current Folder

Add the matlab.unittest.TestSuite class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFolder(pwd);
result = run(suite);
```

Run Tests in Subfolders

```
suite = TestSuite.fromFolder(pwd, 'IncludingSubfolders', true);
result = run(suite);
```

See Also

TestRunner | fromFile |

Purpose

Create `TestSuite` array from single test method

Syntax

```
suite = matlab.unittest.TestSuite.fromMethod(testClass,
   testMethod)
```

Description

`suite =`
`matlab.unittest.TestSuite.fromMethod(testClass,testMethod)` creates a TestSuite array from the test class described by `testClass` and the test method described by `testMethod` and returns it in `suite`.

Tips

- `testClass` must be on the MATLAB path when using this method to create `suite`, as well as when `suite` is run.

Input Arguments

testClass

Class describing the test methods, specified as a `meta.class` instance which must derive from matlab.unittest.TestCase.

testMethod

Test method, specified by either the `meta.method` instance or the name as a string. The method must be defined with a `Test` method attribute.

Output Arguments

suite

Set of tests, specified as a matlab.unittest.TestSuite array.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run a Single Test Method

Add the matlab.unittest.TestSuite class to the current import list.

```
import matlab.unittest.TestSuite;

cls = ?mypackage.MyTestClass;

% Create the suite using the method name
suite = TestSuite.fromMethod(cls, 'testMethod');
result = run(suite)

% Create the suite using the meta.method instance
metaMethod = findobj(cls.MethodList, 'Name', 'testMethod');
suite = TestSuite.fromMethod(cls, metaMethod);
result = run(suite)
```

See Also

`TestRunner` | `fromClass` | `fromPackage` |

Purpose

Create `TestSuite` array from all tests in package

Syntax

```
suite = matlab.unittest.TestSuite.fromPackage(package)
```

Description

`suite = matlab.unittest.TestSuite.fromPackage(package)` creates a TestSuite array from all of the `Test` methods of all concrete TestCase classes contained in `package` and returns that array in `suite`. The method is not recursive, returning only those tests directly in the package specified.

Tips

- The root folder(s) where `package` is defined must be on the MATLAB path when creating `suite` using this method as well as when `suite` is run.

Input Arguments

package

The name of the desired package to find tests, specified as a string.

Output Arguments

suite

Set of tests, specified as a matlab.unittest.TestSuite array.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run All Tests in a Package

Add the matlab.unittest.TestSuite class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromPackage('mypackage.subpackage');
result = run(suite)
```

See Also

`TestRunner` | `fromMethod` | `fromClass` |

Purpose

Run `TestSuite` array using `TestRunner` object configured for text output

Syntax

```
result = run(suite)
```

Description

`result = run(suite)` runs the TestSuite object defined by `suite` using a TestRunner object configured for text output.

Tips

- This is a convenience method which is equivalent to using a TestRunner object created from the TestRunner.withTextOutput method to run `suite`.

Input Arguments

suite

Set of tests, specified as a matlab.unittest.TestSuite array.

Output Arguments

result

A matlab.unittest.TestResult object containing the result of the test run. `result` is the same size as `suite` and each element is the result of the corresponding element in `suite`.

Examples

Compare TestSuite.run with TestRunner.run

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a test suite and a test runner.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
runner = TestRunner.withTextOutput;
```

The following test results are equivalent.

```
result = runner.run(suite)
result = run(suite)
```

See Also

`matlab.unittest.TestRunner.run` | `matlab.unittest.TestCase.run` |

Purpose

Format text into TeX string

Syntax

```
TeXString = texlabel(f)
TeXString = texlabel(f,'literal')
```

Description

`TeXString = texlabel(f)` converts the MATLAB expression `f` into the TeX equivalent for use in text strings. `texlabel` converts Greek variable names (for example, lambda, delta, and so on) into a string that is displayed as Greek letters. The `TeXString` output is useful as an argument to annotation functions such as `title`, `xlabel`, and `text`.

If `TeXString` is too long to fit into a figure window, then the center of the expression is replaced with a tilde ellipsis (~~~).

`TeXString = texlabel(f,'literal')` interprets Greek variable names literally.

Input Arguments

f - Input MATLAB expression

string

Input MATLAB expression, specified as a string.

Example: `'theta (degrees)'`

Data Types

`char`

Examples

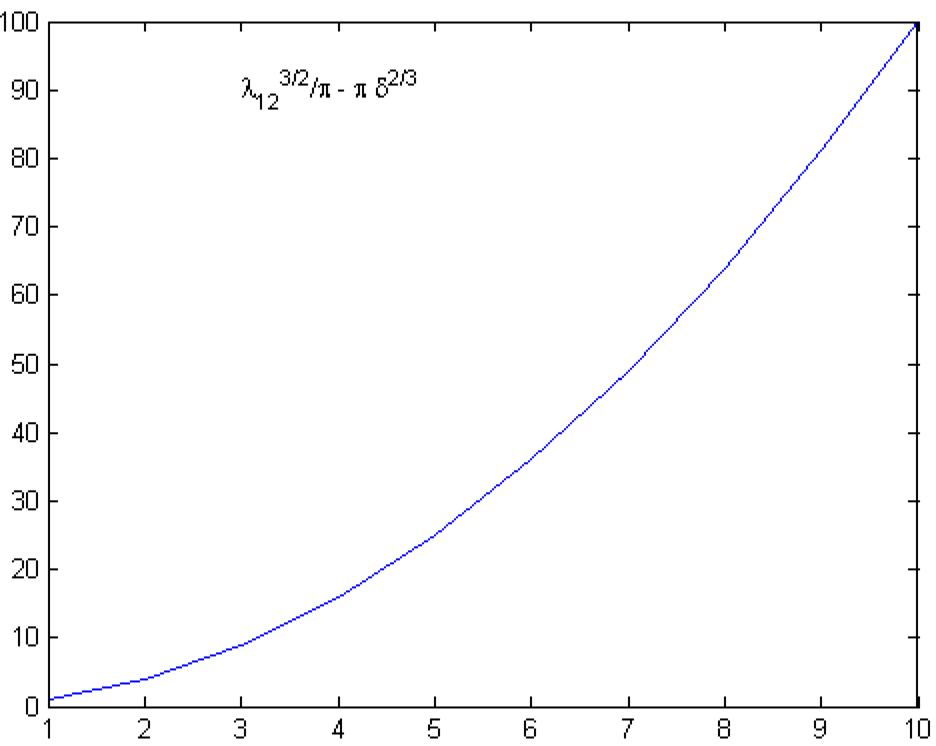
Insert TeX String in Figure

Create a figure and a TeX string for use in a text graphics object.

```
figure
plot((1:10).^2)
TeXString = texlabel('lambda12^(3/2)/pi - pi*delta^(2/3)');
```

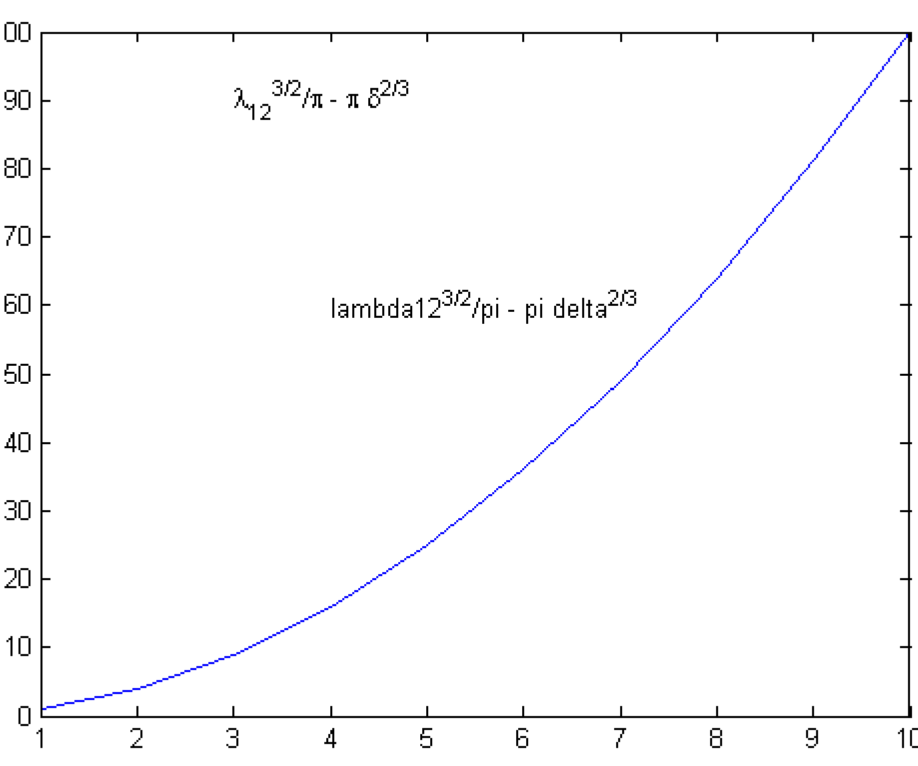
Add a text object containing the TeX string to the figure.

```
text(3,90,TeXString)
```



If you include the `'literal'` argument, `texlabel` interprets Greek variable names literally. Add a text object containing the literal string.

```
text(4,60,texlabel('lambda12^(3/2)/pi - pi*delta^(2/3)','literal'))
```



See Also

`text` | `title` | `xlabel` | `ylabel` | `zlabelString`

Purpose

Create text object in current axes

Syntax

```
text(x,y,'string')
text(x,y,z,'string')
text(x,y,z,'string','PropertyName',PropertyValue....)
text('PropertyName',PropertyValue....)
h = text(...)
```

Properties

For a list of properties, see `Text Properties`.

Description

`text` is the low-level function for creating text graphics objects. Use `text` to place character strings at specified locations.

`text(x,y,'string')` adds the string in quotes to the location specified by the point `(x,y)` `x` and `y` must be numbers of class `double`.

`text(x,y,z,'string')` adds the string in 3-D coordinates. `x`, `y` and `z` must be numbers of class `double`.

`text(x,y,z,'string','`*`PropertyName`*`',PropertyValue....)` adds the string in quotes to the location defined by the coordinates and uses the values for the specified text properties. For a description of the properties, see `Text Properties`.

`text('`*`PropertyName`*`',PropertyValue....)` omits the coordinates entirely and specifies all properties using property name/property value pairs.

`h = text(...)` returns a column vector of handles to text objects, one handle per object. All forms of the `text` function optionally return this output argument.

See the `String` property for a list of symbols, including Greek letters.

Tips

Position Text Within the Axes

The default text units are the units used to plot data in the graph. Specify the text location coordinates (the `x`, `y`, and `z` arguments) in the data units of the current graph (see “Examples” on page 1-5518. You can use other units to position the text by setting the text `Units`

property to `normalized` or one of the nonrelative units (`pixels`, `inches`, `centimeters`, `points`, or `characters`).

Note that the Axes Units property controls the positioning of the Axes within the figure and is not related to the axes data units used for graphing.

The `Extent`, `VerticalAlignment`, and `HorizontalAlignment` properties control the positioning of the character string with regard to the text location point.

If the coordinates are vectors, `text` writes the string at all locations defined by the list of points. If the character string is an array the same length as `x`, `y`, and `z`, `text` writes the corresponding row of the string array at each point specified.

Multiline Text

When specifying strings for multiple text objects, the string can be:

- A cell array of strings
- A padded string matrix

Each element of the specified string array creates a different text object.

When specifying the string for a single text object, cell arrays of strings and padded string matrices result in a text object with a multiline string, while vertical slash characters are not interpreted as separators and result in a single line string containing vertical slashes.

Behavior of the Text Function

`text` is a low-level function that accepts property name/property value pairs as input arguments. However, the convenience form:

```
text(x,y,z,'string')
```

is equivalent to:

```
text('Position',[x,y,z],'String','string')
```

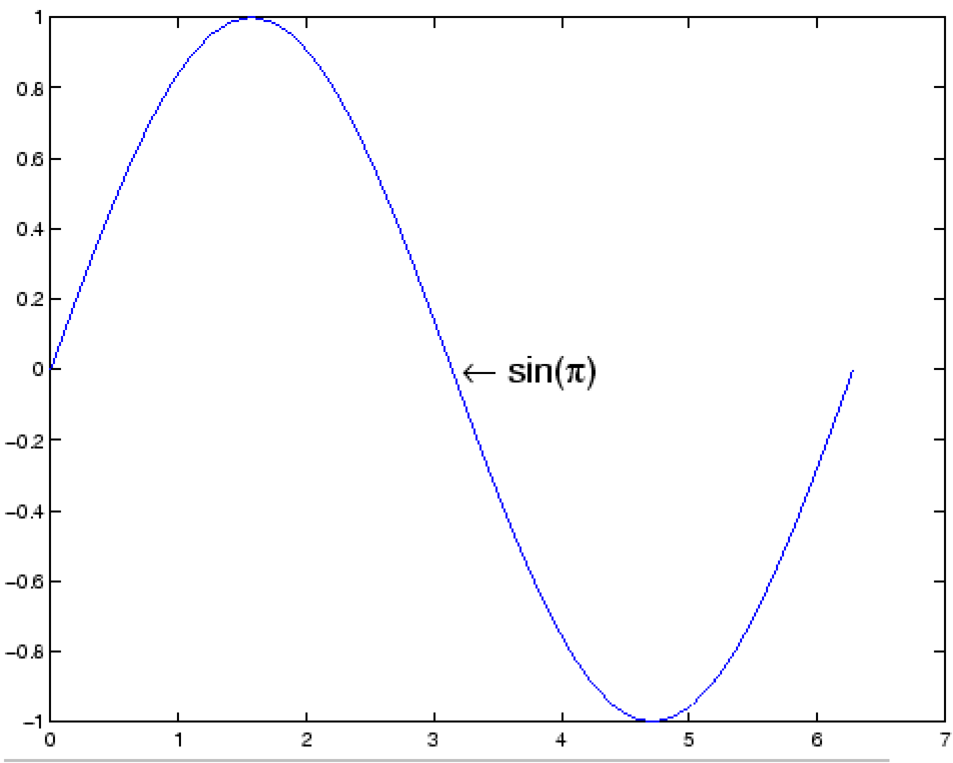
You can specify other properties only as property name/property value pairs. For a description of each property, see Text Properties. You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the set and get reference pages for examples of how to specify these data types).

text does not respect the setting of the figure or axes NextPlot property. This allows you to add text objects to an existing axes without setting hold to on.

Examples

Annotate the point (pi,0) with the string sin(π) on the following graph:

```
plot(0:pi/20:2*pi,sin(0:pi/20:2*pi))
text(pi,0,' \leftarrow sin(\pi)','FontSize',18)
```



Use embedded TeX sequences to display an equation:

```
axes
text(0.5,0.5,'\ite^{i\omega\tau} = cos(\omega\tau) + i sin(\omega\tau)')
```

MATLAB displays:

$$e^{i\omega\tau} = \cos(\omega\tau) + i\sin(\omega\tau)$$

Setting Default Properties

You can set default text properties on the axes, figure, and `root object` levels:

```
set(0,'DefaulttextProperty',PropertyValue...)
set(gcf,'DefaulttextProperty',PropertyValue...)
set(gca,'DefaulttextProperty',PropertyValue...)
```

Where *`Property`* is the name of the text property and `PropertyValue` is the value you are specifying. Use `set` and `get` to access text properties.

See Also

`annotation` | `gtext` | `int2str` | `num2str` | `strings` | `title` | `xlabel` | `ylabel` | `zlabel` | `Text Properties`

Purpose

Text properties

Creating Text Objects

Use `text` to create text objects.

Modifying Properties

You can set and query graphics object properties using the property editor or the `set` and `get` commands.

- Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see Setting Default Property Values.

See Core Objects for general information about this type of object.

Text Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Annotation`

`hg.Annotation` object (read-only)

Handle of `Annotation` object. The `Annotation` property enables you to specify whether this text object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the text object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
on	Represent this text object in a legend (default)
off	Do not include this text object in a legend
children	Same as on because text objects do not have children

Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle hobj to off:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','off')
```

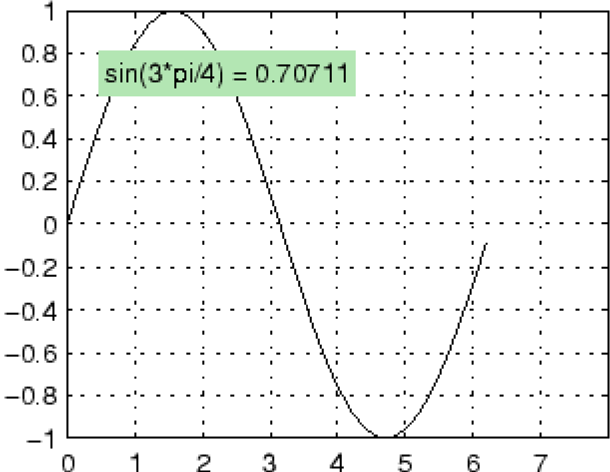
Using the IconDisplayStyle property

See "Controlling Legends" for more information and examples.

BackgroundColor
ColorSpec | {none}

Color of text extent rectangle. Defines a color for the rectangle that encloses the text Extent plus the text Margin. For example, the following code creates a text object that labels a plot and sets the background color to light green.

```
text(3*pi/4,sin(3*pi/4),...
 ['sin(3*pi/4) = ',num2str(sin(3*pi/4))],...
 'HorizontalAlignment','center',...
 'BackgroundColor',[.7 .9 .7]);
```



For additional features, see the following properties:

- `EdgeColor` — Color of the rectangle's edge (`none` by default).
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)
- `Margin` — Increase the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

See also Drawing Text in a Box in the MATLAB Graphics documentation for an example using background color with contour labels.

`BeingDeleted`
`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`
`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Button press callback function. Executes whenever you press a mouse button while the pointer is over the text object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).
The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
   sel_typ = get(gcbf,'SelectionType')
   switch sel_typ
      case 'normal'
         disp('User clicked left-mouse button')
         set(src,'Selected','on')
      case 'extend'
         disp('User did a shift-click')
         set(src,'Selected','on')
      case 'alt'
         disp('User did a control-click')
         set(src,'Selected','on')
         set(src,'SelectionHighlight','off')
   end
end
```

Suppose `h` is the handle of a text object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h,'ButtonDownFcn',@button_down)
```

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`Children`
: matrix (read-only)

The empty matrix; text objects have no children.

`Clipping`
: `on | {off}`

Clipping mode. When `Clipping` is `on`, MATLAB does not display any portion of the text that is outside the axes.

`Color`
: `ColorSpec`

Text color. A three-element RGB vector or one of the predefined names, specifying the text color. The default value is `[0 0 0]` (`black`). See the `ColorSpec` reference page for more information on specifying color.

`CreateFcn`
: function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Executes when MATLAB creates a text object. You must define this property as a default value for text or in a call to the `text` function that creates a new text object. For example, the statement:

```
set(0,'DefaultTextCreateFcn',@text_create)
```

defines a default value on the root level that sets the figure `Pointer` property to crosshairs whenever you create a text object. The callback function must be on your MATLAB path when you execute the above statement.

```
function text_create(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
 set(gcbf,'Pointer','crosshair')
end
```

MATLAB executes this function after setting all text properties. Setting this property on an existing text object has no effect. The function must define at least two input arguments (handle of object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Delete text callback function. Executes when you delete the text object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
```

```
% evnt - empty for this property
   obj_tp = get(src,'Type');
   disp([obj_tp, ' object deleted'])
   disp('Its user data is:')
   disp(get(src,'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DisplayName`
string

String used by legend. The `legend` function uses the `DisplayName` property to label the text object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

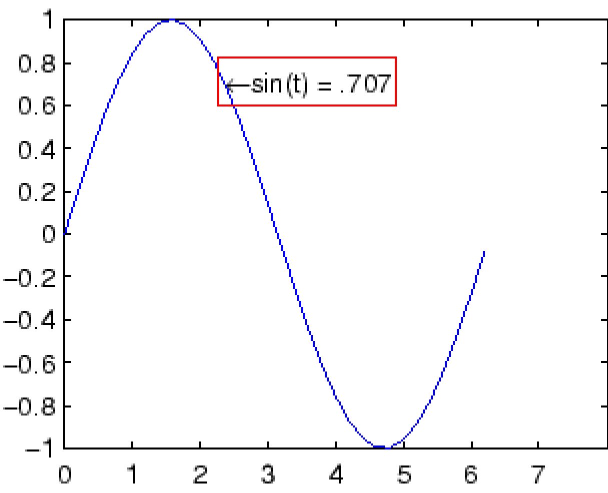
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EdgeColor`
`ColorSpec | {none}`

Color of edge drawn around text extent rectangle plus margin. Specifies the color of a box drawn around the text `Extent` plus the text `Margin`. For example, the following code draws a red rectangle around text that labels a plot.

```
text(3*pi/4,sin(3*pi/4),...
'\leftarrowsin(t) = .707',...
'EdgeColor','red');
```



For additional features, see the following properties:

- `BackgroundColor` — Color of the rectangle's interior (`none` by default)
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)
- `Margin` — Increases the size of the rectangle by adding a margin to the area defined by the text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

`Editing`
`on | {off}`

Enable or disable editing mode. When this property is `off` (the default), you cannot edit the text string interactively (i.e., you must change the `String` property to change the text). When you set this property to `on`, MATLAB enables editing and places an insert cursor wherever the mouse is within the text. To apply the new text string, do any one of the following:

- Press the **Esc** key.
- Click anywhere away from the text string.
- Reset the `Editing` property to `off.`

MATLAB updates the `String` property to contain the new text and resets the `Editing` property to `off`. You must reset the `Editing` property to `on` to resume editing.

`EraseMode`
`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase text objects. Alternative erase modes are useful for creating animated sequences where controlling the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the text when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the text by performing an exclusive OR (XOR) with each pixel index of the screen beneath it. When the text is erased, it does not damage the objects beneath it. However, when text is drawn in `xor` mode, its color depends on the color of the screen beneath it. It is correctly colored only when it is over axes background `Color`, or the figure background `Color` if the axes `Color` is `none`.
- `background` — Erase the text by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is `none`. This damages objects that are behind the erased text, but text is always properly colored.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`Extent`

position rectangle (read-only)

Position and size of text. A four-element vector that defines the size and position of the text string:

`[left,bottom,width,height]`

If the `Units` property is `data` (the default), `left` and `bottom` are the *x*- and *y*-coordinates of the lower left corner of the text `Extent`.

For all other values of `Units`, `left` and `bottom` are the distance from the lower left corner of the axes `Position` rectangle to the lower left corner of the text `Extent`. `width` and `height` are the dimensions of the `Extent` rectangle. All measurements are in units specified by the `Units` property.

`FontAngle`

`{normal} | italic | oblique`

Character slant. MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

`FontName`

name (such as `Courier`) | `FixedWidth`

Font family. Specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports. The default font is `Helvetica`.

Specifying a Fixed-Width Font

If you want text to use a fixed-width font that looks good in any locale, you should set FontName to the string FixedWidth:

```
set(text_handle,'FontName','FixedWidth')
```

This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding (such as in Japan where multibyte character sets are used). A properly written MATLAB application that needs to use a fixed-width font should set FontName to FixedWidth (note that this string is case sensitive) and rely on FixedWidthFontName to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root FixedWidthFontName property to the appropriate value for that locale from startup.m.

Note that setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

FontSize
size in FontUnits

Font size. Specifies the font size to use for text in units determined by the FontUnits property. The default is 10 points. 1 point = $^1/_{72}$ inch.

FontWeight
{normal} | bold | light | demi

Weight of text characters. MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to bold or demi causes MATLAB to use a bold font.

`FontUnits`
`{points} | normalized | inches | centimeters | pixels`

Font size units. MATLAB uses this property to determine the units used by the `FontSize` property.

- `normalized` — Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $^1/_{72}$ inch.

Note that if you are setting both the `FontSize` and the `FontUnits` in one function call, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`,

- The object's handle does not appear in its parent's `Children` property.
- Figures do not appear in the root's `CurrentFigure` property.
- Objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property.
- Axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

`HitTest`
`{on} | off`

Selectable by mouse click. Determines if the text can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the text. If `HitTest` is `off`, clicking the text selects the object below it (which is usually the axes containing it).

For example, suppose you define the button down function of an image (see the `ButtonDownFcn` property) to display text at the location you click with the mouse.

First define the callback routine.

```
function bd_function
pt = get(gca,'CurrentPoint');
text(pt(1,1),pt(1,2),pt(1,3),...
 '{\fontsize{20}\oplus} The spot to label',...
 'HitTest','off')
```

Now display an image, setting its `ButtonDownFcn` property to the callback routine.

```
load earth
image(X,'ButtonDownFcn','bd_function'); colormap(map)
```

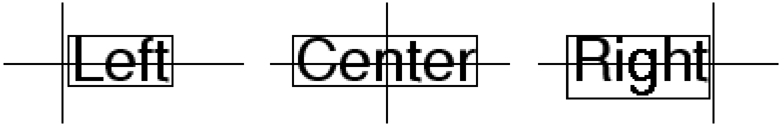
When you click the image, MATLAB displays the text string at that location. With `HitTest` set to `off`, existing text cannot intercept any subsequent button down events that occur over the text. This enables the image's button down function to execute.

`HorizontalAlignment`

`{left} | center | right`

Horizontal alignment of text. Specifies the horizontal justification of the text string. It determines where MATLAB places the string with regard to the point specified by the `Position` property. The following picture illustrates the alignment options.

`HorizontalAlignment` **viewed with the** `VerticalAlignment` **set to middle (the default).**



See the `Extent` property for related information.

See "Text Alignment" for more information and examples.

`Interpreter`

`latex | {tex} | none`

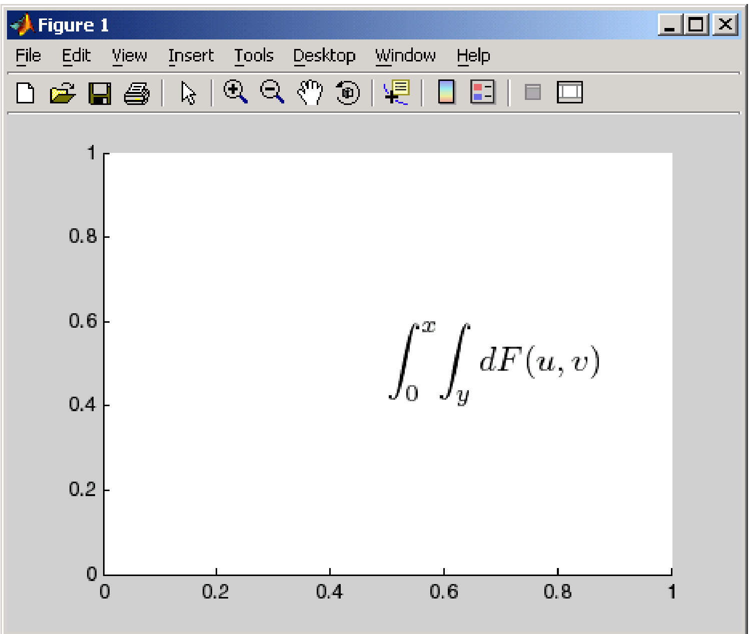
Interpret TeXinstructions. Controls whether MATLAB interprets certain characters in the `String` property as TeX instructions (default) or displays all characters literally.

- `latex` — Supports a basic subset of the LaTeX markup language.
- `tex` — Supports a subset of plain TeX markup language. See the `String` property for a list of supported TeX instructions.
- `none` — Displays literal characters.

LaTeX Interpreter

To enable the LaTeX interpreter for text objects, set the `Interpreter` property to `latex`. For example, the following statement displays an equation in a figure at the point `[.5 .5]`, and enlarges the font to 16 points.

```
text('Interpreter','latex',...
 'String','$$\int_0^x\!\int_y dF(u,v)$$',...
 'Position',[.5 .5],...
 'FontSize',16)
```



Note The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, reduce this amount by about 10 characters per line.

Information About Using TeX

The following references may be useful to people who are not familiar with TeX.

- Donald E. Knuth, *The TEXbook*, Addison Wesley, 1986.
- The TeX Users Group home page: http://www.tug.org

```
Interruptible
    off | {on}
```

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

`LineStyle`

`{-} | -- | : | -. | none`

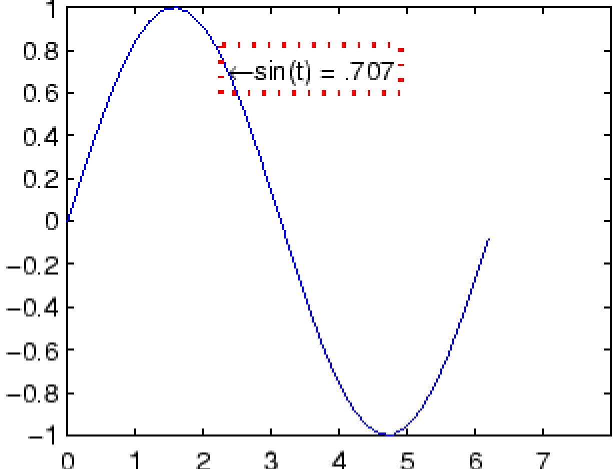
Edge line type. Specifies the line style used to draw the edges of the text `Extent`.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

For example, the following code draws a red rectangle with a dotted line style around text that labels a plot.

```
text(3*pi/4,sin(3*pi/4),...
     '\leftarrowsin(t) = .707',...
     'EdgeColor','red',...
     'LineWidth',2,...
     'LineStyle',':');
```



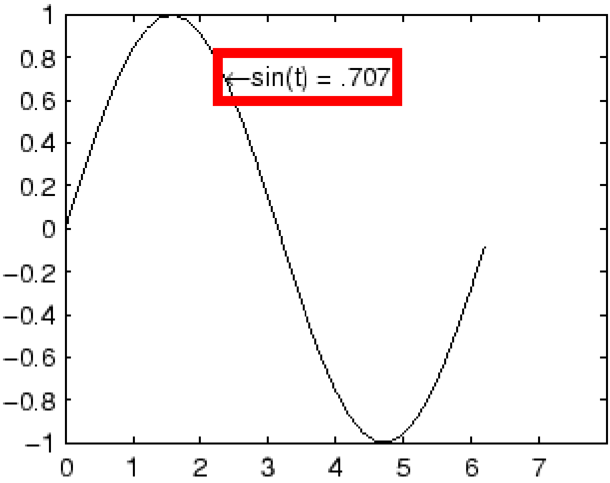
For additional features, see the following properties:

- `BackgroundColor` — Color of the rectangle's interior (`none` by default)
- `EdgeColor` — Color of the rectangle's edge (`none` by default)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)
- `Margin` — Increases the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

`LineWidth`
scalar (points)

Width of line used to draw text extent rectangle. When you set the text `EdgeColor` property to a color (the default is `none`), MATLAB displays a rectangle around the text `Extent`. Use the `LineWidth` property to specify the width of the rectangle edge. For example, the following code draws a red rectangle around text that labels a plot and specifies a line width of 3 points:

```
text(3*pi/4,sin(3*pi/4),...
'\leftarrowsin(t) = .707',...
'EdgeColor','red',...
'LineWidth',3);
```



For additional features, see the following properties:

- `BackgroundColor` — Color of the rectangle's interior (`none` by default)
- `EdgeColor` — Color of the rectangle's edge (`none` by default)
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)

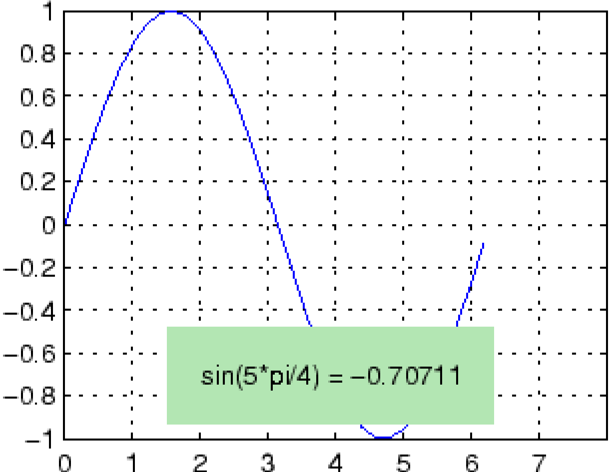
- `Margin` — Increases the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

`Margin`

scalar (pixels)

Distance between the text extent and the rectangle edge. When you specify a color for the `BackgroundColor` or `EdgeColor` text properties, MATLAB draws a rectangle around the area defined by the text `Extent` plus the value specified by the `Margin`. For example, the following code displays a light green rectangle with a 10-pixel margin.

```
text(5*pi/4,sin(5*pi/4),...
 ['sin(5*pi/4) = ',num2str(sin(5*pi/4))],...
 'HorizontalAlignment','center',...
 'BackgroundColor',[.7 .9 .7],...
 'Margin',10);
```



For additional features, see the following properties:

- `BackgroundColor` — Color of the rectangle's interior (`none` by default)
- `EdgeColor` — Color of the rectangle's edge (`none` by default)
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)

See how margin affects text extent properties

This example enables you to change the values of the `Margin` property and observe the effects on the `BackgroundColor` area and the `EdgeColor` rectangle.

Click to view in editor — This link opens the MATLAB editor with the following example.

Click to run example — Use your scroll wheel to vary the `Margin`.

`Parent`
handle of axes, hggroup, or hgtransform

Parent of text object. Handle of the text object's parent. The parent of a text object is the axes, hggroup, or hgtransform object that contains it.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Position`
`[x,y,[z]]`

Location of text. A two- or three-element vector, `[x y [z]]`, that specifies the location of the text in three dimensions. If you omit the `z` value, it defaults to 0. All measurements are in units specified by the `Units` property. Initial value is `[0 0 0]`.

`Rotation`
scalar (default = 0)

Text orientation. Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation).

`Selected`
`on | {off}`

Is object selected? When this property is `on`, MATLAB displays selection handles if the `SelectionHighlight` property is also set to `on`. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by

drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`String`
string

Text string. Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See Mathematical Symbols, Greek Letters, and TeX Characters for an example.

Note The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

When the text `Interpreter` property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. The following table lists these characters and the character sequences used to define them.

TeX Character Sequence Table

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\alpha	α	\upsilon	υ	\sim	~
\angle	∠	\phi	Φ	\leq	≤
\ast	*	\chi	χ	\infty	∞
\beta	β	\psi	ψ	\clubsuit	♣

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\gamma	γ	\omega	ω	\diamondsuit	♦
\delta	δ	\Gamma	Γ	\heartsuit	♥
\epsilon	ε	\Delta	Δ	\spadesuit	♠
\zeta	ζ	\Theta	Θ	\leftrightarrow	↔
\eta	η	\Lambda	Λ	\leftarrow	←
\theta	Θ	\Xi	Ξ	\Leftarrow	⇐
\vartheta		\Pi	Π	\uparrow	↑
\iota	ι	\Sigma	Σ	\rightarrow	→
\kappa	κ	\Upsilon		\Rightarrow	⇒
\lambda	λ	\Phi	Φ	\downarrow	↓
\mu	µ	\Psi	Ψ	\circ	º
\nu	ν	\Omega	Ω	\pm	±
\xi	ξ	\forall	∀	\geq	≥
\pi	π	\exists	∃	\propto	∝
\rho	ρ	\ni	э	\partial	∂
\sigma	σ	\cong	≅	\bullet	•
\varsigma	ς	\approx	≈	\div	÷
\tau	τ	\Re	ℜ	\neq	≠
\equiv	≡	\oplus	⊕	\aleph	
\Im	ℑ	\cup	∪	\wp	℘
\otimes	⊗	\subseteq	⊆	\oslash	∅

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\cap	∩	\in		\supseteq	⊇
\supset	⊃	\lceil	⌈	\subset	⊂
\int	∫	\cdot	·	\o	ο
\rfloor	⌋	\neg	¬	\nabla	∇
\lfloor	⌊	\times	x	\ldots	...
\perp	⊥	\surd	√	\prime	′
\wedge	∧	\varpi	ϖ	\0	∅
\rceil	⌉	\rangle	〉	\mid	|
\vee	∨			\copyright	©
\langle	〈				

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers:

- `\bf` — Bold font
- `\it` — Italic font
- `\sl` — Oblique font (rarely available)
- `\rm` — Normal font
- `\fontname{`*`fontname`*`}` — Specify the name of the font family to use.
- `\fontsize{`*`fontsize`*`}` — Specify the font size in `FontUnits`.

- `\color(`*colorSpec*`)` — Specify color for succeeding characters

  Stream modifiers remain in effect until the end of the string or only within the context defined by braces `{ }`.

Specifying Text Color in TeX Strings

Use the `\color` modifier to change the color of characters following it from the previous color (which is `black` by default). Syntax is:

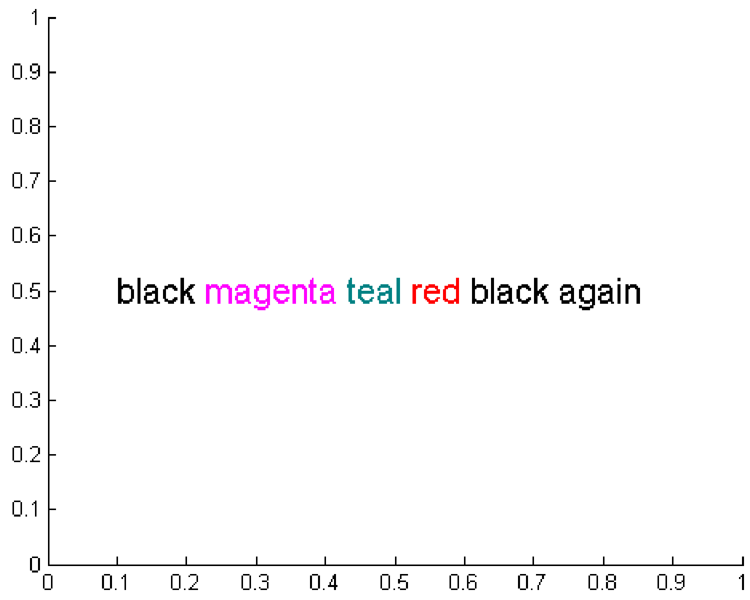
- `\color{colorname}` — Use for the eight basic named colors (`red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`), and plus the four Simulink colors (`gray`, `darkGreen`, `orange`, and `lightBlue`).

  Note that short names (one-letter abbreviations) for colors are not supported by the `\color` modifier.

- `\color[rgb]{r g b}` — Use to specify an RGB triplet with values between `0` and `1` as a cell array

For example:

```
text(.1,.5,['\fontsize{16}black {\color{magenta}magenta '...
'\color[rgb]{0 .5 .5}teal \color{red}red} black again'])
```



Specifying Subscript and Superscript Characters

The subscript character "_" and the superscript character "^" modify the character or substring defined in braces immediately following.

To print the special characters used to define the TeX strings when `Interpreter` is `tex`, prefix them with the backslash "\" character: \\, \{, \} _, \^.

See the "Examples" on page 1-5518 in the `text` reference page for more information.

When `Interpreter` is `none`, no characters in the `String` are interpreted, and all are displayed when the text is drawn.

When `Interpreter` is `latex`, MATLAB provides a complete LaTeX interpreter for text objects. See the `Interpreter` property for more information.

`Tag`

string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

`Type`

string (read-only)

Class of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For text objects, `Type` is always '`text`'.

`UIContextMenu`

handle of uicontextmenu object

Associate a context menu with the text. The handle of a uicontextmenu object created in the same figure as the text. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the text.

`Units`

`pixels | normalized | inches |`
`| characters | centimeters | points | {data}`

Units of measurement. Specifies the units MATLAB uses to interpret the `Extent` and `Position` properties. All units are measured from the lower left corner of the axes plot box.

- `normalized` — Units map the lower left corner of the rectangle defined by the axes to (0,0) and the upper right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $^1/_{72}$ inch.

- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.
- `data` — Data units of the parent axes as determined by the data graphed (not the axes `Units` property, which controls the positioning of the axes within the figure window).

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

`UserData`
matrix

User-specified data. Data you want to associate with the text object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`VerticalAlignment`
`top | cap | {middle} | baseline | bottom`

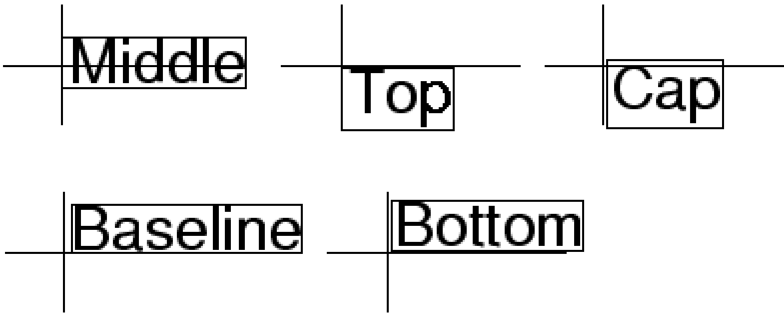
Vertical alignment of text. Specifies the vertical justification of the text string. It determines where MATLAB places the string vertically with regard to the points specified by the `Position` property.

- `top` — Place the top of the string' s `Extent` rectangle at the specified *y*-position.
- `cap` — Place the string so that the top of a capital letter is at the specified *y*-position.
- `middle` — Place the middle of the string at the specified *y*-position.
- `baseline` — Place font baseline at the specified *y*-position.

- `bottom` — Place the bottom of the string's `Extent` rectangle at the specified *y*-position.

The following picture illustrates the alignment options.

Text `VerticalAlignment` property viewed with the `HorizontalAlignment` property set to `left` (the default).



See "Text Alignment" for more information and examples.

`Visible`

`{on} | off`

Text visibility. By default, all text is visible. When set to `off`, the text is not visible, but still exists, and you can query and set its properties.

See Also

`text`

textread

Purpose

Read data from text file; write to multiple outputs

Note `textread` is not recommended. Use `textscan` instead.

Syntax

```
[A,B,C,...] = textread(filename,format)
[A,B,C,...] = textread(filename,format,N)
[...] = textread(...,param,value,...)
```

Description

`[A,B,C,...]  = textread(filename,format)` reads data from the file `filename` into the variables `A,B,C,` and so on, using the specified `format`, until the entire file is read. The `filename` and `format` inputs are strings, each enclosed in single quotes. `textread` is useful for reading text files with a known format. `textread` handles both fixed and free format files.

Note When reading large text files, reading from a specific point in a file, or reading file data into a cell array rather than multiple outputs, you might prefer to use the `textscan` function.

`textread` matches and converts groups of characters from the input. Each input field is defined as a string of non-white-space characters that extends to the next white-space or delimiter character, or to the maximum field width. Repeated delimiter characters are significant, while repeated white-space characters are treated as one.

The `format` string determines the number and types of return arguments. The number of return arguments is the number of items in the `format` string. The `format` string supports a subset of the conversion specifiers and conventions of the C language `fscanf` routine. Values for the `format` string are listed in the table below. White-space characters in the `format` string are ignored.

format	Action	Output
Literals (ordinary characters)	Ignore the matching characters. For example, in a file that has `Dept` followed by a number (for department number), to skip the `Dept` and read only the number, use `'Dept'` in the `format` string.	None
`%d`	Read a signed integer value.	Double array
`%u`	Read an integer value.	Double array
`%f`	Read a floating-point value.	Double array
`%s`	Read a white-space or delimiter-separated string.	Cell array of strings
`%q`	Read a double quoted string, ignoring the quotes.	Cell array of strings
`%c`	Read characters, including white space.	Character array
`%[...]`	Read the longest string containing characters specified in the brackets.	Cell array of strings
`%[^...]`	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
`%*...` `instead of %`	Ignore the matching characters specified by `*`.	No output
`%w...` `instead of %`	Read field width specified by `w`. The `%f` format supports `%w.pf`, where `w` is the field width and `p` is the precision.	

`[A,B,C,...] = textread(filename,format,N)` reads the data, reusing the `format` string `N` times, where `N` is an integer greater than zero. If `N` is smaller than zero, `textread` reads the entire file.

`[...] = textread(...,param,value,...)` customizes `textread` using `param/value` pairs, as listed in the table below.

param	value	Action
bufsize	Positive integer	Specifies the maximum string length, in bytes. Default is 4095.
commentstyle	matlab	Ignores characters after %.
commentstyle	shell	Ignores characters after #.
commentstyle	c	Ignores characters between /* and */.
commentstyle	c++	Ignores characters after //.
delimiter	One or more characters	Act as delimiters between elements. Default is none.
emptyvalue	Scalar double	Value given to empty cells when reading delimited files. Default is 0.
endofline	Single character or '\r\n'	Character that denotes the end of a line. Default is determined from file
expchars	Exponent characters	Default is eEdD.
headerlines	Positive integer	Ignores the specified number of lines at the beginning of the file.
whitespace	Any from the list below: ' ' Space \b Backspace \n Newline \r Carriage return \t Horizontal tab	Treats vector of characters as white space. Default is ' \b\t'.

Note When `textread` reads a consecutive series of `whitespace` values, it treats them as one white space. When it reads a consecutive series of `delimiter` values, it treats each as a separate delimiter.

Tips

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
textread('myfile.txt', '%s', 'whitespace', '')
ans =
    '   An  example      of preserving    spaces      '
```

Examples

Example 1 — Read All Fields in Free Format File Using %

The first line of `mydata.dat` is

```
Sally    Level1 12.34 45 Yes
```

Read the first line of the file as a free format file using the `%` format.

```
[names, types, x, y, answer] = textread('mydata.dat', ...
'%s %s %f %d %s', 1)
```

returns

```
names =
    'Sally'
types =
    'Level1'
x =
  12.34000000000000
y =
    45
answer =
    'Yes'
```

Example 2 — Read as Fixed Format File, Ignoring the Floating Point Value

The first line of `mydata.dat` is

```
Sally    Level1 12.34 45 Yes
```

Read the first line of the file as a fixed format file, ignoring the floating-point value.

```
[names, types, y, answer] = textread('mydata.dat', ...
'%9c %6s %*f %2d %3s', 1)
```

returns

```
names =
Sally
types =
    'Level1'
y =
    45
answer =
    'Yes'
```

`%*f` in the `format` string causes `textread` to ignore the floating point value, in this case, `12.34`.

Example 3 — Read Using Literal to Ignore Matching Characters

The first line of `mydata.dat` is

```
Sally    Type1 12.34 45 Yes
```

Read the first line of the file, ignoring the characters `Type` in the second field.

```
[names, typenum, x, y, answer] = textread('mydata.dat', ...
'%s Type%d %f %d %s', 1)
```

returns

```
names =
    'Sally'
typenum =
    1
x =
  12.34000000000000
y =
    45
```

```
answer =
    'Yes'
```

`Type%d` in the `format` string causes the characters `Type` in the second field to be ignored, while the rest of the second field is read as a signed integer, in this case, `1`.

Example 4 — Specify Value to Fill Empty Cells

For files with empty cells, use the `emptyvalue` parameter. Suppose the file `data.csv` contains:

```
1,2,3,4,,6
7,8,9,,11,12
```

Read the file using `NaN` to fill any empty cells:

```
data = textread('data.csv', '', 'delimiter', ',', ...
                'emptyvalue', NaN);
```

Example 5 — Read File into a Cell Array of Strings

Read the file `fft.m` into cell array of strings.

```
file = textread('fft.m', '%s', 'delimiter', '\n', ...
                'whitespace', '');
```

See Also

`textscan` | `dlmread` | `fscanf`

Purpose

Read formatted data from text file or string

Syntax

```
C = textscan(fileID,formatSpec)
C = textscan(fileID,formatSpec,N)

C = textscan(str,formatSpec)
C = textscan(str,formatSpec,N)

C = textscan(___,Name,Value)

[C,position] = textscan(___)
```

Description

`C = textscan(fileID,formatSpec)` reads data from an open text file into cell array, `C`. The text file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading from a file, close the file by calling `fclose(fileID)`.

`textscan` attempts to match the data in the file to `formatSpec`, which is a string of conversion specifiers.

`C = textscan(fileID,formatSpec,N)` reads file data, using the `formatSpec` `N` times, where `N` is a positive integer. To read additional data from the file after `N` cycles, call `textscan` again using the original `fileID`. If you resume a text scan of a file by calling `textscan` with the same file identifier (`fileID`), then `textscan` automatically resumes reading at the point where it terminated the last read.

`C = textscan(str,formatSpec)` reads data from a string, `str` into cell array `C`. For strings, repeated calls to `textscan` restart the scan from the beginning each time. To restart a scan from the last position, request a `position` output.

`textscan` attempts to match the data in the string, `str`, to `formatSpec`, which is a string of conversion specifiers.

`C = textscan(str,formatSpec,N)` reads string data, using the `formatSpec` `N` times, where `N` is a positive integer.

`C = textscan(___,Name,Value)` specifies options using one or more `Name,Value` pair arguments, in addition to any of the input arguments in the previous syntaxes.

`[C,position] = textscan(___)` returns the file or string position at the end of the scan as the second output argument, using any of the input arguments in the previous syntaxes. For a file, this is the value that `ftell(fileID)` would return after calling `textscan`. For a string, `position` indicates how many characters `textscan` read.

Input Arguments

fileID - File identifier

numeric scalar

File identifier of an open text file, specified as a number. Before reading a file with `textscan`, you must use `fopen` to open the file and obtain the `fileID`.

Data Types

`double`

formatSpec - Format of the data fields

string

Format of the data fields, specified as a string of one or more conversion specifiers. When `textscan` reads a file or string, it attempts to match the data to the `formatSpec` string. If `textscan` fails to match a data field, it stops reading and returns all fields read before the failure.

The number of conversion specifiers determines the number of cells in output array, `C`.

Numeric Fields

This table lists available conversion specifiers for numeric inputs.

Numeric Input Type	Conversion Specifier	Output Class
Integer, signed	%d	int32
	%d8	int8
	%d16	int16
	%d32	int32
	%d64	int64
Integer, unsigned	%u	uint32
	%u8	uint8
	%u16	uint16
	%u32	uint32
	%u64	uint64
Floating-point number	%f	double
	%f32	single
	%f64	double
	%n	double

Character Fields

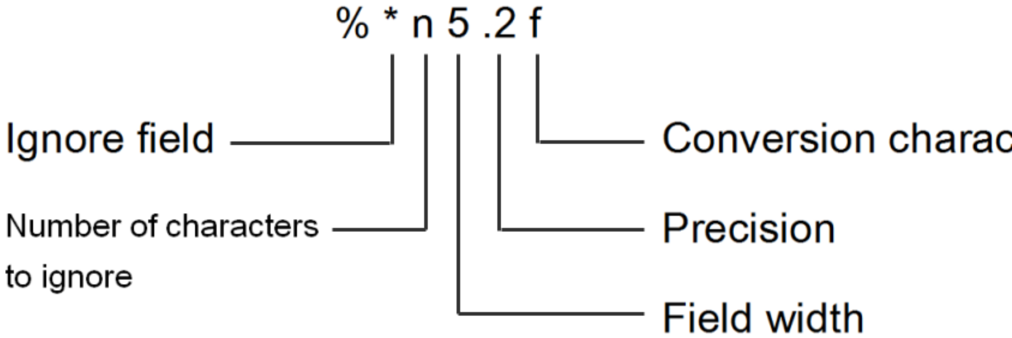
This table lists available conversion specifiers for character inputs.

Character Strings	Conversion Specifier	Details
Characters	%s	String
	%q	String, where double quotation marks indicate text to keep together
	%c	Any single character, including a delimiter

Character Strings	Conversion Specifier	Details
Pattern-matching strings	%[...]	Read only the characters inside the brackets up to the first nonmatching character. To include] in the set, specify it first: %[]...]. Example: %[mus] reads 'summer ' as 'summ'.
	%[^...]	Exclude characters inside the brackets, reading until the first matching character. To exclude], specify it first: %[^]...]. Example: %[^xrg] reads 'summer ' as 'summe'.

Optional Operators

Conversion specifiers in formatSpec can include optional operators, which appear in the following order (includes spaces for clarity):



Optional operators include:

- Fields and Characters to Ignore

textscan reads all characters in your file in sequence, unless you tell it to ignore a particular field or a portion of a field.

Use the following operators to skip or read portions of fields.

Operator	Action Taken
%*	Skip the field. textscan does not create an output cell for any field that it skips. Example: '%s %*s %s %s %*s %*s %s' (spaces are optional) converts the string 'Blackbird singing in the dead of night' to four output cells with the strings 'Blackbird' 'in' 'the' 'night'
%*n	Ignore n characters of the field, where n is an integer less than or equal to the number of characters in the field. Example: %*4s ignores 4 characters, so '%*4s %s' reads 'summer' as 'er'.

- Field Width

  textscan reads the number of characters or digits specified by the field width or precision, or up to the first delimiter, whichever comes first. A decimal point is counted as a digit. Specify the field width by inserting a number after the percent character (%) in the conversion specifier.

  Example: %5f reads '123.456' as 123.4.

Note When the field width operator is used with single characters (%c), textscan also reads delimiter characters.
Example: %7c reads 7 characters, including white-space, so'Day and night' reads as 'Day and'.

- Precision

  For floating-point numbers (`%n`, `%f`, `%f32`, `%f64`), you can specify the number of decimal digits to read.

  Example: `%7.2f` reads `'123.456'` as `123.45`.

- Literal Text to Ignore

  `textscan` ignores specified text appended to the `formatSpec` string.

  Example: `Level%u8` reads `'Level1'` as `1`.

  Example: `%u8Step` reads `'2Step'` as `2`.

N - Number of times to apply `formatSpec`

integer

Number of times to apply `formatSpec`, specified as an integer.

Data Types
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

str - Input string

string

Input string to read.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Names are not case sensitive.

Example: `C = textscan(fileID,formatSpec,'HeaderLines',3,'Delimiter',',')` skips the first three lines of the data, and then reads the remaining data, treating commas as a delimiter.

'CollectOutput' - Logical indicator determining data concatenation
`false` (default) | `true`

Logical indicator determining data concatenation, specified as the comma-separated pair consisting of `'CollectOutput'` and either `true` or `false`. If `true`, then `textscan` concatenates consecutive output cells of the same fundamental MATLAB class into a single array.

'CommentStyle' - Symbols designating text to ignore
string | cell array of strings

Symbols designating text to ignore, specified as the comma-separated pair consisting of `'CommentStyle'` and a string or cell array of strings.

For example, specify a string such as `'%'` to ignore characters following the string on the same line. Specify a cell array of two strings, such as `{'/*', '*/'}`, to ignore characters between the strings.

`textscan` checks for comments only at the start of each field, not within a field.

Example: `'CommentStyle',{'/*', '*/'}`

'Delimiter' - Field delimiter characters
`{' ','\b','\t'}` (default) | string | cell array of strings

Field delimiter characters, specified as the comma-separated pair consisting of `'Delimiter'` and a string or a cell array of strings. Specify multiple delimiters in a cell array of strings.

Example: `'delimiter',{';','*'}`

`textscan` interprets repeated delimiter characters as separate delimiters, and returns an empty value to the output cell.

Within each row of data, the default field delimiter is white space. White space can be any combination of space (`' '`), backspace (`'\b'`), or tab (`'\t'`) characters. If you do not specify a delimiter, `textscan` interprets repeated white-space characters as a single delimiter.

When you specify one of the following escape sequences as a delimiter, `textscan` converts that sequence to the corresponding control character:

`\b`	Backspace
`\n`	Newline
`\r`	Carriage return
`\t`	Tab
`\\`	Backslash (\)

'EmptyValue' - Returned value for empty numeric fields

`NaN` (default) | scalar

Returned value for empty numeric fields in delimited text files, specified as the comma-separated pair consisting of `'EmptyValue'` and a scalar.

'EndOfLine' - End-of-line characters

string

End-of-line characters, specified as the comma-separated pair consisting of `'EndOfLine'` and a string. The default end-of-line sequence depends on the format of your file and can include a newline character (`'\n'`), a carriage return (`'\r'`), or a combination of the two (`'\r\n'`).

If there are missing values and an end-of-line sequence at the end of the last line in a file, then `textscan` returns empty values for those fields. This ensures that individual cells in output cell array, `C`, are the same size.

'ExpChars' - Exponent characters

`'eEdD'` (default) | string

Exponent characters, specified as the comma-separated pair consisting of `'ExpChars'` and a string. The default exponent characters are `e`, `E`, `d`, and `D`.

'HeaderLines' - Number of header lines

`0` (default) | positive integer

Number of header lines, specified as the comma-separated pair consisting of 'HeaderLines' and a positive integer. textscan skips the header lines, including the remainder of the current line.

'MultipleDelimsAsOne' - Multiple delimiter handling

0 (false) (default) | 1 (true)

Multiple delimiter handling, specified as the comma-separated pair consisting of 'MultipleDelimsAsOne' and either true or false. If true, textscan treats consecutive delimiters as a single delimiter. Repeated delimiters separated by white-space are also treated as a single delimiter. You must also specify the Delimiter option.

Example: 'MultipleDelimsAsOne',1

'ReturnOnError' - Behavior when textscan fails to read or convert

1 (true) (default) | 0 (false)

Behavior when textscan fails to read or convert, specified as the comma-separated pair consisting of 'ReturnOnError' and either true or false. If true, textscan terminates without an error and returns all fields read. If false, textscan terminates with an error and does not return an output cell array.

'TreatAsEmpty' - Strings to treat as empty value

string | cell array of strings

Strings to treat as empty values, specified as the comma-separated pair consisting of 'TreatAsEmpty' and a single string or cell array of strings. This option only applies to numeric fields.

'Whitespace' - White-space characters

' \b\t' (default) | string

White-space characters, specified as the comma-separated pair consisting of 'Whitespace' and a string of one or more characters. textscan adds a space character, char(32), to any specified

Whitespace, unless Whitespace is empty ('') and formatSpec includes any string conversion specifier.

When you specify one of the following escape sequences as any white-space character, textscan converts that sequence to the corresponding control character:

\b	Backspace
\n	Newline
\r	Carriage return
\t	Tab
\\	Backslash (\)

Output Arguments

C - File or string data

cell array

File or string data, returned as a cell array.

For each numeric conversion specifier in formatSpec, the textscan function returns a K-by-1 MATLAB numeric vector to the output cell array, C, where K is the number of times that textscan finds a field matching the specifier.

For each string conversion specifier in formatSpec, the textscan function returns a K-by-1 cell vector of strings, where K is the number of times that textscan finds a field matching the specifier. For each character conversion that includes a field width operator, textscan returns a K-by-M character array, where M is the field width.

position - File or string position

integer

File or string position at the end of the scan, returned as an integer of class double. For a file, ftell(fileID) would return the same value after calling textscan. For a string, position indicates how many characters textscan read.

Examples

Read a String

Read a string of floating-point numbers.

```
str = '0.41 8.24 3.57 6.24 9.27';

C = textscan(str,'%f');
```

The `formatSpec` string `'%f'` tells `textscan` to match each field in `str` to a double-precision floating-point number.

Display the contents of cell array `C`.

```
celldisp(C)
```

```
C{1} =

    0.4100
    8.2400
    3.5700
    6.2400
    9.2700
```

Read the same string, truncating each value to one decimal digit.

```
C = textscan(str,'%3.1f %*1d');
```

The specifier `%3.1f` indicates a field width of 3 digits and a precision of 1. `textscan` reads a total of 3 digits, including the decimal point and the 1 digit after the decimal point. The specifier, `%*1d`, tells `textscan` to skip the remaining digit.

Display the contents of cell array `C`.

```
celldisp(C)
```

```
C{1} =

    0.4000
```

```
    8.2000
    3.5000
    6.2000
    9.2000
```

Read Different Types of Data

Using a text editor, create a file `scan1.dat` that contains data in the following form:

```
09/12/2005 Level1 12.34 45 1.23e10 inf Nan Yes 5.1+3i
10/12/2005 Level2 23.54 60 9e19 -inf  0.001 No 2.2-.5i
11/12/2005 Level3 34.90 12 2e5   10  100   No 3.1+.1i
```

Open the file, and read each column with the appropriate conversion specifier.

```
fileID = fopen('scan1.dat');
C = textscan(fileID, '%s %s %f32 %d8 %u %f %f %s %f');
fclose(fileID);
celldisp(C)
```

```
C{1}{1} =

09/12/2005

C{1}{2} =

10/12/2005

C{1}{3} =

11/12/2005

C{2}{1} =
```

```
Level1

C{2}{2} =

Level2

C{2}{3} =

Level3

C{3} =

   12.3400
   23.5400
   34.9000

C{4} =

   45
   60
   12

C{5} =

  4294967295
  4294967295
      200000
```

```
C{6} =

   Inf
  -Inf
    10

C{7} =

        NaN
     0.0010
   100.0000

C{8}{1} =

Yes

C{8}{2} =

No

C{8}{3} =

No

C{9} =

   5.1000 + 3.0000i
   2.2000 - 0.5000i
   3.1000 + 0.1000i
```

`textscan` returns a 1-by-9 cell array `C`.

View the MATLAB data type of each of the cells in `C`.

```
C
```

```
C =

  Columns 1 through 5

    {3x1 cell}    {3x1 cell}    [3x1 single]    [3x1 int8]    [3x1 uint32

  Columns 6 through 9

    [3x1 double]    [3x1 double]    {3x1 cell}    [3x1 double]
```

For example, `C{1}` and `C{2}` are cell arrays. `C{5}` is of data type `uint32`, so the first two elements of `C{5}` are the maximum values for a 32-bit unsigned integer, or `intmax('uint32')`.

Remove a Literal String

Remove the text `'Level'` from each field in the second column of the data from the previous example.

Match the literal string in the `formatSpec` input.

```
fileID = fopen('scan1.dat');
C = textscan(fileID, '%s Level%d %f32 %d8 %u %f %f %s %f');
fclose(fileID);
C{2}
```

```
ans =

           1
           2
           3
```

View the MATLAB data type of the second cell in `C`.

```
class(C{2})

ans =

int32
```

The second cell of the 1-by-9 cell array, `C`, is now of data type `int32`.

Skip the Remainder of a Line

Read the first column of the file in the previous example into a cell array, skipping the rest of the line.

```
fileID = fopen('scan1.dat');
dates = textscan(fileID, '%s %*[^\n]');
fclose(fileID);
dates{1}

ans =

    '09/12/2005'
    '10/12/2005'
    '11/12/2005'
```

`textscan` returns a 1-by-1 cell array `dates`.

Specify Delimiter and Empty Value Conversion

Using a text editor, create a comma-delimited file, `data.csv`, that contains

```
1,  2,  3,  4,   ,  6
7,  8,  9,   , 11, 12
```

Read the file, converting empty cells to `-Inf`.

```
fileID = fopen('data.csv');
C = textscan(fileID, '%f %f %f %f %u8 %f','delimiter', ',', 'EmptyValu
fclose(fileID);
column4 = C{4}, column5 = C{5}
```

```
column4 =

     4
  -Inf

column5 =

    0
   11
```

textscan returns a 1-by-6 cell array, C. The textscan function converts the empty value in C{4} to -Inf, where C{4} is associated with a floating-point format. Because MATLAB represents unsigned integer -Inf as 0, textscan converts the empty value in C{5} to 0, and not -Inf.

Read Custom Empty Value Strings and Comments

Using a text editor, create a comma-delimited file, data2.csv, that contains the lines

```
abc, 2, NA, 3, 4
// Comment Here
def, na, 5, 6, 7
```

Designate the input that textscan should treat as comments or empty values.

```
fileID = fopen('data2.csv');
C = textscan(fileID, '%s %n %n %n %n', 'delimiter', ',', 'treatAsEmpty',
fclose(fileID);
celldisp(C)
```

```
C{1}{1} =
abc

C{1}{2} =
def
```

```
C{2} =
     2
   NaN

C{3} =
   NaN
     5

C{4} =
     3
     6

C{5} =
     4
     7
```

Treat Repeated Delimiters as One

Using a text editor, create a file, `data3.csv`, that contains

```
1,2,3,,4
5,6,7,,8
```

To treat the repeated commas as a single delimiter, use the `MultipleDelimsAsOne` parameter, and set the value to `1 (true)`.

```
fileID = fopen('data3.csv');
C = textscan(fileID, '%f %f %f %f', 'delimiter', ',', 'MultipleDelimsA
fclose(fileID);
celldisp(C)

C{1} =
     1
     5

C{2} =
     2
     6
```

```
C{3} =
     3
     7

C{4} =
     4
     8
```

Collect Numeric Data

Using a text editor, create a file, `grades.txt`, that contains:

```
Student_ID  | Test1  | Test2  | Test3
   1           91.5     89.2     77.3
   2           88.0     67.8     91.0
   3           76.3     78.1     92.5
   4           96.4     81.2     84.6
```

Read the column headers using the format `'%s'` four times.

```
fileID = fopen('grades.txt');

formatSpec = '%s';
N = 4;
C_text = textscan(fileID, formatSpec, N, 'delimiter', '|');
```

Read the numeric data in the file.

```
C_data0 = textscan(fileID, '%d %f %f %f')
```

```
C_data0 =
  [4x1 int32]    [4x1 double]    [4x1 double]    [4x1 double]
```

The default value for `CollectOutput` is 0 `(false)`, so `textscan` returns each column of the numeric data in a separate array.

Set `CollectOutput` to `1 (true)` to collect the consecutive columns of the same class into a single array.

```
frewind(fileID);

C_text = textscan(fileID, '%s', N, 'delimiter', '|');

C_data1 = textscan(fileID, '%d %f %f %f', 'CollectOutput', 1)
```

```
C_data1 =
    [4x1 int32]    [4x3 double]
```

The test scores, which are all `double`, are collected into a single 4-by-3 array.

Close the file, `grades.txt`.

```
fclose(fileID);
```

Read Nondefault Control Characters

Use `sprintf` to convert nondefault escape sequences in your data.

Create a string that includes a form feed character, `\f`. Then, to read the string using `textscan`, call `sprintf` to explicitly convert the form feed.

```
lyric = sprintf('Blackbird\fsinging\fin\fthe\fdead\fof\fnight');
C = textscan(lyric, '%s', 'delimiter', sprintf('\f'));
C{1}
```

```
ans =

    'Blackbird'
    'singing'
    'in'
    'the'
    'dead'
    'of'
    'night'
```

`textscan` returns a 1-by-1 cell array, `C`.

Resume a Text Scan of a String

Resume a scan of a string from a position other than the beginning.

If you resume a text scan of a string, `textscan` reads from the beginning of the string each time. To resume a scan from any other position in the string, use the two-output argument syntax in your initial call to `textscan`.

For example, create a string called `lyric`. Read the first word of the string, and then resume the scan.

```
lyric = 'Blackbird singing in the dead of night';
[firstword, pos] = textscan(lyric,'%9c', 1);
lastpart = textscan(lyric(pos+1:end), '%s');
```

Algorithms

`textscan` converts numeric fields to the specified output type according to MATLAB rules regarding overflow, truncation, and the use of `NaN`, `Inf`, and `-Inf`. For example, MATLAB represents an integer `NaN` as zero. If `textscan` finds an empty field associated with an integer format specifier (such as `%d` or `%u`), it returns the empty value as zero and not `NaN`.

`textscan` does not include leading white-space characters in the processing of any data fields. When processing numeric data, `textscan` also ignores trailing white space.

`textscan` imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type (such as `%d` or `%f`). Valid forms for a complex number are:

`±<real>±<imag>i|j`	Example: `5.7-3.1i`
`±<imag>i|j`	Example: `-7j`

Do not include embedded white space in a complex number. `textscan` interprets embedded white space as a field delimiter.

Purpose

Wrapped string matrix for given uicontrol

Syntax

```
outstring = textwrap(h,instring)
outstring = textwrap(h,instring,columns)
[outstring,position] = textwrap(...)
```

Description

`outstring = textwrap(h,instring)` returns a wrapped string cell array, `outstring`, that fits inside the uicontrol with handle `h`. `instring` is a cell array, with each cell containing a single line of text. `outstring` is the wrapped string matrix in cell array format. Each cell of the input string is considered a paragraph.

`outstring = textwrap(h,instring,columns)` returns an `outstring` with each line wrapped at `columns` characters. Spaces are included in the character count.

`[outstring,position] = textwrap(...)` returns the recommended position of the uicontrol in the units of the uicontrol. `position` considers the extent of the multiline text in the x and y directions.

`textwrap` maintains the original line breaks in the input cell array and adds new ones. It can calculate uicontrol positions with any type of `Units`, including normalized units.

Tips

When programming a GUI, do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

Examples

Place two text-wrapped strings in text uicontrols. The left one has a `Position` calculated by `textwrap` in `Units` of `pixels`; the right one's `Position` is calculated manually in `Units` of `characters`:

```
figure('Position',[560 528 350 250]);
% Make a text uicontrol to wrap in Units of Pixels
% Create it in Units of Pixels, 100 wide, 10 high
pos = [10 100 100 10];
ht = uicontrol('Style','Text','Position',pos);
```

```
string = {'This is a string for the left text uicontrol.',...
          'to be wrapped in Units of Pixels,',...
          'with a position determined by TEXTWRAP.'};
% Wrap string, also returning a new position for ht
[outstring,newpos] = textwrap(ht,string) %#ok<NOPRT>

outstring =
    'This is a string for'
    'the left text'
    'uicontrol.'
    'to be wrapped in'
    'Units of Pixels,'
    'with a position'
    'determined by'
    'TEXTWRAP.'

newpos =
    10   100    91   124

set(ht,'String',outstring,'Position',newpos)

% Make another text uicontrol to wrap to a column width of 15
colwidth = 15;
% Create it in Units of Pixels, 100 wide, 10 high
pos1 = [150 100 100 10];
ht1 = uicontrol('Style','Text','Position',pos1);
string1 = {'This is a string for the right text uicontrol.',...
          'to be wrapped in Units of Characters,',...
          'into lines 15 columns wide.'};
outstring1 = textwrap(ht1,string1,colwidth);
% Reset Units of ht1 to Characters to use the result
set(ht1,'Units','characters')
newpos1 = get(ht1,'Position')

newpos1 =
   29.8000    7.6154   20.0000    0.7692
```

```
% Set new Position in Characters to be specified colwidth
% with height the length of the outstring1 cell array + 1.
newpos1(3) = colwidth;
newpos1(4) = length(outstring1)+1

newpos1 =
   29.8000    7.6154   15.0000   10.0000

set(ht1,'String',outstring1,'Position',newpos1)
```

align | uicontrol

Purpose

Transpose-free quasi-minimal residual method

Syntax

```
x = tfqmr(A,b)
x = tfqmr(afun,b)
x = tfqmr(a,b,tol)
x = tfqmr(a,b,tol,maxit)
x = tfqmr(a,b,tol,maxit,m)
x = tfqmr(a,b,tol,maxit,m1,m2,x0)
[x,flag] = tfqmr(A,B,...)
[x,flag,relres] = tfqmr(A,b,...)
[x,flag,relres,y]y(A,b,...)
[x,flag,relres,iter,resvec] = tfqmr(A,b,...)
```

Description

`x = tfqmr(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and the right-hand side column vector `b` must have length `n`.

`x = tfqmr(afun,b)` accepts a function handle, `afun`, instead of the matrix `A`. The function, `afun(x)`, accepts a vector input `x` and returns the matrix-vector product `A*x`. In all of the following syntaxes, you can replace `A` by `afun`. "Parameterizing Functions" explains how to provide additional parameters to the function `afun`.

`x = tfqmr(a,b,tol)` specifies the tolerance of the method. If `tol` is `[]` then `tfqmr` uses the default, 1e-6.

`x = tfqmr(a,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]` then `tfqmr` uses the default, `min(N,20)`.

`x = tfqmr(a,b,tol,maxit,m)` and `x = tfqmr(a,b,tol,maxit,m1,m2)` use preconditioners `m` or `m=m1*m2` and effectively solve the system `A*inv(M)*x = B` for `x`. If `M` is `[]` then a preconditioner is not applied. `M` may be a function handle `mfun` such that `mfun(x)` returns `m\x`.

`x = tfqmr(a,b,tol,maxit,m1,m2,x0)` specifies the initial guess. If `x0` is `[]` then `tfqmr` uses the default, an all zero vector.

`[x,flag] = tfqmr(A,B,...)` also returns a convergence flag:

Flag	Convergence
0	`tfqmr` converged to the desired tolerance `tol` within `maxit` iterations.
1	`tfqmr` iterated `maxit` times but did not converge.
2	Preconditioner `m` was ill-conditioned.
3	`tfqmr` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `tfqmr` became too small or too large to continue computing.

`[x,flag,relres] = tfqmr(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is 0, then `relres <= tol`.

`[x,flag,relres,y]y(A,b,...)` also returns the iteration number at which `x` was computed: `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = tfqmr(A,b,...)` also returns a vector of the residual norms at each iteration, including `norm(b-A*x0)`.

Examples

Example 1

This example shows how to use `tfqmr` with a matrix input and with a function input.

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = tfqmr(A,b,tol,maxit,M1,M2,[]);
```

You can also use a matrix-vector product function as input:

```
function y = afun(x,n)
```

```
y = 4 * x;
y(2:n) = y(2:n) - 2 * x(1:n-1);
y(1:n-1) = y(1:n-1) - x(2:n);
x1 = tfqmr(@(x)afun(x,n),b,tol,maxit,M1,M2);
```

If `applyOp` is a function suitable for use with `qmr`, it may be used with `tfqmr` by wrapping it in an anonymous function:

```
x1 = tfqmr(@(x)applyOp(x,'notransp'),b,tol,maxit,M1,M2);
```

Example 2

This example demonstrates the use of a preconditioner.

1

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

2

Define `b` so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

3

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

4

Use `tfqmr` to find a solution at the requested tolerance and number of iterations:

```
[x0,fl0,rr0,it0,rv0] = tfqmr(A,b,tol,maxit);
```

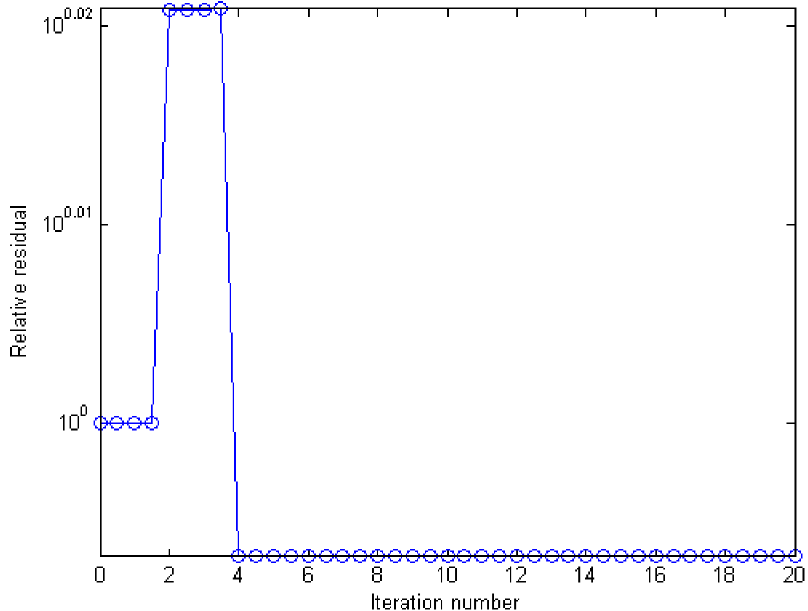
`fl0` is 1 because `tfqmr` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The seventeenth iterate is the

best approximate solution and is the one returned as indicated by `it0` = 17. MATLAB stores the residual history in `rv0`.

5

Plot the behavior of `tfqmr`:

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



Note that like `bicgstab`, `tfqmr` keeps track of half iterations. The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

6

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
Error using ilu
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

MATLABcannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = tfqmr(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `tfqmr` drives the relative residual to `4.1410e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)`, and the output `rv1(7)` is `norm(b-A*x2)`.

8

You can follow the progress of `tfqmr` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

Purpose

Issue exception and terminate function

Syntax

`throw(exception)`

Description

`throw(exception)` issues an exception based on the information contained in *`exception`*. The exception terminates the currently running function and returns control to its caller. The *`exception`* argument is scalar object of the `MException` class that contains information on the cause of the error and where it occurred. The `throw` function passes *`exception`* back to the caller of the currently running function. and eventually back to the Command Window when the program terminates. The exception is made available to any calling function by means of the `catch` function, and to the Command Window by means of the `MException.last` function.

Unlike `throwAsCaller` and `rethrow`, the `throw` function also sets the *stack* field of the *`exception`* to the location from which `throw` was called.

Tips

There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining three techniques to throw an existing exception.

1. Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.

2. Reissue the original exception by throwing the initial exception unmodified. Use the `MException` `rethrow` method to do this.

3. Collect additional information on the cause of the error, store it in a new or modified exception, and issue a new exception based on that record. Use the `MException` `addCause` and `throw` methods to do this.

4. Make it appear that the error originated in the caller of the currently running function. Use the `MException` `throwAsCaller` method to do this.

Examples

Example 1

This example tests the output of function `evaluate_plots` and throws an exception if it is not acceptable:

```
[minval, maxval] = evaluate_plots(p24, p28, p41);
if minval < lower_bound || maxval > upper_bound
    exception = MException('VerifyOutput:OutOfBounds', ...
       'Results are outside the allowable limits');
    throw(exception);
end
```

Example 2

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested `try-catch` block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second using `addCause`:

```
function data = read_it(filename);
try
   % Attempt to open and read from a file.
   fid = fopen(filename, 'r');
   data = fread(fid);
catch exception1
   % If the error was caused by an invalid file ID, try
   % reading from another location.
   if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
      msg = sprintf( ...
         '\nCannot open file %s. Try another location?  ', ...
         filename);
      reply = input(msg, 's')
      if reply(1) == 'y'
          newFolder = input('Enter folder name:  ', 's');
```

```
        else
            throw(exception1);
        end
        oldpath = addpath(newFolder);
        try
           fid = fopen(filename, 'r');
           data = fread(fid);
        catch exception2
           exception3 = addCause(exception2, exception1)
           path(oldpath);
           throw(exception3);
        end
        path(oldpath);
    end
end
fclose(fid);

try
   d = read_it('anytextfile.txt');
catch exception
end

exception
exception =
 MException object with properties:

    identifier: 'MATLAB:FileIO:InvalidFid'
       message: 'Invalid file identifier.  Use fopen
                 to generate a valid file identifier.'
         stack: [1x1 struct]
         cause: {[1x1 MException]}

  Cannot open file anytextfile.txt. Try another location?y
Enter folder name:  xxxxxxx
Warning: Name is nonexistent or not a directory: xxxxxxx.
> In path at 110
  In addpath at 89
```

`try` | `catch` | `error` | `assert` | `MException` | `throwAsCaller(MException)` | `rethrow(MException)` | `addCause(MException)` | `getReport(MException)` | `last(MException)`

Purpose

Throw exception as if from calling function

Syntax

```
throwAsCaller(exception)
```

Description

`throwAsCaller(exception)` throws an exception from the currently running function based on the `exception` input, a scalar object of the `MException` class. The MATLAB software exits the currently running function and returns control to either the keyboard or an enclosing `catch` block in a calling function. Unlike the `throw` function, MATLAB omits the current stack frame from the `stack` field of the `MException`, thus making the exception look as if it is being thrown by the caller of the function.

In some cases, it is not relevant to show the person running your program the true location that generated an exception, but is better to point to the calling function where the problem really lies. You might also find `throwAsCaller` useful when you want to simplify the error display, or when you have code that you do not want made public.

Tips

There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining three techniques to throw an existing exception.

1. Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.

2. Reissue the original exception by throwing the initial exception unmodified. Use the `MException` `rethrow` method to do this.

3. Collect additional information on the cause of the error, store it in a new or modified exception, and issue a new exception based on that record. Use the `MException` `addCause` and `throw` methods to do this.

4. Make it appear that the error originated in the caller of the currently running function. Use the `MException` `throwAsCaller` method to do this.

Examples

The function `klein_bottle`, in this example, generates a Klein Bottle figure by revolving the figure-eight curve defined by XYKLEIN. It defines a few variables and calls the function `draw_klein`, which executes three functions in a `try-catch` block. If there is an error, the `catch` block issues an exception using either `throw` or `throwAsCaller`:

```
function klein_bottle(pq)
ab = [0 2*pi];
rtr = [2 0.5 1];
box = [-3 3 -3 3 -2 2];
vue = [55 60];
draw_klein(ab, rtr, pq, box, vue)

function draw_klein(ab, rtr, pq, box, vue)
clf
try
   tube('xyklein',ab, rtr, pq, box, vue);
   shading interp
   colormap(pink);
catch exception
   throw(exception)
%   throwAsCaller(exception)
end
```

Call the `klein_bottle` function, passing a vector, and the function completes normally by drawing the figure.

```
klein_bottle([40 40])
```

Call the function again, this time passing a scalar value. Because the `catch` block issues the exception using `throw`, MATLAB displays error messages for line 16 of function `draw_klein`, and for line 6 of function `klein_bottle`:

```
klein_bottle(40)
Error using klein_bottle>draw_klein (line 16)
Attempted to access pq(2); index out of bounds because numel(pq)=1.

Error in klein_bottle (line 6)
draw_klein(ab, rtr, pq, box, vue)
```

Run the function again, this time changing the `klein_bottle.m` file so that the `catch` block uses `throwAsCaller` instead of `throw`. This time, MATLAB only displays the error at line 6 of the main program:

```
klein_bottle(40)
Error using klein_bottle (line 6)
Attempted to access pq(2); index out of bounds because numel(pq)=1.
```

`try` | `catch` | `error` | `assert` | `MException` | `throw(MException)` | `rethrow(MException)` | `addCause(MException)` | `getReport(MException)` | `last(MException)`

Purpose

Start clock to measure performance

Syntax

```
tic
ticID = tic
```

Description

`tic` starts a stopwatch timer. Stop the timer with the `toc` function.

`ticID = tic` stores an identifier for the `tic` command, so that you can nest timing operations.

Tips

- Consecutive `tic` commands overwrite the internally recorded starting time.
- The `clear` function does not reset the starting time recorded by a `tic` command.

Output Arguments

ticID

Value to use as an input argument for a subsequent call to `toc`. The value has no independent meaning.

Examples

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
    A = rand(n,n);
    b = rand(n,1);
    tic;
    x = A\b;
    t(n) = toc;
end
plot(t)
```

Measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000;   minTime = Inf;   nsum = 10;
tic;

for i=1:REPS
   tStart = tic;   total = 0;
   for j=1:nsum
      total = total + besselj(j,REPS);
   end

   tElapsed = toc(tStart);
   minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS;
```

See Also

clock | cputime | etime | profile | toc

Purpose

Stop clock to measure performance

Syntax

```
toc
toc(ticID)
elapsedTime = toc
elapsedTime = toc(ticID)
```

Description

`toc` stops a stopwatch timer started by the `tic` function, and displays the time elapsed in seconds.

`toc(ticID)` displays the time elapsed since the `tic` command corresponding to `ticID`.

`elapsedTime = toc` stores the elapsed time in a variable.

`elapsedTime = toc(ticID)` stores in a variable the time elapsed since the `tic` command corresponding to `ticID`.

Tips

- Consecutive `toc` commands return the increasing time that has elapsed since the most recent `tic`. Therefore, you can take multiple measurements from a single point in time.
- The `toc` function displays the time elapsed unless you specify an output argument.

Input Arguments

ticID

Identifier generated by a previous call to `tic` with an output argument.

Output Arguments

elapsedTime

Scalar `double` representing the time elapsed between `tic` and `toc` commands, in seconds.

Examples

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
```

```
    A = rand(n,n);
    b = rand(n,1);
    tic;
    x = A\b;
    t(n) = toc;
end
plot(t)
```

Measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000;   minTime = Inf;   nsum = 10;
tic;

for i=1:REPS
   tStart = tic;   total = 0;
   for j=1:nsum
      total = total + besselj(j,REPS);
   end

   tElapsed = toc(tStart);
   minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS;
```

Purpose

MATLAB Gateway to LibTIFF library routines

Description

The `Tiff` class represents a connection to a Tagged Image File Format (TIFF) file and provides access to many of the capabilities of the LibTIFF library. Use the methods of the `Tiff` object to call routines in the LibTIFF library. While you can use the `imread` and `imwrite` functions to read and write TIFF files, the `Tiff` class offers capabilities that these functions don't provide, such as reading subimages, writing tiles and strips of image data, and modifying individual TIFF tags.

In most cases, the syntax of the `Tiff` method is similar to the syntax of the corresponding LibTIFF library function. To get the most out of the `Tiff` object, you must be familiar with the LibTIFF API, as well as the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

MATLAB supports LibTIFF version 4.0.0.

For copyright information, see the `libtiffcopyright.txt` file.

Construction

`obj = Tiff(filename,mode)` creates a `Tiff` object associated with the TIFF file `filename`. `mode` specifies the type of access to the file.

A TIFF file is made up of one or more image file directories (IFDs). An IFD contains image data and associated metadata. IFDs can also contain subIFDs which also contain image data and metadata. When you open a TIFF file for reading, the Tiff object makes the first IFD in the file the *current* IFD. `Tiff` methods operate on the current IFD. You can use `Tiff` object methods to navigate among the IFDs and the subIFDs in a TIFF file.

When you open a TIFF file for writing or appending, the `Tiff` object automatically creates a IFD in the file for writing subsequent data. This IFD has all the default values specified in TIFF Revision 6.0.

When creating a new TIFF file, before writing any image to the file, you must create certain required fields (tags) in the file. These tags include `ImageWidth`, `ImageHeight`, `BitsPerSample`, `SamplesPerPixel`, `Compression`, `PlanarConfiguration`, and `Photometric`. If the image data has a stripped layout, the IFD contains the `RowsPerStrip` tag. If

the image data has a tiled layout, the IFD contains the `TileWidth` and `TileHeight` tags. Use the `setTag` method to define values for these tags.

Input Arguments

filename

Text string specifying name of file.

mode

One of the following text strings specifying the type of access to the TIFF file.

Supported Values

Parameter	Description
`'r'`	Open file for reading (default)
`'w'`	Open file for writing; discard existing contents
`'w8'`	Open file for writing a BigTIFF file; discard existing contents
`'a'`	Open or create file for writing; append data to end of file.
`'r+'`	Open (do not create) file for reading and writing

Properties

Compression

Specify scheme used to compress image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

None
CCITTRLE (Read-only)
CCITTFax3
CCITTFax4
LZW
JPEG
CCITTRLEW (Read-only)
PackBits
SGILog
SGILog24
Deflate
AdobeDeflate (Same as deflate)

Example: Set the `Compression` tag to the value `JPEG`. Note how you use the property to specify the value.

```
tiffobj.setTag('Compression', Tiff.Compression.JPEG);
```

ExtraSamples

Describe extra components

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This field is required if there are extra channels in addition to the usual colormetric channels.

Supported Values

Value of `ExtraSamples`	Description
`Unspecified`	Unspecified data
`AssociatedAlpha`	Associated alpha (pre-multiplied)
`UnassociatedAlpha`	Unassociated alpha data

Example: Set the `ExtraSamples` tag to the value `AssociatedAlpha`. Note how you use the property to specify the value.

```
tiffobj.setTag('ExtraSamples', Tiff.ExtraSamples.AssociatedAlpha)
```

See Also "Specify Tiff object properties and describe alpha channel" on page 1-5616

Group3Options

Options for Group 3 Fax Compression

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property is also referred to as `Fax3` and `T4Options`. This value is a bit mask controlled by the first three bits.

Supported Values

Supported values include the following.

Encoding2D	Bit 0 is 1. This specifies two-dimensional coding. If more than one strip is specified, each strip must begin with a one-dimensionally coded line. That is, RowsPerStrip should be a multiple of Parameter K, as documented in the CCITT specification.
Uncompressed	Bit 1 is 1. This specifies an uncompressed mode when encoding.
FillBits	Bit 2 is 1. Fill bits are added as necessary before EOL codes such that EOL always ends on a byte boundary. This ensures an EOL-sequence of 1 byte preceded by a zero nibble, for example, xxxx-0000 0000-0001.

Example:

```
mask = bitor(Tiff.Group3Options.Encoding2D,Tiff.Group3Options.Uncomp
tiffobj.setTag('Group3Options',mask);
```

InkSet

Specify set of inks used in separated image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the setTag method. For more clarification, see the example.

In this context, separated refers to photometric interpretation, not the planar configuration.

Supported Values

`CMYK`	Order of components: cyan, magenta, yellow, black. Usually, a value of 0 represents 0% ink coverage and a value of 255 represents 100% ink coverage for that component, but consult the TIFF specification for `DotRange`. When you specify CMYK, do not set the `InkNames` tag.
`MultiInk`	Any ordering other than CMYK. Consult the TIFF specification for `InkNames` field for a description of the inks used.

Example:

```
tiffobj.setTag('InkSet', Tiff.InkSet.CMYK);
```

JPEGColorMode

Specify control of YCbCr/RGB conversion

Use these values only when the photometric interpretation is YCbCr.

This property should not be used for the purpose of reading YCbCr imagery as RGB. In this case, use the RGBA interface provided by the `readRGBAImage`, `readRGBAStrip`, and `readRGBATile` methods.

Supported Values

`Raw` (default)	Keep input as separate Y, Cb, and Cr matrices.
`RGB`	Convert RGB input to YCbCr.

Example:

```
tiffobj.setTag('JPEGColorMode',Tiff/JPEGColorMode.RGB);
```

See also “Create YCbCr/JPEG image from RGB data” on page 1-5616

Orientation

Specify visual orientation of the image data.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

The first row represents the top of the image, and the first column represents the left side. Support for this tag is for informational purposes only, and it does not affect how MATLAB reads or writes the image data.

Supported Values

TopLeft
TopRight
BottomRight
BottomLeft
LeftTop
RightTop
RightBottom
LeftBottom

Example:

```
tiffobj.setTag('Orientation', Tiff.Orientation.TopRight);
```

Photometric

Specify color space of image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

MinIsWhite
MinIsBlack
RGB
Palette
Mask
Separated (CMYK)
YCbCr
CIELab
ICCLab
ITULab
LogL
LogLUV
CFA
LinearRaw

Example:

```
tiffobj.setTag('Photometric', Tiff.Photometric.RGB);
```

PlanarConfiguration

Specifies how image data components are stored on disk

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

`Chunky`	Store component values for each pixel contiguously. For example, in the case of RGB data, the first three pixels would be stored in the file as RGBRGBRGB etc. Almost all TIFF images have contiguous planar configurations.
`Separate`	Store component values for each pixel separately. For example, in the case of RGB data, the red component would be stored separately in the file from the green and blue components.

Example:

```
tiffobj.setTag('PlanarConfiguration', Tiff.PlanarConfiguration.Chunk
```

ResolutionUnit

Specify unit of measure used to interpret the `XResolution` and `YResolution` tags.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

`None` (default)
`Inch`
`Centimeter`

Example: Set `ResolutionUnit` tag to the value `Inch`. Then, setting `XResolution` tag to 300 means pixels per inch.

```
tiffObj.setTag('ResolutionUnit', Tiff.ResolutionUnit.Inch);
tiffObj.setTag('XResolution', 300);
```

```
tiffObj.setTag('YResolution', 300);
```

SampleFormat

Specify how to interpret each pixel sample

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

Supported Values
`UInt` (default)
`Int`
`IEEEFP`
`Void`
`ComplexInt`
`ComplexIEEEFP`

Example:

```
tiffobj.setTag('SampleFormat', Tiff.SampleFormat.IEEEFP);
```

SGILogDataFmt

Specify control of client data for SGILog codec

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

These enumerated values should only be used when the photometric interpretation value is `LogL` or `LogLUV`. The `BitsPerSample`, `SamplesPerPixel`, and `SampleFormat` tags should not be set if the image type is `LogL` or `LogLuv`. The choice of `SGILogDataFmt` will set these tags automatically. The `Float` and `Bits8` settings imply a `SamplesPerPixel` value of 3 for `LogLUV` images, but only 1 for `LogL` images.

Supported Values

Float	Single precision samples
Bits8	uint8 samples (read only)

This tag can be set only once per instance of a LogL/LogLuv Tiff image object instance.

Example:

```
tiffobj = Tiff('example.tif','r');
tiffobj.setDirectory(3); % image three is a LogLuv image
tiffobj.setTag('SGILogDataFmt', Tiff.SGILogDataFmt.Float);
imdata = tiffobj.read();
```

SubFileType

Specify type of image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the setTag method. For more clarification, see the example.

SubFileType is a bitmask that indicates the type of the image.

Supported Values

Default	Default value for single image file or first image.
ReducedImage	The current image is a thumbnail or reduced-resolution image that typically would be found in a sub-IFD.
Page	The image is a single image of a multi-image (or multipage) file.
Mask	The image is a transparency mask for another image in the file. The photometric interpretation value must be Photometric.Mask.

Example:

```
tiffobj.setTag('SubFileType', Tiff.SubFileType.Mask);
```

TagID

List of recognized TIFF tag names with their ID numbers

This property identifies all the supported TIFF tags with their ID numbers. Use this property to specify a tag when using the `setTag` method. For example, `Tiff.TagID.ImageWidth` returns the ID of the `ImageWidth` tag. To get a list of the names of supported tags, use the `getTagNames` method.

Example:

```
tiffobj.setTag(Tiff.TagID.ImageWidth, 300);
```

Thresholding

Specifies technique used to convert from gray to black and white pixels.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

Supported Values
`BiLevel` (default)
`HalfTone`
`ErrorDiffuse`

Example:

```
tiffobj.setTag('Thresholding', Tiff.Thresholding.HalfTone);
```

YCbCrPositioning

Specify relative positioning of chrominance samples

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property identifies all supported values for the `YCbCrPositioning` tag.

Supported Values

`Centered`	Specify for compatibility with industry standards such as PostScript Level 2
`Cosited`	Specify for compatibility with most digital video standards such as CCIR Recommendation 601-1.

Example:

```
tiffobj.setTag('YCbCrPositioning', Tiff.YCbCrPositioning.Centered);
```

Methods

close	Close Tiff object
computeStrip	Index number of strip containing specified coordinate
computeTile	Index number of tile containing specified coordinates
currentDirectory	Index of current IFD
getTag	Value of specified tag
getTagNames	List of recognized TIFF tags
getVersion	LibTIFF library version
isTiled	Determine if tiled image
lastDirectory	Determine if current IFD is last in file
nextDirectory	Make next IFD current IFD

numberOfStrips	Total number of strips in image
numberOfTiles	Total number of tiles in image
read	Read entire image
readEncodedStrip	Read data from specified strip
readEncodedTile	Read data from specified tile
readRGBAImage	Read image using RGBA interface
readRGBAStrip	Read strip data using RGBA interface
readRGBATile	Read tile data using RGBA interface
rewriteDirectory	Write modified metadata to existing IFD
setDirectory	Make specified IFD current IFD
setSubDirectory	Make subIFD specified by byte offset current IFD
setTag	Set value of tag
write	Write entire image
writeDirectory	Create new IFD and make it current IFD
writeEncodedStrip	Write data to specified strip
writeEncodedTile	Write data to specified tile

Examples

Create New TIFF File Using `Tiff` object

Create a new file called `myfile.tif`. To run this example, your directory must be writable.

```
t = Tiff('myfile.tif', 'w');
```

Close the Tiff object.

```
t.close();
```

Specify Tiff object properties and describe alpha channel

For this example, create an array of data, `data`, that contains colormetric channels and an alpha channel.

```
rgb = imread('example.tif');
numrows = size(rgb,1);
numcols = size(rgb,2);
alpha = 255*ones([numrows numcols], 'uint8');
data = cat(3,rgb,alpha);
```

Create a `Tiff` object, `t`, and set the object properties. Set the value of the `ExtraSamples` tag because the data contains the alpha channel in addition to the colormetric channels.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.RGB);
t.setTag('Compression',Tiff.Compression.None);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',4);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ExtraSamples',Tiff/ExtraSamples.Unspecified);
t.setTag('ImageLength',numrows);
t.setTag('ImageWidth',numcols);
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
```

Write the data to the `Tiff` object.

```
t.write(data);
t.close();
```

Create YCbCr/JPEG image from RGB data

Get RGB data.

```
rgb = imread('example.tif');
```

Create a `Tiff` object, `t`, and set the object properties. Specify RGB input data using the `JPEGColorMode` property.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.YCbCr);
t.setTag('Compression',Tiff.Compression.JPEG);
t.setTag('YCbCrSubSampling',[2 2]);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',3);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ImageLength',size(rgb,1));
t.setTag('ImageWidth',size(rgb,2));
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
t.setTag('JPEGColorMode',Tiff/JPEGColorMode.RGB);
t.setTag('JPEGQuality',75);
```

Write the data to the `Tiff` object.

```
t.write(rgb);
t.close();
```

- "Reading Image Data and Metadata from TIFF Files"

Purpose

Construct timer object

Syntax

```
T = timer
T = timer('PropertyName1', PropertyValue1, 'PropertyName2',
   PropertyValue2,...)
```

Description

`T = timer` constructs a timer object with default attributes.

`T = timer('PropertyName1', PropertyValue1, 'PropertyName2', PropertyValue2,...)` constructs a timer object in which the given property name/value pairs are set on the object. See “Timer Object Properties” on page 1-5618 for a list of all the properties supported by the timer object.

Note that the property name/property value pairs can be in any format supported by the `set` function, i.e., property/value string pairs, structures, and property/value cell array pairs.

Note The `timer` object is subject to the limitations of your hardware, operating system, and software. It is not intended to be used for real-time applications.

Timer Object Properties

The timer object supports the following properties that control its attributes. The table includes information about the data type of each property and its default value.

To view the value of the properties of a particular timer object, use the `get(timer)` function. To set the value of the properties of a timer object, use the `set(timer)` function.

Property Name	Property Description	Data Types, Values, Defaults, Access	
AveragePeriod	Average time between TimerFcn executions since the timer started. Note: Value is NaN until timer executes two timer callbacks.	Data type	double
		Default	NaN
		Read only	Always
BusyMode	Action taken when a timer has to execute TimerFcn before the completion of previous execution of TimerFcn. 'drop' — Skip execution when there is a function already pending in the queue. If the queue is empty, add the function to the queue and execute at the next opportunity. 'error' — Call the error handling function specified by ErrorFcn when there is already a function in the queue. 'queue' — Execute function at next opportunity. See "Handling Callback Function Queuing Conflicts" for more information.	Data type	Enumerated string
		Values	'drop' 'error' 'queue'
		Default	'drop'
		Read only	While Running = 'on'

Property Name	Property Description	Data Types, Values, Defaults, Access	
ErrorFcn	Function that the timer executes when an error occurs. This function executes before the StopFcn. See "Creating Callback Functions" for more information.	Data type	Text string, function handle, or cell array
		Default	None
		Read only	Never
ExecutionMode	Determines how the timer object schedules timer events. See "Timer Object Execution Modes" for more information.	Data type	Enumerated string
		Values	'singleShot' 'fixedDelay' 'fixedRate' 'fixedSpacing'
		Default	'singleShot'
		Read only	While Running = 'on'
InstantPeriod	The time between the last two executions of TimerFcn.	Data type	double
		Default	NaN
		Read only	Always

Property Name	Property Description	Data Types, Values, Defaults, Access	
`Name`	User-supplied name.	Data type	Text string
		Default	`'timer-`*`i`*`'`, where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.
		Read only	Never
`ObjectVisibility`	Provides a way for application developers to prevent end-user access to the timer objects created by their application. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to `'off'`. Objects that are not visible are still valid. If you have access to the object (for example, from within the file that created it), you can set its properties.	Data type	Enumerated string
		Values	`'off'` `'on'`
		Default	`'on'`
		Read only	Never
`Period`	Specifies the delay, in seconds, between executions of `TimerFcn`.	Data type	`double`
		Value	Any number >= 0.001
		Default	1.0
		Read only	While `Running` = `'on'`

Property Name	Property Description	Data Types, Values, Defaults, Access	
`Running`	Indicates whether the timer is currently executing.	Data type	Enumerated string
		Values	`'off'` `'on'`
		Default	`'off'`
		Read only	Always
`StartDelay`	Specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`.	Data type	`double`
		Values	Any number >= 0
		Default	0
		Read only	While `Running = 'on'`
`StartFcn`	Function the timer calls when it starts. See "Creating Callback Functions" for more information.	Data type	Text string, function handle, or cell array
		Default	None
		Read only	Never

Property Name	Property Description	Data Types, Values, Defaults, Access	
`StopFcn`	Function the timer calls when it stops. The timer stops when • You call the timer `stop` function • The timer finishes executing `TimerFcn`, i.e., the value of `TasksExecuted` reaches the limit set by `TasksToExecute`. • An error occurs (The `ErrorFcn` is called first, followed by the `StopFcn`.) See "Creating Callback Functions" for more information.	Date type	Text string, function handle, or cell array
		Default	None
		Read only	Never
`Tag`	User supplied label.	Data type	Text string
		Default	Empty string ('')
		Read only	Never

Property Name	Property Description	Data Types, Values, Defaults, Access	
`TasksToExecute`	Specifies the number of times the timer should execute the function specified in the `TimerFcn` property.	Data type	`double`
		Values	Any number > 0
		Default	`Inf`
		Read only	Never
`TasksExecuted`	The number of times the timer has called `TimerFcn` since the timer was started.	Data type	`double`
		Values	Any number >= 0
		Default	0
		Read only	Always
`TimerFcn`	Timer callback function. See “Creating Callback Functions” for more information.	Data type	Text string, function handle, or cell array
		Default	None
		Read only	Never
`Type`	Identifies the object type.	Data type	Text string
		Values	`'timer'`
		Read only	Always
`UserData`	User-supplied data.	Data type	User-defined
		Default	`[]`
		Read only	Never

Examples

This example constructs a timer object with a timer callback function handle, `mycallback`, and a 10 second interval.

```
t = timer('TimerFcn',@mycallback, 'Period', 10.0);
```

timerfind

Purpose

Find timer objects

Syntax

```
out = timerfind
out = timerfind('P1', V1, 'P2', V2,...)
out = timerfind(S)
out = timerfind(obj, 'P1', V1, 'P2', V2,...)
```

Description

`out = timerfind` returns an array, `out`, of all the timer objects that exist in memory.

`out = timerfind('P1', V1, 'P2', V2,...)` returns an array, `out`, of timer objects whose property values match those passed as parameter/value pairs, `P1`, `V1`, `P2`, `V2`. Parameter/value pairs may be specified as a cell array.

`out = timerfind(S)` returns an array, `out`, of timer objects whose property values match those defined in the structure, `S`. The field names of `S` are timer object property names and the field values are the corresponding property values.

`out = timerfind(obj, 'P1', V1, 'P2', V2,...)` restricts the search for matching parameter/value pairs to the timer objects listed in `obj`. `obj` can be an array of timer objects.

Note When specifying parameter/value pairs, you can use any mixture of strings, structures, and cell arrays in the same call to `timerfind`.

Note that, for most properties, `timerfind` performs case-sensitive searches of property values. For example, if the value of an object's `Name` property is `'MyObject'`, `timerfind` will not find a match if you specify `'myobject'`. Use the `get` function to determine the exact format of a property value. However, properties that have an enumerated list of possible values are not case sensitive. For example, `timerfind` will find an object with an `ExecutionMode` property value of `'singleShot'` or `'singleshot'`.

Examples

These examples use `timerfind` to find timer objects with the specified property values.

```
t1 = timer('Tag', 'broadcastProgress', 'Period', 5);
t2 = timer('Tag', 'displayProgress');
out1 = timerfind('Tag', 'displayProgress')
out2 = timerfind({'Period', 'Tag'}, {5, 'broadcastProgress'})
```

See Also

`get(timer)` | `timer` | `timerfindall`

timerfindall

Purpose

Find timer objects, including invisible objects

Syntax

```
out = timerfindall
out = timerfindall('P1', V1, 'P2', V2,...)
out = timerfindall(S)
out = timerfindall(obj, 'P1', V1, 'P2', V2,...)
```

Description

`out = timerfindall` returns an array, `out`, containing all the timer objects that exist in memory, regardless of the value of the object's `ObjectVisibility` property.

`out = timerfindall('P1', V1, 'P2', V2,...)` returns an array, `out`, of timer objects whose property values match those passed as parameter/value pairs, `P1`, `V1`, `P2`, `V2`. Parameter/value pairs may be specified as a cell array.

`out = timerfindall(S)` returns an array, `out`, of timer objects whose property values match those defined in the structure, `S`. The field names of `S` are timer object property names and the field values are the corresponding property values.

`out = timerfindall(obj, 'P1', V1, 'P2', V2,...)` restricts the search for matching parameter/value pairs to the timer objects listed in `obj`. `obj` can be an array of timer objects.

Note When specifying parameter/value pairs, you can use any mixture of strings, structures, and cell arrays in the same call to `timerfindall`.

Note that, for most properties, `timerfindall` performs case-sensitive searches of property values. For example, if the value of an object's `Name` property is `'MyObject'`, `timerfindall` will not find a match if you specify `'myobject'`. Use the `get` function to determine the exact format of a property value. However, properties that have an enumerated list of possible values are not case sensitive. For example, `timerfindall` will find an object with an `ExecutionMode` property value of `'singleShot'` or `'singleshot'`.

Examples

Create several timer objects.

```
t1 = timer;
t2 = timer;
t3 = timer;
```

Set the `ObjectVisibility` property of one of the objects to `'off'`.

```
t2.ObjectVisibility = 'off';
```

Use `timerfind` to get a listing of all the timer objects in memory. Note that the listing does not include the timer object (`timer-2`) whose `ObjectVisibility` property is set to `'off'`.

```
timerfind

Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:   Name:
   1       singleShot      1        ''          timer-1
   2       singleShot      1        ''          timer-3
```

Use `timerfindall` to get a listing of all the timer objects in memory. This listing includes the timer object whose `ObjectVisibility` property is set to `'off'`.

```
timerfindall

Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:   Name:
   1       singleShot      1        ''          timer-1
   2       singleShot      1        ''          timer-2
   3       singleShot      1        ''          timer-3
```

See Also

`get(timer)` | `timer` | `timerfind`

times

Purpose

Array multiply

Syntax

```
c = a.*b
c = times(a,b)
```

Description

`c = a.*b` multiplies arrays `a` and `b` element-by-element and returns the result in `c`. Inputs `a` and `b` must have the same size unless one is a scalar.

`c = times(a,b)` is called for the syntax `a.*b` when `a` or `b` is an object.

See Also

`mtimes`

Purpose

Add title to current axes

Syntax

```
title(str)
title(str,Name,Value)

title(axes_handle,___)

h = title(___)
```

Description

`title(str)` adds the title consisting of a string, `str`, at the top and in the center of the current axes. Each axes graphics object has one predefined title.

`title(str,Name,Value)` additionally specifies the title properties using one or more `Name,Value` pair arguments.

`title(axes_handle,___)` adds the title to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a title. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = title(___)` returns the handle to the text object used as the title. The handle is useful when making future modifications to the title.

Input Arguments

str - Text to display as title

string

Text to display as a title, specified as a string. You also can specify the name of a function that returns a string.

Example: `'myTitle'`

Example: `date`

Note The words `default`, `factory`, and `remove` are reserved words that will not appear in a title when quoted as a normal string. To display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

axes_handle - Axes handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Color','red','FontSize',14` adds a title with red, 14-point font.

In addition to the following, you can specify other text object properties using `Name,Value` pair arguments. See Text Properties.

'Color' - Text color

`[0 0 0]` (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`.

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	blue
[1 1 1]	w	white
[0 0 0]	k	black

Example: `'Color',[0 1 0]`

Example: `'Color','green'`

'FontAngle' - Character slant

`'normal'` (default) | `'italic'` | `'oblique'`

Character slant, specified as the comma-separated pair consisting of `'FontAngle'` and one of these values: `'normal'`, `'italic'`, or `'oblique'`. MATLAB uses the `FontAngle` property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

Example: `'FontAngle','italic'`

'FontName' - Font name

`'Helvetica'` (default) | string | `'FixedWidth'`

Font name, specified as the comma-separated pair consisting of `'FontName'` and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to

hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

Example: `'FontName','Courier'`

'FontSize' - Font size

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of `'FontSize'` and a scalar in units determined by the `FontUnits` property. The default value for `FontUnits` is `points`.

Example: `'FontSize',12.5`

'FontUnits' - Font size units

`'points'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'pixels'`

Font size units, specified as the comma-separated pair consisting of `'FontUnits'` and one of the following strings:

- `'points'`
- `'normalized'`
- `'inches'`
- `'centimeters'`
- `'pixels'`

When the value of `FontUnits` is `'normalized'`, MATLAB interprets the value of `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly. `points`, `inches`, `centimeters`, and `pixels` are absolute units. 1 point = $^1/_{72}$ inch

---

Note When setting both the `FontSize` and the `FontUnits`, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`. For example, to set the font size to 0.3 inches, call `'FontUnits','inches','FontSize',0.3` in the argument list.

'FontWeight' - Weight of text characters

`'normal'` (default) | `'bold'` | `'light'` | `'demi'`

Weight of text characters, specified as the comma-separated pair consisting of `'FontWeight'` and one of the following strings:

- `'normal'`
- `'bold'`
- `'light'`
- `'demi'`

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to `'bold'` or `'demi'` causes MATLAB to use a bold font.

Example: `'FontWeight','bold'`

'Interpreter' - Character interpretation

`'tex'` (default) | `'latex'` | `'none'`

Character interpretation, specified as the comma-separated pair consisting of `'Interpreter'` and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the String property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

Example: 'Interpreter','latex'

Output Arguments

h - Handle to text object used as title

Handle to the text object used as the title. This is a unique identifier, which you can use to query and modify the properties of the title.

Examples

Add Title to Current Figure

Create a figure and display a title in the current axes.

```
figure
plot((1:10).^2)
title('My Title')
```

You also can call title with a function that returns a string. For example, the date function returns a string containing today's date.

```
title(date)
```

MATLAB sets the output of date as the axes title.

Include Variable's Value in Title

Include the value of variable c in a title.

```
figure
plot((1:10).^2)
```

```
f = 70;
c = (f-32)/1.8;
title(['Temperature is ',num2str(c),' C'])
```

Create Multicolored Title Using TeX Markup

In a TeX string, use the color modifier `\color` to change the color of characters following it from the previous color.

```
figure
plot((1:10).^2)
title(['\fontsize{16}black {\color{magenta}magenta '...
'\color[rgb]{0 .5 .5}teal \color{red}red} black again'])
```

Create Colored Title Using Name,Value Pair Argument

Include the value of variable `n` in a title, and set the color of the title.

Use the `Name,Value` pair `'Color','y'` to set the color of the title to yellow.

```
figure
plot((1:10).^2)
title('Case number # 3','Color', 'y')
```

Include Greek Symbols in Title

Use a TeX string to include Greek symbols in a title.

```
t = (0:0.01:0.2);
y = exp(-25*t);
figure
plot(t,y)
title('y = \ite^{\lambda t}','Color','b')
```

The text object `String` property lists the available symbols. The `'Interpreter'` property must be `'tex'` (the default).

Include Superscript or Subscript Character in Title

```
figure
```

```
plot((1:10).^2)
title('\alpha^2 and X_1')
```

The superscript character "^" and the subscript character "_" modify the character or substring defined in braces immediately following.

Create Multiline Title

Create a multiline title using a multiline cell array.

```
figure
plot((1:10).^2)
title({'First line';'Second line'})
```

Display Text As Typed

Set the `Interpreter` property as `'none'` so that the string `X_1` is displayed in the figure as typed, without making `1` a subscript of `X`.

```
figure
plot((1:10).^2)
title('X_1','Interpreter','none')
```

MATLAB displays the string `X_1` in the title of the figure.

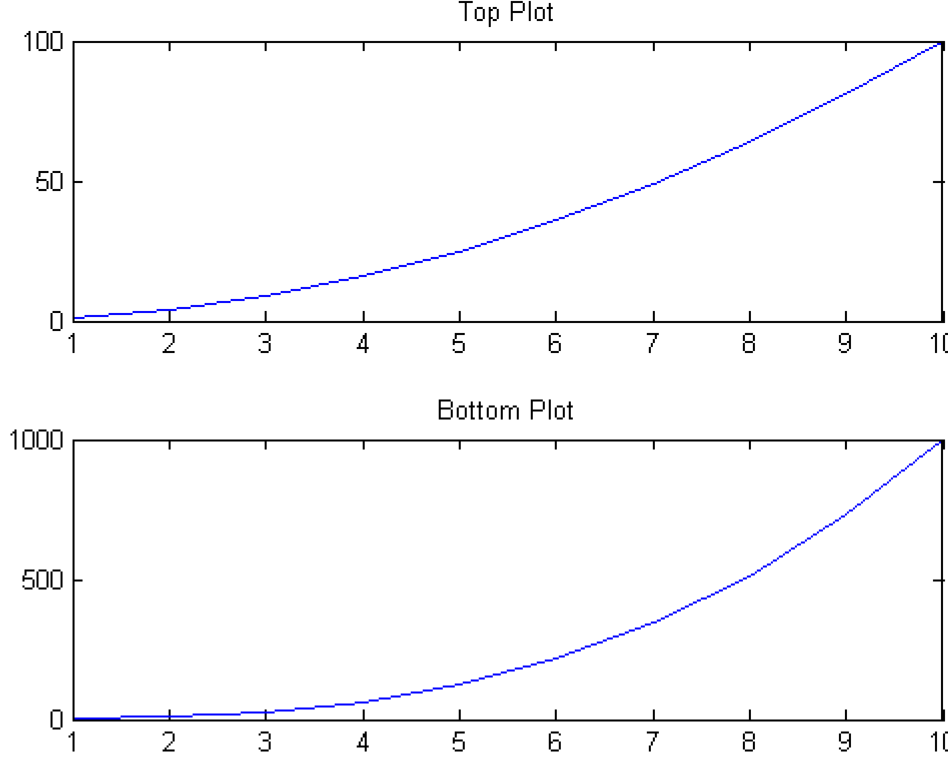
Add Title to Specific Axes

Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Add a title to each subplot by referring to its axes handle, `s(1)`, or `s(2)`.

```
title(s(1),'Top Plot')
title(s(2),'Bottom Plot')
```



Add Title and Return Object Handle

Add a title to a plot and return the handle to the text object used as the title.

```
figure
plot((1:10).^2)
h = title('My Title');
```

MATLAB returns the object handle in the output variable, `h`.

Set the color of the title to red, using the object handle.

```
set(h,'Color','red')
```

Concepts

- Adding Titles to Graphs

Text Properties

todatenum

Purpose

Convert CDF epoch object to MATLAB datenum

Syntax

```
n = todatenum(obj)
```

Description

`n = todatenum(obj)` converts the CDF epoch object `ep_obj` into a MATLAB serial date number. Note that a CDF epoch is the number of milliseconds since `01-Jan-0000` whereas a MATLAB datenum is the number of days since 00`-Jan-0000`.

Examples

Construct a CDF epoch object from a date string, and then convert the object back into a MATLAB date string:

```
dstr = datestr(today)
dstr =
   08-Oct-2003

obj = cdfepoch(dstr)
obj =
     cdfepoch object:
     08-Oct-2003 00:00:00

dstr2 = datestr(todatenum(obj))
dstr2 =
   08-Oct-2003
```

See Also

`cdfepoch` | `cdfinfo` | `cdfread` | `datenum`

toeplitz

Purpose

Toeplitz matrix

Syntax

```
T = toeplitz(c,r)
T = toeplitz(r)
```

Description

A *Toeplitz* matrix is defined by one row and one column. A *symmetric Toeplitz* matrix is defined by just one row. `toeplitz` generates Toeplitz matrices given just the row or row and column description.

`T = toeplitz(c,r)` returns a nonsymmetric Toeplitz matrix `T` having `c` as its first column and `r` as its first row. If the first elements of `c` and `r` are different, a message is printed and the column element is used.

For a real vector `r`, `T = toeplitz(r)` returns the symmetric Toeplitz matrix formed from vector `r`, where `r` defines the first row of the matrix. For a complex vector `r` with a real first element, `T = toeplitz(r)` returns the Hermitian Toeplitz matrix formed from `r`, where `r` defines the first row of the matrix and `r'` defines the first column. When the first element of `r` is not real, the resulting matrix is Hermitian off the main diagonal, i.e., $T_{ij} = \text{conj}(T_{ji})$ for $i \neq j$.

Examples

A Toeplitz matrix with diagonal disagreement is

```
c = [1  2  3  4  5];
r = [1.5  2.5  3.5  4.5  5.5];
toeplitz(c,r)
Column wins diagonal conflict:
ans =
    1.000    2.500    3.500    4.500    5.500
    2.000    1.000    2.500    3.500    4.500
    3.000    2.000    1.000    2.500    3.500
    4.000    3.000    2.000    1.000    2.500
    5.000    4.000    3.000    2.000    1.000
```

See Also

`hankel` | `kron`

Purpose

Root folder for specified toolbox

Syntax

```
toolboxdir('tbxFolderName')
s = toolboxdir('tbxFolderName')
s = toolboxdir tbxFolderName
```

Description

`toolboxdir('tbxFolderName')` returns a string that is the absolute path to the specified toolbox, `tbxFolderName`, where `tbxFolderName` is the folder name for the toolbox.

`s = toolboxdir('tbxFolderName')` returns the absolute path to the specified toolbox to the output argument, `s`.

`s = toolboxdir tbxFolderName` is the command form of the syntax.

Tips

`toolboxdir` is particularly useful for MATLAB Compiler software. The base folder of all toolboxes installed with MATLAB software is:

matlabroot/**toolbox**/tbxFolderName

However, in deployed mode, the base folders of the toolboxes are different. `toolboxdir` returns the correct root folder, whether running from MATLAB or from an application deployed with the MATLAB Compiler software.

To determine the folder name for a given toolbox, run the following code, substituting the name of a product function for *toolbxfcn*:

```
n = 'toolbxfcn';
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

For example, to determine the product name for Control System Toolbox set `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss'
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+'
regexp(which(n), pat, 'match', 'once')
```

`control`

Examples

Obtain the path for the Control System Toolbox software:

```
s = toolboxdir('control')
```

MATLAB returns:

```
s = C:\Program Files\MATLAB\R2012a\toolbox\control
```

See Also

`fullfile` | `matlabroot` | `path`

Purpose

Sum of diagonal elements

Syntax

```
b = trace(A)
```

Description

`b = trace(A)` is the sum of the diagonal elements of the matrix `A`.

Algorithms

```
t = sum(diag(A));
```

See Also

`det` | `eig`

transpose

Purpose Transpose

Syntax

```
b = a.'
b = transpose(a)
```

Description

`b = a.'` computes the non-conjugate transpose of matrix `a` and returns the result in `b`.

`b = transpose(a)` is called for the syntax `a.'` when `a` is an object.

See Also

`ctranspose` | `permute`

Purpose

Trapezoidal numerical integration

Syntax

```
Z = trapz(Y)
Z = trapz(X,Y)
Z = trapz(...,dim)
```

Description

`Z = trapz(Y)` computes an approximation of the integral of `Y` via the trapezoidal method (with unit spacing). To compute the integral for spacing other than one, multiply `Z` by the spacing increment. Input `Y` can be complex.

If `Y` is a vector, `trapz(Y)` is the integral of `Y`.

If `Y` is a matrix,`trapz(Y)` is a row vector with the integral over each column.

If `Y` is a multidimensional array, `trapz(Y)` works across the first nonsingleton dimension.

`Z = trapz(X,Y)` computes the integral of `Y` with respect to `X` using trapezoidal integration. Inputs `X` and `Y` can be complex.

If `X` is a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`, `trapz(X,Y)` operates across this dimension.

`Z = trapz(...,dim)` integrates across the dimension of `Y` specified by scalar `dim`. The length of `X`, if given, must be the same as `size(Y,dim)`.

Examples

Example 1

The exact value of $\int_0^{\pi} \sin(x)\, dx$ is 2.
To approximate this numerically on a uniformly spaced grid, use

```
X = 0:pi/100:pi;
Y = sin(X);
```

Then both

```
Z = trapz(X,Y)
```

and

```
Z = pi/100*trapz(Y)
```

produce

```
Z =
    1.9998
```

Example 2

A nonuniformly spaced example is generated by

```
X = sort(rand(1,101)*pi);
Y = sin(X);
Z = trapz(X,Y);
```

The result is not as accurate as the uniformly spaced grid. One random sample produced

```
Z =
    1.9984
```

Example 3

This example uses two complex inputs:

```
z = exp(1i*pi*(0:100)/100);

trapz(z, 1./z)
ans =
   0.0000 + 3.1411i
```

Purpose

Lay out tree or forest

Syntax

```
[x,y] = treelayout(parent,post)
[x,y,h,s] = treelayout(parent,post)
```

Description

`[x,y] = treelayout(parent,post)` lays out a tree or a forest. `parent` is the vector of parent pointers, with `0` for a root. `post` is an optional postorder permutation on the tree nodes. If you omit `post`, `treelayout` computes it. `x` and `y` are vectors of coordinates in the unit square at which to lay out the nodes of the tree to make a nice picture.

`[x,y,h,s] = treelayout(parent,post)` also returns the height of the tree `h` and the number of vertices `s` in the top-level separator.

See Also

`etree` | `treeplot` | `etreeplot` | `symbfact`

treeplot

Purpose

Plot picture of tree

Syntax

```
treeplot(p)
treeplot(p,nodeSpec,edgeSpec)
```

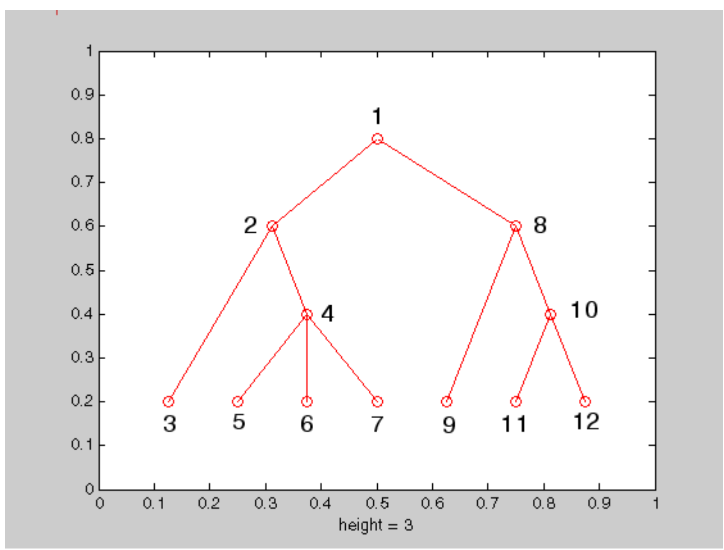
Description

`treeplot(p)` plots a picture of a tree given a vector of parent pointers, with `p(i)` = 0 for a root.

`treeplot(p,nodeSpec,edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `''` to omit one or both.

Examples

To plot a tree with 12 nodes, call `treeplot` with a 12-element input vector. The index of each element in the vector is shown adjacent to each node in the figure below. (These indices are shown only for the point of illustrating the example; they are not part of the `treeplot` output.)



To generate this plot, set the value of each element in the `nodes` vector to the index of its parent, (setting the parent of the root node to zero).

The node marked `1` in the figure is represented by `nodes(1)` in the input vector, and because this is the root node which has a parent of zero, you set its value to zero:

```
nodes(1) = 0;     % Root node
```

`nodes(2)` and `nodes(8)` are children of `nodes(1)`, so set these elements of the input vector to `1`:

```
nodes(2) = 1;     nodes(8) = 1;
```

`nodes(5:7)` are children of `nodes(4)`, so set these elements to `4`:

```
nodes(5) = 4;     nodes(6) = 4;     nodes(7) = 4;
```

Continue in this manner until each element of the vector identifies its parent. For the plot shown above, the `nodes` vector now looks like this:

```
nodes = [0 1 2 2 4 4 4 1 8 8 10 10];
```

Now call `treeplot` to generate the plot:

```
treeplot(nodes)
```

`etree` | `etreeplot` | `treelayout`

Purpose Lower triangular part of matrix

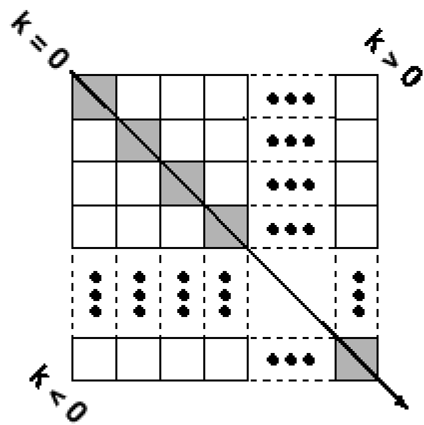
Syntax

```
L = tril(X)
L = tril(X,k)
```

Description

`L = tril(X)` returns the lower triangular part of `X`.

`L = tril(X,k)` returns the elements on and below the kth diagonal of `X`. `k = 0` is the main diagonal, `k > 0` is above the main diagonal, and `k < 0` is below the main diagonal.



Examples

```
tril(ones(4,4),-1)

ans =

     0     0     0     0
     1     0     0     0
     1     1     0     0
     1     1     1     0
```

See Also

`diag` | `triu`

Purpose

Triangular mesh plot

Syntax

```
trimesh(Tri,X,Y,Z,C)
trimesh(Tri,X,Y,Z)
trimesh(Tri,X,Y)
trimesh(TR)
trimesh(...'PropertyName',PropertyValue...)
h = trimesh(...)
```

Description

`trimesh(Tri,X,Y,Z,C)` displays triangles defined in the *m*-by-3 face matrix `Tri` as a mesh. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the `X`, `Y`, and `Z` vertices. The edge color is defined by the vector `C`.

`trimesh(Tri,X,Y,Z)` uses `C = Z` so color is proportional to surface height.

`trimesh(Tri,X,Y)` displays the triangles in a 2-D plot.

`trimesh(TR)` displays the triangles in a triangulation representation.

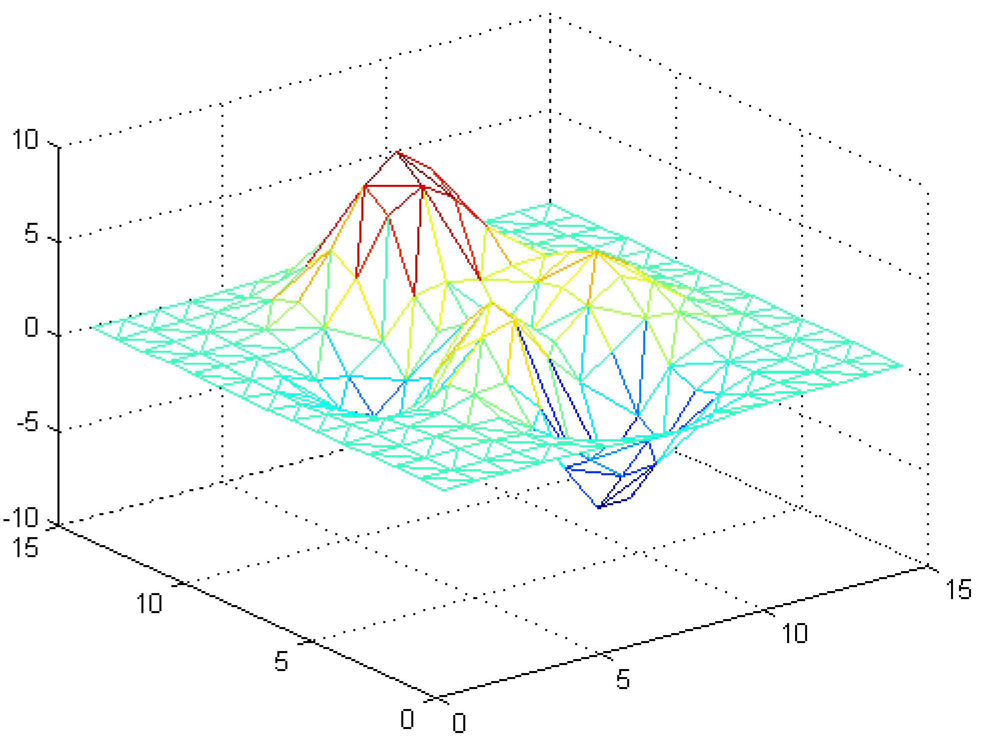
`trimesh(...'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trimesh(...)` returns a handle to the displayed triangles.

Examples

Create vertex vectors and a face matrix, then create a triangular mesh plot.

```
[x,y]=meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trimesh(tri,x,y,z)
```



If the surface is already a triangulation representation, then you can pass the triangulation to `trimesh`:

```
tr = triangulation(tri,x(:),y(:),z(:));
trimesh(tr)
```

See Also

`patch` | `trisurf` | `delaunay` | `delaunayTriangulation` | `triangulation`

Purpose

Numerically evaluate triple integral

Compatibility

`triplequad` will be removed in a future release. Use `integral3` instead.

Syntax

```
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)
```

Description

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)` evaluates the triple integral `fun(x,y,z)` over the three dimensional rectangular region `xmin <= x <= xmax`, `ymin <= y <= ymax`, `zmin <= z <= zmax`. The first input, `fun`, is a function handle. `fun(x,y,z)` must accept a vector `x` and scalars `y` and `z`, and return a vector of values of the integrand.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)` uses a tolerance `tol` instead of the default, which is `1.0e-6`.

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quadl` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quadl`.

Examples

Pass function handle `@integrnd` to `triplequad`:P

```
Q = triplequad(@integrnd,0,pi,0,1,-1,1);
```

where the file `integrnd.m` is

```
function f = integrnd(x,y,z)
f = y*sin(x)+z*cos(x);
```

Pass anonymous function handle `F` to `triplequad`:

```
F = @(x,y,z)y*sin(x)+z*cos(x);
Q = triplequad(F,0,pi,0,1,-1,1);
```

This example integrates `y*sin(x)+z*cos(x)` over the region `0 <= x <= pi`, `0 <= y <= 1`, `-1 <= z <= 1`. Note that the integrand can be evaluated with a vector `x` and scalars `y` and `z`.

How To

- "Anonymous Functions"

Purpose

2-D triangular plot

Syntax

```
triplot(TRI,x,y)
triplot(TRI,x,y,color)
triplot(TR)
h = triplot(...)
triplot(...,'param','value','param','value'...)
```

Description

`triplot(TRI,x,y)` displays the triangles defined in the `m`-by-3 matrix `TRI`. A row of `TRI` contains indices into the vectors `x` and `y` that define a single triangle. The default line color is blue.

`triplot(TRI,x,y,color)` uses the string `color` as the line color. `color` can also be a line specification. See `ColorSpec` for a list of valid color strings. See `LineSpec` for information about line specifications.

`triplot(TR)` displays the triangles in a triangulation representation.

`h = triplot(...)` returns a vector of handles to the displayed triangles.

`triplot(...,'param','value','param','value'...)` allows additional line property name/property value pairs to be used when creating the plot. See `Line Properties` for information about the available properties.

Examples

Plot a Delaunay triangulation for 10 randomly generated points.

```
P = gallery('uniformdata',10,2,2);
DT = delaunayTriangulation(P);
triplot(DT)
```

`delaunayTriangulation` | `triangulation` | `delaunay` | `trimesh` | `trisurf`

Purpose

(Will be removed) Triangulation representation

Note `TriRep` will be removed in a future release. Use `triangulation` instead.

Description

`TriRep` provides topological and geometric queries for triangulations in 2-D and 3-D space. For example, for triangular meshes you can query triangles attached to a vertex, triangles that share an edge, neighbor information, circumcenters, or other features. You can create a `TriRep` directly using existing triangulation data. Alternatively, you can create a Delaunay triangulation, via `DelaunayTri`, which provides access to the `TriRep` functionality.

Construction

TriRep	(Will be removed) Triangulation representation

Methods

baryToCart	(Will be removed) Convert point coordinates from barycentric to Cartesian
cartToBary	(Will be removed) Convert point coordinates from cartesian to barycentric
circumcenters	(Will be removed) Circumcenters of specified simplices
edgeAttachments	(Will be removed) Simplices attached to specified edges
edges	(Will be removed) Triangulation edges

faceNormals	(Will be removed) Unit normals to specified triangles
featureEdges	(Will be removed) Sharp edges of surface triangulation
freeBoundary	(Will be removed) Facets referenced by only one simplex
incenters	(Will be removed) Incenters of specified simplices
isEdge	(Will be removed) Test if vertices are joined by edge
neighbors	(Will be removed) Simplex neighbor information
size	(Will be removed) Size of triangulation matrix
vertexAttachments	(Will be removed) Return simplices attached to specified vertices

Properties

X	Coordinates of the points in the triangulation
Triangulation	Triangulation data structure

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

Indexing

`TriRep` objects support indexing into the triangulation using parentheses (). The syntax is the same as for arrays.

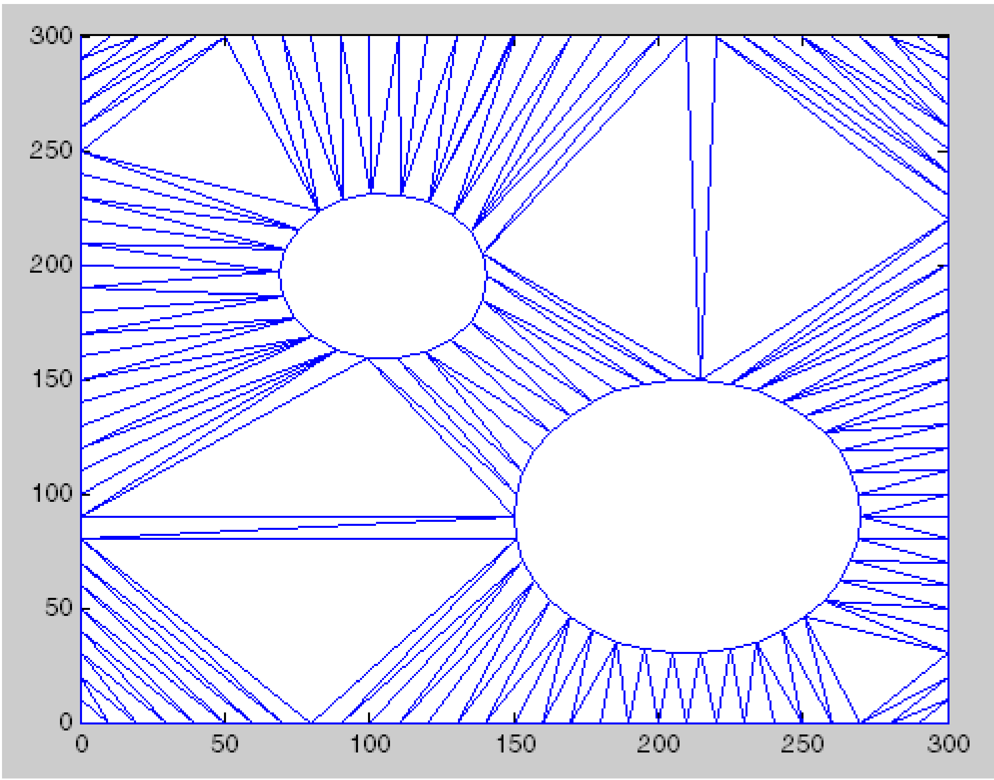
Examples

Load a 2-D triangulation and use the `TriRep` constructor to build an array of the free boundary edges:

```
load trimesh2d
```

This loads triangulation `tri` and vertex coordinates `x`, `y`:

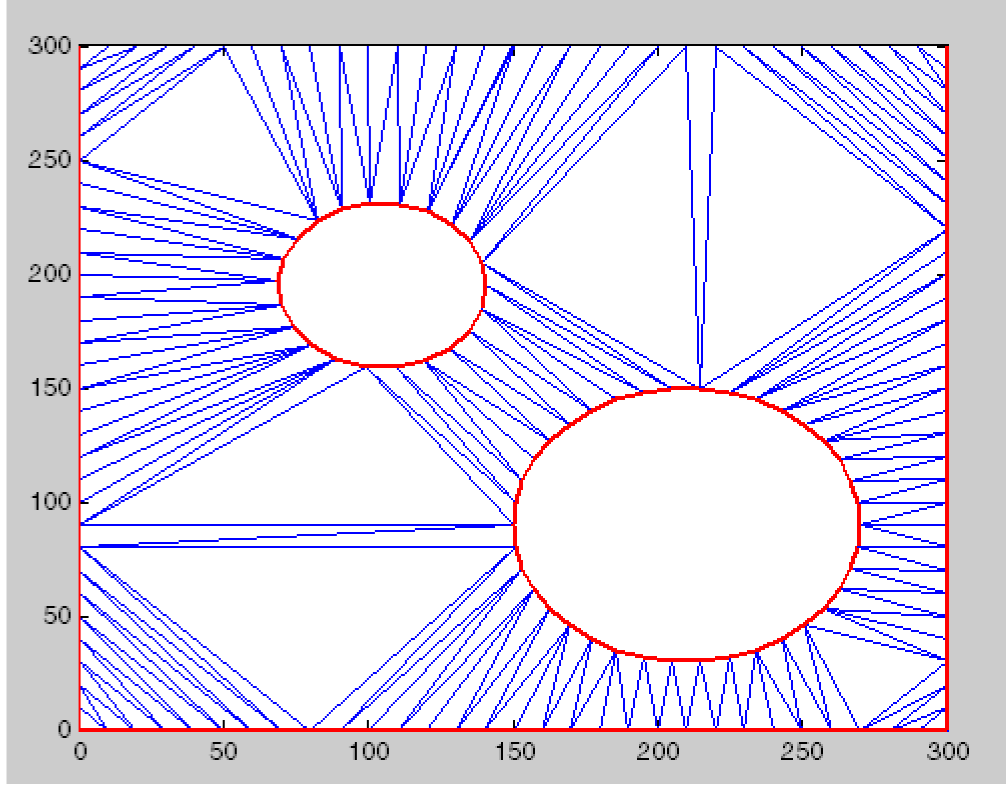
```
trep = TriRep(tri, x,y);
fe = freeBoundary(trep)';
triplot(trep);
```



You can add the free edges `fe` to the plot:

```
hold on;
plot(x(fe), y(fe), 'r','LineWidth',2);
hold off;
```

```
axis([-50 350 -50 350]);
axis equal;
```



See Also

delaunayTriangulation | triangulation | scatteredInterpolant

Purpose

(Will be removed) Triangulation representation

Note `TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
TR = TriRep(TRI, X, Y)
TR = TriRep(TRI, X, Y, Z)
TR = TriRep(TRI, X)
```

Description

`TR = TriRep(TRI, X, Y)` creates a 2-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y)`. `TRI` is an `m`-by-3 matrix that defines the triangulation in face-vertex format, where `m` is the number of triangles. Each row of `TRI` is a triangle defined by indices into the column vector of vertex coordinates `(X, Y)`.

`TR = TriRep(TRI, X, Y, Z)` creates a 3-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y, Z)`. `TRI` is an `m`-by-3 or `m`-by-4 matrix that defines the triangulation in simplex-vertex format, where where m is the number of simplices; triangles or tetrahedra in this case. Each row of `TRI` is a simplex defined by indices into the column vector of vertex coordinates `(X, Y, Z)`.

`TR = TriRep(TRI, X)` creates a triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `X`. `TRI` is an `m`-by-`n` matrix that defines the triangulation in simplex-vertex format, where `m` is the number of simplices and `n` is the number of vertices per simplex. Each row of `TRI` is a simplex defined by indices into the array of vertex coordinates `X`. `X` is an `mpts`-by-`ndim` matrix where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, where $2 \le$ `ndim` ≤ 3.

Examples

Load a 3-D tetrahedral triangulation compute the free boundary. First, load triangulation `tet` and vertex coordinates `X`.

```
load tetmesh
```

Create the triangulation representation and compute the free boundary.

```
trep = TriRep(tet, X);
[tri, Xb] = freeBoundary(trep);
```

See Also

scatteredInterpolant | delaunayTriangulation

Purpose

(Will be removed) Interpolate scattered data

Note `TriScatteredInterp` will be removed in a future release. Use `scatteredInterpolant` instead.

Description

`TriScatteredInterp` is used to perform interpolation on a scattered dataset that resides in 2-D or 3-D space. A scattered data set defined by locations `X` and corresponding values `V` can be interpolated using a Delaunay triangulation of `X`. This produces a surface of the form `V = F(X)`. The surface can be evaluated at any query location `QX`, using `QV = F(QX)`, where `QX` lies within the convex hull of `X`. The interpolant `F` always goes through the data points specified by the sample.

Definitions

The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set. The *convex hull* of a set of points is the smallest convex set containing all points of the original set. These definitions extend naturally to higher dimensions.

Construction

TriScatteredInterp	(Will be removed) Interpolate scattered data

Properties

`X`	Defines locations of scattered data points in 2-D or 3-D space.
`V`	Defines value associated with each data point.

<table>
<tr><td rowspan="4">Method</td><td colspan="2">Defines method used to interpolate the data .</td></tr>
<tr><td>natural</td><td>Natural neighbor interpolation</td></tr>
<tr><td>linear</td><td>Linear interpolation (default)</td></tr>
<tr><td>nearest</td><td>Nearest neighbor interpolation</td></tr>
</table>

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

Examples

Create a data set:

```
x = rand(100,1)*4-2;
y = rand(100,1)*4-2;
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz:

```
ti = -2:.25:2;
[qx,qy] = meshgrid(ti,ti);
qz = F(qx,qy);
mesh(qx,qy,qz);
hold on;
plot3(x,y,z,'o');
```

TriScatteredInterp

Purpose

(Will be removed) Interpolate scattered data

Note `TriScatteredInterp` will be removed in a future release. Use `scatteredInterpolant` instead.

Syntax

```
F = TriScatteredInterp()
F = TriScatteredInterp(X, V)
F = TriScatteredInterp(X, Y, V)
F = TriScatteredInterp(X, Y, Z, V)
F = TriScatteredInterp(DT, V)
F = TriScatteredInterp(..., method)
```

Description

`F = TriScatteredInterp()` creates an empty scattered data interpolant. This can subsequently be initialized with sample data points and values (`Xdata`, `Vdata`) via `F.X = Xdata` and `F.V = Vdata`.

`F = TriScatteredInterp(X, V)` creates an interpolant that fits a surface of the form `V = F(X)` to the scattered data in (`X`, `V`). `X` is a matrix of size `mpts`-by-`ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside (`ndim` is 2 or 3). The column vector `V` defines the values at `X`, where the length of `V` equals `mpts`.

`F = TriScatteredInterp(X, Y, V)` and `F = TriScatteredInterp(X, Y, Z, V)` allow the data point locations to be specified in alternative column vector format when working in 2-D and 3-D.

`F = TriScatteredInterp(DT, V)` uses the specified `DelaunayTri` object `DT` as a basis for computing the interpolant. `DT` is a Delaunay triangulation of the scattered data locations, `DT.X`. The matrix `DT.X` is of size `mpts`-by-`ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, `2 <= ndim <= 3`. `V` is a column vector that defines the values at `DT.X`, where the length of `V` equals `mpts`.

`F = TriScatteredInterp(..., method)` allows selection of the technique `method` used to interpolate the data.

Input Arguments

X	Matrix of size mpts-by-ndim, where mpts is the number of points and ndim is the dimension of the space where the points reside. Input may also be specified as column vectors (X, Y) or (X, Y, Z)	
V	Column vector that defines the values at X, where the length of V equals mpts.	
DT	Delaunay triangulation of the scattered data locations	
method	natural	Natural neighbor interpolation
	linear	Linear interpolation (default)
	nearest	Nearest-neighbor interpolation

Output Arguments

F	Creates an interpolant that fits a surface of the form V = F(X) to the scattered data.

Evaluation

To evaluate the interpolant, express the statement in Monge's form Vq = F(Xq), Vq = F(Xq,Yq), or Vq = F(Xq,Yq,Zq) where Vq is the value of the interpolant at the query location and Xq, Yq, and Zq are the vectors of point locations.

Definitions

The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set.

Examples

Create a data set:

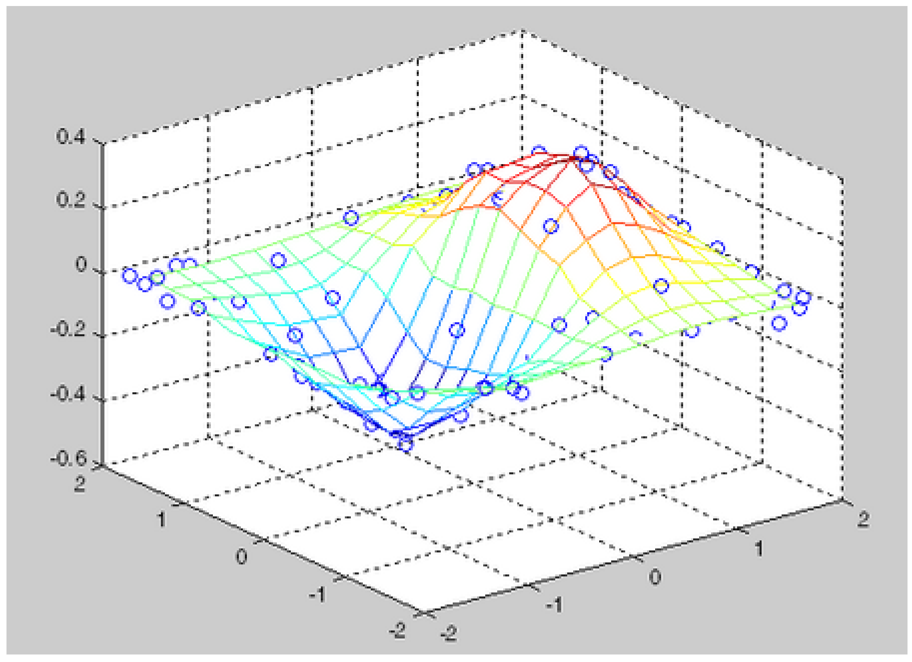
```
x = rand(100,1)*4-2;
y = rand(100,1)*4-2;
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz .

```
ti = -2:.25:2;
[qx,qy] = meshgrid(ti,ti);
qz = F(qx,qy);
mesh(qx,qy,qz);
hold on;
plot3(x,y,z,'o');
```



See Also

delaunayTriangulation | interp1 | interp2 | interp3 | meshgrid

Purpose

Triangular surface plot

Syntax

```
trisurf(Tri,X,Y,Z,C)
trisurf(Tri,X,Y,Z)
trisurf(TR)
trisurf(...'PropertyName',PropertyValue...)
h = trisurf(...)
```

Description

`trisurf(Tri,X,Y,Z,C)` displays triangles defined in the *m*-by-3 face matrix `Tri` as a surface. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the `X`, `Y`, and `Z` vertices. The color is defined by the vector `C`.

`trisurf(Tri,X,Y,Z)` uses `C=Z` so color is proportional to surface height.

`trisurf(TR)` displays the triangles in a triangulation representation. It uses `C = TR.Points(:,3)` to make the the surface color is proportional to height.

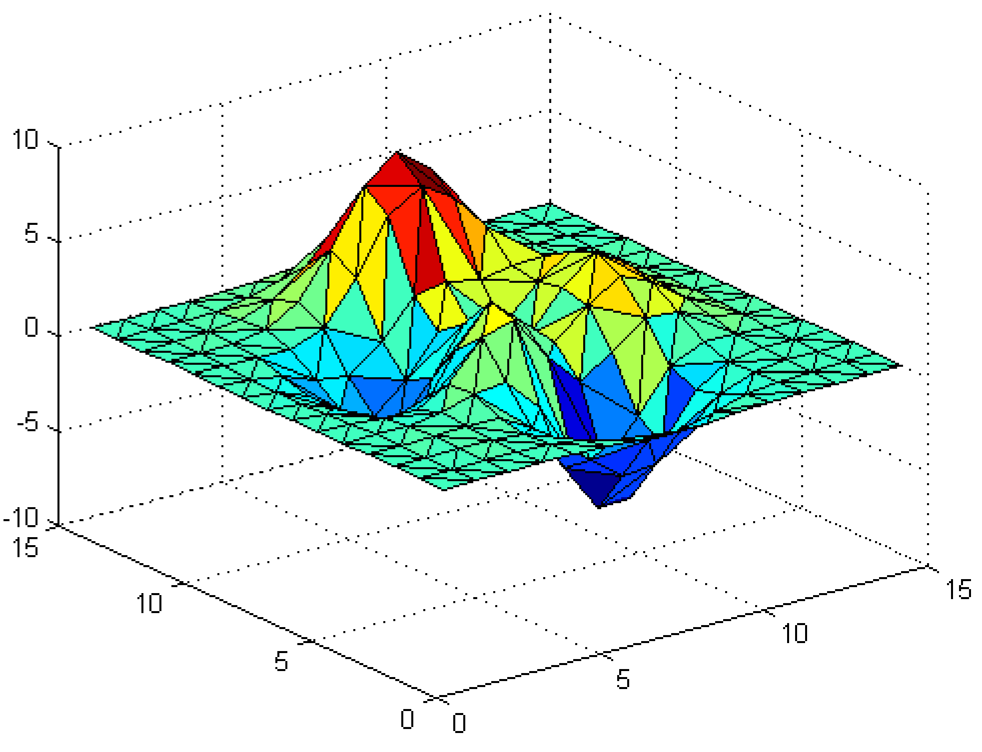
`trisurf(...'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trisurf(...)` returns a patch handle.

Examples

Create vertex vectors and a face matrix, then create a triangular surface plot.

```
[x,y] = meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trisurf(tri,x,y,z)
```



If the surface is in the form of a triangulation representation, you can pass it to `trisurf` alone:

```
tr = triangulation(tri,x(:),y(:),z(:));
trisurf(tr)
```

See Also

`patch` | `surf` | `tetramesh` | `trimesh` | `triplot` | `delaunay` | `triangulation` | `delaunayTriangulation`

Purpose

Upper triangular part of matrix

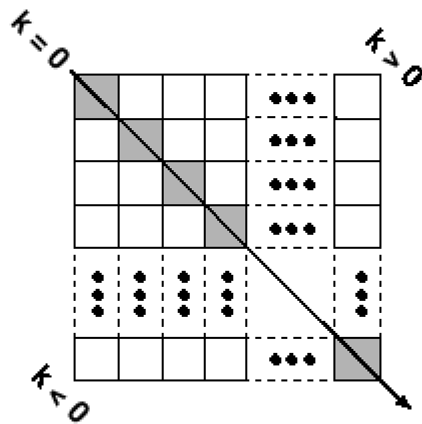
Syntax

```
U = triu(X)
U = triu(X,k)
```

Description

`U = triu(X)` returns the upper triangular part of `X`.

`U = triu(X,k)` returns the element on and above the kth diagonal of `X`. `k = 0` is the main diagonal, `k > 0` is above the main diagonal, and `k < 0` is below the main diagonal.



Examples

```
triu(ones(4,4),-1)

ans =

     1     1     1     1
     1     1     1     1
     0     1     1     1
     0     0     1     1
```

See Also

`diag` | `tril`

true

Purpose

Logical 1 (true)

Syntax

```
true
true(n)
true(m, n)
true(m, n, p, ...)
true(size(A))
true(...,'like',p)
```

Description

`true` is shorthand for `logical(1)`.

`true(n)` is an `n`-by-`n` matrix of logical ones.

`true(m, n)` or `true([m, n])` is an `m`-by-`n` matrix of logical ones.

`true(m, n, p, ...)` or `true([m n p ...])` is an `m`-by-`n`-by-`p`-by-`...` array of logical ones.

Note The size inputs `m`, `n`, `p`, `...` should be nonnegative integers. Negative integers are treated as 0.

`true(size(A))` is an array of logical ones that is the same size as array `A`.

`true(...,'like',p)` is an array of logical ones of the same data type and sparsity as the logical array `p`.

Tips

`true(n)` is much faster and more memory efficient than `logical(ones(n))`.

See Also

`false` | `logical`

Purpose

Execute statements and catch resulting errors

Syntax

```
try
   statements
catch exception
   statements
end
```

Description

`try` and `catch` blocks allow you to override the default error behavior for a set of program statements. If any statement in a `try` block generates an error, program control goes immediately to the `catch` block, which contains your error handling statements.

`exception` is an optional `MException` object input to the `catch` block that allows you to identify the error.

Both `try` and `catch` blocks can contain nested `try/catch` statements.

Examples

Provide more information about a dimension mismatch error:

```
A = rand(3);
B = ones(5);

try
   C = [A; B];
catch err

   % Give more information for mismatch.
   if (strcmp(err.identifier,'MATLAB:catenate:dimensionMismatch'))

      msg = sprintf('%s', ...
           'Dimension mismatch occured: First argument has ', ...
            num2str(size(A,2)), ' columns while second has ', ...
            num2str(size(B,2)), ' columns.');
      error('MATLAB:myCode:dimensions', msg);

   % Display any other errors as usual.
   else
```

```
      rethrow(err);
   end

end  % end try/catch
```

Catch an error when reading an image file, and try adjusting the file extension to resolve the error (`.jpg` and `.jpeg` are similar, as are `.tif` and `.tiff`):

```
function imageData = readImage(filename)
try
   imageData = imread(filename);
catch exception

   % Is the error because MATLAB could not find the file?
   if ~exist(filename, 'file')

      % Check for common typos in the extension.
      [~, ~, extension] = fileparts(filename);
      switch extension
         case '.jpg'
            altFilename = strrep(filename, '.jpg', '.jpeg');
         case '.jpeg'
            altFilename = strrep(filename, '.jpeg', '.jpg');
         case '.tif'
            altFilename = strrep(filename, '.tif', '.tiff');
         case '.tiff'
            altFilename = strrep(filename, '.tiff', '.tif');
         otherwise
            rethrow(exception);
      end

      % Try again, with modifed filename.
      try
         imageData = imread(altFilename);
      catch exception2
```

```
            % Rethrow original error.
            rethrow(exception)
        end

    else
        rethrow(exception)
    end

end
```

See Also

error | assert | MException

tscollection

Purpose

Create `tscollection` object

Syntax

```
tsc = tscollection(TimeSeries)
tsc = tscollection(Time)
tsc = tscollection(...,'Parameter',Value,...)
```

Description

`tsc = tscollection(TimeSeries)` creates a `tscollection` object `tsc` with one or more `timeseries` objects already in the MATLAB workspace. The argument `TimeSeries` can be a

- Single `timeseries` object
- Cell array of `timeseries` objects

`tsc = tscollection(Time)` creates an empty `tscollection` object with the time vector `Time`. When time values are date strings, you must specify `Time` as a cell array of date strings.

`tsc = tscollection(...,'Parameter',Value,...)` creates a `tscollection` object with optional parameter-value pairs you enter after specifying either a time vector or a `timeseries` object. You can specify the following parameter:

- `Name` — String that specifies the name of this `tscollection` object

Tips

Definition: Time Series Collection

A time series collection object is a MATLAB variable that groups several time series with a common time vector. The time series that you include in the collection are called members of this collection.

Properties of Time Series Collection Objects

This table lists the properties of the `tscollection` object. You can specify the `Time`, `TimeSeries`, and `Name` properties as input arguments in the constructor.

Property	Description
Name	`tscollection` name as a string. This can differ from the `tscollection` name in the MATLAB workspace.
Time	When `TimeInfo.StartDate` is empty, values are measured relative to `0` . When `TimeInfo.StartDate` is defined, values represent date strings measured relative to the `StartDate`. The length of `Time` must be the same as the first or the last dimension of `Data` for each collection .
TimeInfo	Contains fields for contextual information about `Time`: • `Units` — Time units with any of the following values: `'weeks'`, `'days'`, `'hours'`, `'minutes'`, `'seconds'`, `'milliseconds'`, `'microseconds'`, `'nanoseconds'` • `Start` — Start time • `End` — End time (read only) • `Increment` — Interval between subsequent time values. `NaN` when times are not uniformly sampled. • `Length` — Length of the time vector (read only) • `Format` — String defining the date string display format. See `datestr`. • `StartDate` — Date string defining the reference date. See `setabstime (tscollection)`. • `UserData` — Any additional user-defined information

Examples

The following example shows how to create a `tscollection` object.

1 Import the sample data.

```
load count.dat
```

2 Create three `timeseries` objects to store each set of data:

```
count1 = timeseries(count(:,1),1:24,'name', 'ts1');
count2 = timeseries(count(:,2),1:24,'name', 'ts2');
count3 = timeseries(count(:,3),1:24,'name', 'ts3');
```

3 Create a `tscollection` object named `tsc` and add to it two out of three time series already in the MATLAB workspace, by using the following syntax:

```
tsc = tscollection({count1 count2},'name','tsc')
```

See Also

`addts` | `datestr` | `setabstime (tscollection)` | `timeseries`

Purpose

Construct event object for `timeseries` object

Syntax

```
e = tsdata.event(Name,Time)
e = tsdata.event(Name,Time,'Datenum')
```

Description

`e = tsdata.event(Name,Time)` creates an event object with the specified Name that occurs at the time Time. Time can either be a real value or a date string.

`e = tsdata.event(Name,Time,'Datenum')` uses `'Datenum'` to indicate that the `Time` value is a serial date number generated by the `datenum` function. The `Time` value is converted to a date string after the event is created.

Tips

You add events by using the `addevent` method.

Fields of the `tsdata.event` object include the following:

- `EventData` — MATLAB array that stores any user-defined information about the event
- `Name` — String that specifies the name of the event
- `Time` — Time value when this event occurs, specified as a real number
- `Units` — Time units
- `StartDate` — A reference date, specified in MATLAB `datestr` format. `StartDate` is empty when you have a numerical (non-date-string) time vector.

tsearchn

Purpose

N-D closest simplex search

Syntax

```
t = tsearchn(X,TRI,XI)
[t,P] = tsearchn(X,TRI,XI)
```

Description

`t = tsearchn(X,TRI,XI)` returns the indices `t` of the enclosing simplex of the Delaunay triangulation `TRI` for each point in `XI`. `X` is an `m`-by-`n` matrix, representing `m` points in N-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in N-dimensional space. `tsearchn` returns `NaN` for all points outside the convex hull of `X`. `tsearchn` requires a triangulation `TRI` of the points `X` obtained from `delaunayn`.

`[t,P] = tsearchn(X,TRI,XI)` also returns the barycentric coordinate `P` of `XI` in the simplex `TRI`. `P` is a `p`-by-`n+1` matrix. Each row of `P` is the barycentric coordinate of the corresponding point in `XI`. It is useful for interpolation.

`delaunayTriangulation`

Purpose

Open Time Series Tools GUI

Syntax

```
tstool
tstool(ts)
tstool(tsc)
```

Note `tstool(sldata)` and `tstool(ModelDataLogs,'replace')` have been removed. To view logged signal data, use the Simulink Simulation Data Inspector instead.

Description

`tstool` starts the Time Series Tools GUI without loading any data.

`tstool(ts)` starts the Time Series Tools GUI and loads the time-series object `ts` from the MATLAB workspace.

`tstool(tsc)` starts the Time Series Tools GUI and loads the time-series collection object `tsc` from the MATLAB workspace.

`timeseries` | `tscollection`

How To

- "View Logged Signal Data with the Simulation Data Inspector"

type

Purpose

Display contents of file

Syntax

```
type('filename')
type filename
```

Description

`type('filename')` displays the contents of the specified file in the MATLAB Command Window. Use the full path for `filename`, or use a MATLAB relative partial path.

If you do not specify a file extension and there is no `filename` file without an extension, the `type` function adds the `.m` extension by default. The `type` function checks the folders specified in the MATLAB search path, which makes it convenient for listing the contents of files on the screen. Use `type` with `more on` to see the listing one screen at a time.

`type filename` is the command form of the syntax.

Examples

`type('foo.bar')` lists the contents of the file `foo.bar`.

`type foo` lists the contents of the file `foo.` If `foo` does not exist, `type foo` lists the contents of the file `foo.m`.

`cd` | `dbtype` | `delete` | `dir` | `more` | `path` | `what` | `who`

Purpose

Convert data types without changing underlying data

Syntax

```
Y = typecast(X, type)
```

Description

`Y = typecast(X, type)` converts a numeric value in `X` to the data type specified by `type`. Input `X` must be a full, noncomplex, numeric scalar or vector. The `type` input is a string set to one of the following: `'uint8'`, `'int8'`, `'uint16'`, `'int16'`, `'uint32'`, `'int32'`, `'uint64'`, `'int64'`, `'single'`, or `'double'`.

`typecast` is different from the MATLAB `cast` function in that it does not alter the input data. `typecast` always returns the same number of bytes in the output `Y` as were in the input `X`. For example, casting the 16-bit integer 1000 to `uint8` with `typecast` returns the full 16 bits in two 8-bit segments (3 and 232) thus keeping its original value (3*256 + 232 = 1000). The `cast` function, on the other hand, truncates the input value to 255.

The output of `typecast` can be formatted differently depending on what system you use it on. Some computer systems store data starting with its most significant byte (an ordering called *big-endian*), while others start with the least significant byte (called *little-endian*).

Note MATLAB issues an error if `X` contains fewer values than are needed to make an output value.

Examples

Example 1

This example converts between data types of the same size:

```
typecast(uint8(255), 'int8')
ans =
   -1

typecast(int16(-1), 'uint16')
ans =
```

```
65535
```

Example 2

Set X to a 1-by-3 vector of 32-bit integers, then cast it to an 8-bit integer type:

```
X = uint32([1 255 256])
X =
           1          255          256
```

Running this on a little-endian system produces the following results. Each 32-bit value is divided up into four 8-bit segments:

```
Y = typecast(X, 'uint8')
Y =
   1   0   0   0  255   0   0   0   0   1   0   0
```

The third element of `X`, 256, exceeds the 8 bits that it is being converted to in `Y`(9) and thus overflows to `Y`(10):

```
Y(9:12)
ans =
    0    1    0    0
```

Note that `length(Y)` is equal to `4.*length(X)`. Also note the difference between the output of `typecast` versus that of `cast`:

```
Z = cast(X, 'uint8')
Z =
    1  255  255
```

Example 3

This example casts a smaller data type (`uint8`) into a larger one (`uint16`). Displaying the numbers in hexadecimal format makes it easier to see just how the data is being rearranged:

```
format hex
X = uint8([44 55 66 77])
X =
```

```
   2c   37   42   4d
```

The first `typecast` is done on a big-endian system. The four 8-bit segments of the input data are combined to produce two 16-bit segments:

```
Y = typecast(X, 'uint16')
Y =
   2c37   424d
```

The second is done on a little-endian system. Note the difference in byte ordering:

```
Y = typecast(X, 'uint16')
Y =
   372c   4d42
```

You can format the little-endian output into big-endian (and vice versa) using the `swapbytes` function:

```
Y = swapbytes(typecast(X, 'uint16'))
Y =
   2c37   424d
```

Example 4

This example attempts to make a 32-bit value from a vector of three 8-bit values. MATLAB issues an error because there are an insufficient number of bytes in the input:

```
format hex
typecast(uint8([120 86 52]), 'uint32')

Error using typecast
Too few input values to make output type.
```

Repeat the example, but with a vector of four 8-bit values, and it returns the expected answer:

```
typecast(uint8([120 86 52 18]), 'uint32')
ans =
```

```
12345678
```

cast | class | swapbytes

Purpose

Create container object to exclusively manage radio buttons and toggle buttons

Syntax

```
uibuttongroup('PropertyName1',Value1,'PropertyName2',Value2,
   ...)
handle = uibuttongroup(...)
```

Description

A uibuttongroup groups components and manages exclusive selection behavior for radio buttons and toggle buttons that it contains. It can also contain other user interface controls, axes, uipanels, and uibuttongroups. It cannot contain ActiveX controls.

`uibuttongroup('PropertyName1',Value1,'PropertyName2',Value2,...)` creates a visible container component in the current figure window. This component manages exclusive selection behavior for uicontrols of style `radiobutton` and `togglebutton`.

`handle = uibuttongroup(...)` creates a uibuttongroup object and returns a handle to it in `handle`.

A `uibuttongroup` object can have `axes`, `uicontrol`, `uipanel`, and `uibuttongroup` objects as children. However, only uicontrols of style `radiobutton` and `togglebutton` are managed by the component.

When programming a button group, you do not code callbacks for the individual buttons; instead, use its `SelectionChangeFcn` callback to manage responses to selections. The following example illustrates how you use `uibuttongroup` event data to do this.

For the children of a `uibuttongroup` object, the `Position` property is interpreted relative to the button group. If you move the button group, the children automatically move with it and maintain their positions in the button group.

If you have a button group that contains a set of radio buttons and toggle buttons and you want:

- An immediate action to occur when a radio button or toggle button is selected, you must include the code to control the radio and toggle buttons in the button group's `SelectionChangeFcn` callback function,

not in the individual toggle button `Callback` functions. See the `SelectionChangeFcn` property and the example on this reference page for more information.

- Another component such as a push button to base its action on the selection, then that component's `Callback` callback can get the handle of the selected radio button or toggle button from the button group's `SelectedObject` property.

Use the `Parent` property to specify the parent as a figure, uipanel, or uibuttongroup. If you do not specify a parent, `uibuttongroup` adds the button group to the current figure. If no figure exists, one is created.

See the Uibuttongroup Properties reference page for more information.

After creating a uibuttongroup, you can set and query its property values using `set` and `get`. Run `get(handle)` to see a list of properties and their current values. Run `set(handle)` to see a list of object properties you can set and their legal values.

Tips

If you set the `Visible` property of a `uibuttongroup` object to `'off'`, any child objects it contains (buttons, button groups, etc.) become invisible along with the `uibuttongroup` panel itself. However, doing this does *not* affect the settings of the `Visible` property of any of its child objects, even though all of them remain invisible until the button group's visibility is set to `'on'`. `uipanel` components also behave in this manner.

Do not use the `CreateFcn` of a button group to create the buttons it contains. You can toggle buttons created in the button group `CreateFcn` on and off, but clicking them does not trigger the button group `SelectionChangeCallback` and the buttons do not display the expected mutually-exclusive behavior.

Examples

This example creates a uibuttongroup with three radio buttons. It manages the radio buttons with the `SelectionChangeFcn` callback, `selcbk`.

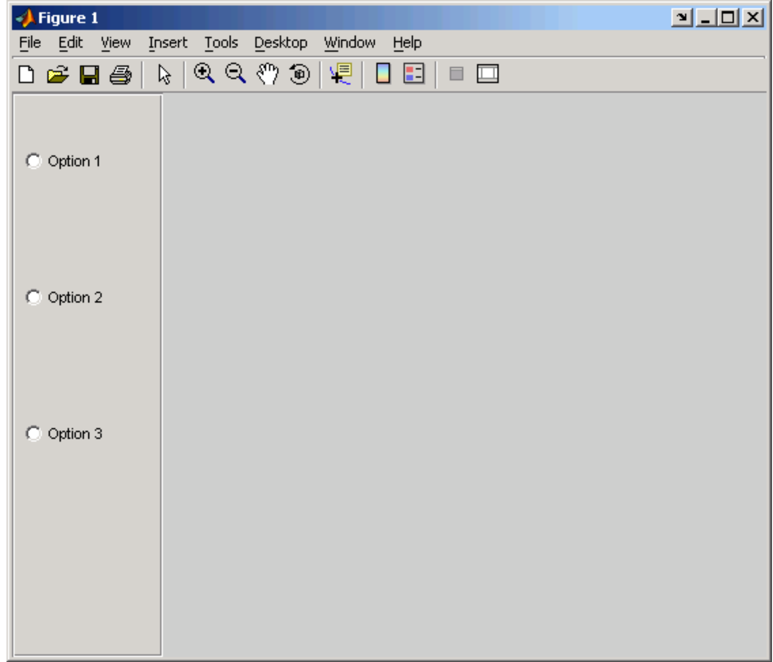
When you select a new radio button, `selcbk` displays the uibuttongroup handle on one line, the `EventName`, `OldValue`, and `NewValue` fields

of the event data structure on a second line, and the value of the `SelectedObject` property on a third line.

```
% Create the button group.
h = uibuttongroup('visible','off','Position',[0 0 .2 1]);
% Create three radio buttons in the button group.
u0 = uicontrol('Style','radiobutton','String','Option 1',...
    'pos',[10 350 100 30],'parent',h,'HandleVisibility','off');
u1 = uicontrol('Style','radiobutton','String','Option 2',...
    'pos',[10 250 100 30],'parent',h,'HandleVisibility','off');
u2 = uicontrol('Style','radiobutton','String','Option 3',...
    'pos',[10 150 100 30],'parent',h,'HandleVisibility','off');
% Initialize some button group properties.
set(h,'SelectionChangeFcn',@selcbk);
set(h,'SelectedObject',[]);  % No selection
set(h,'Visible','on');
```

For the `SelectionChangeFcn` callback, `selcbk`, the source and event data structure arguments are available only if `selcbk` is called using a function handle. See `SelectionChangeFcn` for more information.

```
function selcbk(source,eventdata)
disp(source);
disp([eventdata.EventName,'  ',...
     get(eventdata.OldValue,'String'),'  ', ...
     get(eventdata.NewValue,'String')]);
disp(get(get(source,'SelectedObject'),'String'));
```



If you click `Option 2` with no option selected, the `SelectionChangeFcn` callback, `selcbk`, displays:

```
    3.0011

SelectionChanged    Option 2
Option 2
```

If you then click `Option 1`, the `SelectionChangeFcn` callback, `selcbk`, displays:

```
    3.0011

SelectionChanged  Option 2  Option 1
Option 1
```

Uibuttongroup Properties

Purpose

Describe button group properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

Uibuttongroup takes its default property values from uipanel. To set a uibuttongroup default property value, set the default for the corresponding `uipanel` property. Note that you can set no default values for the uibuttongroup `SelectedObject` and `SelectionChangeFcn` properties.

For more information about changing the default value of a property see "Setting Default Property Values". For an example, see the `CreateFcn` property.

Uibuttongroup Properties

This section describes all properties useful to `uibuttongroup` objects and lists valid values. Curly braces { } enclose default values.

Property Name	Description
`BackgroundColor`	Color of the button group background
`BeingDeleted`	This object is being deleted
`BorderType`	Type of border around the button group
`BorderWidth`	Width of the button group border in pixels
`BusyAction`	Interruption of other callback routines
`ButtonDownFcn`	Button-press callback routine
`Children`	All children of the button group

Property Name	Description
`Clipping`	Clipping of child axes, panels, and button groups to the button group. Does not affect child user interface controls (`uicontrol`)
`CreateFcn`	Callback routine executed during object creation
`DeleteFcn`	Callback routine executed during object deletion
`FontAngle`	Title font angle
`FontName`	Title font name
`FontSize`	Title font size
`FontUnits`	Title font units
`FontWeight`	Title font weight
`ForegroundColor`	Title font color and color of 2-D border line
`HandleVisibility`	Handle accessibility from command line and GUIs
`HighlightColor`	3-D frame highlight color
`Interruptible`	Callback routine interruption mode
`Parent`	`uibuttongroup` object's parent
`Position`	Button group position relative to parent figure, panel, or button group
`ResizeFcn`	User-specified resize routine
`Selected`	Whether object is selected
`SelectedObject`	Currently selected uicontrol of style `radiobutton` or `togglebutton`
`SelectionChangeFcn`	Callback routine executed when the selected radio button or toggle button changes
`SelectionHighlight`	Object highlighted when selected

Property Name	Description
ShadowColor	3-D frame shadow color
Tag	User-specified object identifier
Title	Title string
TitlePosition	Location of title string in relation to the button group
Type	Object class
UIContextMenu	Associate context menu with the button group
Units	Units used to interpret the position vector
UserData	User-specified data
Visible	Button group visibility **Note** Controls the visibility of a uibuttongroup and of its child axes, uibuttongroups. uipanels, and child uicontrols. Setting it does not change their `Visible` property.

`BackgroundColor`
: `ColorSpec`

Color of the uibuttongroup background. A three-element RGB vector or one of the MATLAB predefined names, specifying the background color. See the `ColorSpec` reference page for more information on specifying color.

`BeingDeleted`
: `on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called

(see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BorderType`

`none | {etchedin} | etchedout | beveledin | beveledout | line`

Border of the uibuttongroup area. Used to define the button group area graphically. Etched and beveled borders provide a 3-D look. Use the `HighlightColor` and `ShadowColor` properties to specify the border color of etched and beveled borders. A line border is 2-D. Use the `ForegroundColor` property to specify its color.

`BorderWidth`

integer

Width of the button group border. The width of the button group borders in pixels. The default border width is 1 pixel. 3-D borders wider than 3 may not appear correctly at the corners.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`
string or function handle

Button-press callback routine. A callback routine that executes when you press a mouse button while the pointer is in a 5-pixel wide border around the uibuttongroup. This is useful for implementing actions to interactively modify object properties, such as size and position, when they are clicked on (using the `selectmoveresize` function, for example).

If you define this routine as a string, the string can be a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

`Children`
vector of handles

Children of the uibuttongroup. A vector containing the handles of all children of the uibuttongroup. Although a uibuttongroup manages only uicontrols of style `radiobutton` and `togglebutton`, its children can be axes, uipanels, uibuttongroups, and other uicontrols. You can use this property to reorder the children.

`Clipping`
`{on} | off`

Clipping mode. By default, MATLAB clips a uibuttongroup's child axes, uipanels, and uibuttongroups to the uibuttongroup rectangle. If you set `Clipping` to `off`, the axis, uipanel, or

uibuttongroup is displayed outside the button group rectangle. This property does not affect child uicontrols which, by default, can display outside the button group rectangle.

`CreateFcn`

string or function handle

Callback routine executed during object creation. The specified function executes when MATLAB creates a `uibuttongroup` object. MATLAB sets all property values for the uibuttongroup before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uibuttongroup being created.

Setting this property on an existing uibuttongroup object has no effect.

To define a default `CreateFcn` callback for all new uibuttongroups you must define the same default for all uipanels. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uibuttongroup`. For example, the code

```
set(0,'DefaultUipanelCreateFcn','set(gcbo,...
    ''FontName'',''arial'',''FontSize'',12)')
```

creates a default `CreateFcn` callback that runs whenever you create a new panel or button group. It sets the default font name and font size of the uipanel or uibuttongroup title.

To override this default and create a button group whose `FontName` and `FontSize` properties are set to different values, call `uibuttongroup` with code similar to

```
hpt = uibuttongroup(...,'CreateFcn','set(gcbo,...
''FontName'',''times'',''FontSize'',14)')
```

Note To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uibuttongroup` call. In the example above, if instead of redefining the `CreateFcn` property for this uibuttongroup, you had explicitly set `FontSize` to `14`, the default `CreateFcn` callback would have set `FontSize` back to the system dependent default.

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`DeleteFcn`

string or function handle

Callback routine executed during object deletion. A callback routine that executes when you delete the `uibuttongroup` object (e.g., when you issue a delete command or clear the figure containing the uibuttongroup). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine. The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

`FontAngle`

`{normal} | italic | oblique`

Character slant used in the Title. MATLAB uses this property to select a font from those available on your particular system.

Setting this property to `italic` or `oblique` selects a slanted version of the font, when it is available on your system.

`FontName`
string

Font family used in the Title. The name of the font in which to display the `Title`. To display and print properly, this must be a font that your system supports. The default font is system dependent. To eliminate the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan), set `FontName` to the string `FixedWidth`. This string value is case insensitive.

```
set(uicontrol_handle,'FontName','FixedWidth')
```

This then uses the value of the root `FixedWidthFontName` property, which can be set to the appropriate value for a locale from `startup.m` in the end user's environment. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

`FontSize`
integer

Title font size. A number specifying the size of the font in which to display the `Title`, in units determined by the `FontUnits` property. The default size is system dependent.

`FontUnits`
`inches | centimeters | normalized |`
`{points} |pixels`

Title font size units. `Normalized` units interpret `FontSize` as a fraction of the height of the uibuttongroup. When you resize the uibuttongroup, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

`FontWeight`
: `light | {normal} | demi | bold`

Weight of characters in the title. MATLAB uses this property to select a font from those available on your particular system. Setting this property to bold causes MATLAB to use a bold version of the font, when it is available on your system.

`ForegroundColor`
: `ColorSpec`

Color used for title font and 2-D border line. A three-element RGB vector or one of the MATLAB predefined names, specifying the font or line color. See the `ColorSpec` reference page for more information on specifying color.

`HandleVisibility`
: `{on} | callback | off`

Control access to object's handle. This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

Note Uicontrols of style `radiobutton` and `togglebutton` that are managed by a uibuttongroup should not be accessed outside the button group. Set the `HandleVisibility` of such radio buttons and toggle buttons to `off` or `callback` to prevent inadvertent access.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HighlightColor`
`ColorSpec`

3-D frame highlight color. A three-element RGB vector or one of the MATLAB predefined names, specifying the highlight color. See the `ColorSpec` reference page for more information on specifying color.

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

Note If the interrupting callback is a `DeleteFcn`nor `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

`Parent`
handle

Uibuttongroup parent. The handle of the uibuttongroup's parent figure, uipanel, or uibuttongroup. You can move a uibuttongroup object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

`Position`
position rectangle

Size and location of uibuttongroup relative to parent. The rectangle defined by this property specifies the size and location of the button group within the parent figure window, uipanel, or uibuttongroup. Specify `Position` as

```
[left bottom width height]
```

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the `uibuttongroup` object. `width` and `height` are the dimensions of the uibuttongroup rectangle, including the title. All measurements are in units specified by the `Units` property.

`ResizeFcn`
string or function handle

Resize callback routine. MATLAB executes this callback routine whenever a user resizes the uibuttongroup and the figure `Resize` property is set to `on`, or in GUIDE, the **Resize behavior** option is set to `Other`. You can query the uibuttongroup `Position` property to determine its new size and position. During execution of the callback routine, the handle to the figure being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

You can use `ResizeFcn` to maintain a GUI layout that is not directly supported by the MATLAB `Position`/`Units` paradigm.

For example, consider a GUI layout that maintains an object at a constant height in pixels and attached to the top of the figure, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the uicontrol whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the uicontrol handle, and the `gcbo` function to retrieve the figure handle. Also note the defensive programming regarding figure `Units`, which the callback requires to be in pixels in order to work

correctly, but which the callback also restores to their previous value afterwards.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

You can change the figure `Position` from within the `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

Note that the `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is set to `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`Selected`
`on | off` (read only)

Is object selected? This property indicates whether the button group is selected. When this property is `on`, MATLAB displays selection handles if the `SelectionHighlight` property is also `on`. You can, for example, define the `ButtonDownFcn` function to set this property, allowing users to select the object with the mouse.

`SelectedObject`
scalar handle

Currently selected radio button or toggle button uicontrol in the managed group of components. Use this property to determine the currently selected component or to initialize selection of one of

the radio buttons or toggle buttons. By default, `SelectedObject` is set to the first uicontrol radio button or toggle button that is added. Set it to `[]` if you want no selection. Note that `SelectionChangeFcn` does not execute when this property is set by the user.

`SelectionChangeFcn`
string or function handle

Callback routine executed when the selected radio button or toggle button changes. If this routine is called as a function handle, `uibuttongroup` passes it two arguments. The first argument, `source`, is the handle of the uibuttongroup. The second argument, `eventdata`, is an event data structure that contains the fields shown in the following table.

Event Data Structure Field	Description
`EventName`	`'SelectionChanged'`
`OldValue`	Handle of the object selected before this event. `[]` if none was selected.
`NewValue`	Handle of the currently selected object.

If you have a button group that contains a set of radio buttons and/or toggle buttons and you want an immediate action to occur when a radio button or toggle button is selected, you must include the code to control the radio and toggle buttons in the button group's `SelectionChangeFcn` callback function, not in the individual toggle button `Callback` functions.

If you want another component such as a push button to base its action on the selection, then that component's `Callback` callback can get the handle of the selected radio button or toggle button from the button group's `SelectedObject` property.

Note For GUIDE GUIs, `hObject` contains the handle of the selected radio button or toggle button. See "Add Code for Components in Callbacks" for more information.

`SelectionHighlight`
`{on} | off`

Object highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`ShadowColor`
`ColorSpec`

3-D frame shadow color. `ShadowColor` is a three-element RGB vector or one of the MATLAB predefined names, specifying the shadow color. See the `ColorSpec` reference page for more information on specifying color.

`Tag`
string

User-specified object identifier. The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the `Tag` value `'FormatTb'`.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

Uibuttongroup Properties

`Title`
string

Title string. The text displayed in the button group title. You can position the title using the `TitlePosition` property.

If the string value is specified as a cell array of strings or padded string matrix, only the first string in the cell array or padded string matrix is displayed; the rest are ignored. Vertical slash ('`|`') characters are not interpreted as line breaks and instead show up in the text displayed in the uibuttongroup title.

Setting a property value to `default`, `remove`, or `factory` produces the effect described in "Defining Default Values". To set `Title` to one of these words, you must precede the word with the backslash character. For example,

```
hp = uibuttongroup(...,'Title','\Default');
```

`TitlePosition`
`{lefttop} | centertop | righttop |`
`leftbottom | centerbottom | rightbottom`

Location ofthe title. This property determines the location of the title string, in relation to the uibuttongroup.

`Type`
`string` (read-only)

Object class. This property identifies the kind of graphics object. For uibuttongroup objects, `Type` is always the string `'uipanel'`, because its default properties derive from uipanels.

`UIContextMenu`
handle

Associate a context menu with a uibuttongroup. Assign this property the handle of a `Uicontextmenu` object. MATLAB displays

the context menu whenever you right-click the `uibuttongroup`. Use the `uicontextmenu` function to create the context menu.

`Units`

`inches | centimeters | {normalized} |`
`points | pixels | characters`

Units of measurement. MATLAB uses these units to interpret the `Position` property. For the button group itself, units are measured from the lower-left corner of its parent figure window, panel, or button group. For children of the button group, they are measured from the lower-left corner of the button group.

- `Normalized` units map the lower-left corner of the button group or figure window to (0,0) and the upper-right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).
- `Character` units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

`UserData`

matrix

User-specified data. Any data you want to associate with the `uibuttongroup` object. MATLAB does not use this data, but you can access it using `set` and `get`.

`Visible`

`{on} | off`

Uibuttongroup visibility. By default, a `uibuttongroup` object is visible. When set to `'off'`, the uibuttongroup is not visible, as are all child objects of the button group. When a button group is hidden in this manner, you can still query and set its properties.

Note The value of a uibuttongroup's `Visible` property determines whether its child components, such as axes, buttons, uipanels, and other uibuttongroups, are visible. However, changing the `Visible` property of a button group does *not* change the settings of the `Visible` property of its child components even though hiding the button group causes them to be hidden.

Purpose

Create context menu

Syntax

```
handle = uicontextmenu('PropertyName',PropertyValue,...)
```

Description

`handle = uicontextmenu('PropertyName',PropertyValue,...)` creates a context menu, which is a menu that appears when the user right-clicks on a graphics object. See Uicontextmenu Properties for more information.

In its initial state, a context menu has no menu items. You create menu items within the context menu using the `uimenu` function. Menu items appear in the order in which the `uimenu` statements appear. You then associate a context menu with an object by specifying the handle of the context menu as the value for its `UIContextMenu` property.

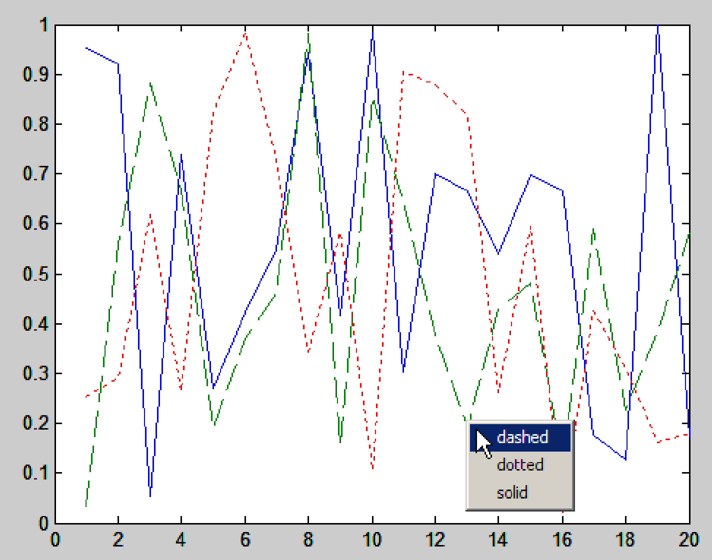
Examples

The following statements define a context menu associated with a line on a graph. The menu items enable you to change the line style.

```
% Create axes and save handle
hax = axes;
% Plot three lines
plot(rand(20,3));
% Define a context menu; it is not attached to anything
hcmenu = uicontextmenu;
% Define callbacks for context menu items that change linestyle
hcb1 = ['set(gco, ''LineStyle'', ''--'')'];
hcb2 = ['set(gco, ''LineStyle'', '':'')'];
hcb3 = ['set(gco, ''LineStyle'', ''-'')'];
% Define the context menu items and install their callbacks
item1 = uimenu(hcmenu, 'Label', 'dashed', 'Callback', hcb1);
item2 = uimenu(hcmenu, 'Label', 'dotted', 'Callback', hcb2);
item3 = uimenu(hcmenu, 'Label', 'solid',  'Callback', hcb3);
% Locate line objects
hlines = findall(hax,'Type','line');
% Attach the context menu to each line
for line = 1:length(hlines)
    set(hlines(line),'uicontextmenu',hcmenu)
```

```
end
```

When you right-click on any line (or, on a Macintosh computer with a one-button mouse, press the **Ctrl** key and click), the context menu appears, as shown in the following figure.



To make context menus available immediately, attach them to lines at the time they are plotted. Therefore, when creating a GUI that uses such context menus, place code like the preceding in the callbacks that perform plotting for the GUI.

A best practice is to use function handles for callbacks. Only define callbacks as strings for simple actions. For example, you can add check marks to menu items (using the `Checked` uimenu property) to indicate the current style for each line. To manage the check marks, define the menu item callbacks as function handles. Place the code for the functions in the GUI code file rather than placing callback strings in the figure.

Generally, you need to attach context menus to lines at the time they are plotted in order to be sure that the menus are immediately available. Therefore, code such as the above could be placed in or called from the callbacks that perform plotting for the GUI.

Uicontextmenu Properties

Purpose

Describe context menu properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

For more information about changing the default value of a property see "Setting Default Property Values". For an example, see the `CreateFcn` property.

Uicontext-menu Properties

This section lists all properties useful to `uicontextmenu` objects along with valid values and descriptions of their use. Curly braces `{}` enclose default values.

Property	Purpose
`BeingDeleted`	This object is being deleted
`BusyAction`	Callback routine interruption
`Callback`	Control action
`Children`	The uimenus defined for the uicontextmenu
`CreateFcn`	Callback routine executed during object creation
`DeleteFcn`	Callback routine executed during object deletion
`HandleVisibility`	Whether handle is accessible from command line and GUIs
`Interruptible`	Callback routine interruption mode
`Parent`	Uicontextmenu object's parent

Property	Purpose
`Position`	Location of uicontextmenu when `Visible` is `on`
`Tag`	User-specified object identifier
`Type`	Class of graphics object
`UserData`	User-specified data
`Visible`	Uicontextmenu visibility

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`Callback`
string

Control action. A routine that executes whenever you right-click an object for which a context menu is defined. The routine executes immediately before the context menu is posted. Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

`Children`
matrix

The uimenu items defined for the uicontextmenu.

`CreateFcn`
string or function handle

Callback routine executed during object creation. The specified function executes when MATLAB creates a `uicontextmenu` object. MATLAB sets all property values for the uicontextmenu before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uicontextmenu being created.

Setting this property on an existing uicontextmenu object has no effect.

You can define a default `CreateFcn` callback for all new uicontextmenus. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uicontextmenu`. For example, the code

```
set(0,'DefaultUicontextmenuCreateFcn','set(gcbo,...
    ''Visible'',''on'')')
```

creates a default `CreateFcn` callback that runs whenever you create a new context menu. It sets the default `Visible` property of a context menu.

To override this default and create a context menu whose `Visible` property is set to a different value, call `uicontextmenu` with code similar to

```
hpt = uicontextmenu(...,'CreateFcn','set(gcbo,...
''Visible'',''off'')')
```

Note To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uicontextmenu` call. In the example above, if instead of redefining the `CreateFcn` property for this uicontextmenu, you had explicitly set `Visible` to `off`, the default `CreateFcn` callback would have set `Visible` back to the default, i.e., `on`.

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

string or function handle

Delete uicontextmenu callback routine. A callback routine that executes when you delete the uicontextmenu object (for example, when you issue a `delete` command or clear the figure containing the uicontextmenu). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle. This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from

command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see “Control Callback Execution and Interruption”.

Note If the interrupting callback is a `DeleteFcn`or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

`Parent`
handle

Uicontextmenu’s parent. The handle of the uicontextmenu’s parent object, which must be a figure.

`Position`
vector

Uicontextmenu’s position. A two-element vector that defines the location of a context menu posted by setting the `Visible` property value to `on`. Specify `Position` as

```
[x y]
```

where vector elements represent the horizontal and vertical distances in pixels from the bottom left corner of the figure window.

`Tag`
string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This

is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

`Type`
string

Class of graphics object. For uicontextmenu objects, `Type` is always the string `'uicontextmenu'`.

`UserData`
matrix

User-specified data. Any data you want to associate with the uicontextmenu object. MATLAB does not use this data, but you can access it using `set` and `get`.

`Visible`
`on | {off}`

Uicontextmenu visibility. The `Visible` property can be used in two ways:

- Its value indicates whether the context menu is currently posted. While the context menu is posted, the property value is `on`; when the context menu is not posted, its value is `off`.
- Its value can be set to `on` to force the posting of the context menu. Similarly, setting the value to `off` forces the context menu to be removed. When used in this way, the `Position` property determines the location of the posted context menu.

`uicontextmenu`

Purpose

Create user interface control object

Syntax

```
handle = uicontrol('Name',Value,...)
handle = uicontrol(parent,'Name',Value,...)
handle = uicontrol
uicontrol(uich)
```

Description

`handle = uicontrol('Name',Value,...)` creates a uicontrol and assigns the specified properties and values to it. It assigns the default values to any properties you do not specify. The default uicontrol style is `pushbutton`. The default parent is the current figure. See the Uicontrol Properties reference page for more information.

`handle = uicontrol(parent,'Name',Value,...)` creates a uicontrol in the object specified by the handle, `parent`. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence. `parent` can be the handle of a figure, uipanel, or uibuttongroup.

`handle = uicontrol` creates a push button in the current figure. The `uicontrol` function assigns all properties their default values.

`uicontrol(uich)` gives focus to the uicontrol specified by the handle, `uich`.

`uicontrol` creates a uicontrol graphics objects (user interface controls), which you use to implement graphical user interfaces.

Specifying the Uicontrol Style

When selected, most uicontrol objects perform a predefined action. To create a specific type of uicontrol, set the `Style` property as one of the strings that follow. You can specify a partial string if it is unique among all the styles. For example, instead of `'radiobutton'`, you can specify `'radio'`.

- `'checkbox'` – A check box generates an action when you select it. Use check boxes to provide a number of independent choices. To activate a check box, click the mouse button on the object. The check box updates its appearance when its state changes.

- `'edit'` – Editable text fields enable you to enter or modify text values. Use editable text when you want free text as input. To enable multiple lines of text, set `Max-Min>1`. Multiline edit boxes provide a vertical scroll bar for scrolling. The arrow keys also provide a way to scroll. Obtain the current text by getting the `String` property. The `String` property does not update as you type in an edit box. To execute the callback routine for an edit text control, type in the desired text and then do one of the following:
  - Click another component, the menu bar, or the background of the GUI.
  - For a single line editable text box, press **Enter**.
  - For a multiline editable text box, press **Ctl+Enter**.
- `'frame'`

  Note MathWorks recommends you use `uipanel` or `uibuttongroup` instead of frames.

  GUIDE continues to support frames in those GUIs that contain them, but the frame component does not appear in the GUIDE Layout Editor component palette.

- `'listbox'` – List boxes display a list of items, from which you can select one or more items. Unlike pop-up menus, list boxes do not expand when clicked. The `Min` and `Max` properties control the selection mode:
  - To enable multiple selection of items, set `Max-Min > 1`.
  - To enable selection of only one item at a time, set `Max-Min <= 1`

  The `Value` property stores the row indexes of currently selected list box items, and is a vector value when you select multiple items. After any mouse button up event that changes the `Value` property, MATLAB evaluates the list box's callback routine. To delay action

when multiple items can be selected, you can associate a "Done" push button with the list box. Use the callback for that button to evaluate the list box `Value` property.

List boxes with the `Enable` property set to `on` differentiate between single and double left clicks. MATLAB sets the figure `SelectionType` property to `normal` or `open` accordingly before evaluating the list box `Callback` property. For enabled list boxes, **Ctrl**-left click and **Shift**-left click also set the figure `SelectionType` property to `normal` or `open`, respectively indicating a single or double click.

- `'popupmenu'` – Pop-up menus (also known as drop-down menus or combo boxes) display a list of choices when you open them with a button-press. When closed, a pop-up menu indicates the current choice. Pop-up menus are useful when you want to provide a number of mutually exclusive choices, but do not want to take up the amount of space that a group of radio buttons requires.
- `'pushbutton'` – Push buttons generate an action when activated. Left-click a push button to activate it. The button appears to depress until you release the mouse button. The callback activates when you release the mouse button while still pointing within the push button.
- `'radiobutton'` – Radio buttons are similar to check boxes, but are intended to be mutually exclusive within a group of related radio buttons. When used this way, you can only select one radio button at any given time). To activate a radio button, click and release the mouse button over it. The easiest way to implement mutually exclusive behavior for a set of radio buttons is to place them within a `uibuttongroup`.
- `'slider'` – Sliders accept numeric input within a specific range when you move the “thumb” button along a bar. The location of the thumb indicates a numeric value, assigned to the `Value` property when you release the mouse button. You can set the minimum, maximum, and current values, and step sizes of a slider.

  Move the thumb by doing any one of the following:

  - Press the mouse button on the thumb, and drag it along the bar.

- Click in the bar or on arrow buttons located at both ends of the bar.
- Click the keyboard arrow keys when the slider is in focus.

- `'text'` – Static text boxes display lines of text. You typically use static text to label other controls, provide information to the user, or indicate values associated with a slider. Users cannot change static text interactively. Static text controls do not activate callback routines when clicked.
- `'togglebutton'` – Toggle buttons are similar in appearance to push buttons, but they visually indicate their state, either `on` (pressed down) or `off` (up). Clicking a toggle button changes its state, and switches its `Value` property between `Min` and `Max`.

Tips

- To simulate activation on static text by a mouse click, set the text *object's* `Enable` property to `Inactive`, and set its `ButtonDownFcn` callback to perform an action. For example, the following code displays 'Pressed' in the Command Window when you click on the`Click me!` text in the running GUI. (Without the `set` command, it would do nothing.)

```
h = uicontrol('Style','text','String','Click Me!');
set(h,'Enable','Inactive','ButtonDownFcn',...
   'disp(''Text was clicked'')')
```

- Adding a uicontrol to a figure removes the figure toolbar when the figure `Toolbar` property is `'auto'` (which is the default). To prevent this from happening, set the `Toolbar` property to `'figure'`. You can restore the toolbar by selecting **Figure Toolbar** from the **View** menu regardless of this property setting.
- The `uicontrol` function accepts property name/property value pairs, structures, and cell arrays as input arguments and optionally returns the handle of the created object. You can also use the `set` and `get` functions to set and query property values after creating the control.
- A `uicontrol` object is a child of a figure, uipanel, or uibuttongroup. Therefore, the uicontrol object does not require an axes to exist when placed in a figure window, uipanel, or uibuttongroup.

- When you pause MATLAB and a uicontrol has focus, pressing a keyboard key does not cause MATLAB to resume. Click anywhere outside a uicontrol and then press any key. For more information, see the `pause` function.

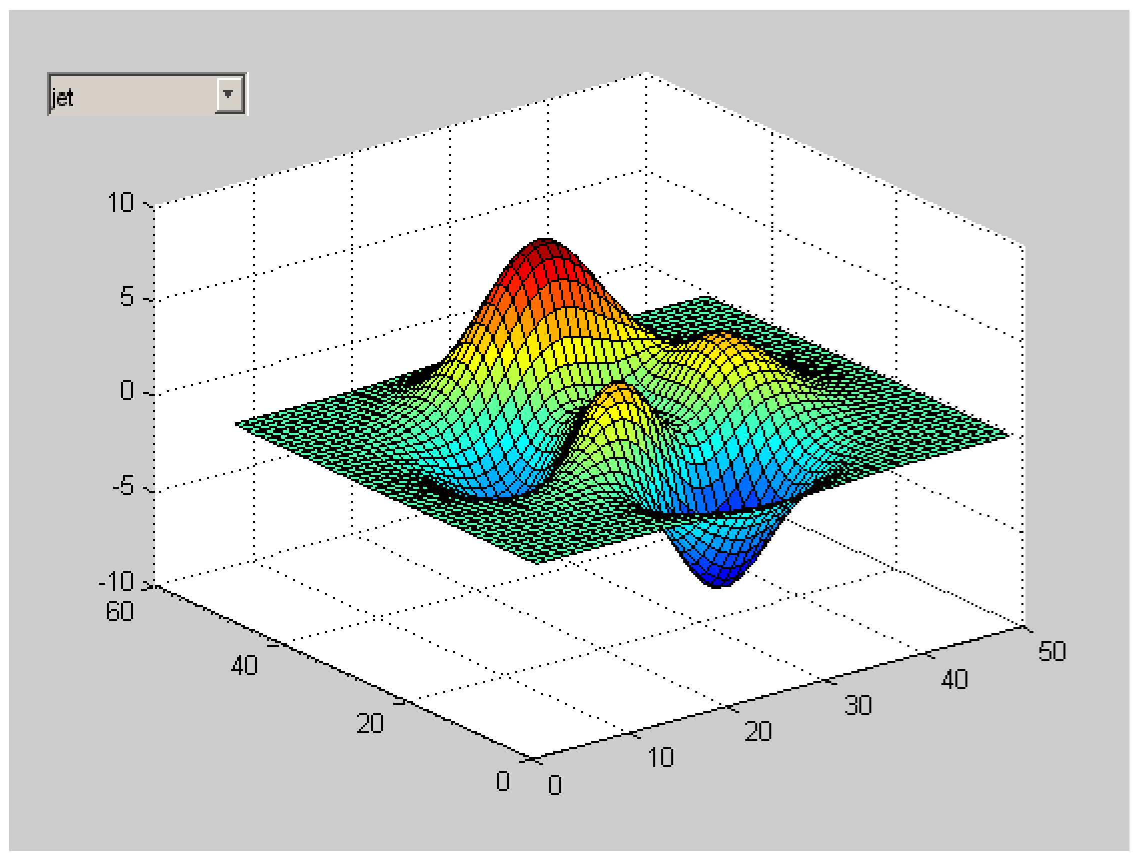
Examples

Create a figure and an axes to contain a 3-D surface plot.

```
figure
hax = axes('Units','pixels');
surf(peaks)
```

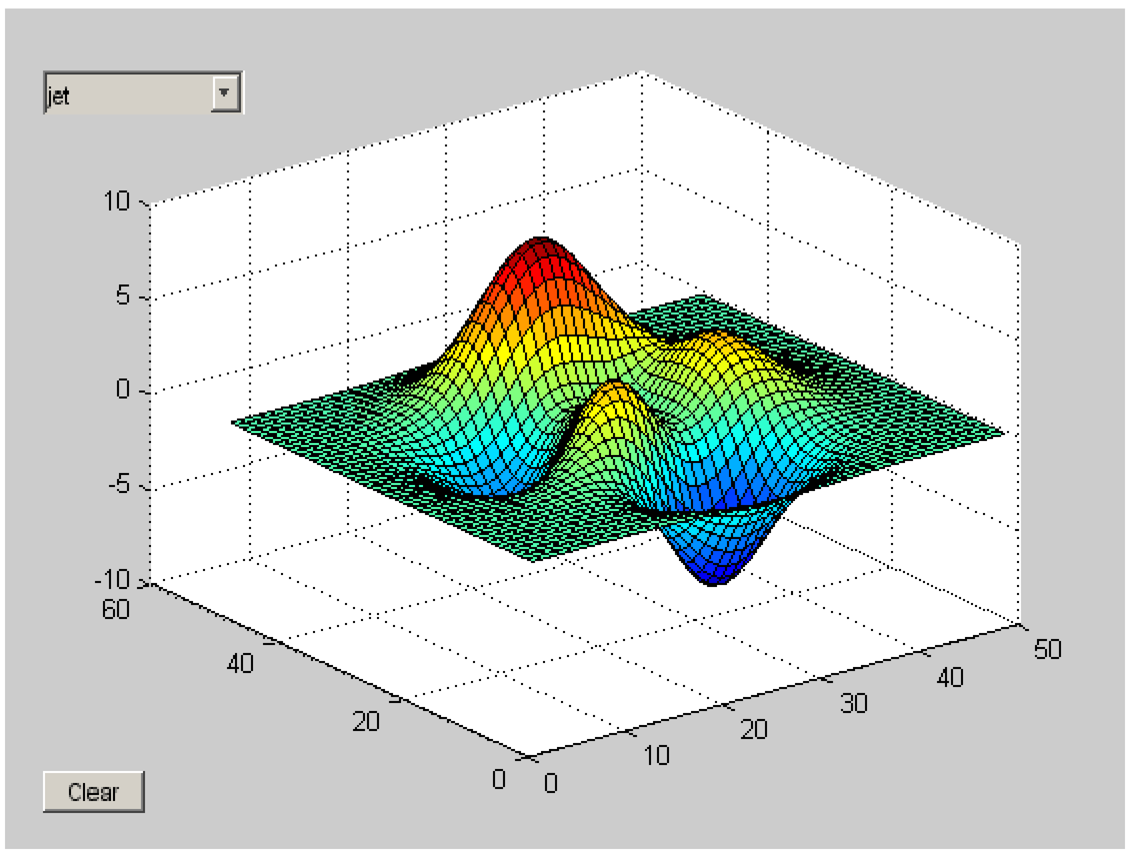
Place a uicontrol object to let users change the colormap with a pop-up menu. Supply a function handle as the object's `Callback` property:

```
uicontrol('Style', 'popup',...
          'String', 'jet|hsv|hot|cool|gray',...
          'Position', [20 340 100 50],...
          'Callback', @setmap);   % Popup function handle callback
                                  % Implemented as a local function
```



Add a different uicontrol. Create a push button that clears the current axes when pressed. Position the button inside the axes at the lower left. All uicontrols have default units of pixels. In this example, the axes has units of pixels, as well.

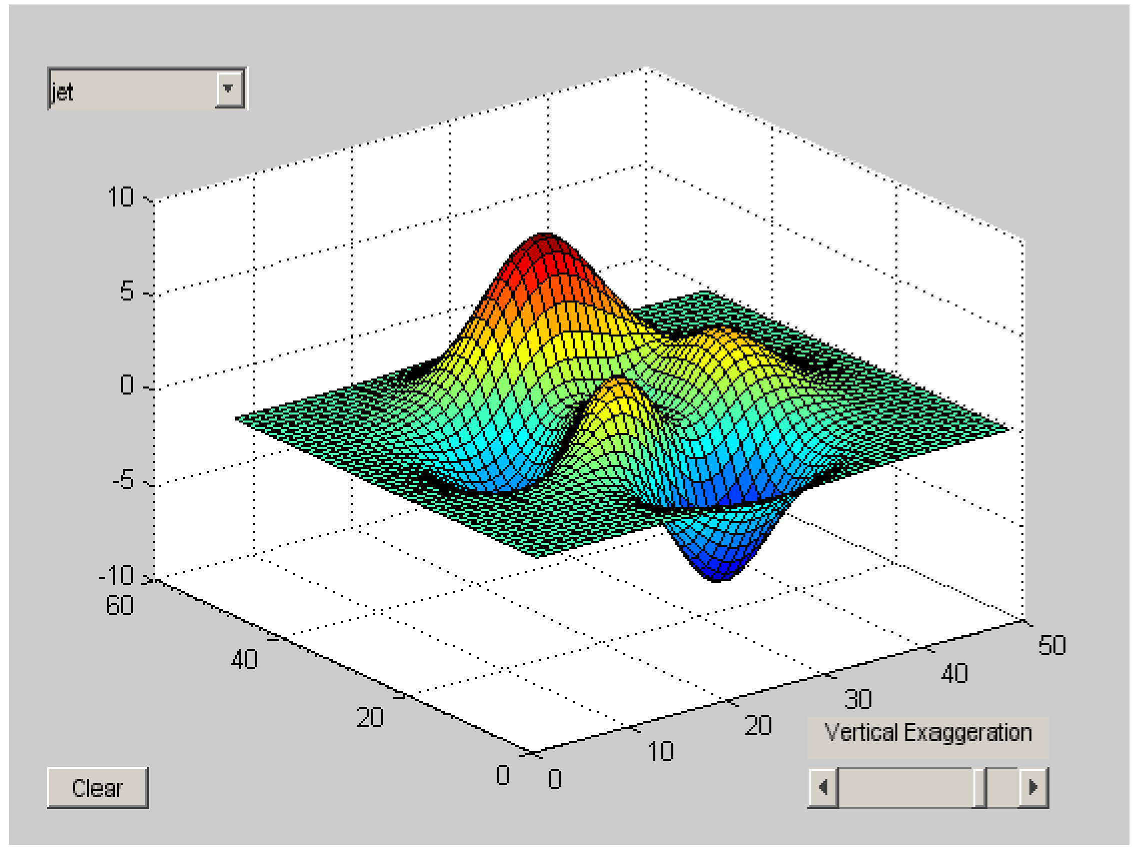
```
uicontrol('Style', 'pushbutton', 'String', 'Clear',...
        'Position', [20 20 50 20],...
        'Callback', 'cla');        % Pushbutton string callback
                                   % that calls a MATLAB function
```



Add a slider uicontrol to control the vertical scaling of the surface object. Position it at the bottom right corner of the figure. Then add a text uicontrol as a label for the slider.

```
uicontrol('Style', 'slider',...
        'Min',1,'Max',50,'Value',41,...
        'Position', [400 20 120 20],...
        'Callback', {@surfzlim,hax});
% Uses cell array function handle callback
% Implemented as a local function with an argument
```

```
uicontrol('Style','text',...
        'Position',[400 45 120 20],...
        'String','Vertical Exaggeration')
```



To operate the controls, you need callback functions. The callback for the pop-up menu is a local function called `setmap` that contains the following code.

```
function setmap(hObj,event) %#ok<INUSD>
```

```
        % Called when user activates popup menu
        val = get(hObj,'Value');
        if val ==1
            colormap(jet)
        elseif val == 2
            colormap(hsv)
        elseif val == 3
            colormap(hot)
        elseif val == 4
            colormap(cool)
        elseif val == 5
            colormap(gray)
        end
    end
```

The callback for the slider is also a local function in the same file, and contains the following code.

```
function surfzlim(hObj,event,ax) %#ok<INUSL>
    % Called to set zlim of surface in figure axes
    % when user moves the slider control
    val = 51 - get(hObj,'Value');
    zlim(ax,[-val val]);
end
```

To use the uicontrols in the example, you need to put all the functions in a MATLAB code file. Copy the following code and paste it into a new file. Save the file as `ex_uicontrol.m` on your search path, and then run it.

```
function ex_uicontrol
    % Example code for uicontrol reference page

    % Create a figure and an axes to contain a 3-D surface plot.
    figure
    hax = axes('Units','pixels');
    surf(peaks)
    % Create a uicontrol object to let users change the colormap
```

```
    % with a pop-up menu. Supply a function handle as the object's
    % Callback:
    uicontrol('Style', 'popup',...
           'String', 'hsv|hot|cool|gray',...
           'Position', [20 340 100 50],...
           'Callback', @setmap);    % Popup function handle callback
                                    % Implemented as a local function

    % Add a different uicontrol. Create a push button that clears
    % the current axes when pressed. Position the button inside
    % the axes at the lower left. All uicontrols have default units
    % of pixels. In this example, the axes does as well.
    uicontrol('Style', 'pushbutton', 'String', 'Clear',...
        'Position', [20 20 50 20],...
        'Callback', 'cla');        % Pushbutton string callback
                                   % that calls a MATLAB function

    % Add a slider uicontrol to control the vertical scaling of the
    % surface object. Position it under the Clear button.
    uicontrol('Style', 'slider',...
        'Min',1,'Max',50,'Value',41,...
        'Position', [400 20 120 20],...
        'Callback', {@surfzlim,hax});
     % Slider function handle callback
          % Implemented as a local function

    % Add a text uicontrol to label the slider.
    uicontrol('Style','text',...
        'Position',[400 45 120 20],...
        'String','Vertical Exaggeration')
end

function setmap(hObj,event) %#ok<INUSD>
    % Called when user activates popup menu
    val = get(hObj,'Value');
    if val ==1
```

```
        colormap(jet)
    elseif val == 2
        colormap(hsv)
    elseif val == 3
        colormap(hot)
    elseif val == 4
        colormap(cool)
    elseif val == 5
        colormap(gray)
    end
end

function surfzlim(hObj,event,ax) %#ok<INUSL>
    % Called to set zlim of surface in figure axes
    % when user moves the slider control
    val = 51 - get(hObj,'Value');
    zlim(ax,[-val val]);
end
```

How To

- Examples: Programming GUI Components
- "A Working GUI with Many Components"

Uicontrol Properties

Purpose

Describe user interface control (`uicontrol`) properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` commands enable you to set and query the values of properties

To change the default value of properties see “Setting Default Property Values”. You can also set default uicontrol properties on the root and figure levels:

```
set(0,'DefaultUicontrolProperty',PropertyValue...)
set(gcf,'DefaultUicontrolProperty',PropertyValue...)
```

where *Property* is the name of the uicontrol property whose default value you want to set and `PropertyValue` is the value you are specifying as the default. Use `set` and `get` to access uicontrol properties.

For information on using these uicontrols within GUIDE, the MATLAB GUI development environment, see Programming GUI Components in the MATLAB Creating GUIs documentation.

Uicontrol Properties

This section lists all properties useful to `uicontrol` objects along with valid values and descriptions of their use. Curly braces `{}` enclose default values.

Property	Purpose
`BackgroundColor`	Object background color
`BeingDeleted`	This object is being deleted
`BusyAction`	Callback routine interruption
`ButtonDownFcn`	Button-press callback routine

Property	Purpose
Callback	Control action
CData	Truecolor image displayed on the control
Children	Uicontrol objects have no children
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
Enable	Enable or disable the uicontrol
Extent	position rectangle (read only)
FontAngle	Character slant
FontName	Font family
FontSize	Font size
FontUnits	Font size units
FontWeight	Weight of text characters
ForegroundColor	Color of text
HandleVisibility	Whether handle is accessible from command line and GUIs
HitTest	Whether selectable by mouse click
HorizontalAlignment	Alignment of label string
Interruptible	Callback routine interruption mode
KeyPressFcn	Key press callback routine
ListboxTop	Index of top-most string displayed in list box
Max	Maximum value (depends on uicontrol object)
Min	Minimum value (depends on uicontrol object)

Property	Purpose
Parent	Uicontrol object's parent
Position	Size and location of uicontrol object
Selected	Whether object is selected
SelectionHighlight	Object highlighted when selected
SliderStep	Slider step size
String	Uicontrol object label, also list box and pop-up menu items
Style	Type of uicontrol object
Tag	User-specified object identifier
TooltipString	Content of object's tooltip
Type	Class of graphics object
UIContextMenu	Uicontextmenu object associated with the uicontrol
Units	Units to interpret position vector
UserData	User-specified data
Value	Current value of uicontrol object
Visible	Uicontrol visibility

BackgroundColor
    ColorSpec

Object background color. The color used to fill the uicontrol rectangle. Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default color is determined by system settings. See ColorSpec for more information on specifying color.

Note Platform look and feel for a GUI element can override change requests from MATLAB. It is possible your system will not honor a request to change the background color.

`BeingDeleted`
`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`
`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.

- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`
string or function handle (GUIDE sets this property)

Button-press callback routine. A callback routine that can execute when you press a mouse button while the pointer is on or near a uicontrol. Specifically:

- If the uicontrol's `Enable` property is set to `on`, the `ButtonDownFcn` callback executes when you click the right or left mouse button in a 5-pixel border around the uicontrol or when you click the right mouse button on the control itself.
- If the uicontrol's `Enable` property is set to `inactive` or `off`, the `ButtonDownFcn` executes when you click the right or left mouse button in the 5-pixel border or on the control itself.

This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on (using selectmoveresize, for example).

Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

To add a `ButtonDownFcn` callback in GUIDE, select **View Callbacks** from the Layout Editor **View** menu, then select `ButtonDownFcn`. GUIDE sets this property to the appropriate string and adds the callback to the code file the next time you save the GUI. Alternatively, you can set this property to the string `%automatic`. The next time you save the GUI, GUIDE sets

this property to the appropriate string and adds the callback to the code file.

Use the `Callback` property to specify the callback routine that executes when you activate the enabled uicontrol (e.g., click a push button).

`Callback`
string or function handle (GUIDE sets this property)

Control action. A routine that executes whenever you activate the uicontrol object (e.g., when you click on a push button or move a slider). Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

For examples of `Callback` callbacks for each style of component:

- For GUIDE GUIs, see "Add Code for Components in Callbacks".
- For programmatically created GUIs, see "Examples: Program GUI Components".

`CData`
matrix

Truecolor image displayed on control. A three-dimensional matrix of RGB values that defines a truecolor image displayed on a control, which must be a **push button** or **toggle button**. Each value must be between `0.0` and `1.0`. Setting `CData` on a **radio button** or **checkbox** will replace the default `CData` on these controls. The control will continue to work as expected, but its state is not reflected by its appearance when clicked.

For **push buttons** and **toggle buttons**, `CData` overlaps the `String`. In the case of **radio buttons** and **checkboxes**, `CData` takes precedence over `String` and, depending on its size, it can displace the text.

Setting `CData` to `[]` restores the default `CData` for **radio buttons** and **checkboxes**.

`Children`
matrix

The empty matrix; `uicontrol` objects have no children.

`Clipping`
`{on} | off`

This property has no effect on `uicontrol` objects.

`CreateFcn`
string or function handle

Callback routine executed during object creation. The specified function executes when MATLAB creates a `uicontrol` object. MATLAB sets all property values for the uicontrol before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uicontrol being created.

Setting this property on an existing uicontrol object has no effect.

You can define a default `CreateFcn` callback for all new uicontrols. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uicontrol`. For example, the code

```
set(0,'DefaultUicontrolCreateFcn','set(gcbo,...
    ''BackgroundColor'',''white'')')
```

creates a default `CreateFcn` callback that runs whenever you create a new uicontrol. It sets the default background color of all new uicontrols.

To override this default and create a uicontrol whose `BackgroundColor` is set to a different value, call `uicontrol` with code similar to

```
hpt = uicontrol(...,'CreateFcn','set(gcbo,...
''BackgroundColor'',''blue'')')
```

Note To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uicontrol` call. In the example above, if instead of redefining the `CreateFcn` property for this uicontrol, you had explicitly set `BackgroundColor` to `blue`, the default `CreateFcn` callback would have set `BackgroundColor` back to the default, i.e., `white`.

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`DeleteFcn`
string or function handle

Delete uicontrol callback routine. A callback routine that executes when you delete the uicontrol object (e.g., when you issue a `delete` command or clear the figure containing the uicontrol). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root CallbackObject property, which you can query using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`Enable`
`{on} | inactive | off`

Enable or disable the uicontrol. This property controls how uicontrols respond to mouse button clicks, including which callback routines execute.

- `on` – The uicontrol is operational (the default).
- `inactive` – The uicontrol is not operational, but looks the same as when `Enable` is `on`.
- `off` – The uicontrol is not operational and its image (set by the `Cdata` property) is grayed out.

When you left-click on a uicontrol whose `Enable` property is `on`, MATLAB performs these actions in this order:

1. Sets the figure `SelectionType` property.
2. Executes the uicontrol `Callback` routine, if any. (Static text components do not use callbacks.)
3. Does *not* set the figure `CurrentPoint` property and does *not* execute either the uicontrol `ButtonDownFcn` or the figure `WindowButtonDownFcn` callback.

Single-clicking or double-clicking an enabled uicontrol with the left mouse button sets the figure `SelectionType` property to `normal`, unless the uicontrol `Style` is `listbox`. For list boxes, double-clicking sets the figure `SelectionType` property to `open` on the second of the two clicks, enabling the list box callback to detect a set of multiple choices.

When you left-click on a uicontrol whose `Enable` property is `off` or `inactive`, or when you right-click a uicontrol whose `Enable` property has any value, MATLAB performs these actions in this order:

1. Sets the figure `SelectionType` property.
2. Sets the figure `CurrentPoint` property.
3. Executes the figure `WindowButtonDownFcn` callback, if provided.
4. Executes the uicontrol `ButtonDownFcn` callback, if provided.

`Extent`

position rectangle (read only)

Size of uicontrol character string. A four-element vector that defines the size and position of the character string used to label the uicontrol. It has the form:

```
[0,0,width,height]
```

The first two elements are always zero. `width` and `height` are the dimensions of the rectangle. All measurements are in units specified by the `Units` property.

Since the `Extent` property is defined in the same units as the uicontrol itself, you can use this property to determine proper sizing for the uicontrol with regard to its label. Do this by

- Defining the `String` property and selecting the font using the relevant properties.
- Getting the value of the `Extent` property.
- Defining the `width` and `height` of the `Position` property to be somewhat larger than the `width` and `height` of the `Extent`.

For multiline strings, the `Extent` rectangle encompasses all the lines of text. For single line strings, the `height` element of the `Extent` property returned always indicates the height of a

single line, and its `width` element always indicates the width of the longest line, even if the string wraps when displayed on the control. Edit boxes are considered multiline if `Max` - `Min` > 1.

`FontAngle`
`{normal} | italic | oblique`

Character slant. MATLAB uses this property to select a font from those available on your particular system. Setting this property to `italic` or `oblique` selects a slanted version of the font, when it is available on your system.

`FontName`
string

Font family. The name of the font in which to display the String. To display and print properly, this must be a font that your system supports. The default font is system dependent.

Note MATLAB GUIs do not support the `Marlett` and `Symbol` font families.

To use a fixed-width font that looks good in any locale (and displays properly in Japan, where multibyte character sets are used), set `FontName` to the string `FixedWidth` (this string value is case sensitive):

```
set(uicontrol_handle, 'FontName', 'FixedWidth')
```

This parameter value eliminates the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` and rely on the root `FixedWidthFontName` property to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Tip To determine what fonts exist on your system (which can differ from the GUI user's system), use the `uisetfont` GUI to select a font and return its name and other characteristics in a MATLAB structure.

`FontSize`
size in `FontUnits`

Font size. A number specifying the size of the font in which to display the String, in units determined by the `FontUnits` property. The default point size is system dependent.

`FontUnits`
`{points} | normalized | inches |`
`centimeters | pixels`

Font size units. This property determines the units used by the `FontSize` property. `Normalized` units interpret `FontSize` as a fraction of the height of the uicontrol. When you resize the uicontrol, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = $^1/_{72}$ inch).

`FontWeight`
`light | {normal} | demi | bold`

Weight of text characters. MATLAB uses this property to select a font from those available on your particular system. Setting this property to `bold` causes MATLAB to use a bold version of the font, when it is available on your system.

`ForegroundColor`
`ColorSpec`

Color of text. This property determines the color of the text defined for the `String` property (the uicontrol label). Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default text color is black. See `ColorSpec` for more information on specifying color.

Note If you change the `ForegroundColor` for a uicontrol `listbox`, MATLAB uses that color for all `listbox` items *except* selected `listbox` items. For selected items MATLAB uses a color that ensures good contrast between the text of selected items and the color that indicates a selection.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from

command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to on to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

Note Radio buttons and toggle buttons that are managed by a uibuttongroup should not be accessed outside the button group. Set the `HandleVisibility` of such radio buttons and toggle buttons to `off` to prevent inadvertent access.

`HitTest`
`{on} | off`

Selectable by mouse click. This property has no effect on uicontrol objects.

`HorizontalAlignment`
`left | {center} | right`

Horizontal alignment of label string. This property determines the justification of the text defined for the `String` property (the uicontrol label):

- `left` — Text is left justified with respect to the uicontrol.
- `center` — Text is centered with respect to the uicontrol.
- `right` — Text is right justified with respect to the uicontrol.

The contents of `edit` and `text` uicontrols are always vertically aligned to the top of the rectangle.

Note On Microsoft Windows systems, although this property can be specified on all uicontrols, it affects only `edit` and `text` uicontrols.

`Interruptible`

`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

Note If the interrupting callback is a `DeleteFcn`or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

`KeyPressFcn`
string or function handle

Key press callback function. A callback routine invoked by a key press when the callback's uicontrol object has focus. Focus is denoted by a border or a dotted border, respectively, in UNIX and Microsoft Windows. If no uicontrol has focus, the figure's key press callback function, if any, is invoked. `KeyPressFcn` can be a function handle, the name of a code file, or any legal MATLAB expression.

If the specified value is the name of a code file, the callback routine can query the figure's `CurrentCharacter` property to determine what particular key was pressed and thereby limit the callback execution to specific keys.

If the specified value is a function handle, the callback routine can retrieve information about the key that was pressed from its event data structure argument.

Event Data Structure Field	Description	Examples:			
		a	=	Shift	Shift/a
Character	Character interpretation of the key that was pressed.	'a'	'='	''	'A'
Modifier	Current modifier, such as 'control', or an empty cell array if there is no modifier	{1x0 cell}	{1x0 cell}	{'shift'}	{'shift'}
Key	Name of the key that was pressed.	'a'	'equal'	'shift'	'a'

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

ListboxTop
scalar

Index of top-most string displayed in list box. This property applies only to the listbox style of uicontrol. It specifies which string appears in the top-most position in a list box that is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer.

Max
scalar

Maximum value. This property specifies the largest value allowed for the Value property. Different styles of uicontrols interpret Max differently:

- Check boxes – Max is the setting of the Value property while the check box is selected.
- Editable text – The Value property does not apply. If Max - Min > 1, then editable text boxes accept multiline input. If Max - Min

<= 1, then editable text boxes accept only single line input. The absolute values of `Max` and `Min` have no effect on the number of lines an edit box can contain; a multiline edit box can contain any number of lines.

- List boxes – If `Max - Min` > 1, then list boxes allow multiple item selection. If `Max - Min` <= 1, then list boxes do not allow multiple item selection. When they do, `Value` can be a vector of indices.
- Radio buttons – `Max` is the setting of the `Value` property when the radio button is selected.
- Sliders – `Max` is the maximum slider value and must be greater than the `Min` property. The default is 1.
- Toggle buttons – `Max` is the value of the `Value` property when the toggle button is selected. The default is 1.
- Pop-up menus, push buttons, and static text do not use the `Max` property.

`Min`

scalar

Minimum value. This property specifies the smallest value allowed for the `Value` property. Different styles of uicontrols interpret `Min` differently:

- Check boxes – `Min` is the setting of the `Value` property while the check box is not selected.
- Editable text – The `Value` property does not apply. If `Max - Min` > 1, then editable text boxes accept multiline input. If `Max - Min` <= 1, then editable text boxes accept only single line input. The absolute values of `Max` and `Min` have no effect on the number of lines an edit box can contain; a multiline edit box can contain any number of lines.
- List boxes – If `Max - Min` > 1, then list boxes allow multiple item selection. If `Max - Min` <= 1, then list boxes allow only single item selection. When they do, `Value` can be a vector of indices.

- Radio buttons – `Min` is the setting of the `Value` property when the radio button is not selected.
- Sliders – `Min` is the minimum slider value and must be less than `Max`. The default is 0.
- Toggle buttons – `Min` is the value of the `Value` property when the toggle button is not selected. The default is 0.
- Pop-up menus, push buttons, and static text do not use the `Min` property.

`Parent`

handle

Uicontrol parent. The handle of the uicontrol's parent object. You can move a uicontrol object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

`Position`

position rectangle

Size and location of uicontrol. The rectangle defined by this property specifies the size and location of the control within the parent figure window, uipanel, or uibuttongroup. Specify `Position` as

```
[left bottom width height]
```

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the uicontrol object. `width` and `height` are the dimensions of the uicontrol rectangle. All measurements are in units specified by the `Units` property.

On Microsoft Windows systems, the height of pop-up menus is automatically determined by the size of the font. The value you specify for the `height` of the `Position` property has no effect.

The `width` and `height` values determine the orientation of sliders. If `width` is greater than `height`, then the slider is oriented horizontally, If `height` is greater than `width`, then the slider is oriented vertically.

Note The height of a pop-up menu is determined by the font size. The height you set in the position vector is ignored. The height element of the position vector is not changed.

On Mac platforms, the height of a horizontal slider is constrained. If the height you set in the position vector exceeds this constraint, the displayed height of the slider is the maximum allowed. The height element of the position vector is not changed.

`Selected`

`on | {off}` (read only)

Is object selected. When this property is `on`, MATLAB displays selection handles if the `SelectionHighlight` property is also `on`. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

`SelectionHighlight`

`{on} | off`

Object highlight when selected. When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`SliderStep`

`[minor_step major_step]`

Slider step size, a two-element vector of positive values that indicates the size of the major and minor steps as a percent change in slider value. Both steps should be greater than `1e-6`,

and `minor_step` should be less than or equal to `major_step`. The slider `Value` changes up or down by `minor_step` when you click the arrow button, and up or down by `major_step` when you click the slider trough, also called the channel.

The actual step size is a function of the specified `SliderStep` and the total slider range (`Max - Min`). The default, `[0.01 0.10]`, provides a 1 percent change for clicks on the arrow button and a 10 percent change for clicks in the trough.

For example, if you create the following slider,

```
uicontrol('Style','slider','Min',1,'Max',7,...
         'Value',2,'SliderStep',[0.1 0.6])
```

clicking an arrow button moves the thumb indicator toward it by `minor_step*(max-min)`:

```
0.1*(7-1)
ans =
    0.6000
```

Clicking the trough moves the thumb indicator toward the mouse pointer by `major_step*(max-min)`:

```
0.6*(7-1)
ans =
    3.6000
```

If clicking moves the slider to a value outside the range, the thumb indicator moves only to the `Max` or `Min` value.

As `major_step` increases, the slider thumb indicator grows longer. When `major_step` is 1, the thumb is half as long as the trough. When `major_step` is greater than 1, the thumb continues to grow, slowly approaching the full length of the trough.

See also the `Max`, `Min`, and `Value` properties.

`String`

string

Uicontrol label, list box items, pop-up menu choices.

For check boxes, editable text, push buttons, radio buttons, static text, and toggle buttons, the text displayed on the object. For list boxes and pop-up menus, the set of entries or items displayed in the object.

Note If you specify a numerical value for `String`, MATLAB converts it to `char` but the result may not be what you expect. If you have numerical data, you should first convert it to a string, e.g., using `num2str`, before assigning it to the `String` property.

For uicontrol objects that display only one line of text (check box, push button, radio button, toggle button), if the string value is specified as a cell array of strings or padded string matrix, only the first string of a cell array or of a padded string matrix is displayed; the rest are ignored. Vertical slash ('`|`') characters are not interpreted as line breaks and instead show up in the text displayed in the uicontrol.

For multiple line editable text or static text controls, line breaks occur between each row of the string matrix, and each cell of a cell array of strings. Vertical slash ('`|`') characters and `\n` characters are not interpreted as line breaks, and instead show up in the text displayed in the uicontrol. Text in edit text and static text boxes is always vertically top-aligned. For **editable text**, the `String` property value is set to the string entered by the user when the control loses focus. The `String` property for **static text** can only be set programmatically (or when authoring a GUI in GUIDE).

To place multiple items on a list box or pop-up menu, you can specify the items in any of the formats shown in the following table.

String Property Format	Example
Cell array of strings	`{'one' 'two' 'three'}`
Padded string column matrix	`['one  ';'two  ';'three']`
String vector using vertical slash (|) as a line separator	`['one|two|three']`

If you specify a component width that is too small to accommodate one or more of the specified strings, MATLAB truncates those strings with an ellipsis. Use the `Value` property to set the index of the initial item selected.

For **check boxes**, **push buttons**, **radio buttons**, **toggle buttons**, and the selected item in **popup menus**, when the specified text is clipped because it is too long for the uicontrol, an ellipsis (...) is appended to the text in the active GUI to indicate that it has been clipped.

For **push buttons** and **toggle buttons**, `CData` overlaps the `String`. In the case of **radio buttons** and **checkboxes**, `CData` takes precedence over `String` and, depending on its size, can displace the text.

Reserved Words There are three reserved words: `default`, `remove`, `factory` (case sensitive). If you want to use one of these reserved words in the `String` property, you must precede it with a backslash (`'\'`) character. For example,

```
h = uicontrol('Style','edit','String','\default');
```

`Style`

`{pushbutton} | togglebutton | radiobutton | checkbox | edit | text | slider | frame | listbox | popupmenu`

Style of uicontrol object to create. The `Style` property specifies the kind of uicontrol to create. See the `uicontrol` Description section for information on each type.

`Tag`

string (GUIDE sets this property)

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

`TooltipString`

string

Content of tooltip for object. The `TooltipString` property specifies the text of the tooltip associated with the uicontrol. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uicontrol('Style','pushbutton');
s = sprintf('Button tooltip line 1\nButton tooltip line 2');
set(h,'TooltipString',s)
```

`Type`

string (read only)

Class of graphics object. For uicontrol objects, `Type` is always the string `'uicontrol'`.

`UIContextMenu`

handle

Associate a context menu with uicontrol. Assign this property the handle of a `uicontextmenu` object. MATLAB displays the context menu whenever you right-click over the uicontrol. Use the `uicontextmenu` function to create the context menu.

`Units`

`{pixels} | normalized | inches | centimeters | points | characters` (GUIDE default: `normalized`)

Units of measurement. MATLAB uses these units to interpret the `Extent` and `Position` properties. All units are measured from the lower-left corner of the parent object.

- `Normalized` units map the lower-left corner of the parent object to (0,0) and the upper-right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).
- `Character` units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

`UserData`
matrix

User-specified data. Any data you want to associate with the uicontrol object. MATLAB does not use this data, but you can access it using `set` and `get`.

`Value`
scalar or vector

Current value of uicontrol. The uicontrol style determines the possible values this property can have:

- Check boxes set `Value` to `Max` when they are on (when selected) and `Min` when off (not selected).
- List boxes set `Value` to a vector of indices corresponding to the selected list entries, where 1 corresponds to the first item in the list.
- Pop-up menus set `Value` to the index of the item selected, where 1 corresponds to the first item in the menu. The Examples section shows how to use the `Value` property to determine which item has been selected.
- Radio buttons set `Value` to `Max` when they are on (when selected) and `Min` when off (not selected).
- Sliders set `Value` to the number indicated by the slider bar.
- Toggle buttons set `Value` to `Max` when they are down (selected) and `Min` when up (not selected).
- Editable text, push buttons, and static text do not set this property.

Set the `Value` property either interactively with the mouse or through a call to the `set` function. The display reflects changes made to `Value`.

`Visible`
`{on} | off`

Uicontrol visibility. By default, all uicontrols are visible. When set to `off`, the uicontrol is not visible, but still exists and you can query and set its properties.

Note Setting `Visible` to `off` for uicontrols that are not displayed initially in the GUI, can result in faster startup time for the GUI.

---

uigetdir

Purpose

Open standard dialog box for selecting directory

Syntax

```
folder_name = uigetdir
folder_name = uigetdir(start_path)
folder_name = uigetdir(start_path,dialog_title)
```

Description

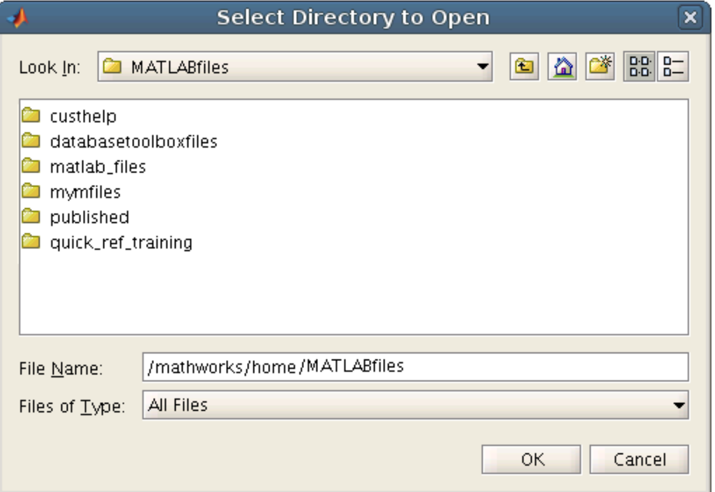
`folder_name = uigetdir` displays a modal dialog box enabling you to navigate the folder hierarchy and select a folder or type the name of a folder. If the folder exists, `uigetdir` returns the selected path when you click **OK**. If you type the name of a folder that does not exist, `uigetdir` returns the name of the current folder. If you click **Cancel**, or close the dialog box, `uigetdir` returns `0`. On Microsoft Windows platforms, `uigetdir` opens a dialog box in the base folder (the Windows desktop) with the current folder selected.

`folder_name = uigetdir(start_path)`opens a dialog box with the folder specified by `start_path` selected. If `start_path` is a valid path, the dialog box opens in the specified folder. If `start_path` is an empty string (`''`) or is not a valid path, the dialog box opens in the current folder.

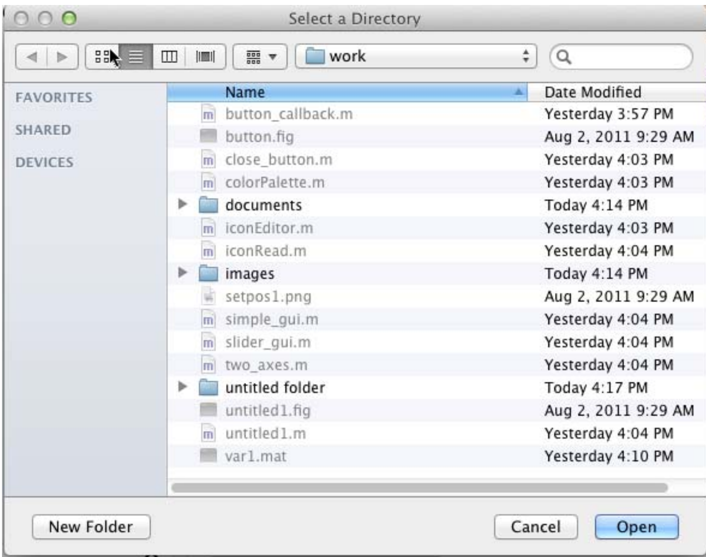
`folder_name = uigetdir(start_path,dialog_title)` opens a dialog box with the specified title. On Windows and UNIX platforms, the string replaces the default caption inside the dialog box for specifying instructions to the user. The default `dialog_title` is **Select folder to Open**.

On Windows platforms, you can click the **New Folder** button to add a new folder to the folder hierarchy displayed. You can also drag and drop existing directories into different folders.

On UNIX platforms, `uigetdir` opens a dialog box in the startup folder (the one you are in when you start MATLAB), with the current directory selected. The `dialog_title` string replaces the default title of the dialog box. The dialog box looks similar to the following figure.



On Mac platforms, `uigetdir` opens a dialog box in the startup folder (the one you are in when you start MATLAB), with the current directory selected. The dialog box looks similar to the following figure.



Note A modal dialog box prevents you from interacting with other MATLAB windows before responding. To block MATLAB program execution as well, use the `uiwait` function. For more information about modal dialog boxes, see `WindowStyle` in the MATLAB Figure Properties.

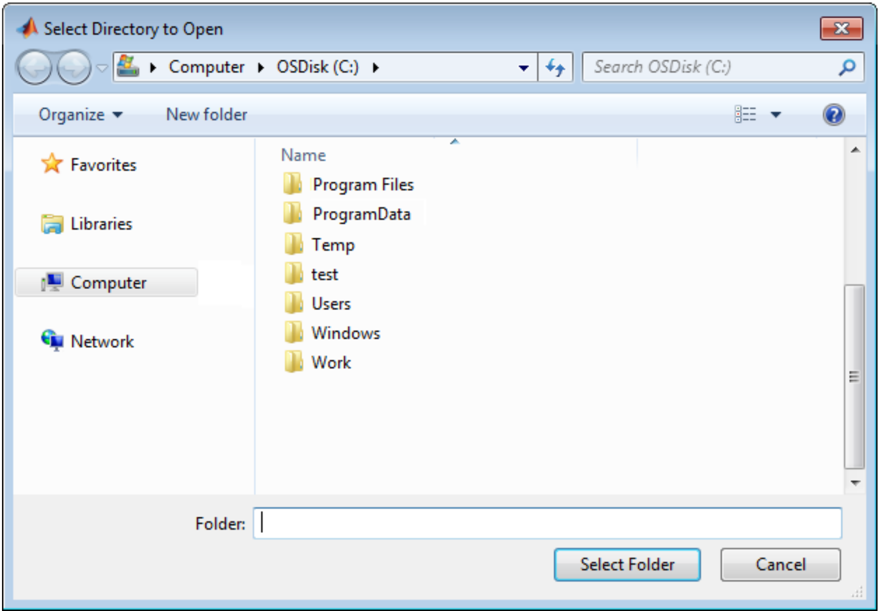
The `pwd` and `cd` functions return the name of the current folder.

Examples

The following statement displays directories on the `C:` drive.

```
dname = uigetdir('C:\');
```

A dialog box such as the following displays (on Windows).



If you double-click the `Program Files` folder, and the `MATLAB` subfolder, and then click **Select Folder**, `uigetdir` returns `C:\Program Files\MATLAB`to `dname`:

The following statement uses `matlabroot` to display the MATLAB root folder in the dialog box:

```
uigetdir(matlabroot,'MATLAB Root Directory')
```

Assuming that MATLAB is installed on drive `C:\`, selecting the folder `MATLAB\R2012b\notebook\pc` from the dialog box, returns this string:

```
C:\Program Files\MATLAB\R2012b\notebook\pc
```

See Also

`uigetfile` | `uiputfile`

uigetfile

Purpose

Open standard dialog box for retrieving files

Syntax

```
filename = uigetfile
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,
   DialogTitle)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,
   DialogTitle,DefaultName)
[FileName,PathName,FilterIndex] = uigetfile(...,'MultiSelect',
   selectmode)
```

Description

`filename = uigetfile` displays a modal dialog box that lists files in the current folder and enables you to select or enter the name of a file. If the file name is valid and the file exists, `uigetfile` returns the file name as a string when you click **Open**. Otherwise `uigetfile` displays an appropriate error message, after which control returns to the dialog box. You can then enter another file name or click **Cancel**. If you click **Cancel** or close the dialog window, `uigetfile` returns `0`.

Note Successful execution of `uigetfile` does not open a file; it only returns the name of an existing file that you identify.

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uigetfile` also displays in gray the files that do not match `FilterSpec`. The `uigetfile` function appends `'All Files'` to the list of file types. `FilterSpec` can be a string or a cell array of strings, and can include the `*` wildcard.

- If `FilterSpec` is a file name, that file name displays, selected in the **File name** field. The extension of the file is the default filter.
- `FilterSpec` can include a path. That path can contain `'.'`,`'..'`, `\`, `'/'`, or `'~'`. For example, `'../*.m'` lists all code files in the folder above the current folder.

- If FilterSpec is a folder name, uigetfile displays the contents of that folder, the **File name** field is empty, and no filter applies. To specify a folder name, make the last character of FilterSpec either '\' or '/'.
- If FilterSpec is a cell array of strings, it can include two columns. The first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace standard descriptions in the **Files of type** field. A description cannot be an empty string. The second and third examples illustrate use of a cell array as FilterSpec.

If FilterSpec is missing or empty, uigetfile uses the default list of file types (for example, all MATLAB files).

After you click **Open** and if the file name exists,uigetfile returns the name of the file in FileName and its path in PathName. If you click **Cancel** or close the dialog window, the function sets FileName and PathName to 0.

FilterIndex is the index of the filter selected in the dialog box. Indexing starts at 1. If you click **Cancel** or close the dialog window, the function sets FilterIndex to 0.

[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle)displays a dialog box that has the title DialogTitle. To use the default file types and specify a dialog title, enter

```
uigetfile('',DialogTitle)
```

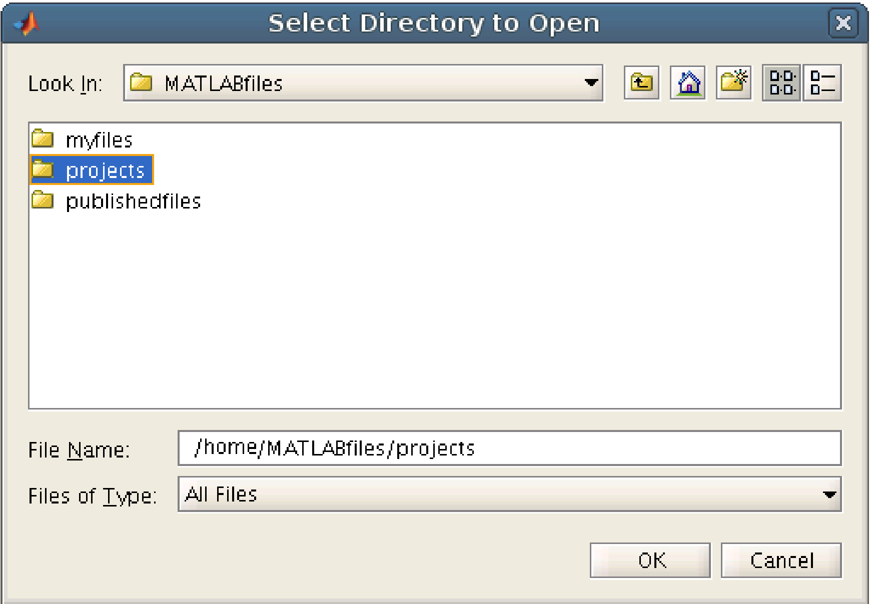
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle,DefaultName)displays a dialog box in which the file name specified by DefaultName appears in the **File name** field. DefaultName can also be a path or a path/filename. In this case, uigetfile opens the dialog box in the folder specified by the path. You can use '.','..', \, or '/' in the DefaultName argument. To specify a folder name, make the last character of DefaultName either '\' or '/'. If the specified path does not exist, uigetfile opens the dialog box in the current folder.

`[FileName,PathName,FilterIndex] = uigetfile(...,'MultiSelect',selectmode)` opens the dialog box in *multiselect* mode. Valid values for `selectmode` are `'on'` and `'off'` (the default, which allows single selection only). If `'MultiSelect'` is `'on'` and you select more than one file in the dialog box, then `FileName` is a cell array of strings. Each array element contains the name of a selected file. File names in the cell array are sorted in the order your platform uses. If you select multiple files, they must be in the same folder, otherwise MATLAB displays a warning dialog box. Be aware that Microsoft Windows libraries can span multiple folders. `PathName` is a string identifying the folder containing the files.

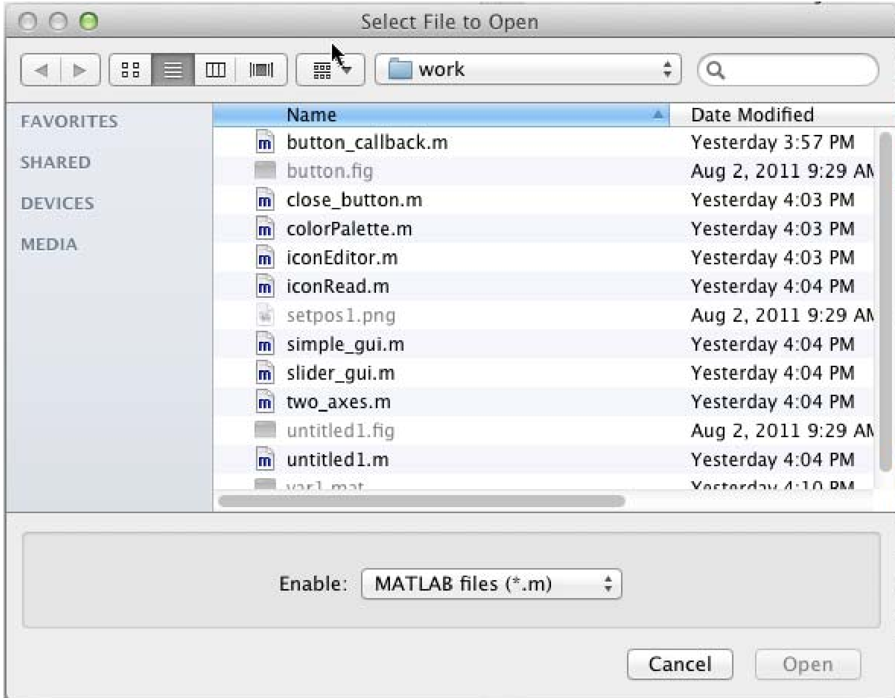
If you include either of the wildcard characters, `'*'` or `'?'`, in a file name, `uigetfile` does not respond to clicking **Open**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

For Windows platforms, the dialog box is the Windows dialog box native to your platform. Depending on your version of Windows, dialogs you see can differ from the figures shown in following examples.

For UNIX platforms, the dialog box is like the one shown in the following figure.



For Mac platforms, the dialog box is like the one shown in the following figure.



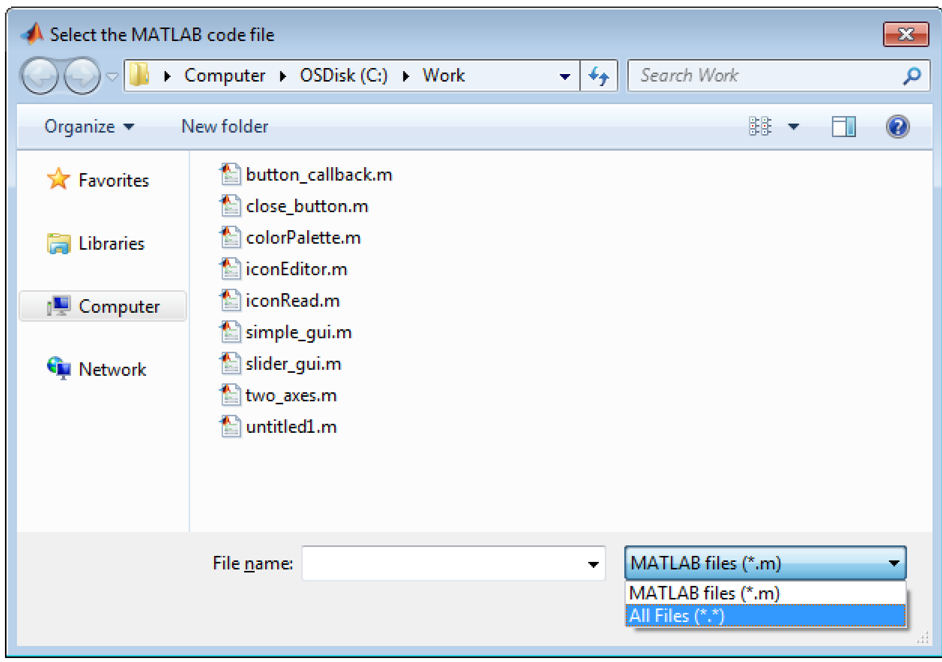
Note A modal dialog box prevents you from interacting with other windows before responding. To block MATLAB program execution, use the `uiwait` function. For more information about modal dialog boxes, see `WindowStyle` in the MATLAB Figure Properties.

Examples

The following statement displays a dialog box for retrieving a file. The dialog box lists all MATLAB code files within a selected directory. `uigetfile` returns the name and path of the selected file in `FileName` and `PathName`. `uigetfile` appends `All Files(*.*)` to the file types when `FilterSpec` is a string.

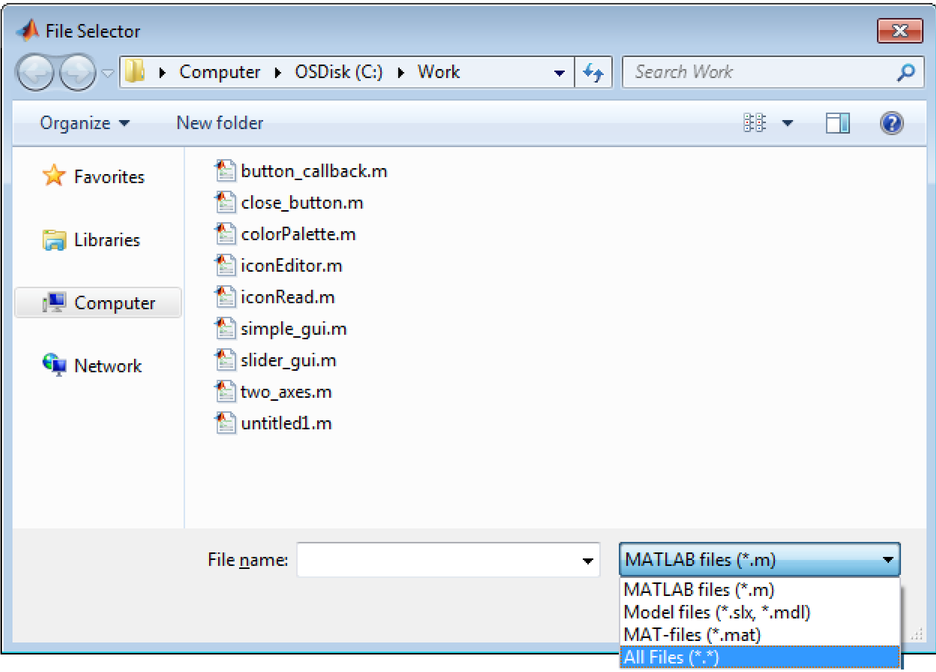
```
[FileName,PathName] = uigetfile('*.m','Select the MATLAB code file');
```

The following figure shows the dialog box with the file type drop-down list open.



To create a list of file types that appears in the file type drop-down list, separate the file extensions with semicolons, as in the following code. `uigetfile` displays a default description for each known file type, such as "Model files" for Simulink `.slx` and `.mdl` files.

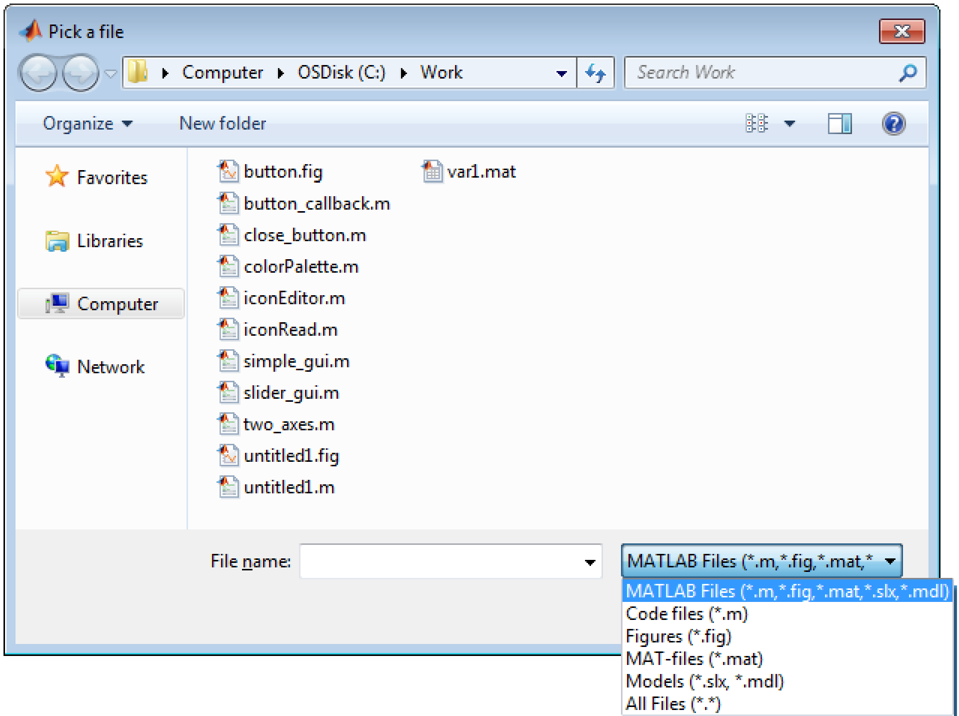
```
[filename, pathname] = ...
     uigetfile({'*.m';'*.slx';'*.mat';'*.*'},'File Selector');
```



If you want to create a list of file types and give them descriptions that are different from the defaults, use a cell array, as in the following code. This example also associates multiple file types with the `'MATLAB Files'` and `'Models'` descriptions.

```
[filename, pathname] = uigetfile( ...
{'*.m;*.fig;*.mat;*.slx;*.mdl','MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';
   '*.m',  'Code files (*.m)'; ...
   '*.fig','Figures (*.fig)'; ...
   '*.mat','MAT-files (*.mat)'; ...
   '*.mdl;*.slx','Models (*.slx, *.mdl)'; ...
   '*.*',  'All Files (*.*)'}, ...
   'Pick a file');
```

The first column of the cell array contains the file extensions, while the second contains your descriptions of the file types. In this example, the first entry of column one contains several extensions, separated by semicolons, which are all associated with the description `'MATLAB Files (*.m,*.fig,*.mat,*.mdl)'`. The code produces the dialog box shown in the following figure.



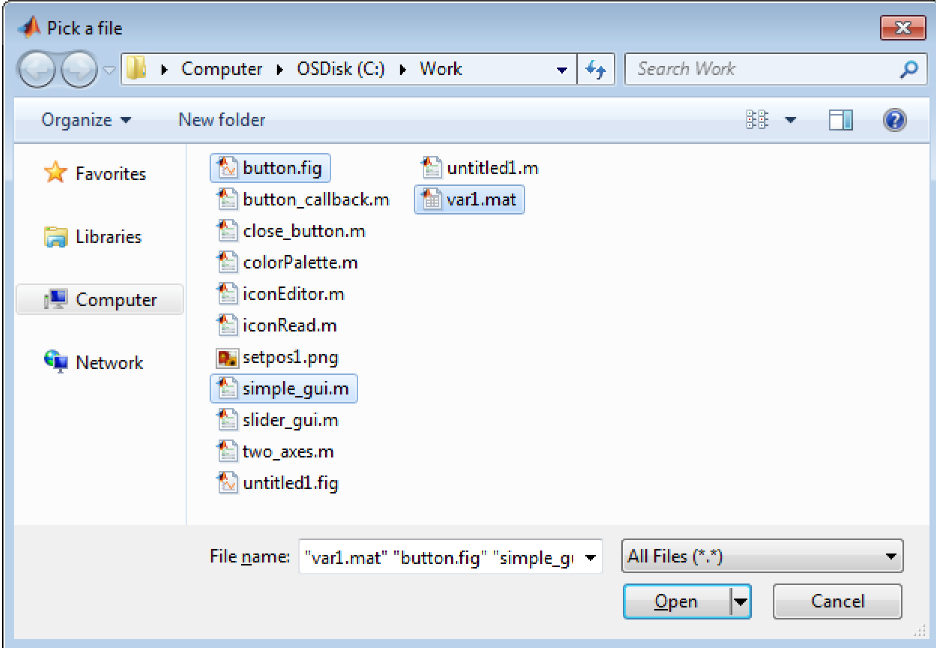
The following code lets you select a file and then displays a message in the Command Window that summarizes the result.

```
[filename, pathname] = uigetfile('*.m', 'Select a MATLAB code file');
if isequal(filename,0)
   disp('User selected Cancel')
```

```
else
   disp(['User selected ', fullfile(pathname, filename)])
end
```

This code creates a list of file types and gives them descriptions that are different from the defaults. It also enables multiple-file selection. Select multiple files by holding down the **Shift** or **Ctrl** key and clicking on additional file names.

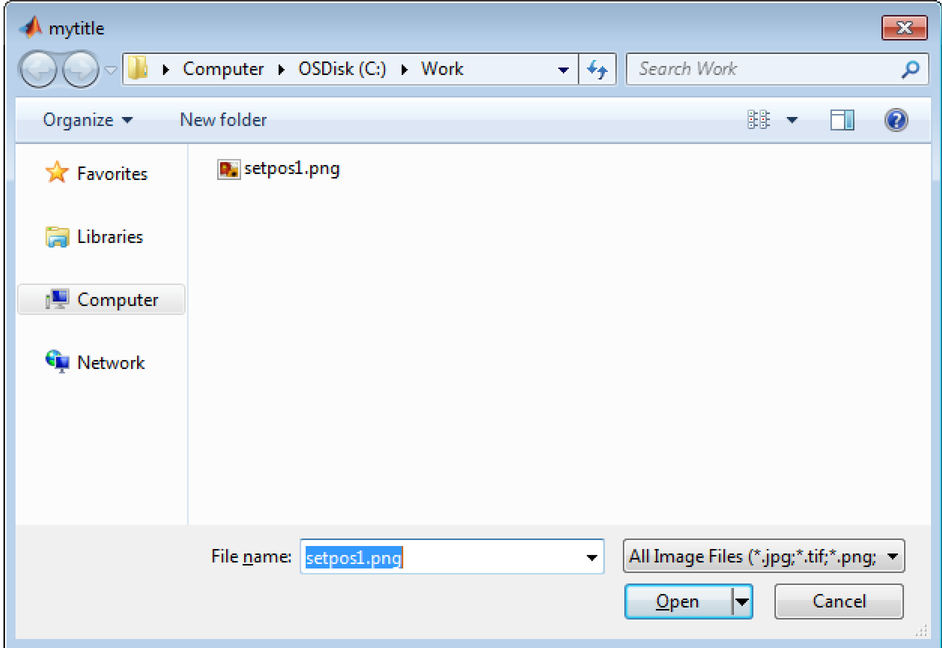
```
[filename, pathname, filterindex] = uigetfile( ...
{  '*.mat','MAT-files (*.mat)'; ...
   '*.slx;*.mdl','Models (*.slx, *.mdl)'; ...
   '*.*',  'All Files (*.*)'}, ...
   'Pick a file', ...
   'MultiSelect', 'on');
```



As mentioned previously, `uigetfile` does not open the file or files you select.

You can use the `DefaultName` argument to specify a start path and a default file name for the dialog box.

```
uigetfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...
          '*.*','All Files' },'mytitle',...
          'C:\myfiles\my_examples\gbtools\setpos1.png')
```



Alternatives

Use the `dir` function to return a filtered or unfiltered list of files in your current folder or a folder you specify. `dir` also can return file attributes.

See Also

`uigetdir` | `uiopen` | `uiputfile`

Purpose

Specify and conditionally open dialog box according to user preference

Syntax

```
pref_value = uigetpref(group,pref,title,question,
   pref_choices)
[pref_value,dlgshown] = uigetpref(...)
[...] = uigetpref(... 'Name',value)
```

Description

`pref_value = uigetpref(group,pref,title,question,pref_choices)` returns one of the strings in `pref_choices` in either of two ways:

- Displays a multiple-choice dialog box that prompts you to answer a question. The dialog box includes a check box with the label **Do not show this dialog again**.
- Retrieves a previous answer from the preferences data base and returns it without displaying a dialog. No dialog is displayed if you previously selected the check box **Do not show this dialog again**.

`[pref_value,dlgshown] = uigetpref(...)` also returns in `dlgshown` whether or not the dialog displayed.

`[...]  = uigetpref(...  'Name',value)` specify optional name-value pairs to control how dialogs display.

Tips

- You must supply all input arguments up to and including `pref_choices`.
- `uigetpref` creates specified groups and preferences, if they do not currently exist. To delete a preference group you no longer need, use `rmpref`.
- The string returned in `pref_value` is a preference name (as specified in `pref`), not its button label (as specified in `pref_choices`).
- After you select the check box **Do not show this dialog again** and close the dialog box, the dialog box does not display again for the same preference. To reenable dialogs that are being suppressed by preferences, use the command:

```
uisetpref('clearall')
```

Executing `uisetpref` with this command re-enables *all* preference dialogs you have defined with `uigetpref`, not just the most recent one.

Input Arguments

group

String specifying the name of the preference group that preference `pref` belongs to. If the group does not already exist, `uigetpref` creates it.

Default: None

pref

String specifying the name of the preference that controls whether the dialog displays. If the preference does not already exist, `uigetpref` creates it.

Default: None

title

String to display in the dialog box title bar

question

String or cell array of strings specifying a descriptive paragraph for the dialog to display. Use `question` to define what you are asking the user to decide. Clearly state the alternatives and the consequences of choosing among them. The dialog box that `uigetpref` generates inserts line breaks between rows of the string array, between elements of the cell array of strings, and between '`|`' or newline characters within a string vector.

Default: None

pref_choices

String, cell array of strings, or `'|'`-separated strings specifying the labels for the dialog box push buttons. The string on the selected push button is returned.

If the internal preference values are different from the strings displayed on the push buttons, provide a 2-by-n cell array of strings. The first row contains the preference strings, and the second row contains the associated push button strings. When `pref_choices` is not a 2-by-n cell array, MATLAB constructs lowercase versions of the button labels and returns them in `pref_value`. If your code tests returned values, make sure it compares them against the appropriate strings.

Default: None

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'CheckboxState'

State of check box when dialog box opens:

- `false` or `0`: Check box is not initially selected.
- `true` or `1`: Check box is initially selected.

Default: `0`

'CheckboxString'

String specifying the label for the check box.

Default: `'Do not show this dialog again'`

'HelpString'

String specifying the label for **Help** button.

Default: No **Help** button displays.

'HelpFcn'

String or function handle specifying the callback that executes when you click the **Help** button. Also, to have a button to trigger the callback, you must specify the `HelpString` option.

Default: `doc('uigetpref')`

'ExtraOptions'

String or cell array of strings specifying extra buttons. The additional buttons are not mapped to any preference settings. If you click any of these buttons, the dialog closes and `uigetpref` returns the string in `value`.

Default: `{}`

'DefaultButton'

String specifying the value that `uigetpref` returns if you close the dialog without clicking a button. This string does not have to correspond to any preference or `ExtraOption`.

Default: The first button specified in `pref_choices`

Output Arguments

pref_value

String containing the preference corresponding to the button you press. If you cancel the dialog by clicking its close box, `uigetpref` returns the label of the first button specified in `pref_choices` or the value for `DefaultButton`, if specified. After you select the **Do not show this dialog again** check box, `uigetpref` does not display a dialog box when you call it with the same `group` and `pref` arguments. Instead, it returns the last choice you made (your registered preference) in `pref_value` immediately.

dlgshown

Logical value that specifies the state of the check box when the dialog box closed. The value is `1` if selected, `0` if not selected. After you select the **Do not show this dialog again** check box, `uigetpref` does not display a dialog box when you call it with the same `group` and `pref` arguments. Instead, it returns `0` in `dlgshown` immediately.

Definitions

Preferences

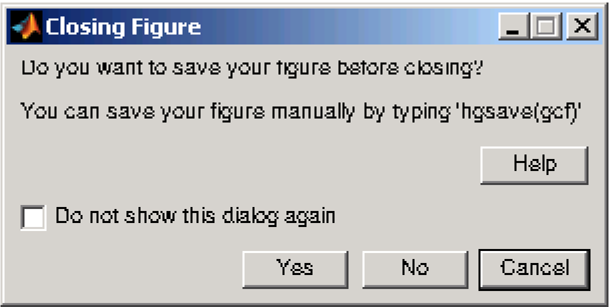
Preferences provide the ability to specify how applications behave and how users interact with them. For example, you can set a preference for which products display their documentation in the Help browser, or which messages the Code Analyzer displays. In MathWorks software products, preferences persist across sessions and are stored in a preference data base, the location of which is system-dependent. Use the **Preferences** option on the **File** menu to access all built-in preferences.

`uigetpref` uses the same preference data base as `addpref`, `getpref`, `ispref`, `rmpref`, and `setpref`. However, `uigetpref` registers the preferences it sets as a separate list, so that it and `uisetpref` can manage those preferences.

To modify preferences registered with `uigetpref`, you can use `setpref` and `uisetpref` to explicitly change preference values to `'ask'`. If you specify a preference that does not already exist in the preference data base, `uigetpref` creates it.

Examples

Create a preference dialog for the `'savefigurebeforeclosing'` preference in the `'mygraphics'` group of preferences.



Call `uigetpref` to display the dialog (or not) from a figure window `CloseRequestFcn` callback. The callback code takes action via a `switch` statement. The action (to delete or not to delete the figure) depends on whether the answer returned by `uigetpref` was `'always'` or `'never'`:

```
function save_figure_perhaps
% Closes figure conditionally, asking whether to save it first.
% User can suppress the dialog from UIGETPREF permanently by selecting
% "Do not show this dialog again".

fig = gcf;
[selectedButton dlgshown] = uigetpref(...
    'mygraphics',...                        % Group
    'savefigurebeforeclosing',...           % Preference
    'Closing Figure',...                    % Window title
    {'Do you want to save your figure before closing?'
     ''
     'You can save your figure manually by typing ''hgsave(gcf)'''},...
    {'always','never';'Yes','No'},...        % Values and button strings
     'ExtraOptions','Cancel',...             % Additional button
     'DefaultButton','Cancel',...            % Default choice
     'HelpString','Help',...                 % String for Help button
     'HelpFcn','doc(''closereq'');');        % Callback for Help button
switch selectedButton
    case 'always'  % Open a Save dialog (without testing if saved before)
    [fileName,pathName,filterIndex] = uiputfile('fig', ...
                              'Save current figure', ...
```

```
                                 'untitled.fig');
        if filterIndex == 0     % User cancelled save or named no file
            delete(fig);
        else                    % Use filename returned from UIPUTFILE
            saveas(fig,[pathName fileName])
            delete(fig);
        end
    case 'never'                % Close the figure without saving it
        delete(fig);
    case 'cancel'               % Do not close the figure
        return
  end
```

To execute the example, copy it and paste the code into a new program file. Name the file `save_figure_perhaps.m` and place it on your search path. To use the function as a `CloseRequestFcn`, create a figure as follows:

```
figure('CloseRequestFcn','save_figure_perhaps');
```

Clicking the figure close box or selecting **File > Close** displays the dialog box until you select **Do not show this dialog again**.

uiimport

Purpose

Import data interactively

Syntax

```
uiimport
uiimport(filename)
uiimport('-file')
uiimport('-pastespecial')
S = uiimport(___)
```

Description

`uiimport` opens a dialog to interactively load data from a file or the clipboard. MATLAB displays a preview of the data in the file.

`uiimport(filename)` opens the file specified in `filename`.

`uiimport('-file')` presents the file selection dialog first.

`uiimport('-pastespecial')` presents the clipboard contents first.

`S = uiimport(___)` stores the resulting variables as fields in the struct `S`.

How To

- "Supported File Formats"

Purpose

Create menus and menu items on figure windows

Syntax

```
handle = uimenu('PropertyName',PropertyValue,...)
handle = uimenu(parent,'PropertyName',PropertyValue,...)
```

Description

`handle = uimenu('PropertyName',PropertyValue,...)` creates a menu in the current figure's menu bar using the values of the specified properties and assigns the menu handle to `handle`.

`handle = uimenu(parent,'PropertyName',PropertyValue,...)` creates a submenu of a parent menu or a menu item on a context menu specified by `parent` and assigns the menu handle to `handle`. If `parent` refers to a figure instead of another uimenu object or a uicontextmenu, MATLAB software creates a new menu on the referenced figure's menu bar.

Tips

MATLAB adds the new menu to the existing menu bar. If the figure does not have a menu bar, MATLAB creates one. Each menu choice can itself be a menu that displays its items when you select it. `uimenu` accepts property name/property value pairs as well as structures and cell arrays of properties as input arguments.

Use the uimenu `Callback` property to define the action taken when you activate the created menu item.

Uimenus only appear in figures whose `Window Style` is `normal`. If a figure containing uimenu children is changed to `modal`, the uimenu children still exist and are contained in the `Children` list of the figure, but are not displayed until the `WindowStyle` is changed to `normal`.

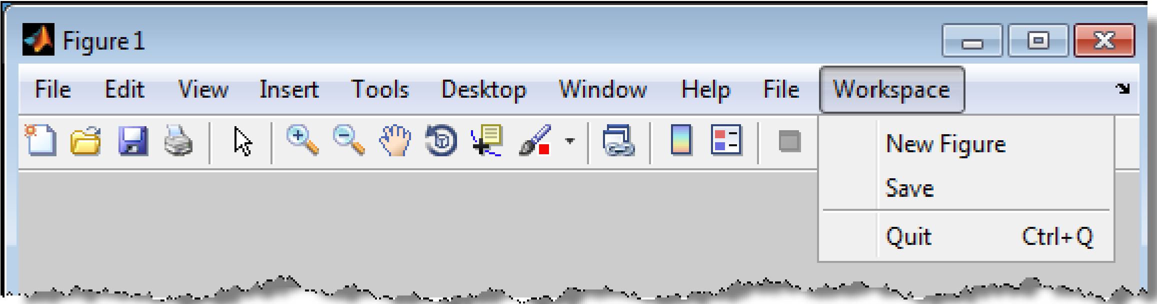
The value of the figure `MenuBar` property affects the content of the figure menu bar. When `MenuBar` is `figure`, a set of built-in menus precedes any user-created uimenus on the menu bar (MATLAB controls the built-in menus and their handles are not available to the user). When `MenuBar` is `none`, uimenus are the only items on the menu bar (that is, the built-in menus do not appear).

See the Uimenu Properties reference page for more information. You can set and query property values after creating a menu with the `set` and `get` functions.

Examples

This example creates a menu labeled **Workspace** with menu options for creating a new figure window, saving workspace variables, and exiting MATLAB. In addition, it defines an accelerator key for the Quit option.

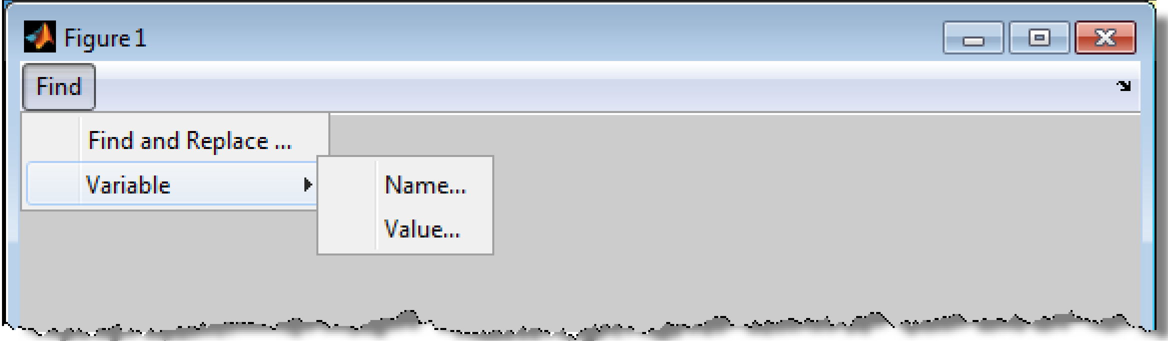
```
f = uimenu('Label','Workspace');
    uimenu(f,'Label','New Figure','Callback','figure');
    uimenu(f,'Label','Save','Callback','save');
    uimenu(f,'Label','Quit','Callback','exit',...
           'Separator','on','Accelerator','Q');
```



This example creates a new figure with a menu bar that excludes the built-in menus. It creates a **Find** menu with options **Find & Replace**, and **Variable**. For the Variable option, it creates a submenu with options of **Name** and **Value**.

```
f=figure('MenuBar','None');
mh = uimenu(f,'Label','Find');
frh = uimenu(mh,'Label','Find and Replace ...',...
           'Callback','goto');
frh = uimenu(mh,'Label','Variable');
uimenu(frh,'Label','Name...', ...
          'Callback','variable');
```

```
uimenu(frh,'Label','Value...', ...
          'Callback','value');
```



This example creates a context menu, **Font**, on a figure with menu options **Helvetica** and **Monospace**. When you run the code and then right-click anywhere within the figure window, the context menu displays.

```
% Create the UICONTEXTMENU
cmenu = uicontextmenu;

% Create the parent menu
fontmenu = uimenu(cmenu, 'label','Font');

% Create the submenus
font1 = uimenu(fontmenu, 'label','Helvetica','Callback', 'HelvFont');
font2 = uimenu(fontmenu, 'label','Monospace','Callback', 'MonoFont');
set(gcf,'uicontextmenu',cmenu);
```

Uimenu Properties | `uicontrol` | `uicontextmenu` | `gcbo` | `set` | `get` | `figure`

Purpose

Describe menu properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` commands enable you to set and query the values of properties

You can set default Uimenu properties on the root, figure and menu levels:

```
set(0,'DefaultUimenuPropertyName',PropertyValue...)
set(gcf,'DefaultUimenuPropertyName',PropertyValue...)
set(menu_handle,'DefaultUimenuPropertyName',PropertyValue...)
```

Where *`PropertyName`* is the name of the Uimenu property and `PropertyValue` is the value you specify as the default for that property.

For more information about changing the default value of property see "Setting Default Property Values"

Uimenu Properties

This section lists all properties useful to `uimenu` objects along with valid values and instructions for their use. Curly braces { } enclose default values.

Property Name	Property Description
`Accelerator`	Keyboard equivalent
`BeingDeleted`	This object is being deleted
`BusyAction`	Callback routine interruption
`Callback`	Control action
`Checked`	Menu check indicator
`Children`	Handles of submenus

Property Name	Property Description
`CreateFcn`	Callback routine executed during object creation
`DeleteFcn`	Callback routine executed during object deletion
`Enable`	Enable or disable the uimenu
`ForegroundColor`	Color of text
`HandleVisibility`	Whether handle is accessible from command line and GUIs
`Interruptible`	Callback routine interruption mode
`Label`	Menu label
`Parent`	Uimenu object's parent
`Position`	Relative uimenu position
`Separator`	Separator line mode
`Tag`	User-specified object identifier
`Type`	Class of graphics object
`UserData`	User-specified data
`Visible`	Uimenu visibility

`Accelerator`

character

Keyboard equivalent. An alphabetic character specifying the keyboard equivalent for the menu item. This allows users to select a particular menu choice by pressing the specified character in conjunction with another key, instead of selecting the menu item with the mouse. The key sequence is platform specific:

- For Microsoft Windows systems, the sequence is **Ctrl**+`Accelerator`. Windows reserves these keys for default

menu items: **c**, **v**, and **x**. For more information, see Keyboard shortcuts for Windows on the Microsoft support Web site.

- For Macintosh systems, the sequence is **Cmd**+`Accelerator`. Apple reserves these keys for default menu items: **a**, **c**, **v**, and **x**. For more information, see Mac OS X keyboard shortcuts on the Apple Computer support Web site.
- For UNIX systems, the sequence is **Ctrl**+`Accelerator`. These keys are reserved for default menu items: **o**, **p**, **s**, and **w**. Many UNIX applications also use **a**, **c**, **v**, and **x** in the same manner as the other platforms.

Accelerated menu items do not have to be displayed for the accelerator key to work (you can accelerate a submenu). However, some restrictions apply:

- You can define an accelerator only for menu items that do not have children menus.
- Accelerators work only for menu items that directly execute a callback routine.
- The figure must be in focus when entering the accelerator key sequence.

To remove an accelerator, set `Accelerator` to an empty string, `''`.

For a cross-platform comparison of accelerators, see the article Table of Keyboard Shortcuts.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback routine interruption. If a callback is executing and the user triggers an event (such as a mouse click) on an object for which a callback is defined, the callback associated with the new event uses the value of `BusyAction` to decide whether or not to attempt to interrupt the executing callback.

- If the value is `cancel`, the event is discarded and the second callback does not execute.
- If the value is `queue`, and the `Interruptible` property of the first callback is `on`, the second callback is added to the event queue and executes in its turn after the first callback finishes execution.

Note If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. See the`Interruptible` property for information about controlling a callback's interruptibility.

`Callback`

string or function handle

Menu action. A callback routine that executes whenever you activate the menu or its submenu (if one exists). Activation is platform dependent. Typically, it is clicking the menu or, if the menu has one, its submenu. Define this routine as a string that

is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB base workspace.

Caution Do not use a uimenu callback to dynamically change menu items. Deleting, adding, and replacing menu items in a callback can result in a blank menu on some platforms. You can hide, show, and disable menu items in a callback to achieve the same effect. To fully repopulate menu items, delete and create them outside the callback.

`Checked`
`on | {off}`

Menu check indicator. Setting this property to `on` places a check mark next to the corresponding menu item. Setting it to `off` removes the check mark. You can use this feature to create menus that indicate the state of a particular option. For example, suppose you have a menu item called **Show axes** that toggles the visibility of an axes between visible and invisible each time the user selects the menu item. If you want a check to appear next to the menu item when the axes are visible, add the following code to the callback for the **Show axes** menu item:

```
if strcmp(get(gcbo, 'Checked'),'on')
    set(gcbo, 'Checked', 'off');
else
    set(gcbo, 'Checked', 'on');
end
```

This changes the value of the `Checked` property of the menu item from `on` to `off` or vice versa each time a user selects the menu item.

Note that there is no formal mechanism for indicating that an unchecked menu item will become checked when selected.

Note This property is ignored for top level and parent menus.

`Children`

vector of handles

Handles of submenus. A vector containing the handles of all children of the uimenu object. The children objects of uimenus are other uimenus, which function as submenus. You can use this property to reorder the menus.

`CreateFcn`

string or function handle

Callback routine executed during object creation. The specified function executes when MATLAB creates a `uimenu` object. MATLAB sets all property values for the uimenu before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uimenu being created.

Setting this property on an existing uimenu object has no effect.

You can define a default `CreateFcn` callback for all new uimenus. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uimenu`. For example, the code

```
set(0,'DefaultUimenuCreateFcn','set(gcbo,...
    ''Visible'',''on'')')
```

creates a default `CreateFcn` callback that runs whenever you create a new menu. It sets the default `Visible` property of a `uimenu` object.

To override this default and create a menu whose `Visible` property is set to a different value, call `uimenu` with code similar to

```
hpt = uimenu(...,'CreateFcn','set(gcbo,...
''Visible'',''off'')')
```

Note To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uimenu` call. In the example above, if instead of redefining the `CreateFcn` property for this uimenu, you had explicitly set `Visible` to `off`, the default `CreateFcn` callback would have set `Visible` back to the default, i.e., `on`.

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`DeleteFcn`

string or function handle

Delete uimenu callback routine. A callback routine that executes when you delete the uimenu object (e.g., when you issue a `delete` command or cause the figure containing the uimenu to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose DeleteFcn is being executed is accessible only through the root `CallbackObject` property, which is more simply queried using gcbo.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`Enable`
`{on} | off`

Enable or disable the uimenu. This property controls whether a menu item can be selected. When not enabled (set to `off`), the menu `Label` appears dimmed, indicating the user cannot select it.

`ForegroundColor`
`ColorSpec` X-Windows only

Color of menu label string. This property determines color of the text defined for the `Label` property. Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default text color is black. See `ColorSpec` for more information on specifying color.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to on to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`Interruptible`
`{on} | off`

Callback routine interruption mode. If a callback is executing and the user triggers an event (such as a mouse click) on an object for which a callback is defined, that callback attempts to interrupt the first callback. MATLAB processes the callbacks according to these factors:

- The `Interruptible` property of the object whose callback is executing
- Whether the executing callback contains `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statements
- The `BusyAction` property of the object whose callback is waiting to execute

If the `Interruptible` property of the object whose callback is executing is `on` (the default), the callback can be interrupted. Whenever the callback calls one of the `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` functions, the function processes any events in the event queue, including the waiting callback, before performing its defined task.

If the `Interruptible` property of the object whose callback is executing is `off`, the callback cannot be interrupted (except by certain callbacks; see the note below). The `BusyAction` property

of the object whose callback is waiting to execute determines what happens to the callback.

Note If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. A figure's `WindowButtonDownFcn` callback routine, or an object's `ButtonDownFcn` or `Callback` routine are processed according to the rules described above.

`Label`

string

Menu label. A string specifying the text label on the menu item. You can specify a mnemonic for the label using the `'&'` character. Except as noted below, the character that follows the `'&'` in the string appears underlined and selects the menu item when you type **Alt+** followed by that character while the menu is visible. The `'&'` character is not displayed. To display the `'&'` character in a label, use two `'&'` characters in the string:

'O&pen selection' yields **Open selection**

'Save && Go' yields **Save & Go**

`'Save&&Go'` yields **Save & Go**

`'Save& Go'` yields **Save& Go** (the space is not a mnemonic)

Tip Avoid specifying mnemonics for applications designed to run on Macintosh computers. Accessing menus with mnemonics violates the principles of Apple Human Interface Guidelines. However, you can set the `Accelerator` property to access individual menu items with key sequences on a Mac.

Avoid including the reserved words, `default`, `remove`, and `factory`, in menu labels unless you escape them. They are case sensitive. To use one of these words in the `Label` property, escape it by preceding it with a backslash (`'\'`) character. For example:

`'\remove'` yields **remove**

`'\default'` yields **default**

`'\factory'` yields **factory**

`Parent`
handle

Uimenu's parent. The handle of the uimenu's parent object. The parent of a uimenu object is the figure on whose menu bar it displays, or the uimenu of which it is a submenu. You can move a uimenu object to another figure by setting this property to the handle of the new parent.

`Position`
scalar

Relative menu position. The value of `Position` indicates placement on the menu bar or within a menu. Top-level menus are placed from left to right on the menu bar according to the value of their `Position` property, with 1 representing the left-most position. The individual items within a given menu are placed from top to bottom according to the value of their `Position` property, with 1 representing the top-most position.

`Separator`
: `on | {off}`

Separator line mode. Setting this property to `on` draws a dividing line above the menu item.

`Tag`
: string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

`Type`
: string (read only)

Class of graphics object. For uimenu objects, `Type` is always the string `'uimenu'`.

`UserData`
: matrix

User-specified data. Any matrix you want to associate with the uimenu object. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
: `{on} | off`

Uimenu visibility. By default, all uimenus are visible. When set to `off`, the uimenu is not visible, but still exists and you can query and set its properties.

Purpose

Convert to 8-bit unsigned integer

Syntax

```
intArray = uint8(array)
```

Description

`intArray = uint8(array)` converts the elements of an array into unsigned 8-bit (1-byte) integers of class `uint8`.

Input Arguments

array

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint8`, the `uint8` function has no effect.

Output Arguments

intArray

Array of class `uint8`. Values range from 0 to $2^8 - 1$.

The `uint8` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint8(2^8)   %  2^8 = 256
```

returns

```
ans =
    255
```

Examples

Convert a `double` array to `uint8`:

```
mydata = uint8(magic(10));
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint8(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint8');   % Preferred
```

See Also

Tutorials

- "Integers"
- "Arithmetic Operations on Integer Classes"

Purpose

Convert to 16-bit unsigned integer

Syntax

```
intArray = uint16(array)
```

Description

`intArray = uint16(array)` converts the elements of an array into unsigned 16-bit (2-byte) integers of class `uint16`.

Input Arguments

array

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint16`, the `uint16` function has no effect.

Output Arguments

intArray

Array of class `uint16`. Values range from 0 to $2^{16} - 1$.

The `uint16` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint16(2^16)   %  2^16 = 65536
```

returns

```
ans =
    65535
```

Examples

Convert a `double` array to `uint16`:

```
mydata = uint16(magic(100));
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint16(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint16');   % Preferred
```

See Also

`double` | `single` | `uint8` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64` | `intmax` | `intmin`

Tutorials

- "Integers"
- "Arithmetic Operations on Integer Classes"

uint32

Purpose

Convert to 32-bit unsigned integer

Syntax

```
intArray = uint32(array)
```

Description

`intArray = uint32(array)` converts the elements of an array into unsigned 32-bit (4-byte) integers of class `uint32`.

Input Arguments

array

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint32`, the `uint32` function has no effect.

Output Arguments

intArray

Array of class `uint32`. Values range from 0 to $2^{32} - 1$.

The `uint32` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint32(2^32)   % 2^32 = 4294967296
```

returns

```
ans =
    4294967295
```

Examples

Convert a `double` array to `uint32`:

```
mydata = uint32(magic(1000));
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint32(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint32');   % Preferred
```

See Also

`double` | `single` | `uint8` | `uint16` | `uint64` | `int8` | `int16` | `int32` | `int64` | `intmax` | `intmin`

Tutorials

- "Integers"
- "Arithmetic Operations on Integer Classes"

Purpose

Convert to 64-bit unsigned integer

Syntax

```
intArray = uint64(array)
```

Description

`intArray = uint64(array)` converts the elements of an array into unsigned 64-bit (8-byte) integers of class `uint64`.

Tips

Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, `double` values cannot represent all integers greater than 2^{53} correctly. Before performing arithmetic operations on values larger than 2^{53} in magnitude, convert the values to 64-bit integers. For example,

```
x = uint64(2^53+1);    % Floating-point arithmetic, loses precision
```

is not as accurate as the 64-bit integer arithmetic operation:

```
x = uint64(2^53) + 1;  % Preferred
```

Input Arguments

array

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint64`, the `uint64` function has no effect.

Output Arguments

intArray

Array of class `uint64`. Values range from 0 to $2^{64} - 1$.

The `uint64` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint64(2^64)   % 2^64 = 18446744073709551616
```

returns

```
ans =
    18446744073709551615
```

Examples

Convert a literal value to `uint64`:

```
x = uint64(9007199254740993);
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint64(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint64');   % Preferred
```

Tutorials

- "Integers"
- "Arithmetic Operations on Integer Classes"

Purpose

Interactively select file to open and load data

Syntax

```
uiopen
uiopen(type)
uiopen(filename)
uiopen(filename, TF)
```

Description

`uiopen` displays the dialog box with the file filter set to all MATLAB files (with file extensions `*.m`, `*.mat`, `*.fig`, `*.mdl, and *.slx`).

`uiopen(type)` sets the file filter according to the `type`.

`uiopen(filename)` displays `filename` as the default value for **File name** in the dialog box and lists only files having the same extension.

`uiopen(filename, TF)` directly opens file `filename` without displaying a dialog box if `TF` is true, and displays the dialog box if `TF` is false.

Tips

When you select a file and click **open**, `uiopen` does the following:

- Gets the file using `uigetfile`.
- Opens the file using the `open` command.
  - Files with a file extension of `.m` open in the Editor.
  - Variables stored in files with a file extension of `.mat` appear in the caller's workspace.
  - Files with a file extension of `.fig` open as figure windows.
  - Files with a file extension of `.mdl` or `.slx` open as models in Simulink.
- `uiopen('load')` is the only the form of `uiopen` that you can compile into a standalone application. You can create a file selection dialog box that you can compile using `uigetfile`.
- The `uiopen` dialog box is modal. A modal dialog box prevents you from interacting with other windows until you respond to the modal one.

- `uiopen` displays the same dialog box that opens when you use the MATLAB desktop toolstrip to open a file. (On the **Home** tab, in the **File** section, click **Open** .)

Input Arguments

type

String that specifies the kind of file to show in the dialog box (the file filter). Acceptable values for `type` are the following.

Type string	Files Displayed
`matlab`	All MATLAB files (with file extensions `*.m`, `*.mat`, `*.fig`, `*.mdl`, and `*.slx`.)
`load`	All MAT-files (`*.mat`)
`figure`	All figure files (`*.fig`)
`simulink`	All Simulink model files (`*.mdl` and `*.slx`)
`editor`	All MATLAB files except for `.mat`, `.fig`, and `.slx` files.

filename

A string, including the file extension, naming a file to open. The filename can be a wildcard character plus extension. For example, `*.txt` displays a list of all files with the file extension `.txt`.

TF

A MATLAB expression that evaluates to `true` or `false`. If `true`, `filename` opens directly, without displaying the dialog.

Definitions

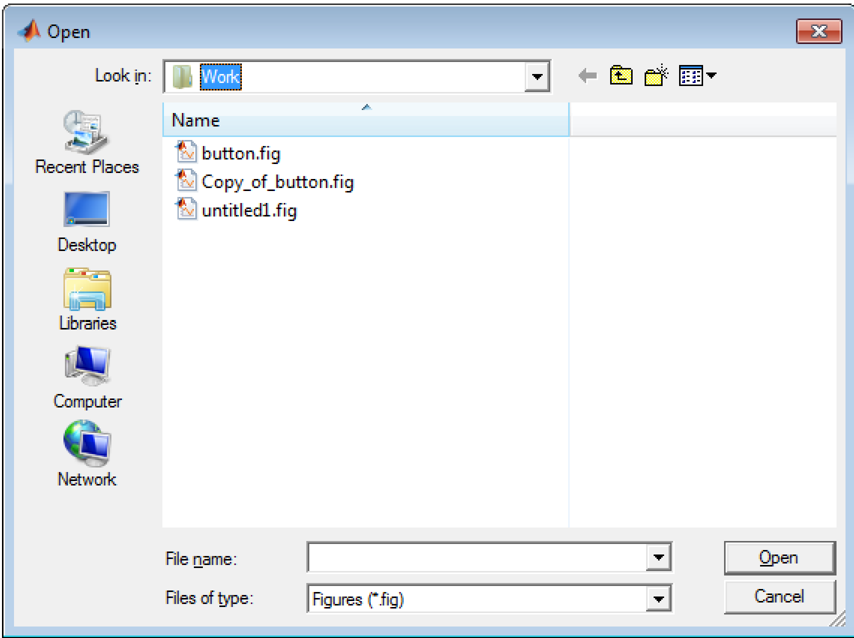
Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

Examples

Filter to display only FIG-files by setting the **Files of type** field to `Figures (*.fig)`:

```
uiopen('figure')
```



Alternatives

In MATLAB code or in a command:

- To open a file appropriately based on its file extension, use the `open` function.
- To open a file in the Editor, use the `edit` function.
- To open a MAT-file and load its contents into the workspace, use the `load` function.
- To open a FIG-file, use the `openfig` function.
- To open a file in an application in Microsoft Windows, use the `winopen` function.

Purpose

Create panel container object

Syntax

```
h = uipanel('PropertyName1',value1,'PropertyName2',value2,
   ...)
h = uipanel(parent,'PropertyName1',value1,'PropertyName2',
   value2,...)
```

Description

A uipanel groups components. It can contain user interface controls with which the user interacts directly. It can also contain axes, other uipanels, and uibuttongroups. It cannot contain ActiveX controls.

`h = uipanel('PropertyName1',value1,'PropertyName2',value2,...)` creates a `uipanel` container object in a figure, uipanel, or uibuttongroup. Use the `Parent` property to specify the parent figure, uipanel, or uibuttongroup. If you do not specify a parent, `uipanel` adds the panel to the current figure. If no figure exists, one is created. See the Uipanel Properties reference page for more information.

`h = uipanel(parent,'PropertyName1',value1,'PropertyName2',value2,...)` creates a uipanel in the object specified by the handle, `parent`. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence. `parent` must be a `figure`, `uipanel`, or `uibuttongroup`.

A `uipanel` object can have `axes`, `uicontrol`, `uipanel`, and `uibuttongroup` objects as children. For the children of a uipanel, the `Position` property is interpreted relative to the uipanel. If you move the panel, the children automatically move with it and maintain their positions relative to the panel.

After creating a `uipanel` object, you can set and query its property values using `set` and `get`.

Tips

If you set the `Visible` property of a uipanel object to `'off'`, any child objects it contains (buttons, button groups, axes, etc.) become invisible along with the panel itself. However, doing this does *not* affect the

settings of the `Visible` property of any of its child objects, even though all of them remain invisible until the uipanel's visibility is set to `'on'`. `uibuttongroup` components also behave in this manner.

Examples

This example creates a uipanel in a figure, then creates a subpanel in the first panel. Finally, it adds a pushbutton to the subpanel. Both panels use the default `Units` property value, `normalized`. Note that default `Units` for the `uicontrol` pushbutton is pixels.

```
h = figure;
hp = uipanel('Title','Main Panel','FontSize',12,...
             'BackgroundColor','white',...
             'Position',[.25 .1 .67 .67]);
hsp = uipanel('Parent',hp,'Title','Subpanel','FontSize',12,...
              'Position',[.4 .1 .5 .5]);
hbsp = uicontrol('Parent',hsp,'String','Push here',...
              'Position',[18 18 72 36]);
```

Uipanel Properties

Purpose

Describe panel properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default uipanel properties by typing:

```
set(h,'DefaultUipanelPropertyName',PropertyValue...)
```

Where h can be the root handle (0), a figure handle, or a uipanel handle. *`PropertyName`* is the name of the uipanel property and `PropertyValue` is the value you specify as the default for that property.

Note Default properties you set for uipanels also apply to uibuttongroups.

For more information about changing the default value of a property see "Setting Default Property Values". For an example, see the `CreateFcn` property.

Uipanel Properties

This section lists all properties useful to `uipanel` objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property Name	Description
`BackgroundColor`	Color of the uipanel background
`BeingDeleted`	This object is being deleted
`BorderType`	Type of border around the uipanel area.

Property Name	Description
BorderWidth	Width of the panel border.
BusyAction	Interruption of other callback routines
ButtonDownFcn	Button-press callback routine
Children	All children of the uipanel
Clipping	Clipping of child axes, uipanels, and uibuttongroups to the uipanel. Does not affect child uicontrols.
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
FontAngle	Title font angle
FontName	Title font name
FontSize	Title font size
FontUnits	Title font units
FontWeight	Title font weight
ForegroundColor	Title font color and/or color of 2-D border line
HandleVisibility	Handle accessibility from commandline and GUIs
HighlightColor	3-D frame highlight color
HitTest	Selectable by mouse click
Interruptible	Callback routine interruption mode
Parent	Uipanel object's parent
Position	Panel position relative to parent figure or uipanel
ResizeFcn	User-specified resize routine

Property Name	Description
`Selected`	Whether object is selected
`SelectionHighlight`	Object highlighted when selected
`ShadowColor`	3-D frame shadow color
`Tag`	User-specified object identifier
`Title`	Title string
`TitlePosition`	Location of title string in relation to the panel
`Type`	Object class
`UIContextMenu`	Associates uicontextmenu with the uipanel
`Units`	Units used to interpret the position vector
`UserData`	User-specified data
`Visible`	Uipanel visibility. **Note** Controls the visibility of a uipanel and of its child axes, uibuttongroups. uipanels, and child uicontrols. Setting it does not change their `Visible` property.

`BackgroundColor`
`ColorSpec`

Color of the uipanel background. A three-element RGB vector or one of the MATLAB predefined names, specifying the background color. See the `ColorSpec` reference page for more information on specifying color.

`BeingDeleted`
`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BorderType`

`none | {etchedin} | etchedout | beveledin | beveledout | line`

Border of the uipanel area. Used to define the panel area graphically. Etched and beveled borders provide a 3-D look. Use the `HighlightColor` and `ShadowColor` properties to specify the border color of etched and beveled borders. A line border is 2-D. Use the `ForegroundColor` property to specify its color.

`BorderWidth`

`integer`

Width of the panel border. The width of the panel borders in pixels. The default border width is 1 pixel. 3-D borders wider than 3 may not appear correctly at the corners.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

running callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`
string or function handle

Button-press callback routine. A callback routine that executes when you press a mouse button while the pointer is in a 5-pixel wide border around the uipanel. This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on (using the selectmoveresize function, for example).

If you define this routine as a string, the string can be a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

`Children`
vector of handles

Children of the uipanel. A vector containing the handles of all children of the uipanel. A `uipanel` object's children are axes, uipanels, uibuttongroups, and uicontrols. You can use this property to reorder the children.

`Clipping`
`{on} | off`

Clipping mode. By default, MATLAB clips a uipanel's child axes, uipanels, and uibuttongroups to the uipanel rectangle. If you set `Clipping` to `off`, the axis, uipanel, or uibuttongroup is displayed outside the panel rectangle. This property does not affect child uicontrols which, by default, can display outside the panel rectangle.

`CreateFcn`

string or function handle

Callback routine executed during object creation. The specified function executes when MATLAB creates a `uipanel` object. MATLAB sets all property values for the uipanel before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uipanel being created.

Setting this property on an existing uipanel object has no effect.

You can define a default `CreateFcn` callback for all new uipanels. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uipanel`. For example, the code

```
set(0,'DefaultUipanelCreateFcn','set(gcbo,...
    ''FontName'',''arial'',''FontSize'',12)')
```

creates a default `CreateFcn` callback that runs whenever you create a new panel. It sets the default font name and font size of the uipanel title.

Note Uibuttongroup takes its default property values from uipanel. Defining a default property for all uipanels defines the same default property for all uibuttongroups.

To override this default and create a panel whose `FontName and FontSize` properties are set to different values, call `uipanel` with code similar to

```
hpt = uipanel(...,'CreateFcn','set(gcbo,...
''FontName'',''times'',''FontSize'',14)')
```

Note To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uipushtool` call. In the example above, if instead of redefining the `CreateFcn` property for this uipanel, you had explicitly set `Fontsize` to `14`, the default `CreateFcn` callback would have set `FontSize` back to the system dependent default.

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`DeleteFcn`
string or function handle

Callback routine executed during object deletion. A callback routine that executes when you delete the uipanel object (e.g., when you issue a delete command or clear the figure containing the uipanel). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine. The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

`FontAngle`
    `{normal} | italic | oblique`

Character slant used in the Title. MATLAB uses this property to select a font from those available on your particular system. Setting this property to `italic` or `oblique` selects a slanted version of the font, when it is available on your system.

`FontName`
    string

Font family used in the Title. The name of the font in which to display the `Title`. To display and print properly, this must be a font that your system supports. The default font is system dependent. To eliminate the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan), set `FontName` to the string `FixedWidth` (this string value is case insensitive).

```
set(uicontrol_handle,'FontName','FixedWidth')
```

This then uses the value of the root `FixedWidthFontName` property which can be set to the appropriate value for a locale from `startup.m` in the end user's environment. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font

`FontSize`
    integer

Title font size. A number specifying the size of the font in which to display the Title, in units determined by the `FontUnits` property. The default size is system dependent.

`FontUnits`
    `inches | centimeters | normalized | {points} |pixels`

Title font size units. `Normalized` units interpret `FontSize` as a fraction of the height of the uipanel. When you resize the uipanel, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

`FontWeight`
: `light | {normal} | demi | bold`

Weight of characters in the title. MATLAB uses this property to select a font from those available on your particular system. Setting this property to bold causes MATLAB to use a bold version of the font, when it is available on your system.

`ForegroundColor`
: `ColorSpec`

Color used for title font and 2-D border line. A three-element RGB vector or one of the MATLAB predefined names, specifying the font or line color. See the `ColorSpec` reference page for more information on specifying color.

`HandleVisibility`
: `{on} | callback | off`

Control access to object's handle. This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.

- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to on to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HighlightColor`
`ColorSpec`

3-D frame highlight color. A three-element RGB vector or one of the MATLAB predefined names, specifying the highlight color. See the `ColorSpec` reference page for more information on specifying color.

`HitTest`
`{on} | off`

Selectable by mouse click. `HitTest` determines if the uipanel can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the panel. If `HitTest` is `off`, clicking the panel sets the `CurrentObject` to the closest ancestor of the panel that registers `HitTest`. The uipanel property `HandleVisibility` must be `'on'` for it to become the `CurrentObject`. If the uipanel `HandleVisibility` is `'off'` or `'callback'`, or if the panel and all

its ancestors have `HitTest` set to `'off'`, the figure `CurrentObject` is the empty matrix.

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:

- If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

Note If the interrupting callback is a `DeleteFcn`or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

`Parent`
handle

Uipanel parent. The handle of the uipanel's parent figure, uipanel, or uibuttongroup. You can move a uipanel object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

`Position`
position rectangle

Size and location of uipanel relative to parent. The rectangle defined by this property specifies the size and location of the panel within the parent figure window, uipanel, or uibuttongroup. Specify `Position` as

```
[left bottom width height]
```

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the `uipanel` object. `width` and `height` are the dimensions of the uipanel rectangle, including the title. All measurements are in units specified by the `Units` property.

`ResizeFcn`
function handle or string

Resize callback routine. MATLAB executes this callback routine whenever a user manually or programmatically resizes the uipanel, or in GUIDE, the Resize behavior option is set to `other`. You can query the uipanel `Position` property to determine its new size and position. During execution of the callback routine, the handle to the uipanel being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

All axes, uipanel, uitable and uicontrol objects that have their `Units` set to `normalized` automatically resize proportionally to the figure. You can define individual resize functions for any such object as needed. For example, you can use `ResizeFcn` to maintain a GUI layout that is not directly supported by the MATLAB `Position`-and-`Units` paradigm.

For example, consider a GUI layout that maintains an object attached to the top of the figure at a constant height in pixels, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the uicontrol whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the uicontrol handle, and the `gcbo` function to retrieve the figure handle. The code also does “defensive programming” to save and restores figure `Units`. The callback requires `Units` in pixels in order to work correctly, but takes care not to permanently alter that property.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

You can change the figure `Position` from within a uipanel `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

A figure's uipanels resize before the figure itself does. Nested uipanels resize from inner to outer, with child `ResizeFcn`s being called before parent `ResizeFcn`s.

The `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is set to `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

See Resize Behavior for information on creating resize functions using GUIDE.

`Selected`
`on | off` (read only)

Is object selected? This property indicates whether the panel is selected. When this property is `on`, MATLAB displays selection handles if the `SelectionHighlight` property is also `on`. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

`SelectionHighlight`
`{on} | off`

Object highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`ShadowColor`
`ColorSpec`

3-D frame shadow color. A three-element RGB vector or one of the MATLAB predefined names, specifying the shadow color. See the `ColorSpec` reference page for more information on specifying color.

`Tag`
string

User-specified object identifier. The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the `Tag` value `'FormatTb'`.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

`Title`
string

Title string. The text displayed in the panel title. Vertical slash ('`|`') characters are not interpreted as line breaks and instead show up in the text displayed in the uipanel title. You can position the title using the `TitlePosition` property.

Setting a property value to `default`, `remove`, or `factory` produces the effect described in "Defining Default Values". To set `Title` to one of these words, you must precede the word with the backslash character. For example,

```
hp = uipanel(...,'Title','\Default');
```

`TitlePosition`
`{lefttop} | centertop | righttop | leftbottom | centerbottom | rightbottom`

Location of the title. This property determines the location of the title string, in relation to the uipanel.

`Type`
: `string` (read-only)

  Object class. This property identifies the kind of graphics object. For uipanel objects, `Type` is always the string `'uipanel'`.

`UIContextMenu`
: handle

  Associate a context menu with a uipanel. Assign this property the handle of a `Uicontextmenu` object. MATLAB displays the context menu whenever you right-click the `uipanel`. Use the `uicontextmenu` function to create the context menu.

`Units`
: `inches | centimeters | {normalized} | points | pixels | characters`

  Units of measurement. MATLAB uses these units to interpret the `Position` property. For the panel itself, units are measured from the lower-left corner of the figure window. For children of the panel, they are measured from the lower-left corner of the panel.

  - `Normalized` units map the lower-left corner of the panel or figure window to (0,0) and the upper-right corner to (1.0,1.0).
  - `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).
  - `Character` units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

  If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not

to affect other functions that assume `Units` is set to the default value.

`UserData`

matrix

User-specified data. Any data you want to associate with the `uipanel` object. MATLAB does not use this data, but you can access it using `set` and `get`.

`Visible`

`{on} | off`

Uipanel visibility. By default, a `uipanel` object is visible. When set to `'off'`, the uipanel is not visible, as are all child objects of the panel. When a panel is hidden in this manner, you can still query and set its properties.

Note The value of a uipanel's `Visible` property determines whether its child components, such as axes, buttons, uibuttongroups, and other uipanels, are visible. However, changing the `Visible` property of a panel does *not* change the settings of the `Visible` property of its child components even though hiding the panel causes them to be hidden.

Purpose

Create push button on toolbar

Syntax

```
hpt = uipushtool
hpt = uipushtool('PropertyName1',value1,'PropertyName2',
   value2,...)
hpt = uipushtool(ht,...)
```

Description

`hpt = uipushtool` creates a push button on the uitoolbar at the top of the current figure window, sets all its properties to default values, and returns a handle to the tool. If no uitoolbar exists, one is created. The uitoolbar is the parent of the uipushtool. Use the returned handle `hpt` to set properties of the tool. The `ClickedCallback` passes the handle as its first argument. The button has no icon, but its border highlights when you hover over it with the mouse cursor. Add an icon by setting `CData` for the tool.

`hpt = uipushtool('`*`PropertyName1`*`',value1,'`*`PropertyName2`*`',value2,...)`, creates a uipushtool and returns a handle to it. `uipushtool` assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the `set` function. You can specify properties as parameter name/value pairs, cell arrays containing parameter names and values, or structures with fields containing parameter names and values as input arguments. For a complete list, see Uipushtool Properties. Type `get(hpt)` to see a list of uipushtool object properties and their current values. Type `set(hpt)` to see a list of uipushtool object properties that you can set and their legal property values.

`hpt = uipushtool(ht,...)` creates a button with `ht` as a parent. `ht` must be a uitoolbar handle.

Uipushtools appear in figures whose `Window Style` is `'normal'` or `'docked'`. Push tools do not appear in figures with `'modal'` `WindowStyle`. If you change the `WindowStyle` of a figure containing a uitoolbar and its uipushtool children to `'modal'`, the uipushtools continue to exist as `Children` of the uitoolbar. However, they do

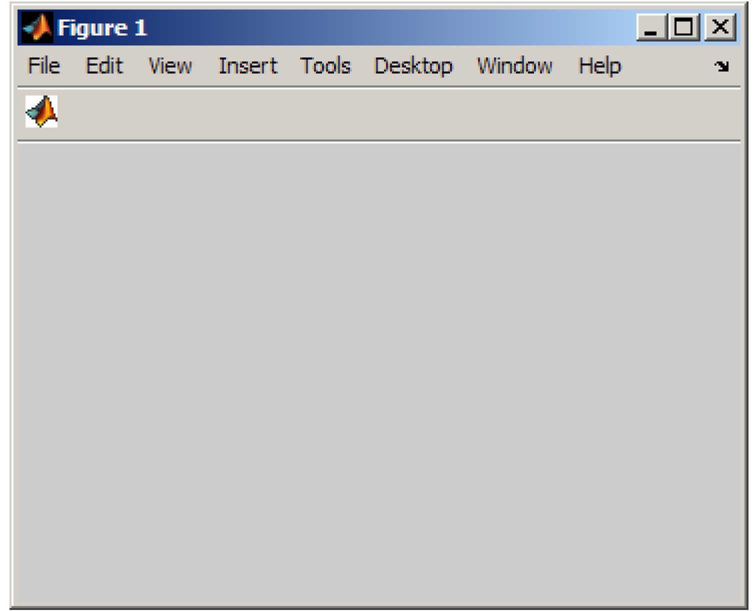
not display until you change the figure `WindowStyle` to `'normal'` or `'docked'`.

Unlike push buttons, uipushtools have no way to indicate that you have double-clicked them. That is, a double click does not set the figure `SelectionType` property to `'open'`. Double-clicking a uipushtool simply executes its `ClickedCallback` twice in succession. Also, uipushtools cannot have context menus.

Examples

Create a uitoolbar object and places a uipushtool object on it. Generate an icon for the tool by reading a GIF file containing a MATLAB icon. Convert the indexed image to a truecolor image before specifying it as `CData`.

```
h  = figure('ToolBar','none');
ht = uitoolbar(h);
% Use a MATLAB icon for the tool
[X map] = imread(fullfile(...
    matlabroot,'toolbox','matlab','icons','matlabicon.gif'));
% Convert indexed image and colormap to truecolor
icon = ind2rgb(X,map);
% Create a uipushtool in the toolbar
hpt = uipushtool(ht,'CData',icon,...
                 'TooltipString','Toolbar push button',...
                 'ClickedCallback',...
                 'disp(''Thank you for clicking a uipushtool.'')')
```



Alternatives

You can also create toolbars with push tools using GUIDE.

Tutorials

- "GUI with Axes, Menu, and Toolbar"

How To

- "Create Toolbars for Programmatic GUIs"

Purpose

Describe push tool properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uipushtool properties by typing:

```
set(h,'DefaultUipushtoolPropertyName',PropertyValue...)
```

Where h can be the root handle (0), a figure handle, a uitoolbar handle, or a uipushtool handle. *`PropertyName`* is the name of the `Uipushtool` property and `PropertyValue` is the value you specify as the default for that property.

For more information about changing the default value of a property see Setting Default Property Values.

Uipushtool Properties

This section lists all properties useful to `uipushtool` objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property	Purpose
`BeingDeleted`	This object is being deleted.
`BusyAction`	Callback routine interruption.
`CData`	Truecolor image displayed on the control.
`ClickedCallback`	Control action.
`CreateFcn`	Callback routine executed during object creation.
`DeleteFcn`	Delete uipushtool callback routine.

Property	Purpose
Enable	Enable or disable the uipushtool.
HandleVisibility	Control access to object's handle.
HitTest	Whether selectable by mouse click
Interruptible	Callback routine interruption mode.
Parent	Handle of uipushtool's parent.
Separator	Separator line mode
Tag	User-specified object label.
TooltipString	Content of object's tooltip.
Type	Object class.
UIContextMenu	Uicontextmenu object associated with the uipushtool
UserData	User specified data.
Visible	Uipushtool visibility.

`BeingDeleted`

`on | {off}` (read only)

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`CData`

3-dimensional array

Truecolor image displayed on control. An *n*-by-*m*-by-3 array of RGB values that defines a truecolor image displayed on either a push button or toggle button. Each value must be between 0.0 and 1.0. If your `CData` array is larger than 16 in the first or second dimension, it may be clipped or cause other undesirable effects. If the array is clipped, only the center 16-by-16 part of the array is used.

`ClickedCallback`

string or function handle

Control action. A routine that executes when the uipushtool's `Enable` property is set to `on`, and you press a mouse button while the pointer is on the push tool itself or in a 5-pixel wide border around it.

`CreateFcn`

string or function handle

Callback routine executed during object creation. The specified function executes when MATLAB creates a uipushtool object. MATLAB sets all property values for the uipushtool before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the push tool being created.

Setting this property on an existing uipushtool object has no effect.

You can define a default `CreateFcn` callback for all new uipushtools. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uipushtool`. For example, the code

```
imga(:,:,1) = rand(20);
imga(:,:,2) = rand(20);
imga(:,:,3) = rand(20);
set(0,'DefaultUipushtoolCreateFcn','set(gcbo,''Cdata'',imga)')
```

creates a default `CreateFcn` callback that runs whenever you create a new push tool. It sets the default image `imga` on the push tool.

To override this default and create a push tool whose `Cdata` property is set to a different image, call `uipushtool` with code similar to

```
a = [.05:.05:0.95];
imgb(:,:,1) = repmat(a,19,1)';
imgb(:,:,2) = repmat(a,19,1);
```

```
imgb(:,:,3) = repmat(flipdim(a,2),19,1);
hpt = uipushtool(...,'CreateFcn','set(gcbo,''CData'',imgb)',...)
```

Note To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uipushtool` call. In the example above, if instead of redefining the `CreateFcn` property for this push tool, you had explicitly set `CData` to `imgb`, the default `CreateFcn` callback would have set `CData` back to `imga`.

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`DeleteFcn`

string or function handle

Callback routine executed during object deletion. A callback routine that executes when you delete the uipushtool object (e.g., when you call the `delete` function or cause the figure containing the uipushtool to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose DeleteFcn is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`Enable`
`{on} | off`

Enable or disable the uipushtool. This property controls how uipushtools respond to mouse button clicks, including which callback routines execute.

- `on` – The uipushtool is operational (the default).
- `off` – The uipushtool is not operational and its image (set by the `Cdata` property) is grayed out.

When you left-click a uipushtool whose `Enable` property is `on`, MATLAB performs these actions in this order:

1. Executes the push tool's `ClickedCallback` routine.
2. Does *not* set the figure `CurrentPoint` property and does not execute the figure's `WindowButtonDownFcn` callback.
3. Does *not* set the figure `SelectionType` property.

When you left-click a uipushtool whose `Enable` property is `off`, or when you right-click a uipushtool whose `Enable` property has any value, no action is reported, no callback executes, and neither the `SelectionType` nor `CurrentPoint` figure properties are modified.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to on to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`
`{on} | off`

Selectable by mouse click. This property has no effect on uipushtool objects.

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`

- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

Note If the interrupting callback is a `DeleteFcn`nor `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

`Parent`

handle

Uipushtool parent. The handle of the uipushtool's parent toolbar. You can move a uipushtool object to another toolbar by setting this property to the handle of the new parent.

`Separator`

`on | {off}`

Separator line mode. Setting this property to `on` draws a dividing line to the left of the uipushtool.

`Tag`

string

User-specified object identifier. The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified toolbars) that have the `Tag` value `'Copy'`.

```
h = findobj(uitoolbarhandles,'Tag','Copy')
```

`TooltipString`
string

Content of tooltip for object. The `TooltipString` property specifies the text of the tooltip associated with the uipushtool. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uipushtool;
s = sprintf('Pushtool tooltip line 1\nPushtool tooltip line 2');
set(h,'TooltipString',s)
```

`Type`
string (read-only)

Object class. This property identifies the kind of graphics object. For uipushtool objects, `Type` is always the string `'uipushtool'`.

`UIContextMenu`
handle

Associate a context menu with uicontrol. This property has no effect on uipushtool objects.

`UserData`

array

User specified data. You can specify `UserData` as any array you want to associate with the uipushtool object. The object does not use this data, but you can access it using the `set` and `get` functions.

`Visible`

`{on} | off`

Uipushtool visibility. By default, all uipushtools are visible. When set to `off`, the uipushtool is not visible, but still exists and you can query and set its properties.

uiputfile

Purpose

Open standard dialog box for saving files

Syntax

```
FileName = uiputfile
[FileName,PathName] = uiputfile
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,
   DialogTitle)
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,
   DialogTitle,DefaultName)
```

Description

Note Successful execution of `uiputfile` does not create a file; it only returns the name of a new or existing file that you designate.

`FileName = uiputfile` displays a modal dialog box for selecting or specifying a file you want to create or save. The dialog box lists the files and folders in the current folder. If the selected or specified file name is valid, `uiputfile` returns it in `FileName`.

`[FileName,PathName] = uiputfile` also returns the path to `FileName` in `PathName`, or if you cancel the dialog, returns `0` for both arguments. If you do not provide any output arguments, the file name alone is returned in `ans`.

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uiputfile` also displays in gray any files that do not match `FilterSpec`. The `uiputfile` function appends `'All Files'` to the list of file types. `FilterSpec` can be a string or a cell array of strings, and can include the `*` and `?` wildcard characters. For example, `'*.m'` lists all MATLAB program files in a folder.

`FilterSpec` can be a string that contains a file name. `uiputfile` displays the file name selected in the **File name** field and uses the file extension as the default filter. The `FilterSpec` string can include a path, or consist of a path only. To specify a folder only, make the

last character in `DefaultName` `'\'` or `'/'`. A path can contain special path characters, such as `'.'`, `'..'`, `'/'`, `'\'`, or `'~'`. For example, `'../*.m'` lists all program files in the folder above the current folder. If `FilterSpec` is a cell array of strings, the first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace the default descriptions in the **Save as type** pop-up menu. A description cannot be an empty string. See the "Examples" on page 1-5853 for illustration of using cell arrays as `FilterSpec`. If you do not specify `FilterSpec`, `uiputfile` uses the default list of file types (all MATLAB files). `FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click the **Cancel** button, close the dialog window, or if the file does not exist, `uiputfile` returns `FilterIndex` as `0`.

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,DialogTitle)` displays a dialog box that has the title `DialogTitle`. To use the default file types and to specify a dialog title, enter `uiputfile('','DialogTitle')`

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,DialogTitle,DefaultName)` displays a dialog box in which the file name specified by `DefaultName` appears in the **File name** field. `DefaultName` can also be a path or a path+filename. To specify a folder only, make the last character in `DefaultName` `'\'` or `'/'`. In this case, `uiputfile` opens the dialog box in the folder specified by the path. If you specify a path in `DefaultName` that does not exist, `uiputfile` opens the dialog box in the current folder. You can use `'.'`,`'..'`, `'\'`, `'/'`, or ~ in the `DefaultName` argument.

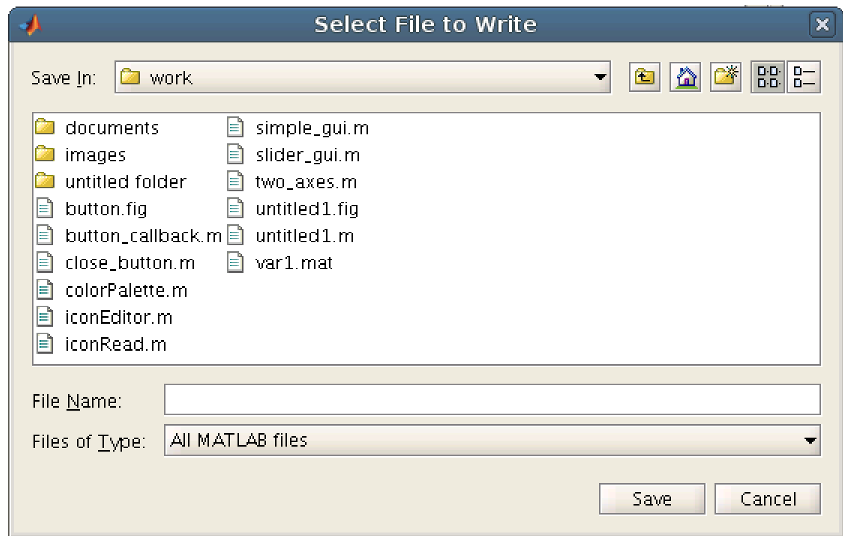
When typing into the dialog box, if you include either of the wildcard characters `'*'` or `'?'` in a file name, `uiputfile` does not respond to clicking **Save**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

If you select or specify an existing file name, a warning dialog box opens stating that the file already exists and asks if you want to replace it.

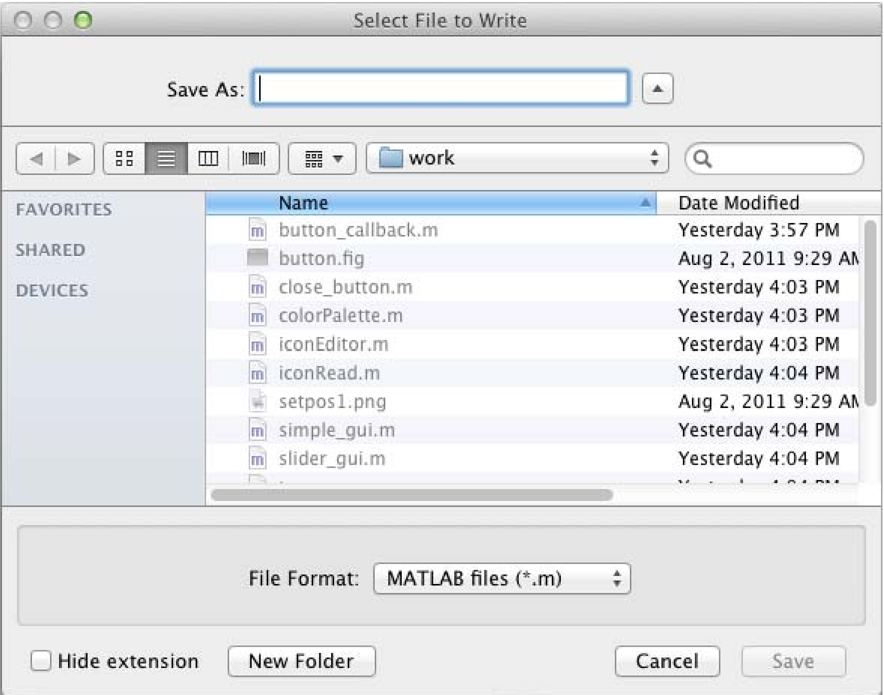
Select **Yes** to replace the existing file or **No** to return to the dialog to select another file name. Selecting **Yes** returns the name of the file. Selecting **No** returns 0.

For Microsoft Windows platforms, the dialog box is the Windows dialog box native to your platform, and thus can differ from what you see in the examples that follow.

For UNIX platforms, the dialog box is like the one shown in the following figure.



For Mac platforms, the dialog box is like the one shown in the following figure.

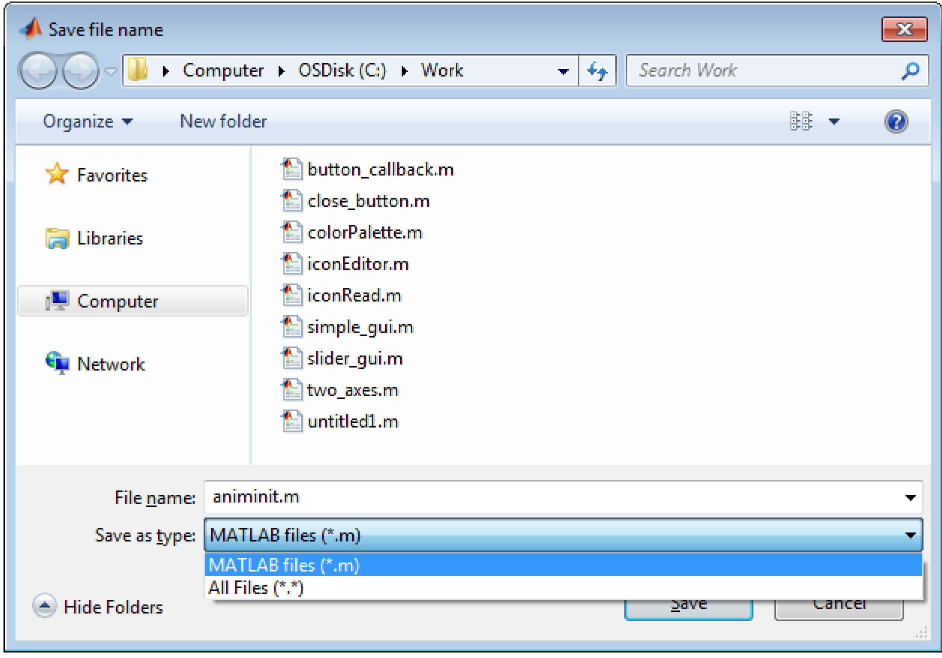


Note A modal dialog box prevents you from interacting with other MATLAB windows before responding. To block MATLAB program execution as well, use the `uiwait` function. For more information about modal dialog boxes, see `WindowStyle` in MATLAB Figure Properties.

Examples

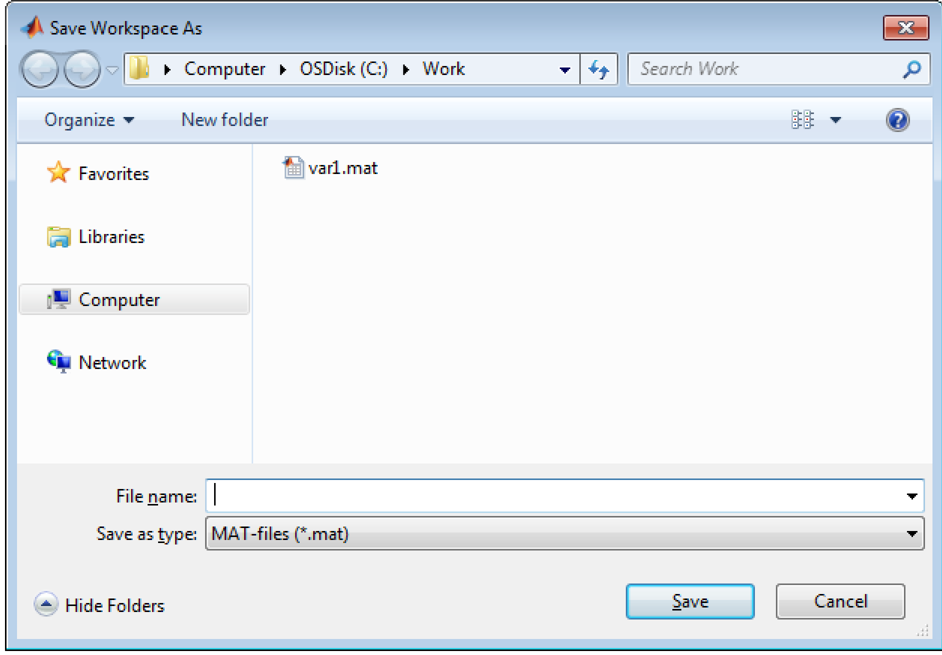
The following statement displays a dialog box entitled `'Save file name'`, setting the **File name** field to `animinit.m` and the filter to `program files (*.m)`. Because `FilterSpec` is a string, the filter also includes `All Files (*.*)`

```
[file,path] = uiputfile('animinit.m','Save file name');
```



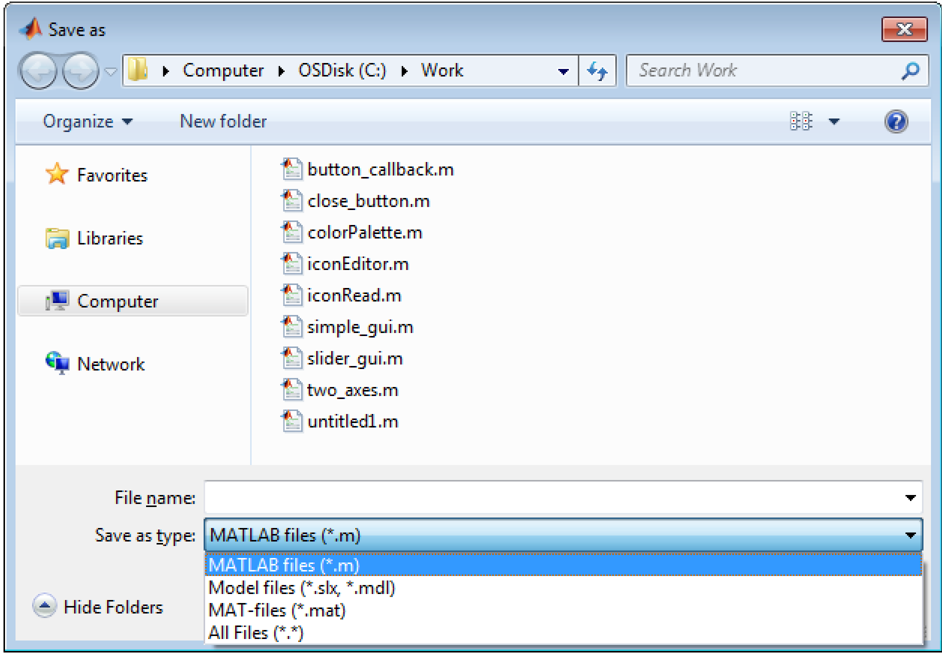
The following statement displays a dialog box entitled `'Save Workspace As'` with the filter set to MAT-files.

```
[file,path] = uiputfile('*.mat','Save Workspace As');
```



To display several file types in the **Save as type** list box, separate each file extension with a semicolon, as in the following code. `uiputfile` displays a default description for each known file type, such as "Model files" for Simulink `.mdl` and `.slx` files.

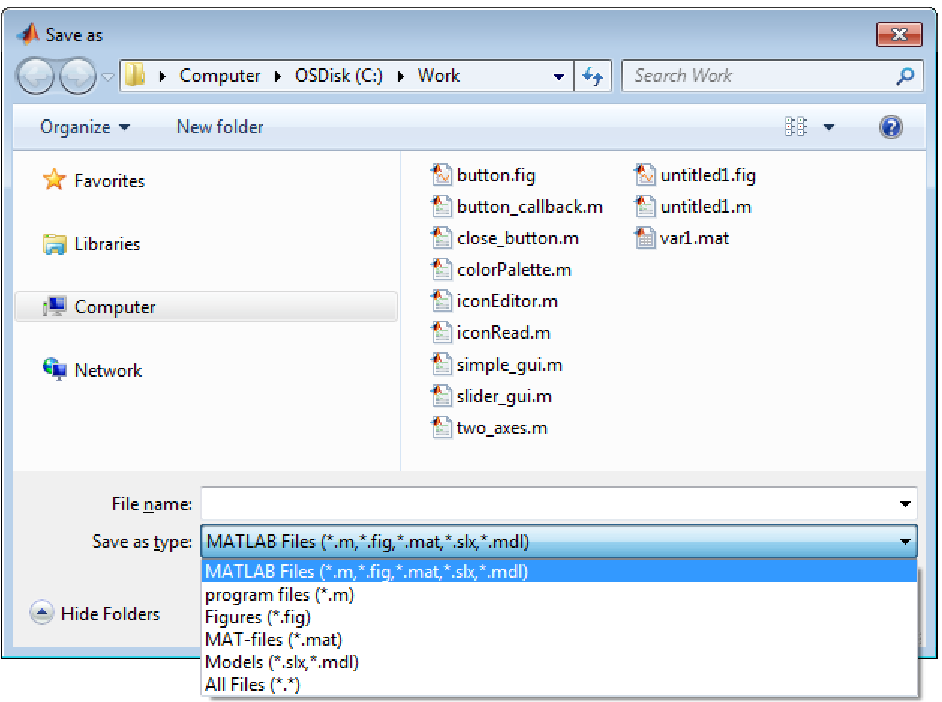
```
[filename, pathname] = uiputfile(...
 {'*.m';'*.slx';'*.mat';'*.*'},...
 'Save as');
```



To create a list of file types and give them descriptions that are different from the defaults, use a cell array. This example also associates multiple file types with the `'MATLAB Files'` and `'Models'` descriptions.

```
[filename, pathname, filterindex] = uiputfile( ...
{'*.m;*.fig;*.mat;*.slx;*.mdl',...
 'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';
 '*.m', 'program files (*.m)';...
 '*.fig','Figures (*.fig)';...
 '*.mat','MAT-files (*.mat)';...
 '*.slx;*.mdl','Models (*.slx,*.mdl)';...
 '*.*',  'All Files (*.*)'},...
 'Save as');
```

The first column of the cell array contains the file extensions, while the second contains the descriptions you want to provide for the file types. The first entry of column one contains several extensions separated by semicolons. These file types all associate with the description `'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)'`. The code produces the dialog box shown in the following figure.



The following code checks for the existence of the file and displays a message about the result of the file selection operation.

```
[filename, pathname] = uiputfile('*.m','Pick a MATLAB program file');
if isequal(filename,0) || isequal(pathname,0)
   disp('User selected Cancel')
else
```

```
   disp(['User selected ',fullfile(pathname,filename)])
end
```

Select or enter a file name for saving a figure as an image in one of four formats, described in a cell array.

```
uiputfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...
          '*.*','All Files' },'Save Image',...
          'C:\Work\newfile.jpg')
```

save | uigetdir | uigetfile | uisave

Purpose

Resume execution of blocked program

Syntax

```
uiresume(h)
```

Description

`uiresume(h)` resumes the program execution that `uiwait` suspended.

Tips

The `uiwait` and `uiresume` functions block and resume MATLAB program execution. When creating a dialog box, you should have a uicontrol component with a callback that calls `uiresume` or a callback that destroys the dialog box. These are the only methods that resume program execution after the `uiwait` function blocks execution.

When used in conjunction with a modal dialog box, `uiresume` can resume the execution of the program that `uiwait` suspended while presenting a dialog box.

Examples

This example creates a GUI with a **Continue** push button. The example calls `uiwait` to block MATLAB execution until `uiresume` is called. This happens when the user clicks the **Continue** push button because the push button's `Callback`, which responds to the click, calls `uiresume`.

```
f = figure;
h = uicontrol('Position',[20 20 200 40],'String','Continue',...
              'Callback','uiresume(gcbf)');
disp('This will print immediately');
uiwait(gcf);
disp('This will print after you click Continue');
close(f);
```

`gcbf` is the handle of the figure that contains the object whose callback is executing.

"Modal Dialog Box (GUIDE)" is a more complex example for a GUIDE GUI.

uisave

Purpose

Interactively save workspace variables to MAT-file

Syntax

```
uisave
uisave(variables)
uisave(variables,filename)
```

Description

`uisave`, with no arguments, prompts you for a file name, and then saves all variables from your workspace to that file.

`uisave(variables)` saves one or more workspace variables listed in `variables`.

`uisave(variables,filename)` uses the specified `filename` as the default **File name** in the Save Workspace Variables dialog box, instead of the default `matlab.mat`.

Tips

- If you type a name in the **File name** field, such as `my_vars`, and click **Save**, the dialog saves all workspace variables to the file `my_vars.mat`. The default filename is `matlab.mat`.
- `uisave` calls `uiputfile` to choose a filename.
- If the filename you specify exists in that folder, `uisave` informs you and gives you a chance to cancel the operation.
- The `uisave` dialog box is modal.
- The `uisave` dialog is modal. A modal dialog box prevents you from interacting with other windows until you respond to it.

Input Arguments

variable

String containing the name of a variable in the current workspace or cell array of strings when specifying more than one variable.

> **Default:** All variables in the current workspace are saved to a MAT-file.

filename

String naming a file to appear in the dialog **File name** field when the dialog opens. You can omit a file extension, or specify the file extension as `.mat`.

Default: `matlab.mat`

Definitions

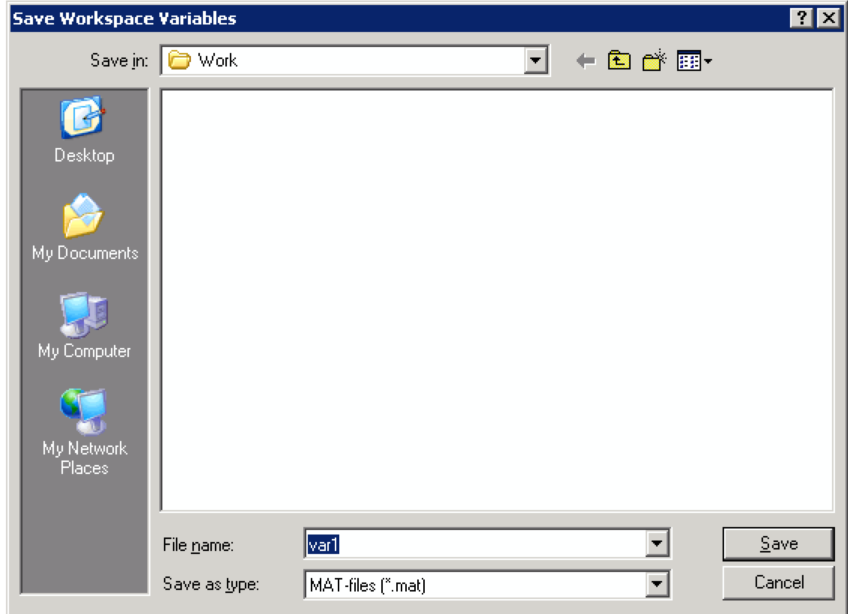
Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

Examples

Create workspace variables `h` and `g`, and then display the Save Workspace Variables dialog box in the current folder with the default **File name** set to `var1`.

```
h = 365;
g = 52;
uisave({'h','g'},'var1');
```



Clicking **Save** stores the workspace variables `h` and `g` in the file `var1.mat` in the displayed folder.

Alternatives

Use any of the following GUI options to save workspace variables:

- Use **File > Save** to save workspace variables.
- Click the Save icon in the Workspace Browser.
- Select one or more variables in the Workspace Browser, right-click, and choose **Save as** from the context menu.

`save` | `uigetfile` | `uiputfile` | `uiopen`

Tutorials

- "Save, Load, and Delete Workspace Variables"

Purpose

Open standard dialog box for setting object's ColorSpec

Syntax

```
c = uisetcolor
c = uisetcolor([r g b])
c = uisetcolor(h)
c = uisetcolor(...,'dialogTitle')
```

Description

`c = uisetcolor` displays a modal color selection dialog appropriate to the platform, and returns the color selected by the user. The dialog box is initialized to `white`.

`c = uisetcolor([r g b])` displays a dialog box initialized to the specified color, and returns the color selected by the user. `r`, `g`, and `b` must be values between 0 and 1.

`c = uisetcolor(h)` displays a dialog box initialized to the color of the object specified by handle `h`, returns the color selected by the user, and applies it to the object. `h` must be the handle to an object containing a color property.

`c = uisetcolor(...,'dialogTitle')` displays a dialog box with the specified title.

If the user presses **Cancel** from the dialog box, or if any error occurs, the output value is set to the input RGB triple, if provided; otherwise, it is set to 0.

Note A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

See Also

`ColorSpec`

uisetfont

Purpose

Open standard dialog box for setting object's font characteristics

Syntax

```
uisetfont
uisetfont(h)
uisetfont(S)
uisetfont(...,'DialogTitle')
S = uisetfont(...)
```

Description

`uisetfont` enables you to change font properties (`FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle`) for a `text`, `axes`, or `uicontrol` object. The function returns a structure consisting of font properties and values. You can specify an alternate title for the dialog box.

`uisetfont` displays a modal dialog box and returns the selected font properties.

Note A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

`uisetfont(h)` displays a modal dialog box, initializing the font property values with the values of those properties for the object whose handle is `h`. Selected font property values are applied to the current object. If a second argument is supplied, it specifies a name for the dialog box.

`uisetfont(S)` displays a modal dialog box, initializing the font property values with the values defined for the specified structure (`S`). `S` must define legal values for one or more of these properties: `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` and the field names must match the property names exactly. If other properties are defined, they are ignored. If a second argument is supplied, it specifies a name for the dialog box.

`uisetfont(...,'DialogTitle')` displays a modal dialog box with the title `DialogTitle` and returns the values of the font properties selected in the dialog box.

`S = uisetfont(...)` returns the properties `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` as fields in a structure. If the user presses **Cancel** from the dialog box or if an error occurs, the output value is set to 0.

Examples

These statements create a text object, then display a dialog box (labeled Update Font) that enables you to change the font characteristics:

```
h = text(.5,.5,'Figure Annotation');
uisetfont(h,'Update Font')
```

These statements create two push buttons, then set the font properties of one based on the values set for the other:

```
% Create push button with string ABC
c1 = uicontrol('Style', 'pushbutton', ...
     'Position', [10 10 100 20], 'String', 'ABC');
% Create push button with string XYZ
c2 = uicontrol('Style', 'pushbutton', ...
     'Position', [10 50 100 20], 'String', 'XYZ');
% Display set font dialog box for c1, make selections,
& and save to d
d = uisetfont(c1);
% Apply those settings to c2
set(c2, d)
```

See Also

`axes` | `text` | `uicontrol`

uisetpref

Purpose Manage preferences used in `uigetpref`

Syntax

```
uisetpref('clearall')
```

Description `uisetpref('clearall')` resets the value of all preferences registered through `uigetpref` to `'ask'`. This causes the dialog box to display when you call `uigetpref`.

Note Use `setpref` to set the value of a particular preference to `'ask'`.

See Also `setpref` | `uigetpref`

Purpose

Reorder visual stacking order of objects

Syntax

```
uistack(h)
uistack(h,stackopt)
uistack(h,stackopt,step)
```

Description

`uistack(h)` raises the visual stacking order of the objects specified by the handles in `h` by one level (`step` of 1). All handles in `h` must have the same parent.

`uistack(h,*stackopt*)` moves the objects specified by `h` in the stacking order, where *`stackopt`* is one of the following:

- `'up'` – moves `h` up one position in the stacking order
- `'down'` – moves `h` down one position in the stacking order
- `'top'` – moves `h` to the top of the current stack
- `'bottom'` – moves `h` to the bottom of the current stack

`uistack(h,*stackopt*,step)` moves the objects specified by `h` up or down the number of levels specified by `step`.

Note In a GUI, `axes` objects are always at a lower level than `uicontrol` objects. You cannot stack an `axes` object on top of a `uicontrol` object.

See "Set Tab Order in a Programmatic GUI" in the MATLAB documentation for information about changing the tab order.

Examples

The following code moves the child that is third in the stacking order of the figure handle `hObject` down two positions.

```
v = allchild(hObject)
uistack(v(3),'down',2)
```

uitable

Purpose

Create 2-D graphic table GUI component

Syntax

```
uitable
uitable('PropertyName1', value1,'PropertyName2',value2,...)
uitable(parent,...)
handle = uitable(...)
```

Description

`uitable` creates an empty `uitable` object in the current figure window, using default property values. If no figure exists, a new figure window opens.

`uitable('PropertyName1', value1,'PropertyName2',value2,...)` creates a `uitable` object with specified property values. Properties that you do not specify assume the default property values. See the Uitable Properties reference page for information about the available properties.

`uitable(parent,...)` creates a `uitable` object as a child of the specified parent handle `parent`. The parent can be a figure or `uipanel` handle. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence.

`handle = uitable(...)` creates a `uitable` object and returns its handle.

Tips

After creating a `uitable` object, you can set and query its property values using the `set` and `get` functions.

If the `ColumnEditable` property is `true` for columns you edit, you can change values in a displayed table. By default, this property is `false` for all columns. If a noneditable column contains pop-up choices, only the current choice is visible (and not the pop-up menu control).

If you attempt to create a `uitable` object when running MATLAB on a UNIX[9] system without a Java virtual machine (`matlab -nojvm`) or without a display (`matlab  nodisplay`), no table generates and you receive an error.

9. UNIX is a registered trademark of The Open Group in the United States and other countries.

The **CellEditCallback** executes after you edit a value and do any of the following:

- Type **Enter**.
- Click another table cell.
- Click anywhere else within the table.
- Click another control or area within the same figure window.
- Click another window, click again on the GUI containing the table (or use **Alt+Tab** to switch windows), and then perform any of the above four actions.

When the `CellEditCallback` callback executes, `uitable` updates the underlying data matrix (the table `Data` property) to contain the value that the cell now displays.

The **CellSelectionCallback** executes when you select a table cell or remove one from the current selection by **Ctrl**+clicking it. Clicking a cell without pressing any key selects it and deselects all currently selected cells. You can define a range of table cells by **Shift**+clicking an unselected cell after selecting one or more cells. The callback provides event data that identifies the rows and columns of all cells in the current selection.

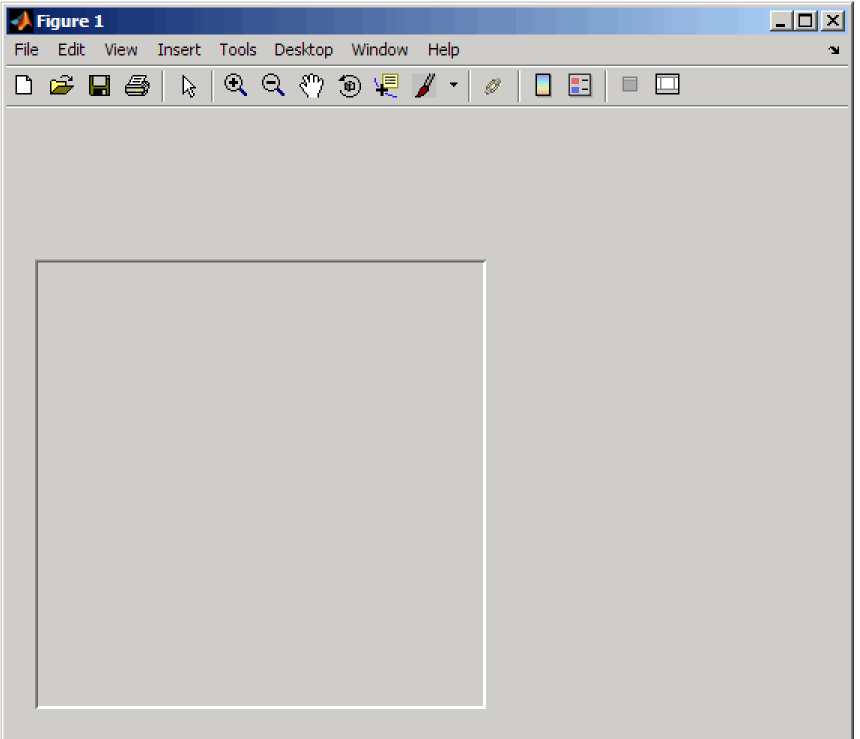
You cannot select table cells programmatically. Directly clicking cells is the only method of selection.

Examples

Create a table, provide magic-square data, set column widths uniformly, and specify the uitable `ColumnWidth` property as a cell array:

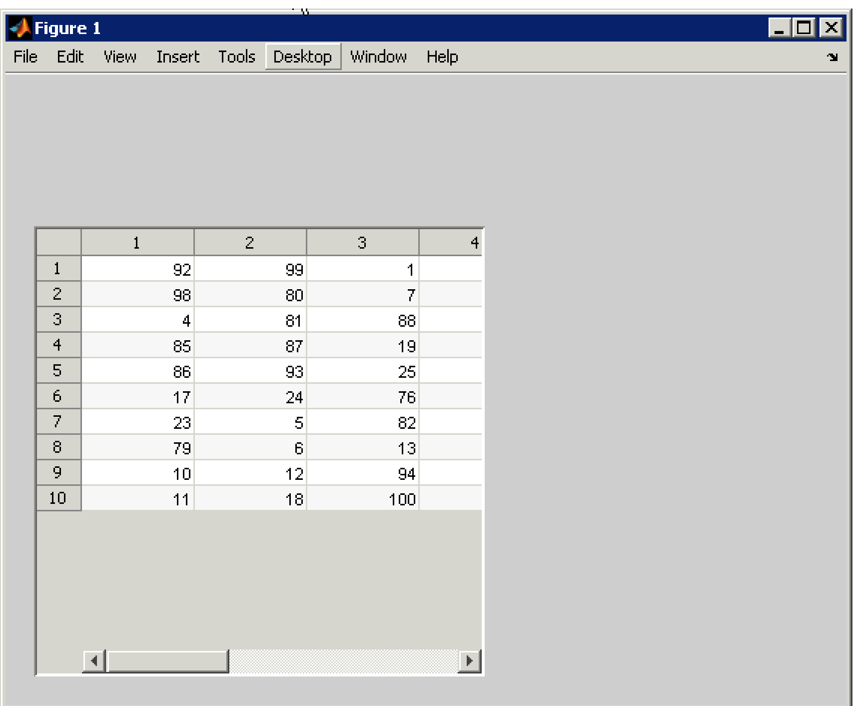
1. Create a table in the current figure. If no figure exists, one opens:

```
t = uitable;
```



2 As the table has no content (its `Data` property is empty), it initially displays no rows or columns. Provide data (a magic square)

```
set(t,'Data',magic(10))
```



3 Make the entire table contents visible. Set column widths to 25 pixels uniformly. Specify the `ColumnWidth` property of the table as a cell array.

```
set(t,'ColumnWidth',{25})
```

	1	2	3	4	5	6	7	8	9	10
1	92	99	1	8	15	67	74	51	58	40
2	98	80	7	14	16	73	55	57	64	41
3	4	81	88	20	22	54	56	63	70	47
4	85	87	19	21	3	60	62	69	71	28
5	86	93	25	2	9	61	68	75	52	34
6	17	24	76	83	90	42	49	26	33	65
7	23	5	82	89	91	48	30	32	39	66
8	79	6	13	95	97	29	31	38	45	72
9	10	12	94	96	78	35	37	44	46	53
10	11	18	100	77	84	36	43	50	27	59

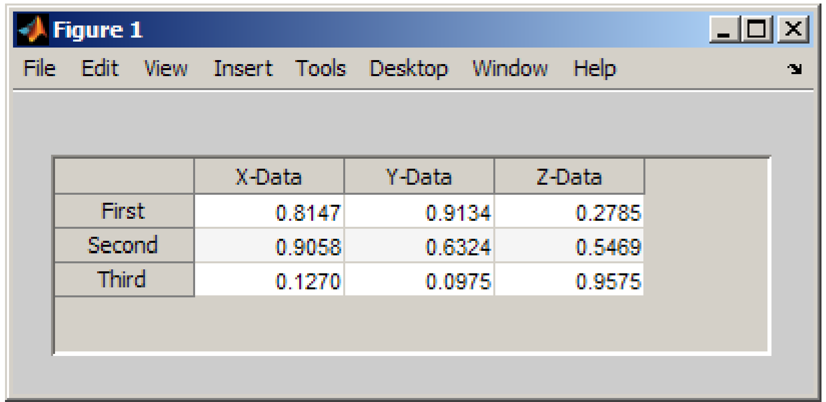
Cell arrays that specify `ColumnWidth` can contain:

- One number (a width measured in pixels, as shown here) or the string `'auto'`.
- A cell array containing a list of pixel sizes having up to as many entries as the table has columns .

If a list of column widths has `n` entries, where `n` is smaller than the number of columns, it sets the first `n` column widths only. You can substitute `'auto'` for any value in the cell array to have the width of that column calculated automatically.

Create a figure and add a table to contain a 3-by-3 data matrix. The code specifies the column names, row names, parent, and position of the table:

```
f = figure('Position',[200 200 400 150]);
dat = rand(3);
cnames = {'X-Data','Y-Data','Z-Data'};
rnames = {'First','Second','Third'};
t = uitable('Parent',f,'Data',dat,'ColumnName',cnames,...
            'RowName',rnames,'Position',[20 20 360 100]);
```

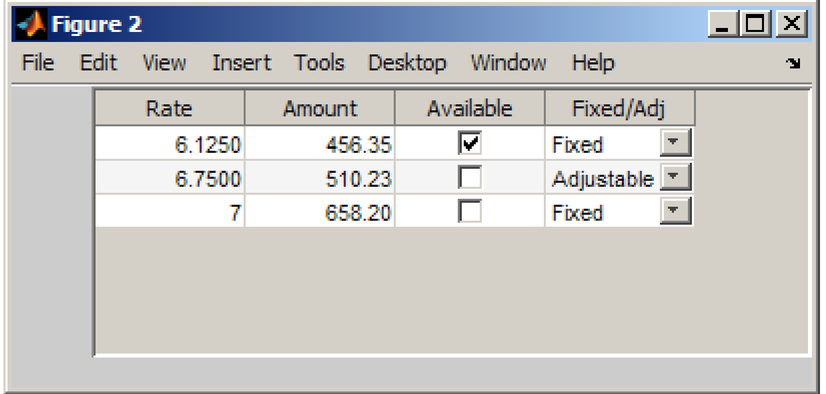


Create a table to contain a 3-by-4 array that contains numeric, logical, and string data, as follows:

- First column (**Rate**): Numeric, with three decimals (not editable)
- Second column (**Amount**): Currency (not editable)
- Third column (**Available**): Check box (editable)
- Fourth column (**Fixed/Adj**): Pop-up menu with two choices: `Fixed` and `Adjustable` (editable)
- Specify the `RowName` property as empty to remove row names from the table.

```
f = figure('Position',[100 100 400 150]);
```

```
dat =  {6.125, 456.3457, true,  'Fixed';...
        6.75,  510.2342, false, 'Adjustable';...
        7,     658.2,    false, 'Fixed';};
columnname =   {'Rate', 'Amount', 'Available', 'Fixed/Adj'};
columnformat = {'numeric', 'bank', 'logical', {'Fixed' 'Adjustable'}};
columneditable =  [false false true true];
t = uitable('Units','normalized','Position',...
            [0.1 0.1 0.9 0.9], 'Data', dat,...
            'ColumnName', columnname,...
            'ColumnFormat', columnformat,...
            'ColumnEditable', columneditable,...
            'RowName',[]);
```



Alternatives

You can add tables to GUIs you create with "Table".

How To

- “Table”

Uitable Properties

Purpose

Describe table properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default uitable properties by typing:

```
set(h,'DefaultUitablePropertyName',PropertyValue...)
```

Where `h` can be the root handle (`0`), a figure handle, or a uitable handle. *`PropertyName`* is the name of the uitable property and `PropertyValue` is the value you specify as the default for that property.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

Uitable Properties

This section lists all properties useful to `uitable` objects along with valid values and descriptions of their use. In the property descriptions, curly braces { } enclose default values.

Property Name	Description
`BackgroundColor`	Background color of cells.
`BeingDeleted`	This object is being deleted.
`BusyAction`	Callback routine interruption
`ButtonDownFcn`	Button-press callback routine
`CellEditCallback`	Callback when data in a cell is changed.

Property Name	Description
CellSelectionCallback	Callback when cell is selected
Children	uitable objects have no children
Clipping	Does not apply to uitable objects
ColumnEditable	Determines data in a column as editable
ColumnFormat	Determines display and editablility of columns
ColumnName	Column header label
ColumnWidth	Width of each column in pixels
CreateFcn	Callback routine during object creation
Data	Table data
DeleteFcn	Callback routine during object deletion
Enable	Enable or disable the uitable
Extent	Size of uitable rectangle
FontAngle	Character slant of cell content
FontName	Font family for cell content
FontSize	Font size of cell content
FontUnits	Font size units for cell content
FontWeight	Weight of cell text characters
ForegroundColor	Color of text in cells
HandleVisibility	Control access to object's handle
HitTest	Selectable by mouse click
Interruptible	Callback routine interruption mode
KeyPressFcn	Key press callback function
Parent	uitable parent

Property Name	Description
Position	Size and location of uitable
RearrangeableColumns	Location of the column
RowName	Row header label names
RowStriping	Color striping of label rows
Selected	Is object selected?
SelectionHighlight	Object highlight when selected
Tag	Use-specified object label
TooltipString	Content of tooltip for object
Type	Class of graphics object
UIContextMenu	Associate context menu with uitable
Units	Units of measurement
UserData	User-specified data
Visible	uitable visibility

BackgroundColor
    1-by-3 or 2-by-3 matrix of RGB triples

Cell background color. Color used to fill the uitable cells. Specify as an 1-by-3 or 2-by-3 matrix of RGB triples, such as [.8 .9. .8] or [1 1 .9; .9 1 1]. Each row is an RGB triplet of real numbers between 0.0 and 1.0 that defines one color. (Color names are not allowed.) The default is a 1-by-3 matrix of platform-dependent colors. See ColorSpec for information about RGB colors.

Row 2 of the matrix is used only if the `RowStriping` property is `on`. The table background is not striped unless both `RowStriping` is on and the `BackgroundColor` color matrix has two rows.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property) It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

string or function handle (GUIDE sets this property)

Button-press callback routine. A callback routine that can execute when you press a mouse button while the pointer is on or near a `uitable`. Specifically:

- If the `uitable` `Enable` property is set to `on`, the `ButtonDownFcn` callback executes when you click the right or left mouse button in a 5-pixel border around the `uitable` or when you click the right mouse button on the control itself.
- If the `uitable` `Enable` property is set to `inactive` or `off`, the `ButtonDownFcn` executes when you click the right or left mouse button in the 5-pixel border or on the control itself.

This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on.

Define this routine as a string that is a valid MATLAB expression or the name of a MATLAB function file. The expression executes in the MATLAB workspace.

To add a `ButtonDownFcn` callback in GUIDE, select **View Callbacks** from the Layout Editor **View** menu, then select `ButtonDownFcn`. GUIDE sets this property to the appropriate string and adds the callback to the program file the next time you save the GUI. Alternatively, you can set this property to the string `%automatic`. The next time you save the GUI, GUIDE sets this property to the appropriate string and adds the callback to the program file.

`CellEditCallback`

function handle, cell array containing function handle and additional arguments, or string (not recommended)

Callback to edit user-entered data

Callback function executed when the user modifies a table cell. It can perform evaluations, validations, or other customizations. If this function is called as a function handle, `uitable` passes it two arguments. The first argument, `source`, is the handle of the `uitable`. The second argument, `eventdata`, is an event data structure that contains the fields shown in the following table. All fields in the event data structure are read only.

Event Data Structure Field	Type	Description
`Indices`	1-by-2 matrix	Row index and column index of the cell the user edited.
`PreviousData`	1-by-1 matrix or cell array	Previous data for the changed cell. The default is an empty matrix, `[]`.
`EditData`	String	User-entered string.

Event Data Structure Field	Type	Description
NewData	1-by-1 matrix or cell array	Value that uitable wrote to Data. It is either the same as EditData or a converted value, for example, 2 where EditData is '2' and the cell is numeric. Empty if uitable detected an error in the user-entered data and did not write it to Data.
Error	String	Error that occurred when uitable tried to convert the EditData string into a value appropriate for Data. For example, uitable could not convert the EditData string consistent with the Column Format property, if any, or the data type for the changed cell. Empty if uitable wrote the value to Data. If Error is not empty, the CellEditCallback can pass the error string to the user or can attempt to manipulate the data. For example, the string 'pi' would raise an error in a numeric cell but the CellEditCallback could convert it to its numerical equivalent and store it in Data without passing the error to the user.

When a user edits a cell, uitable first attempts to store the user-entered value in Data, converting the value if necessary. It then calls the CellEditCallback and passes it the event data structure. If there is no CellEditCallback and the user-entered data results it an error, the contents of the cell reverts to its previous value and no error is displayed. The CellEditCallback

is issued when the user has modified a table cell and presses **Enter** or clicks anywhere outside the cell.

`CellSelectionCallback`

function handle, cell array containing function handle and additional arguments, or string (not recommended)

Callback that executes when cell is selected. Callback function that executes when the user highlights a cell by navigating to it or clicking it. For multiple selection, this callback executes when new cells are added to the selection. The callback includes event data, a structure with one member

Event Data Structure Field	Type	Description
`Indices`	n-by-2 matrix	Row index and column index of the cells the user currently has selected

Once a cell selection has been made, cells within it can be removed one at a time by **Ctrl**-clicking them.

`Children`

matrix

The empty matrix; `uitable` objects have no children.

`Clipping`

`{on} | off`

This property has no effect on `uitable` objects.

`ColumnEditable`

logical 1–by-n matrix | scalar logical value |{ empty matrix ([])}

Determines if column is user-editable.

Determines if the data can be edited by the end user. Each value in the cell array corresponds to a column. False is default because the developer needs to have control over changes users potentially might make to data.

Specify elements of a logical matrix as `true` if the data in a column is editable by the user or `false` if it is not. An empty matrix indicates that no columns are editable.

Columns that contain check boxes or pop-up menus must be editable for the user to manipulate these controls. If a column that contains pop-up menus is not editable, the currently selected choice appears without displaying the pop-up control. The Elements of the `ColumnEditable` matrix must be in the same order as columns in the `Data` property. If you do not specify `ColumnEditable`, the default is an empty matrix (`[]`).

`ColumnFormat`
cell array of strings

Cell display formatting. Determines how the data in each column displays and is edited. Elements of the cell array must be in the same order as table columns in the `Data` property. If you do not want to specify a display format for a particular column, enter `[]` as a placeholder. If no format is specified for a column, the default display is determined by the data type of the data in the cell. Default `ColumnFormat` is an empty cell array (`{}`). In most cases, the default is similar to the command window.

Elements of the cell array must be one of the strings described in the following table.

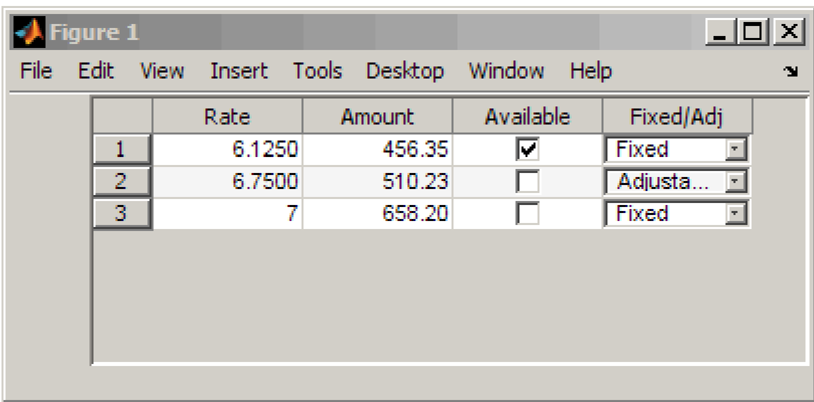
Cell Format	Description
`'char'`	Displays a left-aligned string. To edit, the user types a string that replaces the existing string.
`'logical'`	Displays a check box. To edit, the user checks or unchecks the check box. `uitable` sets the corresponding `Data` value to `true` or `false` accordingly. Initially, the check box is checked if the corresponding `Data` value would produce
`'numeric'`	Displays a right-aligned string equivalent to the command window, for numeric data. If the cell `Data` value is boolean, then 1 or 0 is displayed. If the cell `Data` value is not numeric and not boolean, then `NaN` is displayed. To edit, the user can enter any string. This enables a user to enter a value such as `'pi'` that can be converted to its numeric equivalent by a `CellEditCallback`. The `uitable` function first attempts to convert the user-entered string to a numeric value and store it in `Data`. It then calls the `CellEditCallback`. See `CellEditCallback` for more information.

Cell Format	Description
1–by-n cell array of strings that define a pop-up menu, e.g., {'one' 'two' 'three'}	Displays a pop-up menu. To edit, the user makes a selection from the pop-up menu. uitable sets the corresponding Data value to the selected menu item. The initial values for the pop-up menus in the column are the corresponding strings in Data. These initial values do not have to be items in the pop-up menu. See Example 3 on the uitable reference page.
Valid string accepted by the format function, e.g.,'short' or 'bank'	Displays the Data value using the specified format. For example, for a two-column table, set(htable,'ColumnFormat',{'short','bank'}).

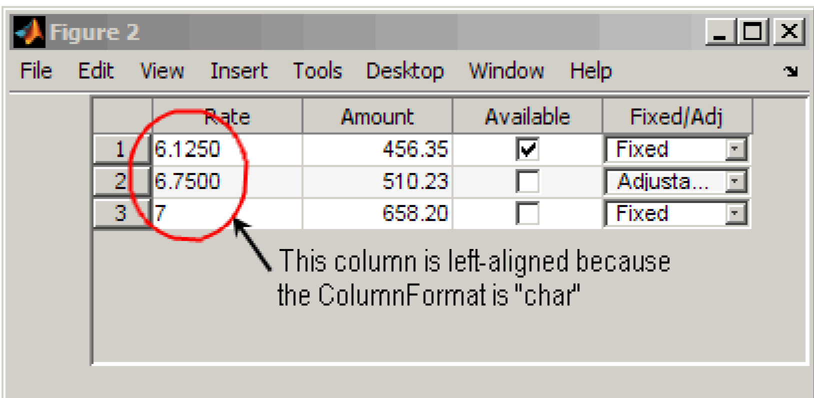
In some cases, you may need to insert an appropriate column in Data. If Data is a numerical or logical matrix, you must first convert it to a cell array using the mat2cell function.

Data and ColumnFormat

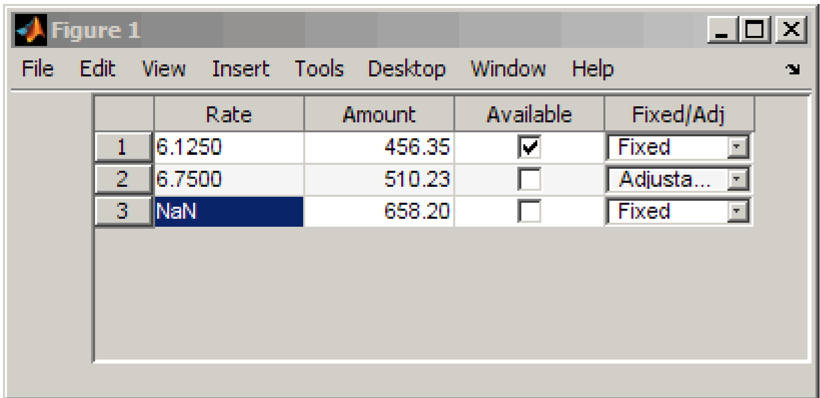
When you create a table, you must specify value of Data. The Data property dictates what type of data can exist in any given cell. By default, the value of the Data also dictates the display of the cell to the end user, unless you specify a different format using the ColumnFormat property.



`ColumnFormat` controls the presentation of the `Data` to the end user. Therefore, if you specify a `ColumnFormat` of `char` (or pick **Text** from the Table Property Editor), you are asking the table to display the `Data` associated with that column as a string. For example, if the `Data` for a particular column is `numeric`, and you specify the `ColumnFormat` as `char`, then the display of the numeric data will be left-aligned



If your column is editable and the user enters a number, the number will be left-aligned. However, if the user enters a text string, the table displays a **NaN**.



Another possible scenario is that the value `Data` is `char` and you set the `ColumnFormat` to be a pop-up menu. Here, if the value of the `Data` in the cell matches one of the pop-up menu choices you define in `ColumnFormat`, then the `Data` is shown in the cell. If it does not match, then the cell defaults to display the first option from the choices you specify in `ColumnFormat`. Similarly, if `Data` is numeric or logical with the `ColumnFormat` as pop-up menu, if the `Data` value in the cell does not match any of the choices you specify in `ColumnFormat`, the cell defaults to display the first option in the pop-menu choice.

This table describes how `Data` values correspond with your `ColumnFormat` when the columns are editable.

	`ColumnFormat` Selections		
	`numeric`	`char`	`logical`

Data Type	`numeric`	Values match. MATLAB displays numbers as is.	MATLAB converts the text string entered to a double. See `str2double` for more information. If string cannot be converted, **NaN** is displayed.	Does not work: warning is thrown. **Note** If you have defined `CellEditCallback`, this warning will not be thrown
	`char`	MATLAB converts the entered number to a text string.	Values match. MATLAB displays the string as is.	Does not work: warning is thrown. **Note** If you have defined `CellEditCallback`, this warning will not be thrown
	`logical`	Does not work: warning is thrown. **Note** If you have defined `CellEditCallback`, this warning will not be thrown	If text string entered is `true` or `false`, MATLAB converts string to the corresponding logical value and displays it. For all others, it Does not work: warning is thrown.	Values match. MATLAB displays logical value as a check box as is.

			Note If you have defined `CellEditCallback`, this warning will not be thrown	

If you get a mismatch error, you have the following options:

- Change the `ColumnFormat` or value of `Data` to match.
- Implement the `CellEditCallback` to handle custom data conversion.

`ColumnName`

1–by-*n* cell array of strings`|` {`'numbered'`} `|` empty matrix (`[]`)

Column heading names. Each element of the cell array is the name of a column. Multiline column names can be expressed as a string vector separated by vertical slash (`|`) characters, e.g.,`'Standard|Deviation'`

For sequentially numbered column headings starting with `1`, specify `ColumnName` as `'numbered'`. This is the default.

To remove the column headings, specify `ColumnName` as the empty matrix (`[]`).

The number of columns in the table is the larger of `ColumnName` and the number of columns in the `Data` property matrix or cell array.

`ColumnWidth`

1–by-*n* cell array or `'auto'`

Column widths. The width of each column in units of pixels. Column widths are always specified in pixels; they do not obey the `Units` property. Each column in the cell array corresponds to a column in the uitable. By default, the width of the column name, as specified in `ColumnName`, along with some other factors, is used to determine the width of a column. If `ColumnWidth` is a cell array and the width of a column is set to `'auto'`or if **auto** is selected for that column in the Property Inspector GUI for columns, the column width defaults to a size determined by the table. The table decides the default size using a number of factors, including the `ColumnName` and the minimum column size.

To default all column widths in an existing table, use

```
set(uitable_handle,'ColumnWidth','auto')
```

To default some column widths but not others, use a cell array containing a mixture of pixel values and `'auto'`. For example,

```
set(uitable_handle,'ColumnWidth',{64 'auto' 40 40 'auto' 72})
```

`CreateFcn`

string or function handle

Callback routine executed during object creation. The specified function executes when MATLAB creates a `uitable` object. MATLAB sets all property values for the uitable before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uitable being created.

Setting this property on an existing uitable object has no effect.

You can define a default `CreateFcn` callback for all new uitables. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uitable`. For example, the code

```
set(0,'DefaultUitableCreateFcn','set(gcbo,...
```

```
  ''BackGroundColor'',''blue'')')
```

creates a default `CreateFcn` callback that runs whenever you create a new uitable. It sets the default background color of all new uitables.

To override this default and create a uitable whose `BackgroundColor` is set to a different value, call `uitable` with code similar to

```
hpt = uitable(...,'CreateFcn','set(gcbo,...
''BackgroundColor'',''white'')')
```

Note To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitable` call. In the example above, if instead of redefining the `CreateFcn` property for this uitable, you had explicitly set `BackgroundColor` to `white`, the default `CreateFcn` callback would have set `BackgroundColor` back to the default, i.e., `blue`.

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`Data`

matrix or cell array of numeric, logical, or character data

Data content of uitable. The matrix or cell array must be 2–dimensional. A cell array can mix data types.

Use `get` and `set` to modify `Data`. For example,

```
data = get(tablehandle,'Data')
data(event.indices(1),event.indices(2)) = pi();
set(tablehandle,'Data',data);
```

See `CellEditCallback` for information about the event data structure. See `ColumnFormat` for information about specifying the data display format.

The number of rows in the table is the larger of `RowName` and the number of rows in `Data`. The number of columns in the table is the larger of `ColumnName` and the number of columns in `Data`.

`DeleteFcn`
string or function handle

Delete uitable callback routine. A callback routine that executes when you delete the `uitable` object (e.g., when you issue a `delete` command or clear the figure containing the `uitable`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root CallbackObject property, which you can query using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define a callback function.

`Enable`
`{on} | inactive | off`

Enable or disable the uitable. This property determines how uitables respond to mouse button clicks, including which callback routines execute.

- `on` – The uitable is operational (the default).

- inactive – The uitable is not operational, but looks the same as when Enable is on.
- off – The uitable is not operational and its image is grayed out.

When you left-click on a uitable whose Enable property is on, MATLAB performs these actions in this order:

1. Sets the figure's SelectionType property.
2. Executes the uitable's CellSelectionCallback routine (but only for table cells, not header cells). Row and column indices of the cells the user selects continuously update the Indices field in the eventdata passed to the callback.
3. Does not set the figure's CurrentPoint property and does not execute either the table's ButtonDownFcn or the figure's WindowButtonDownFcn callback.

When you left-click on a uitable whose Enable property is off, or when you right-click a uitable whose Enable property has any value, MATLAB performs these actions in this order:

1. Sets the figure's SelectionType property.
2. Sets the figure's CurrentPoint property.
3. Executes the figure's WindowButtonDownFcn callback.

Extent

position rectangle (read only)

Size of uitable rectangle. A four-element vector of the form [0,0,width,height] that contains the calculated values of the largest extent of the table based on the current Data, RowName and ColumnName property values. Calculation depends on column and row widths, when they are available. The calculated extent can be larger than the figure.

The first two elements are always zero. `width` and `height` are the dimensions of the rectangle. All measurements are in units specified by the `Units` property.

When the uitable's `Units` property is set to `'Normalized'`, its `Extent` is measured relative to the figure, regardless of whether the table is contained in (parented to) a uipanel or not.

You can use this property to determine proper sizing for the uitable with respect to its content. Do this by setting the `width` and `height` of the uitable `Position` property to the width and height of the `Extent` property. However, doing this can cause the table to extend beyond the right or top edge of the figure and/or its uipanel parent, if any, for tables with large extents.

`FontAngle`

`{normal} | italic | oblique`

Character slant of cell content. MATLAB uses this property to select a font from those available on your particular system. Setting this property to `italic` or `oblique` selects a slanted version of the font, when it is available on your system.

`FontName`

string

Font family for cell content. The name of the font in which to display cell content. To display and print properly, this must be a font that your system supports. The default font is system dependent.

To use a fixed-width font that looks good in any locale (and displays properly in Japan, where multibyte character sets are used), set `FontName` to the string `FixedWidth` (this string value is case sensitive):

```
set(uitable_handle,'FontName','FixedWidth')
```

This parameter value eliminates the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` and rely on the root `FixedWidthFontName` property to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

`FontSize`
size in `FontUnits`

Font size for cell contents. A number specifying the size of the font in which to display cell contents, in units determined by the `FontUnits` property. The default point size is system dependent. If `FontUnits` is set to `normalized`, `FontSize` is a number between 0 and 1.

`FontUnits`
`{points} | normalized | inches |`
`centimeters | pixels`

Font size units for cell contents. This property determines the units used by the `FontSize` property. `Normalized` units interpret `FontSize` as a fraction of the height of the uitable. When you resize the uitable, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = $^1/_{72}$ inch).

`FontWeight`
`light | {normal} | demi | bold`

Weight of cell text characters. MATLAB uses this property to select a font from those available on your particular system. Setting this property to `bold` causes MATLAB to use a bold version of the font, when it is available on your system.

`ForegroundColor`

`1-by-3 matrix of RGB triples or a color name`

Color of text in cells. Determines the color of the text defined for cell contents. Text in all cells share the current color. Specify as a 1-by-3 matrix of RGB triples, such as `[0 0 .8]` or as a color name. The default is a 1-by-3 matrix of platform-dependent colors. See `ColorSpec` for information about specifying RGB colors.

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle. This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine

invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`
`{on} | off`

Selectable by mouse click. When `HitTest` is `off`, the `ButtonDownFcn` callback does not execute.

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`

- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see "Control Callback Execution and Interruption".

Note If the interrupting callback is a `DeleteFcn`or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

`KeyPressFcn`

string or function handle

Key press callback function. A callback routine invoked by a key press when the callback's uitable object has focus. Focus is denoted by a border or a dotted border, respectively, in UNIX and Microsoft Windows. If no uitable has focus, the figure's key press callback function, if any, is invoked. `KeyPressFcn` can be a function handle, the name of a MATLAB function file, or any legal MATLAB expression.

If the specified value is the name of a function code file, the callback routine can query the figure's `CurrentCharacter` property to determine what particular key was pressed and thereby limit the callback execution to specific keys.

If the specified value is a function handle, the callback routine can retrieve information about the key that was pressed from its event data structure argument.

Event Data Structure Field	Description	Examples:			
		a	=	Shift	Shift/a
Character	Character interpretation of the key that was pressed.	'a'	'='	''	'A'
Modifier	Current modifier, such as 'control', or an empty cell array if there is no modifier	{1x0 cell}	{1x0 cell}	{'shift'}	{'shift'}
Key	Name of the key that was pressed.	'a'	'equal'	'shift'	'a'

The uitable KeyPressFcn callback executes for all keystrokes, including arrow keys or when a user edits cell content.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

Parent
handle

Uitable parent. The handle of the uitable's parent object. You can move a uitable object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

Position
position rectangle

Size and location of uitable. The rectangle defined by this property specifies the size and location of the table within the parent figure window, ui, or uibuttongroup. Specify Position as a 4–element vector:

```
[left bottom width height]
```

left and bottom are the distance from the lower-left corner of the parent object to the lower-left corner of the uitable object.

`width` and `height` are the dimensions of the uitable rectangle. All measurements are in units specified by the `Units` property.

Note If you are specifying both `Units` and `Position` in the same call to `uitable`, specify `Units` first if you want `Position` to be interpreted using those units.

`RearrangeableColumns`

`on | {off}`

This object can be rearranged. The `RearrangeableColumns` property provides a mechanism that you can use to reorder the columns in the table. All columns are rearrangable when this property is turned on. MATLAB software sets the `RearrangeableColumns` property to `off` by default.

When this property is on, the user of a table can move any column of data (but not the row labels) at a time left or right to reorder it by clicking and dragging its header. Rearranging columns does not affect the ordering of columns in the table's `Data`, only the user's view of it.

`RowName`

1–by-n cell array of strings`|` {`'numbered'`} `|` empty matrix (`[]`)

Row heading names. Each element of the cell array is the name of a row. Row names are restricted to one line of text.

For sequentially numbered row headings starting with `1`, specify `RowName` as `'numbered'`. This is the default.

To remove the row headings, specify `RowName` as the empty matrix (`[]`).

The number of rows in the table is the larger of `RowName` and the number of rows in the `Data` property matrix or cell array.

`RowStriping`
: `{on} | off`

Color striping of table rows. When `RowStriping` is `on`, the background of consecutive rows of the table display in the pair of colors that the `BackgroundColor` color matrix specifies. The first color matrix row applies to odd-numbered rows, and the second to even-numbered rows. If the `BackgroundColor` matrix has only one row, it is applied to all rows (that is, no striping occurs).

When `RowStriping` is `off`, the first color specified for `BackgroundColor` is applied to all rows.

`Selected`
: `on | {off}`

Is object selected. When this property is `on`, MATLAB displays selection handles if the `SelectionHighlight` property is also `on`. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

`SelectionHighlight`
: `{on} | off`

Object highlight when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`Tag`
: string (GUIDE sets this property)

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as

global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

`TooltipString`
string

Content of tooltip for object. The `TooltipString` property specifies the text of the tooltip associated with the uitable. When the user moves the mouse pointer over the table and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uitable;
s = sprintf('UITable tooltip line 1\nUITable tooltip line 2');
set(h,'TooltipString',s)
```

`Type`
string (read only)

Class of graphics object. For uitable objects, `Type` is always the string `'uitable'`.

`UIContextMenu`
handle

Associate a context menu with uitable. Assign this property the handle of a `uicontextmenu` object. MATLAB displays the context menu whenever you right-click over the uitable. Use the `uicontextmenu` function to create the context menu.

`Units`
`{pixels} | normalized | inches | centimeters | points | characters` (GUIDE default: `normalized`)

Units of measurement. MATLAB uses these units to interpret the `Extent` and `Position` properties. All units are measured from the lower-left corner of the parent object.

- `Normalized` units map the lower-left corner of the parent object to (0,0) and the upper-right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).
- `Character` units are characters using the default system font; the width of one character is the width of the letter `x`, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

`UserData`
matrix

User-specified data. Any data you want to associate with the uitable object. MATLAB does not use this data, but you can access it using `set` and `get`.

`Visible`
`{on} | off`

Uitable visibility. By default, all uitables are visible. When set to `off`, the uitable is not visible, but still exists and you can query and set its properties.

Note Setting `Visible` to `off` for uitables that are not displayed initially in the GUI, can result in faster startup time for the GUI.

---

uitoggletool

Purpose

Create toggle button on toolbar

Syntax

```
htt = uitoggletool
htt = uitoggletool('PropertyName1',value1,'PropertyName2',
   value2,...)
htt = uitoggletool(ht,...)
```

Description

`htt = uitoggletool` creates a toggle button on the uitoolbar at the top of the current figure window, sets all its properties to default values, and returns a handle to the tool. If no uitoolbar exists, one is created. The uitoolbar is the parent of the uitoggletool. Use the returned handle `htt` to set properties of the uitoggletool. The `OnCallback`, `OffCallback` and `ClickedCallback` use the handle as their first argument. The button has no icon, but its border highlights when you hover over it with the mouse cursor. Add an icon by setting `CData` for the tool. Type `get(htt)` to see a list of uitoggletool object properties and their current values. Type `set(htt)` to see a list of uitoggletool object properties you can set and legal property values.

`htt = uitoggletool('`*`PropertyName1`*`',value1,'`*`PropertyName2`*`',value2,...)` assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the `set` function. You can specify properties as parameter name/value pairs, cell arrays containing parameter names and values, or structures with fields containing parameter names and values as input arguments. For a complete list, see Uitoggletool Properties. Type `get(htt)` to see a list of uipushtool object properties and their current values. Type `set(htt)` to see a list of uipushtool object properties that you can set and their legal property values.

`htt = uitoggletool(ht,...)` creates a button with `ht` as a parent. `ht` must be a uitoolbar handle.

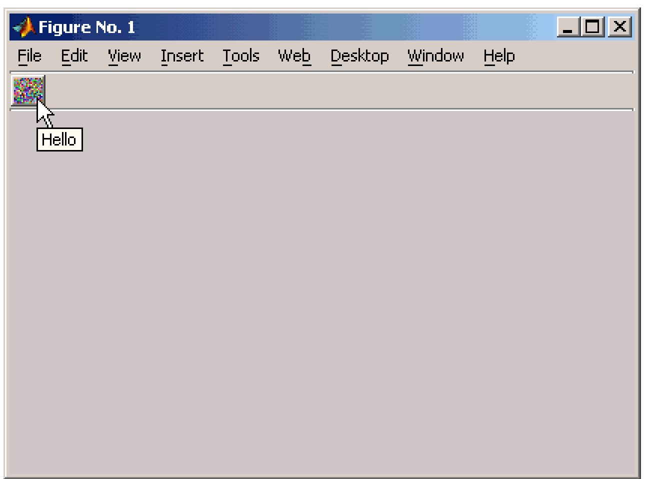
Toggle tools appear in figures whose `Window Style` is `normal` or `docked`. They do not appear in figures with a `'modal' WindowStyle`. If the `WindowStyle` property of a figure containing a tool bar and its toggle tool children changes to `modal`, the toggle tools continue to exist

as `Children` of the tool bar. The toggle tools do not display until you change the `WindowStyle` to `normal` or `docked`.

Examples

Create a `uitoolbar` object and places a `uitoggletool` object on it by specifying the toolbar handle as the toggle tool parent. Generate a random set of colors for the tool icon and specify a tool tip.

```
h = figure('ToolBar','none');
ht = uitoolbar(h);
a = rand(16,16,3);
htt = uitoggletool(ht,'CData',a,'TooltipString','Hello');
```



Alternatives

You can create toolbars with toggle tools using GUIDE.

Uitoggletool Properties property

Purpose

Describe toggle tool properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uitoggletool properties by typing:

```
set(h,'DefaultUitoggletoolPropertyName',PropertyValue...)
```

Where h can be the root handle (0), a figure handle, a uitoolbar handle, or a uitoggletool handle. *`PropertyName`* is the name of the Uitoggletool property and `PropertyValue` is the value you specify as the default for that property.

For more information about changing the default value of a property see "Setting Default Property Values".

Properties

This section lists all properties useful to `uitoggletool` objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property	Purpose
`BeingDeleted`	This object is being deleted.
`BusyAction`	Callback routine interruption.
`CData`	Truecolor image displayed on the toggle tool.
`ClickedCallback`	Control action independent of the toggle tool position.

Property	Purpose
`CreateFcn`	Callback routine executed during object creation.
`DeleteFcn`	Callback routine executed during object deletion.
`Enable`	Enable or disable the uitoggletool.
`HandleVisibility`	Control access to object's handle.
`HitTest`	Whether selectable by mouse click
`Interruptible`	Callback routine interruption mode.
`OffCallback`	Control action when toggle tool is set to the off position.
`OnCallback`	Control action when toggle tool is set to the on position.
`Parent`	Handle of uitoggletool's parent toolbar.
`Separator`	Separator line mode.
`State`	Uitoggletool state.
`Tag`	User-specified object label.
`TooltipString`	Content of object's tooltip.
`Type`	Object class.
`UIContextMenu`	Uicontextmenu object associated with the uitoggletool
`UserData`	User specified data.
`Visible`	Uitoggletool visibility.

`BeingDeleted`

`on | {off}` (read only)

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are

in the process of being deleted. MATLAB software sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property) It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`CData`

3-dimensional array

Truecolor image displayed on control as its icon. An *n*-by-*m*-by-3 array of RGB values that defines a truecolor image displayed

on either a push button or toggle button. Each value must be between 0.0 and 1.0. If your `CData` array is larger than 16 in the first or second dimension, it can be clipped or result in other undesirable effects. If the array is clipped, only the center 16-by-16 part of the array is used.

`ClickedCallback`
string or function handle

Control action independent of the toggle tool position. A routine that executes after either the `OnCallback` routine or `OffCallback` routine runs to completion. The uitoggletool `Enable` property must be set to `on`.

`CreateFcn`
string or function handle

Callback routine executed during object creation. The specified function executes when MATLAB creates a uitoggletool object. MATLAB sets all property values for the uitoggletool before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the toggle tool being created.

Setting this property on an existing uitoggletool object has no effect.

You can define a default `CreateFcn` callback for all new uitoggletools. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uitoggletool`. For example, the statement,

```
set(0,'DefaultUitoggletoolCreateFcn',...
    'set(gcbo,''Enable'',''off'')'
```

creates a default `CreateFcn` callback that runs whenever you create a new toggle tool. It sets the toggle tool `Enable` property to `off`.

To override this default and create a toggle tool whose `Enable` property is set to `on`, you could call `uitoggletool` with code similar to

```
htt = uitoggletool(...,'CreateFcn',...
                   'set(gcbo,''Enable'',''on'')',...)
```

Note To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitoggletool` call. In the example above, if instead of redefining the `CreateFcn` property for this toggle tool, you had explicitly set `Enable` to `on`, the default `CreateFcn` callback would have set `CData` back to `off`.

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See Function Handle Callbacks for information on how to use function handles to define a callback function.

`DeleteFcn`
: string or function handle

Callback routine executed during object deletion. A callback routine that executes when you delete the uitoggletool object (e.g., when you call the `delete` function or cause the figure containing the uitoggletool to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define a callback function.

`Enable`
{on} | off

Enable or disable the uitoggletool. This property controls how uitoggletools respond to mouse button clicks, including which callback routines execute.

- `on` – The uitoggletool is operational (the default).
- `off` – The uitoggletool is not operational and its icon (set by the `Cdata` property) is grayed out.

When you left-click on a uitoggletool whose `Enable` property is `on`, MATLAB performs these actions in this order:

1. Executes the toggle tool `OnCallback` or `OffCallback` routine, depending on its current state, and its `ClickedCallback` routine.
2. Does *not* set the figure `CurrentPoint` property and does *not* execute the figure's `WindowButtonDownFcn` callback.
3. Does *not* set the figure `SelectionType` property.

When you left-click a uitoggletool whose `Enable` property is `off`, or when you right-click a uitoggletool whose `Enable` property has any value, no action is reported, no callback executes, and neither the `SelectionType` nor `CurrentPoint` figure properties are modified.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to on to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`
`{on} | off`

Selectable by mouse click. This property has no effect on uitoggletool objects.

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

Note If the interrupting callback is a `DeleteFcn`or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

`OffCallback`
string or function handle

Control action. A routine that executes if the uitoggletool's `Enable` property is set to `on`, and either

- The toggle tool `State` is set to `off`.
- The toggle tool is set to the `off` position by pressing a mouse button while the pointer is on the toggle tool itself or in a 5-pixel wide border around it.

The `ClickedCallback` routine, if there is one, runs after the `OffCallback` routine runs to completion.

`OnCallback`
string or function handle

Control action. A routine that executes if the uitoggletool's `Enable` property is set to `on`, and either

- The toggle tool `State` is set to `on`.
- The toggle tool is set to the `on` position by pressing a mouse button while the pointer is on the toggle tool itself or in a 5-pixel wide border around it.

The `ClickedCallback` routine, if there is one, runs after the `OffCallback` routine runs to completion.

`Parent`
handle

Uitoggletool parent. The handle of the uitoggletool's parent toolbar. You can move a uitoggletool object to another toolbar by setting this property to the handle of the new parent.

`Separator`
`on | {off}`

Separator line mode. Setting this property to `on` draws a dividing line to left of the uitoggletool.

`State`

`on | {off}`

Uitoggletool state. When the state is `on`, the toggle tool appears in the down, or pressed, position. When the state is `off`, it appears in the up position. Changing the state causes the appropriate `OnCallback` or `OffCallback` routine to run.

`Tag`

string

User-specified object identifier. The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified toolbars) that have the `Tag` value `'Bold'`.

```
h = findobj(uitoolbarhandles, 'Tag', 'Bold')
```

`TooltipString`

string

Content of tooltip for object. The `TooltipString` property specifies the text of the tooltip associated with the uitoggletool. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uitoggletool;
s = sprintf('Toggletool tooltip line 1\nToggletool tooltip line 2');
set(h,'TooltipString',s)
```

`Type`
: `string` (read-only)

  Object class. This property identifies the kind of graphics object. For uitoggletool objects, `Type` is always the string `'uitoggletool'`.

`UIContextMenu`
: handle

  Associate a context menu with uicontrol. This property has no effect on uitoggletool objects.

`UserData`
: array

  User specified data. You can specify `UserData` as any array you want to associate with the uitoggletool object. The object does not use this data, but you can access it using the `set` and `get` functions.

`Visible`
: `{on} | off`

  Uitoggletool visibility. By default, all uitoggletools are visible. When set to `off`, the uitoggletool is not visible, but still exists and you can query and set its properties.

Purpose

Create toolbar on figure

Syntax

```
ht =
uitoolbar('PropertyName1',value1,'PropertyName2',value2,
   ...)
ht = uitoolbar(h,...)
```

Description

`ht =`
`uitoolbar('`*`PropertyName1`*`',value1,'`*`PropertyName2`*`',value2,...)` creates an empty toolbar at the top of the current figure window, and returns a handle to it. `uitoolbar` assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the `set` function.

Type `get(ht)` to see a list of `uitoolbar` object properties and their current values. Type `set(ht)` to see a list of `uitoolbar` object properties that you can set and legal property values. See the Uitoolbar Properties reference page for more information.

`ht = uitoolbar(h,...)` creates a toolbar with `h` as a parent. `h` must be a figure handle.

Tips

`uitoolbar` accepts property name/property value pairs, as well as structures and cell arrays of properties as input arguments.

Uitoolbars appear in figures whose `Window Style` is `normal` or `docked`. They do not appear in figures whose `WindowStyle` is `modal`. If the `WindowStyle` property of a figure containing a uitoolbar is changed to `modal`, the uitoolbar still exists and is contained in the `Children` list of the figure, but is not displayed until the `WindowStyle` is changed to `normal` or `docked`.

Examples

This example creates a figure with no toolbar, then adds a toolbar to it.

```
h = figure('ToolBar','none')
ht = uitoolbar(h)
```

Uitoolbar Properties

Purpose

Describe toolbar properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uitoolbar properties by typing:

```
set(h,'DefaultUitoolbarPropertyName',PropertyValue...)
```

Where h can be the root handle (0), a figure handle, or a uitoolbar handle. *`PropertyName`* is the name of the Uitoolbar property and `PropertyValue` is the value you specify as the default for that property.

For more information about changing the default value of a property see Setting Default Property Values.

Uitoolbar Properties

This section lists all properties useful to `uitoolbar` objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property	Purpose
`BeingDeleted`	This object is being deleted.
`BusyAction`	Callback routine interruption.
`Children`	Handles of uitoolbar's children.
`CreateFcn`	Callback routine executed during object creation.
`DeleteFcn`	Callback routine executed during object deletion.
`HandleVisibility`	Control access to object's handle.

Property	Purpose
HitTest	Whether selectable by mouse click
Interruptible	Callback routine interruption mode.
Parent	Handle of uitoolbar's parent.
Tag	User-specified object identifier.
Type	Object class.
UIContextMenu	Uicontextmenu object associated with the uitoolbar
UserData	User specified data.
Visible	Uitoolbar visibility.

BeingDeleted
`on | {off}` (read-only)

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property) It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

BusyAction
`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`Children`
vector of handles

Handles of tools on the toolbar. A vector containing the handles of all children of the uitoolbar object, in the order in which they appear on the toolbar. The children objects of uitoolbars are uipushtools and uitoggletools. You can use this property to reorder the children.

`CreateFcn`
string or function handle

Callback routine executed during object creation. The specified function executes when MATLAB creates a uitoolbar object. MATLAB sets all property values for the uitoolbar before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the toolbar being created.

Setting this property on an existing uitoolbar object has no effect.

You can define a default CreateFcn callback for all new uitoolbars. This default applies unless you override it by specifying a different CreateFcn callback when you call uitoolbar. For example, the statement,

```
set(0,'DefaultUitoolbarCreateFcn',...
    'set(gcbo,''Visibility'',''off'')')
```

creates a default CreateFcn callback that runs whenever you create a new toolbar. It sets the toolbar visibility to off.

To override this default and create a toolbar whose Visibility property is set to on, you could call uitoolbar with a call similar to

```
ht = uitoolbar(...,'CreateFcn',...
               'set(gcbo,''Visibility'',''on'')',...)
```

Note To override a default CreateFcn callback you must provide a new callback and not just provide different values for the specified properties. This is because the CreateFcn callback runs after the property values are set, and can override property values you have set explicitly in the uitoolbar call. In the example above, if instead of redefining the CreateFcn property for this toolbar, you had explicitly set Visibility to on, the default CreateFcn callback would have set Visibility back to off.

Do not call copyobj or textwrap (which calls copyobj) inside a CreateFcn. The act of copying the uicontrol object fires the CreateFcn repeatedly, which raises a series of error messages after exceeding the root object's RecursionLimit property.

See Function Handle Callbacks for information on how to use function handles to define a callback function.

`DeleteFcn`

string or function handle

Callback routine executed during object deletion. A callback function that executes when the uitoolbar object is deleted (e.g., when you call the `delete` function or cause the figure containing the uitoolbar to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

Within the function, use `gcbo` to get the handle of the toolbar being deleted.

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle. This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI

(such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to on to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`
`{on} | off`

Selectable by mouse click. This property has no effect on uitoolbar objects.

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see "Control Callback Execution and Interruption".

Note If the interrupting callback is a `DeleteFcn`or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

`Parent`
handle

Uitoolbar parent. The handle of the uitoolbar's parent figure. You can move a uitoolbar object to another figure by setting this property to the handle of the new parent.

`Tag`
string

User-specified object identifier. The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the `Tag` value `'FormatTb'`.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

`Type`
`string` (read-only)

Object class. This property identifies the kind of graphics object. For uitoolbar objects, `Type` is always the string `'uitoolbar'`.

`UIContextMenu`
handle

Associate a context menu with uicontrol. This property has no effect on uitoolbar objects.

`UserData`
array

User specified data. You can specify `UserData` as any array you want to associate with the uitoolbar object. The object does not use this data, but you can access it using the `set` and `get` functions.

`Visible`
`{on} | off`

Uitoolbar visibility. By default, all uitoolbars are visible. When set to `off`, the uitoolbar is not visible, but still exists and you can query and set its properties.

Purpose

Block program execution and wait to resume

Syntax

```
uiwait
uiwait(h)
uiwait(h,timeout)
```

Description

`uiwait` blocks execution until `uiresume` is called or the current figure is deleted. This syntax is the same as `uiwait(gcf)`.

`uiwait(h)` blocks execution until `uiresume` is called or the figure `h` is deleted.

`uiwait(h,timeout)` blocks execution until `uiresume` is called, the figure `h` is deleted, or `timeout` seconds elapse. The minimum value of `timeout` is 1. If `uiwait` receives a smaller value, it issues a warning and uses a 1 second `timeout`.

Tips

The `uiwait` and `uiresume` functions block and resume MATLAB and Simulink program execution. `uiwait` also blocks the execution of Simulink models. The functions `pause` (with no argument) and `waitfor` also block execution in this manner.`uiwait` is a convenient way to use the `waitfor` command. You typically use it in conjunction with a dialog box. It provides a way to block the execution of the MATLAB program that created the dialog, until the user responds to the dialog box. When used in conjunction with a modal dialog, `uiwait` can block the execution of the program file *and* restrict user interaction to the dialog only.

Examples

This example creates a GUI with a **Continue** push button. The example calls `uiwait` to block MATLAB execution until `uiresume` is called. This happens when the user clicks the **Continue** push button because the push button's `Callback`, which responds to the click, calls `uiresume`.

```
f = figure;
h = uicontrol('Position',[20 20 200 40],'String','Continue',...
              'Callback','uiresume(gcbf)');
disp('This will print immediately');
uiwait(gcf);
```

```
disp('This will print after you click Continue');
close(f);
```

`gcbf` is the handle of the figure that contains the object whose callback is executing.

See Also

`dialog` | `figure` | `uicontrol` | `uimenu` | `uiresume` | `waitfor`

Purpose Unary minus

Syntax

```
b = -a
b = uminus(a)
```

Description

`b = -a` negates the elements of array `a` and returns the result in array `b`.

`b = uminus(a)` is called for the syntax `-a` when `a` is an object.

See Also

`uplus`

undocheckout

Purpose

Undo previous checkout from source control system (UNIX platforms)

Syntax

```
undocheckout('filename')
undocheckout({'filename1','filename2', ...,'filenamen'})
```

Description

`undocheckout('filename')` makes the file `filename` available for checkout, where `filename` does not reflect any of the changes you made after you last checked it out. Use the full path for `filename` and include the file extension.

`undocheckout({'filename1','filename2', ...,'filenamen'})` makes `filename1` through `filenamen` available for checkout, where the files do not reflect any of the changes you made after you last checked them out. Use the full paths for the file names and include the file extensions.

Examples

Undo the checkouts of `/myserver/myfiles/clock.m` and `/myserver/myfiles/calendar.m` from the source control system:

```
undocheckout({'/myserver/myfiles/clock.m', ...
'/myserver/myfiles/calendar.m'})
```

See Also

`checkin` | `checkout` | `verctrl`

How To

- "Undo the Checkout (UNIX Platforms)"

Purpose

Convert Unicode characters to numeric bytes

Syntax

```
bytes = unicode2native(unicodestr)
bytes = unicode2native(unicodestr, encoding)
```

Description

`bytes = unicode2native(unicodestr)` takes a `char` vector of Unicode characters, `unicodestr`, converts it to the MATLAB default character encoding scheme, and returns the bytes as a `uint8` vector, `bytes`. Output vector `bytes` has the same general array shape as the `unicodestr` input. You can save the output of `unicode2native` to a file using the `fwrite` function.

`bytes = unicode2native(unicodestr, encoding)` converts the Unicode characters to the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string (`''`) or a name or alias for an encoding scheme. Some examples are `'UTF-8'`, `'latin1'`, `'US-ASCII'`, and `'Shift_JIS'`. For common names and aliases, see the Web site `http://www.iana.org/assignments/character-sets`. If `encoding` is unspecified or is the empty string (`''`), the MATLAB default encoding scheme is used.

Examples

This example begins with two strings containing Unicode characters. It assumes that string `str1` contains text in a Western European language and string `str2` contains Japanese text. The example writes both strings into the same file, using the ISO-8859-1 character encoding scheme for the first string and the Shift-JIS encoding scheme for the second string. The example uses `unicode2native` to convert the two strings to the appropriate encoding schemes.

```
fid = fopen('mixed.txt', 'w');
bytes1 = unicode2native(str1, 'ISO-8859-1');
fwrite(fid, bytes1, 'uint8');
bytes2 = unicode2native(str2, 'Shift_JIS');
fwrite(fid, bytes2, 'uint8');
fclose(fid);
```

See Also

`native2unicode`

Purpose

Set union of two arrays

Syntax

```
C = union(A,B)
C = union(A,B,'rows')
[C,ia,ib] = union(A,B)
[C,ia,ib] = union(A,B,'rows')

[C,ia,ib] = union( ___ ,setOrder)

[C,ia,ib] = union(A,B,'legacy')

[C,ia,ib] = union(A,B,'rows','legacy')
```

Description

`C = union(A,B)` returns the combined values from `A` and `B` with no repetitions. The values of `C` are in sorted order.

`C = union(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns the combined rows from `A` and `B` with no repetitions. The rows of the matrix `C` are in sorted order.

The `'rows'` option does not support cell arrays.

`[C,ia,ib] = union(A,B)` also returns index vectors `ia` and `ib`, such that the values in `C` are the combined values of `A(ia)` and `B(ib)`.

`[C,ia,ib] = union(A,B,'rows')` also returns index vectors `ia` and `ib` such that the rows of `C` are the combined rows of `A(ia,:)` and `B(ib,:)`.

`[C,ia,ib] = union( ___ ,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A` then `B`. If no value is specified, the default is `'sorted'`.

`[C,ia,ib] = union(A,B,'legacy')` and `[C,ia,ib] = union(A,B,'rows','legacy')` preserve the behavior of the `union` function from R2012b and prior releases.

Input Arguments

A,B - Input arrays

vectors | matrices | N-D arrays

Input arrays, specified as vectors, matrices, or N-D arrays whose elements can be any numeric, `logical`, or `char` data type. `A` and `B` also can be cell arrays of strings. Furthermore, `A` and `B` can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option), where the second output of this method is `double` or another built-in numeric class
- `ne`

These objects include heterogeneous arrays derived from the same root class.

`A` and `B` must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.

If you specify the `'rows'` option, `A` and `B` must have the same number of columns.

Data Types
`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell`
Complex Number Support: Yes

setOrder - Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in `C`.

Order Flag	Meaning
`'sorted'`	The values (or rows) in `C` return in sorted order. For example: `C = union([5 5 3],[1 2],'sorted')` returns `C = [1 2 3 5]`.
`'stable'`	The values (or rows) in `C` return in the same order as they appear in `A` and `B`. For example: `C = union([5 5 3],[1 2],'stable')` returns `C = [5 3 1 2]`.

Data Types
`char`

Output Arguments

`C` - Combined values of `A` and `B`

vector | matrix

Combined values of `A` and `B`, returned as a vector or matrix. The following describes the shape of `C` when the `'legacy'` flag is not specified:

- If the `'rows'` flag is not specified, then `C` is a column vector unless both `A` and `B` are row vectors.
- If the `'rows'` flag is not specified and both `A` and `B` are row vectors, then `C` is a row vector.
- If the `'rows'` flag is specified, then `C` is a matrix containing the combined rows of `A` and `B`.

The class of the inputs `A` and `B` determines the class of `C`:

- If the class of `A` and `B` are the same, then `C` is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then `C` is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then `C` is `double`.

- If you combine a cell array of strings with `char`, then `C` is a cell array of strings.

ia - Index to A

column vector

Index to `A`, returned as a column vector when the `'legacy'` flag is not specified. `ia` indicates the values (or rows) in `A` that contribute to the union. If a value (or row) appears multiple times in `A`, then `ia` contains the index to the first occurrence of the value (or row). If a value appears in both `A` and `B`, then `ia` contains the index to the first occurrence in `A`.

ib - Index to B

column vector

Index to `B`, returned as a column vector when the `'legacy'` flag is not specified. `ib` indicates the values (or rows) in `B` that contribute to the union. If there is a repeated value (or row) appearing exclusively in `B`, then `ib` contains the index to the first occurrence of the value. If a value (or row) appears in both `A` and `B`, then `ib` does not contain an index to the value (or row).

Examples

Union of Two Vectors

Define two vectors with a value in common.

```
A = [5 7 1]; B = [3 1 1];
```

Find the union of vectors `A` and `B`.

```
C = union(A,B)
```

```
C =

     1     3     5     7
```

Union of Two Vectors and Their Indices

Define two vectors with a value in common.

```
A = [5 7 1]; B = [3 1 1];
```

Find the union of vectors `A` and `B` as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = union(A,B)

C =

     1     3     5     7

ia =

     3
     1
     2

ib =

     1
```

The values in `C` are the combined values of `A(ia)` and `B(ib)`.

Union of the Rows in Two Matrices

Define two matrices with a row in common.

```
A = [2 2 2; 0 0 1];
B = [1 2 3; 2 2 2; 2 2 2];
```

Find the combined rows of `A` and `B`, with no repetition, as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = union(A,B,'rows')

C =
```

```
     0     0     1
     1     2     3
     2     2     2

ia =

     2
     1

ib =

     1
```

The rows of `C` are the combined rows of `A(ia,:)` and `B(ib,:)`.

Union of Two Vectors with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` if you want the values in `C` to have the same order as in `A` and `B`.

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B,'stable')
```

```
C =

     5     7     1     3

ia =

     1
     2
     3
```

```
ib =

     1
```

Alternatively, you can specify 'sorted' order.

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B,'sorted')
```

```
C =

     1     3     5     7

ia =

     3
     1
     2

ib =

     1
```

Union of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN 1]; B = [4 NaN NaN];
```

Find the union of vectors A and B.

```
C = union(A,B)
```

```
C =

     1     4     5   NaN   NaN   NaN
```

`union` treats `NaN` values as distinct.

Cell Array of Strings with Trailing White Space

Create a cell array of strings, `A`.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, `B`, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Combine the elements of `A` and `B`.

```
[C,ia,ib] = union(A,B)
```

```
C =

    'cat'    'dog'    'dog '    'fish'    'fish '    'horse'

ia =

     2
     1
     3
     4

ib =

     1
     3
```

`union` treats trailing white space in cell arrays of strings as distinct characters.

Union of Vectors of Different Classes and Shapes

Create a column vector character array.

```
A = ['A';'B';'C'], class(A)
```

```
A =

A
B
C

ans =

char
```

Create a row vector containing elements of numeric type `double`.

```
B = [68 69 70], class(B)
```

```
B =

    68    69    70

ans =

double
```

The `union` of `A` and `B` returns a column vector character array.

```
C = union(A,B), class(C)
```

```
C =
```

```
A
B
C
D
E
F

ans =

char
```

Union of Char and Cell Array of Strings

Create a character array containing the letters `a` , `b`, and `c`.

```
A = ['a';'b';'c'];
class(A)

ans =

char
```

Create a cell array of strings containing the letters `c`, `d`, and `e`.

```
B = {'c','d','e'};
class(B)

ans =

cell
```

Combine the elements of `A` and `B`.

```
C = union(A,B)
```

```
C = 

    'a'
    'b'
    'c'
    'd'
    'e'
```

The result, `C`, is a cell array of strings.

```
class(C)

ans =

cell
```

Preserve Legacy Behavior of union

Use the `'legacy'` flag to preserve the behavior of `union` from R2012b and prior releases in your code.

Find the union of `A` and `B` with the current behavior.

```
A = [5 7 1]; B = [3 1 1];
[C1,ia1,ib1] = union(A,B)

C1 =

     1     3     5     7

ia1 =

     3
     1
     2
```

```
ib1 =

     1
```

Find the union of A and B, and preserve the legacy behavior.

```
A = [5 7 1]; B = [3 1 1];
[C2,ia2,ib2] = union(A,B,'legacy')

C2 =

     1     3     5     7

ia2 =

     1     2

ib2 =

     3     1
```

See Also

unique | intersect | ismember | issorted | setdiff | setxor | sort

unique

Purpose

Unique values in array

Syntax

```
C = unique(A)
C = unique(A,'rows')
[C,ia,ic] = unique(A)
[C,ia,ic] = unique(A,'rows')

[C,ia,ic] = unique(A,setOrder)

[C,ia,ic] = unique(A,'rows',setOrder)

[C,ia,ic] = unique(A,'legacy')

[C,ia,ic] = unique(A,'rows','legacy')

[C,ia,ic] = unique(A,occurrence,'legacy')

[C,ia,ic] = unique(A,'rows',occurrence,'legacy')
```

Description

`C = unique(A)` returns the same values as in `A`, but with no repetitions. The values of `C` are in sorted order.

`C = unique(A,'rows')` treats each row of `A` as a single entity and returns the unique rows of `A`. The rows of the matrix `C` are in sorted order.

The `'rows'` option does not support cell arrays.

`[C,ia,ic] = unique(A)` also returns index vectors `ia` and `ic`, such that `C = A(ia)` and `A = C(ic)`.

`[C,ia,ic] = unique(A,'rows')` also returns index vectors `ia` and `ic`, such that `C = A(ia,:)` and `A = C(ic,:)`.

[C,ia,ic] = unique(A,setOrder) and [C,ia,ic] = unique(A,'rows',setOrder) return C in a specific order. setOrder='sorted' returns the values (or rows) of C in sorted order. setOrder='stable' returns the values (or rows) of C in the same order as A. If no value is specified, the default is 'sorted'.

[C,ia,ic] = unique(A,'legacy'), [C,ia,ic] = unique(A,'rows','legacy'), [C,ia,ic] = unique(A,occurrence,'legacy'),and [C,ia,ic] = unique(A,'rows',occurrence,'legacy') preserve the behavior of the unique function from R2012b and prior releases.

Input Arguments

A - Input array

vector | matrix | N-D array

Input array, specified as a vector, matrix, or N-D array whose elements can be any numeric, logical, or char data type. A also can be a cell array of strings. Furthermore, A can be an object with the following class methods:

- sort (or sortrows for the 'rows' option), where the second output of this method is double or another built-in numeric class
- ne

These objects include heterogeneous arrays derived from the same root class.

Data Types
double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | cell
Complex Number Support: Yes

setOrder - Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: C = unique([5 5 3 4],'sorted') returns C = [3 4 5].
'stable'	The values (or rows) in C return in the same order as in A. For example: C = unique([5 5 3 4],'stable') returns C = [5 3 4].

Data Types
char

occurrence - Occurrence flag for legacy behavior

'last' (default) | 'first'

Occurrence flag for legacy behavior, specified as 'first' or 'last', indicates whether ia should contain the first or last indices to repeated values found in A.

Occurrence Flag	Meaning
'last'	If there are repeated values (or rows) in A, then ia contains the index to the last occurrence of the repeated value. For example: [C,ia,ic] = unique([9 9 9],'last','legacy') return ia = 3.
'first'	If there are repeated values (or rows) in A, then ia contains the index to the first occurrence of the repeated value. For example: [C,ia,ic] = unique([9 9 9],'first','legacy') retur ia = 1.

Data Types
`char`

Output Arguments

`C` - Unique values of `A`

vector | matrix

Unique values of `A`, returned as a vector or matrix. The following describes the shape of `C`:

- If the `'rows'` flag is not specified and `A` is a row vector, then `C` is a row vector.
- If the `'rows'` flag is not specified and `A` is not a row vector, then `C` is a column vector.
- If the `'rows'` flag is specified, then `C` is a matrix containing the unique rows of `A`.

The class of `C` is the same as the class of the input `A`.

ia - Index to `A`

column vector

Index to `A`, returned as a column vector when the `'legacy'` flag is not specified. `ia` contains indices, such that `C = A(ia)` (or `C = A(ia,:)` for the `'rows'` option).

ic - Index to `C`

column vector

Index to `C`, returned as a column vector when the `'legacy'` flag is not specified. `ic` contains indices, such that `A = C(ic)` (or `A = C(ic,:)` for the `'rows'` option).

Examples

Unique Values in a Vector

Define a vector with a repeated value.

```
A = [9 2 9 5];
```

Find the unique values of A.

```
C = unique(A)
```

```
C =

     2     5     9
```

Unique Values and their Indices

Define a vector with a repeated value.

```
A = [9 2 9 5];
```

Find the unique values of A and the index vectors ia and ic, such that C = A(ia) and A = C(ic).

```
[C, ia, ic] = unique(A)
```

```
C =

     2     5     9

ia =

     2
     4
     1

ic =

     3
     1
     3
     2
```

Unique Rows in a Matrix

Define a matrix with a repeated row.

```
A = [9 2 9 5; 9 2 9 0; 9 2 9 5];
```

Find the unique rows of `A` and the index vectors `ia` and `ic`, such that `C = A(ia,:)` and `A = C(ic,:)`.

```
[C, ia, ic] = unique(A,'rows')

C =

     9     2     9     0
     9     2     9     5

ia =

     2
     1

ic =

     2
     1
     2
```

Notice that the second row in `A` is identified as unique even though the elements `9`, `2`, and `9` are repeated in the other rows.

Unique Values in a Vector with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` if you want the values in `C` to have the same order as in `A`.

```
A = [9 2 9 5];
[C, ia, ic] = unique(A,'stable')

C =

     9     2     5

ia =

     1
     2
     4

ic =

     1
     2
     1
     3
```

Alternatively, you can specify `'sorted'` order.

```
[C, ia, ic] = unique(A,'sorted')

C =

     2     5     9

ia =

     2
     4
     1
```

```
ic =

     3
     1
     3
     2
```

Unique Values in Array Containing NaNs

Define a vector containing NaN.

```
A = [5 5 NaN NaN];
```

Find the unique values of A.

```
C = unique(A)
```

```
C =

     5   NaN   NaN
```

unique treats NaN values as distinct.

Unique Entries in Cell Array of Strings

Define a cell array of strings.

```
A = {'one','two','twenty-two','One','two'};
```

Find the unique strings contained in A.

```
C = unique(A)
```

```
C =

    'One'    'one'    'twenty-two'    'two'
```

Cell Array of Strings with Trailing White Space

Define a cell array of strings, A, where some of the strings have trailing white space.

```
A = {'dog','cat','fish','horse','dog ','fish '};
```

Find the unique strings contained in A.

```
C = unique(A)
```

```
C =

    'cat'    'dog'    'dog '    'fish'    'fish '    'horse'
```

unique treats trailing white space in cell arrays of strings as distinct characters.

Preserve Legacy Behavior of unique

Use the 'legacy' flag to preserve the behavior of unique from R2012b and prior releases in your code.

Find the unique elements of A with the current behavior.

```
A = [9 2 9 5];
[C1, ia1, ic1] = unique(A)
```

```
C1 =

     2     5     9

ia1 =

     2
     4
     1
```

```
ic1 =

     3
     1
     3
     2
```

Find the unique elements of A, and preserve the legacy behavior.

```
[C2, ia2, ic2] = unique(A, 'legacy')
```

```
C2 =

     2     5     9

ia2 =

     2     4     3

ic2 =

     3     1     3     2
```

See Also

union | intersect | ismember | issorted | setdiff | setxor | sort

Purpose

Execute UNIX command and return output

Syntax

```
status = unix(command)
[status,cmdout] = unix(command)
[status,cmdout] = unix(command,'-echo')
```

Description

`status = unix(command)` calls the UNIX operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the `status` variable.

`[status,cmdout] = unix(command)` additionally returns the standard output of the command to `cmdout`. This syntax is most useful for commands that do not require user input.

`[status,cmdout] = unix(command,'-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.

Input Arguments

command - UNIX command

string

UNIX command, specified as a string. The `command` executes in a UNIX shell, which might not be the shell from which you launched MATLAB.

Example: `'ls'`

Output Arguments

status - Command exit status

0 | nonzero integer

Command exit status, returned as either `0` or a nonzero integer. When the command is successful, `status` is `0`. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (&), then `status` is the exit status upon command launch.

- If `command` does not include the ampersand character (`&`), then `status` is the exit status upon command completion.

cmdout - Output of operating system command
string

Output of the operating system command, returned as a string.

Examples

Save UNIX Command Exit Status and Output

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';
[status,cmdout] = unix(command);
status
```

```
status =

     0
```

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the `command` argument (for example, `'emacs &'`). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

  Note If `command` includes the trailing `&` character, `cmdout` is empty.

- The `unix` function redirects `stdin` to the invoked command, `command`, by default. This redirection also forwards MATLAB script commands and the keyboard type-ahead buffer to the invoked command while

the `unix` function executes. This can lead to corrupted output when `unix` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

Algorithms

MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

Concepts

- "Running External Commands, Scripts, and Programs"

Purpose

Unload shared library from memory

Syntax

```
unloadlibrary libname
```

Description

`unloadlibrary libname` unloads library `libname` from memory.

Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

Input Arguments

libname - Name of shared library

string

Name of shared library, specified as a string. If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types
`char`

Examples

Unload Library

Add path to examples folder.

```
addpath(fullfile(matlabroot,'extern','examples','shrlib'))
```

Load the library, if it is not already loaded.

```
if ~libisloaded('shrlibsample')
   loadlibrary('shrlibsample')
end
```

Clean up.

```
unloadlibrary shrlibsample
```

Tips

- To unload a MEX-file, use the `clear` function.

See Also

`loadlibrary` | `libisloaded` | `clear`

unmesh

Purpose

Convert edge matrix to coordinate and Laplacian matrices

Syntax

```
[L,XY] = unmesh(E)
```

Description

`[L,XY] = unmesh(E)` returns the Laplacian matrix `L` and mesh vertex coordinate matrix `XY` for the `M`-by-4 edge matrix `E`. Each row of the edge matrix must contain the coordinates `[x1 y1 x2 y2]` of the edge endpoints.

Input Arguments

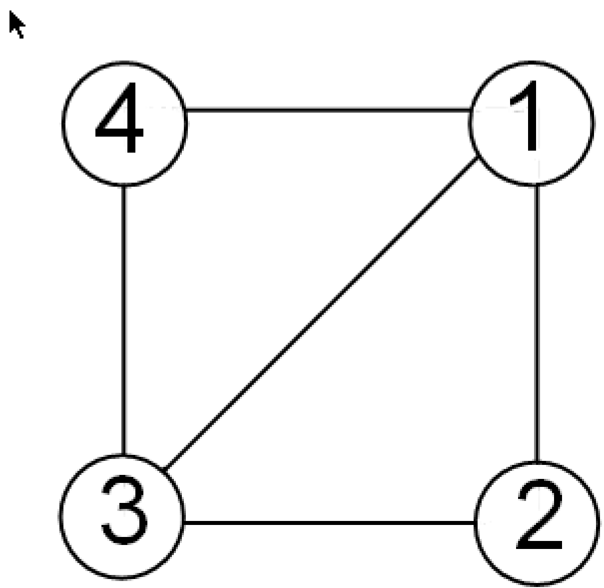
`E`	M-by-4 edge matrix `E`.

Output Arguments

`L`	Laplacian matrix representation of the graph.
`XY`	Mesh vertex coordinate matrix.

Examples

Take a simple example of a square with vertices at (1,1), (1,–1),(–1,–1), and (–1,1), where the connections between vertices are the four perpendicular edges of the square plus one diagonal connection between (–1, –1) and (1,1).



The edge matrix E for this graph is:

```
E=[1 1 1 -1;  % edge from 1 to 2
1 -1 -1 -1;   % edge from 2 to 3
-1 -1 -1 1;   % edge from 3 to 4
-1 -1 1 1;    % edge from 4 to 1
-1 1 1 1]     % edge from 3 to 1
```

Use `unmesh` to create the output matrices,

```
[A,XY]=unmesh(E);
4 vertices:
4/4
```

The Laplacian matrix is defined as

$$L_{ij} = \begin{cases} \deg(v_i) & \text{if } i = j \\ -1 & \text{if } i \neq j \text{ and } v_i \text{ is adjacent to } v_j \\ 0 & \text{otherwise} \end{cases}$$

`unmesh` returns the Laplacian matrix `L` in sparse notation.

```
L

L =

   (1,1)        3
   (2,1)       -1
   (3,1)       -1
   (4,1)       -1
   (1,2)       -1
   (2,2)        2
   (4,2)       -1
   (1,3)       -1
   (3,3)        2
   (4,3)       -1
   (1,4)       -1
   (2,4)       -1
   (3,4)       -1
```

To see `L` in regular matrix notation, use the `full` command.

```
full(L)

ans =

     3    -1    -1    -1
    -1     2     0    -1
    -1     0     2    -1
    -1    -1    -1     3
```

The mesh coordinate matrix `XY` returns the coordinates of the corners of the square.

```
XY

XY =

    -1    -1
    -1     1
     1    -1
     1     1
```

See Also

gplot | treeplot

unmkpp

Purpose

Piecewise polynomial details

Syntax

```
[breaks,coefs,l,k,d] = unmkpp(pp)
```

Description

`[breaks,coefs,l,k,d] = unmkpp(pp)` extracts, from the piecewise polynomial `pp`, its breaks `breaks`, coefficients `coefs`, number of pieces `l`, order `k`, and dimension `d` of its target. Create `pp` using `spline` or the spline utility `mkpp`.

Examples

This example creates a description of the quadratic polynomial

$$\frac{-x^2}{4} + x$$

as a piecewise polynomial `pp`, then extracts the details of that description.

```
pp = mkpp([-8 -4],[-1/4 1 0]);
[breaks,coefs,l,k,d] = unmkpp(pp)

breaks =
    -8    -4

coefs =
   -0.2500    1.0000         0

l =
     1

k =
     3

d =
     1
```

See Also

`mkpp` | `ppval` | `spline`

Purpose

Unregister all event handlers associated with COM object events at run time

Syntax

```
h.unregisterallevents
unregisterallevents(h)
```

Description

`h.unregisterallevents` unregisters all events previously registered with COM object `h`. After calling `unregisterallevents`, the object no longer responds to any events until you register them again using the `registerevent` function.

`unregisterallevents(h)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

Examples

Register and unregister events for an instance of the `mwsamp` control, using the `eventlisteners` function to see the event handler associated with each event:

1. Register three events and their respective handler routines.

   ```
   f = figure ('position', [100 200 200 200]);
   h = actxcontrol('mwsamp.mwsampctrl.2', ...
       [0 0 200 200], f, ...
       {'Click' 'myclick'; 'DblClick' 'my2click'; ...
       'MouseDown' 'mymoused'});
   h.eventlisteners
   ```

   MATLAB displays:

   ```
   ans =
       'click'        'myclick'
       'dblclick'     'my2click'
       'mousedown'    'mymoused'
   ```

2. Unregister all events simultaneously with `unregisterallevents`. `eventlisteners` returns an empty cell array, indicating that there are no longer any events registered with the control:

```
h.unregisterallevents;
h.eventlisteners
```

MATLAB displays:

```
ans =
     {}
```

See Also

events (COM) | eventlisteners | registerevent | unregisterevent | isevent

Purpose

Unregister event handler associated with COM object event at run time

Syntax

```
h.unregisterevent(eventhandler)
unregisterevent(h, eventhandler)
```

Description

`h.unregisterevent(eventhandler)` unregisters specific event handler routines from their corresponding events. Once you unregister an event, the object no longer responds to the event.

`unregisterevent(h, eventhandler)` is an alternate syntax.

You can unregister events at any time after creating a control. The `eventhandler` argument, which is a cell array, specifies both events and event handlers.

```
h.unregisterevent({'event_name',@event_handler});
```

Specify events in the `eventhandler` argument using the names of the events. Strings used in the `eventhandler` argument are not case sensitive. `unregisterevent` does not accept numeric event identifiers.

COM functions are available on Microsoft Windows systems only.

Examples

Unregister events for a control:

1. Create an `mwsamp` control and register all events with the same handler routine, `sampev`. Use `eventlisteners` to see the event handler used by each event. In this case, each event, when fired, calls `sampev.m`:

   ```
   f = figure ('position', [100 200 200 200]);
   h = actxcontrol('mwsamp.mwsampctrl.2', ...
       [0 0 200 200], f, ...
       'sampev');
   h.eventlisteners
   ```

   MATLAB displays:

```
ans =
    'Click'          'sampev'
    'DblClick'       'sampev'
    'MouseDown'      'sampev'
    'Event_Args'     'sampev'
```

2 Unregister just the `dblclick` event. Now, when you list the registered events using `eventlisteners`, `dblclick` is no longer registered and the control does not respond when you double-click the mouse over it:

```
h.unregisterevent({'dblclick' 'sampev'});
h.eventlisteners
```

MATLAB displays:

```
ans =
    'Click'          'sampev'
    'MouseDown'      'sampev'
    'Event_Args'     'sampev'
```

3 Now, register the `click` and `dblclick` events with a different event handler for `myclick` and `my2click`, respectively:

```
h.unregisterallevents;
h.registerevent({'click' 'myclick'; ...
    'dblclick' 'my2click'});
h.eventlisteners
```

MATLAB displays:

```
ans =
    'click'        'myclick'
    'dblclick'     'my2click'
```

4 Unregister these same events by specifying event names and their handler routines in a cell array. `eventlisteners` now returns an

empty cell array, meaning that no events are registered for the `mwsamp` control:

```
h.unregisterevent({'click' 'myclick'; ...
    'dblclick' 'my2click'});
h.eventlisteners
```

MATLAB displays:

```
ans =
     {}
```

Unregister Microsoft Excel workbook events:

1. Create a `Workbook` object and register two events with the event handler routines, `EvtActivateHndlr` and `EvtDeactivateHndlr`:

   ```
   myApp = actxserver('Excel.Application');
   wbs = myApp.Workbooks;
   wb = wbs.Add;wb.registerevent({'Activate' 'EvtActivateHndlr'; ...
       'Deactivate' 'EvtDeactivateHndlr'})
   wb.eventlisteners
   ```

   MATLAB shows the events with the corresponding event handlers.

   ```
   ans =
       'Activate'      'EvtActivateHndlr'
       'Deactivate'    'EvtDeactivateHndlr'
   ```

2. Next, unregister the `Deactivate` event handler:

   ```
   wb.unregisterevent({'Deactivate' 'EvtDeactivateHndlr'})
   wb.eventlisteners
   ```

   MATLAB shows the remaining registered event (`Activate`) with its corresponding event handler.

```
ans =
    'Activate'    'EvtActivateHndlr'
```

`events (COM)` | `eventlisteners` | `registerevent` | `unregisterallevents` | `isevent`

How To

- "Writing Event Handlers"

Purpose

Extract contents of tar file

Syntax

```
untar(tarfilename)
untar(tarfilename,outputdir)
untar(url, ...)
filenames = untar(...)
```

Description

`untar(tarfilename)` extracts the archived contents of `tarfilename` into the current directory and sets the files' attributes. It overwrites any existing files with the same names as those in the archive if the existing files' attributes and ownerships permit it. For example, if you rerun `untar` on the same `tarfilename`, MATLAB software does not overwrite files with a read-only attribute; instead, `untar` displays a warning for such files. On Microsoft Windows platforms, the hidden, system, and archive attributes are not set.

`tarfilename` is a string specifying the name of the tar file. `tarfilename` is gunzipped to a temporary directory and deleted if its extension ends in `.tgz` or `.gz`. If an extension is omitted, `untar` searches for `tarfilename` appended with `.tgz`, `.tar.gz`, or `.tar`. `tarfilename` can include the directory name; otherwise, the file must be in the current directory or in a directory on the MATLAB path.

`untar(tarfilename,outputdir)` uncompresses the archive `tarfilename` into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`untar(url, ...)` extracts the tar archive from an Internet URL. The URL must include the protocol type (for example, `'http://'` or `'ftp://'`). MATLAB downloads the URL is to a temporary directory, and then deletes it.

`filenames = untar(...)` extracts the tar archive and returns the names of the extracted files in the string cell array `filenames`. If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

Examples

Using tar and untar to Copy Files

Copy all `.m` files in the current directory to the directory `backup`.

```
tar('mymfiles.tar.gz','*.m');
untar('mymfiles','backup');
```

Using untar with URL

Run `untar` to list Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory `ncm`.

```
url ='http://www.mathworks.com/moler/ncm.tar.gz';
ncmFiles = untar(url,'ncm')
```

See Also

`gzip` | `gunzip` | `tar` | `unzip` | `zip`

Purpose

Correct phase angles to produce smoother phase plots

Syntax

```
Q = unwrap(P)
Q = unwrap(P,tol)
Q = unwrap(P,[],dim)
Q = unwrap(P,tol,dim)
```

Description

`Q = unwrap(P)` corrects the radian phase angles in a vector `P` by adding multiples of $\pm 2\pi$ when absolute jumps between consecutive elements of `P` are greater than or equal to the default jump tolerance of π radians. If `P` is a matrix, `unwrap` operates columnwise. If `P` is a multidimensional array, `unwrap` operates on the first nonsingleton dimension.

`Q = unwrap(P,tol)` uses a jump tolerance `tol` instead of the default value, π.

`Q = unwrap(P,[],dim)` unwraps along `dim` using the default tolerance.

`Q = unwrap(P,tol,dim)` uses a jump tolerance of `tol`.

Note A jump tolerance less than π has the same effect as a tolerance of π. For a tolerance less than π, if a jump is greater than the tolerance but less than π, adding $\pm 2\pi$ would result in a jump larger than the existing one, so `unwrap` chooses the current point. If you want to eliminate jumps that are less than π, try using a finer grid in the domain.

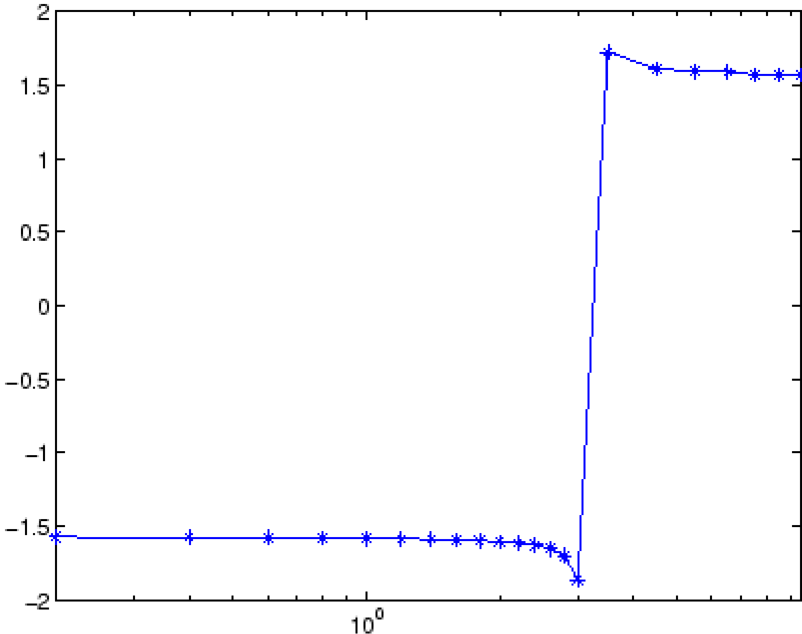
Examples

Example 1

The following phase data comes from the frequency response of a third-order transfer function. The phase curve jumps `3.5873` radians between `w = 3.0` and `w = 3.5`, from `-1.8621` to `1.7252`.

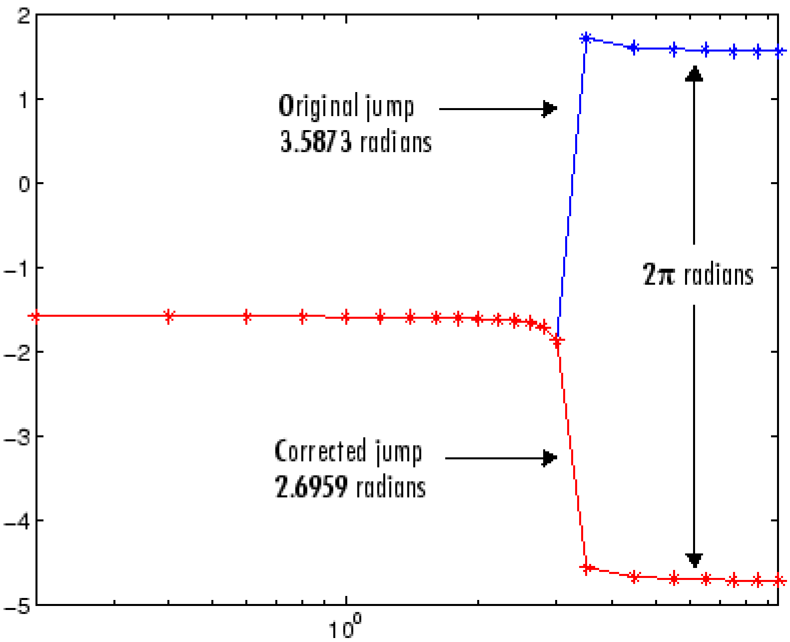
```
w = [0:.2:3,3.5:1:10];
p = [    0
     -1.5728
     -1.5747
     -1.5772
```

```
      -1.5790
      -1.5816
      -1.5852
      -1.5877
      -1.5922
      -1.5976
      -1.6044
      -1.6129
      -1.6269
      -1.6512
      -1.6998
      -1.8621
       1.7252
       1.6124
       1.5930
       1.5916
       1.5708
       1.5708
       1.5708 ];
semilogx(w,p,'b*-'), hold
```



Using `unwrap` to correct the phase angle, the resulting jump is `2.6959`, which is less than the default jump tolerance π. This figure plots the new curve over the original curve.

```
semilogx(w,unwrap(p),'r*-')
```



Example 2

Array `P` features smoothly increasing phase angles except for discontinuities at elements `(3,1)` and `(1,2)`.

```
P = [       0     7.0686     1.5708     2.3562
       0.1963     0.9817     1.7671     2.5525
       6.6759     1.1781     1.9635     2.7489
       0.5890     1.3744     2.1598     2.9452 ]
```

The function `Q = unwrap(P)` eliminates these discontinuities.

```
Q =
            0     7.0686     1.5708     2.3562
       0.1963     7.2649     1.7671     2.5525
       0.3927     7.4613     1.9635     2.7489
       0.5890     7.6576     2.1598     2.9452
```

See Also

`abs` | `angle`

unzip

Purpose

Extract contents of zip file

Syntax

```
unzip(zipfilename)
unzip(zipfilename,outputdir)
filenames = unzip(zipfilename,outputdir)
```

Description

`unzip(zipfilename)` extracts the archived contents of `zipfilename` into the current folder, preserving the files' attributes and timestamps. The `unzip` function can extract files from your local system or files from an Internet URL.

`unzip(zipfilename,outputdir)` extracts the contents of `zipfilename` into the folder `outputdir`.

`filenames = unzip(zipfilename,outputdir)` returns the names of the extracted files in the string cell array `filenames`. Specifying `outputdir` is optional.

Tips

- `unzip` does not support password-protected or encrypted zip archives.
- If any files in the target folder have the same name as files in the zip file, and you have write permission to the files, `unzip` overwrites the existing files with the archived versions. If you do not have write permission, `unzip` issues a warning.
- Extract files that contain non-7-bit ASCII characters on a machine that has the appropriate language/encoding settings.

Input Arguments

zipfilename

String that specifies the name of the zip file.

If `zipfilename` does not include the full path, `unzip` searches for the file in the current folder and along the MATLAB path. If you do not specify the file extension, `unzip` appends `.zip`.

If you are downloading a URL, `zipfilename` must include the protocol type (for example, `http://`). The `unzip` function downloads the URL to the temporary folder on your system, and deletes the URL on cleanup.

outputdir

String that specifies the target folder for the extracted files.

Default: current folder ('.')

Output Arguments

entrynames

Cell array of strings that contain the paths of the extracted files.

If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

Examples

Copy the example MAT-files to the folder `archive`:

```
% Zip the example MAT-files to examples.zip
zip('examples.zip','*.mat',...
    fullfile(matlabroot,'toolbox','matlab','demos'))

% Unzip examples.zip to the folder 'archive'
unzip('examples','archive')
```

Download Cleve Moler's "Numerical Computing with MATLAB" examples to the output folder `ncm`:

```
url ='http://www.mathworks.com/moler/ncm.zip';
ncmFiles = unzip(url,'ncm')
```

Alternatives

To extract files from a zip file using the Current Folder browser, select the zip file, right-click to open the context menu, and then select **Extract**.

See Also

`fileattrib` | `gzip` | `gunzip` | `tar` | `untar` | `zip`

uplus

Purpose

Unary plus

Syntax

```
b = +a
b = uplus(a)
```

Description

`b = +a` for numeric arrays is `a`.

`b = uplus(a)` is called for the syntax `+a` when `a` is an object.

See Also

`uminus`

Purpose

Convert string to uppercase

Syntax

```
t  = upper('str')
B = upper(A)
```

Description

`t = upper('str')` converts any lowercase characters in the string `str` to the corresponding uppercase characters and leaves all other characters unchanged.

`B = upper(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `upper` to each string within `A`.

Examples

`upper('attention!')` is `ATTENTION!`.

Tips

Character sets supported:

- PC: Windows Latin-1
- Other: ISO Latin-1 (ISO 8859-1)

See Also

`lower`

Purpose

Download URL content to MATLAB string

Syntax

```
str = urlread(URL)
str = urlread(URL,Name,Value)
[str,status] = urlread( ___ )
```

Description

`str = urlread(URL)` downloads the HTML Web content from the specified `URL` into the string `str`. `urlread` does not retrieve hyperlink targets and images.

`str = urlread(URL,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[str,status] = urlread( ___ )` suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is `1`. Otherwise, `status` is `0`

Input Arguments

URL - Content location

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

Example: `'http://www.mathworks.com/matlabcentral'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

'Get' - Data to send to the Web form using the GET method

cell array

Parameters of the data to send to the Web form using the GET method, specified as the comma-separated pair consisting of `'get'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Get'` includes the data in the URL, separated by `?` and `&` characters.

Example: `'Get',{'term','urlread'}`

'Post' - Data to send to the Web form using the POST method

cell array

Parameters of the data to send to the Web form using the POST method, specified as the comma-separated pair consisting of `'post'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Post'` submits the data as part of the request headers, not explicitly in the URL.

'Charset' - Character encoding

string

Character encoding, specified as the comma-separated pair consisting of `'Charset'` and a string. If you do not specify `Charset`, the function attempts to determine the character encoding from the headers of the file. If the character encoding cannot be determined, `Charset` defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

Example: `'Charset','ISO-8859-1'`

'Timeout' - Timeout duration

scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of `'Timeout'` and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

Example: `'Timeout',10`

'UserAgent' - Client user agent identification

string

Client user agent identification, specified as the comma-separated pair consisting of `'UserAgent'` and a string.

Example: `'UserAgent','MATLAB R2012b'`

'Authentication' - HTTP authentication mechanism

`'Basic'`

HTTP authentication mechanism, specified as the comma-separated pair consisting of `'Authentication'` and a string. Currently, only the value `'Basic'` is supported. `'Authentication','Basic'` specifies basic authentication.

If you include the `Authentication` argument, you must also include the `Username` and `Password` arguments.

'Username' - User identifier

string

User identifier, specified as the comma-separated pair consisting of `'Username'` and a string. If you include the `Username` argument, you must also include the `Password` and `Authentication` arguments.

Example: `'Username','myName'`

'Password' - User authentication password

string

User authentication password, specified as the comma-separated pair consisting of `'Password'` and a string. If you include the `Password` argument, you must also include the `Username` and `Authentication` arguments.

Example: `'Password','myPassword123'`

Output Arguments

str - Contents of the file at the specified URL

string

Contents of the file at the specified URL, returned as a string. For example, if the URL corresponds to an HTML page, `str` contains the text and markup in the HTML file. If the URL corresponds to a binary file, `str` is not readable.

status - Download status

1 | 0

Download status, returned as either `1` or `0`. When the download is successful, `status` is `1`. Otherwise, `status` is `0`.

Examples

Download Web Content by Specifying Complete URL

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
    '?term=urlread'];
str = urlread(fullURL);
```

`urlread` reads from the specified URL and downloads the HTML content to the string `str`.

Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';
str = urlread(URL,'Get',{'term','urlread'});
```

`urlread` reads from http://www.mathworks.com/matlabcentral/fileexchange/?term=urlread and downloads the HTML content to the string `str`.

Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
    '?term=urlread'];
str = urlread(fullURL,'Timeout',5);
```

Tips

- `urlread` saves Web content to a string. To save content to a file, use `urlwrite`.
- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.

urlwrite

Purpose

Download URL content and save to file

Syntax

```
urlwrite(URL,filename)
urlwrite(URL,filename,Name,Value)

[filestr,status] = urlwrite( ___ )
```

Description

`urlwrite(URL,filename)` reads Web content at the specified `URL` and saves it to the file specified by `filename`.

`urlwrite(URL,filename,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[filestr,status] = urlwrite( ___ )` stores the file path in variable `filestr`, and suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is `1`. Otherwise, `status` is `0`.

Input Arguments

URL - Content location

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

Example: `'http://www.mathworks.com/matlabcentral'`

filename - Name of file to store Web content

string

Name of the file to store the Web content, specified as a string. If you do not specify the path for `filename`, `urlwrite` saves the file in the current folder.

Example: `'myfile.html'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

'Get' - Data to send to the Web form using the GET method

cell array

Parameters of the data to send to the Web form using the GET method, specified as the comma-separated pair consisting of `'get'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Get'` includes the data in the URL, separated by `?` and `&` characters.

Example: `'Get',{'term','urlread'}`

'Post' - Data to send to the Web form using the POST method

cell array

Parameters of the data to send to the Web form using the POST method, specified as the comma-separated pair consisting of `'post'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Post'` submits the data as part of the request headers, not explicitly in the URL.

'Charset' - Character encoding

string

Character encoding, specified as the comma-separated pair consisting of `'Charset'` and a string. If you do not specify `Charset`, the function attempts to determine the character encoding from the headers of the

file. If the character encoding cannot be determined, `Charset` defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

Example: `'Charset','ISO-8859-1'`

'Timeout' - Timeout duration

scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of `'Timeout'` and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

Example: `'Timeout',10`

'UserAgent' - Client user agent identification

string

Client user agent identification, specified as the comma-separated pair consisting of `'UserAgent'` and a string.

Example: `'UserAgent','MATLAB R2012b'`

'Authentication' - HTTP authentication mechanism

`'Basic'`

HTTP authentication mechanism, specified as the comma-separated pair consisting of `'Authentication'` and a string. Currently, only the value `'Basic'` is supported. `'Authentication','Basic'` specifies basic authentication.

If you include the `Authentication` argument, you must also include the `Username` and `Password` arguments.

'Username' - User identifier

string

User identifier, specified as the comma-separated pair consisting of `'Username'` and a string. If you include the `Username` argument, you must also include the `Password` and `Authentication` arguments.

Example: `'Username','myName'`

'Password' - User authentication password

string

User authentication password, specified as the comma-separated pair consisting of `'Password'` and a string. If you include the `Password` argument, you must also include the `Username` and `Authentication` arguments.

Example: `'Password','myPassword123'`

Output Arguments

filestr - Path of the file

string

Path of the file specified by `filename`, returned as a string.

status - Download status

1 | 0

Download status, returned as either `1` or `0`. When the download is successful, `status` is `1`. Otherwise, `status` is `0`.

Examples

Download Web Content by Specifying Complete URL

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlwrite`. Save the results to `samples.html` in the current directory.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
           '?term=urlwrite'];
filename = 'samples.html';
urlwrite(fullURL,filename);
```

View the file.

```
web(filename)
```

Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlwrite`. Save the results to `samples.html` in the current directory.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';
filename = 'samples.html';
urlwrite(URL,filename,'get',{'term','urlwrite'});
```

`urlwrite` downloads the HTML content from http://www.mathworks.com/matlabcentral/fileexchange/?term=urlwrite and writes it to `samples.html`.

Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
    '?term=urlwrite'];
filename = 'samples.html';
urlwrite(fullURL,filename,'Timeout',5);
```

Tips

- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.

`urlreadmget` **|** | `webftp` **|**

Concepts

- “Specify Proxy Server Settings for Connecting to the Internet”

Purpose

Determine if Java feature is supported in MATLAB

Syntax

```
tf = usejava(feature)
```

Description

`tf = usejava(feature)` returns logical `1` (`true`) if the specified feature is supported. Otherwise, it returns logical `0` (`false`).

Input Arguments

feature - Java feature

`'awt'` | `'desktop'` | `'jvm'` | `'swing'`

Java feature, specified as one of these values:

`'awt'`	Java GUI components in the Abstract Window Toolkit (AWT) components are available.
`'desktop'`	The MATLAB interactive desktop is running.
`'jvm'`	The Java Virtual Machine software (JVM) is running.
`'swing'`	Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.

Examples

Display Error Message

Use the following code snippet to test that the AWT GUI components are available before attempting to display a Java Frame.

```
if usejava('awt')
   myFrame = java.awt.Frame;
else
   disp('Unable to open a Java Frame');
end
```

If the AWT is not available on your system, MATLAB displays the message.

Call error Function

Use the following code snippet to terminate a script if MATLAB does not have access to JVM software.

The variable, `filename`, is a function that contains Java code.

```
if ~usejava('jvm')
   error([filename ' requires Java to run.']);
end
```

See Also

`javachk` | `error`

userpath

Purpose

View or change user portion of search path

Syntax

```
userpath

userpath(newpath)
userpath('reset')
userpath('clear')
```

Description

`userpath` returns a string specifying the first folder on the search path. MATLAB adds the *`userpath`* to the search path upon startup.

`userpath(newpath)` sets the primary *`userpath`* folder to `newpath`. The `newpath` folder appears at the top of the search path immediately and at startup in future sessions. MATLAB removes the folder previously specified by *`userpath`* from the search path.

`userpath('reset')` sets the primary *`userpath`* folder to the default for that platform, creating the `Documents/MATLAB` (or `My Documents/MATLAB`) folder, if it does not exist. MATLAB immediately adds the default folder to the top of the search path, and also adds it to the search path at startup in future sessions. On Linux, the `MATLAB` directory is not created if the `Documents` directory does not exist.

`userpath('clear')` clears the value for the primary *`userpath`* immediately, and for future MATLAB sessions. MATLAB removes the folder previously specified by *`userpath`* from the search path.

Input Arguments

newpath - New userpath value
string

New userpath value, specified as a string. `newpath` must be an absolute path.

Example: `'C:\myFolder'`

Examples

View userpath Folder

This example assumes `userpath` is set to the default value on the Windows XP platform, `My Documents\MATLAB`. Start MATLAB and display the current folder:

```
pwd

H:\My Documents\MATLAB
```

In this example, `H` is the drive at which `My Documents` is located.

Confirm that the current folder is the *`userpath`*.

```
userpath

H:\My Documents\MATLAB;
```

Display the search path.

```
path

MATLABPATH

 H:\My Documents\MATLAB
 C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
 C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

MATLAB returns the search path. The *`userpath`* portion is at the top.

Set New Value for userpath

Assume *`userpath`* is set to the default value on the Windows XP platform, `My Documents\MATLAB`. Change the value from the default for *`userpath`* to `C:\Research_Project`.

```
newpath = 'C:\Research_Project';
userpath(newpath)
```

View the effect of the change on the search path.

```
path
```

```
MATLABPATH

 C:\Research_Project
 C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
 C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

MATLAB displays the search path, with the new value for *userpath* portion at the top. Note that MATLAB automatically removed the previous value of *userpath*, `H:\My Documents\MATLAB`, from the search path when you assigned a new value to *userpath*.

Clear the Value for userpath

Assume `userpath` is set to the default value and you do not want any folders to be added to the search path upon startup. Confirm the default is currently set.

```
userpath
```

```
H:\My Documents\MATLAB;
```

Verify that the `userpath` folder is at the top of the search path.

```
path
```

```
MATLABPATH

H:\My Documents\MATLAB
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

Clear the value.

```
userpath('clear')
```

Verify the result.

```
userpath
```

```
ans =
     ''
```

Confirm the *userpath* folder was removed from the search path.

```
path
```

```
MATLABPATH

C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

Note By default, the startup folder is the *userpath* folder when you start MATLAB by double-clicking the shortcut on Windows platforms, or by double-clicking the application on Macintosh platforms. If you clear the value for *userpath*, the startup folder will not necessarily be on the search path. Removing the *userpath* folder from the search path *and* saving the changes to the path has the same effect.

Tips

- On Macintosh and UNIX platforms, you can automatically add subfolders to the top of the search path upon startup by specifying the path for the subfolders via the `MATLABPATH` environment variable.

See Also

`addpath` | `path` | `rmpath` | `savepath` | `startup`

Concepts

- “What Is the MATLAB Search Path?”

validateattributes

Purpose

Check validity of array

Syntax

```
validateattributes(A,classes,attributes)
validateattributes(A,classes,attributes,argIndex)
validateattributes(A,classes,attributes,funcName)
validateattributes(A,classes,attributes,funcName,varName)
validateattributes(A,classes,attributes,funcName,varName,
   argIndex)
```

Description

`validateattributes(A,classes,attributes)` validates that array `A` belongs to at least one of the specified classes (or its subclass) and has all of the specified attributes. If `A` does not meet the criteria, MATLAB throws an error and displays a formatted error message. Otherwise, `validateattributes` completes without displaying any output.

`validateattributes(A,classes,attributes,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validateattributes(A,classes,attributes,funcName)` includes the specified function name in generated error identifiers.

`validateattributes(A,classes,attributes,funcName,varName)` includes the specified variable name in generated error messages.

`validateattributes(A,classes,attributes,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

Input Arguments

A - Input

any type of array

Input, specified as any type of array.

Data Types
`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | cell | function_handle`
Complex Number Support: Yes

classes - Valid data types

cell array of strings

Valid data types, specified as a cell array of strings. Each string can be the name of any built-in or custom class, including:

`'single'`	Single-precision number
`'double'`	Double-precision number
`'int8'`	Signed 8-bit integer
`'int16'`	Signed 16-bit integer
`'int32'`	Signed 32-bit integer
`'int64'`	Signed 64-bit integer
`'uint8'`	Unsigned 8-bit integer
`'uint16'`	Unsigned 16-bit integer
`'uint32'`	Unsigned 32-bit integer
`'uint64'`	Unsigned 64-bit integer
`'logical'`	Logical `true` or `false`
`'char'`	Character or string
`'struct'`	Structure array
`'cell'`	Cell array
`'function_handle'`	function handle

'numeric'	Any value for which the isnumeric function returns true, including int8, int16, int32, int64, uint8, uint16, uint32, uint64, single, or double
'<*class_name*>'	Any other class name

Data Types
cell

attributes - Valid attributes

cell array of strings

Valid attributes, specified as a cell array of strings.

Some attributes also require numeric values, such as attributes that specify the size or number of elements of A. For these attributes, the numeric value or vector must immediately follow the attribute name string in the cell array.

Attributes that describe the size and shape of array A:

'2d'	Two-dimensional array, including scalars, vectors, matrices, and empty arrays
'3d'	Array with three or fewer dimensions
'column'	Column vector, N-by-1
'row'	Row vector, 1-by-N
'scalar'	Scalar value, 1-by-1
'vector'	Row or column vector, or a scalar value
'size', [d1,...,dN]	Array with dimensions d1-by-...-by-dN. To skip checking a particular dimension, specify NaN for that dimension, such as [3,4,NaN,2].
'numel', N	Array with N elements
'ncols', N	Array with N columns

'nrows', N	Array with N rows
'ndims', N	N-dimensional array
'square'	Square matrix; in other words, a two-dimensional array with equal number of rows and columns
'diag'	Diagonal matrix
'nonempty'	No dimensions that equal zero
'nonsparse'	Array that is not sparse

Attributes that specify valid ranges for values in A:

'>', N	All values greater than N
'>=', N	All values greater than or equal to N
'<', N	All values less than N
'<=', N	All values less than or equal to N

Attributes that check types of values in a numeric or logical array, A:

'binary'	Array of ones and zeros
'even'	Array of even integers (includes zero)
'odd'	Array of odd integers
'integer'	Array of integer values
'real'	Array of real values
'finite'	Array of finite values
'nonnan'	No NaN (Not a Number) elements
'nonnegative'	No elements less than zero

'nonzero'	No elements equal to zero
'positive'	No elements less than or equal to zero

Data Types
`cell`

funcName - Name of function whose input you are validating

string

Name of function whose input you are validating, specified as a string. If you specify an empty string, `''`, the `validateattribute` function ignores the `funcName` input.

Data Types
`char`

varName - Name of input variable

string

Name of input variable, specified as a string. If you specify an empty string, `''`, the `validateattribute` function ignores the `varName` input.

Data Types
`char`

argIndex - Position of input argument

positive integer

Position of input argument, specified as a positive integer.

Data Types
`double`

Examples

Validate the Size of an Array

```
classes = {'numeric'};
attributes = {'size',[4,6,2]};

A = rand(3,5,2);
```

```
validateattributes(A,classes,attributes)
```

```
Expected input to be of size 4x6x2 when it is actually size 3x5x2.
```

Because A did not match the specified attributes, MATLAB throws an error message.

Check the Attributes of a Complex Number

Assuming that a is to be the second input argument to a function, check that it is nonnegative.

```
a = complex(1,1);
validateattributes(a,{'numeric'},{'nonnegative'},2);
```

```
Expected input number 2 to be nonnegative.
```

Because complex numbers lack a well-defined ordering in the complex plane, validateattributes does not recognize them as positive or negative.

Ensure Array Values Are Within a Specified Range

Check that the values in an array are 8-bit integers between 0 and 10.

Assume that this code occurs in a function called Rankings.

```
classes = {'uint8','int8'};
attributes = {'>',0,'<',10};
funcName = 'Rankings';
A = int8(magic(4));

validateattributes(A,classes,attributes,funcName)
```

```
Error using Rankings
Expected input to be an array with all of the values < 10.
```

Validate Function Input Parameters Using `inputParser`

Create a custom function that checks input parameters with `inputParser`, and use `validateattributes` as the validating function for the `addRequired` and `addOptional` methods.

Define the function.

```
function a = findArea(shape,dim1,varargin)
   charchk = {'char'};
   numchk = {'double'};
   nempty = {'nonempty'};

   validateattributes(shape,charchk,nempty,'findArea','shape');
   validateattributes(dim1,numchk,nempty,'findArea','dim1');
   validateattributes(varargin,numchk,nempty,'findArea','varargin');

   switch shape
      case 'circle'
         a = pi * dim1.^2;
      case 'rectangle'
         a = dim1 .* p.Results.dim2;
   end
```

Call the function with a nonnumeric third input.

```
myarea = findArea('rectangle',3,'x')
```

```
Error using findArea
Expected varargin to be one of these types:

double

Instead its type was cell.

Error in findArea (line 8)
   validateattributes(varargin,numchk,nempty,'findArea','varargin');
```

Validate Arguments of a Function

Check the inputs of a function and include information about the input name and position in generated error.

Define the function.

```
function v = findVolume(shape,ht,wd,ln)
   validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
   validateattributes(ht,{'numeric'},{'nonempty'},mfilename,'Height',2
   validateattributes(wd,{'numeric'},{'nonempty'},mfilename,'Width',3)
   validateattributes(ln,{'numeric'},{'nonempty'},mfilename,'Length',4
```

Call the function without the shape input string.

```
vol = findVolume(10,7,4)
```

```
Error using findVolume
Expected input number 1, Shape, to be one of these types:

char

Instead its type was double.

Error in findVolume (line 2)
validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
```

The function name becomes part of the error identifier.

```
MException.last.identifier
```

```
ans =

MATLAB:findVolume:invalidType
```

See Also

validatestring | is* | isa | isnumericinputParser |

validatestring

Purpose

Check validity of text string

Syntax

```
validStr = validatestring(str,validStrings)
validStr = validatestring(str,validStrings,argIndex)
validStr = validatestring(str,validStrings,funcName)
validStr =
validatestring(str,validStrings,funcName,varName)
validStr =
validatestring(str,validStrings,funcName,varName,
   argIndex)
```

Description

`validStr = validatestring(str,validStrings)` checks the validity of text string `str`. If `str` is an unambiguous, case-insensitive match to a string in cell array `validStrings`, the `validatestring` function returns the matching string in `validstr`. Otherwise, MATLAB throws an error and issues a formatted error message.

`validStr = validatestring(str,validStrings,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validStr = validatestring(str,validStrings,funcName)` includes the specified function name in generated error identifiers.

`validStr =`
`validatestring(str,validStrings,funcName,varName)` includes the specified variable name in generated error messages.

`validStr =`
`validatestring(str,validStrings,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

Input Arguments

str

String to validate, of type `char`.

validStrings

Cell array of allowed strings.

funcName

String that specifies the name of the function whose input you are validating. If you specify an empty string, `''`, the `validatestring` function ignores the `funcname` input.

varName

String that specifies the name of the input variable. If you specify an empty string, `''`, the `validatstring` function ignores the `varName` input.

argIndex

Positive integer that specifies the position of the input argument.

Output Arguments

validStr

String that contains the element of `validStrings` that is an unambiguous, case-insensitive match to `str`.

Example — Match 'ball' with . . .	Return Value	Type of Match
`ball`, `barn`, `bell`	`ball`	Exact match
`balloon`, `barn`	`balloon`	Partial match (leading characters)
`ballo`, `balloo`, `balloon`	`ballo` (shortest match)	Multiple partial matches where each string is a subset of another
`balloon`, `ballet`	Error	Multiple partial matches to unique strings
`barn`, `bell`	Error	No match

Examples

Check whether a string is in a set of valid values.

```
str = 'won';
validStrings = {'wind','wonder','when'};

validStr = validatestring(str,validStrings)
```

Because `str` is a partial match to a unique string, this code returns

```
validStr =
     wonder
```

However, if `str` is a partial match to multiple strings, and the strings are not subsets of each other, `validatestring` throws an error and displays a formatted message.

```
str = 'won';
validStrings = {'wonder','wondrous','wonderful'};

validStr = validatestring(str,validStrings)
```

The error message is

```
Expected argument to match one of these strings:

  wonder, wondrous, wonderful

The input, 'won', matched more than one valid string.
```

Check inputs to a custom function, and include information about the input name and position in generated errors.

```
function a = findArea(shape,ht,wd,units)
   a = 0;
   expectedShapes = {'square','rectangle','triangle'};
   expectedUnits = {'cm','m','in','ft','yds'};
```

```
shapeName = validatestring(shape,expectedShapes,mfilename,'Shape',1
unitAbbrev = validatestring(units,expectedUnits,mfilename,'Units',4
```

When you call the function with valid input strings,

```
myarea = findArea('rect',10,3,'cm')
```

the function stores the inputs in local variables `shapeName` and `unitAbbrev`:

```
shapeName =
     rectangle

unitAbbrev =
     cm
```

However, if the inputs are not valid, such as

```
myarea = findArea('circle',10,3,'cm')
```

MATLAB displays

```
Error using findArea
Expected argument 1, Shape, to match one of these strings:

  square, rectangle, triangle

The input, 'circle', did not match any of the valid strings.
```

The function name is part of the error identifier, so

```
MException.last.identifier
```

returns

```
MATLAB:findArea:unrecognizedStringChoice
```

See Also

`validateattributes` | `is*` | `isa` | `inputParser`

containers.Map.values

Purpose

Identify values in `containers.Map` object

Syntax

```
valueSet = values(mapObj)
valueSet = values(mapObj,keySet)
```

Description

`valueSet = values(mapObj)` returns all of the values in `mapObj`.

`valueSet = values(mapObj,keySet)` returns values that correspond to the specified keys.

Input Arguments

mapObj

Object of class `containers.Map`.

keySet

Cell array that specifies keys in `mapObj`.

Output Arguments

valueSet

Cell array containing values from `mapObj`. If you specify `keySet`, the `valueSet` array has the same size and dimensions as `keySet`.

Examples

Get All Values in a Map

Create a map, and view all values in the map:

```
myKeys = {'a','b','c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);

valueSet = values(mapObj)
```

This code returns 1-by-3 cell array `valueSet`:

```
valueSet =
    [1]    [2]    [3]
```

Get Selected Values in a Map

View the values corresponding to keys a and c in mapObj, created in the previous example:

```
keySet = {'a','c'};
valueSet = values(mapObj,keySet)
```

This code returns 1-by-2 cell array valueSet:

```
valueSet =
    [1]    [3]
```

containers.Map | keys | isKey

Purpose

Vandermonde matrix

Syntax

```
A = vander(v)
```

Description

`A = vander(v)` returns the Vandermonde matrix whose columns are powers of the vector `v`, that is, `A(i,j) = v(i)^(n-j)`, where `n = length(v)`.

Examples

```
vander(1:.5:3)

ans =

    1.0000    1.0000    1.0000    1.0000    1.0000
    5.0625    3.3750    2.2500    1.5000    1.0000
   16.0000    8.0000    4.0000    2.0000    1.0000
   39.0625   15.6250    6.2500    2.5000    1.0000
   81.0000   27.0000    9.0000    3.0000    1.0000
```

`gallery`

Purpose

Variance

Syntax

```
V = var(X)
V = var(X,1)
V = var(X,w)
V = var(X,w,dim)
```

Description

`V = var(X)` returns the variance of `X` for vectors. For matrices, `var(X)`is a row vector containing the variance of each column of `X`. For `N`-dimensional arrays, `var` operates along the first nonsingleton dimension of `X`. The result `V` is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples.

`var` normalizes `V` by `N 1` if `N > 1`, where `N` is the sample size. This is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples. For `N = 1`, `V` is normalized by 1.

`V = var(X,1)` normalizes by `N` and produces the second moment of the sample about its mean. `var(X,0)` is equivalent to `var(X)`.

`V = var(X,w)` computes the variance using the weight vector `w`. The length of `w` must equal the length of the dimension over which `var` operates, and its elements must be nonnegative. If `X(i)` is assumed to have variance proportional to 1/`w(i)`, then `V * mean(w)/w(i)` is an estimate of the variance of `X(i)`. In other words, `V * mean(w)` is an estimate of variance for an observation given weight 1.

`V = var(X,w,dim)` takes the variance along the dimension `dim` of `X`. Pass in `0` for `w` to use the default normalization by N – 1, or 1 to use `N`.

The variance is the square of the standard deviation (STD).

Examples

Create a matrix and find the variance along the dimensions.

```
X = [4 -2 1; 9 5 7]
var(X,0,1)
ans =
```

```
   12.5000   24.5000   18.0000

var(X,0,2)
ans =
     9
     4
```

`corrcoef` | `cov` | `mean` | `median` | `std`

Purpose

Variable-length input argument list

Syntax

```
varargin
```

Description

`varargin` is an input variable in a function definition statement that allows the function to accept any number of input arguments. Specify `varargin` using lowercase characters, and include it as the last input argument after any explicitly declared inputs. When the function executes, `varargin` is a 1-by-N cell array, where N is the number of inputs that the function receives after the explicitly declared inputs.

Examples

Variable Number of Function Inputs

Define a function in a file named `varlist.m` that accepts a variable number of inputs and displays the values of each input.

```
function varlist(varargin)
   fprintf('Number of arguments: %d\n',nargin);
   celldisp(varargin)
```

Call `varlist` with several inputs.

```
varlist(ones(3),'some text',pi)
```

```
Number of arguments: 3

varargin{1} =
     1     1     1
     1     1     1
     1     1     1

varargin{2} =
some text

varargin{3} =
    3.1416
```

varargin and Declared Inputs

Define a function in a file named `varlist2.m` that expects inputs `X` and `Y`, and accepts a variable number of additional inputs.

```
function varlist2(X,Y,varargin)
   fprintf('Total number of inputs = %d\n',nargin);

   nVarargs = length(varargin);
   fprintf('Inputs in varargin(%d):\n',nVarargs)
   for k = 1:nVarargs
      fprintf('   %d\n', varargin{k})
   end
```

Call `varlist2` with more than two inputs.

```
varlist2(10,20,30,40,50)
```

```
Total number of inputs = 5
Inputs in varargin(3):
   30
   40
   50
```

Related Examples

- "Support Variable Number of Inputs"

Concepts

- "Argument Checking in Nested Functions"

Purpose

Variable-length output argument list

Syntax

```
varargout
```

Description

`varargout` is an output variable in a function definition statement that allows the function to return any number of output arguments. Specify `varargout` using lowercase characters, and include it as the last output argument after any explicitly declared outputs. When the function executes, `varargout` is a 1-by-*N* cell array, where *N* is the number of outputs requested after the explicitly declared outputs.

Examples

Variable Number of Function Outputs

Define a function in a file named `sizeout.m` that returns an output size vector `s` and a variable number of additional scalar values.

```
function [s,varargout] = sizeout(x)
nout = max(nargout,1) - 1;
s = size(x);
for k=1:nout
   varargout{k} = s(k);
end
```

Output `s` contains the dimensions of the input array `x`. Additional outputs correspond to the individual dimensions within `s`.

Call `sizeout` on a three-dimensional array and request three outputs.

```
[s,rows,cols] = sizeout(rand(4,5,2))
```

```
s =
     4     5     2

rows =
     4

cols =
     5
```

See Also

varargin | nargout | nargin | nargoutchk | narginchk | inputname

Purpose

Vectorize expression

Syntax

```
vectorize(s)
vectorize(f)
```

Description

`vectorize(s)` where `s` is a string expression, inserts a `.` before any `^`, `*` or `/` in `s`. The result is a character string.

Note `vectorize` will not accept inline function objects (`f`) in a future release.

`vectorize(f)` where `f` is an inline function object, vectorizes the formula for `f`. The result is the vectorized version of the function.

Purpose

Version information for MathWorks products

Syntax

```
ver
ver product

product_info = ver(product)
```

Description

`ver` displays:

- A header containing the current MATLAB product family version number, license number, operating system, and version of Java software for the MATLAB product.
- The version numbers for MATLAB and all other installed MathWorks products.

`ver product` displays, in addition to the header information:

- The current version number for `product`, where `product` is the name of the folder that contains the `Contents.m` file for the product you are inquiring about.

`product_info = ver(product)` returns product information to the structure array, `product_info`.

Input Arguments

product - product-specific information

The product or toolbox for which you want to view version information, specified as a string.

To determine the string to use, run the following code, substituting the name of a product function for *toolbxfcn*:

```
n = 'toolbxfcn';
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

Output Arguments

product_info - product name, version, release, and date

Product name, version, release, and date, returned as a structure array with these fields: `Name`, `Version`, `Release`, and `Date`. If a license is a trial version, the value in the `Version` field is preceded by the letter `T`

Examples

Version for All Installed Products

Display version information for all installed products. The output shown here is representative. Your results may differ.

```
ver
```

```
--------------------------------------------------------------------
MATLAB Version 7.14.0.39041 (R2012a)
MATLAB License Number: 234567
Operating System: Microsoft Windows 7 Version 6.1 (Build 7600)
Java Version: Java 1.6.0_17-b04 with Sun Microsystems Inc. Java HotSpo
--------------------------------------------------------------------
MATLAB                                                  Version 7.14
Simulink                                                Version 8.0
Control System Toolbox                                  Version 9.3
```

Version for a Particular Product

Display version information for MATLAB and the Control System Toolbox product. The output shown here is representative. Your results may differ.

1. Determine the product name for Control System Toolbox by setting `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss';
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

```
ans=
control
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
ver control
```

```
-----------------------------------------------------------------------
MATLAB Version 7.14.0.39041 (R2012a)
MATLAB License Number: 234567
Operating System: Microsoft Windows 7 Version 6.1 (Build 7600)
Java Version: Java 1.6.0_17-b04 with Sun Microsystems Inc. Java HotSpot(T
-----------------------------------------------------------------------
Control System Toolbox                                Version 9.3
```

Structure Containing Version for the MATLAB family of products

Create a structure containing version information, and then display the structure values. The output shown here is representative. Your results may differ.

```
v=ver;
for k = 1:length(v)
  fprintf('%s\n', v(k).Name);
  fprintf('  Version: %s\n', v(k).Version);
end
```

```
MATLAB
 Version: 7.14

MATLAB Builder JA
 Version: 2.2.4

MATLAB Builder NE
 Version: 4.2

MATLAB Compiler
 Version: 4.17
```

```
My Custom Toolbox
 Version: 1.0
```

Structure Containing Version for a Particular Product

Create a structure containing version information for just the Symbolic Math Toolbox™ product. The output shown here is representative. Your results may differ.

1. Determine the product name for Symbolic Math Toolbox by setting `n` to the name of a function unique to Symbolic Math Toolbox, such as `sym`:

```
n = 'sym';
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

```
ans =

symbolic
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
v = ver('symbolic')
```

```
v =

       Name: 'Symbolic Math Toolbox'
    Version: '5.8'
    Release: '(R2012a)'
       Date: '14-Sep-2011'
```

verctrl

Purpose

Source control actions (Windows platforms)

Syntax

```
verctrl('action',{'filename1','filename2',....},0)
result=verctrl('action',{'filename1','filename2',....},0)
verctrl('action','filename',0)
result=verctrl('isdiff','filename',0)
list = verctrl('all_systems')
```

Description

`verctrl('action',{'filename1','filename2',....},0)` performs the source control operation specified by `'action'` for a single file or multiple files. Enter one file as a string; specify multiple files using a cell array of strings. Use the full paths for each file name and include the extensions. Specify `0` as the last argument. Complete the resulting dialog box to execute the operation. Available values for `'action'` are as follows:

action Argument	Purpose
`'add'`	Adds files to the source control system. Files can be open in the Editor or closed when added.
`'checkin'`	Checks files into the source control system, storing the changes and creating a new version.
`'checkout'`	Retrieves files for editing.
`'get'`	Retrieves files for viewing and compiling, but not editing. When you open the files, they are labeled as read-only.
`'history'`	Displays the history of files.
`'remove'`	Removes files from the source control system. It does not delete the files from disk, but only from the source control system.

action Argument	Purpose
`'runscc'`	Starts the source control system. The file name can be an empty string.
`'uncheckout'`	Cancels a previous checkout operation and restores the contents of the selected files to the precheckout version. All changes made to the files since the checkout are lost.

`result=verctrl('`*`action`*`',{'filename1','filename2',....},0)` performs the source control operation specified by `'`*`action`*`'` on a single file or multiple files. The action can be any one of: `'add'`, `'checkin'`, `'checkout'`, `'get'`, `'history'`, or `'undocheckout'`. `result` is a logical `1` (true) when you complete the operation by clicking **OK** in the resulting dialog box, and is a logical `0` (false) when you abort the operation by clicking **Cancel** in the resulting dialog box.

`verctrl('`*`action`*`','filename',0)` performs the source control operation specified by `'`*`action`*`'` for a single file. Use the absolute path for `'filename'`. Specify `0` as the last argument. Complete any resulting dialog boxes to execute the operation. Available values for `'action'` are as follows:

action Argument	Purpose
`'showdiff'`	Displays the differences between a file and the latest checked in version of the file in the source control system.
`'properties'`	Displays the properties of a file.

`result=verctrl('`**`isdiff`**`','filename',0)` compares `filename` with the latest checked in version of the file in the source control system. `result` is a logical `1` (true) when the files are different, and is a logical `0`

(false) when the files are identical. Use the full path for `'filename'`. Specify `0` as the last argument.

`list = verctrl('all_systems')` displays in the Command Window a list of all source control systems installed on your computer.

Examples

Check In a File

Check in `D:\file1.ext` to the source control system:

```
result = verctrl('checkin','D:\file1.ext', 0)
```

This opens the Check in file(s) dialog box. Click **OK** to complete the check in. MATLAB displays

```
result = 1
```

indicating the checkin was successful.

Add Files to the Source Control System

Add `D:\file1.ext` and `D:\file2.ext` to the source control system.

```
verctrl('add',{'D:\file1.ext','D:\file2.ext'}, 0)
```

This opens the Add to source control dialog box. Click **OK** to complete the operation.

Display the Properties of a File

Display the properties of `D:\file1.ext`.

```
verctrl('properties','D:\file1.ext', 0)
```

This opens the source control properties dialog box for your source control system. The function is complete when you close the properties dialog box.

Show Differences for a File

To show the differences between the version of `file1.ext` that you just edited and saved, with the last version in source control, run

```
verctrl('showdiff','D:\file1.ext',0)
```

MATLAB displays differences dialog boxes and results specific to your source control system. After checking in the file, if you run this statement again, MATLAB displays

```
??? The file is identical to latest version under source control.
```

List All Installed Source Control Systems

To view all of the source control systems installed on your computer, type

```
list = verctrl ('all_systems')
```

MATLAB displays all the source control systems currently installed on your computer. For example:

```
list =
'Microsoft Visual SourceSafe'
'ComponentSoftware RCS'
```

See Also

checkin | checkout | undocheckout | cmopts

How To

- “Source Control Interface on Microsoft Windows”

verLessThan

Purpose

Compare toolbox version to specified version string

Syntax

```
verLessThan(toolbox, version)
```

Description

`verLessThan(toolbox, version)` returns logical 1 (`true`) if the version of the toolbox specified by the string `toolbox` is older than the version specified by the string `version`, and logical 0 (`false`) otherwise. Use this function when you want to write code that can run across multiple versions of the MATLAB software, when there are differences in the behavior of the code in the different versions.

The `toolbox` argument is a string enclosed within single quotation marks that contains the name of a MATLAB toolbox folder. The `version` argument is a string enclosed within single quotation marks that contains the version to compare against. This argument must be in the form `major[.minor[.revision]]`, such as `7`, `7.1`, or `7.0.1`. If `toolbox` does not exist, MATLAB generates an error.

To specify `toolbox`, find the folder that holds the `Contents.m` file for the toolbox and use that folder name. To see a list of all toolbox folder names, enter the following statement in the MATLAB Command Window:

```
dir([matlabroot '/toolbox'])
```

Tips

The `verLessThan` function is available with MATLAB Version 7.4 and subsequent versions. If you are running a version of MATLAB prior to 7.4, you can download the `verLessThan` function from the following MathWorks Technical Support solution. You must be running MATLAB Version 6.0 or higher to use this function:

```
http://www.mathworks.com/support/solutions/data/1-38LI61.html?solution=1-
```

Examples

These examples illustrate usage of the `verLessThan` function.

Example 1 – Checking For the Minimum Required Version

```
if verLessThan('simulink', '4.0')
    error('Simulink 4.0 or higher is required.');
```

```
end
```

Example 2 – Choosing Which Code to Run

```
if verLessThan('matlab', '7.0.1')
% -- Put code to run under MATLAB 7.0.0 and earlier here --
else
% -- Put code to run under MATLAB 7.0.1 and later here --
end
```

Example 3 – Looking Up the Folder Name

Find the name of the Data Acquisition Toolbox folder:

```
dir([matlabroot '/toolbox/d*'])

   daq        database   des      distcomp   dotnetbuilder
   dastudio   datafeed   dials    dml        dspblks
```

Use the toolbox folder name, `daq`, to compare the Data Acquisition Toolbox software version that MATLAB is currently running against version number `3`:

```
verLessThan('daq', '3')
ans =
     1
```

See Also

`ver` | `version` | `license` | `ispc` | `isunix` | `ismac` | `dir`

version

Purpose

Version number for MATLAB and libraries

Syntax

```
version
version -date
version -description
version -release
version -java
v = version('-versionOption')
[v d] = version
```

Description

`version` returns in `ans` the version and release number for the MATLAB software currently running.

`version -date` returns in `ans` the release date for the MATLAB software.

`version -description` returns in `ans` a description of the version. Usually, the description is for special versions, such as beta versions.

`version -release` returns in `ans` the release number for the MATLAB software currently running.

`version -java` returns in `ans` the version of the Sun Microsystems™ JVM software that MATLAB is using.

`v = version('-versionOption')`, where *`versionOption`* is one of the above option strings, is an alternate form of the syntax.

`[v d] = version` returns the version and release number in string `v` and the release date in string `d`. No input arguments are allowed in this syntax.

Examples

Display the version:

```
version
```

MATLAB returns:

```
7.9.0.2601 (R2009b)
```

Display the release, prefaced by a descriptor:

```
['Release R' version('-release')]
```

MATLAB returns:

```
Release R2009b
```

Return release version and release date as separate strings:

```
 [v d] = version
```

returns:

```
v =
7.12.0.39132 (R2011a)

d =
December 1, 2010
```

View the Java version:

```
version -java
```

MATLAB returns:

```
Java 1.6.0_17-b04 with Sun Microsystems Inc. Java HotSpot(TM) 64-Bit S
```

How To

- “Check for Software Updates”

Purpose

Concatenate arrays vertically

Syntax

```
C = vertcat(A1, A2, ...)
```

Description

`C = vertcat(A1, A2, ...)` vertically concatenates matrices `A1`, `A2`, and so on. All matrices in the argument list must have the same number of columns.

`vertcat` concatenates N-dimensional arrays along the first dimension. The remaining dimensions must match.

`vertcat` also concatenates character strings. Each string being concatenated must have the same number of characters.

MATLAB calls `C = vertcat(A1, A2, ...)` for the syntax `C = [A1; A2; ...]` when any of `A1`, `A2`, etc. is an object.

Tips

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see "Valid Combinations of Unlike Classes".

Examples

Create a 5-by-3 matrix, `A`, and a 3-by-3 matrix, `B`. Then vertically concatenate `A` and `B`.

```
A = magic(5);            % Create 5-by-3 matrix, A
A(:, 4:5) = []

A =

    17    24     1
    23     5     7
     4     6    13
    10    12    19
    11    18    25

B = magic(3)*100         % Create 3-by-3 matrix, B
```

```
B =

   800   100   600
   300   500   700
   400   900   200

C = vertcat(A,B)        % Vertically concatenate A and B

C =

    17    24     1
    23     5     7
     4     6    13
    10    12    19
    11    18    25
   800   100   600
   300   500   700
   400   900   200
```

horzcat | cat

How To

- "Redefining Concatenation for Your Class"

vertcat (tscollection)

Purpose

Vertical concatenation for `tscollection` objects

Syntax

```
tsc = vertcat(tsc1,tsc2,...)
```

Description

`tsc = vertcat(tsc1,tsc2,...)` performs

```
tsc = [tsc1;tsc2;...]
```

This operation appends `tscollection` objects. The time vectors must not overlap. The last time in tsc1 must be earlier than the first time in tsc2. All `tscollection` objects to be concatenated must have the same `timeseries` members.

See Also

`horzcat (tscollection)` | `tscollection`

Purpose

(Will be removed) Return simplices attached to specified vertices

---

Note `vertexAttachments(TriRep)` will be removed in a future release. Use `vertexAttachments(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
SI = vertexAttachments(TR, VI)
```

Description

`SI = vertexAttachments(TR, VI)` returns the vertex-to-simplex information for the specified vertices `VI`. For 2-D triangulations in MATLAB, the triangles `SI` are arranged in counter-clockwise order around the attached vertex `VI`.

Input Arguments

`TR`	Triangulation representation
`VI`	`VI` is a column vector of indices into the array of points representing the vertex coordinates, `TR.X`. The simplices associated with vertex `i` are the `i`'th entry in the cell array. If `VI` is not specified the vertex-simplex information for the entire triangulation is returned.

Output Arguments

`SI`	Cell array of indices of the simplices attached to a vertex. A cell array is used to store the information because the number of simplices associated with each vertex can vary. The simplices associated with vertex `i` are in the `i`'th entry in the cell array `SI`.

Definitions

A simplex is a triangle/tetrahedron or higher dimensional equivalent.

Examples

Example 1

Load a 2-D triangulation and use `TriRep` to compute the vertex-to-triangle relations.

```
load trimesh2d
trep = TriRep(tri, x, y);
```

Find the indices of the tetrahedra attached to the first vertex:

```
Tv = vertexAttachments(trep, 1)
Tv{:}
```

Example 2

Perform a direct query of a 2-D triangulation created using `DelaunayTri`.

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y);
```

Find the triangles attached to vertex 5:

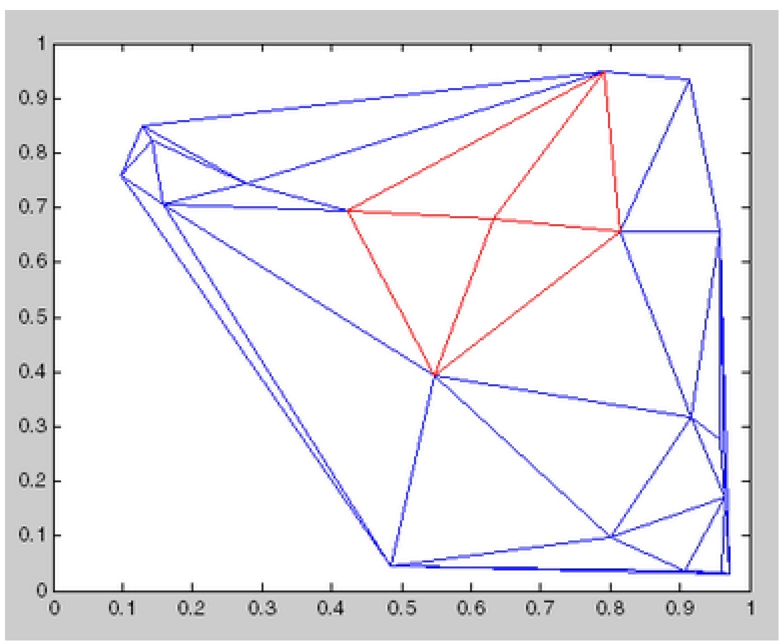
```
t = vertexAttachments(dt,5);
```

Plot the triangulation:

```
triplot(dt);
hold on;
```

Plot the triangles attached to vertex 5 (in red):

```
triplot(dt(t{:},:),x,y,'Color','r');
hold off;
```



See Also

`delaunayTriangulation` | `triangulation`

VideoReader

Purpose

Read video files

Description

Use the `VideoReader` function with the `read` method to read video data from a file into the MATLAB workspace.

The file formats that `VideoReader` supports vary by platform, as follows (with no restrictions on file extensions):

All Platforms	AVI (`.avi`), Motion JPEG 2000 (`.mj2`)
All Windows	MPEG-1 (`.mpg`), Windows Media Video (`.wmv`, `.asf`, `.asx`), and any format supported by Microsoft DirectShow®.
Windows 7	MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`), Apple QuickTime Movie (`.mov`), and any format supported by Microsoft Media Foundation.
Macintosh	MPEG-1 (`.mpg`), MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`), Apple QuickTime Movie (`.mov`), and any format supported by QuickTime as listed on http://support.apple.com/kb/HT3775.
Linux	Any format supported by your installed plug-ins for GStreamer 0.10 or above, as listed on http://gstreamer.freedesktop.org/documentation/plugins.html, including Ogg Theora (`.ogg`).

For more information, see “Supported Video File Formats” in the MATLAB Data Import and Export documentation.

Construction

`obj = VideoReader(filename)` constructs `obj` to read video data from the file named `filename`. If it cannot construct the object for any reason, `VideoReader` generates an error.

`obj = VideoReader(filename,Name,Value)` constructs the object with additional options specified by one or more `Name,Value` pair

arguments. `Name` is `'Tag'` or `'UserData'` and `Value` is the corresponding value. You can specify two name and value pair arguments in any order as `Name1,Value1,Name2,Value2`.

Input Arguments

filename

String in single quotation marks that specifies the video file to read. The `VideoReader` constructor searches for the file on the MATLAB path.

Name-Value Pair Arguments

Optional comma-separated pairs of `Name,Value` arguments, where `Name` is `'Tag'` or `'UserData'` and `Value` is the corresponding value. You can specify two name and value pair arguments in any order as `Name1,Value1,Name2,Value2`.

Tag

String that identifies the object.

Default: `''`

UserData

Generic field for data of any class that you want to add to the object.

Default: `[]`

Properties

All properties are read-only except `Tag` and `UserData`.

BitsPerPixel

Bits per pixel of the video data.

Duration

Total length of the file in seconds.

FrameRate

Frame rate of the video in frames per second.

Height

Height of the video frame in pixels.

Name

Name of the file associated with the object.

NumberOfFrames

Total number of frames in the video stream.

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, `VideoReader` cannot determine the number of frames until you read the last frame. When you construct the object, `VideoReader` returns a warning and does not set the `NumberOfFrames` property.

To count the number of frames in a variable frame rate file, use the `read` method to read the last frame of the file. For example:

```
vidObj = VideoReader('varFrameRateFile.wmv');
lastFrame = read(vidObj, inf);
numFrames = vidObj.NumberOfFrames;
```

For more information, see "Reading Variable Frame Rate Video" in the MATLAB Data Import and Export documentation..

Path

String containing the full path to the file associated with the reader.

Tag

String that identifies the object.

Default: `''`

Type

Class name of the object: `'VideoReader'`.

UserData

Generic field for data of any class that you want to add to the object.

Default: `[]`

VideoFormat

String indicating the MATLAB representation of the video format.

Video Format	Value of `VideoFormat`
AVI or MPEG-4 files with RGB24 video	`'RGB24'`
AVI files with indexed video	`'Indexed'`
AVI files with grayscale video	`'Grayscale'`

For Motion JPEG 2000 files, `VideoFormat` is one of the following.

Format of Image Data	Value of `VideoFormat`
Single-band `uint8`	`'Mono8'`
Single-band `int8`	`'Mono8 Signed'`
Single-band `uint16`	`'Mono16'`
Single-band `int16`	`'Mono16 Signed'`
Three-banded `uint8`	`'RGB24'`
Three-banded `int8`	`'RGB24 Signed'`
Three-banded `uint16`	`'RGB48'`
Three-banded `int16`	`'RGB48 Signed'`

Width

Width of the video frame in pixels.

Methods

get	Query property values for video reader object
getFileFormats	File formats that `VideoReader` supports
read	Read video frame data from file
set	Set property values for video reader object

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Construct a `VideoReader` object for the example movie file `xylophone.mpg` and view its properties:

```
xyloObj = VideoReader('xylophone.mpg', 'Tag', 'My reader object');
get(xyloObj)
```

Read and play back the movie file `xylophone.mpg`:

```
xyloObj = VideoReader('xylophone.mpg');

nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;

% Preallocate movie structure.
mov(1:nFrames) = ...
    struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...
           'colormap', []);

% Read one frame at a time.
```

```
for k = 1 : nFrames
    mov(k).cdata = read(xyloObj, k);
end

% Size a figure based on the video's width and height.
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])

% Play back the movie once at the video's frame rate.
movie(hf, mov, 1, xyloObj.FrameRate);
```

mmfileinfo | VideoWriter

How To

- "Read Video Files"

Purpose

Write video files

Description

Use the `VideoWriter` object with the `open`, `writeVideo`, and `close` methods to create video files from figures, still images, or MATLAB movies. `VideoWriter` can create uncompressed AVI and Motion JPEG 2000 compressed AVI files on all platforms, and MPEG-4 files on Windows 7 and Mac OS X 10.7 and higher. `VideoWriter` supports files larger than 2 GB, which is the limit for `avifile`.

To set video properties, `VideoWriter` includes predefined *profiles* such as `'Uncompressed AVI'` or `'MPEG-4'`.

Construction

`writerObj = VideoWriter(filename)` constructs a `VideoWriter` object to write video data to an AVI file with Motion JPEG compression.

`writerObj = VideoWriter(filename,profile)` applies a set of properties tailored to a specific file format (such as `'MPEG-4'` or `'Uncompressed AVI'`) to a `VideoWriter` object.

Input Arguments

filename

String enclosed in single quotation marks that specifies the name of the file to create.

`VideoWriter` supports these file extensions:

`.avi`	AVI file
`.mj2`	Motion JPEG 2000 file
`.mp4` or `.m4v`	MPEG-4 file (systems with Windows 7 or Mac OS X 10.7 and later)

If you do not specify a valid file extension, `VideoWriter` appends the extension `.avi`, `.mj2` or `.mp4`, depending on the `profile`. If you do not specify a value for `profile`, then `VideoWriter` creates a Motion JPEG compressed AVI file with the extension `.avi`.

profile

String enclosed in single quotation marks that describes the type of file to create. Specifying a profile sets default values for video properties such as `VideoCompressionMethod`. Possible values:

`'Archival'`	Motion JPEG 2000 file with lossless compression
`'Motion JPEG AVI'`	Compressed AVI file using Motion JPEG codec
`'Motion JPEG 2000'`	Compressed Motion JPEG 2000 file
`'MPEG-4'`	Compressed MPEG-4 file with H.264 encoding (systems with Windows 7 or Mac OS X 10.7 and later)
`'Uncompressed AVI'`	Uncompressed AVI file with `RGB24` video
`'Indexed AVI'`	Uncompressed AVI file with indexed video
`'Grayscale AVI'`	Uncompressed AVI file with grayscale video

Default: `'Motion JPEG AVI'`

Properties

ColorChannels

Number of color channels in each output video frame. (Read-only)

AVI and MPEG-4 files with RGB24 data have three color channels. Indexed and Grayscale AVI files have one color channel. The number of channels for Motion JPEG 2000 files depends on the input data to the `writeVideo` method: one for monochrome image data, three for color data.

Colormap

P-by-3 numeric matrix that contains color information about the video file. The colormap can have a maximum of 256 entries of type uint8 or double. The entries of the colormap must be integers. Each row of Colormap specifies the red, green, and blue components of a single color. The colormap can be set explicitly before the call to open, or using the colormap field of a movie frame structure at the time of writing the first frame.

Only applies to objects associated with Indexed AVI files.

After you call open, you cannot change the Colormap value.

Default: none

CompressionRatio

Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. The data is compressed as much as possible, up to the specified target.

Only available for objects associated with Motion JPEG 2000 files. After you call open, you cannot change the CompressionRatio value. If you previously set LosslessCompression to true, setting CompressionRatio generates an error.

Default: 10

Duration

Scalar value specifying the duration of the file in seconds. (Read-only)

FileFormat

String specifying the type of file to write: 'avi', 'mp4', or 'mj2'. (Read-only)

Filename

String specifying the name of the file. (Read-only)

FrameCount

Number of frames written to the video file. (Read-only)

FrameRate

Rate of playback for the video in frames per second. After you call `open`, you cannot change the `FrameRate` value.

Default: `30`

Height

Height of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame height for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a row of black pixels at the bottom.

LosslessCompression

Boolean value (logical `true` or `false`) only available for objects associated with Motion JPEG 2000 files. If `true`:

- The `writeVideo` method uses reversible mode so that the decompressed data is identical to the input data.
- `VideoWriter` ignores any specified value for `CompressionRatio`.

After you call `open`, you cannot change the `LosslessCompression` value.

Default: `false` for the `'Motion JPEG 2000'` profile, `true` for the `'Archival'` profile

MJ2BitDepth

Number of least significant bits in the input image data, from 1 to 16.

Only available for objects associated with Motion JPEG 2000 files. If you do not specify a value before calling the `open` method, `VideoWriter` sets the bit depth based on the input data type. For example, if the input data to `writeVideo` is an array of `uint8` or `int8` values, `MJ2BitDepth` is `8`.

Path

String specifying the fully qualified path. (Read-only)

Quality

Integer from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.

Only available for objects associated with the `MPEG-4` or `Motion JPEG AVI` profile. After you call `open`, you cannot change the `Quality` value.

Default: `75`

VideoBitsPerPixel

Number of bits per pixel in each output video frame. (Read-only)

AVI and MPEG-4 files have 24 bits per pixel (8 bits for each of three color bands).

For Motion JPEG 2000 files, the number of bits per pixel depends on the value of `MJ2BitDepth` and the number of bands of image data. For example, if the input data to `writeVideo` is a three-dimensional array of `uint16` or `int16` values, the default value of `MJ2BitDepth` is `16`, and `VideoBitsPerPixel` is `48` (three times the bit depth).

VideoCompressionMethod

String indicating the type of video compression: 'None', 'H.264', 'Motion JPEG', or 'Motion JPEG 2000'. (Read-only)

VideoFormat

String indicating the MATLAB representation of the video format. (Read-only)

Video Format	Value of VideoFormat
AVI or MPEG-4 files with RGB24 video	'RGB24'
AVI files with indexed video	'Indexed'
AVI files with grayscale video	'Grayscale'

For Motion JPEG 2000 files, VideoFormat depends on the value of MJ2BitDepth and the format of the input image data to the writeVideo method. For example, if you do not specify the MJ2BitDepth property, VideoWriter sets the format as shown in this table.

Format of Image Data	Value of VideoFormat
Single-band uint8	'Mono8'
Single-band int8	'Mono8 Signed'
Single-band uint16	'Mono16'
Single-band int16	'Mono16 Signed'
Three-banded uint8	'RGB24'
Three-banded int8	'RGB24 Signed'
Three-banded uint16	'RGB48'
Three-banded int16	'RGB48 Signed'

Width

Width of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame width for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a column of black pixels along the right side.

Methods

close	Close file after writing video data
getProfiles	List profiles and file formats supported by `VideoWriter`
open	Open file for writing video data
writeVideo	Write video data to file

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

View and Set Object Properties

Construct a `VideoWriter` object and view its properties.

```
writerObj = VideoWriter('newfile.avi')
```

Set the frame rate to 60 frames per second, using the `FrameRate` property.

```
writerObj.FrameRate = 60;
```

AVI File from Animation

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
```

```
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);
axis tight
set(gca,'nextplot','replacechildren');
set(gcf,'Renderer','zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20
   surf(sin(2*pi*k/20)*Z,Z)
   frame = getframe;
   writeVideo(writerObj,frame);
end

close(writerObj);
```

See Also

`VideoReader` | `mmfileinfo`

view

Purpose

Viewpoint specification

Syntax

```
view(az,el)
view([az,el])
view([x,y,z])
view(2)
view(3)
view(ax,...)
[az,el] = view
```

Description

The position of the viewer (the viewpoint) determines the orientation of the axes. You specify the viewpoint in terms of azimuth and elevation, or by a point in three-dimensional space.

`view(az,el)` and `view([az,el])` set the viewing angle for a three-dimensional plot. The azimuth, `az`, is the horizontal rotation about the *z*-axis as measured in degrees from the negative *y*-axis. Positive values indicate counterclockwise rotation of the viewpoint. `el` is the vertical elevation of the viewpoint in degrees. Positive values of elevation correspond to moving above the object; negative values correspond to moving below the object.

`view([x,y,z])` sets the viewpoint to the Cartesian coordinates `x`, `y`, and `z`. The magnitude of `(x,y,z)` is ignored.

`view(2)` sets the default two-dimensional view, `az = 0, el = 90`.

`view(3)` sets the default three-dimensional view, `az =  37.5, el = 30`.

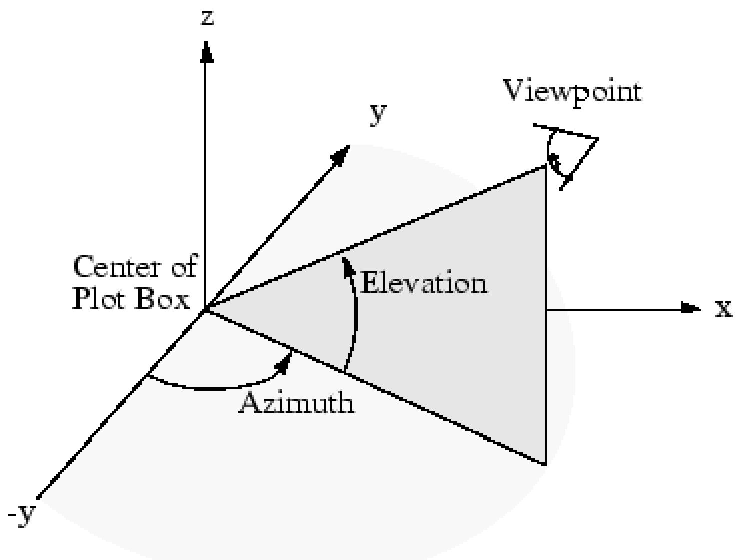
`view(ax,...)` uses axes `ax` instead of the current axes.

`[az,el] = view` returns the current azimuth and elevation.

Tips

Azimuth is a polar angle in the *x*-*y* plane, with positive angles indicating counterclockwise rotation of the viewpoint. Elevation is the angle above (positive angle) or below (negative angle) the *x*-*y* plane.

This diagram illustrates the coordinate system. The arrows indicate positive directions.



Examples

View the object from directly overhead.

```
az = 0;
el = 90;
view(az, el);
```

Set the view along the *y*-axis, with the *x*-axis extending horizontally and the *z*-axis extending vertically in the figure.

```
view([0 0]);
```

Rotate the view about the *z*-axis by 180º.

```
az = 180;
el = 90;
view(az, el);
```

See Also

`hgtransform` | `rotate3d` | CameraPosition | CameraTarget | CameraViewAngle | Projection

How To

- "View Overview"
-

Purpose

View transformation matrices

Syntax

```
viewmtx
T = viewmtx(az,el)
T = viewmtx(az,el,phi)
T = viewmtx(az,el,phi,xc)
```

Description

`viewmtx` computes a 4-by-4 orthographic or perspective transformation matrix that projects four-dimensional homogeneous vectors onto a two-dimensional view surface (e.g., your computer screen).

`T = viewmtx(az,el)` returns an *orthographic* transformation matrix corresponding to azimuth `az` and elevation `el`. `az` is the azimuth (i.e., horizontal rotation) of the viewpoint in degrees. `el` is the elevation of the viewpoint in degrees. This returns the same matrix as the commands

```
view(az,el)
T = view
```

but does not change the current view.

`T = viewmtx(az,el,phi)` returns a *perspective* transformation matrix. `phi` is the perspective viewing angle in degrees. `phi` is the subtended view angle of the normalized plot cube (in degrees) and controls the amount of perspective distortion.

Phi	Description
0 degrees	Orthographic projection
10 degrees	Similar to telephoto lens
25 degrees	Similar to normal lens
60 degrees	Similar to wide-angle lens

`T = viewmtx(az,el,phi,xc)` returns the perspective transformation matrix using `xc` as the target point within the normalized plot cube (i.e., the camera is looking at the point `xc`). `xc` is the target point that is the

center of the view. You specify the point as a three-element vector, `xc = [xc,yc,zc]`, in the interval [0,1]. The default value is `xc = [0,0,0]`.

A four-dimensional homogenous vector is formed by appending a 1 to the corresponding three-dimensional vector. For example, `[x,y,z,1]` is the four-dimensional vector corresponding to the three-dimensional point `[x,y,z]`.

Examples

Determine the projected two-dimensional vector corresponding to the three-dimensional point (0.5,0.0,-3.0) using the default view direction. Note that the point is a column vector.

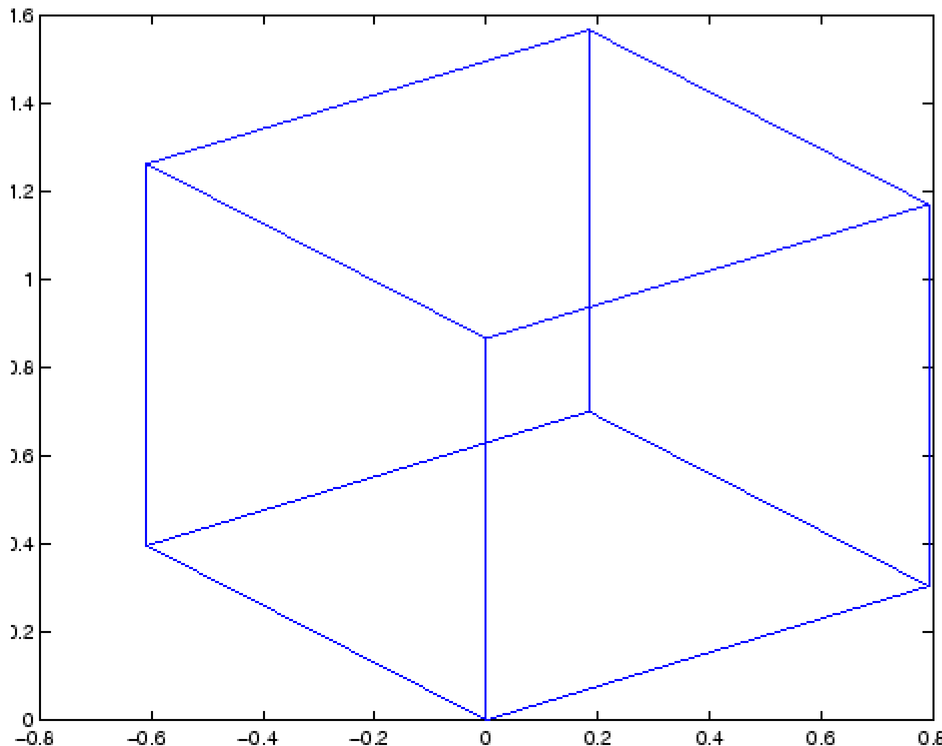
```
A = viewmtx(-37.5,30);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)
x2d =
   0.3967
   -2.4459
```

These vectors trace the edges of a unit cube:

```
x = [0  1  1  0  0  0  1  1  0  0  1  1  1  1  0  0];
y = [0  0  1  1  0  0  0  1  1  0  0  0  1  1  1  1];
z = [0  0  0  0  0  1  1  1  1  1  1  0  0  1  1  0];
```

Transform the points in these vectors to the screen, then plot the object.

```
A = viewmtx(-37.5,30);
[m,n] = size(x);
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:);
y2(:) = x2d(2,:);
figure
plot(x2,y2)
```



Use a perspective transformation with a 25 degree viewing angle:

```
A = viewmtx(-37.5,30,25);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)/x2d(4) % Normalize
x2d =
   0.1777
   -1.8858
```

Transform the cube vectors to the screen and plot the object:

```
figure
A = viewmtx(-37.5,30,25);
```

```
[m,n] = size(x);
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:)./x2d(4,:);
y2(:) = x2d(2,:)./x2d(4,:);
plot(x2,y2)
```

Tutorials

- “Defining Scenes with Cameras”

Purpose

Compare two text files, MAT-Files, binary files, Zip files, or folders

Syntax

```
visdiff('fname1', 'fname2')
visdiff('filename1', 'filename2', 'type')
```

Description

`visdiff('fname1', 'fname2')` opens the Comparison Tool and presents the differences between the two files or folders. Either ensure that the two files or folders appear on the MATLAB path, or provide the full path for each file or folder. You can compare files or any combination of folders, zip files, or Simulink manifests.

If you have Simulink Report Generator™ software, you can select a pair of Simulink models to compare XML text files generated from them.

`visdiff('filename1', 'filename2', 'type')` opens the Comparison Tool and presents the differences between the two files using the specified comparison type. *`type`* can be `'text'` or `'binary'`. If you do not specify `type`, `visdiff` creates the default comparison type for your selected files. The *`type`* option does not apply when comparing folders.

If there are multiple comparison types available for your selections (e.g., text, binary, file list, or XML comparison), you can create a new comparison and choose a different comparison type.

1. In the Comparison Tool, click the New comparison button.

   The dialog box Select Files or Folders for Comparison opens and shows your previous comparison selections in the drop-down lists.

2. Change the comparison type and click **Compare**.

Examples

Specifying Files or Folders to Compare

The `visdiff` function accepts fully qualified file names, relative file names, or names of files on the MATLAB path.

If the files you want to compare appear on the MATLAB path or in the current folder, you can specify the file names without the full path, for example:

```
visdiff('lengthofline.m','lengthofline2.m')
```

or

```
visdiff('lengthofline','lengthofline2')
```

If the files you want to compare are not on the path, either specify the full path to each file, or add the folders to the path.

For example, to specify the fully qualified file names to compare two example files:

```
visdiff(fullfile(matlabroot,'toolbox','matlab','demos','gatlin.mat'), ...
fullfile(matlabroot,'toolbox','matlab','demos','gatlin2.mat'))
```

Specify the full path to files as follows:

```
visdiff('C:\Work\comp\lengthofline.m', 'C:\Work\comp\lengthofline2.m')
```

You can specify paths to files relative to the current folder. For the preceding example, if the current folder is `Work`, then the relative paths are:

```
visdiff('comp\lengthofline.m', 'comp\lengthofline2.m')
```

Compare Two Text Files

To view a comparison of the two example files, `lengthofline.m` and `lengthofline2.m`:

```
visdiff(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','lengthofline.m'), fullfile(matlabroot,'help',...
```

```
'techdoc','matlab_env','examples','lengthofline2.m'))
```

For information about using the report features, see “Comparing Text Files”.

Note If the text files you compare are XML files, you see different results if you have MATLAB Report Generator installed. For details, see “Comparing Files and Folders”.

Compare Two MAT-Files

To compare two example files:

```
visdiff(fullfile(matlabroot,'toolbox','matlab','demos','gatlin.mat'), ...
fullfile(matlabroot,'toolbox','matlab','demos','gatlin2.mat'))
```

For information about the report features, see “Comparing MAT-Files”.

Compare Two Binary Files

The following example code adds a folder containing two MEX-files to the MATLAB path, and then compares the files:

```
addpath([matlabroot '\extern\examples\shrlib'])
visdiff('shrlibsample.mexw32', 'yprime.mexw32')
```

The Comparison Tool opens and indicates that the files are different, but does not provide details about the differences.

For more information on binary comparisons, see “Comparing Binary Files”.

Compare Two Folders or Zip Files

You can perform file list comparisons for any combinations of folders and zip files. To view an example folder comparison and instructions for using the report features, see “Comparing Folders and Zip Files”.

Compare Files and Specify Type

To compare two example text files and specify comparison type as binary:

```
visdiff(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','lengthofline.m'), fullfile(matlabroot,'help',...
'techdoc','matlab_env','examples','lengthofline2.m'), 'binary')
```

If you do not specify type, `visdiff` creates the default comparison type for your selected files, in this case, text comparison. By changing to the binary comparison type you could examine differences such as end-of-line characters.

Similarly, when you compare XML files without specifying type, you get a hierarchical XML comparison report. If instead you want a text or binary comparison, you can specify "text" or "binary" comparison types to see more details. When you compare zip files, the default comparison type is a file list comparison, and you might want to specify a binary comparison instead.

Alternatives

As an alternative to the `visdiff` function, compare files and folders using any of these GUI methods:

- From the Current Folder browser:
  - Select a file or folder. Right-click the file or folder, and select **Compare Against**.
  - For two files or subfolders in the same folder, select the files or folders. Then, right-click, and select **Compare Selected Files/Folders**.
- From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare** and then select the files or folders to compare.
- If you have a file open in the Editor, on the **Editor** tab, in the **File** section, click **Compare**. Alternatively, under **Compare**, you can choose a file to compare against, or compare with the autosave

version or the version on disk. See “Comparing Files with Autosave Version or Version on Disk”.

How To

- “Comparing Files and Folders”

volumebounds

Purpose

Coordinate and color limits for volume data

Syntax

```
lims = volumebounds(X,Y,Z,V)
lims = volumebounds(X,Y,Z,U,V,W)
lims = volumebounds(V), lims = volumebounds(U,V,W)
```

Description

`lims = volumebounds(X,Y,Z,V)` returns the x, y, z, and color limits of the current axes for scalar data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax cmin cmax]
```

You can pass this vector to the `axis` command.

`lims = volumebounds(X,Y,Z,U,V,W)` returns the x, y, and z limits of the current axes for vector data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax]
```

`lims = volumebounds(V), lims = volumebounds(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

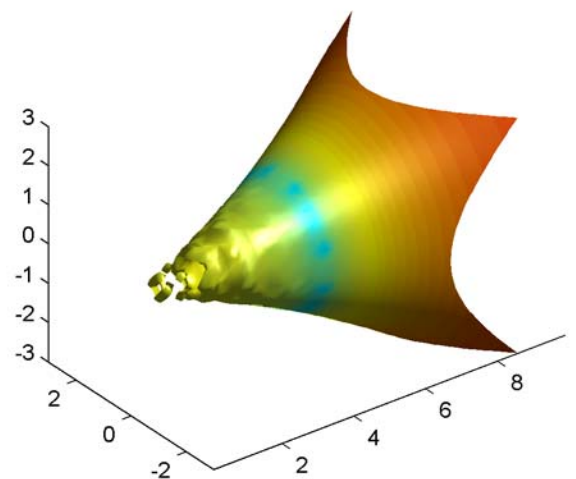
```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(V)`.

Examples

This example uses `volumebounds` to set the axis and color limits for an `isosurface` generated by the `flow` function.

```
[x y z v] = flow;
p = patch(isosurface(x,y,z,v,-3));
isonormals(x,y,z,v,p)
daspect([1 1 1])
isocolors(x,y,z,flipdim(v,2),p)
shading interp
axis(volumebounds(x,y,z,v))
view(3)
camlight
lighting phong
```



See Also

`isosurface` | `streamslice`

Purpose

Voronoi diagram

Note Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `voronoi`.

Syntax

```
voronoi(x,y)
voronoi(x,y,TRI)
voronoi(dt)
voronoi(AX,...)
voronoi(...,'LineSpec')
h = voronoi(...)
[vx,vy] = voronoi(...)
```

Description

`voronoi(x,y)` plots the bounded cells of the Voronoi diagram for the points `x,y`. Lines-to-infinity are approximated with an arbitrarily distant endpoint.

`voronoi(x,y,TRI)` uses the triangulation `TRI` instead of computing internally.

`voronoi(dt)` uses the Delaunay triangulation `dt` instead of computing it.

`voronoi(AX,...)` plots into `AX` instead of `gca`.

`voronoi(...,'LineSpec')` plots the diagram with color and line style specified.

`h = voronoi(...)` returns, in `h`, handles to the line objects created.

`[vx,vy] = voronoi(...)` returns the finite vertices of the Voronoi edges in `vx` and `vy`.

Note For the topology of the Voronoi diagram, i.e., the vertices for each Voronoi cell, use `voronoin`.

```
[v,c] = voronoin([x(:) y(:)])
```

Definitions

Consider a set of coplanar points P. For each point P_x in the set P, you can draw a boundary enclosing all the intermediate points lying closer to P_x than to other points in the set P. Such a boundary is called a *Voronoi polygon*, and the set of all Voronoi polygons for a given point set is called a *Voronoi diagram*.

Visualization

Use one of these methods to plot a Voronoi diagram:

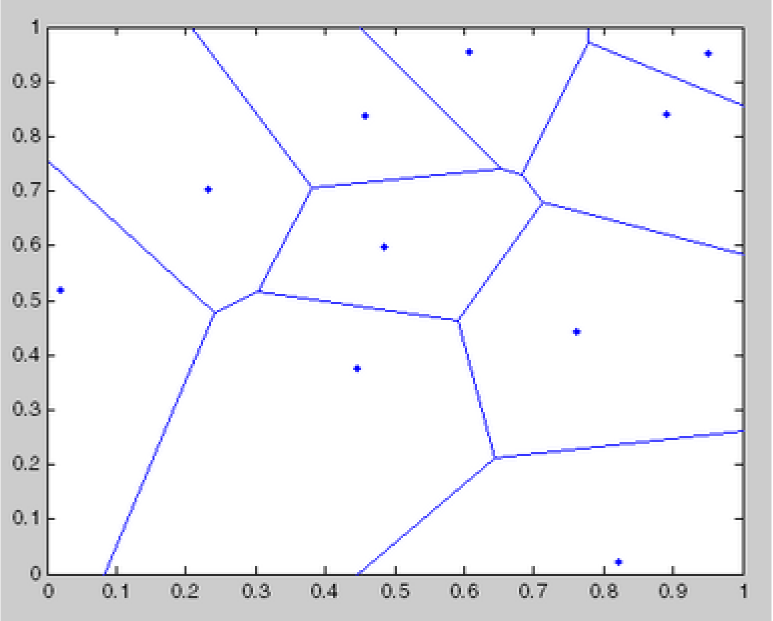
- If you provide no output argument, `voronoi` plots the diagram.
- To gain more control over color, line style, and other figure properties, use the syntax `[vx,vy] = voronoi(...)`. This syntax returns the vertices of the finite Voronoi edges, which you can then plot with the `plot` function.
- To fill the cells with color, use `voronoin` with `n = 2` to get the indices of each cell, and then use `patch` and other plot functions to generate the figure. Note that `patch` does not fill unbounded cells with color.

Examples

Example 1

This code uses the `voronoi` function to plot the Voronoi diagram for 10 randomly generated points.

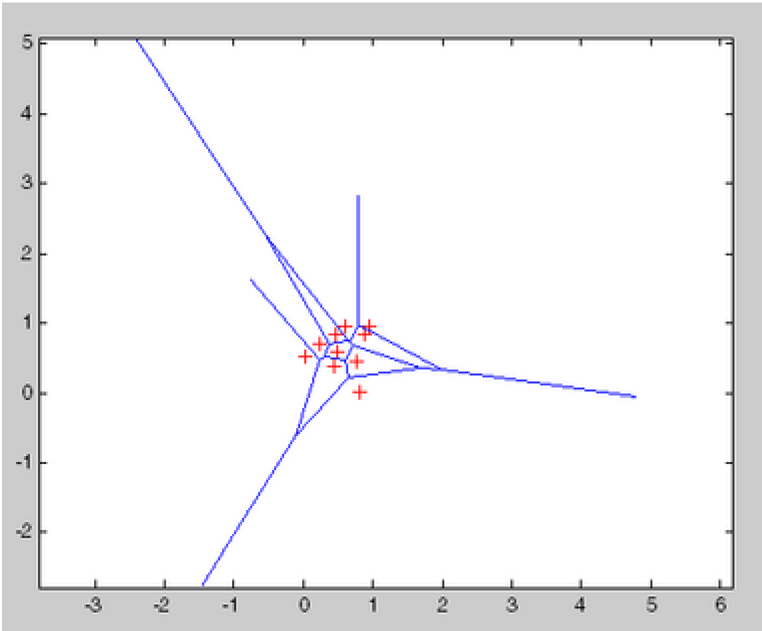
```
x = gallery('uniformdata',[1 10],0);
y = gallery('uniformdata',[1 10],1);
voronoi(x,y)
```



Example 2

This code uses the vertices of the finite Voronoi edges to plot the Voronoi diagram for the same 10 points.

```
x = gallery('uniformdata',[1 10],0);
y = gallery('uniformdata',[1 10],1);
[vx, vy] = voronoi(x,y);
plot(x,y,'r+',vx,vy,'b-'); axis equal
```



Note that you can add this code to get the figure shown in Example 1.

```
xlim([min(x) max(x)])
ylim([min(y) max(y)])
```

Example 3

This code uses `voronoin` and `patch` to fill the bounded cells of the same Voronoi diagram with color.

```
x = gallery('uniformdata',[10 2],5);
[v,c]=voronoin(x);
for i = 1:length(c)
if all(c{i}~=1)   % If at least one of the indices is 1,
                  % then it is an open region and we can't
                  % patch that.
patch(v(c{i},1),v(c{i},2),i); % use color i.
end
```

```
end
```

delaunayTriangulation | convhull | delaunay | LineSpec | plot | voronoin

Purpose

(Will be removed) Voronoi diagram

Note voronoiDiagram(DelaunayTri) will be removed in a future release. Use voronoiDiagram(delaunayTriangulation) instead.

DelaunayTri will be removed in a future release. Use delaunayTriangulation instead.

Syntax

```
[V, R] = voronoiDiagram(DT)
```

Description

[V, R] = voronoiDiagram(DT) returns the vertices V and regions R of the Voronoi diagram of the points DT.X. The region R{i} is a cell array of indices into V that represents the Voronoi vertices bounding the region. The Voronoi region associated with the i'th point, DT.X(i) is R{i}. For 2-D, vertices in R{i} are listed in adjacent order, i.e. connecting them will generate a closed polygon (Voronoi diagram). For 3-D the vertices in R{i} are listed in ascending order.

The Voronoi regions associated with points that lie on the convex hull of DT.X are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in V.

Input Arguments

DT	Delaunay triangulation.

Output Arguments

`V`	`numv`-by-`ndim` matrix representing the coordinates of the Voronoi vertices, where `numv` is the number of vertices and `ndim` is the dimension of the space where the points reside.
`R`	Vector cell array of `length(DR.X)`, representing the Voronoi cell associated with each point.

Definitions

The *Voronoi diagram* of a discrete set of points `X` decomposes the space around each point `X(i)` into a region of influence `R{i}`. Locations within the region are closer to point `i` than any other point. The region of influence is called the Voronoi region. The collection of all the Voronoi regions is the Voronoi diagram.

The *convex hull* of a set of points `X` is the smallest convex polygon (or polyhedron in higher dimensions) containing all of the points of `X`.

Examples

Compute the Voronoi Diagram of a set of points:

```
X = [ 0.5    0
      0      0.5
     -0.5   -0.5
     -0.2   -0.1
     -0.1    0.1
      0.1   -0.1
      0.1    0.1 ]
dt = DelaunayTri(X)
[V,R] = voronoiDiagram(dt)
```

See Also

`voronoi` | `voronoin` | `triangulation` | `delaunayTriangulation`

Purpose

N-D Voronoi diagram

Syntax

```
[V,C] = voronoin(X)
[V,C] = voronoin(X,options)
```

Description

`[V,C] = voronoin(X)` returns Voronoi vertices `V` and the Voronoi cells `C` of the Voronoi diagram of `X`. `V` is a `numv`-by-`n` array of the `numv` Voronoi vertices in n-dimensional space, each row corresponds to a Voronoi vertex. `C` is a vector cell array where each element contains the indices into `V` of the vertices of the corresponding Voronoi cell. `X` is an `m`-by-`n` array, representing `m` n-dimensional points, where `n > 1` and `m >= n+1`.

The first row of `V` is a point at infinity. If any index in a cell of the cell array is `1`, then the corresponding Voronoi cell contains the first point in `V`, a point at infinity. This means the Voronoi cell is unbounded.

`voronoin` uses Qhull.

`[V,C] = voronoin(X,options)` specifies a cell array of strings `options` to be used in Qhull. The default options are

- `{'Qbb'}` for 2- and 3-dimensional input
- `{'Qbb','Qx'}` for 4 and higher-dimensional input

If `options` is `[]`, the default options are used. If `code` is `{''}`, no options are used, not even the default. For more information on Qhull and its options, see `http://www.qhull.org`.

Visualization

You can plot individual bounded cells of an n-dimensional Voronoi diagram. To do this, use `convhulln` to compute the vertices of the facets that make up the Voronoi cell. Then use `patch` and other plot functions to generate the figure.

Examples

Example 1

Let

```
x = [ 0.5    0
      0      0.5
```

```
     -0.5   -0.5
     -0.2   -0.1
     -0.1    0.1
      0.1   -0.1
      0.1    0.1 ]
```

then

```
[V,C] = voronoin(x)

V =
        Inf       Inf
        0.3833    0.3833
        0.7000   -1.6500
        0.2875    0.0000
       -0.0000    0.2875
       -0.0000   -0.0000
       -0.0500   -0.5250
       -0.0500   -0.0500
       -1.7500    0.7500
       -1.4500    0.6500
C =

    [1x4 double]
    [1x5 double]
    [1x4 double]
    [1x4 double]
    [1x4 double]
    [1x5 double]
    [1x4 double]
```

Use a `for` loop to see the contents of the cell array `C`.

```
for i=1:length(C), disp(C{i}), end

     4     2     1     3
    10     5     2     1     9
     9     1     3     7
```

```
    10     8     7     9
    10     5     6     8
     8     6     4     3     7
     6     4     2     5
```

In particular, the fifth Voronoi cell consists of 4 points: `V(10,:)`, `V(5,:)`, `V(6,:)`, `V(8,:)`.

Example 2

The following example illustrates the `options` input to `voronoin`. The commands

```
X = [-1 -1; 1 -1; 1 1; -1 1];
[V,C] = voronoin(X)
```

return an error message.

```
? qhull input error: can not scale last coordinate. Input is
cocircular
   or cospherical. Use option 'Qz' to add a point at infinity.
```

The error message indicates that you should add the option `'Qz'`. The following command passes the option `'Qz'`, along with the default `'Qbb'`, to `voronoin`.

```
[V,C] = voronoin(X,{'Qbb','Qz'})
V =

   Inf   Inf
     0     0

C =

    [1x2 double]
    [1x2 double]
    [1x2 double]
    [1x2 double]
```

Algorithms

`voronoin` is based on Qhull [1]. For information about Qhull, see `http://www.qhull.org/`.

`delaunayTriangulation` | `convhull` | `convhulln` | `delaunay` | `delaunayn` | `voronoi`

Purpose

Wait until timer stops running

Syntax

```
wait(obj)
```

Description

`wait(obj)` blocks the MATLAB command line and waits until the timer, represented by the timer object `obj`, stops running. When a timer stops running, the value of the timer object's `Running` property changes from `'on'` to `'off'`.

If `obj` is an array of timer objects, `wait` blocks the MATLAB command line until all the timers have stopped running.

If the timer is not running, `wait` returns immediately.

See Also

`timer` | `start` | `stop`

Purpose

Open or update wait bar dialog box

Syntax

```
h = waitbar(x,'message')
waitbar(x,'message','CreateCancelBtn','button_callback')
waitbar(x,'message',property_name,property_value,...)
waitbar(x)
waitbar(x,h)
waitbar(x,h,'updated message')
```

Description

A wait bar is a figure that displays what percentage of a calculation is complete as the calculation proceeds by progressively filling a bar with red from left to right.

`h = waitbar(x,'message')` displays a wait bar of fractional length `x`. The wait bar figure displays until the code that controls it closes it or the use clicks its Close Window button. Its (figure) handle is returned in `h`. The argument `x` must be between `0` and `1`.

Note Wait bars are not modal figures (their `WindowStyle` is `'normal'`). They often appear to be modal because the computational loops within which they are called prevent interaction with the Command Window until they terminate. For more information, see `WindowStyle` in the MATLAB Figure Properties documentation.

`waitbar(x,'message','CreateCancelBtn','button_callback')` specifying `CreateCancelBtn` adds a **Cancel** button to the figure that executes the MATLAB commands specified in `button_callback` when the user clicks the **Cancel** button or the **Close Figure** button. `waitbar` sets both the **Cancel** button callback and the figure `CloseRequestFcn` to the string specified in `button_callback`.

`waitbar(x,'message',property_name,property_value,...)` optional arguments `property_name` and `property_value` enable you to set figure properties for the `waitbar`.

`waitbar(x)` subsequent calls to `waitbar(x)` extend the length of the bar to the new position `x`. Successive values of `x` normally increase. If they decrease, the wait bar runs in reverse.

`waitbar(x,h)` extends the length of the bar in the wait bar `h` to the new position `x`.

`waitbar(x,h,'updated message')` updates the message text in the `waitbar` figure, in addition to setting the fractional length to `x`.

Examples

Example 1 — Basic Wait Bar

Typically, you call `waitbar` repeatedly inside a `for` loop that performs a lengthy computation. For example:

```
h = waitbar(0,'Please wait...');
steps = 1000;
for step = 1:steps
    % computations take place here
    waitbar(step / steps)
end
close(h)
```

Example 2 — Wait Bar with Dynamic Text and Cancel Button

Adding a **Cancel** button allows user to abort the computation. Clicking it sets a logical flag in the figure's application data (appdata). The function tests for that value within the main loop and exits the loop as soon as the flag has been set. The example iteratively approximates the value of π. At each step, the current value is encoded as a string and displayed in the wait bar's message field. When the function finishes,

it destroys the wait bar and returns the current estimate of π and the number of steps it ran.

Copy the following function to a code file and save it as `approxpi.m`. Execute it as follows, allowing it to run for 10,000 iterations.

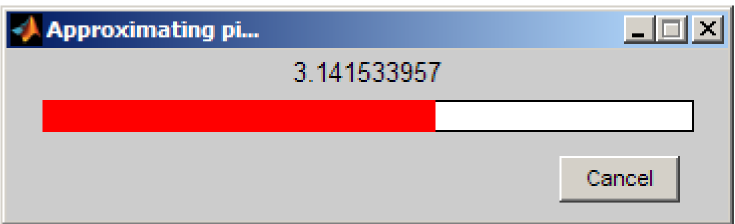
```
[estimated_pi steps] = approxpi(10000)
```

You can click **Cancel** or close the window to abort the computation and return the current estimate of π.

```
function [valueofpi step] = approxpi(steps)
% Converge on pi in steps iterations, displaying waitbar.
% User can click Cancel or close button to exit the loop.
% Ten thousand steps yields error of about 0.001 percent.

h = waitbar(0,'1','Name','Approximating pi...',...
            'CreateCancelBtn',...
            'setappdata(gcbf,''canceling'',1)');
setappdata(h,'canceling',0)
% Approximate as pi^2/8 = 1 + 1/9 + 1/25 + 1/49 + ...
pisqover8 = 1;
denom = 3;
valueofpi = sqrt(8 * pisqover8);
for step = 1:steps
    % Check for Cancel button press
    if getappdata(h,'canceling')
        break
    end
    % Report current estimate in the waitbar's message field
    waitbar(step/steps,h,sprintf('%12.9f',valueofpi))
    % Update the estimate
    pisqover8 = pisqover8 + 1 / (denom * denom);
    denom = denom + 2;
    valueofpi = sqrt(8 * pisqover8);
end
delete(h)       % DELETE the waitbar; don't try to CLOSE it.
```

The function sets the figure `Name` property to describe what is being computed. In the `for` loop, calling `waitbar` sets the fractional progress indicator and displays intermediate results. the code `waitbar(i/steps,h,sprintf('%12.9f',valueofpi))` sets the wait bar's `message` variable to a string representation of the current estimate of *pi*. Naturally, the extra computation involved makes iterations last longer than they need to, but such feedback can be helpful to users.



Note You should call `delete` to remove a wait bar when you give it a `CloseRequestFcn`, as in the preceding code; calling `close` does not close it, and makes its Cancel and Close Window buttons unresponsive. This happens because the figure's `CloseRequestFcn` recursively calls itself. In such a situation you must forcibly remove the wait bar, for example like this:

```
set(0,'ShowHiddenHandles','on')
delete(get(0,'Children'))
```

However, as issuing these commands will delete all open figures—not just the wait bar—it is best never to use `close` in a `CloseRequestFcn` to close a window.

See Also

`close` | `delete` | `dialog` | `msgbox` | `getappdata` | `setappdata`

Purpose

Block execution and wait for event or condition

Syntax

```
waitfor(h)
waitfor(h,'PropertyName')
waitfor(h,'PropertyName',PropertyValue)
```

Description

`waitfor(h)` blocks the caller from executing statements until the graphics object identified by handle `h` closes (is deleted). `h` must be scalar. When object `h` no longer exists, `waitfor` returns, enabling execution to resume. If the object does not exist, `waitfor` returns immediately without processing any events.

`waitfor(h,'PropertyName')` blocks the caller from executing until the value of `'PropertyName'` (any property of the graphics object `h`) changes or `h` closes (is deleted). If `'PropertyName'` is not a valid property for the object, `waitfor` returns immediately without processing any events.

`waitfor(h,'PropertyName',PropertyValue)` blocks the caller from executing until the value of `'PropertyName'` for the graphics object `h` changes to the specific value `PropertyValue` or `h` closes (is deleted). If the value of `'PropertyName'` is already `PropertyValue`, `waitfor` returns immediately without processing any events.

Definitions

- `waitfor` blocks execution so that command-line expressions and subsequent statements in the blocked file do not execute until a specified condition occurs.
- While `waitfor` prevents its caller from continuing, callbacks that respond to various events (for example, pressing a mouse button) can still run, unaffected by `waitfor`.
- `waitfor` also blocks Simulink models from executing, but callbacks do still execute.
- `waitfor` can block nested function calls. For example, a callback invoked while `waitfor` is active can invoke `waitfor`.
- If you type **Ctrl+C** in the Command Window while `waitfor` is blocking execution, the executing program terminates. To avoid

terminating, the program can call `waitfor` within a `try/catch` block that handles the exception that typing **Ctrl+C** generates. To learn more, see the third following example.

Examples

Create a plot and pause execution of the rest of the statements until you close the figure window:

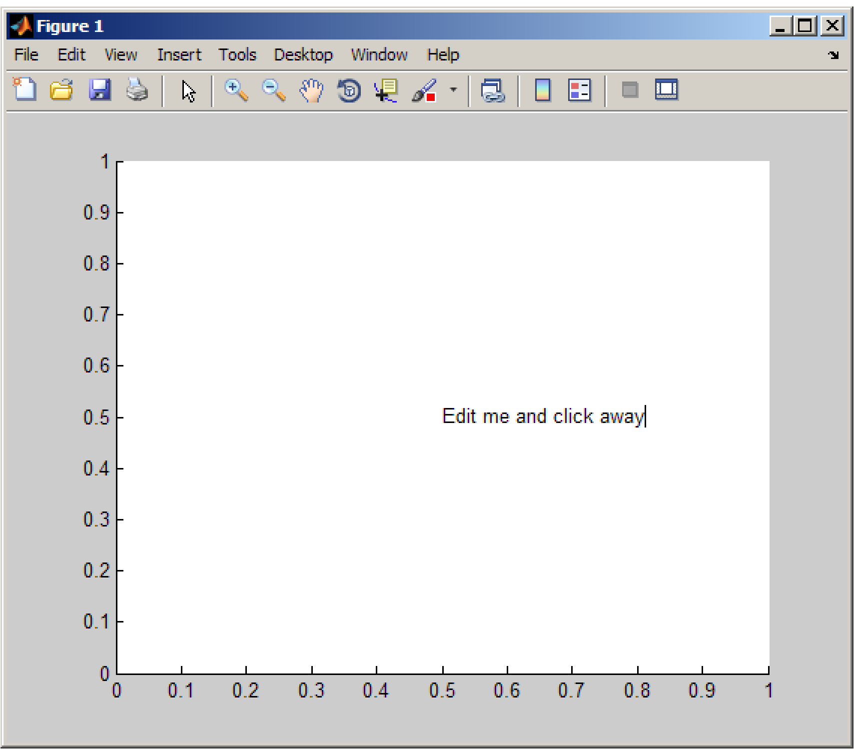
```
f = warndlg('This is a warning.', 'A Warning Dialog');
disp('This prints immediately');
drawnow    % Necessary to print the message
waitfor(f);
disp('This prints after you close the warning dialog');
```

Suspend execution until name of figure changes:

```
f = figure('Name', datestr(now));
h = uicontrol('String', 'Change Name', 'Position', [20 20 100 30], ...
'Callback', 'set(gcbf, ''Name'', datestr(now))');
disp('This prints immediately');
drawnow    % Necessary to print the message
waitfor(f, 'Name');
disp('This prints after button click that changes the figure''s name')
```

Display text object and wait for user to edit it:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH,'Editing','on', 'BackgroundColor',[1 1 1]);
disp('This prints immediately.');
drawnow
waitfor(textH,'Editing','off');
set(textH,'BackgroundColor',[1 1 0]);
disp('This prints after text editing is complete.');
```



If you close the figure while `waitfor` is executing, an error occurs because the code attempts to access handles of objects that no longer exist. You can handle the error by enclosing code starting with the call to `waitfor` in a try/catch block, as follows:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH,'Editing','on', 'BackgroundColor',[1 1 1]);
disp('This prints immediately.');
drawnow
% Use try/catch block to handle errors, such as deleting figure
try
    waitfor(textH,'Editing','off');
    set(textH,'BackgroundColor',[1 1 0]);
```

```
    disp('This prints after text editing is complete.');
catch ME
    disp('This prints if figure is deleted:')
    disp(ME.message)
  % You can place other code to respond to the error here
end
```

The ME variable is a MATLAB Exception object that you can use to determine the type of error that occurred. For more information, see "Respond to an Exception".

How To

- "Control Callback Execution and Interruption"

waitforbuttonpress

Purpose

Wait for key press or mouse-button click

Syntax

`k = waitforbuttonpress`

Description

`k = waitforbuttonpress` blocks the caller's execution stream until the function detects that the user has clicked a mouse button or pressed a key while the figure window is active. The function returns

- `0` if it detects a mouse button click
- `1` if it detects a key press

If a `WindowButtonDownFcn` is defined for the figure, its callback is executed before `waitforbuttonpress` returns a value.

Only keys that generate characters cause the function to return. Pressing any of the following keys by itself does nothing: **Ctrl**, **Shift**, **Alt**, **Caps_lock**, **Num_lock**, **Scroll_lock**.

Additional information about the event that causes execution to resume is available through the figure `CurrentCharacter`, `SelectionType`, and `CurrentPoint` properties.

You can interrupt `waitforbuttonpress` by typing **Ctrl**+C, but an error results unless the function is called from within a `try/catch` block. You also receive an error from `waitforbuttonpress` if you close the figure by clicking the **X** close box unless you call `waitforbuttonpress` within a `try/catch` block.

Examples

These statements display text in the Command Window when the user either clicks a mouse button or types a key in the figure window:

```
w = waitforbuttonpress;
if w == 0
    disp('Button click')
else
    disp('Key press')
end
```

See Also

`dragrect` | `ginput` | `rbbox` | `waitfor`

warndlg

Purpose

Open warning dialog box

Syntax

```
h = warndlg
h = warndlg(warningstring)
h = warndlg(warningstring,dlgname)
h = warndlg(warningstring,dlgname,createmode)
```

Description

`h = warndlg` displays a dialog box named `Warning Dialog` containing the string `This is the default warning string.` The `warndlg` function returns the handle of the dialog box in `h`. The warning dialog box disappears after the user clicks **OK**.

`h = warndlg(warningstring)` displays a dialog box with the title `Warning Dialog` containing the string specified by `warningstring`. The `warningstring` argument can be any valid string format – cell arrays are preferred.

To use multiple lines in your warning, define `warningstring` using either of the following:

- `sprintf` with `newline` characters separating the lines

  ```
  warndlg(sprintf('Message line 1 \n Message line 2'))
  ```

- Cell arrays of strings

  ```
  warndlg({'Message line 1';'Message line 2'})
  ```

`h = warndlg(warningstring,dlgname)` displays a dialog box with title `dlgname`.

`h = warndlg(warningstring,dlgname,createmode)` specifies whether the warning dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `warningstring` and `dlgname`. The *`createmode`* argument can be a string or a structure.

If *`createmode`* is a string, it must be one of the values shown in the following table.

createmode Value	Description
`modal`	Replaces the warning dialog box having the specified `Title`, that was last created or clicked on, with a modal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.
`non-modal` (default)	Creates a new nonmodal warning dialog box with the specified parameters. Existing warning dialog boxes with the same title are not deleted.
`replace`	Replaces the warning dialog box having the specified `Title`, that was last created or clicked on, with a nonmodal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

Note A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

If you open a dialog with `errordlg`, `msgbox`, or `warndlg` using `'CreateMode','modal'` and a non-modal dialog created with any of these functions is already present and *has the same name as the modal dialog*, the non-modal dialog closes when the modal one opens.

For more information about modal dialog boxes, see `WindowStyle` in the Figure Properties.

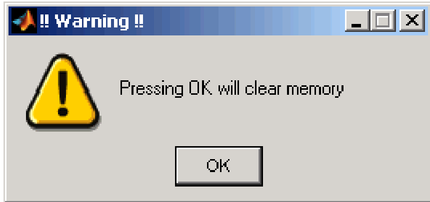
If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings `'tex'` or `'none'`. The default value for `Interpreter` is `'none'`.

Examples

The statement

```
warndlg('Pressing OK will clear memory','!! Warning !!')
```

displays this dialog box:



See Also

`dialog` | `errordlg` | `helpdlg` | `inputdlg` | `listdlg` | `msgbox` | `questdlg` | `figure` | `uiwait` | `uiresume` | `warning`

Purpose

Warning message

Syntax

```
warning('message')
warning('message', a1, a2,...)
warning('message_id', 'message')
warning('message_id', 'message', a1, a2, ..., an)
s = warning(state, 'message_id')
s = warning(state, mode)
```

Description

`warning('message')` displays descriptive text `message` and sets the warning state that `lastwarn` returns. If `message` is an empty string (`''`), `warning` resets the warning state but does not display any text.

`warning('message', a1, a2,...)` displays a message string that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function. Each conversion character in `message` is converted to one of the values `a1`, `a2`, `...` in the argument list.

Note MATLAB converts special characters (like `\n` and `%d`) in the warning message string only when you specify more than one input argument with `warning`. See Example 3 below.

`warning('message_id', 'message')` attaches a unique identifier, or `message_id`, to the warning message. The identifier enables you to single out certain warnings during the execution of your program, controlling what happens when the warnings are encountered.

`warning('message_id', 'message', a1, a2, ..., an)` includes formatting conversion characters in `message`, and the character translations in arguments `a1, a2, ..., an`.

`s = warning(state, 'message_id')` is a warning control statement that enables you to indicate how you want MATLAB to act on certain warnings. The `state` argument can be `'on'`, `'off'`, or `'query'`. The `message_id` argument can be a message identifier string, `'all'`, or `'last'`.

Output `s` is a structure array that indicates the previous state of the selected warnings. The structure has the fields `identifier` and `state`.

`s = warning(state, mode)` is a warning control statement that enables you to display a stack trace or display more information with each warning. The `state` argument can be `'on'`, `'off'`, or `'query'`. The `mode` argument can be `'backtrace'` or `'verbose'`.

Examples

Example 1

Generate a warning that displays a simple string:

```
if ~ischar(p1)
   warning('Input must be a string')
end
```

Example 2

Generate a warning string that is defined at run-time. The first argument defines a message identifier for this warning:

```
warning('MATLAB:paramAmbiguous', ...
        'Ambiguous parameter name, "%s".', param)
```

Example 3

MATLAB converts special characters (like `\n` and `%d`) in the warning message string only when you specify more than one input argument with `warning`. In the single argument case shown below, `\n` is taken to mean `backslash-n`. It is not converted to a newline character:

```
warning('In this case, the newline \n is not converted.')
Warning: In this case, the newline \n is not converted.
```

But, when more than one argument is specified, MATLAB does convert special characters. This is true regardless of whether the additional argument supplies conversion values or is a message identifier:

```
warning('WarnTests:convertTest', ...
      'In this case, the newline \n is converted.')
Warning: In this case, the newline
```

```
is converted.
```

Example 4

Turn on one particular warning, saving the previous state of this one warning in s. Remember that this nonquery syntax performs an implicit query prior to setting the new state:

```
s = warning('on', 'Control:parameterNotSymmetric');
```

After doing some work that includes making changes to the state of some warnings, restore the original state of all warnings:

```
warning(s)
```

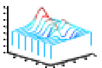
Purpose

Waterfall plot



Syntax

```
waterfall(Z)
waterfall(X,Y,Z)
waterfall(...,C)
waterfall(axes_handles,...)
h = waterfall(...)
```

Description

The `waterfall` function draws a mesh similar to the `meshz` function, but it does not generate lines from the columns of the matrices. This produces a “waterfall” effect.

`waterfall(Z)` creates a waterfall plot using `x = 1:size(Z,2)` and `y = 1:size(Z,1)`. `Z` determines the color, so color is proportional to surface height.

`waterfall(X,Y,Z)` creates a waterfall plot using the values specified in `X`, `Y`, and `Z`. `Z` also determines the color, so color is proportional to the surface height. If `X` and `Y` are vectors, `X` corresponds to the columns of `Z`, and `Y` corresponds to the rows, where `length(x) = n`, `length(y) = m`, and `[m,n] = size(Z)`. `X` and `Y` are vectors or matrices that define the *x*- and *y*-coordinates of the plot. `Z` is a matrix that defines the *z*-coordinates of the plot (i.e., height above a plane). If `C` is omitted, color is proportional to `Z`.

`waterfall(...,C)` uses scaled color values to obtain colors from the current colormap. Color scaling is determined by the range of `C`, which must be the same size as `Z`. MATLAB performs a linear transformation on `C` to obtain colors from the current colormap.

`waterfall(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = waterfall(...)` returns the handle of the `patch` graphics object used to draw the plot.

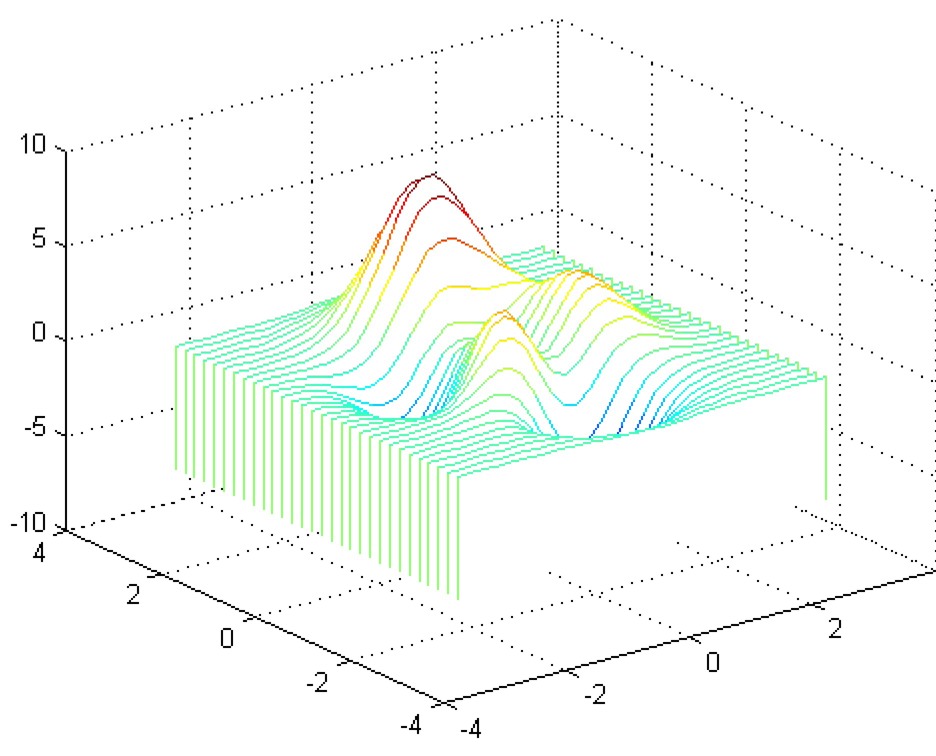
Tips

For column-oriented data analysis, use `waterfall(Z')` or `waterfall(X',Y',Z')`.

Examples

Produce a waterfall plot of the `peaks` function.

```
figure
[X,Y,Z] = peaks(30);
waterfall(X,Y,Z)
```



Algorithms

The range of X, Y, and Z, or the current setting of the axes Xlim, YLim, and ZLim properties, determines the range of the axes (also set by axis). The range of C, or the current setting of the axes CLim property, determines the color scaling (also set by caxis).

The CData property for the patch graphics objects specifies the color at every point along the edge of the patch, which determines the color of the lines.

The waterfall plot looks like a mesh surface; however, it is a patch graphics object. To create a surface plot similar to waterfall, use the meshz function and set the MeshStyle property of the surface to 'Row'. For a discussion of parametric surfaces and related color properties, see surf.

Purpose

Information about WAVE (`.wav`) sound file

Note `wavfinfo` will be removed in a future release. Use `audioinfo` instead.

Syntax

`[m d] = wavfinfo(filename)`

Description

`[m d] = wavfinfo(filename)` returns information about the contents of the WAVE sound file specified by the string *`filename`*. Enclose the *`filename`* input in single quotes.

`m` is the string `'Sound (WAV) file'`, if *`filename`* is a WAVE file. Otherwise, it contains an empty string (`''`).

`d` is a string that reports the number of samples in the file and the number of channels of audio data. If *`filename`* is not a WAVE file, it contains the string `'Not a WAVE file'`.

See Also

`audioplayer` | `audiorecorder` | `audioread` | `audiowrite`

wavplay

Purpose

Play recorded sound on PC-based audio output device

Note `wavplay` will be removed in a future release. Use `audioplayer` instead.

Syntax

```
wavplay(y,Fs)
wavplay(y,Fs,mode)
```

Description

`wavplay(y,Fs)` plays the audio signal stored in the vector `y` on a PC-based audio output device. `Fs` is the integer sample rate in Hz (samples per second). The default value for `Fs` is 11025 Hz. `wavplay` supports only 1- or 2-channel (mono or stereo) audio signals. To play in stereo, `y` must be a two-column matrix.

`wavplay(y,Fs,mode)` specifies how `wavplay` interacts with the command line. The string `mode` is one of the following:

- `'sync'` (default): You do not have access to the command line until the sound has finished playing (a blocking device call).
- `'async'`: You have immediate access to the command line as soon as the sound begins to play on the audio output device (a nonblocking device call). If you call `wavplay` again in `async` mode while the audio is playing, `wavplay` blocks access to the command line until the original playback completes.

The audio signal `y` can be one of four data types. The number of bits used to quantize and play back each sample depends on the data type.

Data Types for wavplay

Data Type	Quantization
Double-precision (default value)	16 bits/sample
Single-precision	16 bits/sample

Data Types for wavplay (Continued)

Data Type	Quantization
16-bit signed integer	16 bits/sample
8-bit unsigned integer	8 bits/sample

Tips

The `wavplay` function is for use only with 32-bit Microsoft Windows operating systems. To play audio data on other platforms, use `audioplayer`.

Examples

The MAT-files `gong.mat` and `chirp.mat` both contain an audio signal `y` and a sampling frequency `Fs`. Load and play the gong and the chirp audio signals. Change the names of these signals in between `load` commands and play them sequentially using the `'sync'` option for `wavplay`.

```
load chirp;
y1 = y; Fs1 = Fs;
load gong;
wavplay(y1,Fs1,'sync') % The chirp signal finishes before the
wavplay(y,Fs)          % gong signal begins playing.
```

See Also

`audioplayer` | `audioinfo` | `audioread` | `audiowrite`

wavread

Purpose

Read WAVE (`.wav`) sound file

Note `wavread` will be removed in a future release. Use `audioread` instead.

Syntax

```
y = wavread(filename)
[y, Fs] = wavread(filename)
[y, Fs, nbits] = wavread(filename)
[y, Fs, nbits, opts] = wavread(filename)
[ ___ ] = wavread(filename, N)
[ ___ ] = wavread(filename, [N1 N2])
[ ___ ] = wavread( ___ , fmt)
siz = wavread(filename,'size')
```

Description

`y = wavread(filename)` loads a WAVE file specified by the string *`filename`*, returning the sampled data in *`y`*. If *`filename`* does not include an extension, `wavread` appends `.wav`.

`[y, Fs] = wavread(filename)` returns the sample rate (*`Fs`*) in Hertz used to encode the data in the file.

`[y, Fs, nbits] = wavread(filename)` returns the number of bits per sample (*`nbits`*).

`[y, Fs, nbits, opts] = wavread(filename)` returns a structure *`opts`* of additional information contained in the WAV file. The content of this structure differs from file to file. Typical structure fields include `opts.fmt` (audio format information) and `opts.info` (text that describes the title, author, etc.).

`[ ___ ] = wavread(filename, N)` returns only the first *`N`* samples from each channel in the file.

`[ ___ ] = wavread(filename, [N1 N2])` returns only samples *`N1`* through *`N2`* from each channel in the file.

`[ ___ ] = wavread( ___ , fmt)` specifies the data format of `y` used to represent samples read from the file. `fmt` can be either of the following values, or a partial match (case-insensitive):

`'double'`	Double-precision normalized samples (default).
`'native'`	Samples in the native data type found in the file.

`siz = wavread(filename,'size')` returns the size of the audio data contained in `filename` instead of the actual audio data, returning the vector `siz = [samples channels]`.

Output Scaling

The range of values in `y` depends on the data format `fmt` specified. Some examples of output scaling based on typical bit-widths found in a WAV file are given below for both `'double'` and `'native'` formats.

Native Formats

Number of Bits	MATLAB Data Type	Data Range
8	`uint8` (unsigned integer)	0 <= y <= 255
16	`int16` (signed integer)	-32768 <= y <= +32767
24	`int32` (signed integer)	-2^23 <= y <= 2^23-1
32	`single` (floating point)	-1.0 <= y < +1.0

Double Formats

Number of Bits	MATLAB Data Type	Data Range
N<32	double	-1.0 <= *y* < +1.0
N=32	double	-1.0 <= *y* <= +1.0 Note: Values in *y* might exceed -1.0 or +1.0 for the case of N=32 bit data samples stored in the WAV file.

`wavread` supports multi-channel data, with up to 32 bits per sample.

`wavread` supports Pulse-code Modulation (PCM) data format only.

Examples

Create a WAV file from the example file `handel.mat`, and read portions of the file back into MATLAB.

```
% Create WAV file in current folder.
load handel.mat

hfile = 'handel.wav';
wavwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits, readinfo] = wavread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = wavread(hfile, nsamples);
```

```
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = wavread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = wavread(hfile, [startpos endpos]);
sound(y3, Fs);
```

See Also

mmfileinfo | audioinfo | audiowrite | audioread | audioplayer | audiorecorder | sound

wavrecord

Purpose

Record sound using PC-based audio input device

Note `wavrecord` will be removed in a future release. Use `audiorecorder` instead.

Syntax

```
y = wavrecord(n,Fs)
y = wavrecord(___,ch)
y = wavrecord(___,'dtype')
```

Description

`y = wavrecord(n,Fs)` records `n` samples of an audio signal, sampled at a rate of `Fs` Hz (samples per second). The default value for `Fs` is 11025 Hz.

`y = wavrecord(___,ch)` uses `ch` number of input channels from the audio device. `ch` can be either 1 or 2, for mono or stereo, respectively. The default value for `ch` is 1.

`y = wavrecord(___,'dtype')` uses the data type specified by the string `'dtype'` to record the sound. The following table lists the string values for `'dtype'` along with the corresponding bits per sample and acceptable data range for `y`.

dtype	Bits/sample	y Data Range
`'double'`	16	–1.0 <= y < +1.0
`'single'`	16	–1.0 <= y < +1.0
`'int16'`	16	–32768 <= y <= +32767
`'uint8'`	8	0 <= y <= 255

Tips

Standard sampling rates for PC-based audio hardware are 8000, 11025, 22050, and 44100 samples per second. Stereo signals are returned as two-column matrices. The first column of a stereo audio matrix corresponds to the left input channel, while the second column corresponds to the right input channel.

The wavrecord function is for use only with 32-bit Microsoft Windows operating systems. To record audio data from audio input devices on other platforms, use audiorecorder.

Examples

Record 5 seconds of 16-bit audio sampled at 11025 Hz. Play back the recorded sound using wavplay. Speak into your audio device (or produce your audio signal) while the wavrecord command runs.

```
Fs = 11025;
y = wavrecord(5*Fs,Fs,'int16');
wavplay(y,Fs);
```

See Also

audiorecorder | audioinfo | audioread | audiowrite

wavwrite

Purpose

Write WAVE (`.wav`) sound file

Note `wavwrite` will be removed in a future release. Use `audiowrite` instead.

Syntax

```
wavwrite(y,filename)
wavwrite(y,Fs,filename)
wavwrite(y,Fs,N,filename)
```

Description

`wavwrite(y,filename)` writes the data stored in the variable `y` to a WAVE file called `filename`. The `filename` input is a string enclosed in single quotes. The data has a sample rate of 8000 Hz and is assumed to be 16-bit. Each column of the data represents a separate channel. Therefore, stereo data should be specified as a matrix with two columns.

`wavwrite(y,Fs,filename)` writes the data stored in the variable `y` to a WAVE file called `filename`. The data has a sample rate of `Fs` Hz and is assumed to be 16-bit.

`wavwrite(y,Fs,N,filename)` writes the data stored in the variable `y` to a WAVE file called `filename`. The data has a sample rate of `Fs` Hz and is `N`-bit, where `N` is 8, 16, 24, or 32.

Input Data Ranges

The range of values in `y` depends on the number of bits specified by `N` and the data type of `y`. The following tables list the valid input ranges based on the value of `N` and the data type of `y`.

If `y` contains integer data:

N Bits	y Data Type	y Data Range	Output Format
8	`uint8`	0 <= *y* <= 255	`uint8`
16	`int16`	–32768 <= *y* <= +32767	`int16`
24	`int32`	–2^23 <= *y* <= 2^23 – 1	`int32`

If y contains floating-point data:

N Bits	y Data Type	y Data Range	Output Format
8	single or double	–1.0 <= *y* < +1.0	uint8
16	single or double	–1.0 <= *y* < +1.0	int16
24	single or double	–1.0 <= *y* < +1.0	int32
32	single or double	–1.0 <= *y* <= +1.0	single

For floating point data where *N* < 32, amplitude values are clipped to the range –1.0 <= *y* < +1.0.

Note 8-, 16-, and 24-bit files are type 1 integer pulse code modulation (PCM). 32-bit files are written as type 3 normalized floating point.

See Also

mmfileinfo | audioinfo | audioread | audiowrite | audioplayer | audiorecorder | sound

Purpose

Open Web page or file in browser

Syntax

```
web
web(url)
web(url,opt)
web(url,opt1,...,optN)

stat = web(___)
[stat,h] = web(___)
[stat,h,url] = web(___)
```

Description

`web` opens an empty MATLAB Web browser.

`web(url)` opens the page specified by `url` in the MATLAB Web browser. If multiple browsers are open, the page displays in the one that was most recently used.

`web(url,opt)` opens the page using the specified browser option, such as `'-new'` to create a new browser instance or `'-browser'` to use the system browser.

`web(url,opt1,...,optN)` opens the page using one or more browser options.

`stat = web(___)` returns the status of the operation: `0` if successful, `1` or `2` if unsuccessful. You can include any of the input arguments in previous syntaxes.

`[stat,h] = web(___)` returns a handle to a MATLAB Web browser that allows you to close it using the command `close(h)`. If you do not specify any inputs to the `web` function, such as `[stat,h] = web`, then the handle corresponds to the most recently used MATLAB Web browser.

`[stat,h,url] = web( ___ )` returns the URL of the current page in the MATLAB Web browser.

Input Arguments

url - Web page address or file location

string

Web page address or file location, specified as a string. File locations can include an absolute or relative path.

If `url` corresponds to a file in the installed product documentation, then the page displays in the MATLAB Help browser instead of the Web browser.

Example: `'http:\\www.mathworks.com'`

Example: `'myfolder/myfile.html'`

opt - Browser option

`'-browser'` | `'-new'` | `'-noaddressbox'` | `'-notoolbar'`

Browser option, specified as one of the following strings. Options can appear in any order.

`'-browser'`	Opens the page in a system browser window instead of the MATLAB Web browser. On Microsoft Windows and Apple Macintosh platforms, the operating system determines the system Web browser. On other systems, the default is the Mozilla® Firefox® browser, but you can change the default using MATLAB Web preferences.
`'-new'`	Opens the page in a new MATLAB Web browser window. Does not apply to the system browser.

`'-noaddressbox'`	Opens the page in a browser that does not display the address box. Only applies to new instances of the MATLAB Web browser.
`'-notoolbar'`	Opens the page in a browser that does not display a toolbar or address box. Only applies to new instances of the MATLAB Web browser.

Example: `'-new','-noaddressbox'`

Output Arguments

stat - Browser status

0 | 1 | 2

Browser status, returned as an integer with one of these values:

0	Found and launched system browser.
1	Could not find system browser.
2	Found, but could not launch system browser.

h - Handle to most recent MATLAB Web browser

scalar

Handle to the most recent MATLAB Web browser, returned as a scalar instance of the associated Java class.

If you do not request the handle when you open the page, be aware that this handle might not correspond to your most recent use of the `web` function. Other MATLAB functionality also uses the `web` function, such as links to external sites from the Help browser.

url - Current page address

string

Current page address in the most recent MATLAB Web browser, returned as a string.

Examples

Web Page in MATLAB Web Browser

Open the MathWorks Web site home page.

```
url = 'http://www.mathworks.com';
web(url)
```

Open the page in a new instance of the browser that does not include a toolbar.

```
web(url,'-new','-notoolbar')
```

File in MATLAB Web Browser

View an HTML file that resides on your system.

Create an HTML file by publishing an example program file. Copy the program file to the current folder so that the code can run during the publishing process.

```
program = fullfile(matlabroot,'help','techdoc','matlab_env','examples
copyfile(program);
htmlFile = publish('fourier_demo2.m');
```

View a file by specifying the file name.

```
web(htmlFile)
```

Alternatively, you can use the `file:///` URL scheme, as long as you include the full path. The `publish` function returns the path in the `htmlFile` output.

```
url = ['file:///',htmlFile];
web(url)
```

Web Page in System Browser

Open the MathWorks Web site home page in the system browser.

```
url = 'http://www.mathworks.com';
web(url,'-browser')
```

Email from System Browser

Send email from your system browser's default mail application using the `mailto:` URL scheme.

To run this example, replace the value for `email` with a valid email address.

```
email = 'myaddress@provider.ext';
url = ['mailto:',email];
web(url)
```

Handle to MATLAB Web Browser

Open the MathWorks Web site home page, and then close the browser using its handle.

```
url = 'http://www.mathworks.com';
[stat,h] = web(url);
```

Close the browser window.

```
close(h)
```

Text Displayed in MATLAB Web Browser

View formatted text using the `text://` URL scheme.

```
web('text://<html><h1>Hello World</h1></html>')
```

Tips

- If you plan to deploy an application that calls the `web` function using the MATLAB Compiler product, then use the `'-browser'` option.
- If you are displaying Japanese streaming text in the MATLAB Web browser, specify a header that includes the `charset` attribute. For example:

```
web(['text://<html><head><meta http-equiv="content-type" ' ...

'content="text/html;charset=utf-8"></head><body>TEXT</body></html>'])
```

- "Specify the System Browser for UNIX Platforms"

weekday

Purpose

Day of week

Syntax

```
DayNumber = weekday(D)
[DayNumber,DayName] = weekday(D)
[DayNumber,DayName] = weekday(D,DayForm)
[DayNumber,DayName] = weekday(D,language)
[DayNumber,DayName] = weekday(D,DayForm,language)
```

Description

`DayNumber = weekday(D)` returns a number representing the day of the week for each element in `D`.

`[DayNumber,DayName] = weekday(D)` additionally returns abbreviated English names for the day of the week, in `DayName`.

`[DayNumber,DayName] = weekday(D,DayForm)` returns the name for the day of the week in the format specified by `DayForm`, in US English.

`[DayNumber,DayName] = weekday(D,language)` returns the abbreviated name for the day of the week in the language of the locale specified in `language`.

`[DayNumber,DayName] = weekday(D,DayForm,language)` returns the name for the day of the week in the specified format and in the language of the specified locale. You can specify `DayForm` and `language` in either order.

Input Arguments

D - Serial date numbers or date strings

vector | matrix | string | cell array of strings | character array

Serial date numbers or date strings. Date numbers can be specified as a vector or matrix. Date strings can be specified as a single string, a cell array of strings, or a character array. If `D` is a cell array of strings, it must be 1-by-`n` or `n`-by-1.

If `D` is a single date string, a cell array of date strings, or a character array of date strings, the date strings can be in one of the following formats.

Date String Format	Example
dd-mmm-yyyy	01-Mar-2000
mm/dd/yyyy	03/01/2000
yyyy-mm-dd	2000-03-01

For date strings in other formats, first convert them to serial date numbers using the `datenum` function, before passing them to `weekday`.

Data Types
single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | cell

DayForm - Format of output day names

'short' (default) | 'long'

Format of the output day names, specified as one of the following strings.

DayForm	Format of DayName Names	Example
'short'	Abbreviated name	Mon
'long'	Full name	Monday

language - Output language of day names

'en_US' (default) | 'local'

Output language of day names in `DayName`, specified as one of the following strings.

language	Description
'en_US'	US English
'local'	Language of the current locale

Output Arguments

DayNumber - Value representing day of week

array of integers in the range [1,7]

Value representing the day of the week, returned as an array of integers in the range [1,7], where 1 represents Sunday, and 7 represents Saturday.

- If input D is a numeric array, then the size of DayNumber is equivalent to the size of D.
- If input D is a cell array of strings, then DayNumber is an m-by-1 vector, where m is equivalent to the length of D.

DayName - Name of day of week

character array

Name of the day of the week, returned as a character array. The content of DayName depends on DayForm.

- If DayForm is 'short', then DayName contains an abbreviated name (for example, Tues).
- If DayForm is 'long', then DayName contains the full name of the weekday (for example, Tuesday).

DayName is m-by-n, where m is the number of serial date numbers or date strings in D.

Examples

Return Day of Week of a Date String

Determine the day of the week of December 21, 2012.

```
D = '21-Dec-2012';
[DayNumber,DayName] = weekday(D)
```

```
DayNumber =

     6

DayName =

Fri
```

December 21, 2012 falls on a Friday.

Return Full Day Names of Multiple Date Numbers

Return the full name of the day of the week for a vector of serial date numbers.

```
D = [734999;735015];
DayForm = 'long';
[DayNumber,DayName] = weekday(D,DayForm)

DayNumber =

     5
     7

DayName =

Thursday
Saturday
```

Return Full Day Names in Local Language

Return day names in U.S. English using the `language` input argument.

```
D = 728647;
DayForm = 'long';
language = 'en_US';
```

```
[DayNumber, DayName] = weekday(D,DayForm,language)

DayNumber =

     2

DayName =

Monday
```

In U.S. English, the name of the day of the week is `Monday`.

Return day names in the language of the current locale.

```
language = 'local';
[DayNumber, DayName] = weekday(D,DayForm,language)

DayNumber =

     2

DayName =

Lundi
```

In a French locale, the name of the day of the week is `Lundi`.

Return Day of Week of a Date String in Custom Format

Determine the day of the week for a date specified in the format `mmm.dd.yyyy`. Call `datenum` inside of `weekday` to specify the format of the input date string.

```
[DayNumber,DayName] = weekday(datenum('Dec.21.2012','mmmm.dd.yyyy'))

DayNumber =
```

```
     6

DayName =

Fri
```

See Also

datenum | datevec | eomday

what

Purpose

List MATLAB files in folder

Syntax

```
what
what folderName
what className
what packageName
s = what('folderName')
```

Description

`what` lists the path for the current folder, and lists all files and folders relevant to MATLAB found in the current folder. Files listed are M, MAT, MEX, MDL, and P-files. Folders listed are all class and package folders.

`what` *`folderName`* lists path, file, and folder information for *`folderName`*.

`what` *`className`* lists path, file, and folder information for method folder `@`*`className`*. For example, `what cfit` lists the MATLAB files and folders in `toolbox/curvefit/curvefit/@cfit`.

`what` *`packageName`* lists path, file, and folder information for package folder `+`*`packageName`*. For example, `what commsrc` lists the MATLAB files and folders in `toolbox/comm/comm/+commsrc`.

`s = what('`*`folderName`*`')` returns the results in a structure array with the fields shown in the following table.

Field	Description
`path`	Path to folder
`m`	Cell array of MATLAB program file names
`mat`	Cell array of MAT-file names
`mex`	Cell array of MEX-file names
`mdl`	Cell array of MDL-file names
`slx`	Cell array of SLX-file names
`p`	Cell array of P-file names

Field	Description
`classes`	Cell array of class folders
`packages`	Cell array of package folders

Examples

List the MATLAB files and folders in `C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo`, where *Rnnnn* represents the folder for the MATLAB release, for example, R2012b:

```
what audiovideo

MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo

FileFormatInfo

Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo

internal  writer

MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

Contents            aufinfo             mmcompinfo          wavplay
audiodevinfo        auread              mmfileinfo          wavread
audioinfo           auwrite             movie2avi           wavrecord
audioplayerreg      avgate              mu2lin              wavwrite
audioread           avifinfo            prefspanel
audiorecorderreg    aviinfo             sound
audiouniquename     aviread             soundsc
audiowrite          lin2mu              wavfinfo

MAT-files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

chirp          handel          splat
gong           laughter        train
```

```
Classes in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

VideoReader    audioplayer    avifile
VideoWriter    audiorecorder  mmreader

Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

audiovideo
```

Obtain a structure array containing the file and folder names in `toolbox/matlab/codetools` that are relevant to MATLAB, where *Rnnnn* represents the folder for the MATLAB release, for example, R2012a:

```
s = what('codetools')

s =

        path: 'C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\codetools'
           m: {76x1 cell}
         mat: {0x1 cell}
         mex: {0x1 cell}
         mdl: {0x1 cell}
           p: {0x1 cell}
     classes: {2x1 cell}
    packages: {3x1 cell}
```

Find the supporting files for one of the packages in the Communications System Toolbox product:

```
p1 = what('comm');
p1.packages
ans =
```

```
    'gpu'
    'internal'

ans =

    'internal'.
.
.
p2 = what('commsrc');
p2.m
ans =
    'abstractJitter.m'
    'abstractPulse.m'
    'combinedjitter.m'
    'diracjitter.m'
    'periodicjitter.m'
    'randomjitter.m'
```

Alternatives

Use the Current Folder browser to view the list of files in a folder.

How To

- "Working with Files and Folders"

whatsnew

Purpose Release Notes

Note `whatsnew` will be removed in a future release.

Syntax `whatsnew`

Description `whatsnew` displays the MATLAB Release Notes in the Help browser, presenting information about new features, problems from previous releases that have been fixed in the current release, and compatibility issues.

See Also `help` | `version`

Purpose

Locate functions and files

Syntax

```
which item
which fun1 in fun2

which ___ -all

str = which(item)
str = which(fun1,'in',fun2)

str = which(___,'-all')
```

Description

`which item` displays the full path for `item`.

- If `item` is a MATLAB function in an M or P file, or a Simulink model in an MDL file, then `which` displays the full path for the corresponding file. `item` must be on the MATLAB path.
- If `item` is a method in a loaded Java class, then `which` displays the package, class, and method name for that method.
- If `item` is a workspace variable, then `which` displays a message identifying `item` as a variable.
- If `item` is a file name including the extension, and it is in the current working folder or on the MATLAB path. then `which` displays the full path of `item`.

If `item` is an overloaded function or method, then `which item` returns only the path of the first function or method found.

`which fun1 in fun2` displays the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

`which ___ -all` displays the paths to all items on the MATLAB path with the requested name. Such items include methods of instantiated

classes. You can use `-all` with the input arguments of any of the previous syntaxes.

`str = which(item)` returns the full path for `item` in the string, `str`.

`str = which(fun1,'in',fun2)` returns the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

`str = which(___,'-all')` returns the results of `which` in the string or cell array of strings, `str`. You can use this syntax with any of the input arguments in the previous syntax group.

Input Arguments

item - Function or file to locate

string

Function or file to locate, specified as a string. When using the function form of `which`, enclose all input strings in single quotes. `item` can be in one of the following forms.

Form of the `item` Input	Path to Display
`fun`	Display full path for `fun`, which can be a MATLAB function, Simulink model,
`classname``/`*`method`*	Display full path for the file that defines a method in a MATLAB class. For
`private/`*`fun`*	Limit the search to private functions named `fun`. For example, `which private/orthog` or `which('private/orthog')` displays the path for `orthog.m` in the `/private` subfolder of the parent folder.
`classname``/private/`*`function`*	Limit the search to private methods defined by the MATLAB class, `classname`.

Form of the `item` Input	Path to Display
`fun1 in fun2`	Display the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions or variables.
`fun(a1,...,an)`	Display the path to the implementation of function `fun` which would be invoked if called with the input arguments `a1,...,an`. Use this syntax to query overloaded functions. See the Example, "Locate Function Invoked with Given Input Arguments" on page 1-6131.

fun1 - Function to locate

string

Function to locate, specified as a string. When using the function form of `which`, enclose all input strings in single quotes, for example, `'myfun1'`.

fun2 - Calling file

string

Calling file, specified as a string. When using the function form of `which`, enclose all input strings in single quotes, for example, `'myfile'`.

Output Arguments

str - Function or file location

string | cell array of strings

Function or file location, returned as a string, or returned as a cell array of strings if you use `'-all'`.

- If `item` is a workspace variable, then `str` is the string `'variable'`.
- If `str` is a cell array of strings, then each row of `str` identifies a function, and the functions are in order of precedence.

Examples

Locate MATLAB Function

Locate the `pinv` function.

```
which pinv
```

```
matlabroot\toolbox\matlab\matfun\pinv.m
```

`pinv` is in the `matfun` folder of MATLAB.

You also can use function syntax to return the path to a string, `str`. When using the function form of `which`, enclose all input strings in single quotes.

```
str = which('pinv');
```

Locate Method in a Loaded Java Class

Create an instance of the Java class. This loads the class into MATLAB.

```
myDate = java.util.Date;
```

Locate the `setMonth` method.

```
which setMonth
```

```
setMonth is a Java method  % java.util.Date method
```

Locate Function in a MATLAB Class

Find the `fopen` function used on MATLAB `serial` class objects.

```
which serial/fopen
```

```
matlabroot\toolbox\matlab\iofun\@serial\fopen.m
% serial method
```

MATLAB displays the path for `fopen.m` in the class folder, `@serial`.

Locate Private Function

Find the `orthog` function in a private folder.

```
which private/orthog
```

```
matlabroot\toolbox\matlab\elmat\private\orthog.m
% Private to elmat
```

MATLAB displays the path for `orthog.m` in the `/private` subfolder of `toolbox/matlab/elmat`.

Determine if Local Function is Called

Determine which `parseargs` function is called by `area.m`.

```
which parseargs in area
```

```
matlabroot\toolbox\matlab\specgraph\area.m (parseargs)
% Subfunction of area
```

You also can use function syntax to return the path to a string, `str`. When using the function form of `which`, enclose all input strings in single quotes.

```
str = which('parseargs','in','area');
```

Locate Function Invoked with Given Input Arguments

Suppose you have a `matlab.io.MatFile` object that corresponds to the example MAT-file `'topography.mat'`:

```
matObj = matfile('topography.mat');
```

Display the path of the implementation of `who` that is invoked when called with the input argument `(matObj)`.

```
which who(matObj)
```

```
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m
% matlab.io.MatFile method
```

Store the result to a string.

```
str = which('who(matObj)')
```

```
str =
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m
```

If you do not specify the input argument `(matObj)`, then `which` returns only the path of the first function or method found.

```
which who
```

```
built-in (matlabroot\\toolbox\matlab\general\who)
```

Locate All Items with Given Name

Display the paths to all items on the MATLAB path with the name `fopen`.

```
which fopen -all
```

```
built-in (matlabroot\toolbox\matlab\iofun\fopen)
matlabroot\toolbox\matlab\iofun\@serial\fopen.m           % serial method
matlabroot\toolbox\shared\instrument\@icinterface\fopen.m  % icinterface m
matlabroot\toolbox\instrument\instrument\@i2c\fopen.m
% i2c method
```

Return Path Names as Strings

Return the results of `which` in the string `str`.

You must use the function form of `which`, enclosing all arguments in parentheses and single quotes.

```
str = which('private/stradd','-all');
whos str
```

```
  Name      Size            Bytes  Class    Attributes

  str       2x1               650  cell
```

Tips

- For more information about how MATLAB uses scope and precedence when calling a function, see “Function Precedence Order”.

Limitations

- When the class is not loaded, `which` only finds methods if they are defined in separate files in an @-folder and are not in any packages.

See Also

`dir` | `doc` | `exist` | `lookfor` | `mfilename` | `path` | `type` | `what` | `who` | `fileparts`

while

Purpose

Repeatedly execute statements while condition is true

Syntax

```
while expression
   statements
end
```

Description

`while` *`expression`*, *`statements`*, `end` repeatedly executes one or more MATLAB program *`statements`* in a loop as long as an expression remains true.

An evaluated expression is true when the result is nonempty and contains all nonzero elements (logical or real numeric). Otherwise, the expression is false.

Expressions can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `||`, or `~`). MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

Tips

- If you inadvertently create an infinite loop (that is, a loop that never ends on its own), stop execution of the loop by pressing **Ctrl+C**.
- To programmatically exit the loop, use a `break` statement. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- You can nest any number of `while` statements. Each `while` statement requires an `end` keyword.
- Within an `if` or `while` expression, all logical operators, including `|` and `&`, short-circuit. That is, if the first part of the expression determines a true or false result, MATLAB does not evaluate the second part of the expression.

Examples

Find the first integer `n` for which `factorial(n)` is a 100-digit number:

```
n = 1;
nFactorial = 1;
while nFactorial < 1e100
    n = n + 1;
```

```
    nFactorial = nFactorial * n;
end
```

Count the number of lines of code in the file `magic.m`, skipping all blank lines and comments:

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) || strncmp(line,'%',1) || ~ischar(line)
        continue
    end
    count = count + 1;
end
fprintf('%d lines\n',count);
fclose(fid);
```

Find the root of the polynomial $x^3 - 2x - 5$ using interval bisection:

```
a = 0; fa = -Inf;
b = 3; fb = Inf;
while b-a > eps*b
   x = (a+b)/2;
   fx = x^3-2*x-5;
   if fx == 0
      break
   elseif sign(fx) == sign(fa)
      a = x; fa = fx;
   else
      b = x; fb = fx;
   end
end
disp(x)
```

Take advantage of short-circuiting to avoid error or warning messages:

```
x = 42;
while exist('myfunction.m') && (myfunction(x) >= pi)
   disp('Condition is true')
   break
end
```

See Also

`end` | `for` | `break` | `continue` | `return` | `if` | `switch`

Tutorials

- "Relational Operators"
- "Logical Operators"

Purpose

Change axes background color

Syntax

```
whitebg
whitebg(fig)
whitebg(ColorSpec)
whitebg(fig, ColorSpec)
whitebg(fig, ColorSpec)
whitebg(fig)
```

Description

`whitebg` complements the colors in the current figure.

`whitebg(fig)` complements colors in all figures specified in the vector `fig`.

`whitebg(ColorSpec)` and `whitebg(fig, ColorSpec)` change the color of the axes, which are children of the figure, to the color specified by `ColorSpec`. Without a figure specification, `whitebg` or `whitebg(ColorSpec)` affects the current figure and the root's default properties so subsequent plots and new figures use the new colors.

`whitebg(fig, ColorSpec)` sets the default axes background color of the figures in the vector `fig` to the color specified by `ColorSpec`. Other axes properties and the figure background color can change as well so that graphs maintain adequate contrast. `ColorSpec` can be a 1-by-3 RGB color or a color string such as `'white'` or `'w'`.

`whitebg(fig)` complements the colors of the objects in the specified figures. This syntax is typically used to toggle between black and white axes background colors, and is where `whitebg` gets its name. Include the root window handle `(0)` in `fig` to affect the default properties for new windows or for `clf reset`.

Tips

`whitebg` works best in cases where all the axes in the figure have the same background color.

`whitebg` changes the colors of the figure's children, with the exception of shaded surfaces. This ensures that all objects are visible against the new background color. `whitebg` sets the default properties on the root such that all subsequent figures use the new background color.

Examples

Set the background color to blue-gray.

```
whitebg([0 .5 .6])
```

Set the background color to blue.

```
whitebg('blue')
```

See Also

ColorSpec | colordef

Purpose

List variables in workspace

Syntax

```
who
who(variables)
who(location)
who(variables,location)
c = who(variables,location)
```

Description

`who` lists in alphabetical order all variables in the currently active workspace.

`who(variables)` lists only the specified variables.

`who(location)` lists variables in the specified location: `'global'` for the global workspace, or `'-file'` for a MAT-file. For MAT-files, you must also include the file name as an input.

`who(variables,location)` lists the specified variables in the specified location. The `location` input can appear before or after `variables`.

`c = who(variables,location)` stores the names of the variables in cell array `c`. Specifying `variables` and `location` is optional.

Tips

- The `who` function displays the variable list unless you specify an output argument.
- When used within a nested function, the `who` function lists the variables in the workspaces of that function and all functions containing that function, grouped by workspace. This applies whether you call `who` from your function code or from the MATLAB debugger.

Input Arguments

variables

Strings that specify the variables to list. Use one of these forms:

var1, var2, ...	List the specified variables. Use the `'*'` wildcard to match patterns. For example, `who('A*')` lists all variables that start with `A`.
`'-regexp'`, *expressions*	List variables whose names match the specified regular expressions.

Default: `'*'` (all variables)

location

String that indicates whether to list variables from the global workspace or from a file:

`'global'`	Global workspace.
`'-file'`, *filename*	MAT-file. The *filename* input can include the full, relative, or partial path.

Default: `''` (current workspace)

Output Arguments

c

Cell array of strings that correspond to each variable name.

Examples

Display information about variables in the current workspace whose names start with the letter `a`:

```
who a*
```

Show variables stored in MAT-file `durer.mat`:

```
who -file durer
```

This code returns:

```
Your variables are:

X        caption  map
```

Store the variable names from `durer.mat` in cell array `durerInfo`:

```
durerInfo = who('-file', 'durer');
```

Display the contents of cell array `durerInfo`:

```
for k=1:length(durerInfo)
   disp(durerInfo{k})
end
```

This code returns:

```
  X
  caption
  map
```

Suppose that a file `mydata.mat` contains variables with names that start with `java` and end with `Array`. Display information about those variables:

```
 whos -file mydata -regexp \<java.*Array\>
```

Call `who` within a nested function (`get_date`):

```
function who_demo
date_time = datestr(now);

[str pos] = textscan(date_time, '%s%s%s', ...
                     1, 'delimiter', '- :');
```

```
get_date(str);

   function get_date(d)
      day = d{1};
      mon = d{2};
      year = d{3};
      who
   end

end
```

When you run `who_demo`, the `who` function displays the variables by function workspace (although the name of the function does not appear in the output):

```
Your variables are:

d          mon        ans        pos
day        year       date_time  str
```

Alternatives

To view the variables in the workspace, use the Workspace browser. To view the contents of MAT-files, use the Details Panel of the Current Folder Browser.

See Also

`assignin` | `clear` | `dir` | `evalin` | `exist` | `inmem` | `load` | `save` | `what` | `whos` | `workspace`

Purpose

Names of variables in MAT-file

Syntax

```
varlist = who(matObj)
varlist = who(matObj,variables)
```

Description

`varlist = who(matObj)` lists alphabetically all variables in the MAT-file associated with `matObj`. Optionally, returns the list in cell array `varlist`.

`varlist = who(matObj,variables)` lists the specified variables.

Input Arguments

matObj

Object created by the `matfile` function.

variables

Names of variables in the MAT-file corresponding to `matObj`. Use one of these forms:

`var1,...,varN`	Comma-separated list of variable name strings. Optionally, match patterns with the `'*'` wildcard, such as `who(matobj,'A*')`.
`'-regexp',expressions`	Regular expression strings that describe variable names.

Output Arguments

varlist

Cell array of strings that correspond to each variable name.

Examples

Display a list of variables in the example file `topography.mat`:

```
matObj = matfile('topography.mat');
who(matObj)
```

This code returns:

```
Your variables are:

topo        topolegend  topomap1    topomap2
```

See Also matfile | whos

Purpose

List variables in workspace, with sizes and types

Syntax

```
whos
whos(variables)
whos(location)
whos(variables,location)

S = whos( ___ )
```

Description

`whos` displays in alphabetical order all variables in the currently active workspace, with information about their sizes and types.

`whos(variables)` displays only the specified variables.

`whos(location)` displays variables in the specified location.

`whos(variables,location)` displays the specified variables in the specified location. The `location` and `variables` inputs can appear in either order.

`S = whos( ___ )` stores information about the variables in structure array, `S`, using no input arguments, or any of the input arguments from the previous syntaxes.

Input Arguments

variables - Variables to display

strings

Variables to display, specified as one or more strings in one of the following forms.

Form of `Variables` Input	Variable Names
var1 ... varN	List the named variables, specified as individual strings. Use the `'*'` wildcard to match patterns. For example, `whos('A*')` lists all variables in the workspace that start with `A`.
`'-regexp'`,*expr1 ... exprN*	List only the variables that match the regular expressions, specified as strings. For example, `whos('-regexp','^Mon','^Tues')` lists only the variables in the workspace that begin with `Mon` or `Tues`.

location - Location of variables
`'global'` \| `'file'`,*filename*

Location of variables, specified as one of the following strings.

Value of `location`	Location of Variables
`'global'`	Global workspace.
`'-file'`,*filename*	MAT-file. The *filename* input can include the full, relative, or partial path. For example, `whos('file','myFile.mat')` lists all variables in the MAT-file named `myFile.mat`. `whos('-file',`*filename*`)` does not return the sizes of any MATLAB objects in file *filename*.

Output Arguments

S - Information about variables

nested structure array

Information about variables, returned as a nested structure array that contains a scalar `struct` for each variable. Each scalar `struct` contains these fields.

Field	Description
`name`	Name of the variable.
`size`	Dimensions of the variable array.
`bytes`	Number of bytes allocated for the variable array.
`class`	Class of the variable. If the variable has no value, class is `'(unassigned)'`.
`global`	True if the variable is global; otherwise, false.
`sparse`	True if the variable is sparse; otherwise, false.
`complex`	True if the variable is complex; otherwise, false.
`nesting`	Structure with these fields: • `function` — Name of the nested or outer function that defines the variable. • `level` — Nesting level of that function.
`persistent`	True if the variable is persistent; otherwise, false.

Examples

Display Information About Workspace Variables

Display information about variables in the current workspace whose names start with the letter `a`.

```
whos('a*')
```

Display Variables Stored in a MAT-File

Display all variables stored in the MAT-file, `durer.mat`.

```
whos('-file','durer.mat')
```

```
  Name             Size                Bytes  Class     Attributes

  X              648x509             2638656  double
  caption          2x28                  112  char
  map            128x3                  3072  double
```

Show only variables in the MAT-file with names that end with `ion`.

```
whos('-file','durer.mat','-regexp','ion$')
```

```
  Name           Size              Bytes  Class    Attributes

  caption        2x28                112  char
```

Store Variable Information in a Structure Array

Store information about the variables in `durer.mat` in structure array `S`.

```
S = whos('-file','durer.mat');
```

Display the contents of `S`.

```
for k = 1:length(S)
   disp(['  ' S(k).name ...
         '  ' mat2str(S(k).size) ...
         '  ' S(k).class]);
end
```

```
  X  [648 509]  double
  caption  [2 28]  char
  map  [128 3]  double
```

Create Function to Display Variable Attribute Information

In the Editor, create a function that creates variables with various persistent, global, sparse, and complex attributes, and then displays information about them.

```
function show_attributes
persistent p;
global g;
p = 1;
g = 2;
s = sparse(eye(5));
c = [4+5i 9-3i 7+6i];
whos
```

When you call the function, `show_attributes` displays the attributes.

```
show_attributes
```

```
Name      Size            Bytes  Class     Attributes

c         1x3                48  double    complex
g         1x1                 8  double    global
p         1x1                 8  double    persistent
s         5x5               128  double    sparse
```

Call `whos` Within a Nested or Anonymous Function

Create a function, `whos_demo`, that contains a nested function, `get_date`. Call `whos` within the nested function.

```
function whos_demo
date_time = datestr(now);

C = strsplit(date_time,{'-',''});
get_date(C);

   function get_date(d)
      day = d{1};
      mon = d{2};
      year = d{3};
      whos
   end
```

```
end
```

When you run the `whos_demo` function, `whos` displays the variables of the nested `get_date` function, and all functions that contain it, grouped by function workspace. This applies whether you call `whos` from your function code or from the MATLAB debugger.

```
whos_demo

  Name              Size              Bytes  Class           Attributes

  ---- get_date ---------------------------------------------------------
  d                 1x3                 372  cell
  day               1x2                   4  char
  mon               1x3                   6  char
  year              1x13                 26  char

  ---- whos_demo --------------------------------------------------------
  C                 1x3                 372  cell
  ans               0x0                   0  (unassigned)
  date_time         1x20                 40  char
```

When called within an anonymous function, variables in the anonymous function also display in a group, titled with the function's signature

Tips

- You also can view the contents of MAT-files using the Details Panel of the Current Folder browser.

Algorithms

`whos` returns the number of bytes each variable occupies in the workspace, not in a MAT-file. Version 7 MAT-files and later are compressed, so the number of bytes in the file is typically fewer than the number of bytes required in the workspace.

See Also

`clear` | `exist` | `what` | `who`

Concepts

- "What Is the MATLAB Workspace?"

Purpose

Names, sizes, and types of variables in MAT-file

Syntax

```
details = whos(matObj)
details = whos(matObj,variables)
```

Description

`details = whos(matObj)` returns information about all variables in the MAT-file associated with `matObj`.

`details = whos(matObj,variables)` returns information about the specified variables.

Input Arguments

matObj

Object created by the `matfile` function.

variables

Names of variables in the MAT-file corresponding to `matObj`. Use one of these forms:

`var1,...,varN`	Comma-separated list of variable name strings. Optionally, match patterns with the `'*'` wildcard, such as `whos(matobj,'A*')`.
`'-regexp',expressions`	Regular expression strings that describe variable names.

Output Arguments

details

Structure array with these fields (identical to the structure returned by the `whos` function):

`name`	Variable name
`size`	Dimensions of the variable

`bytes`	Number of bytes allocated for the array when you load the entire variable
`class`	Class (data type) of the variable
`global`	Whether the variable is global (`true` or `false`)
`sparse`	Whether the variable is sparse
`complex`	Whether the variable is complex
`nesting`	Structure with these fields: • `function` — Name of the nested or outer function that defines the variable • `level` — Nesting level
`persistent`	Whether the variable is persistent

Examples

Display a list of variables in the example file `topography.mat`:

```
matObj = matfile('topography.mat');
whos(matObj)
```

This code returns:

```
  Name              Size                Bytes  Class     Attributes

  topo            180x360              518400  double
  topolegend        1x3                    24  double
  topomap1         64x3                  1536  double
  topomap2        128x3                  3072  double
```

Without loading any data, find the size and number of dimensions of the variable `topo` in `topography.mat`:

```
matObj = matfile('topography.mat');
info = whos(matObj,'topo');
```

```
sizeX = info.size
nDimsX = length(sizeX)
```

This code returns:

```
sizeX =
   180   360

nDimsX =
     2
```

See Also

`matfile` | `size`

wilkinson

Purpose

Wilkinson's eigenvalue test matrix

Syntax

```
W = wilkinson(n)
```

Description

`W = wilkinson(n)` returns one of J. H. Wilkinson's eigenvalue test matrices. It is a symmetric, tridiagonal matrix with pairs of nearly, but not exactly, equal eigenvalues.

Examples

```
wilkinson(7)

ans =

     3     1     0     0     0     0     0
     1     2     1     0     0     0     0
     0     1     1     1     0     0     0
     0     0     1     0     1     0     0
     0     0     0     1     1     1     0
     0     0     0     0     1     2     1
     0     0     0     0     0     1     3
```

The most frequently used case is `wilkinson(21)`. Its two largest eigenvalues are both about 10.746; they agree to 14, but not to 15, decimal places.

See Also

`eig` | `gallery` | `pascal`

Purpose

Open file in appropriate application (Windows)

Syntax

```
winopen(fileName)
```

Description

`winopen(fileName)` opens `fileName` in the associated Microsoft Windows application. The application is associated with the extension in `fileName` in the Windows operating system. `filename` is a string enclosed in single quotes. `winopen` uses a Windows shell command, and performs the same action as double-clicking the file in the Windows Explorer program. That is, `winopen` calls the application associated the file extension to open the file. Use an absolute or relative path for `fileName`.

Examples

Open the file `thesis.doc`, located in the current folder, in the Microsoft Word program:

```
winopen('thesis.doc')
```

Open `myresults.html` in the system Web browser:

```
winopen('D:/myfiles/myresults.html')
```

On Microsoft Windows platforms, open the current folder in the Windows Explorer tool:

```
winopen(cd)
```

To open a file on the MATLAB path, use `winopen` with `which`. For example, to open the `meshgrid` function in the Editor, use:

```
winopen(which('meshgrid'))
```

`dos` | `open` | `web`

How To

- "Opening and Running Files"

Purpose

Item from Windows registry

Syntax

```
valnames = winqueryreg('name', 'rootkey', 'subkey')
value = winqueryreg('rootkey', 'subkey', 'valname')
value = winqueryreg('rootkey', 'subkey')
```

Description

`valnames = winqueryreg('name', 'rootkey', 'subkey')` returns all value names in `rootkey\subkey` of Microsoft Windows operating system registry to a cell array of strings. The first argument is the literal quoted string, `'name'`.

`value = winqueryreg('rootkey', 'subkey', 'valname')` returns the value for value name `valname` in `rootkey\subkey`.

If the value retrieved from the registry is a string, `winqueryreg` returns a string. If the value is a 32-bit integer, `winqueryreg` returns the value as an integer of the MATLAB software type `int32`.

`value = winqueryreg('rootkey', 'subkey')` returns a value in `rootkey\subkey` that has no value name property.

Note The literal **`name`** argument and the `rootkey` argument are case-sensitive. The `subkey` and `valname` arguments are not.

Tips

This function works only for the following registry value types:

- strings (REG_SZ)
- expanded strings (REG_EXPAND_SZ)
- 32-bit integer (REG_DWORD)

Examples

Example 1

Get the value of `CLSID` for the MATLAB sample Microsoft COM control `mwsampctrl.2`:

```
winqueryreg 'HKEY_CLASSES_ROOT' 'mwsamp.mwsampctrl.2\clsid'
```

```
ans =
   {5771A80A-2294-4CAC-A75B-157DCDDD3653}
```

Example 2

Get a list in variable mousechar for registry subkey Mouse, which is under subkey Control Panel, which is under root key HKEY_CURRENT_USER.

```
mousechar = winqueryreg('name', 'HKEY_CURRENT_USER', ...
   'control panel\mouse');
```

For each name in the mousechar list, get its value from the registry and then display the name and its value:

```
for k=1:length(mousechar)
   setting = winqueryreg('HKEY_CURRENT_USER', ...
      'control panel\mouse', mousechar{k});
   str = sprintf('%s = %s', mousechar{k}, num2str(setting));
   disp(str)
   end

ActiveWindowTracking = 0
DoubleClickHeight = 4
DoubleClickSpeed = 830
DoubleClickWidth = 4
MouseSpeed = 1
MouseThreshold1 = 6
MouseThreshold2 = 10
SnapToDefaultButton = 0
SwapMouseButtons = 0
```

Purpose

Determine whether file contains 1-2-3 WK1 worksheet

Note `wk1finfo` has been removed.

Syntax

```
[extens, typ] = wk1finfo(filename)
```

Description

`[extens, typ] = wk1finfo(filename)` returns the string 'WK1' in `extens`, and ' `1-2-3 Spreadsheet`' in `typ` if the file `filename` contains a readable worksheet. The `filename` input is a string enclosed in single quotes.

Examples

This example returns information on spreadsheet file `matA.wk1`:

```
[extens, typ] = wk1finfo('matA.wk1')

extens =
   WK1
typ =
    123 Spreadsheet
```

See Also

`xlsread` | `xlswrite` | `dlmread` | `dlmwrite`

wk1read

Purpose

Read Lotus 1-2-3 WK1 spreadsheet file into matrix

Note `wk1read` has been removed.

Syntax

```
M = wk1read(filename)
M = wk1read(filename,r,c)
M = wk1read(filename,r,c,range)
```

Description

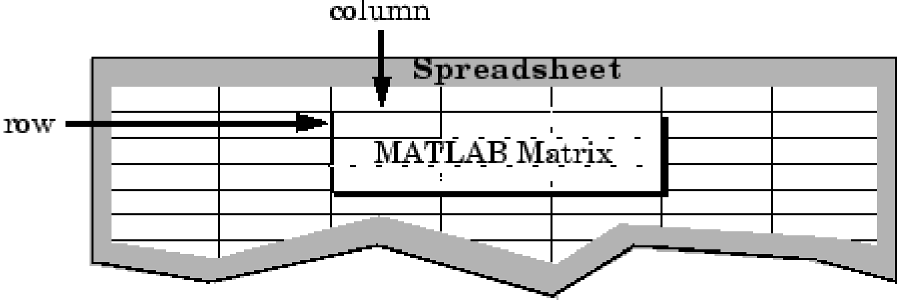
`M = wk1read(filename)` reads a Lotus1-2-3 WK1 spreadsheet file into the matrix `M`. The `filename` input is a string enclosed in single quotes.

`M = wk1read(filename,r,c)` starts reading at the row-column cell offset specified by `(r,c)`. `r` and `c` are zero based so that `r=0`, `c=0` specifies the first value in the file.

`M = wk1read(filename,r,c,range)` reads the range of values specified by the parameter `range`, where `range` can be

- A four-element vector specifying the cell range in the format

```
[upper_left_row upper_left_col lower_right_row lower_right_col]
```



- A cell range specified as a string, for example, `'A1...C5'`
- A named range specified as a string, for example, `'Sales'`

Examples

Create a 8-by-8 matrix A and export it to Lotus spreadsheet matA.wk1:

```
A = [1:8; 11:18; 21:28; 31:38; 41:48; 51:58; 61:68; 71:78]
A =
     1     2     3     4     5     6     7     8
    11    12    13    14    15    16    17    18
    21    22    23    24    25    26    27    28
    31    32    33    34    35    36    37    38
    41    42    43    44    45    46    47    48
    51    52    53    54    55    56    57    58
    61    62    63    64    65    66    67    68
    71    72    73    74    75    76    77    78

wk1write('matA.wk1', A);
```

To read in a limited block of the spreadsheet data, specify the upper left row and column of the block using zero-based indexing:

```
M = wk1read('matA.wk1', 3, 2)
M =
    33    34    35    36    37    38
    43    44    45    46    47    48
    53    54    55    56    57    58
    63    64    65    66    67    68
    73    74    75    76    77    78
```

To select a more restricted block of data, you can specify both the upper left and lower right corners of the block you want imported. Read in a range of values from row 4, column 3 (defining the upper left corner) to row 6, column 6 (defining the lower right corner). Note that, unlike the second and third arguments, the range argument [4 3 6 6] is one-based:

```
M = wk1read('matA.wk1', 3, 2, [4 3 6 6])
M =
    33    34    35    36
    43    44    45    46
    53    54    55    56
```

See Also `xlsread`

Purpose

Write matrix to Lotus 1-2-3 WK1 spreadsheet file

Note `wk1write` has been removed.

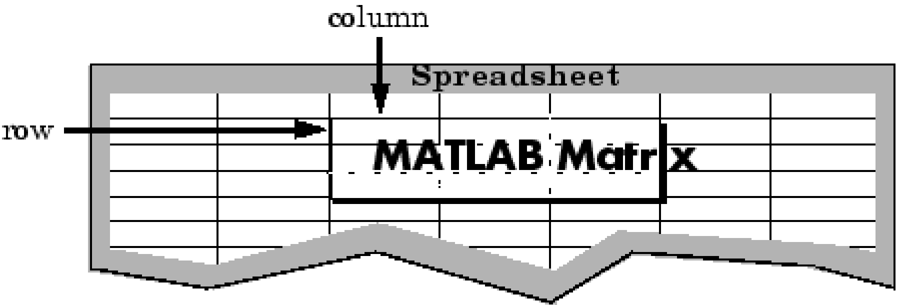
Syntax

```
wk1write(filename,M)
wk1write(filename,M,r,c)
```

Description

`wk1write(filename,M)` writes the matrix `M` into a Lotus1-2-3 WK1 spreadsheet file named `filename`. The `filename` input is a string enclosed in single quotes.

`wk1write(filename,M,r,c)` writes the matrix starting at the spreadsheet location `(r,c)`. `r` and `c` are zero based so that `r=0`, `c=0` specifies the first cell in the spreadsheet.



Examples

Write a 4-by-5 matrix A to spreadsheet file matA.wk1. Place the matrix with its upper left corner at row 2, column 3 using zero-based indexing:

```
A = [1:5; 11:15; 21:25; 31:35]
A =
      1      2      3      4      5
     11     12     13     14     15
     21     22     23     24     25
     31     32     33     34     35
```

```
wk1write('matA.wk1', A, 2, 3)

M = wk1read('matA.wk1')
M =
     0     0     0     0     0     0     0     0
     0     0     0     0     0     0     0     0
     0     0     0     1     2     3     4     5
     0     0     0    11    12    13    14    15
     0     0     0    21    22    23    24    25
     0     0     0    31    32    33    34    35
```

See Also

dlmwrite | dlmread | xlswrite | xlsread

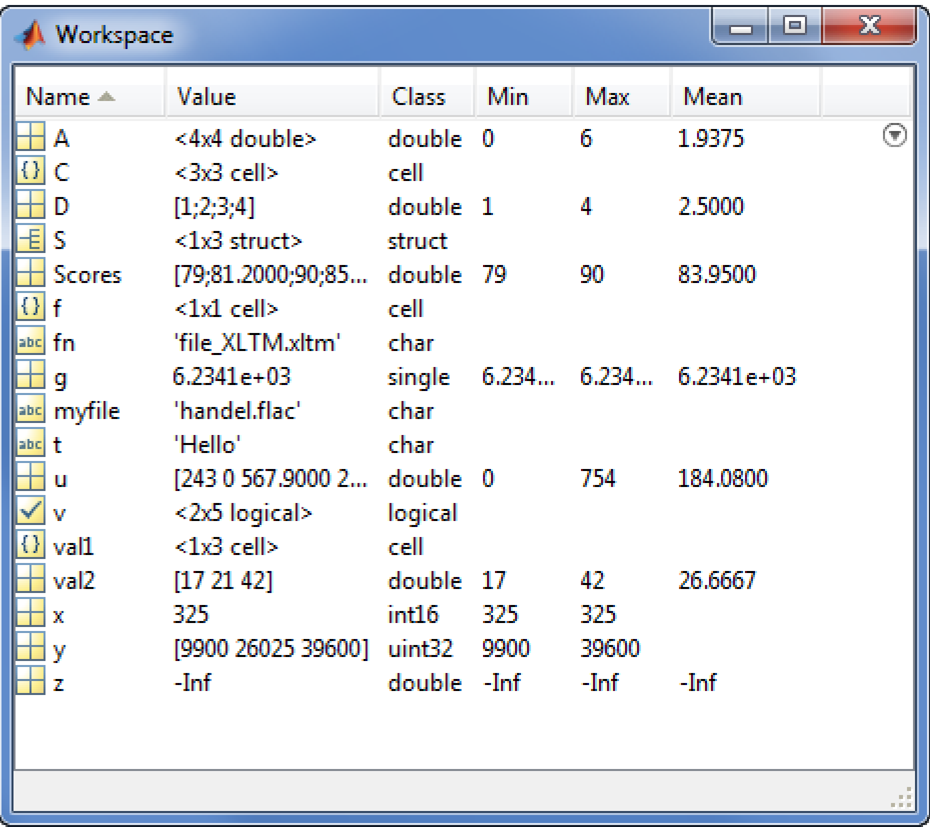
Purpose Open Workspace browser to manage workspace

Syntax

```
workspace
```

Description `workspace` displays the Workspace browser, a graphical user interface that allows you to view and manage the contents of the workspace in MATLAB. It provides a graphical representation of the `whos` display, and allows you to perform the equivalent of the `clear`, `load`, `open`, and `save` functions.

The Workspace browser also displays and automatically updates statistical calculations for each variable, which you can choose to show or hide.



You can edit a value directly in the Workspace browser for small numeric and character arrays. To see and edit a graphical representation of larger variables and for other classes, double-click the variable in the Workspace browser. The variable displays in the Variables editor, where you can view the full contents and make changes.

`openvar` | `who`

How To

- "What Is the MATLAB Workspace?"

Purpose

Write entire image

Syntax

```
tiffobj.write(imageData)
tiffobj.write(Y,Cb,Cr)
```

Description

`tiffobj.write(imageData)` writes imageData to TIFF file associated with the Tiff object, `tiffobj`. The `write` method breaks the data into strips or tiles, depending on the value of the `RowsPerStrip` tag, or the `TileLength` and `TileWidth` tags.

`tiffobj.write(Y,Cb,Cr)` writes the YCbCr component data to the TIFF file.

See Also

`Tiff.writeDirectory`

Tutorials

- "Exporting Image Data and Metadata to TIFF Files"

Tiff.writeDirectory

Purpose

Create new IFD and make it current IFD

Syntax

```
tiffobj.writeDirectory()
```

Description

`tiffobj.writeDirectory()` create a new image file directory (IFD) and makes it the current IFD. `Tiff` object methods operate on the current IFD. If you are creating a TIFF file that only contains one image, you do not need to use this method. With single-image TIFF files, just close the `Tiff` object to write data to the file.

Examples

Open a TIFF file for modification and create a new IFD in the file. `writeDirectory` makes the newly created IFD the current IFD. Replace the name `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');
dnum = t.currentDirectory();
t.writeDirectory();
dnum = t.currentDirectory();
```

References

This method corresponds to the `TIFFWriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

See Also

`Tiff.write` | `Tiff.close`

Tutorials

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

Purpose

Write data to specified strip

Syntax

```
tiffobj.writeEncodedStrip(stripNumber,imageData)
tiffobj.writeEncodedStrip(stripNumber,Y,Cb,Cr)
```

Description

`tiffobj.writeEncodedStrip(stripNumber,imageData)` writes the data in `imageData` to the strip specified by `stripNumber`. Strip identification numbers are one-based. If `imageData` has fewer bytes than fit into a strip, `writeEncodedStrip` silently pads the strip. If `imageData` has more bytes than fit into a strip, `writeEncodedStrip` issues a warning and truncates the data. To determine the size of a strip, view the value of the `RowsPerStrip` tag.

`tiffobj.writeEncodedStrip(stripNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tag.

Examples

Open a `Tiff` object for modification. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path. The folder in which you run the example must be writable.

```
t = Tiff('myfile.tif', 'r+');

if ~t.isTiled()
    width = t.getTag('ImageWidth');
   height = t.getTag('RowsPerStrip');
   numSamples = t.getTag('SamplesPerPixel');
   imageData = zeros(height,width,numSamples,'uint8');
   t.writeEncodedStrip(1,imageData);
end
```

References

This method corresponds to the `TIFFWriteEncodedStrip` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

See Also

`Tiff.writeEncodedTile`

Tutorials

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

Purpose

Write data to specified tile

Syntax

```
tiffobj.writeEncodedTile(tileNumber,imageData)
tiffobj.writeEncodedTile(tileNumber,Y,Cb,Cr)
```

Description

`tiffobj.writeEncodedTile(tileNumber,imageData)` writes the data in `imageData` to the tile specified by `tileNumber`. Tile identification numbers are one-based. If `imageData` has fewer bytes than fit into a tile, `writeEncodedTile` silently pads the tile. If `imageData` has more bytes than fit into a tile, `writeEncodedTile` issues a warning and truncates the data. To determine the size of a tile, view the value of the `tileLength` and `tileWidth` tags.

`tiffobj.writeEncodedTile(tileNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tags.

Examples

Open a TIFF file for modification. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');

if t.isTiled()
   width = t.getTag('tileWidth');
   height = t.getTag('tileLength');
   numSamples = t.getTag('SamplesPerPixel');
   imageData = zeros(height,width,numSamples,'uint8');
   t.writeEncodedTile(1,imageData);
end
```

References

This method corresponds to the `TIFFWriteEncodedTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

- "Reading Image Data and Metadata from TIFF Files"

Purpose

Write video data to file

Syntax

```
writeVideo(writerObj,img)
writeVideo(writerObj,images)
writeVideo(writerObj,frame)
writeVideo(writerObj,mov)
```

Description

`writeVideo(writerObj,img)` writes data from an image to a video file.

`writeVideo(writerObj,images)` writes a sequence of color images to a video file.

`writeVideo(writerObj,frame)` writes a frame to the video file associated with `writerObj`.

`writeVideo(writerObj,mov)` writes a MATLAB movie to a video file. `mov` is an array of frame structures.

You must call `open(writerObj)` before calling `writeVideo`.

Input Arguments

writerObj

`VideoWriter` object created by the `VideoWriter` function.

img

When creating AVI or MPEG-4 files, `img` is an array of `single`, `double`, or `uint8` values representing a grayscale or RGB color image, which `writeVideo` writes as an RGB video frame. Data of type `single` or `double` must be in the range `[0,1]`, except when writing Indexed AVI files.

When creating Motion JPEG 2000 files, `img` is an array of `uint8`, `int8`, `uint16`, or `int16` values representing a monochrome or RGB color image.

For grayscale, monochrome, or indexed data, `img` must be two-dimensional: height-by-width. For color data that is not indexed, `img` is three-dimensional: height-by-width-by-3. The height and width must be consistent for all frames within a file. For more information, see “Image Types”.

VideoWriter.writeVideo

images

Four-dimensional array of grayscale (height-by-width-by-1-by-frames) or RGB (height-by-width-by-3-by-frames) images.

frame

Structure typically returned by the `getframe` function that contains two fields: `cdata` and `colormap`. If the `colormap` is not empty, `writeVideo` expects a two-dimensional (height-by-width) array `cdata`. The height and width must be consistent for all frames within a file. `colormap` can contain a maximum of 256 entries.

The `profile` of `writerObj` and the size of `cdata` determine how the `writeVideo` method uses `frame`.

`profile` of `VideoWriter` object	Size of `cdata`	Behavior of `writeVideo`
`'Indexed AVI'` or `'Grayscale AVI'`	2-dimensional (height-by-width)	Use frame as provided. For `'Grayscale AVI'`, `colormap` should be empty.
	3-dimensional (height-by-width-by-3)	Error
All other profiles	2-dimensional (height-by-width)	Construct RGB image frames using the `colormap` field
	3-dimensional (height-by-width-by-3)	`Colormap` field ignored. Construct RGB image frames using the `cdata` field

mov

1-by-F array of frame structures, where F is the number of images. Each frame structure contains fields cdata and colormap.

Examples

AVI File from Animation

Write a sequence of frames to a compressed AVI file, peaks.avi.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);
axis tight
set(gca,'nextplot','replacechildren');
set(gcf,'Renderer','zbuffer');
```

Setting the Renderer property to zbuffer or Painters works around limitations of getframe with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20
   surf(sin(2*pi*k/20)*Z,Z)
   frame = getframe;
   writeVideo(writerObj,frame);
end

close(writerObj);
```

MPG to AVI Conversion

Convert an example file, xylophone.mpg, to an uncompressed AVI file:

Create objects to read and write the video, and open the AVI file for writing.

```
readerObj = VideoReader('xylophone.mpg');
writerObj = VideoWriter('transcoded_xylophone.avi', ...
                        'Uncompressed AVI');

open(writerObj);
```

Read and write each frame.

```
for k = 1:readerObj.NumberOfFrames
   img = read(readerObj,k);
   writeVideo(writerObj,img);
end

close(writerObj);
```

Purpose

Label *x*-axis

Syntax

```
xlabel(str)
xlabel(str,Name,Value)

xlabel(axes_handle,___)

h = xlabel(___)
```

Description

`xlabel(str)` labels the *x*-axis of the current axes with the string, `str`. Each axes graphics object has one predefined *x*-axis label. Reissuing the `xlabel` command causes the new label to replace the old label. Labels appear beneath the axis in a two-dimensional view and to the side or beneath the axis in a three-dimensional view.

`xlabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`xlabel(axes_handle,___)` adds the label to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a label. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = xlabel(___)` returns the handle to the text object used as the *x*-axis label. The handle is useful when making future modifications to the label.

Input Arguments

str - Text to display as x-axis label

string

Text to display as the *x*-axis label, specified as a string or the name of a function that returns a string.

Example: `'myLabel'`

axes_handle - Axes handle

Axes handle, which is the reference to an axes object. Use the gca function to get the handle to the current axes, for example, axes_handle = gca;.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Color','red','FontSize',12 adds an x-axis label with red, 12-point font.

In addition to the following, you can specify other text object properties using Name,Value pair arguments. See Text Properties.

'Color' - Text color

[0 0 0] (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of 'Color' and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	blue

RGB Value	Short Name	Long Name
[1 1 1]	w	white
[0 0 0]	k	black

Example: `'Color',[0 1 0]`

Example: `'Color','green'`

'FontAngle' - Character slant

`'normal'` (default) | `'italic'` | `'oblique'`

Character slant, specified as the comma-separated pair consisting of `'FontAngle'` and one of these values: `'normal'`, `'italic'`, or `'oblique'`. MATLAB uses the `FontAngle` property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

Example: `'FontAngle','italic'`

'FontName' - Font name

`'Helvetica'` (default) | string | `'FixedWidth'`

Font name, specified as the comma-separated pair consisting of `'FontName'` and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

Example: `'FontName','Courier'`

'FontSize' - Font size

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

Example: 'FontSize',12.5

'FontUnits' - Font size units
'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point = $^1/_{72}$ inch

---

Note When setting both the FontSize and the FontUnits, you must set the FontUnits property first so that MATLAB can correctly interpret the specified FontSize. For example, to set the font size to 0.3 inches, call 'FontUnits','inches','FontSize',0.3 in the argument list.

'FontWeight' - Weight of text characters
'normal' (default) | 'bold' | 'light' | 'demi'

Weight of text characters, specified as the comma-separated pair consisting of 'FontWeight' and one of the following strings:

- `'normal'`
- `'bold'`
- `'light'`
- `'demi'`

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to `'bold'` or `'demi'` causes MATLAB to use a bold font.

Example: `'FontWeight','bold'`

'Interpreter' - Character interpretation

`'tex'` (default) | `'latex'` | `'none'`

Character interpretation, specified as the comma-separated pair consisting of `'Interpreter'` and one of the following strings.

Interpreter value	Result
`'tex'`	Supports a subset of plain TeX markup language. See the `String` property for a list of supported TeX instructions.
`'latex'`	Supports a basic subset of the LaTeX markup language.
`'none'`	Interprets all characters as literal characters.

Example: `'Interpreter','latex'`

Output Arguments

h - Handle to text object used as x-axis label

Handle to the text object used as the *x*-axis label. This is a unique identifier, which you can use to query and modify the properties of the label.

Examples

Label x-axis with String

```
figure
plot((1:10).^2)
xlabel('Population')
```

MATLAB displays `Population` beneath the *x*-axis.

Label x-axis with Numeric Input

```
figure
plot((1:10).^2)
xlabel(123)
```

MATLAB displays `123` beneath the *x*-axis.

Create Multiline Label

Create a multiline label using a multiline cell array.

```
figure
plot((1:10).^2)
xlabel({date;'Population';'in Years'})
```

Create Label and Set Font Properties

Use `Name,Value` pair arguments to set the font size, font weight, and text color properties of the *x*-axis label.

```
figure
plot((1:10).^2)
xlabel('Population','FontSize',12,'FontWeight','bold','Color','r')
```

`'FontSize',12` displays the label text in 12-point font. `'FontWeight','bold'` makes the text bold. `'Color','r'` sets the text color to red.

Label x-Axis of Specific Axes

Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Label the *x*-axis of the top plot by referring to its axes handle, `s(1)`.

```
xlabel(s(1),'Population')
```

Label x-axis and Return Object Handle

Label the *x*-axis and return the handle to the text object used as the label.

```
figure
plot((1:10).^2)
str = 'Population';
h = xlabel(str);
```

MATLAB returns the object handle in the output variable, `h`.

Set the color of the label to red, using the object handle.

```
set(h,'Color','red')
```

Text Properties

ylabel

Purpose

Label *y*-axis

Syntax

```
ylabel(str)
ylabel(str,Name,Value)

ylabel(axes_handle,___)

h = ylabel(___)
```

Description

`ylabel(str)` labels the *y*-axis of the current axes with the string, `str`. Every axes has one predefined *y*-axis label. Reissuing the `ylabel` command causes the new label to replace the old label. Labels appear beside the axis in a two-dimensional view and to the side or in front of the axis in a three-dimensional view.

`ylabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`ylabel(axes_handle,___)` adds the label to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a label. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = ylabel(___)` returns the handle to the text object used as the *y*-axis label. The handle is useful when making future modifications to the label.

Input Arguments

str - Text to display as y-axis label

string

Text to display as the *y*-axis label, specified as a string or the name of a function that returns a string.

Example: `'myLabel'`

axes_handle - Axes handle

Axes handle, which is the reference to an axes object. Use the gca function to get the handle to the current axes, for example, axes_handle = gca;.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Color','red','FontSize',12 adds a y-axis label with red, 12-point font.

In addition to the following, you can specify other text object properties using Name,Value pair arguments. See Text Properties.

'Color' - Text color

[0 0 0] (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of 'Color' and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	blue

RGB Value	Short Name	Long Name
[1 1 1]	w	white
[0 0 0]	k	black

Example: 'Color',[0 1 0]

Example: 'Color','green'

'FontAngle' - Character slant

'normal' (default) | 'italic' | 'oblique'

Character slant, specified as the comma-separated pair consisting of 'FontAngle' and one of these values: 'normal', 'italic', or 'oblique'. MATLAB uses the FontAngle property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

Example: 'FontAngle','italic'

'FontName' - Font name

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

Example: 'FontName','Courier'

'FontSize' - Font size

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

Example: 'FontSize',12.5

'FontUnits' - Font size units

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point = $^1/_{72}$ inch

---

Note When setting both the FontSize and the FontUnits, you must set the FontUnits property first so that MATLAB can correctly interpret the specified FontSize. For example, to set the font size to 0.3 inches, call 'FontUnits','inches','FontSize',0.3 in the argument list.

'FontWeight' - Weight of text characters

'normal' (default) | 'bold' | 'light' | 'demi'

Weight of text characters, specified as the comma-separated pair consisting of 'FontWeight' and one of the following strings:

- 'normal'
- 'bold'
- 'light'
- 'demi'

MATLAB uses the FontWeight property to select a font from those available on your particular system. Generally, setting this property to 'bold' or 'demi' causes MATLAB to use a bold font.

Example: 'FontWeight','bold'

'Interpreter' - Character interpretation

'tex' (default) | 'latex' | 'none'

Character interpretation, specified as the comma-separated pair consisting of 'Interpreter' and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the String property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

Example: 'Interpreter','latex'

Output Arguments

h - Handle to text object used as y-axis label

Handle to the text object used as the *y*-axis label. This is a unique identifier, which you can use to query and modify the properties of the label.

Examples

Label y-axis with String

```
figure
plot((1:10).^2)
ylabel('Population')
```

MATLAB displays `Population` beside the *y*-axis.

Label y-axis with Numeric Input

```
figure
plot((1:10).^2)
ylabel(123)
```

MATLAB displays `123` beside the *y*-axis.

Create Multiline Label

Create a multiline label using a multiline cell array.

```
figure
plot((1:10).^2)
ylabel({2010;'Population';'in Years'})
```

Create Label and Set Font Properties

Use `Name,Value` pairs to set the font size, font weight, and text color properties of the *y*-axis label.

```
figure
plot((1:10).^2)
ylabel('Population','FontSize',12,'FontWeight','bold','Color','r')
```

`'FontSize',12` displays the label text in 12-point font. `'FontWeight','bold'` makes the text bold. `'Color','r'` sets the text color to red.

Label y-Axis of Specific Axes

Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Label the *y*-axis of the top plot by referring to its axes handle, `s(1)`.

```
ylabel(s(1),'Population')
```

Label y-axis and Return Object Handle

Label the *y*-axis and return the handle to the text object used as the label.

```
figure
plot((1:10).^2)
str = 'Population';
h = ylabel(str);
```

MATLAB returns the object handle in the output variable, `h`.

Set the color of the label to red, using the object handle.

```
set(h,'Color','red')
```

Text Properties

Purpose

Label *z*-axis

Syntax

```
zlabel(str)
zlabel(str,Name,Value)

zlabel(axes_handle,___)

h = zlabel(___)
```

Description

`zlabel(str)` labels the *z*-axis of the current axes with the string, `str`. Every axes has one predefined *z*-axis label. Reissuing the `zlabel` command causes the new label to replace the old label.

`zlabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`zlabel(axes_handle,___)` adds the label to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a label. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = zlabel(___)` returns the handle to the text object used as the *z*-axis label. The handle is useful when making future modifications to the label.

Input Arguments

str - Text to display as z-axis label

string

Text to display as the *z*-axis label, specified as a string or the name of a function that returns a string.

Example: `'myLabel'`

axes_handle - Axes handle

Axes handle, which is the reference to an axes object. Use the gca function to get the handle to the current axes, for example, axes_handle = gca;.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Color','red','FontSize',12 adds an z-axis label with red, 12-point font.

In addition to the following, you can specify other text object properties using Name,Value pair arguments. See Text Properties.

'Color' - Text color

[0 0 0] (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of 'Color' and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	blue

RGB Value	Short Name	Long Name
[1 1 1]	w	white
[0 0 0]	k	black

Example: `'Color',[0 1 0]`

Example: `'Color','green'`

'FontAngle' - Character slant

`'normal'` (default) | `'italic'` | `'oblique'`

Character slant, specified as the comma-separated pair consisting of `'FontAngle'` and one of these values: `'normal'`, `'italic'`, or `'oblique'`. MATLAB uses the `FontAngle` property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

Example: `'FontAngle','italic'`

'FontName' - Font name

`'Helvetica'` (default) | string | `'FixedWidth'`

Font name, specified as the comma-separated pair consisting of `'FontName'` and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

Example: `'FontName','Courier'`

'FontSize' - Font size

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of `'FontSize'` and a scalar in units determined by the `FontUnits` property. The default value for `FontUnits` is `points`.

Example: `'FontSize',12.5`

'FontUnits' - Font size units
`'points'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'pixels'`

Font size units, specified as the comma-separated pair consisting of `'FontUnits'` and one of the following strings:

- `'points'`
- `'normalized'`
- `'inches'`
- `'centimeters'`
- `'pixels'`

When the value of `FontUnits` is `'normalized'`, MATLAB interprets the value of `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly. `points`, `inches`, `centimeters`, and `pixels` are absolute units. 1 point = $^1/_{72}$ inch

---

Note When setting both the `FontSize` and the `FontUnits`, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`. For example, to set the font size to 0.3 inches, call `'FontUnits','inches','FontSize',0.3` in the argument list.

'FontWeight' - Weight of text characters
`'normal'` (default) | `'bold'` | `'light'` | `'demi'`

Weight of text characters, specified as the comma-separated pair consisting of `'FontWeight'` and one of the following strings:

- 'normal'
- 'bold'
- 'light'
- 'demi'

MATLAB uses the FontWeight property to select a font from those available on your particular system. Generally, setting this property to 'bold' or 'demi' causes MATLAB to use a bold font.

Example: 'FontWeight','bold'

'Interpreter' - Character interpretation

'tex' (default) | 'latex' | 'none'

Character interpretation, specified as the comma-separated pair consisting of 'Interpreter' and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the String property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

Example: 'Interpreter','latex'

Output Arguments

h - Handle to text object used as z-axis label

Handle to the text object used as the *z*-axis label. This is a unique identifier, which you can use to query and modify the properties of the label.

Examples

Label z-axis with String

```
figure
surf(peaks)
zlabel('Height')
```

MATLAB displays `Height` beside the z-axis.

Label z-axis with Numeric Input

```
figure
surf(peaks)
zlabel(123)
```

MATLAB displays `123` beside the z-axis.

Create Multiline Label

Create a multiline label using a multiline cell array.

```
figure
surf(peaks)
zlabel({'First Line';'Second Line'})
```

Create Label and Set Font Properties

Use `Name,Value` pairs to set the font size, font weight, and text color properties of the z-axis label.

```
figure
surf(peaks)
zlabel('Elevation','FontSize',12,'FontWeight','bold','Color','r');
```

`'FontSize',12` displays the label text in 12-point font. `'FontWeight','bold'` makes the text bold. `'Color','r'` sets the text color to red.

Label z-Axis of Specific Axes

Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
surf(peaks(30))
s(2) = subplot(2,1,2);
surf(peaks(45))
```

Label the *z*-axis of each plot by referring to the axes handles, `s(1)` and `s(2)`.

```
zlabel(s(1),'Height1')
zlabel(s(2),'Height2')
```

Label z-axis and Return Object Handle

Label the *z*-axis and return the handle to the text object used as the label.

```
figure
surf(peaks)
str = 'Population Change';
h = zlabel(str);
```

MATLAB returns the object handle in the output variable, `h`.

Set the color of the label to red, using the object handle.

```
set(h,'Color','red')
```

Concepts

- "Adding Axis Labels to Graphs"

Text Properties

xlim

Purpose

Set or query x-axis limits

Syntax

```
xlim
xlim([xmin xmax])
xlim('mode')
xlim('auto')
xlim('manual')
xlim(axes_handle,...)
```

Description

`xlim` with no arguments returns the limits of the current axes.

`xlim([xmin xmax])` sets the axis limits in the current axes to the specified values.

`xlim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`xlim('auto')` sets the axis limit mode to `auto`.

`xlim('manual')` sets the axis limit mode to `manual`.

`xlim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

Tips

`xlim` sets or queries values of the axes object `XLim`, and `XLimMode` property.

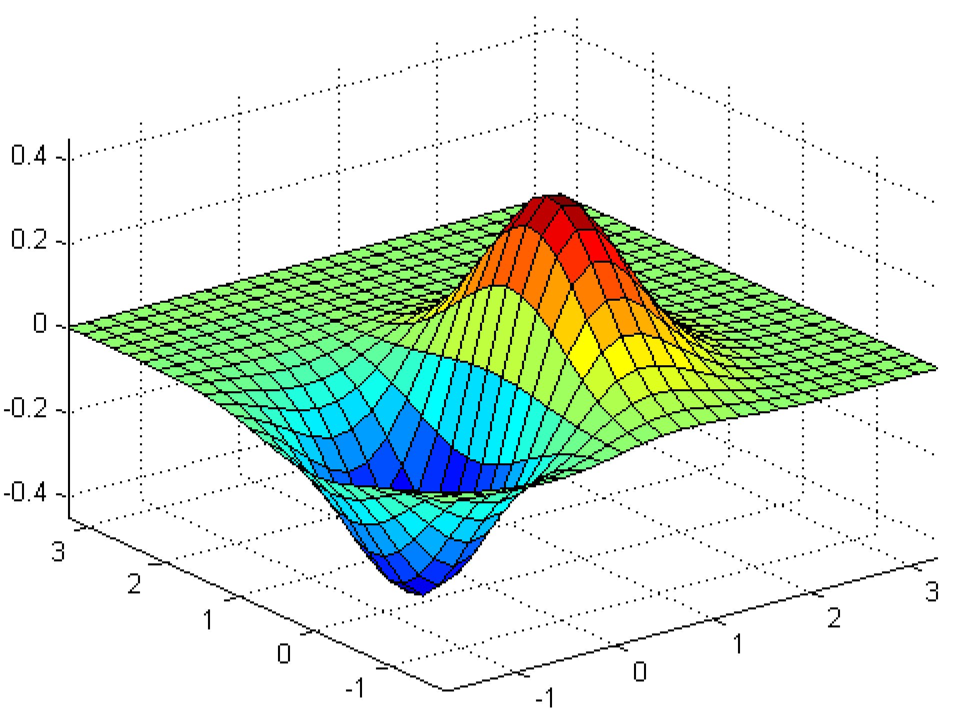
When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

Note High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

Examples

This example illustrates how to set the *x*- and *y*-axis limits to match the actual range of the data, rather than the rounded values of `[-2 3]` for the *x*-axis, `[-2 4]` for the *y*-axis and `[-0.5 0.5]` for *z*-axis originally selected by MATLAB.

```
[x,y] = meshgrid([-1.75:.2:3.25]);
z = x.*exp(-x.^2-y.^2);
surf(x,y,z)
xlim([-1.75 3.25])
ylim([-1.75 3.25])
zlim([-0.45 0.45])
```



Alternatives

To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

`ylim` | `zlim` | `axis`

How To

- `XLim`
- `YLim`

- `ZLim`
- Understanding Axes Aspect Ratio

ylim

Purpose

Set or query *y*-axis limits

Syntax

```
ylim
ylim([ymin ymax])
ylim('mode')
ylim('auto')
ylim('manual')
ylim(axes_handle,...)
```

Description

`ylim` with no arguments returns the limits of the current axes.

`ylim([ymin ymax])` sets the axis limits in the current axes to the specified values.

`ylim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`ylim('auto')` sets the axis limit mode to `auto`.

`ylim('manual')` sets the axis limit mode to `manual`.

`ylim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

Tips

`ylim` sets or queries values of the axes object `YLim`and `YLimMode` property.

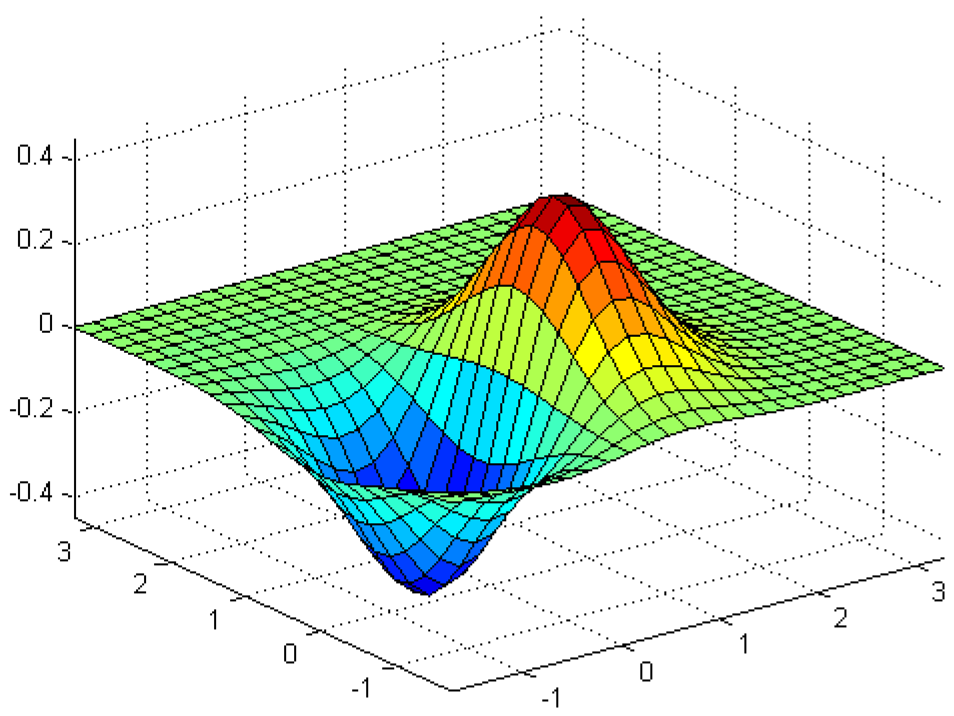
When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

Note High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

Examples

This example illustrates how to set the *x*- and *y*-axis limits to match the actual range of the data, rather than the rounded values of `[-2 3]` for the *x*-axis and `[-2 4]` for the *y*-axis and `[-0.5 0.5]` for *z*-axis originally selected by MATLAB.

```
[x,y] = meshgrid([-1.75:.2:3.25]);
z = x.*exp(-x.^2-y.^2);
surf(x,y,z)
xlim([-1.75 3.25])
ylim([-1.75 3.25])
zlim([-0.45 0.45])
```



Alternatives

To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

zlim

Purpose

Set or query z-axis limits

Syntax

```
zlim
zlim([zmin zmax])
zlim('mode')
zlim('auto')
zlim('manual')
zlim(axes_handle,...)
```

Description

`zlim` with no arguments returns the limits of the current axes.

`zlim([zmin zmax])` sets the axis limits in the current axes to the specified values.

`zlim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`zlim('auto')` sets the axis limit mode to `auto`.

`zlim('manual')` sets the axis limit mode to `manual`.

`zlim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

Tips

`zlim` sets or queries values of the axes object `ZLim` and `ZLimMode` property.

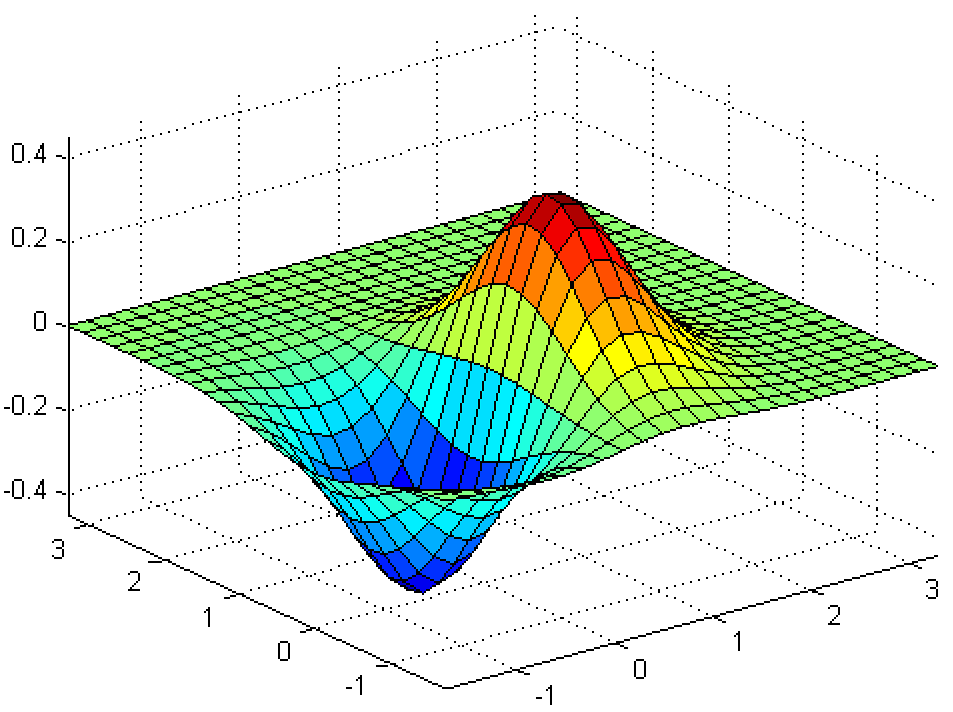
When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

Note High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

Examples

This example illustrates how to set the *x*-, *y*-, and *z*-axis limits to match the actual range of the data, rather than the rounded values of `[-2 3]` for the *x*-axis ,`[-2 4]` for the *y*-axis and `[-0.5 0.5]` for *z*-axis originally selected by MATLAB.

```
[x,y] = meshgrid([-1.75:.2:3.25]);
z = x.*exp(-x.^2-y.^2);
surf(x,y,z)
xlim([-1.75 3.25])
ylim([-1.75 3.25])
zlim([-0.45 0.45])
```



Alternatives

To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

How To

- `XLim`
- `YLim`

- `ZLim`
- Understanding Axes Aspect Ratio

xlsfinfo

Purpose

Determine whether file contains Microsoft Excel spreadsheet

Syntax

```
status = xlsfinfo(filename)
[status,sheets] = xlsfinfo(filename)
[status,sheets,format] = xlsfinfo(filename)
```

Description

`status = xlsfinfo(filename)` returns a nonempty string when the specified file is in an Excel format that `xlsread` can read (for example, `'Microsoft Excel Spreadsheet'`). Otherwise, `status` is an empty string, `''`.

`[status,sheets] = xlsfinfo(filename)` returns a cell array of strings containing the names of each spreadsheet in the file.

`[status,sheets,format] = xlsfinfo(filename)` returns a string containing the format description that Excel returns for the file. On systems without Excel for Windows, `format` is an empty string, `''`.

Input Arguments

filename

String enclosed in single quotation marks that specifies the name of the file.

Output Arguments

status

If the file is in an Excel format that `xlsread` can read, `status` is a nonempty string. Otherwise, `status` is an empty string, `''`.

sheets

If the file is in an Excel format that `xlsread` can read, `sheets` is a `1`-by-`n` cell array of strings, where `n` is the number of worksheets. Each cell contains the name of a worksheet. If MATLAB cannot read a particular worksheet, the corresponding cell contains an error message.

If the file is not in a readable Excel format, `sheets` is a string containing an error message.

format

On Windows systems with Excel software, `format` is a string that contains the description that Excel returns for the file. For example:

`'xlOpenXMLWorkbook'`	Spreadsheet in XLSX format (Excel 2007 or later).
`'xlWorkbookNormal'` or `'xlExcel8'`	Spreadsheet in XLS format (compatible with Excel 97-2003).
`'xlCSV'`	File in comma-separated value (CSV) format.
`'xlHtml'` or `'xlWebArchive'`	Spreadsheet exported to HTML format.

On all other systems, `format` is an empty string, `''`.

Examples

Consider a hypothetical file with worksheets named `Sheet1`, `Income`, and `Expenses`. Get information about the file:

```
[typ, desc, fmt] = xlsfinfo('myaccount.xlsx')
```

This code returns:

```
typ =
    Microsoft Excel Spreadsheet

desc =
    'Sheet1'    'Income'    'Expenses'

fmt =
    xlOpenXMLWorkbook
```

Limitations

- `xlsfinfo` supports only 7-bit ASCII characters.

See Also

`xlsread` | `xlswrite`

xlsread

Purpose

Read Microsoft Excel spreadsheet file

Syntax

```
num = xlsread(filename)
num = xlsread(filename,sheet)
num = xlsread(filename,xlRange)
num = xlsread(filename,sheet,xlRange)
num = xlsread(filename,sheet,xlRange,'basic')
[num,txt,raw] = xlsread(___)

___ = xlsread(filename,-1)

[num,txt,raw,custom] = xlsread(filename,sheet,xlRange,'',
   functionHandle)
```

Description

`num = xlsread(filename)` reads data from the first worksheet in the Microsoft Excel spreadsheet file named `filename` and returns the numeric data in array `num`.

On Windows systems with Microsoft Excel software, `xlsread` reads any file format recognized by your version of Excel.

If your system does not have Excel for Windows, `xlsread` operates in `basic` import mode, and reads only XLS, XLSX, XLSM, XLTX, and XLTM files.

`num = xlsread(filename,sheet)` reads the specified worksheet.

`num = xlsread(filename,xlRange)` reads data from the specified range, `xlRange`, of the first worksheet in the file.

`num = xlsread(filename,sheet,xlRange)` reads from the specified `sheet` and range, `xlRange`.

`num = xlsread(filename,sheet,xlRange,'basic')` reads data from the spreadsheet in `basic` mode, the default on systems without Excel for

Windows. If you do not specify all the arguments, use empty strings as placeholders, for example, `num = xlsread(filename,'','','basic')`.

`[num,txt,raw] = xlsread(___)` additionally returns the text fields in cell array `txt`, and the unprocessed data (numbers and text) in cell array `raw` using any of the input arguments in the previous syntaxes. If `xlRange` is specified, leading blank rows and columns in the worksheet that precede rows and columns with data are returned in `raw`.

`___ = xlsread(filename,-1)` opens an Excel window to interactively select data. Select the worksheet, drag and drop the mouse over the range you want, and click **OK**. This syntax is supported only on Windows systems with Excel software.

`[num,txt,raw,custom] = xlsread(filename,sheet,xlRange,'',functionHandle)` reads from the spreadsheet, executes the function associated with `functionHandle` on the data, and returns the final results as numeric data in array `num`. The `xlsread` function optionally returns the text fields in cell array `txt`, the unprocessed data (numbers and text) in cell array `raw`, and the second output from the function associated with `functionHandle` in array `custom`. The `xlsread` function does not change the data stored in the spreadsheet. This syntax is supported only on Windows systems with Excel software.

Input Arguments

filename - Name of file to read

string

Name of the file to read, specified as a string. If you do not include an extension, `xlsread` searches for a file with the specified name and a supported Excel extension. `xlsread` can read data saved in files that are currently open in Excel for Windows.

Example: `'myFile.xlsx'`

Data Types

`char`

sheet - Worksheet to read

string | positive integer

Worksheet to read, specified as one of the following:

- String that contains the worksheet name. Cannot contain a colon (`:`). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`. For XLS files in `basic` mode, `sheet` is case sensitive.
- Positive integer that indicates the worksheet index. Not supported for XLS files in `basic` mode.

xlRange - Rectangular portion of the worksheet to read

string

Rectangular portion of the worksheet to read, specified as a string.

Specify `xlRange` using the syntax `'C1:C2'`, where `C1` and `C2` are two opposing corners that define the region to read. For example, `'D2:H4'` represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `xlRange` input is not case sensitive, and uses Excel A1 reference style (see Excel help).

Range selection is not supported when reading XLS files in `basic` mode. In this case, use `''` in place of `xlRange`.

If you do not specify `sheet`, then `xlRange` must include both corners and a colon character, even for a single cell (such as `'D2:D2'`). Otherwise, `xlsread` interprets the input as a worksheet name (such as `'sales'` or `'D2'`).

If you specify `sheet`, then `xlRange`:

- Does not need to include a colon and opposite corner to describe a single cell.
- Can refer to a named range that you defined in the Excel file (see the Excel help).

Data Types

`char`

'basic' - Flag to request reading in `basic` mode

Flag to request reading in `basic` mode, which is the default for systems without Excel for Windows. In `basic` mode, `xlsread`:

- Reads XLS, XLSX, XLSM, XLTX, and XLTM files only.
- Does not support an `xlRange` input when reading XLS files. In this case, use `''` in place of `xlRange`.
- Does not support function handle inputs.
- Imports all dates as Excel serial date numbers. Excel serial date numbers use a different reference date than MATLAB date numbers.

functionHandle - Handle to a custom function

function handle

Handle to a custom function, starting with the symbol `@`. Supported only on Windows systems with Excel software. `xlsread` reads from the spreadsheet, executes your function on a copy of the data, and returns the final results. `xlsread` does not change the data stored in the spreadsheet.

When `xlsread` calls the custom function, it passes a range interface from the Excel application to provide access to the data. The custom function must include this interface both as an input and output argument. (See the Examples.)

Example: `@myFunctionHandle`

Output Arguments

num - Numeric data

matrix

Numeric data, returned as a matrix of `double` values. The array does not contain any information from header lines, or from outer rows or columns that contain nonnumeric data. Text data in inner spreadsheet rows and columns appear as `NaN` in the `num` output.

txt - Text data

cell array

Text data, returned as a cell array. Numeric values in inner spreadsheet rows and columns appear as empty strings, `''`, in `txt`.

For XLS files in `basic` import mode, the `txt` output contains empty strings, `''`, in place of leading columns of numeric data that precede text data in the spreadsheet. In all other cases, `txt` does not contain these additional columns.

Undefined values (such as `'#N/A'`) appear in the `txt` output as `'#N/A'`, except for XLS files in `basic` mode.

raw - Unprocessed data
cell array

Unprocessed data from the worksheet, returned as a cell array. Contains both numeric and text data.

On systems with Excel for Windows, undefined values (such as `'#N/A'`) appear in the `raw` output as `'ActiveX VT_ERROR:'`. For XLSX, XLSM, XLTX, and XLTM files on other systems, undefined values appear as `'#N/A'`.

custom - Second output of the function corresponding to `functionHandle`.

Second output of the function corresponding to `functionHandle`. The value and data type of `custom` are determined by the function.

Examples

Read Data from First Worksheet Into Numeric Array

Create an Excel file named `myExample.xlsx`.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};
headers = {'First', 'Second', 'Third'};
xlswrite('myExample.xlsx', [headers; values]);
```

`Sheet1` of `myExample.xlsx` contains:

```
   First    Second    Third
       1         2        3
```

```
        4           5    x
        7           8         9
```

Read data from the first worksheet.

```
filename = 'myExample.xlsx';
A = xlsread(filename)
```

```
A =
     1     2     3
     4     5   NaN
     7     8     9
```

`xlsread` returns the numeric data in array `A`.

Read a Specific Range of Data

Read a specific range of data from the Excel file in the previous example.

```
filename = 'myExample.xlsx';
sheet = 1;
xlRange = 'B2:C3';

subsetA = xlsread(filename, sheet, xlRange)
```

```
subsetA =
     2     3
     5   NaN
```

Read a Column of Data

Read the second column of data from the Excel file in the first example.

```
filename = 'myExample.xlsx';

columnB = xlsread(filename,'B:B')
```

```
columnB =
     2
     5
```

```
     8
```

For better performance, specify the row numbers in the range, as shown in the previous example.

Request Numeric, Text, and Unprocessed Data

Request the numeric data, text, and a copy of the unprocessed (raw) data from the Excel file in the first example.

```
[ndata, text, alldata] = xlsread('myExample.xlsx')
```

```
ndata =
     1     2     3
     4     5   NaN
     7     8     9

text =
    'First'    'Second'    'Third'
    ''         ''          ''
    ''         ''          'x'

alldata =
    'First'    'Second'    'Third'
    [    1]    [     2]    [    3]
    [    4]    [     5]    'x'
    [    7]    [     8]    [    9]
```

`xlsread` returns numeric data in array `ndata`, text data in cell array `text`, and unprocessed data in cell array `alldata`.

Execute a Function on a Worksheet and Return Numeric Data

In the Editor, create a function to process data from a worksheet. In this case, set values outside the range `[-3, 3]` to `-3` or `3`.

```
function [Data] = setMinMax(Data)

  minval = -3; maxval = 3;
```

```
  for k = 1:Data.Count
    v = Data.Value{k};
    if v > maxval || v < minval
       if v > maxval
          Data.Value{k} = maxval;
       else
          Data.Value{k} = minval;
       end
    end
  end
```

In the Command Window, add data to `myExample.xlsx`.

```
misc = pi*gallery('normaldata',[10,3],1);
xlswrite('myExample.xlsx', misc, 'MyData');
```

Worksheet `MyData` contains the following values, which range from -6.6493 to 3.4845:

```
    2.7156   -6.1744    1.8064
    0.2959   -2.3383   -2.7210
   -2.6764   -1.7351   -6.6493
    2.7442   -2.5752   -3.0300
   -1.3761    3.4845    0.6683
   -1.3498   -1.9319    1.5014
   -3.4643   -0.8000    0.3162
    1.2448   -0.8477    0.9344
   -3.0314   -5.2527    1.7912
    0.5292   -5.8938   -5.1035
```

Read the data from the worksheet, and reset any values outside the range `[-3, 3]`. Specify the sheet name, but use `''` as placeholders for the `xlRange` and `'basic'` inputs.

```
trim = xlsread('myExample.xlsx','MyData','','',@setMinMax)

trim =
```

```
   2.7156   -3.0000    1.8064
   0.2959   -2.3383   -2.7210
  -2.6764   -1.7351   -3.0000
   2.7442   -2.5752   -3.0000
  -1.3761    3.0000    0.6683
  -1.3498   -1.9319    1.5014
  -3.0000   -0.8000    0.3162
   1.2448   -0.8477    0.9344
  -3.0000   -3.0000    1.7912
   0.5292   -3.0000   -3.0000
```

Request Custom Output

Execute a function on a worksheet and display the custom index output.

In the Editor, modify the function `setMinMax` from the previous example to return the indices of the changed elements (custom output).

```
function [Data, indices] = setMinMax(Data)

  minval = -3; maxval = 3;
  indices = [];

  for k = 1:Data.Count
    v = Data.Value{k};
    if v > maxval || v < minval
       if v > maxval
          Data.Value{k} = maxval;
       else
           Data.Value{k} = minval;
       end
       indices = [indices k];
    end
  end
```

Read the data from the worksheet `MyData`, and request the custom index output, `idx`.

```
[trim,txt,raw,idx] = xlsread('myExample.xlsx','MyData', '', '', @setMinMa
```

```
disp(idx)
```

```
7       9     11     15     19     20     23     24     30
```

Algorithms

- If you do not specify `xlRange`, then `xlsread` ignores leading blank rows and columns in the worksheet that precede your data.
- If you specify `xlRange`, then leading blank rows and columns in the worksheet that precede your data are returned in `raw`, but not in `num` or `txt`.
- When the specified `xlRange` overlaps merged cells:
  - On Windows systems with Excel, `xlsread` expands the range to include all merged cells.
  - On systems without Excel for Windows, `xlsread` returns data for the specified range only, with empty or `NaN` values for merged cells.
- `xlsread` imports formatted dates as strings (such as `'10/31/96'`), except in `basic` mode and on systems without Excel for Windows.

Limitations

- `xlsread` reads only 7-bit ASCII characters.
- `xlsread` does not support non-contiguous ranges.

See Also

`xlswrite` | `xlsfinfo` | `importdata` | `uiimport` | `function_handle`

Concepts

- “When to Convert Dates from Excel Files”

xlswrite

Purpose

Write Microsoft Excel spreadsheet file

Syntax

```
xlswrite(filename,A)
xlswrite(filename,A,sheet)
xlswrite(filename,A,xlRange)
xlswrite(filename,A,sheet,xlRange)

status = xlswrite( ___ )
[status,message] = xlswrite( ___ )
```

Description

`xlswrite(filename,A)` writes array `A` to the first worksheet in Excel file, `filename`, starting at cell `A1`.

`xlswrite(filename,A,sheet)` writes to the specified worksheet.

`xlswrite(filename,A,xlRange)` writes to the rectangular region specified by `xlRange` in the first worksheet of the file.

`xlswrite(filename,A,sheet,xlRange)` writes to the specified `sheet` and range, `xlRange`.

`status = xlswrite( ___ )` returns the status of the write operation, and can include any of the input arguments in previous syntaxes. When the operation is successful, status is `1`. Otherwise, status is `0`.

`[status,message] = xlswrite( ___ )` additionally returns any warning or error message generated by the write operation in structure `message`.

Input Arguments

filename - Name of file to write

string

Name of file to write, specified as a string.

If `filename` does not exist, `xlswrite` creates a file, determining the format based on the specified extension. To create a file compatible with Excel 97-2003 software, specify an extension of `.xls`. To create files in Excel 2007 formats, specify an extension of `.xlsx`, `.xlsb`, or `.xlsm`. If you do not specify an extension, `xlswrite` uses the default, `.xls`.

Example: `'myFile.xlsx'`

A - Data to write

matrix | cell array

Data to write, specified as a two-dimensional numeric or character array, or, if each cell contains a single element, a cell array.

If `A` is a cell array containing something other than a scalar numeric or a string, then `xlswrite` silently leaves the corresponding cell in the spreadsheet empty.

The maximum size of array `A` depends on the associated Excel version. For more information on Excel specifications and limits, see the Excel help.

Example: `[10,2,45;-32,478,50]`

Example: `{92.0,'Yes',45.9,'No'}`

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell`

sheet - Worksheet name

string | positive integer

Worksheet name, specified as one of the following:

- String that contains the worksheet name. Cannot contain a colon (`:`). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`.
- Positive integer that indicates the worksheet index.

If sheet does not exist, xlswrite adds a new sheet at the end of the worksheet collection. If sheet is an index larger than the number of worksheets, xlswrite appends empty sheets until the number of worksheets in the workbook equals sheet. In either case, xlswrite generates a warning indicating that it has added a new worksheet.

xlRange - Rectangular portion of the worksheet to write
string

Rectangular portion of the worksheet to write, specified as a string.

Specify xlRange using the syntax 'C1:C2', where C1 and C2 are two opposing corners that define the region to write. For example, 'D2:H4' represents the 3-by-5 rectangular region between the two corners D2 and H4 on the worksheet. The xlRange input is not case sensitive, and uses Excel A1 reference style (see Excel help). xlswrite does not recognize named ranges.

- If you do not specify sheet, then xlRange must include both corners and a colon character, even for a single cell (such as 'D2:D2'). Otherwise, xlswrite interprets the input as a worksheet name (such as 'D2').
- If you specify sheet, then xlRange can specify only the first cell (such as 'D2'). xlswrite writes input array A beginning at this cell.
- If xlRange is larger than the size of input array A, Excel software fills the remainder of the region with #N/A. If xlRange is smaller than the size of A, then xlswrite writes only the subset that fits into xlRange to the file.

Output Arguments

status - Status of the write operation
1 | 0

Status of the write operation, returned as either 1 (true) or 0 (false). When the write operation is successful, status is 1. Otherwise, status is 0.

message - Error or warning generated during the write operation

structure array

Error or warning generated during the write operation, returned as a structure array containing two fields:

`message`	Text of the warning or error message, returned as a string.
`identifier`	Message identifier, returned as a string.

Examples

Write Data to a Spreadsheet

Write a 7-element vector to an Excel file, `testdata.xlsx`.

```
filename = 'testdata.xlsx';
A = [12.7, 5.02, -98, 63.9, 0, -.2, 56];
xlswrite(filename,A)
```

Write Data to a Specific Sheet and Range in a Spreadsheet

Write mixed text and numeric data to an Excel file, `testdata.xlsx`, starting at cell `E1` of `Sheet2`.

```
filename = 'testdata.xlsx';
A = {'Time','Temperature'; 12,98; 13,99; 14,97};
sheet = 2;
xlRange = 'E1';
xlswrite(filename,A,sheet,xlRange)
```

Tips

- If your system has Microsoft Office 2003 software, but you want to create a file in an Excel 2007 format, install the Office 2007 Compatibility Pack.
- Excel and MATLAB can store dates as strings (such as `'10/31/96'`) or serial date numbers (such as `729329`). If your array `A` includes serial date numbers, convert the dates to strings using `datestr` before calling `xlswrite`. Alternatively, see Converting Dates.

- To write data to Excel files with custom formats (such as fonts or colors), access the Windows COM server directly using `actxserver` rather than `xlswrite`. For example, Technical Solution 1-QLD4K uses `actxserver` to establish a connection between MATLAB and Excel, writes data to a worksheet, and specifies the colors of the cells.

Algorithms

Excel converts `Inf` values to `65535`. MATLAB converts `NaN` values to empty cells.

If your system does not have Excel for Windows, or if the COM server (part of the typical installation of Excel) is unavailable, then the `xlswrite` function:

- Writes array `A` to a text file in comma-separated value (CSV) format.
- Ignores the `sheet` and `xlRange` arguments.
- Generates an error when input array `A` is a cell array.

`xlsread` | `xlsfinfo`

Purpose

Read XML document and return Document Object Model node

Syntax

```
DOMnode = xmlread(filename)
```

Description

`DOMnode = xmlread(filename)` reads the specified XML file and returns a Document Object Model node representing the document.

Tips

The display for a properly parsed document is `[#document:  null]`. For example,

```
xDoc = xmlread('info.xml')
```

returns

```
xDoc =
[#document: null]
```

Input Arguments

filename

String enclosed in single quotation marks that specifies the name of the local file or URL.

Output Arguments

DOMnode

Document Object Model node, as defined by the World Wide Web consortium. For more information, see "What Is an XML Document Object Model (DOM)?".

Examples

The root element in an XML file sometimes includes an `xsi:noNamespaceSchemaLocation` attribute. The value of this attribute is the name of the preferred schema file. Call the `getAttribute` method to get this value:

```
xDoc = xmlread(fullfile(matlabroot,'toolbox',...
               'matlab','general','info.xml'));

xRoot = xDoc.getDocumentElement;
schema = char(xRoot.getAttribute('xsi:noNamespaceSchemaLocation'))
```

This code returns:

```
schema =
http://www.mathworks.com/namespace/info/v1/info.xsd
```

Create functions that parse data from an XML file into a MATLAB structure array with fields `Name`, `Attributes`, `Data`, and `Children`:

```
function theStruct = parseXML(filename)
% PARSEXML Convert XML file to a MATLAB structure.
try
   tree = xmlread(filename);
catch
   error('Failed to read XML file %s.',filename);
end

% Recurse over child nodes. This could run into problems
% with very deeply nested trees.
try
   theStruct = parseChildNodes(tree);
catch
   error('Unable to parse XML file %s.',filename);
end

% ----- Local function PARSECHILDNODES -----
function children = parseChildNodes(theNode)
% Recurse over node children.
children = [];
if theNode.hasChildNodes
   childNodes = theNode.getChildNodes;
   numChildNodes = childNodes.getLength;
   allocCell = cell(1, numChildNodes);

   children = struct(             ...
      'Name', allocCell, 'Attributes', allocCell,    ...
```

```
        'Data', allocCell, 'Children', allocCell);

      for count = 1:numChildNodes
          theChild = childNodes.item(count-1);
          children(count) = makeStructFromNode(theChild);
      end
end

% ----- Local function MAKESTRUCTFROMNODE -----
function nodeStruct = makeStructFromNode(theNode)
% Create structure of node info.

nodeStruct = struct(                        ...
   'Name', char(theNode.getNodeName),       ...
   'Attributes', parseAttributes(theNode),  ...
   'Data', '',                              ...
   'Children', parseChildNodes(theNode));

if any(strcmp(methods(theNode), 'getData'))
   nodeStruct.Data = char(theNode.getData);
else
   nodeStruct.Data = '';
end

% ----- Local function PARSEATTRIBUTES -----
function attributes = parseAttributes(theNode)
% Create attributes structure.

attributes = [];
if theNode.hasAttributes
   theAttributes = theNode.getAttributes;
   numAttributes = theAttributes.getLength;
   allocCell = cell(1, numAttributes);
   attributes = struct('Name', allocCell, 'Value', ...
                       allocCell);

   for count = 1:numAttributes
```

```
        attrib = theAttributes.item(count-1);
        attributes(count).Name = char(attrib.getName);
        attributes(count).Value = char(attrib.getValue);
    end
end
```

How To

- “What Is an XML Document Object Model (DOM)?”
- “Example — Finding Text in an XML File”

Related Links

- DOM Package Summary (methods and properties for nodes)

Purpose

Write XML Document Object Model node

Syntax

```
xmlwrite(filename,DOMnode)
str = xmlwrite(DOMnode)
```

Description

`xmlwrite(filename,DOMnode)` writes the Document Object Model (DOM) node `DOMnode` to the file `filename`.

`str = xmlwrite(DOMnode)` serializes the DOM node to a string.

Input Arguments

filename

String enclosed in single quotation marks that specifies the name of a local file or a URL.

DOMnode

Document Object Model node, as defined by the World Wide Web consortium. For more information, see "What Is an XML Document Object Model (DOM)?"

Output Arguments

str

String that contains the serialized DOM node as it appears in an XML file.

Examples

Create and view an XML document:

```
docNode = com.mathworks.xml.XMLUtils.createDocument...
    ('root_element')
docRootNode = docNode.getDocumentElement;
docRootNode.setAttribute('attr_name','attr_value');
for i=1:20
    thisElement = docNode.createElement('child_node');
    thisElement.appendChild...
        (docNode.createTextNode(sprintf('%i',i)));
    docRootNode.appendChild(thisElement);
end
```

```
docNode.appendChild(docNode.createComment('this is a comment'));

xmlFileName = [tempname,'.xml'];
xmlwrite(xmlFileName,docNode);
type(xmlFileName);
```

- DOM Package Summary (methods and properties for nodes)

Purpose

Logical exclusive-OR

Syntax

```
C = xor(A, B)
```

Description

`C = xor(A, B)` performs an exclusive OR operation on the corresponding elements of arrays `A` and `B`. The resulting element `C(i,j,...)` is logical true (1) if `A(i,j,...)` or `B(i,j,...)`, but not both, is nonzero.

A	B	C
Zero	Zero	0
Zero	Nonzero	1
Nonzero	Zero	1
Nonzero	Nonzero	0

Examples

Given `A = [0 0 pi eps]` and `B = [0 -2.4 0 1]`, then

```
C = xor(A,B)
C =
   0   1   1   0
```

To see where either `A` or `B` has a nonzero element and the other matrix does not,

```
spy(xor(A,B))
```

See Also

`all` | `any` | `find` | Elementwise Logical Operators | Short-Circuit Logical Operators

Purpose

Transform XML document using XSLT engine

Syntax

```
result = xslt(source, style, dest)
[result,style] = xslt( ___ )
xslt( ___ ,'-web')
```

Description

`result = xslt(source, style, dest)` transforms an XML document using a stylesheet and returns the resulting document's URL. The function uses these inputs, the first of which is required:

- `source` is the filename or URL of the source XML file. `source` can also specify a DOM node.
- `style` is the filename or URL of an XSL stylesheet.
- `dest` is the filename or URL of the desired output document. If `dest` is absent or empty, the function uses a temporary filename. If `dest` is `'-tostring'`, the function returns the output document as a MATLAB string.

`[result,style] = xslt( ___ )` returns a processed stylesheet appropriate for passing to subsequent XSLT calls as `style`. This prevents costly repeated processing of the stylesheet.

`xslt( ___ ,'-web')` displays the resulting document in the Help Browser.

Tips

MATLAB uses the Saxon XSLT processor, version 6.5.5, which supports XSLT 1.0 expressions. For more information, see `http://saxon.sourceforge.net/saxon6.5.5/`

For additional information on writing XSL stylesheets, see the World Wide Web Consortium (W3C®) web site, `http://www.w3.org/Style/XSL/`.

Examples

This example converts the file `info.xml` using the stylesheet `info.xsl`, writing the output to the file `info.html`. It launches the resulting HTML file in the MATLAB Web Browser.

```
xslt('info.xml', 'info.xsl', 'info.html', '-web')
```

See Also

xmlread | xmlwrite

zeros

Purpose

Create array of all zeros

Syntax

```
X = zeros
X = zeros(n)
X = zeros(sz1,...,szN)
X = zeros(sz)

X = zeros(classname)
X = zeros(n,classname)
X = zeros(sz1,...,szN,classname)
X = zeros(sz,classname)

X = zeros('like',p)
X = zeros(n,'like',p)
X = zeros(sz1,...,szN,'like',p)
X = zeros(sz,'like',p)
```

Description

`X = zeros` returns the scalar `0`.

`X = zeros(n)` returns an `n`-by-`n` matrix of zeros.

`X = zeros(sz1,...,szN)` returns an `sz1`-by-...-by-`szN` array of zeros where `sz1,...,szN` indicates the size of each dimension. For example, `zeros(2,3)` returns a 2-by-3 array of zeros.

`X = zeros(sz)` returns an array of zeros where the size vector, `sz`, defines `size(X)`. For example, `zeros([2,3])` returns a 2-by-3 array of zeros.

`X = zeros(classname)` returns a scalar `0` where the string, `classname`, specifies the data type. For example, `zeros('int8')` returns a scalar, 8-bit integer `0`.

`X = zeros(n,classname)` returns an `n`-by-`n` array of zeros of data type `classname`.

`X = zeros(sz1,...,szN,classname)` returns an `sz1`-by-...-by-`szN` array of zeros of data type `classname`.

`X = zeros(sz,classname)` returns an array of zeros where the size vector, `sz`, defines `size(X)` and `classname` defines `class(X)`.

`X = zeros('like',p)` returns a scalar `0` with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`X = zeros(n,'like',p)` returns an `n`-by-`n` array of zeros like `p`.

`X = zeros(sz1,...,szN,'like',p)` returns an `sz1`-by-...-by-`szN` array of zeros like `p`.

`X = zeros(sz,'like',p)` returns an array of zeros like `p` where the size vector, `sz`, defines `size(X)`.

Input Arguments

n - Size of square matrix

integer value

Size of square matrix, specified as an integer value, defines the output as a square, n-by-n matrix of zeros.

- If `n` is `0`, then `X` is an empty matrix.
- If `n` is negative, then it is treated as `0`.

Data Types

`double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

sz1,...,szN - Size of each dimension

two or more integer values

Size of each dimension, specified as two or more integer values, defines X as a sz1-by...-by-szN array.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

Data Types
double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

sz - Output size

row vector of integer values

Output size, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

Example: sz = [2,3,4] defines X as a 2-by-3-by-4 array.

Data Types
double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

classname - Output class

'double' (default) | 'single' | 'int8' | 'uint8'

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

Data Types
char

p - Prototype

numeric variable

Prototype, specified as a numeric variable.

Data Types

`double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

Complex Number Support: Yes

Examples

Square Array of Zeros

Create a 4-by-4 array of zeros.

```
X = zeros(4)
```

```
X =

     0     0     0     0
     0     0     0     0
     0     0     0     0
     0     0     0     0
```

3-D Array of Zeros

Create a 2-by-3-by-4 array of zeros.

```
X = zeros(2,3,4);

size(X)
```

```
ans =

     2     3     4
```

Size Defined by Existing Array

Define a 3-by-2 array A.

```
A = [1 4 ; 2 5 ; 3 6];
```

```
sz = size(A)

sz =

     3     2
```

Create an array of zeros that is the same size as A

```
X = zeros(sz)

X =

     0     0
     0     0
     0     0
```

Nondefault Numeric Data Type

Create a 1-by-3 vector of zeros whose elements are 32-bit unsigned integers.

```
X = zeros(1,3,'uint32'),
class(X)

X =

           0            0            0

ans =

uint32
```

Complex Zero

Create a scalar 0 that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create a scalar 0 that is complex like p.

```
X = zeros('like',p)
```

```
X =

   0.0000 + 0.0000i
```

Sparse Array

Define a 10-by-10 sparse matrix.

```
p = sparse(10,10,pi);
```

Create a 2-by-3 matrix of zeros that is sparse like p.

```
X = zeros(2,3,'like',p)
```

```
X =

   All zero sparse: 2-by-3
```

Size and Numeric Data Type Defined by Existing Array

Define a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of zeros that is the same size and data type as p.

```
X = zeros(size(p),'like',p),
class(X)
```

```
X =

    0    0    0
    0    0    0
```

```
ans =

uint8
```

Concepts

- “Preallocating Arrays”

Purpose

Compress files into zip file

Syntax

```
zip(zipfile,files)
zip(zipfile,files,rootfolder)
entrynames = zip(zipfile,files,rootfolder)
```

Description

`zip(zipfile,files)` creates a zip file with the name `zipfile` from the list of files and folders specified in `files`. Folders recursively include all of their content.

`zip(zipfile,files,rootfolder)` specifies the path for `files` relative to `rootfolder` instead of the current folder.

`entrynames = zip(zipfile,files,rootfolder)` returns a string cell array of the names of the files contained in `zipfile`. Specifying `rootfolder` is optional.

Input Arguments

zipfile

String that specifies the name of the zip file. If `zipfile` has no extension, MATLAB appends the `.zip` extension.

If `files` includes relative paths, the zip file also contains relative paths. The zip file does not include absolute paths.

files

String or cell array of strings containing the list of files or folders to include in `zipfile`.

Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~`*`username`*`/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

rootfolder

String that specifies the root of the paths for the files to zip.

Relative paths in the zip file reflect the relative paths in `files`, and do not include path information from `rootfolder`.

Default: current folder (`'.'`)

Output Arguments

entrynames

Cell array of strings that contain the paths to the files in `zipfile`. If `files` includes relative paths, `entrynames` also contains relative paths.

Examples

Zip a File

Create a zip file of the file `membrane.m`, which is in the MATLAB `general` folder. Save the zip file `tmwlogo.zip` in the current folder:

```
file = fullfile(matlabroot,'toolbox','matlab','general','membrane.m');
zip('tmwlogo',file);
```

Zip Selected Files

Suppose that your system has a folder named `d:/myfiles`. Zip the files `membrane.m` and `logo.m`, which are on the MATLAB search path, into a file named `tmwlogo.zip`:

```
myfile = fullfile('d:','myfiles','tmwlogo.zip');
zip(myfile,{'membrane.m','logo.m'});
```

Zip all `.m` and `.mat` files in the current folder to the file `backup.zip`:

```
zip('backup',{'*.m','*.mat'});
```

Zip a Folder

Suppose that your current folder contains a subfolder named `mywork`. Zip the contents of all subfolders of `mywork`, and store the relative paths in the zip file:

```
zip('myfiles.zip','mywork');
```

Zip Between Folders

Suppose that you have files `thesis.doc` and `defense.ppt` in `d:/PhD`. Zip these files into `thesis.zip`, one level up from the current folder:

```
zip('../thesis.zip',{'thesis.doc','defense.ppt'},'d:/PhD');
```

Alternatives

To zip files in the Current Folder browser, select the files, right-click to open the context menu, and then select **Create Zip File**.

`gzip` | `gunzip` | `tar` | `untar` | `unzip`

zoom

Purpose

Turn zooming on or off or magnify by factor

Syntax

```
zoom on
zoom off
zoom out
zoom reset
zoom
zoom xon
zoom yon
zoom(factor)
zoom(fig, option)
h = zoom(figure_handle)
```

Description

`zoom on` turns on interactive zooming. When interactive zooming is enabled in a figure, pressing a mouse button while your cursor is within an axes zooms into the point or out from the point beneath the mouse. Zooming changes the axes limits. When using zoom mode, you

- Zoom in by positioning the mouse cursor where you want the center of the plot to be and either
  - Press the mouse button or
  - Rotate the mouse scroll wheel away from you (upward).
- Zoom out by positioning the mouse cursor where you want the center of the plot to be and either
  - Simultaneously press **Shift** and the mouse button, or
  - Rotate the mouse scroll wheel toward you (downward).

Each mouse click or scroll wheel click zooms in or out by a factor of 2.

Clicking and dragging over an axes when zooming in is enabled draws a rubberband box. When you release the mouse button, the axes zoom in to the region enclosed by the rubberband box.

Double-clicking over an axes returns the axes to its initial zoom setting in both zoom-in and zoom-out modes.

`zoom off` turns interactive zooming off.

`zoom out` returns the plot to its initial zoom setting.

`zoom reset` remembers the current zoom setting as the initial zoom setting. Later calls to `zoom out`, or double-clicks when interactive `zoom` mode is enabled, will return to this zoom level.

`zoom` toggles the interactive zoom status between off and on (restoring the most recently used zoom tool).

`zoom xon` and `zoom yon` set `zoom on` for the *x*- and *y*-axis, respectively.

`zoom(factor)` zooms in or out by the specified zoom factor, without affecting the interactive zoom mode. Values greater than 1 zoom in by that amount, while numbers greater than 0 and less than 1 zoom out by `1/factor`.

`zoom(fig, option)` Any of the preceding options can be specified on a figure other than the current figure using this syntax.

`h = zoom(figure_handle)` returns a zoom *mode object* for the figure `figure_handle` for you to customize the mode's behavior.

Using Zoom Mode Objects

Access the following properties of zoom mode objects via `get` and modify some of them using `set`.

- *`Enable`* `'on'|'off'` — Specifies whether this figure mode is currently enabled on the figure
- `FigureHandle <handle>` — The associated figure handle, a read-only property that cannot be set
- *`Motion`* `'horizontal'|'vertical'|'both'` — The type of zooming enabled for the figure
- *`Direction`* `'in'|'out'` — The direction of the zoom operation
- *`RightClickAction`* `'InverseZoom'|'PostContextMenu'` — The behavior of a right-click action

  A value of `'InverseZoom'` causes a right-click to zoom out. A value of `'PostContextMenu'` displays a context menu. This setting persists between MATLAB sessions.

- `UIContextMenu <handle>` — Specifies a custom context menu to be displayed during a right-click action

  This property is ignored if the `RightClickAction` property has been set to `'on'`.

Zoom Mode Callbacks

You can program the following callbacks for zoom mode operations.

- `ButtonDownFilter <function_handle>` — Function to intercept `ButtonDown` events

  The application can inhibit the zoom operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

  ```
  function [res] = myfunction(obj,event_obj)
  % obj          handle to the object that has been clicked on
  % event_obj    struct for event data (empty in this release)
  % res [output] a logical flag determines whether the zoom
  %              operation should take place(for 'res' set to 'false'
  %              or the 'ButtonDownFcn' property of the object should
  %              take precedence (when 'res' is 'true')
  ```

- `ActionPreCallback <function_handle>` — Function to execute before zooming

  Set this callback if you want to execute code when a zoom operation starts. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

  ```
  function myfunction(obj,event_obj)
  % obj         handle to the figure that has been clicked on.
  % event_obj   object containing struct of event data
  ```

  The event data has the following field.

Axes	The handle of the axes that is being zoomed

- ActionPostCallback <function_handle> — Function to execute after zooming

  Set this callback if you want to execute code when a zoom operation finishes. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj         handle to the figure that has been clicked on
% event_obj   object containing struct of event data (same as the
%             event data of the 'ActionPreCallback' callback)
```

Zoom Mode Utility Functions

The following functions in zoom mode query and set certain of its properties.

- flags = isAllowAxesZoom(h,axes) — Function querying permission to zoom axes

  Calling the function isAllowAxesZoom on the zoom object, h, with a vector of axes handles, axes, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a zoom operation is permitted on the axes objects.

- setAllowAxesZoom(h,axes,flag) — Function to set permission to zoom axes

  Calling the function setAllowAxesZoom on the zoom object, h, with a vector of axes handles, axes, and a logical scalar, flag, either allows or disallows a zoom operation on the axes objects.

- *info* = getAxesZoomMotion(h,axes) — Function to get style of zoom operations

Calling the function `getAxesZoomMotion` on the zoom object, `H`, with a vector of axes handles, `axes`, as input returns a character cell array of the same dimension as the axes handle vector, which indicates the type of zoom operation for each axes. Possible values for the type of operation are `'horizontal'`, `'vertical'`, or `'both'`.

- `setAxesZoomMotion(h,axes,style)` — Function to set style of zoom operations

  Calling the function `setAxesZoomMotion` on the zoom object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of zooming on each axes.

Examples

Example 1 — Entering Zoom Mode

Plot a graph and turn on Zoom mode:

```
plot(1:10);
zoom on
% zoom in on the plot
```

Example 2 — Constrained Zoom

Create zoom mode object and constrain to *x*-axis zooming:

```
plot(1:10);
 h = zoom;
set(h,'Motion','horizontal','Enable','on');
% zoom in on the plot in the horizontal direction.
```

Example 3 — Constrained Zoom in Subplots

Create four axes as subplots and set zoom style differently for each by setting a different property for each axes handle:

```
ax1 = subplot(2,2,1);
plot(1:10);
h = zoom;
ax2 = subplot(2,2,2);
plot(rand(3));
```

```
setAllowAxesZoom(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesZoomMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesZoomMotion(h,ax4,'vertical');
% Zoom in on the plots.
```

Example 4 — Coding a ButtonDown Callback

Create a buttonDown callback for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zooming behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = zoom;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true.
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
   flag = true;
else
   flag = false;
end
```

Example 5 — Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-buttonDown events for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zoom behavior:

```
function demo
% Listen to zoom events
plot(1:10);
h = zoom;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');
%
function myprecallback(obj,evd)
disp('A zoom is about to occur.');
%
function mypostcallback(obj,evd)
newLim = get(evd.Axes,'XLim');
msgbox(sprintf('The new X-Limits are [%.2f %.2f].',newLim));
```

Example 6 — Creating a Context Menu for Zoom Mode

Coding a context menu that lets the user to switch to Pan mode by right-clicking:

```
figure;plot(magic(10))
hCMZ = uicontextmenu;
hZMenu = uimenu('Parent',hCMZ,'Label','Switch to pan','Callback','pan(gcb
hZoom = zoom(gcf);
set(hZoom,'UIContextMenu',hCMZ);
zoom('on')
```

You cannot add items to the built-in zoom context menu, but you can replace it with your own.

Tips

`zoom` changes the axes limits by a factor of 2 (in or out) each time you press the mouse button while the cursor is within an axes. You can

also click and drag the mouse to define a zoom area, or double-click to return to the initial zoom level.

You can create a zoom mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

Note Do not change figure callbacks within an interactive mode. While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure's callbacks, the GUI should somehow keep track of which interactive mode is active, if any, before attempting to do this.

When you assign different zoom behaviors to different `subplot` axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

Alternatives

Use the **Zoom** tools on the figure toolbar to zoom in or zoom out on a plot, or select **Zoom In** or **Zoom Out** from the figure's **Tools** menu. For details, see "Zooming in Graphs".

NET
 summary of functions 1-3464
.NET
 summary of functions 1-3464
netcdf
 summary of capabilities 1-3576
netcdf.abort
 revert recent netCDF file definitions 1-3517
netcdf.close
 close netCDF file 1-3519
netcdf.copyAtt
 copy attribute to new location 1-3520
netcdf.create
 create netCDF file 1-3522

netcdf.defDim
create dimension in netCDF file 1-3524
netcdf.defVar
define variable in netCDF dataset 1-3526
netcdf.delAtt
delete netCDF attribute 1-3535
netcdf.endDef
takes a netCDF file out of define mode 1-3537
netcdf.getAtt
return data from netCDF attribute 1-3539
netcdf.getConstant
get numeric value of netCDF constant 1-3542
netcdf.getConstantNames
get list of netCDF constants 1-3543
netcdf.getVar
return data from netCDF variable 1-3544
netcdf.inq
return information about netCDF file 1-3547
netcdf.inqAtt
return information about a netCDF attribute 1-3568
netcdf.inqAttID
return identifier of netCDF attribute 1-3570
netcdf.inqAttName
return name of netCDF attribute 1-3571
netcdf.inqDim
return information about netCDF dimension 1-3573
netcdf.inqDimID
return dimension ID for netCDF file 1-3574
netcdf.inqLibVers
return version of netCDF library 1-3575
netcdf.inqVarID
return netCDF variable identifier 1-3578
netcdf.open
open an existing netCDF file 1-3579
netcdf.putAtt
write a netCDF attribute 1-3581
netcdf.putVar
write data to netCDF variable 1-3583
netcdf.reDef
put netCDF file into define mode 1-3586
netcdf.renameAtt
netCDF function to change the name of an attribute 1-3587
netcdf.renameDim
netCDF function to change the name of a dimension 1-3589
netcdf.renameVar
change the name of a netCDF variable 1-3590
netcdf.setDefaultFormat
change the default netCDF file format 1-3594
netcdf.setFill
set netCDF fill behavior 1-3595
netcdf.sync
synchronize netCDF dataset to disk 1-3596
