How to Contact MathWorks

`www.mathworks.com`	Web
`comp.soft-sys.matlab`	Newsgroup
`www.mathworks.com/contact_TS.html`	Technical Support

`suggest@mathworks.com`	Product enhancement suggestions
`bugs@mathworks.com`	Bug reports
`doc@mathworks.com`	Documentation error reports
`service@mathworks.com`	Order status, license renewals, passcodes
`info@mathworks.com`	Sales, pricing, and general information

508-647-7000 (Phone)

508-647-7001 (Fax)

The MathWorks, Inc.
3 Apple Hill Drive
Natick, MA 01760-2098

For contact information about worldwide offices, see the MathWorks Web site.

© COPYRIGHT 1984–2013 by The MathWorks, Inc.

The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See `www.mathworks.com/trademarks` for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see `www.mathworks.com/patents` for more information.

Revision History

December 1996	First printing	For MATLAB 5.0 (Release 8)
June 1997	Online only	Revised for MATLAB 5.1 (Release 9)
October 1997	Online only	Revised for MATLAB 5.2 (Release 10)
January 1999	Online only	Revised for MATLAB 5.3 (Release 11)
June 1999	Second printing	For MATLAB 5.3 (Release 11)
June 2001	Online only	Revised for MATLAB 6.1 (Release 12.1)
July 2002	Online only	Revised for 6.5 (Release 13)
June 2004	Online only	Revised for 7.0 (Release 14)
September 2006	Online only	Revised for 7.3 (Release 2006b)
March 2007	Online only	Revised for 7.4 (Release 2007a)
September 2007	Online only	Revised for Version 7.5 (Release 2007b)
March 2008	Online only	Revised for Version 7.6 (Release 2008a)
October 2008	Online only	Revised for Version 7.7 (Release 2008b)
March 2009	Online only	Revised for Version 7.8 (Release 2009a)
September 2009	Online only	Revised for Version 7.9 (Release 2009b)
March 2010	Online only	Revised for Version 7.10 (Release 2010a)
September 2010	Online only	Revised for Version 7.11 (Release 2010b)
April 2011	Online only	Revised for Version 7.12 (Release 2011a)
September 2011	Online only	Revised for Version 7.13 (Release 2011b)
March 2012	Online only	Revised for Version 7.14 (Release 2012a)
September 2012	Online only	Revised for Version 8.0 (Release 2012b)
March 2013	Online only	Revised for Version 8.1 (Release 2013a)

Arithmetic Operators + - * / \ ^ ’

Purpose

Matrix and array arithmetic

Syntax

```
A+B
A-B
A*B
A.*B
A/B
A./B
A\B
A.\B
A^B
A.^B
A'
A.'
```

Description

MATLAB® software has two different types of arithmetic operations. Matrix arithmetic operations are defined by the rules of linear algebra. Array arithmetic operations are carried out element by element, and can be used with multidimensional arrays. The period character (`.`) distinguishes the array operations from the matrix operations. However, since the matrix and array operations are the same for addition and subtraction, the character pairs `.+` and `.-` are not used.

+	Addition or unary plus. `A+B` adds `A` and `B`. `A` and `B` must have the same size, unless one is a scalar. A scalar can be added to a matrix of any size.
-	Subtraction or unary minus. `A-B` subtracts `B` from `A`. `A` and `B` must have the same size, unless one is a scalar. A scalar can be subtracted from a matrix of any size.

`*`	Matrix multiplication. `C = A*B` is the linear algebraic product of the matrices `A` and `B`. More precisely, $$C(i,j) = \sum_{k=1}^{n} A(i,k)B(k,j)$$ For nonscalar `A` and `B`, the number of columns of `A` must equal the number of rows of `B`. A scalar can multiply a matrix of any size.
`.*`	Array multiplication. `A.*B` is the element-by-element product of the arrays `A` and `B`. `A` and `B` must have the same size, unless one of them is a scalar.
`/`	Slash or matrix right division. `B/A` is roughly the same as `B*inv(A)`. More precisely, `B/A = (A'\B')'`. See the reference page for `mrdivide` for more information.
`./`	Array right division. `A./B` is the matrix with elements `A(i,j)/B(i,j)`. `A` and `B` must have the same size, unless one of them is a scalar.
`\`	Backslash or matrix left division. If `A` is a square matrix, `A\B` is roughly the same as `inv(A)*B`, except it is computed in a different way. If `A` is an `n`-by-`n` matrix and `B` is a column vector with `n` components, or a matrix with several such columns, then `X = A\B` is the solution to the equation $AX = B$. A warning message is displayed if `A` is badly scaled or nearly singular. See the reference page for `mldivide` for more information.

If `A` is an `m`-by-`n` matrix with `m ~= n` and `B` is a column vector with `m` components, or a matrix with several such columns, then `X = A\B` is the solution in the least squares sense to the under- or overdetermined system of equations $AX = B$. The effective rank, `k`, of `A` is determined from the QR decomposition with pivoting. A solution `X` is computed that has at most `k` nonzero components per column. If `k < n`, this is usually not the same solution as `pinv(A)*B`, which is the least squares solution with the smallest norm $\|X\|$.

`.\` Array left division. `A.\B` is the matrix with elements `B(i,j)/A(i,j)`. `A` and `B` must have the same size, unless one of them is a scalar.

`^` Matrix power. `X^p` is `X` to the power `p`, if `p` is a scalar. If `p` is an integer, the power is computed by repeated squaring. If the integer is negative, `X` is inverted first. For other values of `p`, the calculation involves eigenvalues and eigenvectors, such that if `[V,D] = eig(X)`, then `X^p = V*D.^p/V`.

If `x` is a scalar and `P` is a matrix, `x^P` is `x` raised to the matrix power `P` using eigenvalues and eigenvectors. `X^P`, where `X` and `P` are both matrices, is an error.

`.^` Array power. `A.^B` is the matrix with elements `A(i,j)` to the `B(i,j)` power. `A` and `B` must have the same size, unless one of them is a scalar.

`'` Matrix transpose. `A'` is the linear algebraic transpose of `A`. For complex matrices, this is the complex conjugate transpose.

`.'` Array transpose. `A.'` is the array transpose of `A`. For complex matrices, this does not involve conjugation.

Nondouble Data Type Support

This section describes the arithmetic operators' support for data types other than `double`.

Data Type single

You can apply any of the arithmetic operators to arrays of type `single` and MATLAB software returns an answer of type `single`. You can also combine an array of type `double` with an array of type `single`, and the result has type `single`.

Integer Data Types

You can apply most of the arithmetic operators to real arrays of the following integer data types:

- `int8` and `uint8`
- `int16` and `uint16`
- `int32` and `uint32`
- `int64` and `uint64`

All operands must have the same integer data type and MATLAB returns an answer of that type.

Note Except for the unary operators `+A` and `A.'`, the arithmetic operators do not support operations on complex arrays of any integer data type.

For example,

```
x = int8(3) + int8(4);
class(x)

ans =

int8
```

The following table lists the binary arithmetic operators that you can apply to arrays of the same integer data type. In the table, `A` and `B` are arrays of the same integer data type and `c` is a scalar of type `double` or the same type as `A` and `B`.

Operation	Support when A and B Have Same Integer Type
`+A, -A`	Yes
`A+B, A+c, c+B`	Yes
`A-B, A-c, c-B`	Yes
`A.*B`	Yes
`A*c, c*B`	Yes
`A*B`	No
`A/c, c/B`	Yes
`A.\B, A./B`	Yes
`A\B, A/B`	No
`A.^B`	Yes, if `B` has nonnegative integer values.
`c^k`	Yes, for a scalar `c` and a nonnegative scalar integer `k`, which have the same integer data type or one of which has type `double`
`A.', A'`	Yes

Combining Integer Data Types with Type Double

For the operations that support integer data types, you can combine a scalar or array of an integer data type with a scalar, but not an array, of type `double` and the result has the same integer data type as the input of integer type. For example,

```
y = 5 + int32(7);
class(y)
```

```
ans =

int32
```

However, you cannot combine an array of an integer data type with either of the following:

- A scalar or array of a different integer data type
- A scalar or array of type `single`

Tips

The arithmetic operators have function equivalents, as shown here:

Binary addition	`A+B`	`plus(A,B)`
Unary plus	`+A`	`uplus(A)`
Binary subtraction	`A-B`	`minus(A,B)`
Unary minus	`-A`	`uminus(A)`
Matrix multiplication	`A*B`	`mtimes(A,B)`
Arraywise multiplication	`A.*B`	`times(A,B)`
Matrix right division	`A/B`	`mrdivide(A,B)`
Arraywise right division	`A./B`	`rdivide(A,B)`
Matrix left division	`A\B`	`mldivide(A,B)`
Arraywise left division	`A.\B`	`ldivide(A,B)`
Matrix power	`A^B`	`mpower(A,B)`
Arraywise power	`A.^B`	`power(A,B)`

Complex transpose	`A'`	`ctranspose(A)`
Matrix transpose	`A.'`	`transpose(A)`

Note For some toolboxes, the arithmetic operators are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given operator, type `help` followed by the operator name. For example, type `help plus`. The toolboxes that overload `plus` (+) are listed. For information about using the operator in that toolbox, see the documentation for the toolbox.

Examples

Here are two vectors, and the results of various matrix and array operations on them, printed with `format rat`.

Matrix Operations		Array Operations	
x	1 2 3	y	4 5 6
x'	1 2 3	y'	4 5 6
x+y	5 7 9	x-y	-3 -3 -3
x + 2	3 4 5	x-2	-1 0 1
x * y	Error	x.*y	4 10 18

Matrix Operations		Array Operations	
x'*y	32	x'.*y	Error
x*y'	4 5 6 8 10 12 12 15 18	x.*y'	Error
x*2	2 4 6	x.*2	2 4 6
x\y	16/7	x.\y	4 5/2 2
2\x	1/2 1 3/2	2./x	2 1 2/3
x/y	0 0 1/6 0 0 1/3 0 0 1/2	x./y	1/4 2/5 1/2
x/2	1/2 1 3/2	x./2	1/2 1 3/2
x^y	Error	x.^y	1 32 729

Matrix Operations		Array Operations	
`x^2`	Error	`x.^2`	1 4 9
`2^x`	Error	`2.^x`	2 4 8
`(x+i*y)'`	1 - 4i 2 - 5i 3 - 6i		
`(x+i*y).'`	1 + 4i 2 + 5i 3 + 6i		

Diagnostics

- From matrix division, if a square A is singular,

```
Warning: Matrix is singular to working precision.
```

- If the inverse was found, but is not reliable,

```
Warning: Matrix is close to singular or badly scaled.
    Results may be inaccurate.  RCOND = xxx
```

- From matrix division, if a nonsquare A is rank deficient,

```
Warning: Rank deficient, rank = xxx tol = xxx
```

Relational Operators < > <= >= == ~=

Purpose

Relational operations

Syntax

```
A < B
A > B
A <= B
A >= B
A == B
A ~= B
```

Description

The relational operators are <, >, <=, >=, ==, and ~=. Relational operators perform element-by-element comparisons between two arrays. They return a `logical` array of the same size, with elements set to logical `1` (`true`) where the relation is true, and elements set to logical `0` (`false`) where it is not.

The operators <, >, <=, and >= use only the real part of their operands for the comparison. The operators == and ~= test real and imaginary parts.

To test if two strings are equivalent, use `strcmp`, which allows vectors of dissimilar length to be compared.

Note For some toolboxes, the relational operators are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given operator, type `help` followed by the operator name. For example, type `help lt`. The toolboxes that overload `lt (<)` are listed. For information about using the operator in that toolbox, see the documentation for the toolbox.

Examples

If one of the operands is a scalar and the other a matrix, the scalar expands to the size of the matrix. For example, the two pairs of statements

```
X = 5; X >= [1 2 3; 4 5 6; 7 8 10]
X = 5*ones(3,3); X >= [1 2 3; 4 5 6; 7 8 10]
```

produce the same result:

```
ans =

     1     1     1
     1     1     0
     0     0     0
```

See Also

all | any | find | strcmp | Logical Operators: Elementwise & | ~ | Logical Operators: Short-circuit && ||

Purpose

Elementwise logical operations on arrays

Syntax

```
expr1 & expr2
expr1 | expr2
~expr
```

Description

The symbols `&`, `|`, and `~` are the logical array operators `AND`, `OR`, and `NOT`. These operators are commonly used in conditional statements, such as `if` and `while`, to determine whether or not to execute a particular block of code. Logical operations return a `logical` array with elements set to `1` (`true`) or `0` (`false`), as appropriate.

`expr1 & expr2` represents a logical `AND` operation between values, arrays, or expressions `expr1` and `expr2`. In an AND operation, if `expr1` is `true` *and* `expr2` is `true`, then the AND of those inputs is `true`. If either expression is `false`, the result is `false`. Here is a pseudocode example of AND:

```
IF (expr1: all required inputs were passed) AND ...
   (expr2: all inputs are valid)
THEN (result: execute the function)
```

`expr1 | expr2` represents a logical `OR` operation between values, arrays, or expressions `expr1` and `expr2`. In an OR operation, if `expr1` is `true` *or* `expr2` is true, then the OR of those inputs is `true`. If both expressions are `false`, the result is `false`. Here is a pseudocode example of OR:

```
IF (expr1: S is a string) OR ...
   (expr2: S is a cell array of strings)
THEN (result: parse string S)
```

`~expr` represents a logical `NOT` operation applied to expression `expr`. In a NOT operation, if `expr` is `false`, then the result of the operation is `true`. If `expr` is `true`, the result is `false`. Here is a pseudocode example of NOT:

```
IF (expr: function returned a Success status) is NOT true
```

```
THEN (result: throw an error)
```

The function `xor(A,B)` implements the exclusive `OR` operation.

Logical Operations on Arrays

The expression operands for AND, OR, and NOT are often arrays of nonsingleton dimensions. When this is the case, The MATLAB software performs the logical operation on each element of the arrays. The output is an array that is the same size as the input array or arrays.

If just one operand is an array and the other a scalar, then the scalar is matched against each element of the array. When the operands include two or more nonscalar arrays, the sizes of those arrays must be equal.

This table shows the output of AND, OR, and NOT statements that use scalar and/or array inputs. In the table, `S` is a scalar array, `A` is a nonscalar array, and `R` is the resulting array:

Operation	Result
`S1 & S2`	`R = S1 & S2`
`S & A`	`R(1) = S & A(1); ...` `R(2) = S & A(2); ...`
`A1 & A2`	`R(1) = A1(1) & A2(1);` `R(2) = A1(2) & A2(2); ...`
`S1 | S2`	`R = S1 | S2`
`S | A`	`R(1) = S | A(1);` `R(2) = S | A(2); ...`
`A1 | A2`	`R(1) = A1(1) | A2(1);` `R(2) = A1(2) | A2(2); ...`
`~S`	`R = ~S`
`~A`	`R(1) = ~A(1);` `R(2) = ~A(2), ...`

Compound Logical Statements

The number of expressions that you can evaluate with AND or OR is not limited to two (e.g., A & B). Statements such as the following are also valid:

```
expr1 & expr2 & expr3 | expr4 & expr5
```

Use parentheses to establish the order in which MATLAB evaluates a compound operation. Note the difference in the following two statements:

```
(expr1 & expr2) | (expr3 & expr4)   % 2-component OR
 expr1 & (expr2 | expr3) & expr4    % 3-component AND
```

Operator Precedence

The precedence for the logical operators with respect to each other is shown in the table below. MATLAB always gives the & operator precedence over the | operator. Although MATLAB typically evaluates expressions from left to right, the expression a|b&c is evaluated as a|(b&c). It is a good idea to use parentheses to explicitly specify the intended precedence of statements containing combinations of & and |.

Operator	Operation	Priority
~	NOT	Highest
&	Elementwise AND	
		Elementwise OR	
&&	Short-circuit AND	
||	Short-circuit OR	Lowest

Short-Circuiting in Elementwise Operators

The &, and |operators do not short-circuit. See the documentation on the && and || operators if you need short-circuiting capability.

When used in the context of an if or while expression, and only in this context, the elementwise & **and** | operators use short-circuiting in

evaluating their expressions. That is, A&B and A|B ignore the second operand, B, if the first operand, A, is sufficient to determine the result.

So, although the statement 1|[] evaluates to false, the same statement evaluates to true when used in either an if or while expression:

```
A = 1;   B = [];
if(A|B) disp 'The statement is true',  end;
   The statement is true
```

while the reverse logical expression, which does not short-circuit, evaluates to false:

```
if(B|A) disp 'The statement is true',  end;
```

Another example of short-circuiting with elementwise operators shows that a logical expression such as the one shown below, which under most circumstances is invalid due to a size mismatch between A and B, works within the context of an if or while expression:

The A|B statement generates an error:

```
A = [1 1];   B = [2 0 1];
A|B

Error using  |
Inputs must have the same size.
```

But the same statement used to test an if condition does not error:

```
if (A|B) disp 'The statement is true',  end;
   The statement is true
```

Operator Truth Table

The following is a truth table for the operators and functions in the previous example.

Inputs		and	or	not	xor
A	B	A & B	A | B	~A	xor(A,B)
0	0	0	0	1	0
0	1	0	1	1	1
1	0	0	1	0	1
1	1	1	1	0	0

Equivalent Functions

These logical operators have function equivalents, as shown here.

Logical Operation	Equivalent Function
A & B	and(A,B)
A | B	or(A,B)
~A	not(A)

Examples

Example 1 — Conditional Statement with OR

Using OR in a conditional statement, call function `parseString` on `S`, but only if `S` is a character array or a cell array of strings:

```
if ischar(S) | iscellstr(S)
    parseString(S)
end
```

Example 2 — Array AND Array

Find those elements of array `R` that are both greater than 0.3 AND less then 0.9:

```
rng(0,'twister');
R=rand(5,7)
R =
    0.8147    0.0975    0.1576    0.1419    0.6557    0.7577    0.7060
```

```
    0.9058    0.2785    0.9706    0.4218    0.0357    0.7431    0.0318
    0.1270    0.5469    0.9572    0.9157    0.8491    0.3922    0.2769
    0.9134    0.9575    0.4854    0.7922    0.9340    0.6555    0.0462
    0.6324    0.9649    0.8003    0.9595    0.6787    0.1712    0.0971
(R > 0.3) & (R < 0.9)
ans =
     1     0     0     0     1     1     1
     0     0     0     1     0     1     0
     0     1     0     0     1     1     0
     0     0     1     1     0     1     0
     1     0     1     0     1     0     0
```

Example 3 — Array AND Scalar

Find those elements of array R that are greater than the scalar value of 40:

```
rng(0,'twister');
R = rand(3,5) * 50
R =
   40.7362   45.6688   13.9249   48.2444   47.8583
   45.2896   31.6180   27.3441    7.8807   24.2688
    6.3493    4.8770   47.8753   48.5296   40.0140
R > 40
ans =
     1     1     0     1     1
     1     0     0     0     0
     0     0     1     1     1
```

Example 4 — Check Status with NOT

Throw an error if the return status of a function does NOT indicate success:

```
[Z, status] = myfun(X, Y);
if ~(status == SUCCESS);
   error('Error in function myfun')
end
```

Example 5 — OR of Binary Arrays

This example shows the logical `OR` of the elements in the vector `u` with the corresponding elements in the vector `v`:

```
u = [0 0 1 1 0 1];
v = [0 1 1 0 0 1];
u | v

ans =
   0    1    1    1    0    1
```

Logical Operators: Short-circuit && ||

Purpose

Logical operations, with short-circuiting capability

Syntax

```
expr1 && expr2
expr1 || expr2
```

Description

`expr1 && expr2` represents a logical `AND` operation that employs short-circuiting behavior. With short-circuiting, the second operand `expr2` is evaluated only when the result is not fully determined by the first operand `expr1`. For example, if `A` = 0, then the following statement evaluates to `false`, regardless of the value of `B`, so the MATLAB software does not evaluate `B`:

```
A && B
```

These two expressions must each be a valid MATLAB statement that evaluates to a scalar logical result.

`expr1 || expr2` represents a logical `OR` operation that employs short-circuiting behavior.

Note Always use the `&&` and `||` operators when short-circuiting is required. Using the elementwise operators (`&` and `|`) for short-circuiting can yield unexpected results.

Examples

In the following statement, it doesn't make sense to evaluate the relation on the right if the divisor, `b`, is zero. The test on the left is put in to avoid generating a warning under these circumstances:

```
x = (b ~= 0) && (a/b > 18.5)
```

By definition, if any operands of an `AND` expression are `false`, the entire expression must be `false`. So, if `(b ~= 0)` evaluates to `false`, MATLAB assumes the entire expression to be `false` and terminates its evaluation of the expression early. This avoids the warning that would be generated if MATLAB were to evaluate the operand on the right.

Special Characters [ ] ( ) {} = ' . ... , ; : % ! @

Purpose

Special characters

Syntax

```
[ ]
{ }
( )
=
'
.
.
.( )
..
...
,
;
:
%
%{ %}
!
@
```

Description

`[ ]` Brackets are used to form vectors and matrices. `[6.9 9.64 sqrt(-1)]` is a vector with three elements separated by blanks. `[6.9, 9.64, i]` is the same thing. `[1+j 2-j 3]` and `[1 +j 2 -j 3]` are not the same. The first has three elements, the second has five.

`[11 12 13; 21 22 23]` is a 2-by-3 matrix. The semicolon ends the first row.

Vectors and matrices can be used inside `[ ]` brackets. `[A B;C]` is allowed if the number of rows of `A` equals the number of rows of `B` and the number of columns of `A` plus the number of columns of `B` equals the number of columns of `C`. This rule generalizes in a hopefully obvious way to allow fairly complicated constructions.

`A = [ ]` stores an empty matrix in `A`. `A(m,:) = [ ]` deletes row `m` of `A`. `A(:,n) = [ ]` deletes column `n` of `A`. `A(n) = [ ]` reshapes `A` into a column vector and deletes the `n`th element.

`[A1,A2,A3...] = function` assigns function output to multiple variables.

For the use of `[` and `]` on the left of an "=" in multiple assignment statements, see `lu`, `eig`, `svd`, and so on.

`{ }` Curly braces are used in cell array assignment statements. For example, `A(2,1) = {[1 2 3; 4 5 6]}`, or `A{2,2} = ('str')`. See `help paren` for more information about `{ }`.

`( )` Parentheses are used to indicate precedence in arithmetic expressions in the usual way. They are used to enclose arguments of functions in the usual way. They are also used to enclose subscripts of vectors and matrices in a manner somewhat more general than usual. If `X` and `V` are vectors, then `X(V)` is `[X(V(1)), X(V(2)), ..., X(V(n))]`. The components of `V` must be integers to be used as subscripts. An error occurs if any such subscript is less than 1 or greater than the size of `X`. Some examples are

- `X(3)` is the third element of `X`.
- `X([1 2 3])` is the first three elements of `X`.

  See `help paren` for more information about `( )`.

If `X` has `n` components, `X(n: 1:1)` reverses them. The same indirect subscripting works in matrices. If `V` has `m` components and `W` has `n` components, then `A(V,W)` is the `m`-by-`n` matrix formed from the elements of `A` whose subscripts are the elements of `V` and `W`. For example, `A([1,5],:) = A([5,1],:)` interchanges rows 1 and 5 of `A`.

`=` Used in assignment statements. `B = A` stores the elements of `A` in `B`. == is the relational equals operator. See the `Relational Operators < > <= >= == ~=` page.

'	Matrix transpose. `X'` is the complex conjugate transpose of `X`. `X.'` is the nonconjugate transpose.
	Quotation mark. `'any text'` is a vector whose components are the ASCII codes for the characters. A quotation mark within the text is indicated by two quotation marks.
.	Decimal point. `314/100`, `3.14`, and `.314e1` are all the same.
	Element-by-element operations. These are obtained using `.*` , `.^`, `./`, or `.\`. See the Arithmetic Operators page.
.	Field access. `S(m).f` when `S` is a structure, accesses the contents of field `f` of that structure.
.( )	Dynamic Field access. `S.(df)` when `S` is a structure, accesses the contents of dynamic field `df` of that structure. Dynamic field names are defined at runtime.
..	Parent folder. See `cd`.
...	Continuation. Three or more periods at the end of a line continue the current function on the next line. Three or more periods before the end of a line cause the MATLAB software to ignore the remaining text on the current line and continue the function on the next line. This effectively makes a comment out of anything on the current line that follows the three periods. For an example, see "Continue Long Statements on Multiple Lines".
,	Comma. Used to separate matrix subscripts and function arguments. Used to separate statements in multistatement lines. For multistatement lines, the comma can be replaced by a semicolon to suppress printing.
;	Semicolon. Used inside brackets to end rows. Used after an expression or statement to suppress printing or to separate statements.
:	Colon. Create vectors, array subscripting, and `for` loop iterations. See `colon (:)` for details.

`%`	Percent. The percent symbol denotes a comment; it indicates a logical end of line. Any following text is ignored. MATLAB displays the first contiguous comment lines in a function or script file in response to a `help` command.
`%{` `%}`	Percent-brace. The text enclosed within the `%{` and `%}` symbols is a comment block. Use these symbols to insert comments that take up more than a single line in your script of function code. Any text between these two symbols is ignored by MATLAB. With the exception of whitespace characters, the %{ and %} operators must appear alone on the lines that immediately precede and follow the block of help text. Do not include any other text on these lines.
`!`	Exclamation point. Indicates that the rest of the input line is issued as a command to the operating system. See "Running External Commands, Scripts, and Programs" for more information.
`@`	Function handle. MATLAB data type that is a handle to a function. See `function_handle (@)` for details.

Tips

Some uses of special characters have function equivalents, as shown:

Horizontal concatenation	`[A,B,C...]`	`horzcat(A,B,C...)`
Vertical concatenation	`[A;B;C...]`	`vertcat(A,B,C...)`
Subscript reference	`A(i,j,k...)`	`subsref(A,S)`. See help `subsref`.
Subscript assignment	`A(i,j,k...)=B`	`subsasgn(A,S,B)`. See help `subsasgn`.

Note For some toolboxes, the special characters are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given character, type `help` followed by the character name. For example, type `help transpose`. The toolboxes that overload `transpose` (`.'`) are listed. For information about using the character in that toolbox, see the documentation for the toolbox.

`Relational Operators < > <= >= == ~=` | `Logical Operators: Elementwise & | ~` | `Arithmetic Operators + - * / \ ^ '`

Purpose

Create vectors, array subscripting, and `for`-loop iterators

Description

The colon is one of the most useful operators in MATLAB. It can create vectors, subscript arrays, and specify `for` iterations.

The colon operator uses the following rules to create regularly spaced vectors for scalar values `i`, `j`, and `k`:

`j:k`	is the same as `[j,j+1,...,k]`, or empty when `j > k`.
`j:i:k`	is the same as `[j,j+i,j+2i, ...,j+m*i]`, where `m = fix((k-j)/i)`, for integer values. For information on the definition of `j:i:k` with floating-point values, see Technical Solution 1-4FLI96. This syntax returns an empty matrix when `i == 0`, `i > 0` and `j > k`, or `i < 0` and `j < k`.

If you specify nonscalar arrays, MATLAB interprets `j:i:k` as `j(1):i(1):k(1)`.

You can use the colon to create a vector of indices to select rows, columns, or elements of arrays, where:

`A(:,j)`	is the `j`th column of `A`.
`A(i,:)`	is the `i`th row of `A`.
`A(:,:)`	is the equivalent two-dimensional array. For matrices this is the same as `A`.
`A(j:k)`	is `A(j), A(j+1),...,A(k)`.
`A(:,j:k)`	is `A(:,j), A(:,j+1),...,A(:,k)`.
`A(:,:,k)`	is the `k`th page of three-dimensional array `A`.

`A(i,j,k,:)`	is a vector in four-dimensional array `A`. The vector includes `A(i,j,k,1)`, `A(i,j,k,2)`, `A(i,j,k,3)`, and so on.
`A(:)`	is all the elements of `A`, regarded as a single column. On the left side of an assignment statement, `A(:)` fills `A`, preserving its shape from before. In this case, the right side must contain the same number of elements as `A`.

When you create a vector to index into a cell array or structure array (such as *`cellName`*`{:}` or *`structName`*`(:).`*`fieldName`*), MATLAB returns multiple outputs in a comma-separated list. For more information, see "How to Use the Comma-Separated Lists" in the MATLAB Programming Fundamentals documentation.

Examples

Using the colon with integers,

```
D = 1:4
```

results in

```
D =
    1     2     3     4
```

Using two colons to create a vector with arbitrary real increments between the elements,

```
E = 0:.1:.5
```

results in

```
E =
    0     0.1000     0.2000     0.3000     0.4000     0.5000
```

The command

```
A(:,:,2) = pascal(3)
```

generates a three-dimensional array whose first page is all zeros.

```
A(:,:,1) =
     0     0     0
     0     0     0
     0     0     0

A(:,:,2) =
     1     1     1
     1     2     3
     1     3     6
```

Using a colon with characters to iterate a for-loop,

```
for x='a':'d',x,end
```

results in

```
x =
    a
x =
    b
x =
    c
x =
    d
```

for | linspace | logspace | reshape | varargin

Purpose

Absolute value and complex magnitude

Syntax

```
abs(X)
```

Description

`abs(X)` returns an array `Y` such that each element of `Y` is the absolute value of the corresponding element of `X`.

If `X` is complex, `abs(X)` returns the complex modulus (magnitude), which is the same as

```
sqrt(real(X).^2 + imag(X).^2)
```

Examples

```
abs(-5)
ans =
     5

abs(3+4i)
ans =
     5
```

See Also

`angle` | `sign` | `unwrap`

Purpose

Construct array with accumulation

Syntax

```
A = accumarray(subs,val)
A = accumarray(subs,val,sz)
A = accumarray(subs,val,sz,fun)
A = accumarray(subs,val,sz,fun,fillval)
A = accumarray(subs,val,sz,fun,fillval,issparse)
A = accumarray({subs1, subs2, ...}, val, ...)
```

Description

`accumarray` groups elements from a data set and applies a function to each group. `A = accumarray(subs,val)` creates an array `A` by accumulating elements of the vector `val` using the elements of `subs` as indices. The position of an element in `subs` determines which value of `vals` it selects for the accumulated vector; the value of an element in `subs` determines the position of the accumulated vector in the output.

`A = accumarray(subs,val,sz)` creates an array `A` with size `sz`, where `sz` is a vector of positive integers. If `subs` is nonempty with N>1 columns, then `sz` must have N elements, where `all(sz >= max(subs,[],1))`. If `subs` is a nonempty column vector, then `sz` must be `[M 1]`, where `M >= MAX(subs)`. Specify `sz` as `[]` for the default behavior.

`A = accumarray(subs,val,sz,fun)` applies function `fun` to each subset of elements of `val`. The default accumulating function is `sum`. To specify another function `fun`, use the `@` symbol (e.g., `@max`). The function `fun` must accept a column vector and return a numeric, logical, or character scalar, or a scalar cell. Return value `A` has the same class as the values returned by `fun`. Specify `fun` as `[]` for the default behavior.

`A = accumarray(subs,val,sz,fun,fillval)` puts the scalar value `fillval` in elements of `A` that are not referred to by any row of `subs`. For example, if `subs` is empty, then `A` is `repmat(fillval,sz)`. `fillval` and the values returned by `fun` must belong to the same class. The default value of `fillval` is 0.

`A = accumarray(subs,val,sz,fun,fillval,issparse)` creates an array `A` that is sparse if the scalar input `issparse` is equal to logical 1 (i.e., `true`), or full if `issparse` is equal to logical 0 (`false`). `A` is full by

default. If `issparse` is `true`, then `fillval` must be zero or `[]`, and `val` and the output of `fun` must be double.

`A = accumarray({subs1, subs2, ...}, val, ...)` passes multiple `subs` vectors in a cell array. You can use any of the four optional inputs (`sz`, `fun`, `fillval`, or `issparse`) with this syntax.

Note If the subscripts in `subs` are not sorted, `fun` should not depend on the order of the values in its input data.

The function processes the input as follows:

1. Find out how many unique indices there are in subs. Each unique index defines a bin in the output array. The maximum index value in `subs` determines the size of the output array.

2. Find out how many times each index is repeated.

   This determines how many elements of `vals` are going to be accumulated at each bin in the output array.

3. Create an output array. The output array is of size `max(subs)` or of size `sz`.

4. Accumulate the entries in `vals` into bins using the values of the indices in `subs` and apply `fun` to the entries in each bin.

5. Fill the values in the output for positions not referred to by `subs`. Default fill value is zero; use `fillval` to set a different value.

Note `subs` should contain positive integers. `subs` can also be a cell vector with one or more elements, each element a vector of positive integers. All the vectors must have the same length. In this case, `subs` is treated as if the vectors formed columns of an index matrix.`val` must be a numeric, logical, or character vector with the same length as the number of rows in `subs`. `val` can also be a scalar whose value is repeated for all the rows of `subs`.

Examples

Example 1

Create a 5-by-1 vector and sum values for repeated 1-D subscripts:

```
val = 101:105;
subs = [1; 2; 4; 2; 4]
subs =
     1
     2
     4
     2
     4

A = accumarray(subs, val)
A =
   101       % A(1) = val(1) = 101
   206       % A(2) = val(2)+val(4) = 102+104 = 206
     0       % A(3) = 0
   208       % A(4) = val(3)+val(5) = 103+105 = 208
```

Example 2

Create a 4-by-4 matrix and subtract values for repeated 2-D subscripts:

```
val = 101:106;
subs=[1 2; 1 2; 3 1; 4 1; 4 4; 4 1];
B = accumarray(subs,val,[],@(x)sum(diff(x)))

B =
```

```
     0    -1     0     0
     0     0     0     0
     0     0     0     0
     2     0     0     0
```

The order of the subscripts matters:

```
val = 101:106;
subs=[1 2; 3 1; 1 2; 4 4; 4 1; 4 1];
B1 = accumarray(subs,val,[],@(x)sum(diff(x)))

B1 =

     0    -2     0     0
     0     0     0     0
     0     0     0     0
    -1     0     0     0
```

Example 3

Create a 2-by-3-by-2 array and sum values for repeated 3-D subscripts:

```
val = 101:105;
subs = [1 1 1; 2 1 2; 2 3 2; 2 1 2; 2 3 2];

A = accumarray(subs, val)
A(:,:,1) =
   101     0     0
     0     0     0
A(:,:,2) =
     0     0     0
   206     0   208
```

Example 4

Create a 2-by-3-by-2 array, and sum values natively:

```
val = 101:105;
subs = [1 1 1; 2 1 2; 2 3 2; 2 1 2; 2 3 2];
```

```
A = accumarray(subs, int8(val), [], @(x) sum(x,'native'))
A(:,:,1) =
  101    0    0
    0    0    0
A(:,:,2) =
    0    0    0
  127    0  127

class(A)
ans =
    int8
```

Example 5

Pass multiple subscript arguments in a cell array.

1. Create a 12-element vector `V`:

   ```
   V = 101:112;
   ```

2. Create three 12-element vectors, one for each dimension of the resulting array `A`. Note how the indices of these vectors determine which elements of `V` are accumulated in `A`:

   ```
   %        index 1   index 6 => V(1)+V(6) => A(1,3,1)
   %          |         |
   rowsubs = [1 3 3 2 3 1 2 2 3 3 1 2];
   colsubs = [3 4 2 1 4 3 4 2 2 4 3 4];
   pagsubs = [1 1 2 2 1 1 2 1 1 1 2 2];
   %               |
   %              index 4 => V(4) => A(2,1,2)
   %
   % A(1,3,1) = V(1) + V(6) = 101 + 106 = 207
   % A(2,1,2) = V(4) = 104
   ```

3. Call `accumarray`, passing the subscript vectors in a cell array:

   ```
   A = accumarray({rowsubs colsubs pagsubs}, V)
   ```

```
A(:,:,1) =
     0     0   207     0        % A(1,3,1) is 207
     0   108     0     0
     0   109     0   317
A(:,:,2) =
     0     0   111     0
   104     0     0   219        % A(2,1,2) is 104
     0   103     0     0
```

Example 6

Create an array with the `max` function, and fill all empty elements of that array with `NaN`:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @max, NaN)
A =
   101   NaN   NaN   NaN
   104   NaN   105   NaN
```

Example 7

Create a sparse matrix using the `prod` function:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @prod, 0, true)
A =
   (1,1)           101
   (2,1)         10608
   (2,3)         10815
```

Example 8

Count the number of entries accumulated in each bin:

```
val = 1;
```

```
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4])
A =
     1     0     0     0
     2     0     2     0
```

Example 9

Create a logical array that shows which bins will accumulate two or more values:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @(x) length(x) > 1)
A =
     0     0     0     0
     1     0     1     0
```

Example 10

Group values in a cell array:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @(x) {x})
A =
    [       101]     []                []     []
    [2x1 double]     []    [2x1 double]     []

A{2}
ans =
   104
   102
```

See Also

`full` | `sparse` | `sum`

Purpose

Inverse cosine in radians

Syntax

```
Y = acos(X)
```

Description

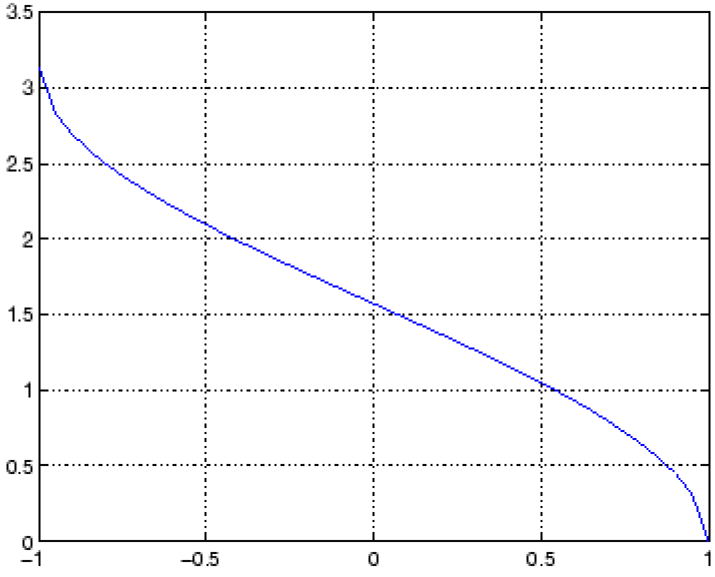
`Y = acos(X)` returns the inverse cosine (arccosine) for each element of `X`. For real elements of `X` in the domain [–1, 1], `acos(X)` is real and in the range [0, π]. For real elements of `X` outside the domain [–1, 1], `acos(X)` is complex.

The `acos` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse cosine function over the domain $-1 \leq x \leq 1$.

```
x = -1:.05:1;
plot(x,acos(x)), grid on
```



See Also

`acosd` | `acosh` | `cos`

Purpose

Inverse cosine in degrees

Syntax

`Y = acosd(X)`

Description

`Y = acosd(X)` returns the inverse cosine of the elements of `X` in degrees.

Input Arguments

X - Cosine of angle

scalar value | vector | matrix | N-D array

Cosine of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `acosd` operation is element-wise when `X` is nonscalar.

Data Types

`single | double`

Complex Number Support: Yes

Output Arguments

Y - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Inverse Cosine of Zero

Verify that inverse cosine of 0 is exactly 90.

```
acosd(0)
```

```
ans =

    90
```

Round Trip Calculation for Complex Angles

Show that inverse cosine, followed by cosine, returns the original values of `X`.

```
cosd(acosd([2 3]))
```

```
ans =

    2.0000    3.0000
```

`acosd([2 3])` returns two complex angles, which are then passed to the `cosd` function. `cosd` returns the original values, `2` and `3`.

See Also

`cosd` | `acos` | `cos`

Purpose

Inverse hyperbolic cosine

Syntax

```
Y = acosh(X)
```

Description

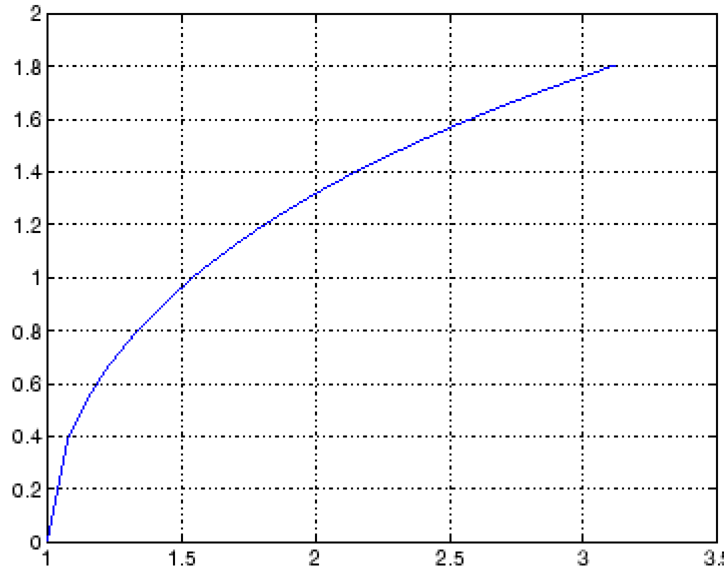
`Y = acosh(X)` returns the inverse hyperbolic cosine for each element of `X`.

The `acosh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic cosine function over the domain $-1 \leq x \leq \pi$.

```
x = 1:pi/40:pi;
plot(x,acosh(x)), grid on
```



See Also

`acos` | `cosh` | `asinh` | `atanh`

acot

Purpose

Inverse cotangent in radians

Syntax

```
Y = acot(X)
```

Description

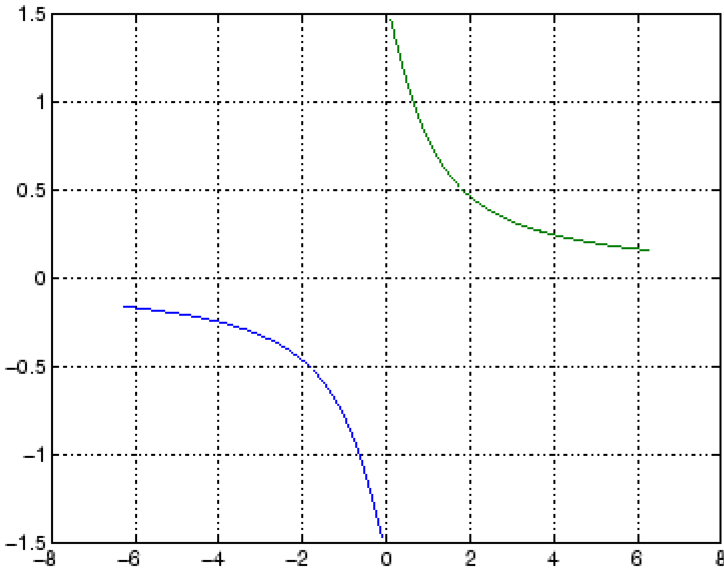
`Y = acot(X)` returns the inverse cotangent (arccotangent) for each element of `X`.

The `acot` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse cotangent over the domains $-2\pi \leq x < 0$ and $0 < x \leq 2\pi$.

```
x1 = -2*pi:pi/30:-0.1;
x2 = 0.1:pi/30:2*pi;
plot(x1,acot(x1),x2,acot(x2)), grid on
```



See Also

`cot` | `acotd` | `acoth`

Purpose

Inverse cotangent in degrees

Syntax

```
Y = acotd(X)
```

Description

`Y = acotd(X)` returns the inverse cotangent of the elements of `X` in degrees.

Input Arguments

X - Cotangent of angle

scalar value | vector | matrix | N-D array

Cotangent of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `acotd` operation is element-wise when `X` is nonscalar.

Data Types
`single | double`
Complex Number Support: Yes

Output Arguments

Y - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Inverse Cotangent of Vector

```
x = [0 20 Inf];
y = acotd(x)
```

```
y =

   90.0000    2.8624         0
```

The `acotd` operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Cotangent of Complex Value

```
acotd(1+i)
```

```
ans =

  31.7175 -23.0535i
```

See Also

cotd | cot | acot

Purpose

Inverse hyperbolic cotangent

Syntax

```
Y = acoth(X)
```

Description

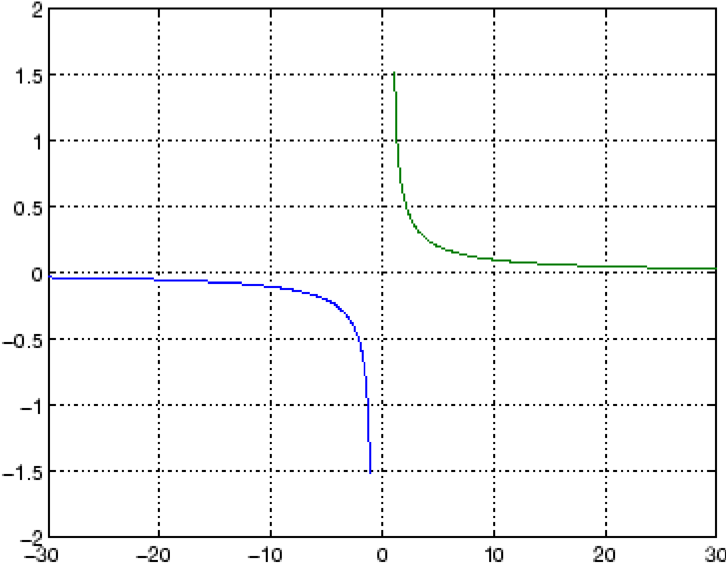
`Y = acoth(X)` returns the inverse hyperbolic cotangent for each element of `X`.

The `acoth` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic cotangent over the domains $-30 \le x < -1$ and $1 < x \le 30$.

```
x1 = -30:0.1:-1.1;
x2 = 1.1:0.1:30;
plot(x1,acoth(x1),x2,acoth(x2)), grid on
```



See Also

`acot` | `coth` | `atanh` | `asinh` | `acosh`

Purpose

Inverse cosecant in radians

Syntax

```
Y = acsc(X)
```

Description

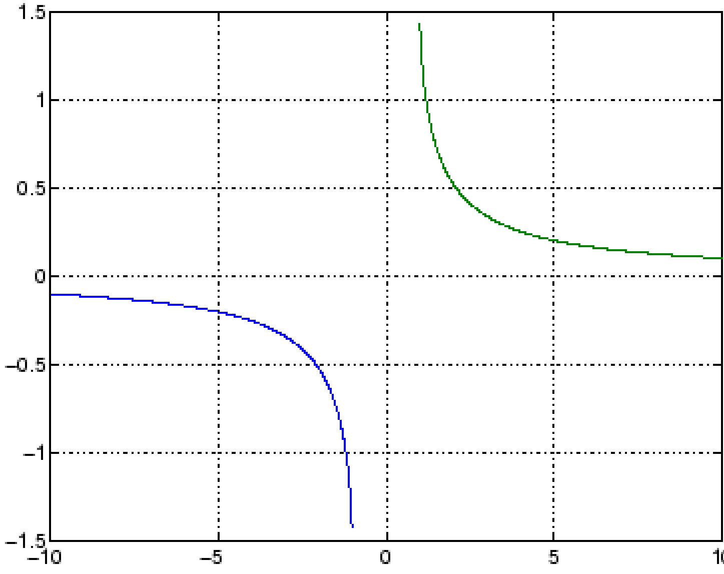
`Y = acsc(X)` returns the inverse cosecant (arccosecant) for each element of `X`.

The `acsc` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse cosecant over the domains $-10 \le x < -1$ and $1 < x \le 10$.

```
x1 = -10:0.01:-1.01;
x2 = 1.01:0.01:10;
plot(x1,acsc(x1),x2,acsc(x2)), grid on
```



See Also

`csc` | `acscd` | `acsch`

Purpose

Inverse cosecant in degrees

Syntax

```
Y = acscd(X)
```

Description

`Y = acscd(X)` returns the inverse cosecant of the elements of `X` in degrees.

Input Arguments

X - Cosecant of angle

scalar value | vector | matrix | N-D array

Cosecant of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `acscd` operation is element-wise when `X` is nonscalar.

Data Types

`single | double`

Complex Number Support: Yes

Output Arguments

Y - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Inverse Cosecant of Vector

```
x = [20 10 Inf];
y = acscd(x)

y =

    2.8660    5.7392         0
```

The `acscd` operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Cosecant of Complex Value

```
acscd(1+i)
```

```
ans =

  25.9136 -30.4033i
```

See Also

cscd | csc | acsc

Purpose

Inverse hyperbolic cosecant

Syntax

```
Y = acsch(X)
```

Description

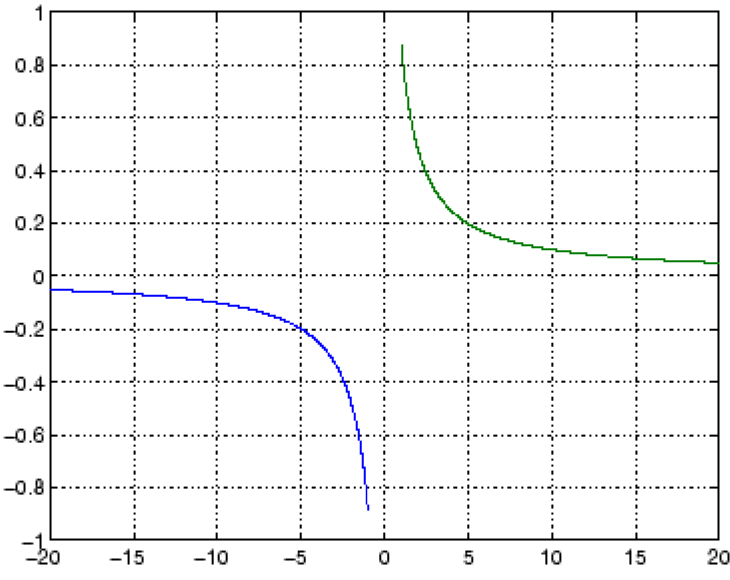
`Y = acsch(X)` returns the inverse hyperbolic cosecant for each element of `X`.

The `acsch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic cosecant over the domains $-20 \le x \le -1$ and $1 \le x \le 20$.

```
x1 = -20:0.01:-1;
x2 = 1:0.01:20;
plot(x1,acsch(x1),x2,acsch(x2)), grid on
```



See Also

`acsc` | `csch` | `asinh` | `acosh`

actxcontrol

Purpose

Create Microsoft ActiveX control in figure window

Syntax

```
h = actxcontrol('progid')
h = actxcontrol('progid','param1',value1,...)
h = actxcontrol('progid',position)
h = actxcontrol('progid', position, fig_handle)
h = actxcontrol('progid',position,fig_handle,event_handler)
h = actxcontrol('progid',position,fig_handle,event_handler,
    'filename')
```

Description

`h = actxcontrol('progid')` creates an ActiveX® control in a figure window. The programmatic identifier (`progid`) for the control determines the type of control created. (See the documentation provided by the control vendor to get this string.) The returned object, `h`, represents the default interface for the control.

You cannot use an ActiveX server for the `progid` because MATLAB software cannot insert ActiveX servers in a figure. See `actxserver` for use with ActiveX servers.

`h = actxcontrol('progid','param1',value1,...)` creates an ActiveX control using the optional parameter name/value pairs. Parameter names include:

- `position` — MATLAB position vector specifying the control's position. The format is [left, bottom, width, height] using pixel units.
- `parent` — Handle to parent figure, model, or command window.
- `callback` — Name of event handler. Specify a single name to use the same handler for all events. Specify a cell array of event name/event handler pairs to handle specific events.
- `filename` — Sets the control's initial conditions to those in the previously saved control.
- `licensekey` — License key to create licensed ActiveX controls that require design-time licenses. See "Deploy ActiveX Controls Requiring Run-Time Licenses" for information on how to use controls that require run-time licenses.

One possible format is:

```
h = actxcontrol('myProgid','newPosition',[0 0 200 200],...
 'myFigHandle',gcf,...
 'myCallback',{'Click' 'myClickHandler';...
 'DblClick' 'myDblClickHandler';...
 'MouseDown' 'myMouseDownHandler'});
```

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the previous syntaxes are preferred.

`h = actxcontrol('progid',position)` creates an ActiveX control having the location and size specified in the vector, `position`. The format of this vector is:

```
[x y width height]
```

The first two elements of the vector determine where the control is placed in the figure window, with `x` and `y` being offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control. The last two elements, `width` and `height`, determine the size of the control itself.

The default `position` vector is `[20 20 60 60]`.

`h = actxcontrol('progid', position, fig_handle)` creates an ActiveX control at the specified `position` in an existing figure window. This window is identified by the Handle Graphics® handle, `fig_handle`.

The current figure handle is returned by the `gcf` command.

Note If the figure window designated by `fig_handle` is invisible, the control is invisible. If you want the control you are creating to be invisible, use the handle of an invisible figure window.

`h = actxcontrol('progid',position,fig_handle,event_handler)` creates an ActiveX control that responds to events. Controls respond to events by invoking a MATLAB function whenever an event (such

as clicking a mouse button) is fired. The `event_handler` argument identifies one or more functions to be used in handling events. For more information, see "Specifying Event Handlers" on page 1-110.

`h = actxcontrol('progid',position,fig_handle,event_handler,'filename')` creates an ActiveX control with the first four arguments, and sets its initial state to that of a previously saved control. MATLAB loads the initial state from the file specified in the string `filename`.

If you do not want to specify an `event_handler`, you can use an empty string (`''`) as the fourth argument.

The `progid` argument must match the `progid` of the saved control.

Specifying Event Handlers

There is more than one valid format for the `event_handler` argument. Use this argument to specify one of the following:

- A different event handler routine for each event supported by the control
- One common routine to handle selected events
- One common routine to handle all events

In the first case, use a cell array for the `event_handler` argument, with each row of the array specifying an event and handler pair:

```
{'event' 'eventhandler'; 'event2' 'eventhandler2'; ...}
```

`event` can be either a string containing the event name or a numeric event identifier (see Example 2), and `eventhandler` is a string identifying the function you want the control to use in handling the event. Include only those events that you want enabled.

In the second case, use the same cell array syntax just described, but specify the same `eventhandler` for each event. Again, include only those events that you want enabled.

In the third case, make `event_handler` a string (instead of a cell array) that contains the name of the one function that is to handle all events for the control.

There is no limit to the number of event and handler pairs you can specify in the `event_handler` cell array. However, if you register the same event name to the same callback handler multiple times, MATLAB executes the event only once.

Event handler functions should accept a variable number of arguments.

Strings used in the `event_handler` argument are not case sensitive.

Note Although using a single handler for all events might be easier in some cases, specifying an individual handler for each event creates more efficient code, resulting in better performance.

Tips

If the control implements any custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

When you no longer need the control, call `release` to release the interface and free memory and other resources used by the interface. Note that releasing the interface does not delete the control itself. Use the `delete` function to do this.

For more information on handling control events, see Writing Event Handlers.

For an example event handler, see the file `sampev.m` in the `toolbox\matlab\winfun\comcli` directory.

COM functions are available on Microsoft® Windows® systems only.

Note If you encounter problems creating Microsoft Forms 2.0 controls in MATLAB or other non-VBA container applications, see "Use Microsoft Forms 2.0 Controls".

Examples

Handling Events

The `event_handler` argument specifies how you want the control to handle any events that occur. The control can handle all events with one common handler function, selected events with a common handler function, or each type of event can be handled by a separate function.

This command creates an `mwsamp` control that uses one event handler, `sampev`, to respond to all events:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
   gcf, 'sampev');
```

The next command also uses a common event handler, but will only invoke the handler when selected events, `Click` and `DblClick` are fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
   gcf, {'Click' 'sampev'; 'DblClick' 'sampev'});
```

This command assigns a different handler routine to each event. For example, `Click` is an event, and `myclick` is the routine that executes whenever a `Click` event is fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
   gcf, {'Click', 'myclick'; 'DblClick' 'my2click'; ...
   'MouseDown' 'mymoused'});
```

The next command does the same thing, but specifies the events using numeric event identifiers:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
gcf, {-600, 'myclick'; -601 'my2click'; -605 'mymoused'});
```

For examples of event handler functions and how to register them with MATLAB, see “Sample Event Handlers”.

See Also

`actxserver` | `release` | `delete (COM)` | `save (COM)` | `load (COM)` | `interfaces`

actxcontrollist

Purpose

List currently installed Microsoft ActiveX controls

Syntax

```
info = actxcontrollist
```

Description

`info = actxcontrollist` returns a list of controls in `info`, a `1-by-3` cell array containing the name, programmatic identifier (ProgID), and file name for the control. Each control has one row, which MATLAB software sorts by file name.

COM functions are available on Microsoft Windows systems only.

Examples

Show information for two controls:

```
list = actxcontrollist;
for k = 1:2
  sprintf(' Name = %s\n ProgID = %s\n File = %s\n', list{k,:})
end
```

MATLAB displays information like:

```
ans =
  Name = Calendar Control 11.0
  ProgID = MSCAL.Calendar.7
  File = C:\Program Files\MSOffice\OFFICE11\MSCAL.OCX

ans =
  Name = CTreeView Control
  ProgID = CTREEVIEW.CTreeViewCtrl.1
  File = C:\WINNT\system32\dmocx.dll
```

See Also

`actxcontrolselect | actxcontrol`

Purpose

Create Microsoft ActiveX control from GUI

Syntax

```
h = actxcontrolselect
[h, info] = actxcontrolselect
```

Description

`h = actxcontrolselect` displays a GUI listing all ActiveX controls installed on the system and creates the one you select from the list. Returns handle `h` for the object. Use the handle to identify this control when calling MATLAB COM functions.

`[h, info] = actxcontrolselect` returns a `1`-by-`3` cell array `info` containing the name, programmatic identifier (ProgID), and file name for the control.

COM functions are available on Microsoft Windows systems only.

See Also

`actxcontrollist` | `actxcontrol`

How To

- “Creating Control Objects Using a GUI”

actxGetRunningServer

Purpose

Handle to running instance of Automation server

Syntax

```
h = actxGetRunningServer('progid')
```

Description

`h = actxGetRunningServer('progid')` gets a reference to a running instance of the OLE Automation server. `progid` is the programmatic identifier of the Automation server object and `h` is the handle to the default interface of the server object.

The function returns an error if the server specified by `progid` is not currently running or if the server object is not registered. When multiple instances of the Automation server are running, the operating system controls the behavior of this function.

COM functions are available on Microsoft Windows systems only.

Examples

Get a handle to the MATLAB application:

```
h = actxGetRunningServer('matlab.application')
```

See Also

`actxcontrol` | `actxserver`

How To

- "MATLAB COM Automation Server Interface"

Purpose

Create COM server

Syntax

```
h = actxserver('progid')
h = actxserver('progid','machine','machineName')
h = actxserver('progid','interface','interfaceName')
h = actxserver('progid','machine','machineName','interface',
   'interfaceName')
h = actxserver('progid',machine)
```

Description

`h = actxserver('progid')` creates a local OLE Automation server, where `progid` is the programmatic identifier of an OLE-compliant COM server, and `h` is the handle of the server's default interface.

Get `progid` from the control or server vendor's documentation. To see the `progid` values for MATLAB software, refer to "Programmatic Identifiers".

`h = actxserver('progid','machine','machineName')` creates an OLE Automation server on a remote machine, where `machineName` is a string specifying the name of the machine on which to start the server.

`h = actxserver('progid','interface','interfaceName')` creates a Custom interface server, where `interfaceName` is a string specifying the interface name of the COM object. Values for `interfaceName` are

- `IUnknown` — Use the IUnknown interface.
- The Custom interface name

You must know the name of the interface and have the server vendor's documentation in order to use the `interfaceName` value. For information about custom COM servers and interfaces, see "COM Server Types".

Note The MATLAB COM Interface does not support invoking functions with optional parameters.

`h = actxserver('progid','machine','machineName','interface','interfaceName')` creates a Custom interface server on a remote machine.

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the syntaxes described earlier are preferred:

`h = actxserver('progid',machine)` creates a COM server running on the remote system named by the `machine` argument. This can be an IP address or a DNS name. Use this syntax only in environments that support Distributed Component Object Model (for more information, see "Using MATLAB Application as DCOM Server").

Tips

For components implemented in a dynamic link library (DLL), `actxserver` creates an in-process server. For components implemented as an executable (EXE), `actxserver` creates an out-of-process server. Out-of-process servers can be created either on the client system or on any other system on a network that supports DCOM.

If the control implements any Custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

You can register events for COM servers.

COM functions are available on Microsoft Windows systems only.

Examples

Microsoft Excel® Workbook Example

This example creates an OLE Automation server, Excel version 9.0, and manipulates a workbook in the application.

Create a COM server running Microsoft Excel.

```
e = actxserver ('Excel.Application')
```

```
e =
    COM.Excel.application
```

Make the Excel frame window visible

```
e.Visible = 1;
```

Use the get method on the Excel object "e" to list all properties of the application:

```
e.get
```

Properties

```
        Application: [1x1
Interface.Microsoft_Excel_9.0_Object_Library._Application]
            Creator: 'xlCreatorCode'
                   .
                   .
                   .
          Workbooks: [1x1
Interface.Microsoft_Excel_9.0_Object_Library.Workbooks]
                   .
                   .
                   .
            Caption: 'Microsoft Excel - Book1'
    CellDragAndDrop: 0
   ClipboardFormats: {3x1 cell}
                   .
                   .
                   .
             Cursor: 'xlNorthwestArrow'
                   .
                   .
                   .
```

Create an interface "eWorkBooks":

```
eWorkbooks = e.Workbooks

eWorkbooks =
```

```
   Interface.Microsoft_Excel_9.0_Object_Library.Workbooks
```

List all methods for that interface

```
eWorkbooks.invoke
```

Methods

```
       Add: 'handle Add(handle, [Optional]Variant)'
     Close: 'void Close(handle)'
      Item: 'handle Item(handle, Variant)'
      Open: 'handle Open(handle, string, [Optional]Variant)'
  OpenText: 'void OpenText(handle, string, [Optional]Variant)'
          .
          .
          .
```

Add a new workbook "w", also creating a new interface:

```
w = eWorkbooks.Add

w =
   Interface.Microsoft_Excel_9.0_Object_Library._Workbook
```

Close Excel and delete the object

```
e.Quit;
e.delete;
```

See Also

Purpose

Create or modify app project file for packaging app into `.mlappinstall` file using interactive dialog box

Syntax

```
matlab.apputil.create
matlab.apputil.create(prjfile)
```

Description

`matlab.apputil.create` opens the Package App dialog box that steps you through the process of creating an `.mlappinstall` file.

`matlab.apputil.create(prjfile)` loads the specified `.prj` file and populates the Package App dialog box with the information from the specified project file. Use this option if you need to update an existing app.

Input Arguments

prjfile - Full or partial path to the `.prj` file

string

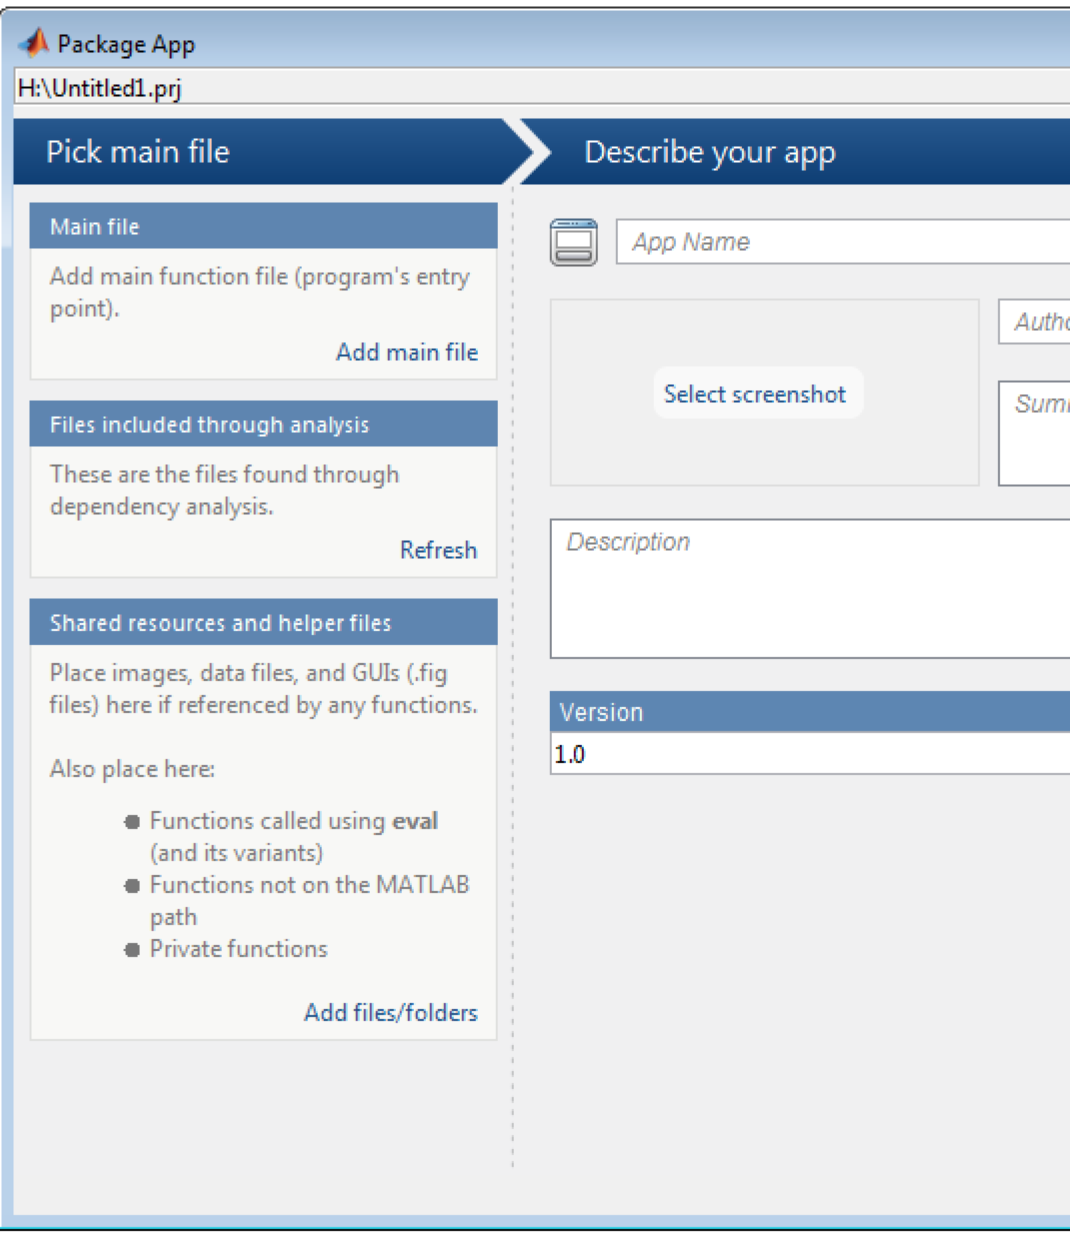
Full or partial path to the `.prj` file you created previously with the Package App dialog box, specified as a string

Example: `'C:\myapp.prj'`

Examples

Open Dialog Box for Creating an App Package

```
matlab.apputil.create
```



Package App
H:\Untitled1.prj
Pick main file
Describe your app
Main file
Add main function file (program's entry point).
Add main file
Files included through analysis
These are the files found through dependency analysis.
Refresh
Shared resources and helper files
Place images, data files, and GUIs (.fig files) here if referenced by any functions.
Also place here:
Functions called using eval (and its variants)
Functions not on the MATLAB path
Private functions
Add files/folders
App Name
Select screenshot
Description
Version
1.0

Minimally, add a main file and specify an app name. MATLAB creates and continuously saves a `.prj` file, regardless of whether you click **Package**. However, MATLAB does not create a `.mlappinstall` file if you do not click **Package**.

Update Existing App Package

Assume you have an existing project file, `myapp.prj`. You want to add a file and update the description.

Open the Package App dialog box, specifying the previously created `.prj` file:

```
matlab.apputil.create('myapp.prj')
```

The dialog box opens populated with the data you previously specified for `myapp`. Adjust the information in the dialog box, as needed.

Concepts

- “MATLAB App Installer File — mlappinstall”

matlab.apputil.getInstalledAppInfo

Purpose

List installed app information

Syntax

```
matlab.apputil.getInstalledAppInfo

appinfo = matlab.apputil.getInstalledAppInfo
```

Description

`matlab.apputil.getInstalledAppInfo` displays the ID and name of all installed custom apps. It does not display this information for apps packaged with MathWorks® products.

`appinfo = matlab.apputil.getInstalledAppInfo` returns structure to `appinfo`, which includes the status, ID, location, and name of all installed custom apps. It does not return this information for apps packaged with MathWorks products.

Output Arguments

appinfo - Information about installed apps
structure array

Information about the installed app, returned as a structure array, with one element for each installed app. Each element of the structure array has the following fields:

status - Installation status
`'installed'`

Status of the installation, returned as the string `'installed'`.

id - Unique identifier for the installed app
string

Unique identifier for the installed app, returned as a string

The ID is for use when running or uninstalling the app programmatically.

location - Folder where the app is installed
string

Folder where the app is installed, returned as a string

name - Name of the installed app
string

Name of the installed app as it appears in the apps gallery, returned as a string

Examples

Display Installed Apps Information in the Command Window

Assume you installed two apps, `LinePlotter` and `PlotRandNumbers`. Display the app information in the Command Window.

```
matlab.apputil.getInstalledAppInfo
```

```
ID                      Name
------------------      ---------------
LinePlotterAPP          LinePlotter
PlotRandNumbersAPP      PlotRandNumbers
```

Store Installed App Information in a Variable

Assume you installed an app, `ColorPalette`. Get the app information and store it in a variable, `myappinfo`.

```
myappinfo = matlab.apputil.getInstalledAppInfo;
```

Store Installed App Information in a Variable and Display IDs

Assume you installed two apps, `LinePlotter` and `PlotRandNumbers`. Get and store the app information for both installed apps in a variable, `myappinfo`. Then, get the `id` for each app.

```
myappinfo = matlab.apputil.getInstalledAppInfo

myappinfo =

1x2 struct array with fields:
    id
```

```
    name
    status
    location
```

Get the id of each installed app:

```
appids={myappinfo.id}

appids =

    'LinePlotterAPP'    'PlotRandNumbersAPP'
```

Concepts

- "MATLAB App Installer File — mlappinstall"

Purpose

Install app from a `.mlappinstall` file

Syntax

`appinfo = matlab.apputil.install(appfile)`

Description

`appinfo = matlab.apputil.install(appfile)` installs the specified app file and returns information about the app.

Input Arguments

appfile - Full or partial path to `.mlappinstall` file
string

Full or partial path of the app file you want to install, specified as a string.

Example: `'C:\myguis\myapps\myapp.mlappinstall'`

Output Arguments

appinfo - Information about installed app
structure

Information about the installed app, returned as a structure with the fields:

status - Installation status
`'installed'` | `'updated'`

Installation status, returned as a string:

- `'installed'` — New app is installed.
- `'updated'` — Previously installed app is updated.

id - Unique identifier
string

Unique identifier for the installed app, returned as a string

The ID is for use when running or uninstalling the app programmatically.

location - Folder where app is installed
string

Folder where app is installed, returned as a string

name - Name of installed app

string

Name of installed app as it appears in the apps gallery, returned as a string

Examples

Install App and Display Information About the Installation

Assume you have downloaded an app from File Exchange named `EmployeeData`. Install it and return information about the installation to the variable `appinfo`. Later, if you decide to deinstall the app programmatically, you have the app id required to do so.

```
appinfo = matlab.apputil.install...
   ('C:\myguis\myapps\EmployeeData.mlappinstall')
```

```
appinfo = 

          id: 'EmployeeDataApp'
        name: 'EmployeeData'
      status: 'installed'
    location: 'C:\myguis\myapps\EmployeeData.mlappinstall'
```

See Also

`matlab.apputil.uninstall` | `matlab.apputil.getInstalledAppInfo` | `matlab.apputil.package`

Concepts

- “MATLAB App Installer File — mlappinstall”

matlab.apputil.package

Purpose

Package app files into `.mlappinstall` file

Syntax

```
matlab.apputil.package(prjfile)
```

Description

`matlab.apputil.package(prjfile)` creates a `.mlappinstall` file based on the information in the specified `prjfile`.

Input Arguments

prjfile - Full or partial path to app project (`.prj`) file
string

Full or partial path to app project (`.prj`) file, specified as a string.

Example: `'plotdata.prj'`

Examples

Create mlappinstall File for Previously Created Project File

Assume you previously created `myprjfile.prj` using `matlab.apputil.create`. The following command creates the corresponding `.mlappinstall` file.

```
matlab.apputil.package('myprjfile.prj')
```

Tips

- To create a `.prj` file, use `matlab.apputil.create`.

See Also

`matlab.apputil.create` | `matlab.apputil.install` | `matlab.apputil.run`

matlab.apputil.run

Purpose

Run app programmatically

Syntax

```
matlab.apputil.run(appid)
```

Description

`matlab.apputil.run(appid)` runs the custom app specified by the unique identifier, `appid`.

Input Arguments

appid - ID of custom app

string

ID of custom app you want to run, specified as a string.

Example: `'DataExplorationAPP'`

Tips

- The ID of a custom app is returned when you install it. You can use `matlab.apputil.getInstalledAppInfo` to get the ID after you have installed an app.
- When a custom app runs, MATLAB adds any folders it needs to have added to the path, as identified when the app was packaged. When the app exits, MATLAB removes those folders from the path.
- You can run multiple, different custom apps concurrently. However, you cannot run two instances of the same app concurrently.

Examples

Run Previously Installed App

Assume you installed two apps, `PlotData` and `setslider`. Run `PlotData` programmatically, using its ID.

Get IDs of all installed apps.

```
matlab.apputil.getInstalledAppInfo
```

```
ID                       Name
-------------------      ----------------
setsliderAPP             setslider
PlotDataAPP              PlotData
```

Run `PlotData`.

```
matlab.apputil.run('PlotDataAPP')
```

See Also

`matlab.apputil.create` | `matlab.apputil.install` | `matlab.apputil.getInstalledAppInfo`

matlab.apputil.uninstall

Purpose

Uninstall app

Syntax

```
matlab.apputil.uninstall(appid)
```

Description

`matlab.apputil.uninstall(appid)` removes the app specified by the unique identifier, `appid`. MATLAB removes all files corresponding to the app and removes the app from the app gallery.

Input Arguments

appid - ID of app
string

ID of app to be uninstalled, specified as a string.

Example: `'DataExplorationAPP'`

Tips

- To determine the appid of an installed app, preserve the value returned when you install the app programmatically with `matlab.apputil.install`, or use `matlab.apputil.getInstalledAppInfo`.

Examples

Uninstall App

Assume you previously installed two apps, `setslider` and `simplegui`. Get the IDs of all installed apps, and then use the ID for `simplegui` to uninstall it.

View the IDs of all apps

```
matlab.apputil.getInstalledAppInfo
```

```
ID                      Name
-------------------     ----------------
setsliderAPP            setslider
simpleguiAPP            simplegui
```

Uninstall the `simplegui` app.

```
matlab.apputil.uninstall('simpleguiAPP')
```

Confirm the app was removed, by running `matlab.apputil.getInstalledAppInfo` again.

```
matlab.apputil.getInstalledAppInfo
```

```
ID                         Name
-------------------        ----------------
setsliderAPP               setslider
```

`matlab.apputil.install` | `matlab.apputil.getInstalledAppInfo`

addCause (MException)

Purpose

Record additional causes of exception

Syntax

`baseExcep = addCause(baseExcep, causeExcep)`

Description

`baseExcep = addCause(baseExcep, causeExcep)` adds information to existing exception *baseExcep* to help determine its cause. The added information is in the form of a second exception *causeExcep*. Both *baseExcep* and *causeExcep* are objects of the `MException` class. The `baseExcep` and `causeExcep` inputs are scalar objects of the `mException` class.

The exception has a property called `cause` in which you can store a series of additional exceptions, each saving information on what caused the initial error. (See the figure in the documentation for "The MException Class".) When your program calls `addCause`, MATLAB appends a new exception *cause* to this field in the base exception *exception*. When your error handling code catches the error in a `try/catch` statement, execution of the `catch` part of this statement makes the base exception, along with all of the appended cause records, available to help diagnose the error.

Examples

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested `try-catch` block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second using `addCause`:

```
function data = read_it(filename);
try
   % Attempt to open and read from a file.
   fid = fopen(filename, 'r');
   data = fread(fid);
catch exception1
   % If the error was caused by an invalid file ID, try
   % reading from another location.
   if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
      msg = sprintf( ...
```

```
            '\nCannot open file %s. Try another location?  ', ...
            filename);
         reply = input(msg, 's')
         if reply(1) == 'y'
             newFolder = input('Enter folder name:  ', 's');
         else
             throw(exception1);
         end
         oldpath = addpath(newFolder);
         try
            fid = fopen(filename, 'r');
            data = fread(fid);
         catch exception2
            exception3 = addCause(exception2, exception1)
            path(oldpath);
            throw(exception3);
         end
         path(oldpath);
      end
   end
   fclose(fid);

   try
      d = read_it('anytextfile.txt');
   catch exception
   end

   exception
   exception =
    MException object with properties:

       identifier: 'MATLAB:FileIO:InvalidFid'
          message: 'Invalid file identifier.  Use fopen
                    to generate a valid file identifier.'
            stack: [1x1 struct]
            cause: {[1x1 MException]}
```

```
  Cannot open file anytextfile.txt. Try another location?y
Enter folder name:  xxxxxxx
Warning: Name is nonexistent or not a directory: xxxxxxx.
> In path at 110
  In addpath at 89
```

See Also

try | catch | error | assert | MException | throw(MException) | rethrow(MException) | throwAsCaller(MException) | getReport(MException) | last(MException)

Purpose

Add event to `timeseries` object

Syntax

```
ts = addevent(ts,e)
ts = addevent(ts,Name,Time)
```

Description

`ts = addevent(ts,e)` adds one or more `tsdata.event` objects, `e`, to the `timeseries` object `ts`. `e` is either a single `tsdata.event` object or an array of `tsdata.event` objects.

`ts = addevent(ts,Name,Time)` constructs one or more `tsdata.event` objects and adds them to the `Events` property of `ts`. `Name` is a cell array of event name strings. `Time` is a cell array of event times.

Examples

Create a time-series object and add an event to this object.

```
%% Import the sample data
load count.dat

%% Create time-series object
count1=timeseries(count(:,1),1:24,'name', 'data');

%% Modify the time units to be 'hours' ('seconds' is default)
count1.TimeInfo.Units = 'hours';

%% Construct and add the first event at 8 AM
e1 = tsdata.event('AMCommute',8);

%% Specify the time units of the time
e1.Units = 'hours';
```

View the properties (`EventData`, `Name`, `Time`, `Units`, and `StartDate`) of the event object.

```
get(e1)
```

MATLAB software responds with

```
    EventData: []
```

```
         Name: 'AMCommute'
         Time: 8
        Units: 'hours'
    StartDate: ''
%% Add the event to count1
count1 = addevent(count1,e1);
```

An alternative syntax for adding two events to the time series `count1` is as follows:

```
count1 = addevent(count1,{'AMCommute' 'PMCommute'},{8 18})
```

See Also

`timeseries` | `tsdata.event`

Purpose

Information about audio file

Syntax

```
info = audioinfo(filename)
```

Description

`info = audioinfo(filename)` returns information about the contents of the audio file specified by `filename`.

Input Arguments

filename - Name of file
string

Name of file, specified as a string. If a path is specified, it can be absolute, relative, or partial.

Example: `'myFile.mp3'`

Example: `'../myFile.mp3'`

Example: `'C:\temp\myFile.mp3'`

`audioinfo` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (`.wav`)
	OGG (`.ogg`)
	FLAC (`.flac`)
	AU (`.au`)
Windows 7 (or later), Macintosh, and Linux®	MP3 (`.mp3`)
	MPEG-4 AAC (`.m4a`, `.mp4`)

On Windows 7 platforms (or later), `audioinfo` might also return information about the contents of any files supported by Windows Media® Foundation.

On Linux platforms, `audioinfo` might also return information about the contents of any files supported by GStreamer.

`audioinfo` can extract audio metadata from MPEG-4 (`.mp4`, `.m4v`) video files on Windows 7 or later, Mac OS X 10.7 Lion or higher, and Linux, and from Windows Media Video (`.wmv`) and AVI (`.avi`) files on Windows 7 (or later) and Linux platforms.

Output Arguments

info - Information about audio file

structure

Information about audio file, returned as a structure. `info` can contain the following fields.

Field Name	Description	Data Type
`Filename`	Filename including the absolute path to the file and the file extension.	`string`
`CompressionMethod`	Compression method used.	`string`
`NumChannels`	Number of audio channels encoded in	`double`
`SampleRate`	Sample rate of the audio data in the file, in hertz.	`double`
`TotalSamples`	Total number of audio samples in the file.	`double`
`Duration`	Duration of the file, in seconds.	`double`
`BitsPerSample`	Number of bits per sample encoded in the audio file. Only valid for WAVE (`.wav`) and FLAC (`.flac`) files.	`double`

Field Name	Description	Data Type
`BitRate`	Number of kilobits per second (kbit/s) used for compressed audio files. Only valid for MP3 (`.mp3`) and MPEG-4 Audio (`.m4a`, `.mp4`) files.	`double`
`Title`	Value of `'Title'`, if any.	`string`
`Artist`	Value of `'Artist'`, if any.	`string`
`Comment`	Value of `'Comment'`, if any.	`string`

Note The `BitRate` property returns the actual bit rate on Mac platforms, and not the encoded bit rate. This means that bit rate values might be lower than specified at the time of the encoding, depending on the source data.

Note On Mac platforms, `audioinfo` returns metadata from `.m4a` and `.mp4` files only on Mac OS X 10.7 Lion or higher. Previous versions of Mac OS X will not read the `'Title'`, `'Author'`, or `'Comment'` fields.

Examples

Get Information About Audio File

Create a WAVE file from the example file `handel.mat`, and get information about the file.

Create a WAVE (.wav) file in the current folder.

```
load handel.mat
filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Use `audioinfo` to return information about the WAVE file.

```
info = audioinfo(filename)
```

```
info =
             Filename: 'S:\handel.wav'
    CompressionMethod: 'Uncompressed'
          NumChannels: 1
           SampleRate: 8192
         TotalSamples: 73113
             Duration: 8.9249
                Title: []
              Comment: []
               Artist: []
        BitsPerSample: 16
```

Limitations

- For MP3 and MPEG-4 AAC audio files on Windows 7 and Linux platforms, `audioinfo` might report fewer samples than expected. On Linux platforms, this is due to a limitation in the underlying GStreamer framework.
- On Linux platforms, `audioinfo` interprets single channel data in MPEG-4 AAC files as stereo data.

See Also

`audioread` | `audiowrite`

Purpose

Read audio file

Syntax

```
[y,Fs] = audioread(filename)
[y,Fs] = audioread(filename,samples)

[y,Fs] = audioread( ___ ,dataType)
```

Description

`[y,Fs] = audioread(filename)` reads data from the file named `filename`, and returns sampled data,`y`, and a sample rate for that data, `Fs`.

`[y,Fs] = audioread(filename,samples)` reads the selected range of audio samples in the file, where `samples` is a vector of the form `[start,finish]`.

`[y,Fs] = audioread( ___ ,dataType)` returns sampled data in the data range corresponding to the `dataType` of `'native'` or `'double'`, and can include any of the input arguments in previous syntaxes.

Input Arguments

filename - Name of file to read

string

Name of file to read, specified as a string that includes the file extension. If a path is specified, it can be absolute, relative or partial.

Example: `'myFile.mp3'`

Example: `'../myFile.mp3'`

Example: `'C:\temp\myFile.mp3'`

`audioread` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
	AU (.au)
Windows 7 (or later), Macintosh, and Linux	MP3 (.mp3)
	MPEG-4 AAC (.m4a, .mp4)

On Windows 7 (or later) platforms, `audioread` might also read any files supported by Windows Media Foundation.

On Linux platforms, `audioread` might also read any files supported by GStreamer.

`audioread` can extract audio from MPEG-4 (`.mp4`, `.m4v`) video files on Windows 7 or later, Macintosh, and Linux, and from Windows Media Video (`.wmv`) and AVI (`.avi`) files on Windows 7 (or later) and Linux platforms.

samples - Audio samples to read

`[1,inf]` (default) | two-element vector of positive scalar integers

Audio samples to read, specified as a two-element vector of the form `[start,finish]`, where `start` and `finish` are the first and last samples to read, and are positive scalar integers.

- `start` must be less than or equal to `finish`.
- `start` and `finish` must be less than the number of audio samples in the file,
- You can use `inf` to indicate the last sample in the file.

Note When reading a portion of some MP3 files on Windows 7 platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying Windows Media Foundation framework.

When reading a portion of MP3 and M4A files on Linux platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying GStreamer framework.

Example: `[1,100]`

Data Types
`double`

dataType - Data format of audio data, `y`

`'double'` (default) | `'native'`

Data format of audio data,`y`, specified as one of the following strings:

`'double'`	Double-precision normalized samples.
`'native'`	Samples in the native format found in the file.

For compressed audio formats, such as MP3 and MPEG-4 AAC that do not store data in integer form, `'native'` defaults to `'single'`.

Output Arguments

y - Audio data

matrix

Audio data in the file, returned as an `m`-by-`n` matrix, where `m` is the number of audio samples read and `n` is the number of audio channels in the file.

- If you do not specify `dataType`, or `dataType` is `'double'`, then `y` is of type `double`, and matrix elements are normalized values between −1.0 and 1.0.

- If `dataType` is `'native'`, then `y` can be one of several MATLAB data types, depending on the file format and the `BitsPerSample` value of the input file. Call `audioinfo` to determine the `BitsPerSample` value of the file.

File Format	BitsPerSample	Data Type of y	Data Range of y
WAVE (`.wav`)	8	`uint8`	0 ≤ y ≤ 255
	16	`int16`	-32768 ≤ y ≤ +32767
	24	`int32`	-2^32 ≤ y ≤ 2^32–1
	32	`int32`	-2^32 ≤ y ≤ 2^32–1
	32	`single`	-1.0 ≤ y ≤ +1.0
	64	`double`	-1.0 ≤ y ≤ +1.0
FLAC (`.flac`)	8	`uint8`	0 ≤ y ≤ 255
	16	`int16`	-32768 ≤ y ≤ +32767
	24	`int32`	-2^32 ≤ y ≤ 2^32–1
MP3 (`.mp3`), MPEG-4 AAC (`.m4a`, `.mp4`), and OGG (`.ogg`)	N/A	`single`	-1.0 ≤ y ≤ +1.0

Note Where `y` is `single` or `double` and the `BitsPerSample` is 32 or 64, values in `y` might exceed −1.0 or +1.0.

Fs - Sample rate
positive scalar

Sample rate, in hertz, of audio data `y`, returned as a positive scalar.

Examples

Read Complete Audio File

Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.

Create a WAVE (`.wav`) file in the current folder.

```
load handel.mat

filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread('handel.wav');
```

Play the audio.

```
sound(y,Fs);
```

Read Portion of Audio File

Create a FLAC file from the example file `handel.mat`, and then read only the first 2 seconds.

Create a FLAC (`.flac`) file in the current folder.

```
load handel.mat
```

```
filename = 'handel.flac';
audiowrite(filename,y,Fs);
```

Read only the first 2 seconds.

```
samples = [1,2*Fs];
clear y Fs
[y,Fs] = audioread(filename,samples);
```

Play the samples.

```
sound(y,Fs);
```

Return Audio in Native Integer Format

Create a FLAC file and read the first 2 seconds according to the previous Example. Then, view the data type of the sampled data `y`.

```
whos y
```

```
  Name           Size                Bytes  Class     Attributes

  y          16384x1                131072  double
```

The data type of `y` is `double`.

Request audio data in the native format of the file, and then view the data type of the sampled data `y`.

```
[y,Fs] = audioread(filename,'native');
whos y
```

```
  Name           Size               Bytes  Class    Attributes
```

```
  y          16384x1              32768  int16
```

The data type of `y` is now `int16`.

Limitations

- For MP3 and MPEG-4 AAC audio files on Windows 7 and Linux platforms, `audioread` might read fewer samples than expected. On Windows 7 platforms, this is due to a limitation in the underlying Media Foundation framework. On Linux platforms, this is due to a limitation in the underlying GStreamer framework. If you require sample-accurate reading, work with WAV or FLAC files.
- On Linux platforms, `audioread` reads MPEG-4 AAC files that contain single-channel data as stereo data.

See Also

`audiowrite` | `audioinfo`

audiowrite

Purpose

Write audio file

Syntax

```
audiowrite(filename,y,Fs)
audiowrite(filename,y,Fs,Name,Value)
```

Description

`audiowrite(filename,y,Fs)` writes a matrix of audio data, `y`, with sample rate `Fs` to a file called `filename`. The output data type depends on the output file format and the data type of the audio data, `y`.

`audiowrite(filename,y,Fs,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

filename - Name of file to write

string

Name of file to write, or the full path to the file, specified as a string that includes the file extension. If a path is specified, it can be absolute or relative. If you do not specify the path, then the destination directory is the current working directory.

`audiowrite` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (`.wav`)
	OGG (`.ogg`)
	FLAC (`.flac`)
Windows and Mac	MPEG-4 AAC (`.m4a`, `.mp4`)

Example: `'myFile.m4a'`

Example: `'../myFile.m4a'`

Example: `'C:\temp\myFile.m4a'`

When writing AAC files on Windows, `audiowrite` pads the front and back of the output signal with extra samples of silence. The Windows AAC encoder also places a very sharp fade-in and fade-out on the audio.

This results in audio with an increased number of samples after being written to disk.

y - Audio data to write

matrix

Audio data to write, specified as an m-by-n matrix, where m is the number of audio samples to write and n is the number of audio channels to write.

If either m or n is 1, then audiowrite assumes that this dimension specifies the number of audio channels, and the other dimension specifies the number of audio samples.

The maximum number of channels depends on the file format.

File Format	Maximum Number of Channels
WAVE (.wav)	256
OGG (.ogg)	255
FLAC (.flac)	8
MPEG-4 AAC (.m4a, .mp4)	2

The valid range for the data in y depends on the data type of y.

Data Type of y	Valid Range for y
uint8	0 ≤ y ≤ 255
int16	-32768 ≤ y ≤ +32767
int32	-2^32 ≤ y ≤ 2^32–1
single	-1.0 ≤ y ≤ +1.0
double	-1.0 ≤ y ≤ +1.0

Data beyond the valid range is clipped.

If y is single or double, then audio data in y should be normalized to values in the range −1.0 and 1.0, inclusive.

Data Types
`single` | `double` | `int16` | `int32` | `uint8`

`Fs` - Sample rate

positive scalar

Sample rate, in hertz, of audio data `y`, specified as a positive scalar greater than 0. Values of `Fs` are truncated to integer boundaries. When writing to `.m4a` or `.mp4` files on Windows platforms, `audiowrite` supports only samples rates of 44100 and 48000.

Example: `44100`

Data Types
`double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Title','Symphony No.  9','Artist','My Orchestra'` instructs `audiowrite` to write an audio file with the title “Symphony No. 9” and the artist information “My Orchestra.”

'BitsPerSample' - Number of output bits per sample

16 (default) | 8 | 24 | 32 | 64

Number of output bits per sample, specified as the comma-separated pair consisting of `'BitsPerSample'` and a number.

Only available for WAVE (`.wav`) and FLAC (`.flac`) files. For FLAC files, only 8, 16, or 24 bits per sample are supported.

Example: `'BitsPerSample',32`

Data Types
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

'BitRate' - Kilobits per second (kbit/s)

128 (default) | 64 | 96 | 160 | 192 | 256 | 320

Number of kilobits per second (kbit/s) used for compressed audio files, specified as the comma-separated pair consisting of `'BitRate'` and an integer. Noninteger values are truncated. On Windows 7 platforms, the only valid values are 96, 128, 160, and 192.

In general, a larger `BitRate` value results in higher compression quality.

Only available for MPEG-4 (`.m4a`, `.mp4`) files.

Example: `'BitRate',96`

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

'Quality' - Quality setting for the Ogg Vorbis Compressor

75 (default) | value in the range [0 100]

Quality setting for the Ogg Vorbis Compressor, specified as the comma-separated pair consisting of `'Quality'` and a number in the range [0 100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression.

Only available for OGG (`.ogg`) files.

Example: `'Quality',25`

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

'Title' - Title information

`[]` (default) | string

Title information, specified as the comma-separated pair consisting of `'Title'` and a string.

'Artist' - Artist information

`[]` (default) | string

Artist information, specified as the comma-separated pair consisting of `'Artist'` and a string.

'Comment' - Additional information
`[]` (default) | string

Additional information, specified as the comma-separated pair consisting of `'Comment'` and a string.

Note On Mac platforms, `audiowrite` writes metadata to WAVE, OGG, and FLAC files only, and will not write the `'Title'`, `'Author'`, or `'Comment'` fields to MPEG-4 AAC files.

Examples

Write an Audio File

Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.

Write a WAVE (`.wav`) file in the current folder.

```
load handel.mat

filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread(filename);
```

Listen to the audio.

```
sound(y,Fs);
```

Specify Bits Per Sample and Metadata

Create a FLAC file from the example file `handel.mat` and specify the number of output bits per sample and a comment.

```
load handel.mat

filename = 'handel.flac';
audiowrite(filename,y,Fs,'BitsPerSample',24,'Comment','This is my new
clear y Fs
```

View information about the new FLAC file.

```
info = audioinfo(filename)
```

```
info =

             Filename: 'S:\handel.flac'
    CompressionMethod: 'FLAC'
          NumChannels: 1
           SampleRate: 8192
         TotalSamples: 73113
             Duration: 8.9249
                Title: []
              Comment: 'This is my new audio file.'
               Artist: []
        BitsPerSample: 24
```

Algorithms

The output data type is determined by the file format, the data type of `y`, and the specified output `BitsPerSample`.

File Formats	Data Type of y	Output BitsPerSample	Output Data Type
WAVE (.wav),	uint8, int16, int32, single, double	8	uint8
		16	int16
		24	int32
	uint8, int16, int32	32	int32
	single, double	32	single
	single, double	64	double
FLAC (.flac)	uint8, int16, int32, single, double	8	int8
		16	int16
		24	int32
MPEG-4 (.m4a, .mp4), OGG (.ogg)	uint8, int16, int32, single, double	N/A	single

audioinfo | audioread

Purpose

Add frame to Audio/Video Interleaved (AVI) file

Syntax

```
aviobj = addframe(aviobj,frame)
aviobj = addframe(aviobj,frame1,frame2,frame3,...)
aviobj = addframe(aviobj,mov)
aviobj = addframe(aviobj,h)
```

Description

`aviobj = addframe(aviobj,frame)` appends the data in `frame` to the AVI file identified by `aviobj`, which was created by a previous call to `avifile`. `frame` can be either an indexed image (m-by-n) or a truecolor image (m-by-n-by-3) of `double` or `uint8` precision. If `frame` is not the first frame added to the AVI file, it must be consistent with the dimensions of the previous frames.

`addframe` returns a handle to the updated AVI file object, `aviobj`. For example, `addframe` updates the `TotalFrames` property of the AVI file object each time it adds a frame to the AVI file.

`aviobj = addframe(aviobj,frame1,frame2,frame3,...)` adds multiple frames to an AVI file.

`aviobj = addframe(aviobj,mov)` appends the frames contained in the MATLAB movie `mov` to the AVI file `aviobj`. MATLAB movies that store frames as indexed images use the colormap in the first frame as the colormap for the AVI file, unless the colormap has been previously set.

`aviobj = addframe(aviobj,h)` captures a frame from the figure or axis handle `h` and appends this frame to the AVI file. `addframe` renders the figure into an offscreen array before appending it to the AVI file. This ensures that the figure is written correctly to the AVI file even if the figure is obscured on the screen by another window or screen saver.

Tips

- `avifile` cannot write files larger than 2 GB. Use `VideoWriter` and `writeVideo` to create larger files.
- If you are creating an animation from a figure with an `EraseMode` property set to `'xor'`, you must use `getframe` to capture the graphics into a frame of a MATLAB movie. Add the frame to the AVI file using

the syntax *aviobj* = addframe(*aviobj*,*mov*). See the example for an illustration.

Examples

This example calls addframe to add frames to the AVI file object aviobj.

```
aviobj = avifile('example.avi','compression','None');

t = linspace(0,2.5*pi,40);
fact = 10*sin(t);
fig=figure;
[x,y,z] = peaks;
for k=1:length(fact)
    h = surf(x,y,fact(k)*z);
    axis([-3 3 -3 3 -80 80])
    axis off
    caxis([-90 90])

    F = getframe(fig);
    aviobj = addframe(aviobj,F);
end
close(fig);
aviobj = close(aviobj);
```

VideoWriter | avifile | close (avifile) | movie2avi

Purpose

Create event listener

Syntax

```
lh = addlistener(Hsource,'EventName',callback)
lh = addlistener(Hsource,property,'EventName',callback)
```

Description

`lh = addlistener(Hsource,'EventName',callback)` creates a listener for the specified event.

`lh = addlistener(Hsource,property,'EventName',callback)` creates a listener for one of the predefined property events. There are four property events:

- `PreSet` — triggered just before the property value is set, before calling its set access method.
- `PostSet` — triggered just after the property value is set.
- `PreGet` — triggered just before a property value query is serviced, before calling its get access method.
- `PostGet` — triggered just after returning the property value to the query

See "Events and Listeners — Syntax and Techniques" for more information.

Input Arguments

`Hsource`
: Handle of the object that is the source of the event, or an array of source handles.

`EventName`
: Name of the event, which is triggered by the source objects.

`callback`
: Function handle referencing a function to execute when the event is triggered.

`property`
: Character string that can be:

  - the name of the property

- a cell array of strings where each string is the name of a property that exists in object array `Hsource`
- a `meta.property` object or an array of `meta.property` objects
- a cell array of `meta.property` objects

If `Hsource` is a scalar, then any of the properties can be dynamic properties. If `Hsource` is non-scalar, then the properties must belong to the class of `Hsource` and can not include dynamic properties (which are not part of the class definition).

For more information, see the following sections:

- The `GetObservable` and `SetObservable` property attributes in the "Property Attributes" table.
- "Creating Property Listeners"
- "Dynamic Properties — Adding Properties to an Instance"

Output Arguments

`lh`

Handle of the `event.listener` object returned by `addlistener`.

Removing a Listener

To remove a listener, delete the listener object returned by `addlistener`. For example,

```
delete(lh)
```

calls the handle class delete method to delete the object from the workspace and remove the listener.

When you use `addlistener` to create a listener, redefining the variable containing the handle to the listener does not delete the listener because the event object still has a reference to the `event.listener` object. `addlistener` ties the listener's lifecycle to the object that is the source of the event. If you want to define a listener that is not tied to the event object, use the `event.listener` constructor directly to create the listener.

See Also

`delete (handle)` | `handle` | `notify (handle)`

How To

- "Limiting Listener Scope — Constructing event.listener Objects Directly"

inputParser.addOptional

Purpose

Add optional argument to Input Parser scheme

Syntax

```
addOptional(p,argName,default)
addOptional(p,argName,default,validationFcn)
```

Description

`addOptional(p,argName,default)` adds optional input `argName` to the input scheme of `inputParser` object `p`. When the inputs that you are checking do not include a value for this optional input, the parser assigns the `default` value to the input.

`addOptional(p,argName,default,validationFcn)` specifies a validation function for the input argument.

Tips

- For optional string inputs, specify a validation function. Without a validation function, the parser interprets valid string inputs as invalid parameter names and throws an error.

Input Arguments

p

Object of class `inputParser`.

argName

String that specifies the internal name for the input argument.

Arguments added with `addOptional` are positional. When you call a function with positional inputs:

- You must specify inputs in the order that they are added to the input parser scheme.
- If you want to specify a value for the `k`th argument, you must also specify values for the first `(k 1)` arguments in the input scheme.

default

Default value for the input. This value can be of any data type.

validationFcn

Handle to a function that checks whether the input argument is of the expected type and value.

Validation functions must accept a single input argument, and they must either return a scalar logical value (`true` or `false`) or an error. If the validation function returns `false` or errors, then parsing fails and the parser throws an error.

Examples

Add Optional Input

Create an `inputParser` object and add an optional input named `myinput` with a default value of `0` to the input scheme.

```
p = inputParser;
argName = 'myinput';
default = 0;
addOptional(p,argName,default);
```

Validate Optional Input

Check whether an optional input named `num` with a default value of `1` is a numeric scalar greater than zero.

```
p = inputParser;
argName = 'num';
default = 1;
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);
addOptional(p,argName,default,validationFcn);
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as `-1`:

```
parse(p,-1)
```

```
Argument 'num' failed validation @(x)isnumeric(x)&&isscalar(x)&&(x>0).
```

See Also

`addParamValue` | `addRequired` | `inputParser` | `function_handle`

Concepts

- “Anonymous Functions”

Purpose

Add parameter name and value argument to Input Parser scheme

Syntax

```
addParamValue(p,paramName,default)
addParamValue(p,paramName,default,validationFcn)
```

Description

`addParamValue(p,paramName,default)` adds parameter name and value argument `paramName` to the input scheme of `inputParser` object `p`. When the inputs that you are checking do not include a value for this optional parameter, the parser assigns the `default` value.

`addParamValue(p,paramName,default,validationFcn)` specifies a validation function for the input argument.

Tips

- If your parameter values do not require validation, you do not have to include them in the input scheme with `addParamValue`. As an alternative, set the `KeepUnmatched` property of the `inputParser` object to `true`. The parser stores extra parameter names and values in the `Unmatched` property rather than in the `Results` property of the object. For an example, see the `inputParser` reference page.

Input Arguments

p

Object of class `inputParser`.

paramName

String that specifies the internal name for the input parameter.

Parameter names and values are optional inputs. When calling the function, name and value pairs can appear in any order, with the general form `Name1,Value1,...,NameN,ValueN`.

default

Default value for the input. This value can be of any data type.

validationFcn

Handle to a function that checks whether the input argument is of the expected type and value.

Validation functions must accept a single input argument, and they must either return a scalar logical value (`true` or `false`) or an error. If the validation function returns `false` or errors, then parsing fails and the parser throws an error.

Examples

Add Optional Parameter Value Input

Create an `inputParser` object and add an optional input named `myparam` with a default value of `0` to the input scheme.

```
p = inputParser;
paramName = 'myparam';
default = 0;
addParamValue(p,paramName,default);
```

Unlike the positional inputs added with the `addRequired` and `addOptional` methods, each parameter added with `addParamValue` corresponds to two input arguments: one for the name and one for the value of the parameter.

Pass both the parameter name and value to the `parse` method.

```
parse(p,'myparam',100);
p.Results
```

```
ans =
    myparam: 100
```

Validate Parameter Value

Check whether the value corresponding to `myparam` is a numeric scalar greater than zero.

```
p = inputParser;
paramName = 'myparam';
default = 1;
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);
addParamValue(p,paramName,default,validationFcn);
```

The syntax @(x) creates a handle to an anonymous function with one input.

Attempt to parse an invalid value, such as -1:

```
parse(p,'myparam',-1)
```

```
Argument 'myparam' failed validation @(x)isnumeric(x)&&isscalar(x)&&(x
```

See Also

addOptional | addRequired | inputParser | function_handle

Concepts

- “Anonymous Functions”

addpath

Purpose

Add folders to search path

Syntax

```
addpath(folderName1,...,folderNameN)
addpath(folderName1,...,folderNameN,position)

addpath( ___ ,'-frozen')

oldpath = addpath( ___ )
```

Description

`addpath(folderName1,...,folderNameN)` adds the specified folders to the top of the search path. Use `addpath` statements in a `startup.m` file to modify the search path programmatically at startup.

`addpath(folderName1,...,folderNameN,position)` adds the specified folders to the top or bottom of the search path, as specified by `position`.

`addpath( ___ ,'-frozen')` additionally disables folder change detection on Windows for folders being added, which conserves Windows change notification resources (Windows only). Type `help changenotification` in the Command Window for more information.

Add `'-frozen'` to the input arguments in any of the previous syntaxes. You can specify `'-frozen'` and `position` in either order.

`oldpath = addpath( ___ )` additionally returns the path prior to adding the specified folders.

Input Arguments

folderName1,...,folderNameN - Names of folders to add to search path

string

Names of folders to add to the search path, specified as strings. Use the full path name for each folder. Use `genpath` with `addpath` to add all subfolders of `folderName`.

Example: `'c:\matlab\work'`

Example: `'/home/user/matlab'`

Example: `'/home/user/matlab','/home/user/matlab/test'`

position - Position on the search path
`'-begin'` (default) | `'-end'`

Position on the search path, specified as one of the following strings.

Value of `position`	Description
`'-begin'`	Add specified folders to the top of the search path.
`'-end'`	Add specified folders to the bottom of the search path.

Output Arguments

oldpath - Path prior to addition of folders
string

Path prior to the addition of folders, returned as a string.

Examples

Add Folder to Top of Search Path

If you do not have a folder called `c:/matlab/myfiles`, create the folder.

```
mkdir('c:/matlab/myfiles')
```

Add `c:/matlab/myfiles` to the top of the search path.

```
addpath('c:/matlab/myfiles')
```

Add Folder to End of Search Path

Add `c:/matlab/myfiles` to the end of the search path.

```
addpath('c:/matlab/myfiles','-end')
```

Add Folder and Its Subfolders to Search Path

Add `c:/matlab/myfiles` and its subfolders to the search path.

Call `genpath` inside of `addpath` to add all subfolders of `c:/matlab/myfiles` to the search path.

```
addpath(genpath('c:/matlab/myfiles'))
```

Add Folder to Search Path and Disable Folder Change Notification

On Windows, add the folder `c:/matlab/myfiles` to the top of the search path, disable folder change notification, and return the search path before adding the folder.

```
oldpath = addpath('c:/matlab/myfiles','-frozen');
```

Tips

- If you use `addpath` within a local function, the path change persists after program control returns from the function. That is, the scope of the path change is global.

`genpath` | `path` | `pathsep` | `rmpath` | `savepath`

Concepts

- "What Is the MATLAB Search Path?"
- "Files and Folders that MATLAB Accesses"
- "Path Names in MATLAB"
- "Specifying Startup Options in the MATLAB Startup File"

Purpose

Add preference

Syntax

```
addpref('group','pref',val)
addpref('group',{'pref1','pref2',...'prefn'},{val1,val2,
   ...valn})
```

Description

`addpref('group','pref',val)` creates the preference specified by `group` and `pref` and sets its value to `val`. It is an error to add a preference that already exists. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. `'ApplicationOnePrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`addpref('group',{'pref1','pref2',...'prefn'},{val1,val2,...valn})` creates the preferences specified by the cell array of names `'pref1'`, `'pref2',...,'prefn'`, setting each to the corresponding value.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

Add a preference called `version` to the `mytoolbox` group of preferences, setting its value to the cell array `{'1.0','beta'}`.

```
addpref('mytoolbox','version',{'1.0','beta'})
```

Add a preference called `documentation` to the `mytoolbox` group of preferences, setting its value to a struct you define as having four fields:

```
mydoc.docexists = 1;
mydoc.docpath = fullfile(docroot,'techdoc',...
```

```
   'matlab_env','examples');
mydoc.demoexists = 1;
mydoc.demopath = fullfile(docroot,'techdoc',...
   'matlab_env','examples','demo_examples');
addpref('mytoolbox','documentation',mydoc)
% Retrieve the preference with GETPREF
p = getpref('mytoolbox','documentation')

p =
     docexists: 1
       docpath: [1x109 char]
    demoexists: 1
      demopath: [1x123 char]
```

getpref | ispref | rmpref | setpref | uigetpref | uisetpref

Purpose

Add dynamic property

Syntax

`P = addprop(Hobj,'PropName')`

Description

`P = addprop(Hobj,'PropName')` adds a property named `PropName` to each object in array `Hobj`. The class definition is not affected by the addition of dynamic properties. Note that you can add dynamic properties only to objects derived from the `dynamicprops` class. You can set and retrieve the data in dynamic properties as you would any property.

The output argument `P` is an array the same size as `Hobj` of `meta.DynamicProperty` objects, which you can use to assign `SetMethod` and `GetMethod` functions to the property. These functions operate just like property set and get access methods.

See "Dynamic Properties — Adding Properties to an Instance" for more information and examples.

See Also

`handle` | `dynamicprops`

addproperty

Purpose

Add custom property to COM object

Syntax

```
h.addproperty('propertyname')
addproperty(h,'propertyname')
```

Description

`h.addproperty('propertyname')` adds the custom property specified in the string `propertyname` to the object or interface `h`. Use the COM `set` function to assign a value to the property.

`addproperty(h,'propertyname')` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

Examples

Add a custom property to an instance of the MATLAB sample control:

1 Create an instance of the control:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.get
```

MATLAB displays its properties:

```
     Label: 'Label'
    Radius: 20
```

2 Add a custom property named `Position` and assign a value:

```
h.addproperty('Position');
h.Position = [200 120];
h.get
```

MATLAB displays (in part):

```
       Label: 'Label'
      Radius: 20
    Position: [200 120]
```

3 Delete the custom property `Position`:

```
h.deleteproperty('Position');
h.get
```

MATLAB displays the original list of properties:

```
  Label: 'Label'
 Radius: 20
```

See Also

deleteproperty | get (COM) | set (COM) | inspect

How To

- "Use Object Properties"

inputParser.addRequired

Purpose

Add required argument to Input Parser scheme

Syntax

```
addRequired(p,argName)
addRequired(p,argName,validationFcn)
```

Description

`addRequired(p,argName)` adds required argument `argName` to the input scheme of `inputParser` object `p`.

`addRequired(p,argName,validationFcn)` includes a validation function for the input argument.

Input Arguments

p

Object of class `inputParser`.

argName

String that specifies the internal name for the input argument.

Arguments added with `addRequired` are positional. When you call a function with positional inputs, you must specify inputs in the order that they are added to the input parser scheme.

validationFcn

Handle to a function that checks whether the input argument is of the expected type and value.

Validation functions must accept a single input argument, and they must either return a scalar logical value (`true` or `false`) or an error. If the validation function returns `false` or errors, then parsing fails and the parser throws an error.

Examples

Add Required Input

Create an `inputParser` object and add a required input named `myinput` to the input scheme.

```
p = inputParser;
argName = 'myinput';
addRequired(p,argName);
```

Validate Required Input

Check whether a required input named `num` is a numeric scalar greater than zero.

```
p = inputParser;
argName = 'num';
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);
addRequired(p,argName,validationFcn);
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as `-1`:

```
parse(p,-1)
```

```
Argument 'num' failed validation @(x)isnumeric(x)&isscalar(x)&&(x>0).
```

Concepts

- "Anonymous Functions"

addsampletocollection

Purpose

Add sample to `tscollection` object

Syntax

```
tsc = addsampletocollection(tsc,'time',Time,TS1Name,TS1Data,
   TSnName,TSnData)
```

Description

`tsc = addsampletocollection(tsc,'time',Time,TS1Name,TS1Data, TSnName,TSnData)` adds data samples `TSnData` to the collection member `TSnName` in the `tscollection` object `tsc` at one or more `Time` values. Here, `TSnName` is the string that represents the name of a time series in `tsc`, and `TSnData` is an array containing data samples.

Tips

If you do not specify data samples for a time-series member in tsc, that time-series member will contain missing data at the times given by Time (for numerical time-series data), `NaN` values, or (for logical time-series data) `false` values.

When a time-series member requires `Quality` values, you can specify data quality codes together with the data samples by using the following syntax:

```
tsc = addsampletocollection(tsc,'time',time,TS1Name,...
         ts1cellarray,TS2Name,ts2cellarray,...)
```

Specify data in the first cell array element and `Quality` in the second cell array element.

Note If a time-series member already has `Quality` values but you only provide data samples, `0`s are added to the existing `Quality` array at the times given by `Time`.

Examples

The following example shows how to create a `tscollection` that consists of two `timeseries` objects, where one `timeseries` does not have quality codes and the other does. The final step of the example adds a sample to the `tscollection`.

1 Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...
                 'name','acceleration');
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...
                 'name','speed');
```

2 Define a dictionary of quality codes and descriptions for `ts2`.

```
ts2.QualityInfo.Code = [0 1];
ts2.QualityInfo.Description = {'bad','good'};
```

3 Assign a quality of code of `1`, which is equivalent to `'good'`, to each data value in `ts2`.

```
ts2.Quality = ones(5,1);
```

4 Create a time-series collection `tsc`, which includes time series `ts1` and `ts2`.

```
tsc = tscollection({ts1,ts2});
```

5 Add a data sample to the collection `tsc` at `3.5` seconds.

```
tsc = addsampletocollection(tsc,'time',3.5,'acceleration',10,'speed',{5 1});
```

The cell array for the `timeseries` object `'speed'` specifies both the data value 5 and the quality code `1`.

Note If you do not specify a quality code when adding a data sample to a time series that has quality codes, then the lowest quality code is assigned to the new sample by default.

`delsamplefromcollection` | `timeseries` | `tscollection`

Purpose Modify date number by field

Syntax

```
R = addtodate(D, Q, F)
```

Description `R = addtodate(D, Q, F)` adds quantity `Q` to the indicated date field `F` of a scalar serial date number `D`, returning the updated date number `R`.

The quantity `Q` to be added can be a positive or negative integer. The absolute value of `Q` must be less than or equal to 1e16. The date field `F` must be a 1-by-`N` character array equal to one of the following: `'year'`, `'month'`, `'day'`, `'hour'`, `'minute'`, `'second'`, or `'millisecond'`.

If the addition to the date field causes the field to roll over, the MATLAB software adjusts the next more significant fields accordingly. Adding a negative quantity to the indicated date field rolls back the calendar on the indicated field. If the addition causes the field to roll back, MATLAB adjusts the next less significant fields accordingly.

Examples Modify the hours, days, and minutes of a given date:

```
t = datenum('07-Apr-2008 23:00:00');
datestr(t)
ans =
   07-Apr-2008 23:00:00

t= addtodate(t, 2, 'hour');
datestr(t)
ans =
   08-Apr-2008 01:00:00

t= addtodate(t, -7, 'day');
datestr(t)
ans =
   01-Apr-2008 01:00:00

t= addtodate(t, 59, 'minute');
datestr(t)
ans =
```

```
   01-Apr-2008 01:59:00
```

Adding 20 days to the given date in late December causes the calendar to roll over to January of the next year:

```
R = addtodate(datenum('12/24/2007 12:45'), 20, 'day');

datestr(R)
ans =
   13-Jan-2008 12:45:00
```

date | datenum | datestr | datevec

addts

Purpose

Add timeseries object to tscollection object

Syntax

```
tsc = addts(tsc,ts)
tsc = addts(tsc,ts)
tsc = addts(tsc,ts,Name)
tsc = addts(tsc,Data,Name)
```

Description

`tsc = addts(tsc,ts)` adds the `timeseries` object ts to `tscollection` object tsc.

`tsc = addts(tsc,ts)` adds a cell array of `timeseries` objects ts to the `tscollection` tsc.

`tsc = addts(tsc,ts,Name)` adds a cell array of `timeseries` objects ts to `tscollection` tsc. Name is a cell array of strings that gives the names of the `timeseries` objects in `ts`.

`tsc = addts(tsc,Data,Name)` creates a new `timeseries` object from Data with the name Name and adds it to the `tscollection` object tsc. Data is a numerical array and Name is a string.

Tips

The `timeseries` objects you add to the collection must have the same time vector as the collection. That is, the time vectors must have the same time values and units.

Suppose that the time vector of a `timeseries` object is associated with calendar dates. When you add this `timeseries` to a collection with a time vector without calendar dates, the time vectors are compared based on the units and the values relative to the `StartDate` property. For more information about properties, see the `timeseries` reference page.

Examples

The following example shows how to add a time series to a time-series collection:

1. Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...
                 'name','acceleration');
```

```
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...
                 'name','speed');
```

2. Create a time-series collection `tsc`, which includes `ts1`.

```
tsc = tscollection(ts1);
```

3. Add `ts2` to the `tsc` collection.

```
tsc = addts(tsc, ts2);
```

4. To view the members of `tsc`, type

```
tsc
```

at the MATLAB prompt. the response is

```
Time Series Collection Object: unnamed

Time vector characteristics

      Start time            1 seconds
      End time              5 seconds

Member Time Series Objects:

      acceleration
      speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of the `timeseries` objects `ts1` and `ts2`, respectively.

`removets` | `tscollection`

Purpose

Airy Functions

Compatibility

The behavior of `airy` has changed in the following ways:

- `airy` no longer supports the syntax `[W,ierr] = airy(k,Z)`.
- `airy` no longer accepts `k` and `Z` passed as a combination of row and column vectors.
- `airy` no longer accepts `k` and `Z` passed as a combination of nonscalar and empty inputs.

For more information, see "Functionality being removed or changed".

Syntax

```
W = airy(Z)
W = airy(k,Z)
W = airy(k,Z,scale)

[W,ierr] = airy(k,Z)
```

Description

`W = airy(Z)` returns the Airy function, $Ai(Z)$, for each element of Z.

`W = airy(k,Z)` returns any of four different Airy functions, depending on the value of `k`, such as the Airy function of the second kind or the first derivative of an Airy function.

`W = airy(k,Z,scale)` scales the resulting Airy function. `airy` applies a specific scaling function to `W` depending on your choice of `k` and `scale`.

`[W,ierr] = airy(k,Z)` returns the Airy function and the completion flags in an array the same size as `W`.

Input Arguments

Z - System variable

vector | matrix | N-D Array

System variable, specified as a real or complex vector, matrix, or N-D array.

Data Types
`single | double`
Complex Number Support: Yes

k - Type of Airy function

0 (default) | 1 | 2 | 3

Type of Airy function, specified as one of four values.

k	Returns
0	Airy function, $Ai(Z)$, which is the same as `airy(Z)`.
1	First derivative of Airy function, $Ai'(Z)$.
2	Airy function of the second kind, $Bi(Z)$
3	First derivative of Airy function of the second kind, $Bi'(Z)$

Data Types
`single | double`

scale - Scaling option

0 (default) | 1

Scaling option, specified as `0` or `1`. Use `scale = 1` to enable the scaling of `Z`. The values you specify for `k` and `scale` determine the scaling function `airy` applies to `Z`.

scale	k	Scaling applied to output
0	Any	None
1	0 or 1	$e^{\frac{2}{3}Z^{(3/2)}}$
1	2 or 3	$e^{-\left\|\frac{2}{3}Re\left(Z^{(3/2)}\right)\right\|}$

Data Types
`single` | `double`

Output Arguments

W - Airy function of `Z`
vector | matrix | N-D Array

Airy function of `Z`, returned as an array the same size as `Z`.

ierr - Completion flags
vector | matrix | N-D Array

Completion flags, returned as a vector, matrix, or N-D array the same size as `Z`. The elements of `ierr` are assigned values between `0` and `5`, representing successful completion or an error state.

Flag Value	Description
0	`airy` successfully computed the Airy function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.

Flag Value	Description
4	Unacceptable loss of accuracy, `Z` too large.
5	No convergence. Returns `NaN`.

The `airy` function no longer supports `ierr`.

Definitions

Airy Functions

The Airy functions form a pair of linearly independent solutions to

$$\frac{d^2W}{dZ^2} - ZW = 0.$$

The relationship between the Airy and modified Bessel functions is

$$Ai(Z) = \left[\frac{1}{\pi}\sqrt{\frac{Z}{3}}\right]K_{1/3}(\zeta)$$

$$Bi(Z) = \sqrt{\frac{Z}{3}}\left[I_{-1/3}(\zeta) + I_{1/3}(\zeta)\right],$$

where

$$\zeta = \frac{2}{3}Z^{3/2}.$$

Examples

Airy Function of Real-Valued *x*

Define x.

```
x = -10:0.01:1;
```

Calculate $Ai(x)$.

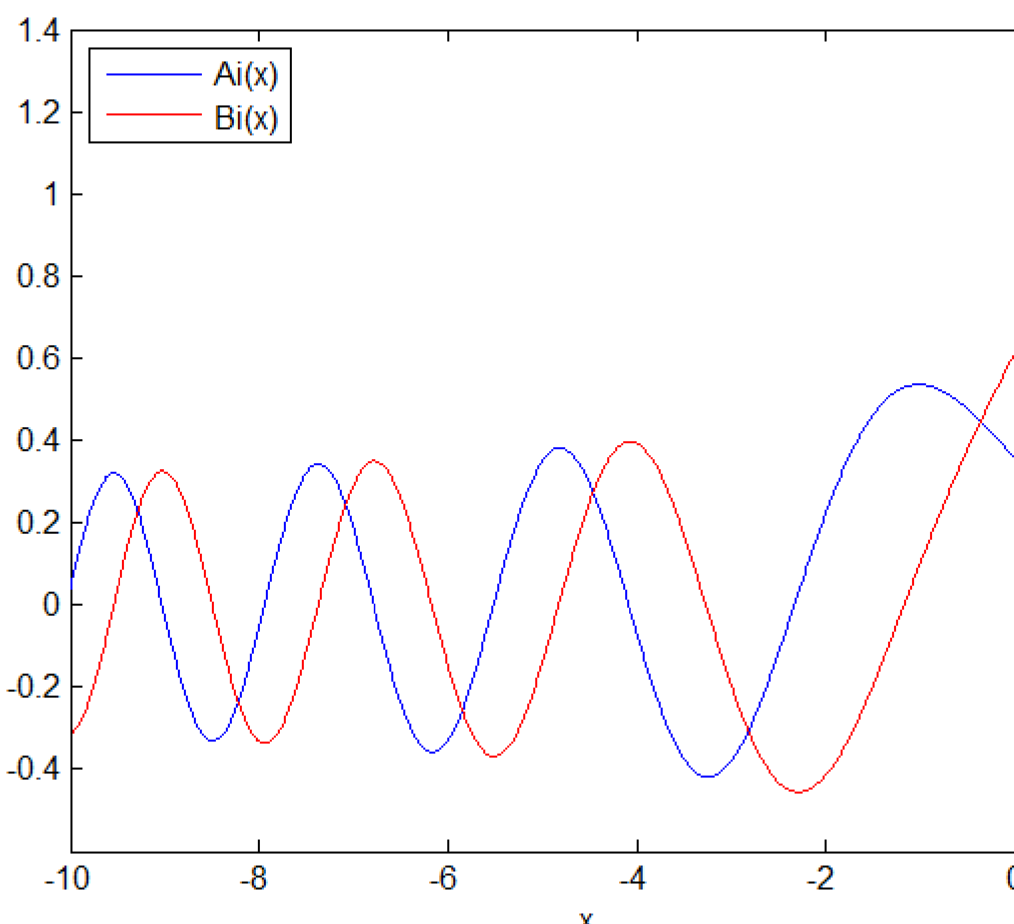
```
ai = airy(x);
```

Calculate $Bi(x)$ using `k = 2`.

```
bi = airy(2,x);
```

Plot both results together on the same axes.

```
figure
plot(x,ai,'-b',x,bi,'-r');
axis([-10 1 -0.6 1.4]);
xlabel('x');
legend('Ai(x)','Bi(x)','Location','NorthWest');
```



Airy Function of Complex-Valued Input

Compute the Airy function at a slice though the complex plane at $x+i$.

Take a slice through the complex plane.

```
x = -4:0.1:4;
```

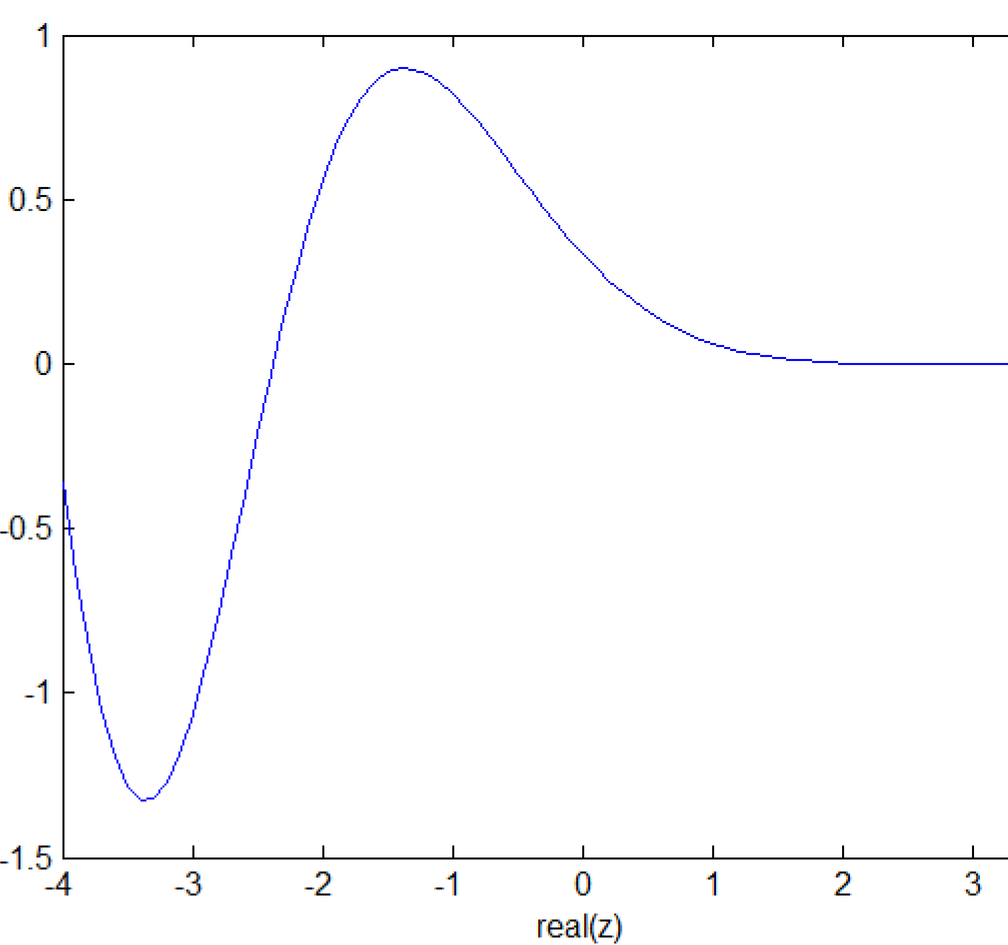
```
z = x+1i;
```

Calculate $Ai(z)$.

```
w = airy(z);
```

Plot the real part of the result.

```
figure
plot(x, real(w));
axis([-4 4 -1.5 1]);
xlabel('real(z)');
```



Scaled Airy Function

Define x.

```
x = -10:0.01:1;
```

Calculate the scaled and unscaled Airy function.

```
scaledAi = airy(0,x,1);
noscaleAi =  airy(0,x,0);
```

Plot the real part of each result.

```
rscaled = real(scaledAi);
rnoscale = real(noscaleAi);
figure
plot(x,rscaled,'-b',x,rnoscale,'-r');
axis([-10 1 -0.60 0.60]);
xlabel('x');
legend('scaled','not scaled','Location','SouthEast');
```

align

Purpose

Align user interface controls (`uicontrols`) and axes

Syntax

```
align(HandleList,'HorizontalAlignment','VerticalAlignment')
Positions = align(HandleList, 'HorizontalAlignment',
   'VerticalAlignment')
Positions = align(CurPositions, 'HorizontalAlignment',
   'VerticalAlignment')
```

Description

`align(HandleList,'HorizontalAlignment','VerticalAlignment')` aligns the `uicontrol` and `axes` objects in `HandleList`, a vector of handles, according to the options `HorizontalAlignment` and `VerticalAlignment`. The following tables show the possible values for `HorizontalAlignment` and `VerticalAlignment`.

HorizontalAlignment	Definition
None	No horizontal alignment
Left	Shifts the objects' left edges to that of the first object selected
Center	Shifts objects to center their positions to the average of the extreme *x*-values of the group
Right	Shifts the objects' right edges to that of the first object selected
Distribute	Equalizes *x*-distances between all objects within the span of the extreme *x*-values
Fixed	Spaces objects to have a specified number of points between them in the *y*-direction

VerticalAlignment	Definition
None	No vertical alignment
Top	Shifts the objects' top edges to that of the first object selected

VerticalAlignment	Definition
Middle	Shifts objects to center their positions to the average of the extreme *y*-values of the group
Bottom	Shifts the objects' bottom edges to that of the first object selected
Distribute	Equalizes *y*-distances between all objects within the span of the extreme *y*-values
Fixed	Spaces objects to have a specified number of points between them in the *x*-direction

Aligning objects does not change their absolute sizes. All alignment options align the objects within the bounding box that encloses the objects. `Distribute` and `Fixed` align objects to the bottom left of the bounding box. `Distribute` evenly distributes the objects while `Fixed` distributes the objects with a fixed distance (in points) between them. When you specify both horizontal and vertical distance together, the keywords `'HorizontalAlignment'` and `'VerticalAlignment'` are not necessary.

If you use `Fixed` for `HorizontalAlignment` or `VerticalAlignment`, you must also specify the distance, in points, where 72 points equals 1 inch. For example:

```
align(HandleList,'Fixed',Distance,'VerticalAlignment')
```

distributes the specified components `Distance` points horizontally and aligns them vertically as specified.

```
align(HandleList,'HorizontalAlignment','Fixed',Distance)
```

aligns the specified components horizontally as specified and distributes them `Distance` points vertically.

```
align(HandleList,'Fixed',HorizontalDistance,...
      'Fixed',VerticalDistance)
```

distributes the specified components `HorizontalDistance` points horizontally and distributes them `VerticalDistance` points vertically.

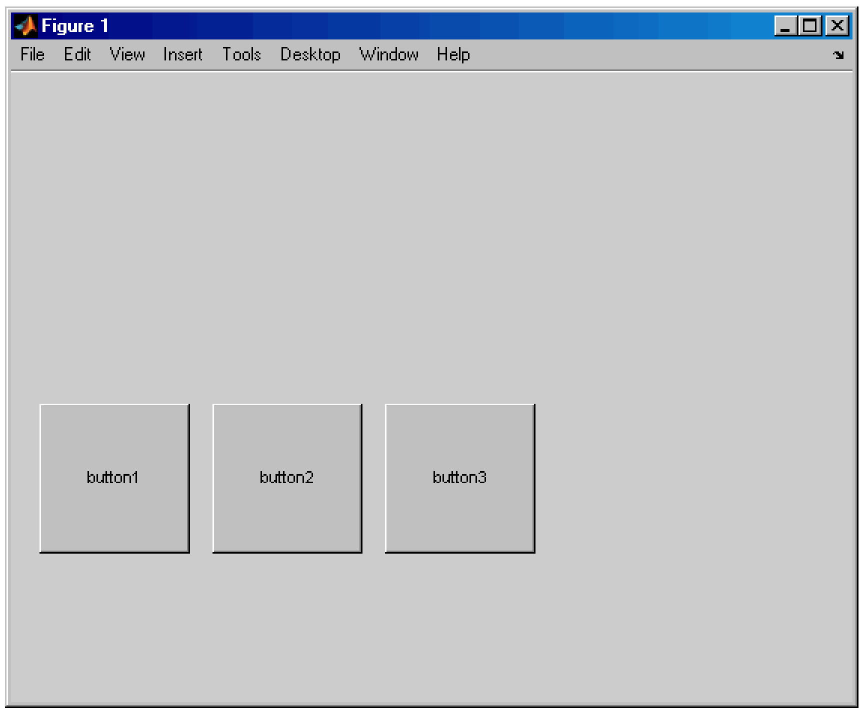
`Positions = align(HandleList, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the specified objects as a vector of `Position` vectors. The position of the objects on the figure does not change.

`Positions = align(CurPositions, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the objects whose positions are contained in `CurPositions`, where `CurPositions` is a vector of `Position` vectors. The position of the objects on the figure does not change.

Examples

Create a GUI with three buttons and use `align` to line up the buttons.

```
% Create a figure window and one button object:
f=figure;
u1 = uicontrol('Style','push', 'parent', f,'pos',...
[20 100 100 100],'string','button1');
% Create two more button objects, not aligned with
% each other or any part of the figure window:
u2 = uicontrol('Style','push', 'parent', f,'pos',...
[150 250 100 100],'string','button2');
u3 = uicontrol('Style','push', 'parent', f,'pos',...
[250 100 100 100],'string','button3');
% Align the button objects with the bottom of the first
% button object, equalizing the distance between the
% objects within the span of the extreme x-values:
align([u1 u2 u3],'distribute','bottom');
```



Alternatives

See “Alignment Tool — Aligning and Distributing Objects” for the GUI alternative.

See Also

`uicontrol` | `uistack`

alim

Purpose

Set or query axes alpha limits

Syntax

```
alpha_limits = alim
alim([amin amax])
alim_mode = alim('mode')
alim('alim_mode')
alim(axes_handle,...)
```

Description

`alpha_limits = alim` returns the alpha limits (`ALim` property) of the current axes.

`alim([amin amax])` sets the alpha limits to the specified values. `amin` is the value of the data mapped to the first alpha value in the alphamap, and `amax` is the value of the data mapped to the last alpha value in the alphamap. Data values in between are linearly interpolated across the alphamap, while data values outside are clamped to either the first or last alphamap value, whichever is closest.

`alim_mode = alim('mode')` returns the alpha limits mode (`ALimMode` property) of the current axes.

`alim('alim_mode')` sets the alpha limits mode on the current axes. `alim_mode` can be

- `auto` — MATLAB automatically sets the alpha limits based on the alpha data of the objects in the axes.
- `manual` — MATLAB does not change the alpha limits.

`alim(axes_handle,...)` operates on the specified axes.

Examples

Map transparency to a surface plot of `z`-data and change the `alim` property to make all values below zero transparent:

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2-y.^2);
% Plot the data, using the gradient of z as
% the alphamap:
surf(x,y,z+.001,'FaceAlpha','flat',...
'AlphaDataMapping','scaled',...
```

```
'AlphaData',gradient(z),...
'FaceColor','blue');
axis tight
% Adjust the alim property to see only where
% the gradient is between 0 and 0.15:
alim([0 .15])
```

- "Making Objects Transparent"

all

Purpose

Determine if all array elements are nonzero or `true`

Syntax

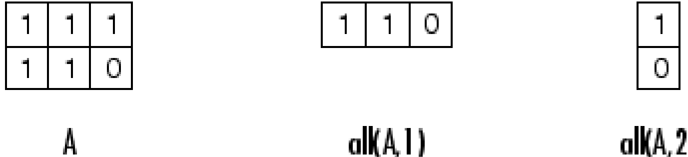
```
B = all(A)
B = all(A, dim)
```

Description

`B = all(A)` tests whether *all* the elements along various dimensions of an array are nonzero or logical `1` (`true`).

- If `A` is a vector, `all(A)` returns logical `1` (`true`) if all the elements are nonzero and returns logical `0` (`false`) if one or more elements are zero.
- If `A` is a nonempty matrix, `all(A)` treats the columns of `A` as vectors, returning a row vector of logical `1`'s and `0`'s.
- If `A` is an empty 0-by-0 matrix, `all(A)` returns logical `1` (`true`).
- If `A` is a multidimensional array, `all(A)` acts along the first nonsingleton dimension and returns an array of logical values. The size of this dimension reduces to `1` while the sizes of all other dimensions remain the same.

`B = all(A, dim)` tests along the dimension of `A` specified by scalar *`dim`*.



Examples

Given

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69]
```

then `B = (A < 0.5)` returns logical `1` (`true`) only where `A` is less than one half:

```
0    0    1    1    1    1    0
```

The all function reduces such a vector of logical conditions to a single condition. In this case, all(B) yields 0.

This makes all particularly useful in if statements:

```
if all(A < 0.5)
    do something
end
```

where code is executed depending on a single condition, not a vector of possibly conflicting conditions.

To determine if all elements in an entire array are nonzero, use all in conjunction with the colon operator.

```
A = eye(3);
all(A(:))

ans =

     0
```

Definitions

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If X is a 1-by-n row vector, then the second dimension is the first nonsingleton dimension of X.
- If X is a 1-by-0-by-n empty array, then the second dimension is the first nonsingleton dimension of X.
- If X is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of X.

any | colon (:) | max | mean | median | min | prod | std | sum | trapz | Logical Operators: Elementwise | Logical Operators: Short-circuit | Relational Operators

allchild

Purpose

Find all children of specified objects

Syntax

```
child_handles = allchild(handle_list)
```

Description

`child_handles = allchild(handle_list)` returns the list of all children (including ones with hidden handles) for each handle. If `handle_list` is a single element, `allchild` returns the output in a vector. If `handle_list` is a vector of handles, the output is a cell array.

Examples

Compare the results these two statements return:

```
axes
get(gca,'Children')
allchild(gca)
```

See Also

`findall` | `findobj`

Purpose

Set transparency properties for objects in current axes

Syntax

```
alpha
alpha(object_handle,value)
alpha(face_alpha)
alpha(alpha_data)
alpha(alpha_data)
alpha(alpha_data_mapping)
```

Description

`alpha` sets one of three transparency properties, depending on what arguments you specify with the call to this function. For available arguments, see Inputs.

`alpha(object_handle,value)` sets the transparency property only on the object identified by `object_handle`.

Input Arguments

Face Alpha

`alpha(face_alpha)` sets the `FaceAlpha` property of all image, patch, and surface objects in the current axes. You can set `face_alpha` to

scalar	Set the `FaceAlpha` property to the specified value (for images, set the `AlphaData` property to the specified value).
`'flat'`	Set the `FaceAlpha` property to `flat`.
`'interp'`	Set the `FaceAlpha` property to `interp`.
`'texture'`	Set the `FaceAlpha` property to `texture`.
`'opaque'`	Set the `FaceAlpha` property to `1`.
`'clear'`	Set the `FaceAlpha` property to `0`.

See “Specifying Transparency” for more information.

AlphaData (Surface Objects)

`alpha(alpha_data)` sets the `AlphaData` property of all surface objects in the current axes. You can set `alpha_data` to

matrix the same size as CData	Set the AlphaData property to the specified values.
'x'	Set the AlphaData property to be the same as XData.
'y'	Set the AlphaData property to be the same as YData.
'z'	Set the AlphaData property to be the same as ZData.
'color'	Set the AlphaData property to be the same as CData.
'rand'	Set the AlphaData property to a matrix of random values equal in size to CData.

AlphaData (Image Objects)

alpha(alpha_data) sets the AlphaData property of all image objects in the current axes. You can set alpha_data to

matrix the same size as CData	Set the AlphaData property to the specified value.
'x'	Ignored.
'y'	Ignored.
'z'	Ignored.
'color'	Set the AlphaData property to be the same as CData.
'rand'	Set the AlphaData property to a matrix of random values equal in size to CData.

AlphaDataMapping

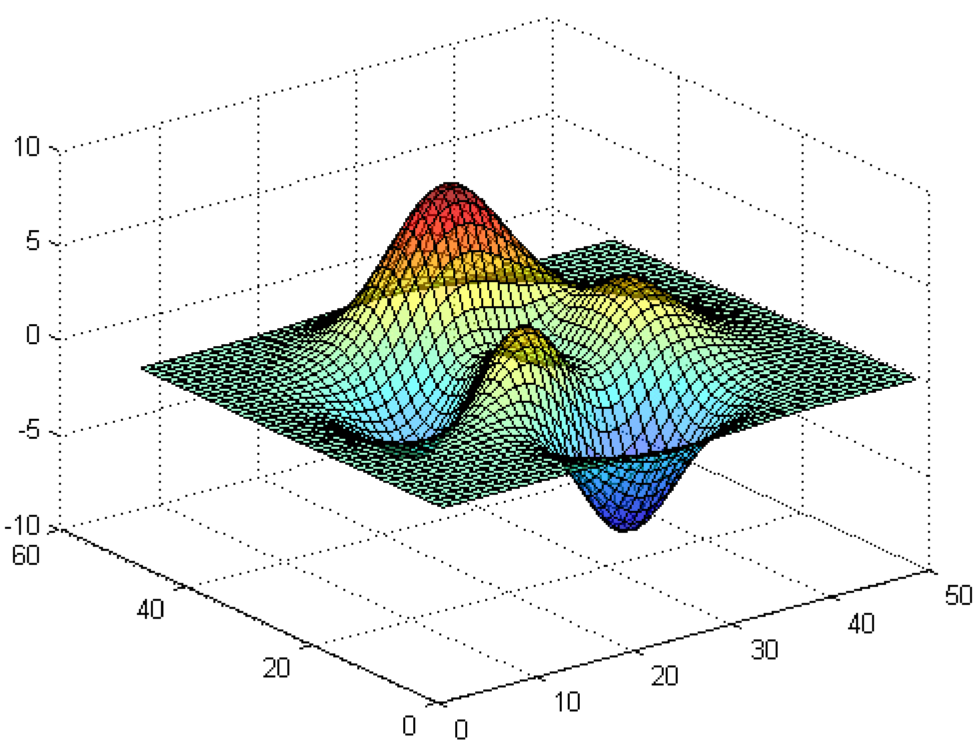
alpha(alpha_data_mapping) sets the AlphaDataMapping property of all image, patch, and surface objects in the current axes. You can set alpha_data_mapping to

'scaled'	Set the AlphaDataMapping property to scaled.
'direct'	Set the AlphaDataMapping property to direct.
'none'	Set the AlphaDataMapping property to none.

Examples

Create a surface plot and change its transparency using alpha:

```
surf(peaks);
alpha(0.5);
```



See Also

`alim` | `alphamap` | Image: `AlphaData` | Image: `AlphaDataMapping` | Patch: `FaceAlpha` | Patch: `FaceVertexAlphaData` | Patch: `AlphaDataMapping` | Surface: `FaceAlpha` | Surface: `AlphaData` | Surface: `AlphaDataMapping`

- "Making Objects Transparent"

Purpose

Specify figure alphamap (transparency)

Syntax

```
alphamap(alpha_map)
alphamap('parameter')
alphamap('parameter',length)
alphamap('parameter',delta)
alphamap(figure_handle,...)
alpha_map = alphamap
alpha_map = alphamap(figure_handle)
alpha_map = alphamap('parameter')
```

Description

`alphamap(alpha_map)` sets the `AlphaMap` of the current figure to the specified `m`-by-1 array of alpha values, `alpha_map`.

`alphamap('parameter')` creates a new alphamap or modifies the current alphamap. You can specify the following parameters:

- `'default'` — Set the `AlphaMap` property to the figure's default alphamap.
- `'rampup'` — Create a linear alphamap with increasing opacity (default `length` equals the current alphamap length).
- `'rampdown'` — Create a linear alphamap with decreasing opacity (default `length` equals the current alphamap length).
- `'vup'` — Create an alphamap that is opaque in the center and becomes more transparent linearly towards the beginning and end (default `length` equals the current alphamap length).
- `'vdown'` — Create an alphamap that is transparent in the center and becomes more opaque linearly towards the beginning and end (default `length` equals the current alphamap length).
- `'increase'` — Modify the alphamap making it more opaque (default `delta` is `.1`, added to the current values).
- `'decrease'` — Modify the alphamap making it more transparent (default `delta` is `.1`, subtracted from the current values).

- `'spin'` — Rotate the current alphamap (default `delta` is 1; `delta` must be an integer).

`alphamap('parameter',length)` creates a new alphamap with the length specified by the integer `length` (used with parameters `'rampup'`, `'rampdown'`, `'vup'`, `'vdown'`).

`alphamap('parameter',delta)` modifies the existing alphamap using the value specified by the integer `delta` (used with parameters `'increase'`, `'decrease'`, `'spin'`).

`alphamap(figure_handle,...)` performs the operation on the alphamap of the figure identified by `figure_handle`.

`alpha_map = alphamap` returns the current alphamap.

`alpha_map = alphamap(figure_handle)` returns the current alphamap from the figure identified by `figure_handle`.

`alpha_map = alphamap('parameter')` returns the alphamap modified by the `parameter`, but does not set the `AlphaMap` property.

Examples

Create a surface plot and change the alphamap

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2-y.^2);
% Plot the data, using the gradient of z as
% the alphamap:
surf(x,y,z+.001,'FaceAlpha','flat',...
'AlphaDataMapping','scaled',...
'AlphaData',gradient(z),...
'FaceColor','blue');
% Change the alphamap to be opaque at the middle and
% transparent towards the ends:
alphamap('vup')
```

- "Making Objects Transparent"

Purpose

Approximate minimum degree permutation

Syntax

```
P = amd(A)
P = amd(A,opts)
```

Description

`P = amd(A)` returns the approximate minimum degree permutation vector for the sparse matrix `C = A + A'`. The Cholesky factorization of `C(P,P)` or `A(P,P)` tends to be sparser than that of `C` or `A`. The `amd` function tends to be faster than `symamd`, and also tends to return better orderings than `symamd`. Matrix `A` must be square. If `A` is a full matrix, then `amd(A)` is equivalent to `amd(sparse(A))`.

`P = amd(A,opts)` allows additional options for the reordering. The `opts` input is a structure with the two fields shown below. You only need to set the fields of interest:

- **dense** — A nonnegative scalar value that indicates what is considered to be dense. If A is n-by-n, then rows and columns with more than `max(16,(dense*sqrt(n)))` entries in `A + A'` are considered to be "dense" and are ignored during the ordering. MATLAB software places these rows and columns last in the output permutation. The default value for this field is 10.0 if this option is not present.
- **aggressive** — A scalar value controlling aggressive absorption. If this field is set to a nonzero value, then aggressive absorption is performed. This is the default if this option is not present.

MATLAB software performs an assembly tree post-ordering, which is typically the same as an elimination tree post-ordering. It is not always identical because of the approximate degree update used, and because “dense” rows and columns do not take part in the post-order. It well-suited for a subsequent `chol` operation, however, If you require a precise elimination tree post-ordering, you can use the following code:

```
P = amd(S);
C = spones(S)+spones(S');
[ignore, Q] = etree(C(P,P));
P = P(Q);
```

If `S` is already symmetric, omit the second line, `C = spones(S)+spones(S')`.

Examples

This example constructs a sparse matrix and computes a two Cholesky factors: one of the original matrix and one of the original matrix preordered by `amd`. Note how much sparser the Cholesky factor of the preordered matrix is compared to the factor of the matrix in its natural ordering:

```
A = gallery('wathen',50,50);
p = amd(A);
L = chol(A,'lower');
Lp = chol(A(p,p),'lower');

figure;
subplot(2,2,1);    spy(A);
title('Sparsity structure of A');

subplot(2,2,2); spy(A(p,p));
title('Sparsity structure of AMD ordered A');

subplot(2,2,3); spy(L);
title('Sparsity structure of Cholesky factor of A');

subplot(2,2,4); spy(Lp);
title('Sparsity structure of Cholesky factor of AMD ordered A');

set(gcf,'Position',[100 100 800 700]);
```

See Also

`colamd` | `colperm` | `symamd` | `symrcm` | `Arithmetic Operator /`

ancestor

Purpose

Ancestor of graphics object

Syntax

```
p = ancestor(h,type)
p = ancestor(h,type,'toplevel')
```

Description

`p = ancestor(h,type)` returns the handle of the closest ancestor of `h`, if the ancestor is one of the types of graphics objects specified by `type`. `type` can be:

- a string that is the name of a single type of object. For example, `'figure'`
- a cell array containing the names of multiple objects. For example, `{'hgtransform','hggroup','axes'}`

If MATLAB cannot find an ancestor of `h` that is one of the specified types, then `ancestor` returns `p` as empty. When `ancestor` searches the hierarchy, it includes the object itself in the search. Therefore, if the object with handle `h` is of one of the types listed in `type`, `ancestor` will return object `h`.

`ancestor` returns `p` as empty but does not issue an error if `h` is not the handle of a Handle Graphics object.

`p = ancestor(h,type,'toplevel')` returns the highest-level ancestor of `h`, if this type appears in the `type` argument.

Examples

Find the ancestors of a line object:

```
% Create some line objects and parent them
% to an hggroup object.
hgg = hggroup;
hgl = line(randn(5),randn(5),'Parent',hgg);
% Now get the ancestor of the lines:
p = ancestor(hgg,{'figure','axes','hggroup'});
get(p,'Type')
% Now get the top-level ancestor:
ptop=ancestor(hgg,{'figure','axes','hggroup'},'toplevel');
get(ptop,'type')
```

See Also

`findobj`

Purpose

Find logical AND of array or scalar inputs

Syntax

```
A & B & ...
and(A, B)
```

Description

`A & B & ...` performs a logical AND of all input arrays `A`, `B`, etc., and returns an array containing elements set to either logical 1 (`true`) or logical 0 (`false`). An element of the output array is set to 1 if all input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input `A` is a 3-by-5 matrix and input `B` is the number 1, then `B` is treated as if it were a 3-by-5 matrix of ones.

`and(A, B)` is called for the syntax `A & B` when either `A` or `B` is an object.

Note The symbols `&` and `&&` perform different operations in the MATLAB software. The element-wise AND operator described here is `&`. The short-circuit AND operator is `&&`.

Examples

If matrix `A` is

```
0.4235    0.5798         0    0.7942         0
0.5155         0    0.7833    0.0592    0.8744
0.3340         0         0         0    0.0150
0.4329    0.6405    0.6808    0.0503         0
```

and matrix `B` is

```
     0     1     0     1     0
     1     1     1     0     1
     0     1     1     1     0
     0     1     0     0     1
```

then

```
A & B
ans =
     0     1     0     1     0
     1     0     1     0     1
     0     0     0     0     0
     0     1     0     0     0
```

See Also

`bitand` | `or` | `xor` | `not` | `any` | `all`

How To

- logical operators
- bitwise functions

Purpose

Phase angle

Syntax

```
P = angle(Z)
```

Description

`P = angle(Z)` returns the phase angles, in radians, for each element of complex array `Z`. The angles lie between $\pm\pi$.

For complex `Z`, the magnitude `R` and phase angle `theta` are given by

```
R = abs(Z)
theta = angle(Z)
```

and the statement

```
Z = R.*exp(i*theta)
```

converts back to the original complex `Z`.

Examples

```
Z = [ 1 - 1i   2 + 1i   3 - 1i   4 + 1i
      1 + 2i   2 - 2i   3 + 2i   4 - 2i
      1 - 3i   2 + 3i   3 - 3i   4 + 3i
      1 + 4i   2 - 4i   3 + 4i   4 - 4i ]

P = angle(Z)

P =
   -0.7854    0.4636   -0.3218    0.2450
    1.1071   -0.7854    0.5880   -0.4636
   -1.2490    0.9828   -0.7854    0.6435
    1.3258   -1.1071    0.9273   -0.7854
```

Algorithms

The `angle` function can be expressed as `angle(z) = imag(log(z)) = atan2(imag(z),real(z))`.

See Also

`abs` | `atan2` | `unwrap`

Purpose

Create annotation objects

Syntax

```
annotation(annotation_type)
annotation('line',x,y)
annotation('arrow',x,y)
annotation('doublearrow',x,y)
annotation('textarrow',x,y)
annotation('textbox',[x y w h])
annotation('ellipse',[x y w h])
annotation('rectangle',[x y w h])
annotation(figure_handle,...)
annotation(...,'PropertyName',PropertyValue,...)
anno_obj_handle = annotation(...)
```

Description

`annotation(`*`annotation_type`*`)` creates the specified annotation type using default values for all properties. *`annotation_type`* can be one of the following strings:

- `'line'`
- `'arrow'`
- `'doublearrow'` (two-headed arrow),
- `'textarrow'` (arrow with attached text box),
- `'textbox'`
- `'ellipse'`
- `'rectangle'`

`annotation('line',x,y)` creates a line annotation object that extends from the point defined by `x(1)`,`y(1)` to the point defined by `x(2)`,`y(2)`, specified in normalized figure units.

`annotation('arrow',x,y)` creates an arrow annotation object that extends from the point defined by `x(1)`,`y(1)` to the point defined by `x(2)`,`y(2)`, specified in normalized figure units.

annotation('doublearrow',x,y) creates a two-headed annotation object that extends from the point defined by x(1),y(1) to the point defined by x(2),y(2), specified in normalized figure units.

annotation('textarrow',x,y) creates a textarrow annotation object that extends from the point defined by x(1),y(1) to the point defined by x(2),y(2), specified in normalized figure units. The tail end of the arrow is attached to an editable text box.

annotation('textbox',[x y w h]) creates an editable text box annotation with its lower left corner at the point x,y, a width w, and a height h, specified in normalized figure units. Specify x, y, w, and h in a single vector.

To type in the text box, enable plot edit mode (plotedit) and double-click within the box.

annotation('ellipse',[x y w h]) creates an ellipse annotation with the lower left corner of the bounding rectangle at the point x,y, a width w, and a height h, specified in normalized figure units. Specify x, y, w, and h in a single vector.

annotation('rectangle',[x y w h]) creates a rectangle annotation with the lower left corner of the rectangle at the point x,y, a width w, and a height h, specified in normalized figure units. Specify x, y, w, and h in a single vector.

annotation(figure_handle,...) creates the annotation in the specified figure.

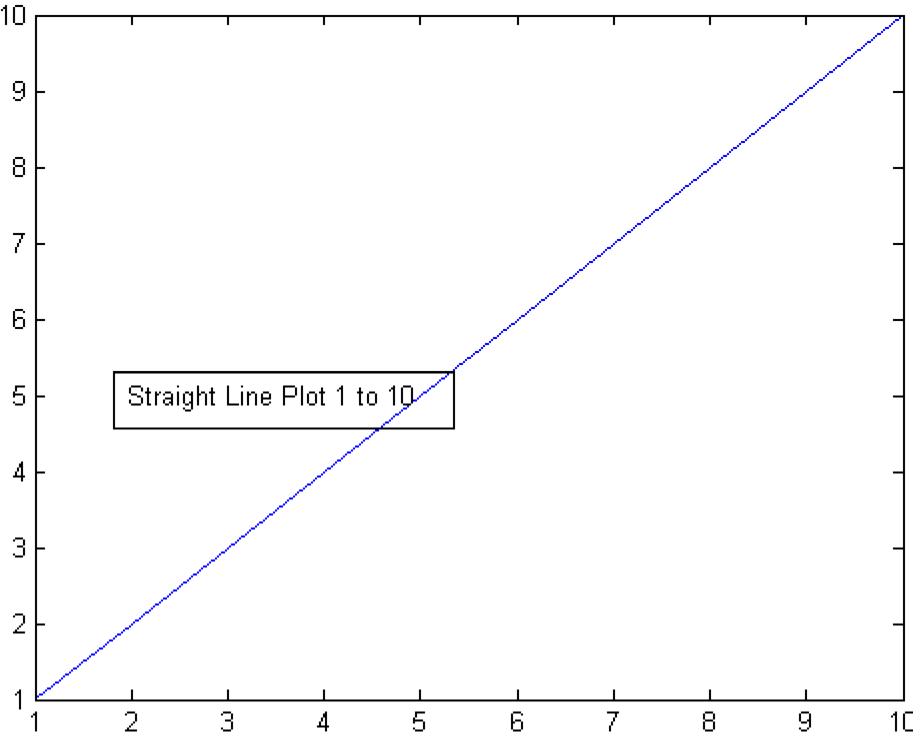
annotation(...,'PropertyName',PropertyValue,...) creates the annotation and sets the specified properties to the specified values.

anno_obj_handle = annotation(...) returns the handle to the "Annotation Objects".

Examples

Annotate a graph with a text box.

```
plot(1:10);
annotation('textbox', [.2 .4 .1 .1], 'String', 'Straight Line Plot 1 to 1
```

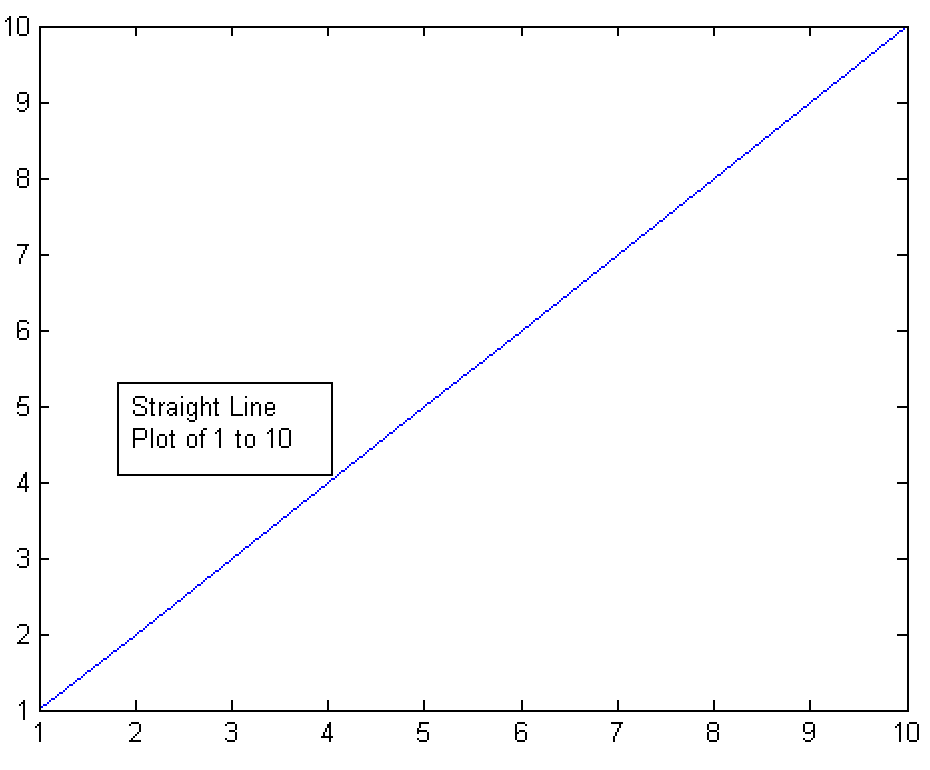


Notice that the locations specified are normalized in the figure coordinates. Length of the string automatically adjusts the width of the text box, as, `FitBoxToText` property of the annotation object is `on` by default.

Insert multiple lines in a text box by creating a cell array of string. Each element is used as a separate line.

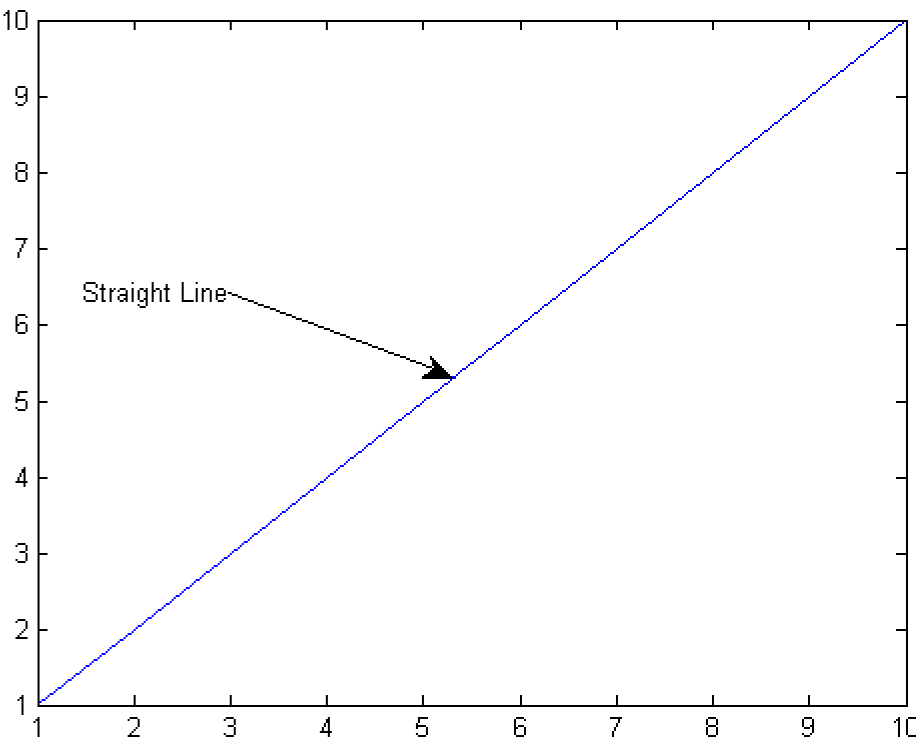
```
plot(1:10);
str = {'Straight Line', 'Plot of 1 to 10'};
```

```
annotation('textbox', [.2 .4, .1, .1], 'String', str);
```



Insert a text arrow in a graph.

```
plot(1:10);
a = annotation('textarrow', [.3 .5], [.6 .5], 'String' , 'Straight Line');
```



The text arrow is defined by points starting from `(.3, .6)` extending to `(.5 ,.5)` in normalized figure coordinates.

Adding Annotations Interactively

It is often convenient to place annotations interactively. For details, see “Working in Plot Edit Mode”.

How To

- "How to Annotate Graphs"
- "Annotation Objects"

Purpose

Define annotation arrow properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see "Positioning Annotations in Data Space" in the MATLAB Graphics documentation.

Annotation Arrow Property Descriptions

`Color`
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is `[0 0 0]` (`black`).

See the `ColorSpec` reference page for more information on specifying color. See "Adding Arrows and Lines to Graphs".

`HeadLength`
size in points

Length of the arrowhead. Specify this property in points. `1` point = $^{1}/_{72}$ inch. The default value is `10`. See also `HeadWidth`.

`HeadStyle`
string

Style of arrowhead. Specify this property as one of the strings from the following table.

Arrow Head Style Table

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	
cback1		deltoid	
cback2			
cback3			

`HeadWidth`
size in points

Width of arrowhead. Specify in points. 1 point = $^1/_{72}$ inch. The default value is 10. See also `HeadLength`.

`LineStyle`
`{-} | -- | : | -. | none`

Style of arrow stem.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

`LineWidth`
size in points

Width of arrow stem. Specify in points. 1 point = $^1/_{72}$ inch. The default is `0.5` points.

`Position`
four-element vector `[x, y, width, height]`

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x*, *y* in units normalized to the figure (when `Units` property is `normalized`). `width` and `height` specify the object's *dx* and *dy*, respectively, in units normalized to the figure. The default value is `[0.3 0.3 0.1 0.1]`.

`Units`
`{normalized} | inches | centimeters | characters | points | pixels`

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $^1/_{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

`X`

vector [X_{begin} X_{end}]

x-coordinates of beginning and ending points for line. A vector of *x*-axis (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

`Y`

vector [Y_{begin} Y_{end}]

y-coordinates of beginning and ending points for line. A vector of *y*-axis (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

Purpose

Define annotation doublearrow properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Positioning Annotations in Data Space” in the MATLAB Graphics documentation.

Annotation Doublearrow Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Color`
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object’s color. The default value is `[0 0 0]` (`black`).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

`Head1Length`
size in points

Length of first arrowhead. Specify in points.`1` point = $^{1}/_{72}$ inch. The default value is `10`.

The first arrowhead is located at the end defined by the point `x(1), y(1)`.

See also the `Head1Style`, `Head1Width`, `X` and `Y` properties.

`Head2Length`
size in points

Length of second arrowhead. Specify in points.1 point = $^{1}/_{72}$ inch. The default value is 10.

The first arrowhead is located at the end defined by the point x(end), y(end).

See also the Head1Style, Head1Width, X and Y properties.

Head1Style
string

Style of first arrowhead. Specify this property as one of the strings from the following table.

Arrow Head Style Table

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	

Head Style String	Head	Head Style String	Head
cback1		deltoid	
cback2			
cback3			

See also `Head1Width`, `Head1Length`, and `LineWidth`.

`Head2Style`
string

Style of second arrowhead. Specify this property as one of the strings shown in the table for the `Head1Style` property.

See also `Head2Width`, `Head2Length`, `LineWidth`.

`Head1Width`
size in points

Width of first arrowhead. Specify in points.1 point = $^1/_{72}$ inch. See also `Head1Length`.

`Head2Width`
size in points

Width of second arrowhead. Specify in points.1 point = $^1/_{72}$ inch. See also `Head2Length`.

`LineStyle`
`{-} | -- | : | -. | none`

Style of arrow stem.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

See also `Head1Style`, `Head1Length`, and `LineWidth`.

`LineWidth`
size in points

Width of arrow stem. Specify in points.1 point = $^1/_{72}$ inch. The default is `0.5` points.

`Position`
four-element vector `[x, y, width, height]`

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x*, *y* in units normalized to the figure (when `Units` property is `normalized`). `width` and `height` specify the object's *dx* and *dy*, respectively, in units normalized to the figure. The default value is `[0.3 0.3 0.1 0.1]`.

`Units`
`{normalized} | inches | centimeters | characters | points | pixels`

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. `1` point = $^{1}/_{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

`X`

vector [X_{begin} X_{end}]

x-coordinates of beginning and ending points for line. A vector of *x*-axis (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

`Y`

vector [Y_{begin} Y_{end}]

y-coordinates of beginning and ending points for line. A vector of *y*-axis (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

Annotation Ellipse Properties

Purpose

Define annotation ellipse properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Positioning Annotations in Data Space” in the MATLAB Graphics documentation.

Annotation Ellipse Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`EdgeColor`

ColorSpec | `none`

Edge color of object'. A three-element RGB vector or one of the MATLAB predefined names, specifying the edge color. The default value is `[0 0 0]` (`black`).

See the `ColorSpec` reference page for more information on specifying color.

`FaceColor`

`{flat} | none | ColorSpec`

Color of filled areas.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- `none` — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.
- `flat` — The object uses the figure `colormap` to determine the color of the filled areas.

`LineStyle`

`{-} | -- | : | -. | none`

Line style of ellipse.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

LineWidth
size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is 0.5 points.

Position
four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x*, *y* in units normalized to the figure (when Units property is normalized). width and height specify the object's *dx* and *dy*, respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

Units
{normalized} | inches | centimeters | characters | points | pixels

Position units. MATLAB uses this property to determine the units used by the Position property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $^1/_{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

`EdgeColor`

ColorSpec | `none`

Edge color of object'. A three-element RGB vector or one of the MATLAB predefined names, specifying the edge color. The default value is `[0 0 0]` (`black`).

See the `ColorSpec` reference page for more information on specifying color.

`FaceAlpha`

Scalar alpha value in range `[0 1]`

Transparency of object background. Defines the degree to which the object's background color is transparent. A value of `1` (the default) makes the background opaque, a value of `0` makes the background completely transparent (that is, invisible). The default value is `1`.

`FaceColor`

`{flat} | none | ColorSpec`

Color of filled areas.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- `none` — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.
- `flat` — The object uses the figure `colormap` to determine the color of the filled areas.

`LineStyle`
`{-} | -- | : | -. | none`

Line style of annotation rectangle object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

`LineWidth`
size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is `0.5` points.

`Position`
four-element vector `[x, y, width, height]`

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x*, *y* in units normalized to the figure (when `Units` property is `normalized`). `width` and `height` specify the object's *dx* and *dy*,

respectively, in units normalized to the figure. The default value is `[0.3 0.3 0.1 0.1]`.

`Units`

`{normalized} | inches | centimeters | characters | points | pixels`

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. `1` point = $^1/_{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

See Also

`annotation`

Purpose

Define annotation textarrow properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see "Positioning Annotations in Data Space" in the MATLAB Graphics documentation.

Annotation Textarrow Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Color`

ColorSpec

Color of the arrow, text and text border. A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the arrow, the color of the text (`TextColor` property), and the rectangle enclosing the text (`TextEdgeColor` property). The default value is `[0 0 0]` (`black`).

Setting the `Color` property also sets the `TextColor` and `TextEdgeColor` properties to the same color. However, if the value of the `TextEdgeColor` is `none`, it remains `none` and the text box is not displayed. You can set `TextColor` or `TextEdgeColor` independently without affecting other properties.

For example, if you want to create a textarrow with a red arrow and black text in a black box, you must:

1. Set the `Color` property to red — `set(h,'Color','r')`
2. Set the `TextColor` to black — `set(h,'TextColor','k')`
3. Set the `TextEdgeColor` to black .— `set(h,'TextEdgeColor','k')`

If you do not want display the text box, set the `TextEdgeColor` to `none`.

See the `ColorSpec` reference page for more information on specifying color.

`FontAngle`

`{normal} | italic | oblique`

Character slant. MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

`FontName`

string

Font family. A string specifying the name of the font to use for the text. To display and print properly, this font must be supported on your system. The default font is `Helvetica`.

`FontSize`

size in points

Approximate size of text characters. Specify in points. 1 point = $^{1}/_{72}$ inch. The default size is `10`.

`FontUnits`

`{points} | normalized | inches | centimeters | pixels`

Font size units. MATLAB uses this property to determine the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units. 1 point = $^{1}/_{72}$ inch.

`FontWeight`

`{normal} | bold | light | demi`

Weight of text characters. MATLAB uses this property to select a font from those available on your system. Generally, setting this property to bold or demi causes MATLAB to use a bold font.

HeadLength
size in points

Length of the arrowhead. Specify this property in points. 1 point = $^1/_{72}$ inch. The default value is 10. See also HeadWidth.

HeadStyle
string

Style of arrowhead. Specify this property as one of the strings from the following table.

Arrow Head Style Table

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	

Head Style String	Head	Head Style String	Head
cback1		deltoid	
cback2			
cback3			

HeadWidth
size in points

Width of arrowhead. Specify in points. 1 point = $^1/_{72}$ inch. The default value is 10. See also HeadLength.

HorizontalAlignment
{left} | center | right

Horizontal alignment of text. Specifies the horizontal justification of the text string. It determines where MATLAB places the string horizontally with regard to the points specified by the Position property.

Interpreter
latex | {tex} | none

Interpret TeX instructions. This property controls whether MATLAB interprets certain characters in the String property as TeX instructions (default) or displays all characters literally. The options are:

- latex — Supports a basic subset of the LaTeX markup language.
- tex — Supports a subset of plain TeX markup language. See the String property for a list of supported TeX instructions.

- none — Displays literal characters.

`LineStyle`
`{-} | -- | : | -. | none`

Line style of arrow stem.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

`LineWidth`
size in points

Width of arrow stem. Specify in points 1 point = $^{1}/_{72}$ inch. The default is `0.5` points.

`Position`
four-element vector `[x, y, width, height]`

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x*, *y* in units normalized to the figure (when `Units` property is `normalized`). `width` and `height` specify the object's *dx* and *dy*, respectively, in units normalized to the figure. The default value is `[0.3 0.3 0.1 0.1]`.

`String`
string

Text string. Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See Mathematical Symbols, Greek Letters, and TeX Characters for an example.

Note The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

When the text `Interpreter` property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. The following table lists these characters and the character sequences used to define them.

TeX Character Sequence Table

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\alpha	α	\upsilon	υ	\sim	~
\angle	∠	\phi	Φ	\leq	≤
\ast	*	\chi	χ	\infty	∞
\beta	β	\psi	ψ	\clubsuit	♣
\gamma	γ	\omega	ω	\diamondsuit	♦
\delta	δ	\Gamma	Γ	\heartsuit	♥
\epsilon	ε	\Delta	Δ	\spadesuit	♠

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\zeta	ζ	\Theta	Θ	\leftrightarrow	↔
\eta	η	\Lambda	Λ	\leftarrow	←
\theta	Θ	\Xi	Ξ	\Leftarrow	⇐
\vartheta		\Pi	Π	\uparrow	↑
\iota	ι	\Sigma	Σ	\rightarrow	→
\kappa	κ	\Upsilon		\Rightarrow	⇒
\lambda	λ	\Phi	Φ	\downarrow	↓
\mu	µ	\Psi	Ψ	\circ	º
\nu	ν	\Omega	Ω	\pm	±
\xi	ξ	\forall	∀	\geq	≥
\pi	π	\exists	∃	\propto	∝
\rho	ρ	\ni	э	\partial	∂
\sigma	σ	\cong	≅	\bullet	•
\varsigma	ς	\approx	≈	\div	÷
\tau	τ	\Re	ℜ	\neq	≠
\equiv	≡	\oplus	⊕	\aleph	
\Im	ℑ	\cup	∪	\wp	℘
\otimes	⊗	\subseteq	⊆	\oslash	∅
\cap	∩	\in		\supseteq	⊇
\supset	⊃	\lceil	⌈	\subset	⊂
\int	∫	\cdot	·	\o	ο

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\rfloor	⌋	\neg	¬	\nabla	∇
\lfloor	⌊	\times	x	\ldots	...
\perp	⊥	\surd	√	\prime	´
\wedge	∧	\varpi	ϖ	\0	∅
\rceil	⌉	\rangle	〉	\mid	|
\vee	∨			\copyright	©
\langle	〈				

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers.

`TextBackgroundColor`

`ColorSpec | {none}`

Color of text background rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color.

See the `ColorSpec` reference page for more information on specifying color.

`TextColor`

`ColorSpec`

Color of text. A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color. The default value is `[0 0 0]` (black).

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`TextEdgeColor`
`ColorSpec | {none}`

Color of edge of text rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the rectangle that encloses the text.

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`TextLineWidth`
width in points

Width of text rectangle edge. Specify in points. `1` point = $^1/_{72}$ inch. The default value is `0.5`.

`TextMargin`
size in pixels

Space around text. A value in pixels that defines the space around the text string, but within the rectangle. Default value is `5` pixels.

`TextRotation`
rotation angle in degrees

Text orientation. Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation). Angles are absolute and not relative to previous rotations; a rotation of `0` degrees is always horizontal. Default is `0`.

`Units`
`{normalized} | inches | centimeters | characters | points | pixels`

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. `1` point = $^1/_{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

`VerticalAlignment`

`top | cap | {middle} | baseline | bottom`

Vertical alignment of text. Specifies the vertical justification of the text string. It determines where MATLAB places the string vertically with regard to the points specified by the `Position` property.

Note that `top` and `cap` both place the text at the top, while `baseline` and `bottom` both align the text on the bottom.

`X`

vector [X_{begin} X_{end}]

x-coordinates of beginning and ending points for line. A vector of *x*-axis (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

`Y`

vector [Y_{begin} Y_{end}]

y-coordinates of beginning and ending points for line. A vector of *y*-axis (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

See Also

`annotation`

Annotation Textbox Properties

Purpose

Define annotation textbox properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Positioning Annotations in Data Space” in the MATLAB Graphics documentation.

Annotation Textbox Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`BackgroundColor`
    `ColorSpec | {none}`

Color of text background rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the rectangle background color. The default value is `none`.

See the `ColorSpec` reference page for more information on specifying color.

`Color`
    `ColorSpec`

Text color. A three-element RGB vector or one of the predefined names, specifying the text color. The default value is black. See `ColorSpec` for more information on specifying color.

`EdgeColor`
    `ColorSpec | {none}`

Color of edge of text rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the rectangle that encloses the text.

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`FaceAlpha`
Scalar alpha value in range `[0 1]`

Transparency of object background. Defines the degree to which the object's background color is transparent. A value of `1` (the default) makes the background opaque, a value of `0` makes the background completely transparent (that is, invisible). The default value is `1`.

`FitBoxToText`
`{on} | off`

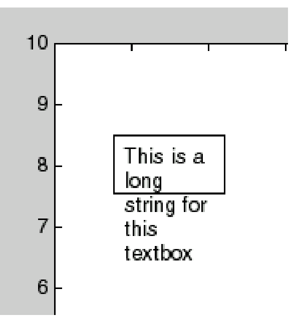
Automatically adjust text box width and height to fit text. When this property is `on` (the default), MATLAB automatically resizes textboxes to fit the *x*-extents and *y*-extents of the text strings they contain. When it is `off`, text strings are wrapped to fit the width of their textboxes, which can cause them to extend below the bottom of the box.

If you resize a textbox in plot edit mode or change the width or height of its `Position` property directly, MATLAB sets the object's `FitBoxToText` property to `off`. You can toggle this property with `set`, with the Property Inspector, or in plot edit mode via the object's context menu.

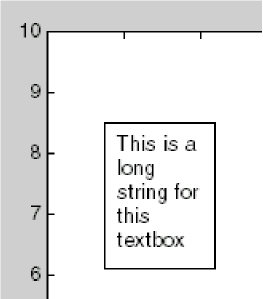
`FitHeightToText`
`on | off`

Automatically adjust text box width and height to fit text. MATLAB automatically wraps text strings to fit the width of the text box. However, if the text string is long enough, it can extend beyond the bottom of the text box.

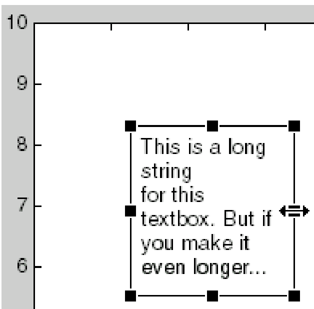
Note The property is obsolete. To control line wrapping behavior in textboxes, use `FitBoxToText` instead.



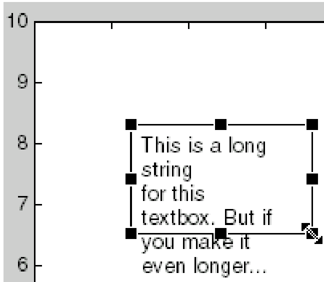
When you set this mode to `on`, MATLAB automatically adjusts the height of the text box to accommodate the string, doing so as you create or edit the string.



The fit-size-to-text behavior turns off if you resize the text box programmatically or manually in plot edit mode.



However, if you resize the text box from any other handles, the position you set is honored without regard to how the text fits the box.



`FontAngle`

`{normal} | italic | oblique`

Character slant. MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

`FontName`

string

Font family. A string specifying the name of the font to use for the text. To display and print properly, this font must be supported on your system. The default font is `Helvetica`.

FontSize
size in points

Approximate size of text characters. Specify in points. 1 point = $^{1}/_{72}$ inch. The default size is 10.

FontUnits
{points} | normalized | inches | centimeters | pixels

Font size units. MATLAB uses this property to determine the units used by the FontSize property. Normalized units interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. pixels, inches, centimeters, and points are absolute units. 1 point = $^{1}/_{72}$ inch.

FontWeight
{normal} | bold | light | demi

Weight of text characters. MATLAB uses this property to select a font from those available on your system. Generally, setting this property to bold or demi causes MATLAB to use a bold font.

HorizontalAlignment
{left} | center | right

Horizontal alignment of text. Specifies the horizontal justification of the text string within the textbox. It determines where MATLAB places the string horizontally with regard to the points specified by the Position property.

Interpreter
latex | {tex} | none

Interpret TeX instructions. This property controls whether MATLAB interprets certain characters in the String property as TeX instructions (default) or displays all characters literally. The options are:

- `latex` — Supports a basic subset of the LaTeX markup language.
- `tex` — Supports a subset of plain TeX markup language. See the `String` property for a list of supported TeX instructions.
- `none` — Displays literal characters.

`LineStyle`

`{-} | -- | :  | -.  | none`

Line style of annotation textbox object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

`LineWidth`

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is `0.5` points.

`Margin`

size in pixels

Space around text. A value in pixels that defines the space around the text string, but within the rectangle. Default value is `5` pixels.

`Position`

four-element vector `[x, y, width, height]`

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x*, *y* in units normalized to the figure (when `Units` property is `normalized`). `width` and `height` specify the object's *dx* and *dy*, respectively, in units normalized to the figure. The default value is `[0.3 0.3 0.1 0.1]`.

`String`
string

Text string. Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See Mathematical Symbols, Greek Letters, and TeX Characters for an example.

Note The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

When the text `Interpreter` property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. The following table lists these characters and the character sequences used to define them.

TeX Character Sequence Table

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\alpha	α	\upsilon	υ	\sim	~
\angle	∠	\phi	Φ	\leq	≤
\ast	*	\chi	χ	\infty	∞
\beta	β	\psi	ψ	\clubsuit	♣
\gamma	γ	\omega	ω	\diamondsuit	♦
\delta	δ	\Gamma	Γ	\heartsuit	♥
\epsilon	ε	\Delta	Δ	\spadesuit	♠
\zeta	ζ	\Theta	Θ	\leftrightarrow	↔
\eta	η	\Lambda	Λ	\leftarrow	←
\theta	Θ	\Xi	Ξ	\Leftarrow	⇐
\vartheta		\Pi	Π	\uparrow	↑
\iota	ι	\Sigma	Σ	\rightarrow	→
\kappa	κ	\Upsilon		\Rightarrow	⇒
\lambda	λ	\Phi	Φ	\downarrow	↓
\mu	µ	\Psi	Ψ	\circ	º
\nu	ν	\Omega	Ω	\pm	±
\xi	ξ	\forall	∀	\geq	≥
\pi	π	\exists	∃	\propto	∝
\rho	ρ	\ni	∍	\partial	∂

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\sigma	σ	\cong	≅	\bullet	•
\varsigma	ς	\approx	≈	\div	÷
\tau	τ	\Re	ℜ	\neq	≠
\equiv	≡	\oplus	⊕	\aleph	
\Im	ℑ	\cup	∪	\wp	℘
\otimes	⊗	\subseteq	⊆	\oslash	∅
\cap	∩	\in		\supseteq	⊇
\supset	⊃	\lceil	⌈	\subset	⊂
\int	∫	\cdot	·	\o	o
\rfloor	⌋	\neg	¬	\nabla	∇
\lfloor	⌊	\times	x	\ldots	...
\perp	⊥	\surd	√	\prime	´
\wedge	∧	\varpi	ϖ	\0	∅
\rceil	⌉	\rangle	〉	\mid	|
\vee	∨			\copyright	©
\langle	〈				

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers.

`Units`
`{normalized} | inches | centimeters | characters | points | pixels`

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $^1/_{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

`VerticalAlignment`
`top | cap | {middle} | baseline | bottom`

Vertical alignment of text. Specifies the vertical justification of the text string within the textbox. It determines where MATLAB places the string vertically with regard to the points specified by the `Position` property.

Note that `top` and `cap` both place the text at the top of the box, while `baseline` and `bottom` both align the text on the bottom.

`annotation`

ans

Purpose

Most recent answer

Syntax

```
ans
```

Description

The MATLAB software creates the `ans` variable automatically when you specify no output argument.

Examples

The statement

```
2+2
```

is the same as

```
ans = 2+2
```

See Also

`display`

Purpose

Determine if any array elements are nonzero

Syntax

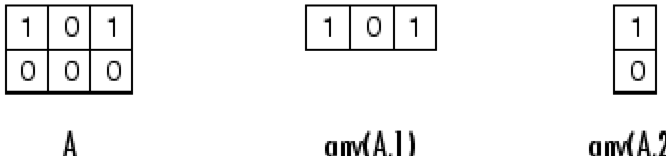
```
B = any(A)
B = any(A,dim)
```

Description

`B = any(A)` tests whether *any* of the elements along various dimensions of an array is a nonzero number or is logical `1` (`true`). The `any` function ignores entries that are `NaN` (Not a Number).

- If `A` is a vector, `any(A)` returns logical `1` (`true`) if any of the elements of `A` is a nonzero number or is logical `1` (`true`), and returns logical `0` (`false`) if all the elements are zero.
- If `A` is a nonempty matrix, `any(A)` treats the columns of `A` as vectors, returning a row vector of logical `1`'s and `0`'s.
- If `A` is an empty 0-by-0 matrix, `any(A)` returns logical `0` (`false`).
- If `A` is a multidimensional array, `any(A)` acts along the first nonsingleton dimension and returns an array of logical values. The size of this dimension reduces to `1` while the sizes of all other dimensions remain the same.

`B = any(A,dim)` tests along the dimension of `A` specified by scalar *`dim`*.



Examples

Example 1 – Reducing a Logical Vector to a Scalar Condition

Given

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69]
```

then `B = (A < 0.5)` returns logical `1` (`true`) only where `A` is less than one half:

```
0    0    1    1    1    1    0
```

The `any` function reduces such a vector of logical conditions to a single condition. In this case, `any(B)` yields logical `1`.

This makes `any` particularly useful in `if` statements:

```
if any(A < 0.5)do something
end
```

where code is executed depending on a single condition, not a vector of possibly conflicting conditions.

Example 2– Reducing a Logical Matrix to a Scalar Condition

To determine if any elements in an entire array are nonzero, use `any` in conjunction with the colon operator.

```
A = eye(3);
any(A(:))

ans =

     1
```

Example 3 – Testing Arrays of Any Dimension

You can use the following type of statement on an array of any dimensions. This example tests a 3-D array to see if any of its elements are greater than 3:

```
x = rand(3,7,5) * 5;

any(x(:) > 3)
ans =
     1
```

or less than zero:

```
any(x(:) < 0)
ans =
```

```
0
```

Definitions

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to `1`.

For example:

- If `X` is a 1-by-n row vector, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-0-by-n empty array, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of `X`.

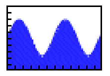
Purpose

Filled area 2-D plot



Syntax

```
area(Y)
area(X,Y)
area(...,basevalue)
area(...,'PropertyName',PropertyValue,...)
area(axes_handle,...)
h = area(...)
```

Description

An area graph displays elements in `Y` as one or more curves and fills the area beneath each curve. When `Y` is a matrix, the curves are stacked showing the relative contribution of each row element to the total height of the curve at each x interval.

`area(Y)` plots the vector `Y` or the sum of each column in matrix `Y`. The *x*-axis automatically scales to `1:size(Y,1)`.

`area(X,Y)` For vectors `X` and `Y`, `area(X,Y)` is the same as `plot(X,Y)` except that the area between `0` and `Y` is filled. When `Y` is a matrix, `area(X,Y)` plots the columns of `Y` as filled areas. For each `X`, the net result is the sum of corresponding values from the columns of `Y`.

If `X` is a vector, `length(X)` must equal `length(Y)`. If `X` is a matrix, `size(X)` must equal `size(Y)`.

`area(...,basevalue)` specifies the base value for the area fill. The default `basevalue` is `0`. See the `BaseValue` property for more information.

`area(...,'`*`PropertyName`*`',PropertyValue,...)` specifies property name and property value pairs for the patch graphics object created by `area`.

`area(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = area(...)` returns handles of `areaseries` graphics objects.

Creating an area graph of an m-by-n matrix creates n areaseries objects (that is, one per column), whereas a 1-by-n vector creates one areaseries object.

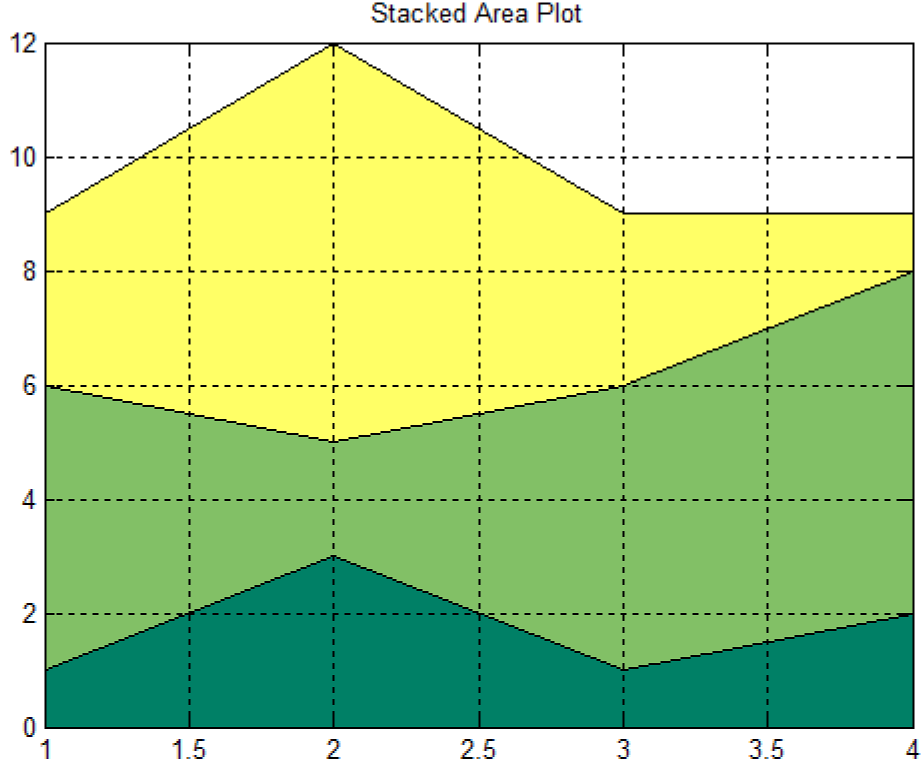
Some areaseries object properties that you set on an individual areaseries object set the values for all areaseries objects in the graph. See the property descriptions for information on specific properties.

Examples

Stacked Area Graph

This example plots the data in the variable `Y` as an area graph. Each subsequent column of `Y` is stacked on top of the previous data. The figure colormap controls the coloring of the individual areas. You can explicitly set the color of an area using the `EdgeColor` and `FaceColor` properties.

```
Y = [1, 5, 3;
 3, 2, 7;
 1, 5, 3;
 2, 6, 1];
area(Y)
grid on
colormap summer
set(gca,'Layer','top')
title 'Stacked Area Plot'
```

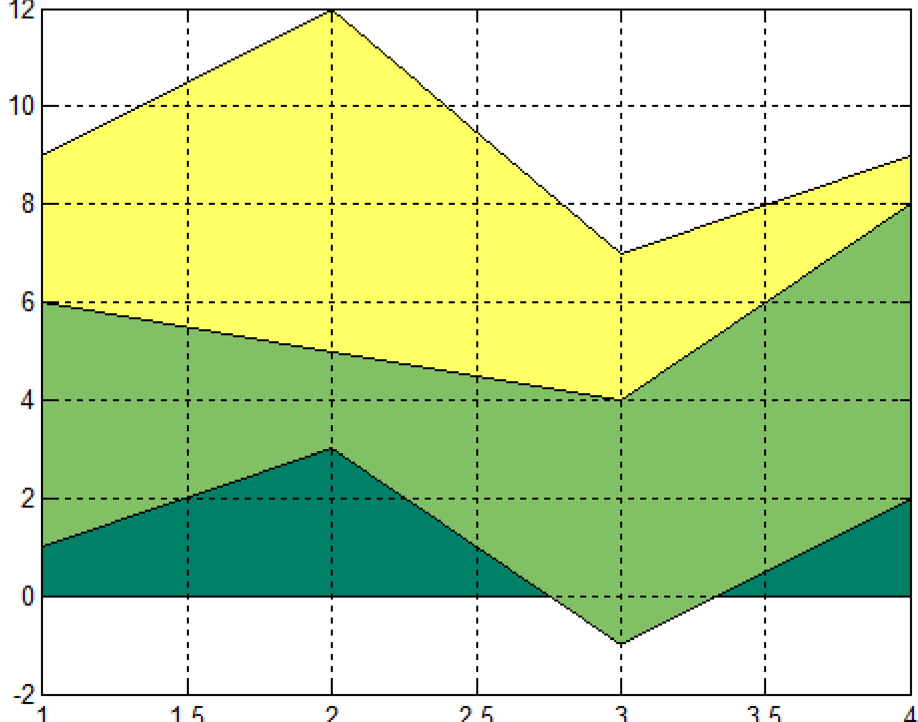


Adjusting the Base Value

The area function uses a *y*-axis value of 0 as the base of the filled areas. You can change this value by setting the area `BaseValue` property. For example, negate one of the values of Y from the previous example and replot the data.

```
Y(3,1) = -1; % Was 1
h = area(Y);
set(gca,'Layer','top')
grid on
colormap summer
```

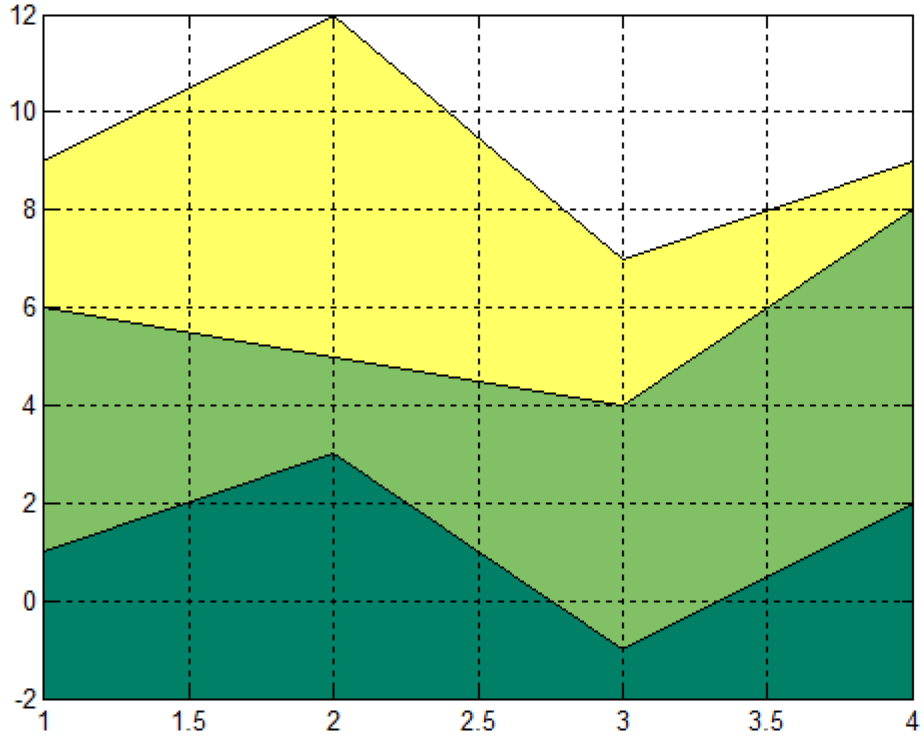
The area graph now looks like this:



Adjusting the `BaseValue` property improves the appearance of the graph:

```
set(h,'BaseValue',-2)
```

Setting the `BaseValue` property on one areaseries object sets the values of all objects.



Specifying Colors and Line Styles

You can specify the colors of the filled areas and the type of lines used to separate them.

```
h = area(Y,-2); % Set BaseValue via argument
set(h(1),'FaceColor',[.5 0 0])
set(h(2),'FaceColor',[.7 0 0])
set(h(3),'FaceColor',[1 0 0])
set(h,'LineStyle',':','LineWidth',2) % Set
all to same value
```

How To

- "Area Graphs"

Areaseries Properties

Purpose

Define areaseries properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or with the property editor (`propertyeditor`).

Note that you cannot define default properties for areaseries objects.

See "Plot Objects" for more information on areaseries objects.

Areaseries Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Annotation`

`hg.Annotation` object (read-only)

Control the display of areaseries objects in legends. Specifies whether this areaseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the areaseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
`on`	Include the areaseries object in a legend as one entry, but not its children objects
`off`	Do not include the areaseries or its children in a legend (default)
`children`	Include only the children of the areaseries as separate entries in the legend

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the IconDisplayStyle Property

See "Controlling Legends" for more information and examples.

`BaseValue`

double: y-axis value

Value where filled area base is drawn. Specify the value along the y-axis at which the MATLAB software draws the baseline of the bottommost filled area. The default is `0`.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`
string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`Children`

array of graphics object handles

Children of this object. The handle of a patch object that is the child of this object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`

`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`CreateFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y,'CreateFcn',@CallbackFcn)
```

where *@CallbackFcn* is a function handle that references the callback function and *graphicfcn* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`

string

String used by legend. The `legend` function uses the `DisplayName` property to label the areaseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EdgeColor`

`{[0 0 0]} | none | ColorSpec`

Color of line separating filled areas. You can set the color of the edges of filled areas to a three-element RGB vector or one of the MATLAB predefined names, including the string `none`. The default value is `[0 0 0]` (`black`). See the `ColorSpec` reference page for more information on specifying color.

`EraseMode`

`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated

sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceColor`
`{flat} | none | ColorSpec`

Color of filled areas.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- `none` — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.
- `flat` — The object uses the figure `colormap` to determine the color of the filled areas.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`

`{on} | off`

Selectable by mouse click. Determines whether this object can become the current object (as returned by the gco command and the figure CurrentObject property) as a result of a mouse click on the objects that compose the area graph. If HitTest is off, clicking this object selects the object below it (which is usually the axes containing it).

HitTestArea
on | {off}

Select areaseries object on filled area or extent of graph. Select plot objects by:

- Clicking an area (default).
- Clicking anywhere in the extent of the area plot.

When HitTestArea is off, you must click an area to select the areaseries object. When HitTestArea is on, you can select the areaseries object by clicking anywhere within the extent of the area graph (that is, anywhere within a rectangle that encloses all the area plots).

Interruptible
off | {on}

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the Interruptible property affects only the callbacks for theButtonDownFcn property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the Interruptible property of the object of the *running* callback.

When the Interruptible property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

`LineStyle`

`{-} | -- | : | -. | none`

Line style of edges of filled areas.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

`LineWidth`

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is 0.5 points.

`Parent`

handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`

on | {off}

Object selection state. When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Object highlighted when selected.

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`Tag`
string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an areaseries object and set the `Tag` property.

```
t = area(Y,'Tag','area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

`Type`
string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For areaseries objects, `Type` is '`hggroup`'.

The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`
handle of uicontextmenu object

Associate context menu with object. Handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

`UserData`
array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Visibility of object and its children.

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

`XData`
vector | matrix

x-axis values for graph. The *x*-axis values for graphs are specified by the `X` input argument. If `XData` is a vector, `length(XData)` must equal `length(YData)` and must be monotonic. If `XData` is a

matrix, `size(XData)` must equal `size(YData)` and each column must be monotonic.

You can use `XData` to define meaningful coordinates for an underlying surface whose topography is being mapped. See “Changing the Offset of a Contour” for more information.

`XDataMode`

`{auto} | manual`

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the `X` input argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

`XDataSource`

MATLAB variable, as a string

Link `XData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h,'XDataSource','xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object’s `XDataSource` does not change the object’s `XData` values, but you can use `refreshdata` to force an update of the object’s data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`

vector | matrix

Area plot data. `YData` contains the data plotted as filled areas (the `Y` input argument). If `YData` is a vector, `area` creates a single filled area whose upper boundary is defined by the elements of `YData`. If `YData` is a matrix, `area` creates one filled area per column, stacking each on the previous plot. The default value is the `Y` input argument.

The input argument `Y` in the `area` function calling syntax assigns values to `YData`.

`YDataSource`

MATLAB variable, as a string

Link `YData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h,'YDataSource','Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

How To

- "Bar and Area Graphs"
- "Plot Objects"
- "Setting Default Property Values"

Purpose

Apply function to each element of array

Syntax

```
[B1,...,Bm] = arrayfun(func,A1,...,An)
[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value)
```

Description

`[B1,...,Bm] = arrayfun(func,A1,...,An)` calls the function specified by function handle `func` and passes elements from arrays `A1,...,An`, where `n` is the number of inputs to function `func`. Output arrays `B1,...,Bm`, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The `i`th iteration corresponds to the syntax `[B1(i),...,Bm(i)] = func(A1{i},...,An{i})`. The `arrayfun` function does not perform the calls to function `func` in a specific order.

`[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

Input Arguments

func

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

A1,...,An

Arrays that contain the `n` inputs required for function `func`. Each array must have the same dimensions. Arrays can be numeric, character, logical, cell, structure, or user-defined object arrays.

If any input `A` is a user-defined object array, and you overloaded the `subsref` or `size` methods, `arrayfun` requires that:

- The `size` method returns an array of type `double`.
- The object array supports linear indexing.

- The product of the sizes returned by the `size` method does not exceed the limit of the array, as defined by linear indexing into the array.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'UniformOutput'

Logical value, as follows:

`true (1)`	Indicates that for all inputs, each output from function `func` is a cell array or a scalar value that is always of the same type. The `arrayfun` function combines the outputs in arrays `B1,...,Bm`, where `m` is the number of function outputs. Each output array is of the same type as the individual function outputs.
`false (0)`	Requests that the `arrayfun` function combine the outputs into cell arrays `B1,...,Bm`. The outputs of function `func` can be of any size or type.

Default: `true`

'ErrorHandler'

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

`identifier`	Error identifier.
`message`	Error message text.
`index`	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

Output Arguments

B1,...,Bm

Arrays that collect the `m` outputs from function `func`. Each array `B` is the same size as each of the inputs `A1,...,An`.

Function `func` can return output arguments of different classes. However, if `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

Examples

To run the examples in this section, create a nonscalar structure array with arrays of different sizes in field `f1`.

```
s(1).f1 = rand(3, 6);
s(2).f1 = magic(12);
s(3).f1 = ones(5, 10);
```

Count the number of elements in each `f1` field.

```
counts = arrayfun(@(x) numel(x.f1), s)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
counts =
```

```
    18   144    50
```

Compute the size of each array in the `f1` fields.

```
[nrows, ncols] = arrayfun(@(x) size(x.f1), s)
```

This code returns

```
nrows =
     3    12     5
ncols =
     6    12    10
```

Compute the mean of each column in the `f1` fields of `s`. Because the output is nonscalar, set `UniformOutput` to `false`.

```
averages = arrayfun(@(x) mean(x.f1), s, 'UniformOutput', false)
```

This code returns

```
averages =
    [1x6 double]    [1x12 double]    [1x10 double]
```

Create additional nonscalar structures `t` and `u`, and test for equality between the arrays in fields `f1` across structures `s`, `t`, and `u`.

```
t = s;  t(1).f1(:)=0;
u = s;  u(2).f1(:)=0;

same = arrayfun(@(x,y,z) isequal(x.f1, y.f1, z.f1), s, t, u)
```

This code returns

```
same =
     0     0     1
```

Tutorials

- "Anonymous Functions"

FTP.ascii

Purpose

Set FTP transfer type to ASCII

Syntax

```
ascii(ftpobj)
```

Description

`ascii(ftpobj)` sets the download and upload FTP mode to ASCII, which converts new line characters. Use this method only for text files, including HTML pages and Rich Text Format (RTF) files.

Input Arguments

ftpobj

FTP object created by `ftp`.

Examples

Connect to the MathWorks FTP server, and switch from binary (default) to ASCII mode:

```
mw=ftp('ftp.mathworks.com');
ascii(mw)
```

See Also

`binary` | `ftp`

Purpose

Inverse secant in radians

Syntax

```
Y = asec(X)
```

Description

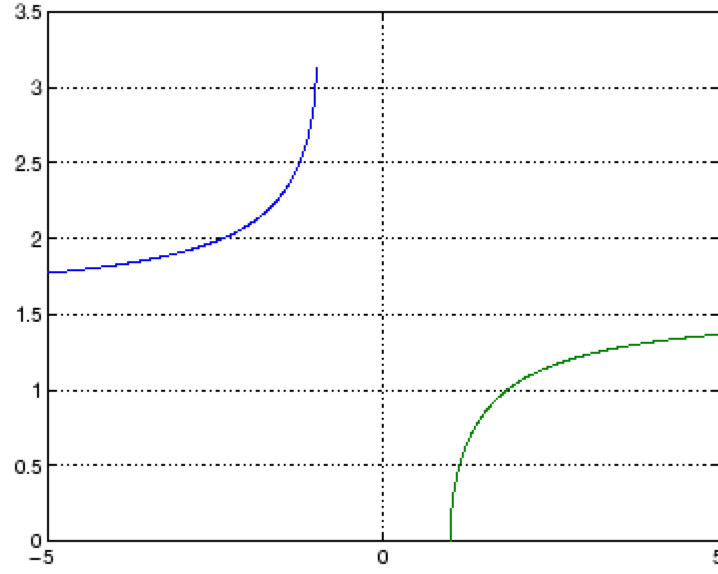
`Y = asec(X)` returns the inverse secant (arcsecant) for each element of `X`.

The `asec` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse secant over the domains $1 \le x \le 5$ and $-5 \le x \le -1$.

```
x1 = -5:0.01:-1;
x2 = 1:0.01:5;
plot(x1,asec(x1),x2,asec(x2)), grid on
```



See Also

`asecd` | `asech` | `sec`

asecd

Purpose

Inverse secant in degrees

Syntax

```
Y = asecd(X)
```

Description

`Y = asecd(X)` returns the inverse secant of the elements of `X` in degrees.

Input Arguments

X - Secant of angle

scalar value | vector | matrix | N-D array

Secant of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `asecd` operation is element-wise when `X` is nonscalar.

Data Types
`single | double`
Complex Number Support: Yes

Output Arguments

Y - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Inverse Secant of Vector

```
x = [10 1 Inf];
y = asecd(x)
```

```
y =

   84.2608         0   90.0000
```

The `asecd` operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Secant of Complex Value

```
asecd(1+i)
```

```
ans =

  64.0864 +30.4033i
```

See Also

secd | asec | sec

asech

Purpose

Inverse hyperbolic secant

Syntax

```
Y = asech(X)
```

Description

`Y = asech(X)` returns the inverse hyperbolic secant for each element of `X`.

The `asech` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic secant over the domain $0.01 \le x \le 1$.

```
x = 0.01:0.001:1;
plot(x,asech(x)), grid on
```

`asec` | `sech` | `asinh` | `acosh`

Purpose Inverse sine in radians

Syntax

```
Y = asin(X)
```

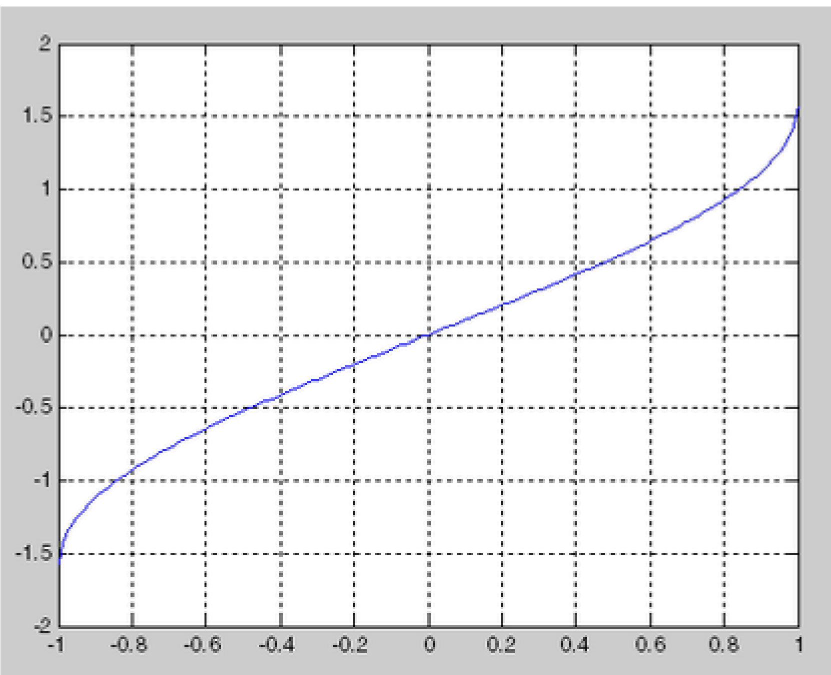
Description `Y = asin(X)` returns the inverse sine (arcsine) for each element of `X`. The `asin` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians. For real elements of `X` in the domain `[-1,1]`, `asin(X)` is in the range

$$\left[-\frac{\pi}{2},\frac{\pi}{2}\right].$$

For real elements of `x` outside the range `[-1,1]`, `asin(X)` is complex.

Examples Graph the inverse sine function over the domain $-1 \leq x \leq 1$.

```
x = -1:.01:1;
plot(x,asin(x)), grid on
```



See Also

`asind` | `sin` | `sind`

asind

Purpose

Inverse sine in degrees

Syntax

```
Y = asind(X)
```

Description

`Y = asind(X)` returns the inverse sine of the elements of `X` in degrees.

Input Arguments

X - Sine of angle
scalar value | vector | matrix | N-D array

Sine of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `asind` operation is element-wise when `X` is nonscalar.

Data Types
`single | double`
Complex Number Support: Yes

Output Arguments

Y - Angle in degrees
scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Inverse sine of one

Show that the inverse sine of 1 is exactly 90°.

```
asind(1)
```

```
ans =

    90
```

Round Trip Calculation for Complex Angles

Show that inverse sine, followed by sine, returns the original values of `X`.

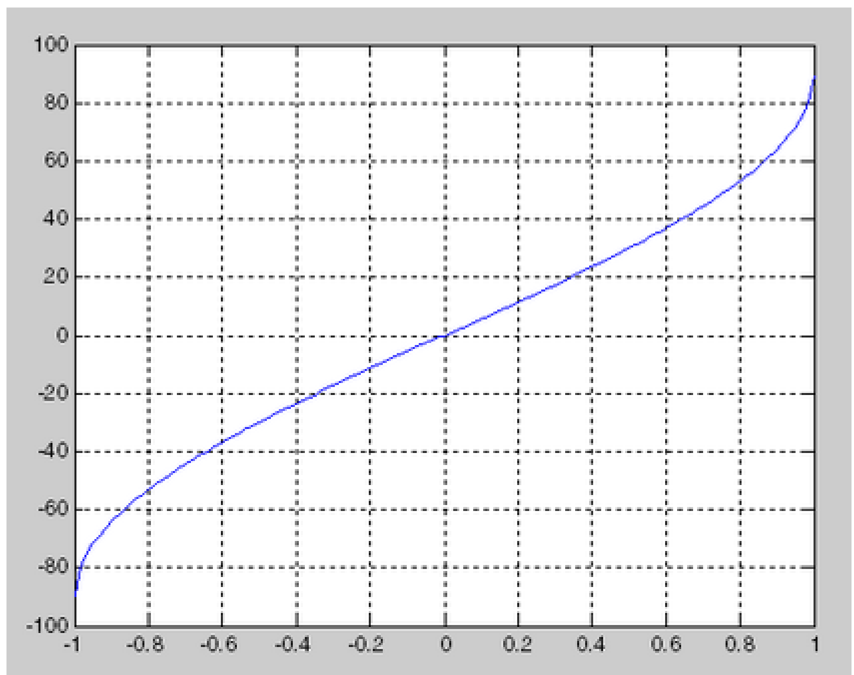
```
sind(asind([2 3]))
```

```
ans =

    2.0000    3.0000
```

Graph inverse sine over the interval [-1,1]

```
x = -1:.01:1;
plot(x,asind(x))
grid on
```



See Also

`sind` | `sin` | `asin`

Purpose

Inverse hyperbolic sine

Syntax

```
Y = asinh(X)
```

Description

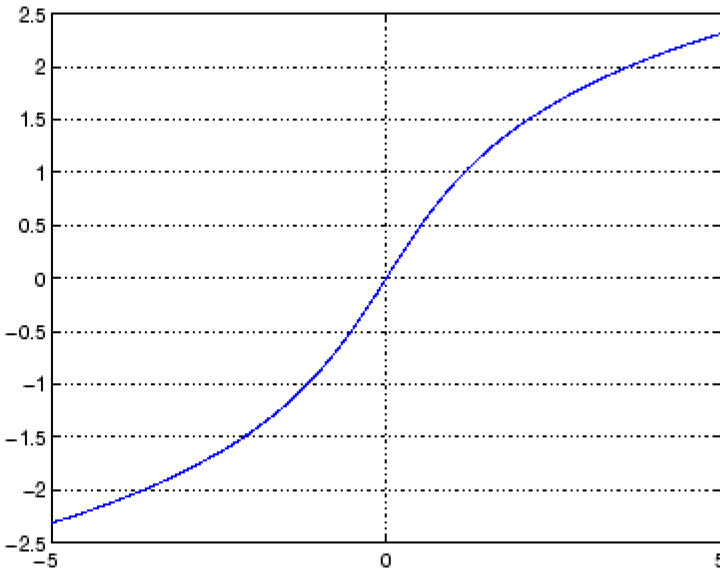
`Y = asinh(X)` returns the inverse hyperbolic sine for each element of `X`.

The `asinh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic sine function over the domain $-5 \leq x \leq 5$.

```
x = -5:.01:5;
plot(x,asinh(x)), grid on
```



See Also

`asin` | `sinh` | `acosh`

assert

Purpose

Generate error when condition is violated

Syntax

```
assert(expression)
assert(expression, 'msgString')
assert(expression, 'msgString', value1, value2, ...)
assert(expression, 'msgIdent', 'msgString', value1, value2,
   ...)
```

Description

`assert(expression)` evaluates *expression* and, if it is `false`, generates an exception.

`assert(expression, 'msgString')` evaluates *expression* and, if it is `false`, generates an exception and displays the string contained in *msgString*. This string must be enclosed in single quotation marks. When *msgString* is the last input to `assert`, the MATLAB software displays it literally, without performing any substitutions on the characters in *msgString*.

`assert(expression, 'msgString', value1, value2, ...)` evaluates *expression* and, if it is `false`, generates an exception and displays the formatted string contained in *msgString*. The *msgString* string can include escape sequences such as `\t` or `\n`, as well as any of the C language conversion operators supported by the `sprintf` function (e.g., `%s` or `%d`). Additional arguments *value1*, *value2*, etc. provide values that correspond to and replace the conversion operators.

See "Formatting Strings" in the MATLAB Programming Fundamentals documentation for more detailed information on using string formatting commands.

MATLAB makes substitutions for escape sequences and conversion operators in *msgString* in the same way that it does for the `sprintf` function.

`assert(expression, 'msgIdent', 'msgString', value1, value2, ...)` evaluates *expression* and, if it is `false`, generates an exception and displays the formatted string *msgString*, also tagging the error with the message identifier *msgIdent*. See "Message Identifiers" in the MATLAB Programming Fundamentals documentation for information.

Examples

This function tests input arguments using assert:

```
function write2file(varargin)
min_inputs = 3;
assert(nargin >= min_inputs, ...
  'You must call function %s with at least %d inputs', ...
  mfilename, min_inputs)

infile = varargin{1};
assert(ischar(infile), ...
      'First argument must be a filename.')
assert(exist(infile)~=0, 'File %s not found.', infile)

fid = fopen(infile, 'w');
assert(fid > 0, 'Cannot open file %s for writing', infile)

fwrite(fid, varargin{2}, varargin{3});
```

assignin

Purpose

Assign value to variable in specified workspace

Syntax

```
assignin(ws, 'var', val)
```

Description

`assignin(ws, 'var', val)` assigns the value `val` to the variable *var* in the workspace `ws`. The *var* input must be the array name only; it cannot contain array indices. If *var* does not exist in the specified workspace, `assignin` creates it. `ws` can have a value of `'base'` or `'caller'` to denote the MATLAB base workspace or the workspace of the caller function.

The `assignin` function is particularly useful for these tasks:

- Exporting data from a function to the MATLAB workspace
- Within a function, changing the value of a variable that is defined in the workspace of the caller function (such as a variable in the function argument list)

Tips

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line. For more information, see “Base and Function Workspaces”.

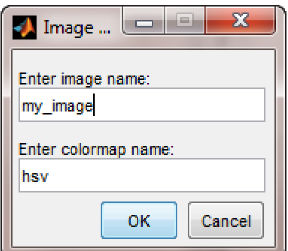
Examples

Example 1

This example creates a dialog box for the image display function, prompting a user for an image name and a colormap name. The `assignin` function is used to export the user-entered values to the MATLAB workspace variables `imfile` and `cmap`.

```
prompt = {'Enter image name:', 'Enter colormap name:'};
title = 'Image display - assignin example';
lines = 1;
def = {'my_image', 'hsv'};
answer = inputdlg(prompt, title, lines, def);
```

```
assignin('base', 'imfile', answer{1});
assignin('base', 'cmap', answer{2});
```



Example 2

`assignin` does not assign to specific elements of an array. The following statement generates an error:

```
X = 1:8;
assignin('base', 'X(3:5)', -1);
```

However, you can use the `evalin` function to do this:

```
evalin('base','X(3:5) = -1')
X =
     1     2    -1    -1    -1     6     7     8
```

See Also

`evalin`

Purpose Inverse tangent in radians

Syntax

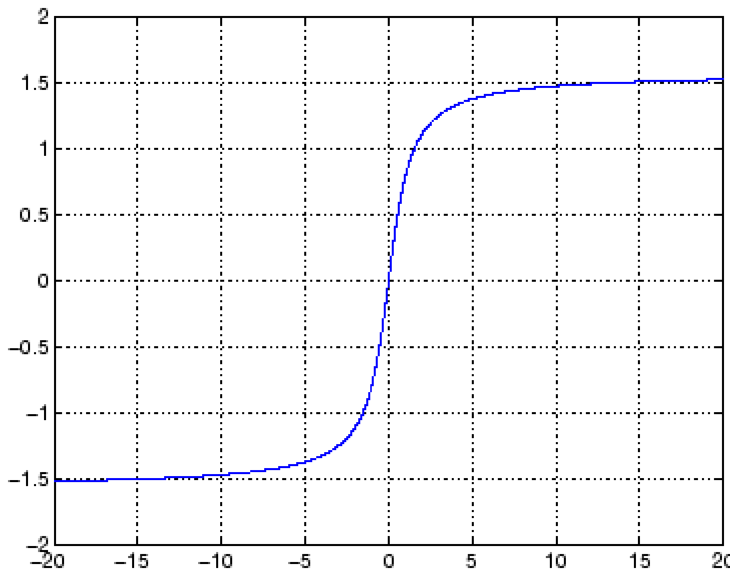
```
Y = atan(X)
```

Description `Y = atan(X)` returns the inverse tangent (arctangent) for each element of `X`. For real elements of `X`, `atan(X)` is in the range $[-\pi/2, \pi/2]$.

The `atan` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples Graph the inverse tangent function over the domain $-20 \le x \le 20$.

```
x = -20:0.01:20;
plot(x,atan(x)), grid on
```



See Also `atan2` | `tan` | `atand` | `atanh`

Purpose

Four-quadrant inverse tangent

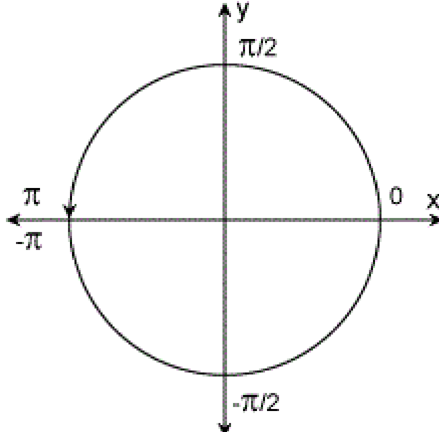
Syntax

```
P = atan2(Y,X)
```

Description

`P = atan2(Y,X)` returns an array `P` the same size as `X` and `Y` containing the element-by-element, four-quadrant inverse tangent (arctangent) of `Y` and `X`, which must be real.

Elements of `P` lie in the closed interval `[-pi,pi]`, where `pi` is the MATLAB floating-point representation of π. `atan` uses `sign(Y)` and `sign(X)` to determine the specific quadrant.



`atan2(Y,X)` contrasts with `atan(Y/X)`, whose results are limited to the interval $[-\pi/2, \pi/2]$, or the right side of this diagram.

Examples

Any complex number $z = x + iy$ is converted to polar coordinates with

```
r = abs(z)
theta = atan2(imag(z),real(z))
```

For example,

```
z = 4 + 3i;
```

```
r = abs(z)
theta = atan2(imag(z),real(z))

r =
     5

theta =
    0.6435
```

This is a common operation, so MATLAB software provides a function, `angle(z)`, that computes `theta = atan2(imag(z),real(z))`.

To convert back to the original complex number

```
z = r * exp(i * theta)
z =

   4.0000 + 3.0000i
```

See Also

`angle` | `atan` | `atanh` | `atan2d`

Purpose

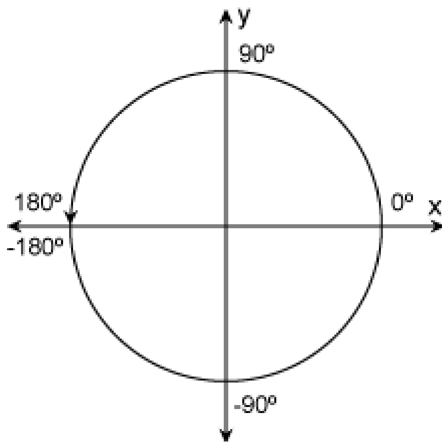
Four-quadrant inverse tangent in degrees

Syntax

```
D = atan2d(Y,X)
```

Description

`D = atan2d(Y,X)` returns the four-quadrant inverse tangent of points specified in the *x*-*y* plane. The result, `D`, is expressed in degrees.



Input Arguments

Y - *y*-coordinates

scalar value | vector | matrix | N-D array

y-coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

Data Types

`single` | `double`

X - *x*-coordinates

scalar value | vector | matrix | N-D array

x-coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

Data Types
`single` | `double`

Output Arguments

D - Angles in degrees
scalar value | vector | matrix | N-D array

Angles in degrees, returned as a scalar, vector, matrix, or N-D array. These angles correspond to the points defined by `X` and `Y`, and they lie in the closed interval [–180,180].

Examples

Inverse Tangent of Four Points on the Unit Circle

```
x = [1 0 -1 0];
y = [0 1 0 -1];
d = atan2d(y,x)

d =

     0    90   180   -90
```

Tips

- Use `atand(Y/X)` for the inverse tangent with results on the interval [–90, 90].

See Also

`atan2` | `atan` | `atand` | `tan` | `tand`

Purpose

Inverse tangent in degrees

Syntax

```
Y = atand(X)
```

Description

`Y = atand(X)` returns the inverse tangent of the elements of `X` in degrees.

Input Arguments

X - Tangent of angle

scalar value | vector | matrix | N-D array

Tangent of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `atand` operation is element-wise when `X` is nonscalar.

Data Types

`single` | `double`

Complex Number Support: Yes

Output Arguments

Y - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Inverse Tangent of Vector

```
x = [-50 -20 0 20 50];
y = atand(x)
```

```
y =

  -88.8542   -87.1376         0    87.1376    88.8542
```

The `atand` operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Tangent of Complex Value

```
atand(10+i)
```

```
ans =

  84.3450 + 0.5618i
```

tand | atan | tan | atan2d

Purpose Inverse hyperbolic tangent

Syntax

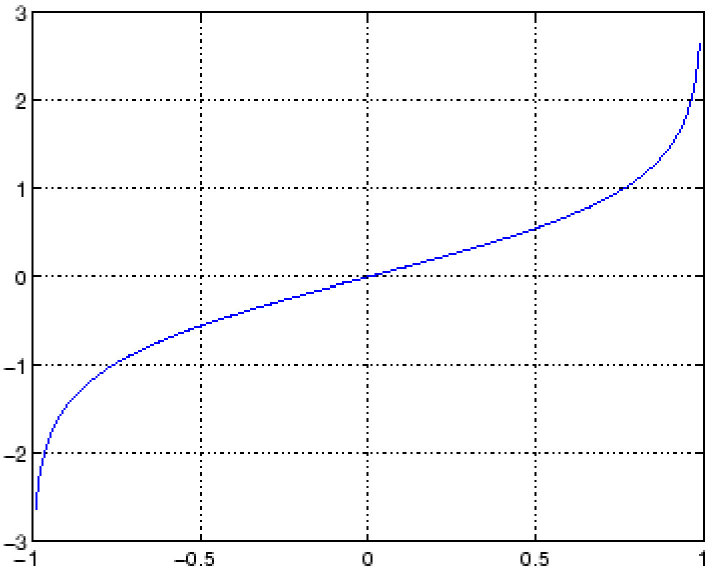
```
Y = atanh(X)
```

Description The `atanh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = atanh(X)` returns the inverse hyperbolic tangent for each element of `X`.

Examples Graph the inverse hyperbolic tangent function over the domain $-1 < x < 1$.

```
x = -0.99:0.01:0.99;
plot(x,atanh(x)), grid on
```



See Also `atan2` | `atan` | `tanh` | `asinh` | `acosh` | `tan`

Purpose

Information about audio device

Syntax

```
devinfo = audiodevinfo
devs = audiodevinfo(IO)
name = audiodevinfo(IO, ID)
ID = audiodevinfo(IO, name)
DriverVersion = audiodevinfo(IO, ID, 'DriverVersion')
ID = audiodevinfo(IO, rate, bits, chans)
doesSupport = audiodevinfo(IO, ID, rate, bits, chans)
```

Description

`devinfo = audiodevinfo` returns a structure, `devinfo`, containing two fields, `input` and `output`. Each field is an array of structures, with each structure containing information about one of the audio input or output devices on the system. The individual device structure fields are:

- `Name` — A string indicating the name of the device.
- `DriverVersion` — A string indicating the type of the installed device driver.
- `ID` — The ID of the device.

`devs = audiodevinfo(IO)` returns the number of input or output audio devices on the system. Use an `IO` value of 1 to indicate input, and an `IO` value of 0 to indicate output.

`name = audiodevinfo(IO, ID)` returns the name of the input or output audio device identified by device `ID`.

`ID = audiodevinfo(IO, name)` returns the device `ID` of the input or output audio device identified by the given `name` (partial matching, case sensitive). If no audio device is found with the given name, -1 is returned.

`DriverVersion = audiodevinfo(IO, ID, 'DriverVersion')` returns a string indicating the type of the specified audio input or output device.

`ID = audiodevinfo(IO, rate, bits, chans)` returns the device `ID` of the first input or output device that supports the sample rate, number of bits, and number of channels specified by the values of `rate`, `bits`, and `chans`, respectively. If no supporting device is found, -1 is returned.

`doesSupport = audiodevinfo(IO, ID, rate, bits, chans)` returns 1 or 0 for whether or not the input or output audio device specified by `ID` can support the given sample rate, number of bits, and number of channels.

See Also

`audioplayer` | `audiorecorder`

audioplayer

Purpose

Create object for playing audio

Syntax

```
player = audioplayer(Y,Fs)
player = audioplayer(Y,Fs,nBits)
player = audioplayer(Y,Fs,nBits,ID)
player = audioplayer(recorder)
player = audioplayer(recorder,ID)
```

Description

`player = audioplayer(Y,Fs)` creates an `audioplayer` object for signal `Y`, using sample rate `Fs`. The function returns a handle to the `audioplayer` object, `player`.

`player = audioplayer(Y,Fs,nBits)` uses `nBits` bits per sample for signal `Y`.

`player = audioplayer(Y,Fs,nBits,ID)` uses the audio device identified by `ID` for output.

`player = audioplayer(recorder)` creates an `audioplayer` object using audio recorder object `recorder`.

`player = audioplayer(recorder,ID)` creates an object from `recorder` that uses the audio device identified by`ID` for output.

Input Arguments

Y

Audio signal represented by a vector or two-dimensional array containing `single`, `double`, `int8`, `uint8`, or `int16` values.

The value range of the input sample depends on the data type. The following table lists these ranges.

Data Type	Sample Value Range
`int8`	-128 to 127
`uint8`	0 to 255
`int16`	-32768 to 32767

Data Type	Sample Value Range
`single`	-1 to 1
`double`	-1 to 1

Fs

Sampling rate in Hz. Valid values depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, 44100, 48000, and 96000 Hz.

nBits

Bits per sample. Specify only when signal `Y` is represented by floating-point values. Valid values depend on the audio hardware installed: `8`, `16`, or `24`.

Default: `16`

ID

Device identifier. To obtain the ID of a device, use the `audiodevinfo` function.

Default: `-1` (default device)

recorder

Audio recorder object created by `audiorecorder`.

Methods

Note When calling any method, include the `audioplayer` object name using function syntax, such as `stop(`*`player`*`)`.

`get`	Query properties of `audioplayer` object.
`isplaying`	Query whether playback is in progress: returns `true` or `false`.

`pause`	Pause playback.
`play`	Play audio from beginning to end.
`playblocking`	Play, and do not return control until playback completes.
`resume`	Restart playback from paused position.
`set`	Set properties of `audioplayer` object.
`stop`	Stop playback.

See the reference pages for `get`, `play`, `playblocking`, and `set` for additional syntax options.

Properties

`BitsPerSample`	Number of bits per sample. (Read-only)
`CurrentSample`	Current sample that the audio output device is playing. If the device is not playing, `CurrentSample` is the next sample to play with `play` or `resume`. (Read-only)
`DeviceID`	Identifier for audio device. (Read-only)
`NumberOfChannels`	Number of audio channels. (Read-only)
`Running`	Status of the audio player: `'on'` or `'off'`. (Read-only)
`SampleRate`	Sampling frequency in Hz.
`TotalSamples`	Total length of the audio data in samples. (Read-only)
`Tag`	String that labels the object.
`Type`	Name of the class: `'audioplayer'`. (Read-only)
`UserData`	Any type of additional data to store with the object.

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audioplayer` object and an *`event`* structure.

`StartFcn`	Function to execute one time when playback starts.
`StopFcn`	Function to execute one time when playback stops.
`TimerFcn`	Function to execute repeatedly during playback. To specify time intervals for the repetitions, use the `TimerPeriod` property.
`TimerPeriod`	Time in seconds between `TimerFcn` callbacks. Default: `.05`

Examples

Load and play a sample audio file of Handel's "Hallelujah Chorus:"

```
load handel;
player = audioplayer(y, Fs);
play(player);
```

See Also

`audiodevinfo` | `audiorecorder` | `sound`

How To

- "Characteristics of Audio Files"
- "Play Audio"

Purpose

Create object for recording audio

Syntax

```
recorder = audiorecorder
recorder = audiorecorder(Fs,nBits,nChannels)
recorder = audiorecorder(Fs,nBits,nChannels,ID)
```

Description

`recorder = audiorecorder` creates an 8000 Hz, 8-bit, 1-channel `audiorecorder` object.

`recorder = audiorecorder(Fs,nBits,nChannels)` sets the sample rate `Fs` (in Hz), the sample size `nBits`, and the number of channels `nChannels`.

`recorder = audiorecorder(Fs,nBits,nChannels,ID)` sets the audio input device to the device specified by `ID`.

Tips

- To use an `audiorecorder` object, your system must have a properly installed and configured sound card.
- `audiorecorder` is not intended for long, high-sample-rate recording. `audiorecorder` uses system memory for storage and does not use disk buffering. When you attempt a large recording, your MATLAB performance sometimes degrades over time.

Input Arguments

Fs

Sampling rate in Hz. Valid values depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, 44100, 48000, and 96000 Hz.

Default: 8000

nBits

Bits per sample. Valid values depend on the audio hardware installed: `8`, `16`, or `24`.

Default: 8

nChannels

The number of channels: `1` (mono) or `2` (stereo).

Default: 1

ID

Device identifier. To obtain the ID of a device, use the `audiodevinfo` function.

Default: `-1` (default device)

Methods

Note When calling any method, include the `audiorecorder` object name using function syntax, such as `stop(`*`recorder`*`)`.

`get`	Query properties of `audiorecorder` object.
`getaudiodata`	Create an array that stores the recorded signal values.
`getplayer`	Create an `audioplayer` object.
`isrecording`	Query whether recording is in progress: returns `true` or `false`.
`pause`	Pause recording.
`play`	Play recorded audio. This method returns an `audioplayer` object.
`record`	Start recording.
`recordblocking`	Record, and do not return control until recording completes. This method requires a second input for the length of the recording in seconds: `recordblocking(recorder,length)`
`resume`	Restart recording from paused position.
`set`	Set properties of `audiorecorder` object.
`stop`	Stop recording.

See the reference pages for `get`, `getaudiodata`, `play`, `record`, `recordblocking`, and `set` for additional syntax options.

Properties

`BitsPerSample`	Number of bits per sample. (Read-only)
`CurrentSample`	Current sample that the audio input device is recording. If the device is not recording, `CurrentSample` is the next sample to record with `record` or `resume`. (Read-only)
`DeviceID`	Identifier for audio device. (Read-only)
`NumberOfChannels`	Number of audio channels. (Read-only)
`Running`	Status of the audio recorder: `'on'` or `'off'`. (Read-only)
`SampleRate`	Sampling frequency in Hz. (Read-only)
`TotalSamples`	Total length of the audio data in samples. (Read-only)
`Tag`	String that labels the object.
`Type`	Name of the class: `'audiorecorder'`. (Read-only)
`UserData`	Any type of additional data to store with the object.

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audiorecorder` object and an *`event`* structure.

`StartFcn`	Function to execute one time when recording starts.
`StopFcn`	Function to execute one time when recording stops.

`TimerFcn`	Function to execute repeatedly during recording. To specify time intervals for the repetitions, use the `TimerPeriod` property.
`TimerPeriod`	Time in seconds between `TimerFcn` callbacks. Default: `.05`

`audiorecorder` ignores any specified values for these properties, which will be removed in a future release.

`BufferLength`	Length of buffer in seconds.
`NumberOfBuffers`	Number of buffers.

Examples

Create an `audiorecorder` object for CD-quality audio in stereo, and view its properties:

```
recObj = audiorecorder(44100, 16, 2);
get(recObj)
```

Collect a sample of your speech with a microphone, and plot the signal data:

```
% Record your voice for 5 seconds.
recObj = audiorecorder;
disp('Start speaking.')
recordblocking(recObj, 5);
disp('End of Recording.');

% Play back the recording.
play(recObj);

% Store data in double-precision array.
myRecording = getaudiodata(recObj);

% Plot the waveform.
plot(myRecording);
```

See Also

`audiodevinfo` | `audioplayer` | `sound`

How To

- "Characteristics of Audio Files"
- "Record Audio"
- "Recording or Playing Audio within a Function"

Purpose

Information about NeXT/SUN (`.au`) sound file

Note `aufinfo` will be removed in a future release. Use `audioinfo` instead.

Syntax

```
[m d] = aufinfo(aufile)
```

Description

`[m d] = aufinfo(aufile)` returns information about the contents of the AU sound file specified by the string `aufile`.

`m` is the string `'Sound (AU) file'`, if `filename` is an AU file. Otherwise, it contains an empty string (`''`).

`d` is a string that reports the number of samples in the file and the number of channels of audio data. If `filename` is not an AU file, it contains the string `'Not an AU file'`.

See Also

`audioread` | `audioinfo`

auread

Purpose

Read NeXT/SUN (`.au`) sound file

Note `auread` will be removed in a future release. Use `audioread` instead.

Syntax

```
y = auread(aufile)
[y,Fs] = auread(aufile)
[y,Fs,nbits] = auread(aufile)
[___] = auread(aufile,N)
[___] = auread(aufile,[N1 N2])
siz = auread(aufile,'size')
```

Description

`y = auread(aufile)` loads a sound file specified by the string `aufile`, returning the sampled data in `y`. The `.au` extension is appended if no extension is given. Amplitude values are in the range `[-1,+1]`. `auread` supports multichannel data in the following formats:

- 8-bit mu-law
- 8-, 16-, and 32-bit linear
- Floating-point

`[y,Fs] = auread(aufile)` returns the sample rate (`Fs`) in Hertz used to encode the data in the file.

`[y,Fs,nbits] = auread(aufile)` returns the number of bits per sample (`nbits`).

`[___] = auread(aufile,N)` returns only the first `N` samples from each channel in the file.

`[___] = auread(aufile,[N1 N2])` returns only samples `N1` through `N2` from each channel in the file.

`siz = auread(aufile,'size')` returns the size of the audio data contained in the file in place of the actual audio data, returning the vector `siz = [samples channels]`.

Examples

Create a sound file from the example file `handel.mat`, and read portions of the file back into MATLAB:

```
% Create .au file in current folder.
load handel.mat

hfile = 'handel.au';
auwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits] = auread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = auread(hfile, nsamples);
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = auread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = auread(hfile, [startpos endpos]);
sound(y3, Fs);
```

See Also

`audiowrite` | `audioinfo` | `audioplayer` | `audiorecorder` | `sound` | `audioread`

auwrite

Purpose

Write NeXT/SUN (`.au`) sound file

Note `auwrite` will be removed in a future release.

Syntax

```
auwrite(y,aufile)
auwrite(y,Fs,aufile)
auwrite(y,Fs,N,aufile)
auwrite(y,Fs,N,method,aufile)
```

Description

`auwrite(y,aufile)` writes a sound file specified by the string *`aufile`*. The data should be arranged with one channel per column. Amplitude values outside the range `[-1,+1]` are clipped prior to writing. `auwrite` supports multichannel data for 8-bit mu-law and 8- and 16-bit linear formats.

`auwrite(y,Fs,aufile)` specifies the sample rate of the data in Hertz.

`auwrite(y,Fs,N,aufile)` selects the number of bits in the encoder. Allowable settings are `N = 8` and `N = 16`.

`auwrite(y,Fs,N,method,aufile)` allows selection of the encoding method, which can be either `'mu'` or `'linear'`. Note that mu-law files must be 8-bit. By default, `method = 'mu'`.

See Also

`audioread` | `audiowrite`

Purpose

Create new Audio/Video Interleaved (AVI) file

Note `avifile` will be removed in a future release. Use `VideoWriter` instead.

Syntax

```
aviobj = avifile(filename)
avifile(filename, ParameterName, ParameterValue)
```

Description

`aviobj = avifile(filename)` creates an `avifile` object, giving it the name specified in *`filename`*, using default values for all `avifile` object properties. If *`filename`* does not include an extension, `avifile` appends `.avi` to the file name. AVI is a file format for storing audio and video data.

`avifile` returns a handle to an AVI file object *`aviobj`*. Use this object to refer to the AVI file in other functions. An AVI file object supports properties and methods that control aspects of the AVI file created.

`aviobj = avifile(filename, ParameterName, ParameterValue)` accepts one or more comma-separated parameter name/value pairs. Set parameter values before any calls to `addframe`. The following table lists the available parameters and values.

Parameter Name	Value	Default
`'colormap'`	An *m*-by-3 matrix defining the colormap for indexed AVI movies, where *m* is no more than 256 (236 for `Indeo` compression). Valid only when the `'compression'` is `'MSVC'`, `'RLE'`, or `'None'`.	No default
`'compression'`	A text string specifying the compression codec to use. To create an uncompressed file, specify a value of `'None'`.	`'Indeo5'` on Windows systems.

Parameter Name	Value	Default
	On UNIX® operating systems, the only valid value is `'None'`. On Windows systems, valid values include: • `'MSVC'` • `'RLE'` • `'Cinepak'` on 32-bit systems. • `'Indeo3'` or `'Indeo5'` on 32-bit Windows XP systems. Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.	`'None'` on UNIX systems.
`'fps'`	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
`'keyframe'`	For compressors that support temporal compression, the number of key frames per second.	2.1429 key frames per second
`'quality'`	A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes. Valid only for compressed movies.	75
`'videoname'`	A descriptive name for the video stream, no more than 64 characters.	*`filename`*

Tips

- On some Windows systems, including all 64-bit systems, the default Indeo® 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer®. Consider specifying a `compression` value of `'None'`.
- `avifile` cannot write files larger than 2 GB.
- You can use dot notation to set `avifile` object properties. For example, set the `quality` property to 100:

  ```
  aviobj = avifile('myavifile');
  aviobj.quality = 100;
  ```

  All property names of an `avifile` object are the same as the parameter names, except for the `keyframe` parameter, which corresponds to the `KeyFramePerSec` property. For example, change `keyframe` to `2.5`:

  ```
  aviobj.KeyFramePerSec = 2.5;
  ```

Examples

Create the AVI file `example.avi`:

```
aviobj = avifile('example.avi','compression','None');

t = linspace(0,2.5*pi,40);
fact = 10*sin(t);
fig=figure;
[x,y,z] = peaks;
for k=1:length(fact)
    h = surf(x,y,fact(k)*z);
    axis([-3 3 -3 3 -80 80])
    axis off
    caxis([-90 90])
```

```
    F = getframe(fig);
    aviobj = addframe(aviobj,F);
end
close(fig);
aviobj = close(aviobj);
```

Alternatives

Use `VideoWriter` rather than `avifile` to create AVI files. `VideoWriter` supports files larger than 2 GB, and by default, creates files with Motion JPEG compression, which all platforms support.

`VideoWriter` | `addframe (avifile)` | `close (avifile)` | `movie2avi`

Purpose

Information about Audio/Video Interleaved (AVI) file

Note `aviinfo` will be removed in a future release. Use `VideoReader` and the `get` method instead.

Syntax

```
fileinfo = aviinfo(filename)
```

Description

`fileinfo` `= aviinfo(`*`filename`*`)` returns a structure whose fields contain information about the AVI file specified in the string *`filename`*. If *`filename`* does not include an extension, then `.avi` is used. The file must be in the current working directory or in a directory on the MATLAB path.

The set of fields in the *`fileinfo`* structure is shown below.

Field Name	Description
`AudioFormat`	String containing the name of the format used to store the audio data, if audio data is present
`AudioRate`	Integer indicating the sample rate in Hertz of the audio stream, if audio data is present
`Filename`	String specifying the name of the file
`FileModDate`	String containing the modification date of the file
`FileSize`	Integer indicating the size of the file in bytes
`FramesPerSecond`	Integer indicating the desired frames per second
`Height`	Integer indicating the height of the AVI movie in pixels

Field Name	Description
`ImageType`	String indicating the type of image. Either `'truecolor'` for a truecolor (RGB) image, or `'indexed'` for an indexed image.
`NumAudioChannels`	Integer indicating the number of channels in the audio stream, if audio data is present
`NumFrames`	Integer indicating the total number of frames in the movie
`NumColormapEntries`	Integer specifying the number of colormap entries. For a truecolor image, this value is 0 (zero).
`Quality`	Number between 0 and 100 indicating the video quality in the AVI file. Higher quality numbers indicate higher video quality; lower quality numbers indicate lower video quality. This value is not always set in AVI files and therefore can be inaccurate.
`VideoCompression`	String containing the compressor used to compress the AVI file. If the compressor is not Microsoft Video 1, Run Length Encoding (RLE), Cinepak, or Intel® Indeo, `aviinfo` returns the four-character code that identifies the compressor.
`Width`	Integer indicating the width of the AVI movie in pixels

See also

`mmfileinfo`, `VideoReader`, `VideoWriter`

Purpose

Read Audio/Video Interleaved (AVI) file

Note `aviread` will be removed in a future release. Use `VideoReader` instead.

Syntax

```
mov = aviread(filename)
mov = aviread(filename, index)
```

Description

`mov = aviread(filename)` reads the AVI movie `filename` into the MATLAB movie structure `mov`. If `filename` does not include an extension, then `.avi` is used. Use the `movie` function to view the movie `mov`. On UNIX platforms, `filename` must be an uncompressed AVI file.

`mov` has two fields, `cdata` and `colormap`. The content of these fields varies depending on the type of image.

Image Type	cdata Field	colormap Field
`Truecolor`	Height-by-width-by-3 array of `uint8` values	Empty
`Indexed`	Height-by-width array of `uint8` values	`m`-by-3 array of `double` values

`aviread` supports 8-bit frames, for indexed and grayscale images, 16-bit grayscale images, or 24-bit truecolor images. Note, however, that `movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale image frames.

`mov = aviread(filename, index)` reads only the frames specified by `index`. `index` can be a single index or an array of indices into the video stream. In AVI files, the first frame has the index value 1, the second frame has the index value 2, and so on.

Purpose

Create axes graphics object

Syntax

```
axes
axes('PropertyName',propertyvalue,...)
axes(h)
h = axes(...)
```

Properties

For a list of properties, see Axes Properties.

Description

`axes` creates an axes graphics object in the current figure using default property values. `axes` is the low-level function for creating axes graphics objects. MATLAB automatically creates an axes, if one does not already exist, when you issue a command that creates a graph.

`axes('`*`PropertyName`*`',propertyvalue,...)` creates an axes object having the specified property values. For a description of the properties, see Axes Properties. MATLAB uses default values for any properties that you do not explicitly define as arguments. The `axes` function accepts property name/property value pairs, structure arrays, and cell arrays as input arguments (see the `set` and `get` commands for examples of how to specify these data types). While the basic purpose of an axes object is to provide a coordinate system for plotted data, axes properties provide considerable control over the way MATLAB displays data.

`axes(h)` makes existing axes `h` the current axes and brings the figure containing it into focus. It also makes `h` the first axes listed in the figure's `Children` property and sets the figure's `CurrentAxes` property to `h`. The current axes is the target for functions that draw image, line, patch, rectangle, surface, and text graphics objects.

If you want to make an axes the current axes without changing the state of the parent figure, set the `CurrentAxes` property of the figure containing the axes:

```
set(figure_handle,'CurrentAxes',axes_handle)
```

This command is useful if you want a figure to remain minimized or stacked below other figures, but want to specify the current axes.

`h = axes(...)` returns the handle of the created axes object.

Use the `set` function to modify the properties of an existing axes or the `get` function to query the current values of axes properties. Use the `gca` command to obtain the handle of the current axes.

The `axis` (not `axes`) function provides simplified access to commonly used properties that control the scaling and appearance of axes.

Set default axes properties on the figure and `root object` levels:

```
set(0,'DefaultAxesPropertyName',PropertyValue,...)
set(gcf,'DefaultAxesPropertyName',PropertyValue,...)
```

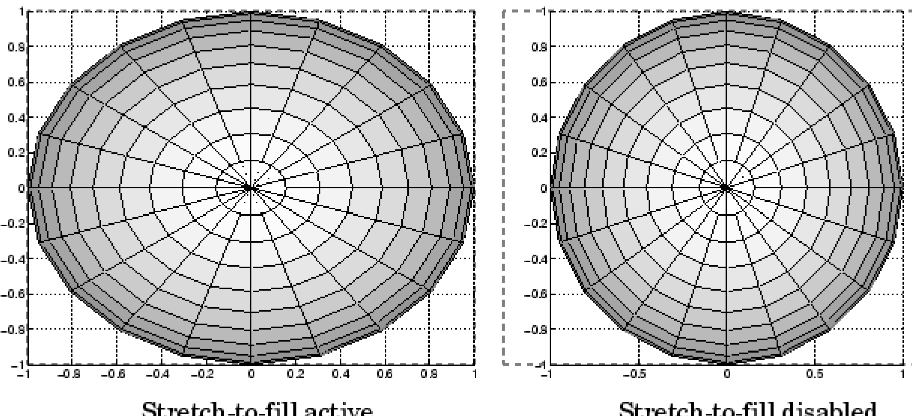
`PropertyName` is the name of the axes property and `PropertyValue` is the value you are specifying. Use `set` and `get` to access axes properties.

Stretch-to-Fill

By default, MATLAB stretches the axes to fill the axes position rectangle (the rectangle defined by the last two elements in the `Position` property). This results in graphs that use the available space in the rectangle. However, some 3-D graphs (such as a sphere) appear distorted because of this stretching, and are better viewed with a specific three-dimensional aspect ratio.

Stretch-to-fill is active when the `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all auto (the default). However, stretch-to-fill is turned off when the `DataAspectRatio`, `PlotBoxAspectRatio`, or `CameraViewAngle` is user-specified, or when one or more of the corresponding modes is set to manual (which happens automatically when you set the corresponding property value).

This picture shows the same sphere displayed both with and without the stretch-to-fill. The dotted lines show the axes rectangle.



Stretch-to-fill active

Stretch-to-fill disabled

When stretch-to-fill is disabled, MATLAB sets the size of the axes to be as large as possible within the constraints imposed by the `Position` rectangle without introducing distortion. In the picture above, the height of the rectangle constrains the axes size.

Examples

Zoom in using aspect ratio and limits:

```
sphere
set(gca,'DataAspectRatio',[1 1 1],...
        'PlotBoxAspectRatio',[1 1 1],'ZLim',[-0.6 0.6])
```

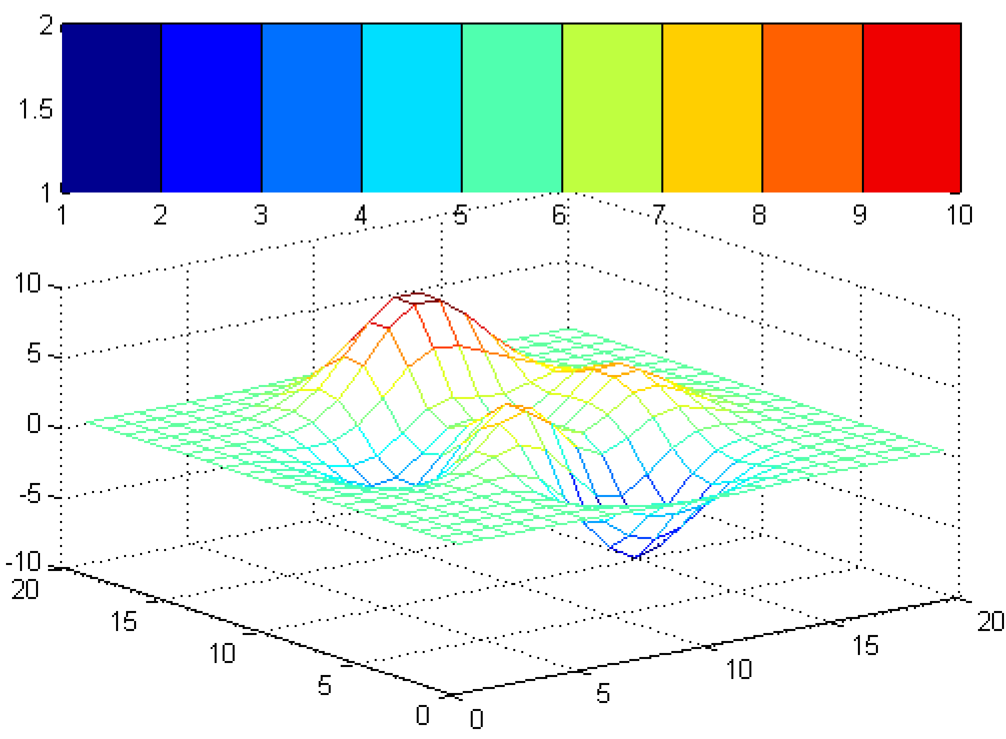
Zoom in and out using the `CameraViewAngle`:

```
sphere
set(gca,'CameraViewAngle',get(gca,'CameraViewAngle')-5)
set(gca,'CameraViewAngle',get(gca,'CameraViewAngle')+5)
```

Define multiple axes in a single figure window:

```
axes('position',[.1  .1  .8  .6])
mesh(peaks(20));
```

```
axes('position',[.1  .7  .8  .2])
pcolor([1:10;1:10]);
```



Alternatives

To create a figure select **New > Figure** from the figure window **File** menu. To add an axes to a figure, click one of the *New Subplots* icons in the Figure Palette, and slide right to select an arrangement of new axes. For details, see "Plotting Tools — Interactive Plotting".

Tutorials

- "Axes Objects — Defining Coordinate Systems for Graphs"

- "Axes Property Operations"

Purpose

Modify axes properties

Creating Axes Objects

Use `axes` to create axes objects.

Modifying Properties

You can set and query graphics object properties in two ways:

- "The Property Editor" is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands let you set and query the values of properties.

To change the default values of properties, see "Setting Default Property Values" in the Handle Graphics Objects documentation.

Axes Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`ActivePositionProperty`
`{outerposition} | position`

Use `OuterPosition` or `Position` property for resize. Specifies which property (`Position` or `OuterPosition`) MATLAB holds constant as you resize the figure (interactively or during a printing or exporting operation).

Setting a value for the `Position` property makes `position` the value of the `ActivePositionProperty`. The same is also true of setting a value for the `OuterPosition` property; `outerposition` becomes the value of the `ActivePositionProperty`.

See `OuterPosition` and `Position` for related properties.

See Automatic Axes Resize for a discussion of how to use axes positioning properties.

`ALim`
`[amin, amax]`

Alpha axis limits. Determines how MATLAB maps the `AlphaData` values of surface, patch, and image objects to the figure's alphamap.

- `amin` — Value of the data mapped to the first alpha value in the alphamap.
- `amax` — Value of the data mapped to the last alpha value in the alphamap.

MATLAB linearly interpolates data values in between across the alphamap and clamps data values outside to either the first or last alphamap value, whichever is closest.

If the axes contains multiple graphics objects, MATLAB sets `ALim` to span the range of all objects' `AlphaData` (or `FaceVertexAlphaData` for patch objects).

See the `alpha` function reference page for additional information.

`ALimMode`
`{auto} | manual`

Alpha axis limits mode.

- `auto` — MATLAB sets the `ALim` property to span the `AlphaData` limits of the graphics objects displayed in the axes.
- `manual` — MATLAB does not change the value of `ALim` when the `AlphaData` limits of axes children change.

Setting the `ALim` property sets `ALimMode` to `manual`.

`AmbientLightColor`
`ColorSpec`

Background light in a scene. Ambient light is a directionless light that shines uniformly on all objects in the axes. However, if there are no visible light objects in the axes, MATLAB does not use `AmbientLightColor`. If there are light objects in the axes, MATLAB adds the `AmbientLightColor` to the other light sources.

`AspectRatio`

(Obsolete)

This property produces a warning message when queried or changed. The `DataAspectRatio[Mode]` and `PlotBoxAspectRatio[Mode]` properties have superseded it.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

See the `close` and `delete` function reference pages for related information.

`Box`

`on | {off}`

Axes box mode. Specifies whether to enclose the axes extent in a box for 2-D views or a cube for 3-D views. The default is to not display the box.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Button press callback function. Executes whenever you press a mouse button while the pointer is within the axes, but not over another graphics object parented to the axes. For 3-D views, the active area is a rectangle that encloses the axes.

See the figure's `SelectionType` property to determine whether modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of axes associated with the button down event and an event structure, which is empty for this property).

See Function Handle Callbacks for information on how to use function handles to define the callback function.

Some Plotting Functions Reset the ButtonDownFcn

Most MATLAB plotting functions clear the axes and reset a number of axes properties, including the `ButtonDownFcn` before plotting data. To create an interface that lets users plot data interactively, consider using a control device such as a push button (`uicontrol`), which plotting functions do not affect. See "Using Function Handles in GUIs" for an example.

If you must use the axes `ButtonDownFcn` to plot data, then you should use low-level functions such as `line`, `patch`, and `surface` and manage the process with the figure and axes `NextPlot` properties.

See "High-Level Versus Low-Level Functions" for information on how plotting functions behave.

See "Preparing Figures and Axes for Graphics" for more information.

Camera Properties

See View Control with the Camera Toolbar for information related to the Camera properties.

See Defining Scenes with Camera Graphics for information on the camera properties.

See View Projection Types for information on orthogonal and perspective projections.

`CameraPosition`

`[x, y, z]` axes coordinates

Location of the camera. Position from which the camera views the scene. Specify the point in axes coordinates.

If you fix `CameraViewAngle`, you can zoom in and out on the scene by changing the `CameraPosition`, moving the camera closer to the `CameraTarget` to zoom in and farther away from the `CameraTarget` to zoom out. As you change the `CameraPosition`, the amount of perspective also changes, if `Projection` is `perspective`. You can also zoom by changing the `CameraViewAngle`; however, this does not change the amount of perspective in the scene.

`CameraPositionMode`
`{auto} | manual`

Auto or manual `CameraPosition`. When set to `auto`, MATLAB automatically calculates the `CameraPosition` such that the camera lies a fixed distance from the `CameraTarget` along the azimuth and elevation specified by `view`. Setting a value for `CameraPosition` sets this property to manual.

`CameraTarget`
`[x, y, z]` axes coordinates

Camera aiming point. Specifies the location in the axes that the camera points to. The `CameraTarget` and the `CameraPosition` define the vector (the view axis) along which the camera looks.

`CameraTargetMode`
`{auto} | manual`

Auto or manual `CameraTarget` placement. When this property is `auto`, MATLAB automatically positions the `CameraTarget` at the centroid of the axes plot box. Specifying a value for `CameraTarget` sets this property to `manual`.

`CameraUpVector`
`[x, y, z]` axes coordinates

Camera rotation. Specifies the rotation of the camera around the viewing axis defined by the `CameraTarget` and the `CameraPosition` properties. Specify `CameraUpVector` as a

three-element array containing the *x*, *y*, and *z* components of the vector. For example, `[0 1 0]` specifies the positive *y*-axis as the up direction.

The default `CameraUpVector` is `[0 0 1]`, which defines the positive *z*-axis as the up direction.

`CameraUpVectorMode`
`{auto} | manual`

Default or user-specified up vector. When `CameraUpVectorMode` is `auto`, MATLAB uses a value of `[0 0 1]` (positive *z*-direction is up) for 3-D views and `[0 1 0]` (positive *y*-direction is up) for 2-D views. Setting a value for `CameraUpVector` sets this property to `manual`.

`CameraViewAngle`
scalar greater than 0 and less than or equal to 180 (angle in degrees)

Field of view. Determines the camera field of view. Changing this value affects the size of graphics objects displayed in the axes, but does not affect the degree of perspective distortion. The greater the angle, the larger the field of view, and the smaller objects appear in the scene.

`CameraViewAngleMode`
`{auto} | manual`

Auto or manual `CameraViewAngle`. When in `auto` mode, MATLAB sets `CameraViewAngle` to the minimum angle that captures the entire scene (up to 180°).

The following table summarizes MATLAB camera behavior using various combinations of `CameraViewAngleMode`, `CameraTargetMode`, and `CameraPositionMode`:

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
auto	auto	auto	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
auto	auto	manual	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene.
auto	manual	auto	Sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
auto	manual	manual	Sets CameraViewAngle to capture entire scene.
manual	auto	auto	Sets CameraTarget to plot box centroid, sets CameraPosition along the view axis.
manual	auto	manual	Sets CameraTarget to plot box centroid.

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
manual	manual	auto	Sets CameraPosition along the view axis.
manual	manual	manual	User specifies all camera properties.

Children
vector of graphics object handles

Handles of all graphics objects rendered within the axes (whether visible or not). The graphics objects that can be children of axes are image, light, line, patch, rectangle, surface, and text. Change the order of the handles to change the stacking of the objects on the display.

The text objects used to label the *x*-, *y*-, and *z*-axes and the title are also children of axes, but their HandleVisibility properties are set to off. This means their handles do not show up in the axes Children property unless you set the Root ShowHiddenHandles property to on.

When an object's HandleVisibility property is off, its parent's Children property does not list it. See HandleVisibility for more information.

CLim
[cmin, cmax]

Color axis limits. Determines how MATLAB maps the CData values of surface and patch objects to the figure's Colormap. cmin is the value of the data mapped to the first color in the colormap. cmax is the value of the data mapped to the last color in the colormap. MATLAB linearly interpolates data values in between across the colormap and clamps data values outside to either the first or last alphamap colormap color, whichever is closest.

When `CLimMode` is `auto` (the default), MATLAB assigns `cmin` the minimum data value and `cmax` the maximum data value in the graphics object's `CData`. This maps `CData` elements with minimum data value to the first `colormap` entry and with maximum data value to the last `colormap` entry.

If the axes contains multiple graphics objects, MATLAB sets `CLim` to span the range of all objects' `CData`.

See the `caxis` function reference page for related information.

`CLimMode`
: `{auto} | manual`

Color axis limits mode.

- `auto` — MATLAB sets the `CLim` property to span the `CData` limits of the graphics objects displayed in the axes.
- `manual` — MATLAB does not change the value of `CLim` when the `CData` limits of axes children change.

Setting the `CLim` property sets this property to `manual`.

`Clipping`
: `{on} | off`

Clipping mode. This property has no effect on axes.

`Color`
: `{[1,1,1]} | ColorSpec`

Color of the axes back planes. Setting this property to `none` means that the axes is transparent and the figure color shows through. A `ColorSpec` is a three-element RGB vector or one of the MATLAB predefined names.

`ColorOrder`
: `m`-by-`3` matrix of RGB values

Colors to use for multiline plots. Defines the colors used by the `plot` and `plot3` functions to color each line plotted. If you do not specify a line color with `plot` and `plot3`, these functions cycle through the `ColorOrder` property to obtain the color for each line plotted. To obtain the current `ColorOrder`, which might be set during startup, get the property value:

```
get(gca,'ColorOrder')
```

Note that if the axes `NextPlot` property is `replace` (the default), high-level functions like `plot` reset the `ColorOrder` property before determining the colors to use. If you want MATLAB to use a `ColorOrder` that is different from the default, set `NextPlot` to `replacechildren`. You can also specify your own default `ColorOrder`.

`CreateFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Executes when MATLAB creates an axes object. You must define this property as a default value for axes. For example, the statement:

```
set(0,'DefaultAxesCreateFcn',@ax_create)
```

defines a default value on the `Root` level that sets axes properties whenever you (or MATLAB) create an axes.

```
function ax_create(src,evnt)
 set(src,'Color','b',...
 'XLim',[1 10],...
 'YLim',[0 100])
end
```

MATLAB executes this function after setting all properties for the axes. Setting the `CreateFcn` property on an existing axes object has no effect.

MATLAB passes the handle of the object whose `CreateFcn` is being executed as the first argument to the callback function and is also accessible through the Root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`CurrentPoint`
2-by-3 matrix

Location of last button click, in axes data units. Contains the coordinates of two points defined by the location of the pointer at the last mouse click. MATLAB returns the coordinates with respect to the requested axes.

Clicking Within the Axes — Orthogonal Projection

The two points lie on the line that is perpendicular to the plane of the screen and passes through the pointer. This is true for both 2-D and 3-D views.

The 3-D coordinates are the points, in the axes coordinate system, where this line intersects the front and back surfaces of the axes volume (which is defined by the axes x, y, and z limits).

The returned matrix is of the form:

$$\begin{bmatrix} x_{front} & y_{front} & z_{front} \\ x_{back} & y_{back} & z_{back} \end{bmatrix}$$

where *`front`* defines the point nearest to the camera position. Therefore, if the `CurrentPoint` property returns the `cp` matrix , then the first row,

```
cp(1,:)
```

specifies the point nearest the viewer and the second row,

```
cp(2,:)
```

specifies the point furthest from the viewer.

Clicking Outside the Axes — Orthogonal Projection

When you click outside the axes volume, but within the figure, the returned values are:

- Back point — a point in the plane of the camera target (which is perpendicular to the viewing axis).
- Front point — a point in the camera position plane (which is perpendicular to the viewing axis).

These points lie on a line that passes through the pointer and is perpendicular to the camera target and camera position planes.

Clicking Within the Axes — Perspective Projection

The values of the current point when using perspective project can be different from the same point in orthographic projection because the shape of the axes volume can be different.

Clicking Outside the Axes — Perspective Projection

Clicking outside of the axes volume returns the front point as the current camera position at all times. Only the back point updates with the coordinates of a point that lies on a line extending from the camera position through the pointer and intersecting the camera target at the point.

Related Information

See the figure `CurrentPoint` property for more information.

DataAspectRatio
[dx dy dz]

Relative scaling of data units. Controls the relative scaling of data units in the *x*, *y*, and *z* directions. For example, setting this property to [1 2 1] causes the length of one unit of data in the *x*-direction to be the same length as two units of data in the *y*-direction and one unit of data in the *z*-direction.

Note that the DataAspectRatio property interacts with the PlotBoxAspectRatio, XLimMode, YLimMode, and ZLimMode properties to control how MATLAB scales the *x*-, *y*-, and *z*-axis. Setting the DataAspectRatio disables the stretch-to-fill behavior if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all auto.

The following table describes the interaction between properties when you disable stretch-to-fill behavior.

Interaction Between Properties With Stretch-to-Fill Disabled

X-, Y-, Z-LimitModes	DataAspectRatio	PlotBoxAspectRatio	Behavior
auto	auto	auto	Limits chosen to span data range in all dimensions.
auto	auto	manual	Limits chosen to span data range in all dimensions. MATLAB modifies DataAspectRatio to achieve the requested PlotBoxAspectRatio

X-, Y-, Z-LimitModes	DataAspectRatio	PlotBoxAspectRatio	Behavior
			within the limits the software selected.
`auto`	`manual`	`auto`	Limits chosen to span data range in all dimensions. MATLAB modifies `PlotBoxAspectRatio` to achieve the requested `DataAspectRatio` within the limits the software selected.
`auto`	`manual`	`manual`	Limits chosen to completely fit and center the plot within the requested `PlotBoxAspectRatio` given the requested `DataAspectRatio` (this might produce empty space around 2 of the 3 dimensions).
`manual`	`auto`	`auto`	MATLAB honors limits and modifies the `DataAspectRatio` and `PlotBoxAspectRatio` as necessary.

X-, Y-, Z-LimitModes	DataAspectRatio	PlotBoxAspectRatio	Behavior
`manual`	`auto`	`manual`	MATLAB honors limits and `PlotBoxAspectRatio` and modifies `DataAspectRatio` as necessary.
`manual`	`manual`	`auto`	MATLAB honors limits and `DataAspectRatio` and modifies the `PlotBoxAspectRatio` as necessary.
`1 manual` `2 auto`	`manual`	`manual`	MATLAB selects the 2 automatic limits to honor the specified aspect ratios and limit. See "Examples."
`2 or 3 manual`	`manual`	`manual`	MATLAB honors limits and `DataAspectRatio` while ignoring`PlotBoxAspectRatio`.

See "Understanding Axes Aspect Ratio" for more information.

`DataAspectRatioMode`
`{auto} | manual`

User or MATLAB controlled data scaling. Controls whether the values of the `DataAspectRatio` property are user-defined or selected automatically by MATLAB. Setting values for the `DataAspectRatio` property automatically sets this property

to `manual`. Changing `DataAspectRatioMode` to `manual` disables the stretch-to-fill behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all auto.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Delete axes callback function. Executes when you delete the axes object (for example, when you issue a `delete` or `clf` command). MATLAB executes the routine before destroying the object's properties so the callback can query these values.

MATLAB passes the handle of the object whose `DeleteFcn` is executing as the first argument to the callback function. The handle is also accessible through the Root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DrawMode`

`{normal} | fast`

Rendering mode. Controls the way MATLAB renders graphics objects displayed in the axes when the figure `Renderer` property is `painters`.

- `normal` — Draws objects in back to front ordering based on the current view in order to handle hidden surface elimination and object intersections.
- `fast` — Draws objects in the order in which you specify the drawing commands, without considering the relationships of the objects in three dimensions. This results in faster rendering because it requires no sorting of objects according to location in the view, but can produce undesirable results because it

bypasses the hidden surface elimination and object intersection handling provided by `normal DrawMode`.

When the figure `Renderer` property is `zbuffer`, MATLAB ignores `DrawMode` and always provides hidden surface elimination and object intersection handling.

`FontAngle`
`{normal} | italic | oblique`

Select italic or normal font. Selects the character slant for axes text. `normal` specifies a nonitalic font. `italic` and `oblique` specify italic font.

`FontName`
name (such as `Courier`) | `FixedWidth`

Font family name. Specifies the font to use for axes labels. To display and print properly, `FontName` must be a font that your system supports. Note that MATLAB does not display the *x*-, *y*-, and *z*-axis labels in a new font until you manually reset them (by setting the `XLabel`, `YLabel`, and `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` command). Tick mark labels change immediately.

Specifying a Fixed-Width Font

If you want an axes to use a fixed-width font that looks good in any locale, set `FontName` to the string `FixedWidth`:

```
set(axes_handle,'FontName','FixedWidth')
```

This eliminates the need to hardcode the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding (such as in Japan, where character sets can be multibyte). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` (note that this string is case sensitive) and rely

on `FixedWidthFontName` to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`.

Note that setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

`FontSize`

Font size specified in `FontUnits`

Font size. An integer specifying the font size to use for axes labels and titles, in units determined by the `FontUnits` property. The default point size is `12` and the maximum allowable font size depends on your operating system. MATLAB does not display *x*-, *y*-, and *z*-axis text labels in a new font size until you manually reset them (by setting the `XLabel`, `YLabel`, or `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` command). Tick mark labels change immediately.

`FontUnits`

`{points} | normalized | inches | centimeters | pixels`

Units used to interpret the `FontSize` property. When set to `normalized`, MATLAB interprets the value of `FontSize` as a fraction of the height of the axes. For example, a `normalized` `FontSize` of `0.1` sets the text characters to a font whose height is one tenth of the axes' height. The default units (`points`), are equal to 1/72 of an inch.

If you set both the `FontSize` and the `FontUnits` in one function call, you must set the `FontUnits` property first so that MATLAB correctly interprets the specified `FontSize`.

`FontWeight`

`{normal} | bold | light | demi`

Select bold or normal font. The character weight for axes text. MATLAB does not display the *x*-, *y*-, and *z*-axis text labels in bold until you manually reset them (by setting the `XLabel`, `YLabel`, and `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` commands). Tick mark labels change immediately.

`GridLineStyle`

`- | --| {:} | -. | none`

Line style used to draw grid lines. The line style is a string consisting of a character, in quotes, specifying solid lines (-), dashed lines (--), dotted lines(:), or dash-dot lines (-.). The default grid line style is dotted. To turn on grid lines, use the `grid` command.

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, functions that obtain handles by searching the object hierarchy or

querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When you restrict a handle's visibility by using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the Root's `CurrentFigure` property, objects do not appear in the Root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the Root `ShowHiddenHandles` property to on to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`
: `{on} | off`

Selectable by mouse click. Determines if the axes can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click the axes. If `HitTest` is `off`, clicking the axes selects the object below it (which is usually the figure containing it).

`Interruptible`
: `off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is

the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see "Control Callback Execution and Interruption".

`Layer`

`{bottom} | top`

Draw axis lines below or above graphics objects. Determines whether to draw axis lines and tick marks on top or below axes children objects for any 2-D view (for example, when you are looking along the *x*-, *y*-, or *z*-axis). Use this property to place grid lines and tick marks on top of images.

`LineStyleOrder`

`LineSpec {a solid line '-'}`

Order of line styles and markers used in a plot. Specifies which line styles and markers to use and in what order when creating multiple-line plots. For example:

```
set(gca,'LineStyleOrder', '-*|:|o')
```

sets `LineStyleOrder` to solid line with asterisk marker, dotted line, and hollow circle marker. The default is (-), which specifies a solid line for all data plotted. Alternatively, you can create a cell array of character strings to define the line styles:

```
set(gca,'LineStyleOrder',{'-*',':','o'})
```

MATLAB supports four line styles, which you can specify any number of times in any order. MATLAB cycles through the line styles only after using all colors defined by the `ColorOrder` property. For example, the first eight lines plotted use the different colors defined by `ColorOrder` with the first line style. MATLAB then cycles through the colors again, using the second line style specified, and so on.

You can also specify line style and color directly with the `plot` and `plot3` functions or by altering the properties of the `line` or `lineseries` objects after creating the graph.

High-Level Functions and LineStyleOrder

Note that, if the axes `NextPlot` property is `replace` (the default), high-level functions like `plot` reset the `LineStyleOrder` property before determining the line style to use. If you want MATLAB to use a `LineStyleOrder` that is different from the default, set `NextPlot` to `replacechildren`.

Specifying a Default LineStyleOrder

You can specify your own default `LineStyleOrder`. For example:

```
set(0,'DefaultAxesLineStyleOrder',{'-*',':','o'})
```

creates a default value for the axes `LineStyleOrder` that high-level plotting functions will not reset.

`LineWidth`

line width in points

Width of axis lines. Specifies the width, in points, of the *x*-, *y*-, and *z*-axis lines. The default line width is 0.5 points 1 point = $^{1}/_{72}$ inch.

`MinorGridLineStyle`

`- | --| {:} | -.  | none`

Line style used to draw minor grid lines. The line style is a string consisting of one or more characters, in quotes, specifying solid lines (-), dashed lines (--), dotted lines (:), or dash-dot lines (-.). The default minor grid line style is dotted. To turn on minor grid lines, use the `grid minor` command.

`NextPlot`

`add | {replace} | replacechildren`

Where to draw the next plot. Determines how high-level plotting functions draw into an existing axes.

- `add` — Use the existing axes to draw graphics objects.

- `replace` — Reset all axes properties except `Position` to their defaults and delete all axes children before displaying graphics (equivalent to `cla reset`).
- `replacechildren` — Remove all child objects, but do not reset axes properties (equivalent to `cla`).

The `newplot` function simplifies the use of the `NextPlot` property and is useful for functions that draw graphs using only low-level object creation routines. Note that figure graphics objects also have a `NextPlot` property.

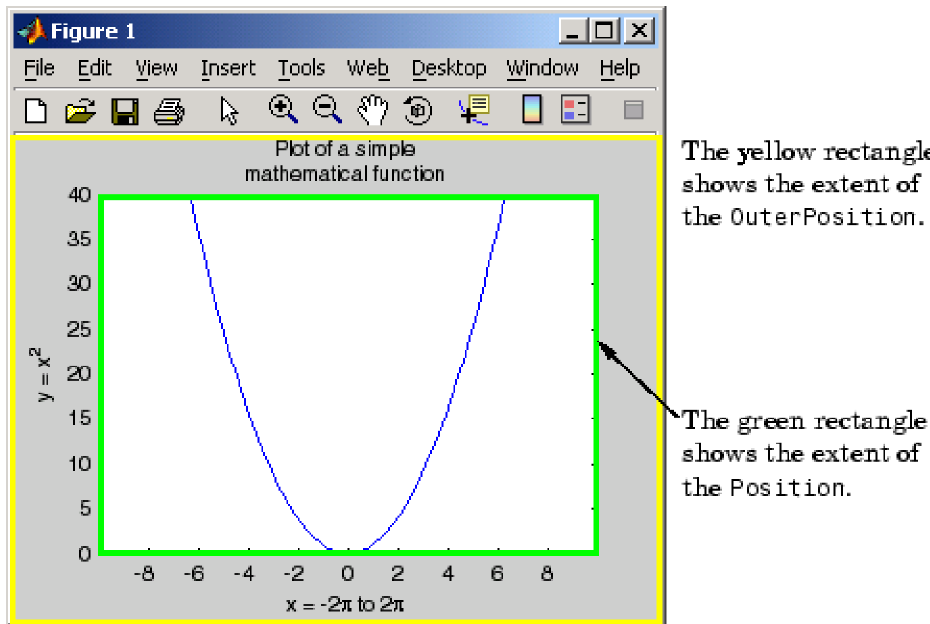
`OuterPosition`
four-element vector

Position of axes including labels, title, and a margin. Specifies a rectangle that locates the outer bounds of the axes, including axis labels, the title, and a margin. The vector is as follows:

```
[left bottom width height]
```

where `left` and `bottom` define the distance from the lower-left corner of the figure window to the lower-left corner of the rectangle. `width` and `height` are the dimensions of the rectangle.

The following picture shows the region defined by the `OuterPosition` enclosed in a yellow rectangle.



When ActivePositionProperty is OuterPosition (the default), resizing the figure will not clip any of the text. The default value of [0 0 1 1] (normalized units) includes the interior of the figure.

The Units property specifies all measurement units.

See the property for related information.

See "Automatic Axes Resize" for a discussion of how to use axes positioning properties.

Parent
figure or uipanel handle

Axes parent. The handle of the axes' parent object. The parent of an axes object is the figure which displays it or the uipanel object that contains it. The utility function gcf returns the handle of

the current axes `Parent`. You can reparent axes to other figure or uipanel objects.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`PlotBoxAspectRatio`
`[px py pz]`

Relative scaling of axes plot box. Controls the relative scaling of the plot box in the *x*, *y*, and *z* directions. The plot box is a box enclosing the axes data region as defined by the *x*-, *y*-, and *z*-axis limits.

Note that the `PlotBoxAspectRatio` property interacts with the `DataAspectRatio`, `XLimMode`, `YLimMode`, and `ZLimMode` properties to control the way MATLAB displays graphics objects. Setting the `PlotBoxAspectRatio` disables stretch-to-fill behavior, if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto`.

`PlotBoxAspectRatioMode`
`{auto} | manual`

User or MATLAB controlled axis scaling. Controls whether the values of the `PlotBoxAspectRatio` property are user-defined or selected automatically by MATLAB. Setting values for the `PlotBoxAspectRatio` property automatically sets this property to `manual`. Changing the `PlotBoxAspectRatioMode` to `manual` disables stretch-to-fill behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto`.

`Position`
four-element vector

Position of axes. Specifies a rectangle that locates the axes within its parent container (figure or uipanel). The vector is of the form:

```
[left bottom width height]
```

where `left` and `bottom` define the distance from the lower-left corner of the container to the lower-left corner of the rectangle. `width` and `height` are the dimensions of the rectangle. The `Units` property specifies the units for all measurements.

When you enable axes stretch-to-fill behavior (when `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto`), MATLAB stretches the axes to fill the `Position` rectangle. When you disable stretch-to-fill, MATLAB makes the axes as large as possible, while obeying all other properties, without extending outside the `Position` rectangle.

See the `OuterPosition` property for related information.

See "Automatic Axes Resize" for a discussion of how to use axes positioning properties.

`Projection`
`{orthographic} | perspective`

Type of projection. Selects one of the following projection types:

- `orthographic` — Maintains the correct relative dimensions of graphics objects regarding the distance a given point is from the viewer and draws parallel lines in the data parallel on the screen.
- `perspective` — Incorporates foreshortening, which allows you to perceive depth in 2-D representations of 3-D objects. Perspective projection does not preserve the relative dimensions of objects; it displays a distant line segment smaller than a nearer line segment of the same length. Parallel lines in the data might not appear parallel on screen.

`Selected`
`on | {off}`

Is object selected? When you set this property to `on`, MATLAB displays selection “handles” at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that the axes has been selected.

`SelectionHighlight`

`{on} | off`

Highlights objects when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`Tag`

string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, suppose you want to direct all graphics output from a file to a particular axes, regardless of user actions that might have changed the current axes. To do this, identify the axes with a `Tag`:

```
axes('Tag','Special Axes')
```

Then make that axes the current axes before drawing by searching for the `Tag` with `findobj`:

```
axes(findobj('Tag','Special Axes'))
```

`TickDir`

`in | out`

Direction of tick marks. For 2-D views, the default is to direct tick marks inward from the axis lines; 3-D views direct tick marks outward from the axis line.

`TickDirMode`
`{auto} | manual`

Automatic tick direction control. In `auto` mode, MATLAB directs tick marks inward for 2-D views and outward for 3-D views. When you specify a setting for `TickDir`, MATLAB sets `TickDirMode` to `manual`. In `manual` mode, MATLAB does not change the specified tick direction.

`TickLength`
`[2DLength 3DLength]`

Length of tick marks. Specifies the length of axes tick marks. The first element is the length of tick marks used for 2-D views and the second element is the length of tick marks used for 3-D views. Specify tick mark lengths in units normalized relative to the longest of the visible *x*-, *y*-, or *z*-axis annotation lines.

`TightInset`
`[left bottom right top]` Read only

Margins added to Position to include text labels. The distances between the bounds of the `Position` property and the extent of the axes text labels and title. When added to the `Position` width and height values, the `TightInset` defines the tightest bounding box that encloses the axes and its labels and title.

See “Automatic Axes Resize” for more information.

`Title`
handle of text object

Axes title. The handle of the `text` object used for the axes title. Use this handle to change the properties of the title text or you can

set `Title` to the handle of an existing text object. For example, the following statement changes the color of the current title to red:

```
set(get(gca,'Title'),'Color','r')
```

To create a new title, set this property to the handle of the text object you want to use:

```
set(gca,'Title',text('String','New Title','Color','r'))
```

However, it is simpler to use the `title` command to create or replace an axes title:

```
title('New Title','Color','r') % Make text color red
title({'This title','has 2 lines'}) % Two line title
```

`Type`
: string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For axes objects, `Type` is always ’`axes`’.

`UIContextMenu`
: handle of uicontextmenu object

Associate a context menu with the axes. Assign this property the handle of a `uicontextmenu` object created in the axes’ parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the axes.

`Units`
: `inches | centimeters | {normalized} | points | pixels | characters`

Axes position units. The units used to interpret the Position property. MATLAB measures all units from the lower left corner of the figure window.

Note The Units property controls the positioning of the axes within the figure. This property does not affect the data units used for graphing. See the axes XLim, YLim, and ZLim properties to set the limits of each axis data units.

- normalized — Units map the lower left corner of the figure window to (0,0) and the upper right corner to (1.0, 1.0).
- inches, centimeters, and points — Absolute units. 1 point = $^1/_{72}$ inch.
- characters — Based on the size of characters in the default system font. The width of one characters unit is the width of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.

When specifying the units as property/value pairs during object creation, you must set the Units property before specifying the properties that you want to use these units.

UserData
matrix

User-specified data. Data you want to associate with the axes object. The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

View
Obsolete

The axes camera properties now controls the functionality provided by the View property — CameraPosition, CameraTarget, CameraUpVector, and CameraViewAngle. See the view command.

`Visible`
`{on} | off`

Visibility of axes. By default, axes are visible. Setting this property to `off` prevents axis lines, tick marks, and labels from being displayed. The `Visible` property does not affect children of axes.

`XAxisLocation`
`top | {bottom}`

Location of x-axis tick marks and labels. Controls where MATLAB displays the *x*-axis tick marks and labels. Setting this property to `top` moves the *x*-axis to the top of the plot from its default position at the bottom. This property applies to 2–D views only.

`YAxisLocation`
`right | {left}`

Location of y-axis tick marks and labels. Controls where MATLAB displays the *y*-axis tick marks and labels. Setting this property to `right` moves the *y*-axis to the right side of the plot from its default position on the left side. This property applies to 2–D views only. See the `plotyy` function for a simple way to use two *y*-axes.

Properties That Control the X-, Y-, or Z-Axis

`XColor`
`YColor`
`ZColor`
`ColorSpec`

Color of axis lines. A three-element vector specifying an RGB triple, or a predefined MATLAB color string. This property determines the color of the axis lines, tick marks, tick mark labels, and the axis grid lines of the respective *x*-, *y*-, and *z*-axis. The default axis color is black. See `ColorSpec` for details on specifying colors.

`XDir`
`YDir`
`ZDir`

`{normal} | reverse`

Direction of increasing values. A mode controlling the direction of increasing axis values. Axes form a right-hand coordinate system. By default:

- *x*-axis values increase from left to right. To reverse the direction of increasing *x* values, set this property to `reverse`.

```
set(gca,'XDir','reverse')
```

- *y*-axis values increase from bottom to top (2-D view) or front to back (3-D view). To reverse the direction of increasing *y* values, set this property to `reverse`.

```
set(gca,'YDir','reverse')
```

- *z*-axis values increase pointing out of the screen (2-D view) or from bottom to top (3-D view). To reverse the direction of increasing *z* values, set this property to `reverse`.

```
set(gca,'ZDir','reverse')
```

`XGrid`
`YGrid`
`ZGrid`

`on | {off}`

Axis gridline mode. When you set any of these properties to `on`, MATLAB draws grid lines perpendicular to the respective axis (for example, along lines of constant *x*, *y*, or *z* values). Use the `grid` command to set all three properties `on` or `off` at once.

```
set(gca,'XGrid','on')
```

`XLabel`
`YLabel`
`ZLabel`

handle of text object

Axis labels. The handle of the `text` object used to label the *x*-, *y*-, or *z*-axis, respectively. To assign values to any of these properties, you must obtain the handle to the text string you want to use as a label. This statement defines a text object and assigns its handle to the `XLabel` property:

```
set(get(gca,'XLabel'),'String','axis label')
```

MATLAB places the string `'axis label'` appropriately for an *x*-axis label and moves any text object whose handle you specify as an `XLabel`, `YLabel`, or `ZLabel` property to the appropriate location for the respective label.

Alternatively, you can use the `xlabel`, `ylabel`, and `zlabel` functions, which generally provide a simpler means to label axis lines.

Note that using a bitmapped font (for example, Courier is usually a bitmapped font) might cause the labels to rotate improperly. As a workaround, use a TrueType font (for example, Courier New) for axis labels. See your system documentation to determine the types of fonts installed on your system.

`XLim`
`YLim`
`ZLim`

`[minimum maximum]`

Axis limits. Specifies the minimum and maximum values of the respective axis. The data you plot determines these values.

Changing these properties affects the scale of the *x*-, *y*-, or *z*-dimension as well as the placement of labels and tick marks on the axis. The default values for these properties are `[0 1]`.

See the `axis`, `datetick`, `xlim`, `ylim`, and `zlim` commands to set these properties.

`XLimMode`
`YLimMode`
`ZLimMode`
`{auto} | manual`

MATLAB or user-controlled limits. The axis limits mode determines whether MATLAB calculates axis limits based on the data plotted (for example, the `XData`, `YData`, or `ZData` of the axes children) or uses the values explicitly set with the `XLim`, `YLim`, or `ZLim` property, in which case, the respective limits mode is set to `manual`.

`XMinorGrid`
`YMinorGrid`
`ZMinorGrid`
`on | {off}`

Enable or disable minor gridlines. When set to `on`, MATLAB draws gridlines aligned with the minor tick marks of the respective axis. Note that you do not have to enable minor ticks to display minor grids.

`XMinorTick`
`YMinorTick`
`ZMinorTick`
`on | {off}`

Enable or disable minor tick marks. When set to `on`, MATLAB draws tick marks between the major tick marks of the respective axis. MATLAB automatically determines the number of minor ticks based on the space between the major ticks.

`XScale`
`YScale`
`ZScale`
`{linear} | log`

Axis scaling. Linear or logarithmic scaling for the respective axis. See also `loglog`, `semilogx`, and `semilogy`.

`XTick`
`YTick`
`ZTick`
vector of data values locating tick marks

Tick spacing. A vector of *x*-, *y*-, or *z*-data values that determine the location of tick marks along the respective axis. If you do not want tick marks displayed, set the respective property to the empty vector, `[ ]`. These vectors must contain monotonically increasing values.

`XTickLabel`
`YTickLabel`
`ZTickLabel`
string

Tick labels. A matrix of strings to use as labels for tick marks along the respective axis. These labels replace the numeric labels generated by MATLAB. If you do not specify enough text labels for all the tick marks, MATLAB uses all of the labels specified, then reuses the specified labels.

For example, the statement:

```
set(gca,'XTickLabel',{'One';'Two';'Three';'Four'})
```

labels the first four tick marks on the *x*-axis and then reuses the labels for the remaining ticks.

Labels can be cell arrays of strings, padded string matrices, string vectors separated by vertical slash characters, or numeric vectors (where MATLAB implicitly converts each number to the equivalent string using `num2str`). All of the following are equivalent:

```
set(gca,'XTickLabel',{'1';'10';'100'})
set(gca,'XTickLabel','1|10|100')
set(gca,'XTickLabel',[1;10;100])
set(gca,'XTickLabel',['1  ';'10 ';'100'])
```

Note that tick labels do not interpret TeX character sequences (however, the `Title`, `XLabel`, `YLabel`, and `ZLabel` properties do).

`XTickMode`
`YTickMode`
`ZTickMode`

`{auto} | manual`

MATLAB or user-controlled tick spacing. The axis tick modes determine whether MATLAB calculates the tick mark spacing based on the range of data for the respective axis (`auto` mode) or uses the values explicitly set for any of the `XTick`, `YTick`, and `ZTick` properties (`manual` mode). Setting values for the `XTick`, `YTick`, or `ZTick` properties sets the respective axis tick mode to `manual`.

`XTickLabelMode`
`YTickLabelMode`
`ZTickLabelMode`

`{auto} | manual`

MATLAB or user-determined tick labels. The axis tick mark labeling modes determine whether MATLAB uses numeric tick mark labels that span the range of the plotted data (`auto` mode) or uses the tick mark labels specified with the `XTickLabel`, `YTickLabel`, or `ZTickLabel` property (`manual` mode). Setting

values for the `XTickLabel`, `YTickLabel`, or `ZTickLabel` property sets the respective axis tick label mode to `manual`.

`axes`

Purpose

Axis scaling and appearance

Syntax

```
axis([xmin xmax ymin ymax])
axis([xmin xmax ymin ymax zmin zmax cmin cmax])
v = axis
axis auto
axis manual
axis tight
axis fill
axis ij
axis xy
axis equal
axis image
axis square
axis vis3d
axis normal
axis off
axis on
axis(axes_handles,...)
[mode,visibility,direction] = axis('state')
```

Description

`axis` manipulates commonly used axes properties. (See Algorithm section.)

`axis([xmin xmax ymin ymax])` sets the limits for the *x*- and *y*-axis of the current axes.

`axis([xmin xmax ymin ymax zmin zmax cmin cmax])` sets the *x*-, *y*-, and *z*-axis limits and the color scaling limits (see `caxis`) of the current axes.

`v = axis` returns a row vector containing scaling factors for the *x*-, *y*-, and *z*-axis. `v` has four or six components depending on whether the current axes is 2-D or 3-D, respectively. The returned values are the current axes `XLim`, `Ylim`, and `ZLim` properties.

`axis auto` sets MATLAB default behavior to compute the current axes limits automatically, based on the minimum and maximum values of *x*, *y*, and *z* data. You can restrict this automatic behavior to a specific

axis. For example, `axis 'auto x'` computes only the *x*-axis limits automatically; `axis 'auto yz'` computes the *y*- and *z*-axis limits automatically.

`axis manual` and `axis(axis)` freezes the scaling at the current limits, so that if `hold` is `on`, subsequent plots use the same limits. This sets the `XLimMode`, `YLimMode`, and `ZLimMode` properties to `manual`.

`axis tight` sets the axis limits to the range of the data.

`axis fill` sets the axis limits and `PlotBoxAspectRatio` so that the axes fill the position rectangle. This option has an effect only if `PlotBoxAspectRatioMode` or `DataAspectRatioMode` is `manual`.

`axis ij` places the coordinate system origin in the upper left corner. The *i*-axis is vertical, with values increasing from top to bottom. The *j*-axis is horizontal with values increasing from left to right.

`axis xy` draws the graph in the default Cartesian axes format with the coordinate system origin in the lower left corner. The *x*-axis is horizontal with values increasing from left to right. The *y*-axis is vertical with values increasing from bottom to top.

`axis equal` sets the aspect ratio so that the data units are the same in every direction. The aspect ratio of the *x*-, *y*-, and *z*-axis is adjusted automatically according to the range of data units in the *x*, *y*, and *z* directions.

`axis image` is the same as `axis equal` except that the plot box fits tightly around the data.

`axis square` makes the current axes region square (or cubed when three-dimensional). This option adjusts the *x*-axis, *y*-axis, and *z*-axis so that they have equal lengths and adjusts the increments between data units accordingly.

`axis vis3d` freezes aspect ratio properties to enable rotation of 3-D objects and overrides stretch-to-fill.

`axis normal` automatically adjusts the aspect ratio of the axes and the relative scaling of the data units so that the plot fits the figure's shape as well as possible.

`axis off` turns off all axis lines, tick marks, and labels.

`axis on` turns on all axis lines, tick marks, and labels.

`axis(axes_handles,...)` applies the `axis` command to the specified axes. For example, the following statements

```
h1 = subplot(221);
h2 = subplot(222);
axis([h1 h2],'square')
```

set both axes to `square`.

`[mode,visibility,direction] = axis('state')` returns three strings indicating the current setting of axes properties:

Output Argument	Strings Returned
mode	'auto' | 'manual'
visibility	'on' | 'off'
direction	'xy' | 'ij'

`mode` is `auto` if `XLimMode`, `YLimMode`, and `ZLimMode` are all set to `auto`. If `XLimMode`, `YLimMode`, or `ZLimMode` is `manual`, `mode` is `manual`.

Keywords to `axis` can be combined, separated by a space (e.g., `axis tight equal`). These are evaluated from left to right, so subsequent keywords can overwrite properties set by prior ones.

Tips

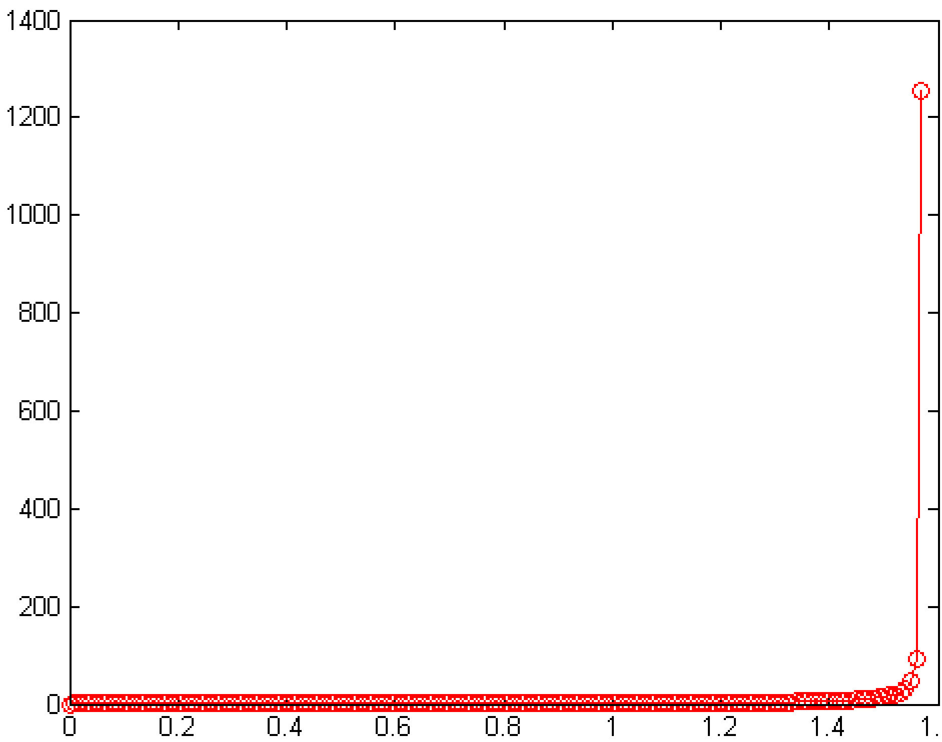
You can create an axes (and a figure for it) if none exists with the `axis` command. However, if you specify non-default limits or formatting for the axes when doing this, such as `[4 8 2 9]`, `square`, `equal`, or `image`, the property is ignored because there are no axis limits to adjust in the absence of plotted data. To use `axis` in this manner, you can set `hold on` to keep preset axes limits from being overridden.

Examples

The statements

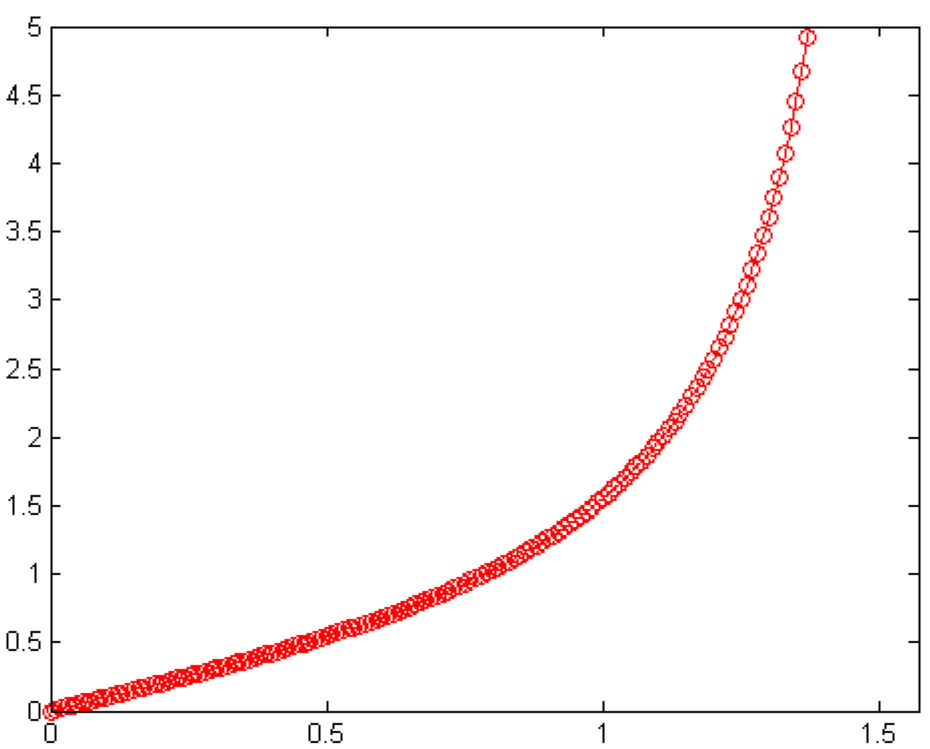
```
x = 0:.01:pi/2;
plot(x,tan(x),'-ro')
```

use the automatic scaling of the *y*-axis based on `ymax = tan(1.57)`, which is well over 1000:



The following figure shows a more satisfactory plot after typing

```
axis([0 pi/2 0 5])
```



Algorithms

When you specify minimum and maximum values for the *x*-, *y*-, and *z*-axes, `axis` sets the `XLim`, `Ylim`, and `ZLim` properties for the current axes to the respective minimum and maximum values in the argument list. Additionally, the `XLimMode`, `YLimMode`, and `ZLimMode` properties for the current axes are set to `manual`.

`axis auto` sets the current axes `XLimMode`, `YLimMode`, and `ZLimMode` properties to `'auto'`.

axis manual sets the current axes XLimMode, YLimMode, and ZLimMode properties to 'manual'.

The following table shows the values of the axes properties set by axis equal, axis normal, axis square, and axis image.

Axes Property or Behavior	axis equal	axis normal	axis square	axis image
DataAspectRatio property	[1 1 1]	not set	not set	[1 1 1]
DataAspectRatioMode property	manual	auto	auto	manual
PlotBoxAspectRatio property	[3 4 4]	not set	[1 1 1]	auto
PlotBoxAspectRatioMode property	manual	auto	manual	auto
Stretch-to-fill behavior;	disabled	active	disabled	disabled

balance

Purpose

Diagonal scaling to improve eigenvalue accuracy

Syntax

```
[T,B] = balance(A)
[S,P,B] = balance(A)
B = balance(A)
B = balance(A,'noperm')
```

Description

`[T,B] = balance(A)` returns a similarity transformation `T` such that `B = T\A*T`, and `B` has, as nearly as possible, approximately equal row and column norms. `T` is a permutation of a diagonal matrix whose elements are integer powers of two to prevent the introduction of roundoff error. If `A` is symmetric, then `B == A` and `T` is the identity matrix.

`[S,P,B] = balance(A)` returns the scaling vector `S` and the permutation vector `P` separately. The transformation `T` and balanced matrix `B` are obtained from `A`, `S`, and `P` by `T(:,P) = diag(S)` and `B(P,P) = diag(1./S)*A*diag(S)`.

`B = balance(A)` returns just the balanced matrix `B`.

`B = balance(A,'noperm')` scales `A` without permuting its rows and columns.

Tips

- Nonsymmetric matrices can have poorly conditioned eigenvalues. Small perturbations in the matrix, such as roundoff errors, can lead to large perturbations in the eigenvalues. The condition number of the eigenvector matrix,

  ```
  cond(V) = norm(V)*norm(inv(V))
  ```

  where

  ```
  [V,T] = eig(A)
  ```

relates the size of the matrix perturbation to the size of the eigenvalue perturbation. Note that the condition number of A itself is irrelevant to the eigenvalue problem.

Balancing is an attempt to concentrate any ill conditioning of the eigenvector matrix into a diagonal scaling. Balancing usually cannot turn a nonsymmetric matrix into a symmetric matrix; it only attempts to make the norm of each row equal to the norm of the corresponding column.

Note The MATLAB eigenvalue function, `eig(A)`, automatically balances `A` before computing its eigenvalues. Turn off the balancing with `eig(A,'nobalance')`.

Examples

This example shows the basic idea. The matrix `A` has large elements in the upper right and small elements in the lower left. It is far from being symmetric.

```
A = [1  100  10000; .01  1  100; .0001  .01  1]
A =
   1.0e+04 *
    0.0001    0.0100    1.0000
    0.0000    0.0001    0.0100
    0.0000    0.0000    0.0001
```

Balancing produces a diagonal matrix `T` with elements that are powers of two and a balanced matrix `B` that is closer to symmetric than `A`.

```
[T,B] = balance(A)
T =
   1.0e+03 *
    2.0480         0         0
         0    0.0320         0
         0         0    0.0003
B =
    1.0000    1.5625    1.2207
```

```
    0.6400    1.0000    0.7813
    0.8192    1.2800    1.0000
```

To see the effect on eigenvectors, first compute the eigenvectors of `A`, shown here as the columns of `V`.

```
[V,E] = eig(A); V
V =
0.9999        -0.9999                -0.9999
0.0100         0.0059 + 0.0085i       0.0059 - 0.0085i
0.0001         0.0000 - 0.0001i       0.0000 + 0.0001i
```

Note that all three vectors have the first component the largest. This indicates `V` is badly conditioned; in fact `cond(V)` is `8.7766e+003`. Next, look at the eigenvectors of `B`.

```
[V,E] = eig(B); V
V =
0.6933        -0.6993                -0.6993
0.4437         0.2619 + 0.3825i       0.2619 - 0.3825i
0.5679         0.2376 - 0.4896i       0.2376 + 0.4896i
```

Now the eigenvectors are well behaved and `cond(V)` is `1.4421`. The ill conditioning is concentrated in the scaling matrix; `cond(T)` is `8192`.

This example is small and not really badly scaled, so the computed eigenvalues of `A` and `B` agree within roundoff error; balancing has little effect on the computed results.

Limitations

Balancing can destroy the properties of certain matrices; use it with some care. If a matrix contains small elements that are due to roundoff error, balancing might scale them up to make them as significant as the other elements of the original matrix.

`eig`

Purpose

Bar graph

Syntax

```
bar(Y)
bar(x,Y)

bar(___,width)
bar(___,style)
bar(___,bar_color)
bar(___,Name,Value)

bar(axes_handle,___)

h = bar(___)
```

Description

`bar(Y)` draws one bar for each element in `Y`.

`bar(x,Y)` draws bars for each column in `Y` at locations specified in `x`.

`bar(___,width)` sets the relative bar width and controls the separation of bars within a group and can include any of the input arguments in previous syntaxes.

`bar(___,style)` specifies the style of the bars and can include any of the input arguments in previous syntaxes.

`bar(___,bar_color)` displays all bars using the color specified by the single-letter abbreviation of `bar_color` and can include any of the input arguments in previous syntaxes.

`bar(___,Name,Value)` sets the property names to the specified values and can include any of the input arguments in previous syntaxes.

Note You cannot specify names and values when using `hist` or `histc` options.

`bar(axes_handle,___)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar(___)` returns a vector of handles to barseries graphics objects, one for each created.

Change the colormap to use a different color scheme. Use the `colormap` function to specify the figure colormap.

Use `shading flat` to turn off bar edges. Use `shading faceted` to turn on bar edges. See the `shading` function for more information.

Input Arguments

x - x-axis intervals

vector | 2D array

x-axis intervals for vertical bars, specified as a vector.

The *x*-values can be nonmonotonic, but cannot contain duplicate values.

Example: `x = 1:10;`

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Y - Bar lengths

vector | 2–D array

Bar lengths, specified as an array.

- If `Y` is a vector, `bar` creates `length(Y)` bars.
- If `Y` is a 2–D array, `bar` groups the bars produced by the elements in each row.

Example: `y = [10,8,5,7,3,9,1];`

Data Types
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

width - Bar width

0.8 (default) | scalar

Bar width of each bar, specified as a fraction of the total width of a bar and the space between bars. The default of 0.8 means the a bar width is 80% of the space from the previous bar to the next bar, with 10% of that space on each side.

If `width` is `1`, the bars within a group touch one another.

Example: `bar(y,0.5);`

Data Types
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

style - Bar style, specified as one of the following strings

`'grouped'` (default) | `'stacked'` | `'hist'` | `'histc'`

Bar style, specified by one of these values.

Style	Purpose
`'grouped'`	Displays *m* groups of *n* vertical bars, where *m* is the number of rows and *n* is the number of columns in `Y`. The group contains one bar per column in `Y`.
`'stacked'`	Displays one bar for each row in `Y`. • If `Y` is a vector, bar ignores the `` `stacked' `` option. • If `Y` is a matrix, the bar height is the sum of the elements in the

Style	Purpose
	row. Each bar is multicolored. Colors correspond to distinct elements and show the relative contribution each row element makes to the total sum.
`'histc'`	Displays the graph in histogram format, in which bars touch one another.
`'hist'`	Displays the graph in histogram format, but centers each bar over the *x*-ticks, rather than making bars span *x*-ticks as the `histc` option does.

Example: `bar(Y,'hist')`

Data Types
`char`

bar_color - Bar color
`'b' | 'r' | 'g' | 'b' | 'c' | 'm' | 'y' | 'k' | 'w'`

Bar color, specified as a single-letter abbreviation, assigns the color specified to all bars.

Example: `bar(Y,'r')`

Data Types
`char`

axes_handle - Axes handle
Current axes (default) | Axes handle

Axes handle specifying the target axes for the bar graph.

Example: `bar(ah,Y);`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `bar(Y,'EdgeColor','g')`

'BarLayout' - Arrangement of bars

`grouped` (default) | `stacked`

Arrangement of bars, specified as the comma-separated pair consisting of `'BarLayout'` and one of these values:

- `grouped` — Display *m* groups of *n* vertical bars, where *m* is the number of rows and *n* is the number of columns in the input argument `Y`. The group contains one bar per column in `Y`.
- `stacked` — Display one bar for each row in the input argument `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

'BaseValue' - Base line location

0 (default) | scalar

Base line location, specified as the comma-separated pair consisting of `'BaseValue'` and the value along the *y*-axis (vertical bars) or *x*-axis (horizontal bars) at which MATLAB draws the baseline.

'BarWidth' - Relative width of bars

0.8 (default) | scalar

Relative bar width, specified as the comma-separated pair consisting of `'BarWidth'` and a value relative to width and spacing. `BarWidth` controls the separation of bars within a group. By default, the bars

within a group have a slight separation. A value of `1` makes bars touch with no space. A value greater than `1` makes the bars overlap.

'EdgeColor' - Color of bar edges

`[0,0,0]` (default) | `none` | `ColorSpec`

Color of bar edges, specified as the comma-separated pair consisting of `'EdgeColor'` and a three-element RGB vector, or one of the MATLAB predefined color specifier names.

'FaceColor' - Color of bars

`flat` (default) | `none` | `ColorSpec`

Color of bars, specified as the comma-separated pair consisting of `'FaceColor'` and one of these values:

- `flat` — Use the figure `colormap` to determine the color of the bars.
- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all bars.
- `none` — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.

'LineStyle' - Line style of bar edges

– (default) | `-` | `--` | `:` | `-.` | `none`

Line style of bar edges, specified as the comma-separated pair consisting of `'LineStyle'` and one of the predefined line style strings.

'LineWidth' - Width of bar edges

0.5 points (default) | Scalar width specified in points

Width of bar edges, specified as the comma-separated pair consisting of `'LineWidth'` and a scalar value representing the line width in points.

Output Arguments

h - Handle to barseries objects, returned as a barseries handle

Array of one or more handles

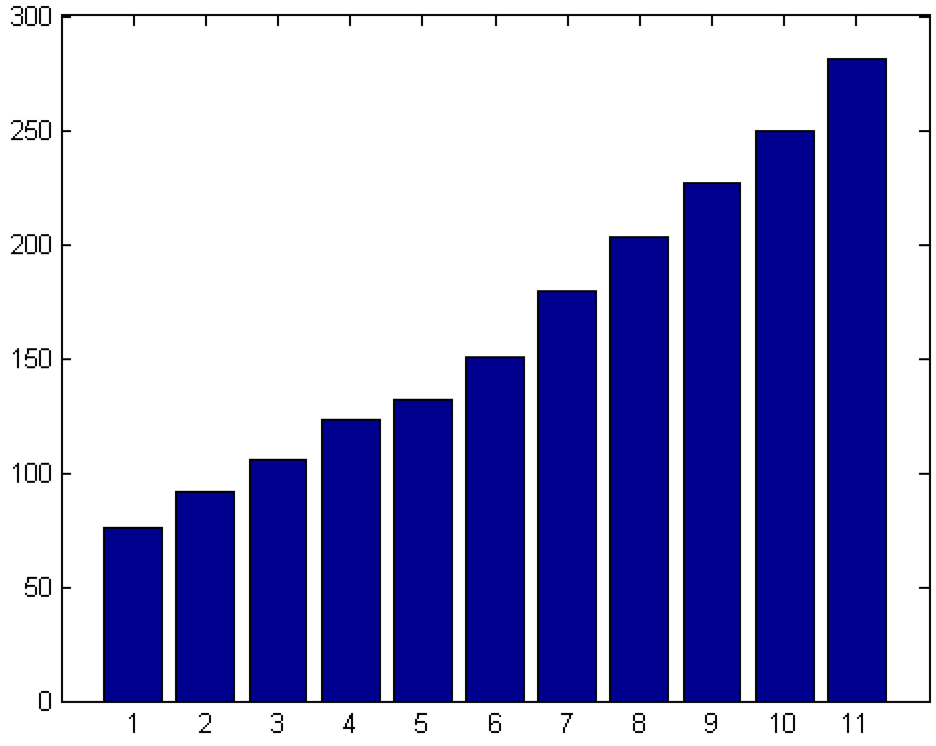
Handles to barseries objects created for the graph.

Examples

Single Data Series

Use the bar function to plot vector data.

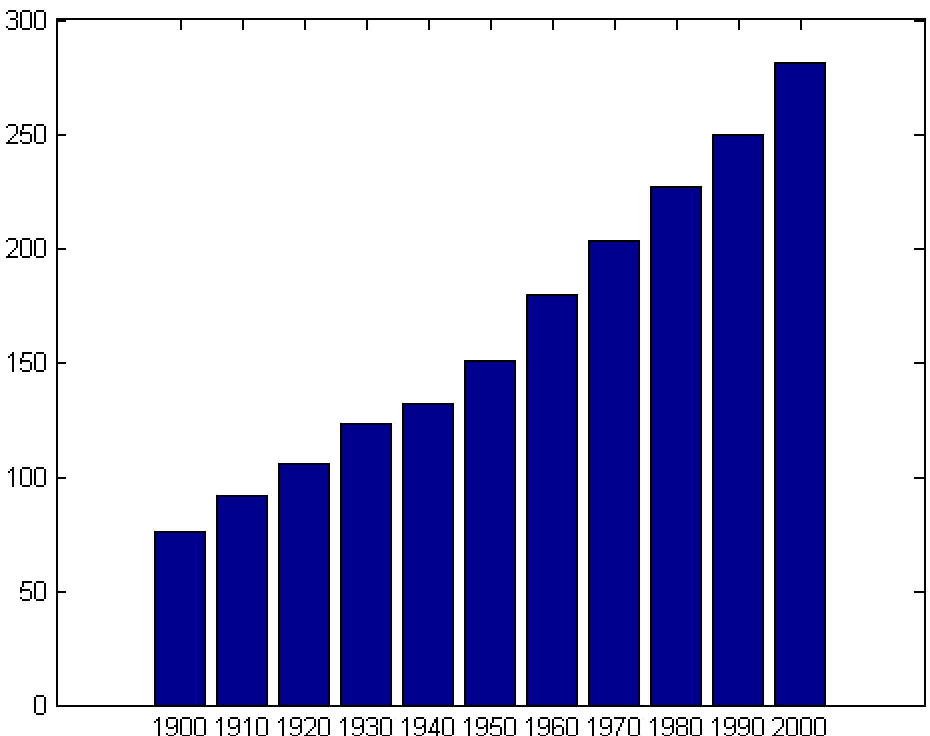
```
y = [75.995,91.972,105.711,123.203,131.669,...
     150.697,179.323,203.212,226.505,249.633,281.422];
figure; bar(y);
```



X-Axis Tick Labels

Specify the numeric values of the x-axis tick labels.

```
x = 1900:10:2000;
y = [75.995,91.972,105.711,123.203,131.669,...
     150.697,179.323,203.212,226.505,249.633,281.422];
figure; bar(x,y);
```

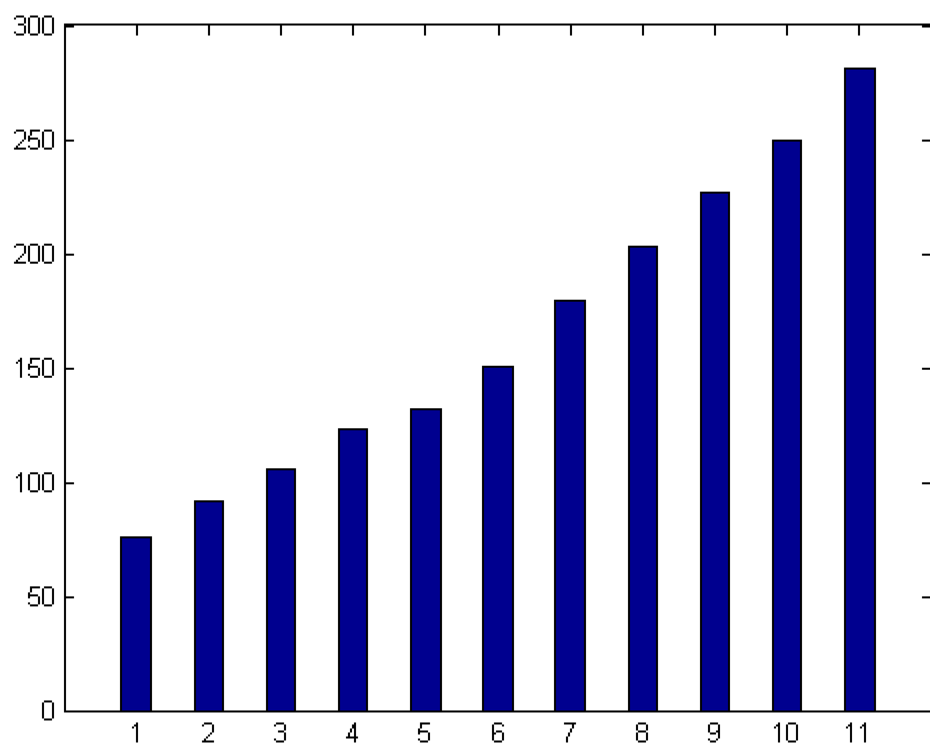


Plot *y* values at each *x* value. Notice that the `length(x)` and `length(y)` have to be same.

Bar Width

Set width of each bar to 40 percent of the total space available for each bar.

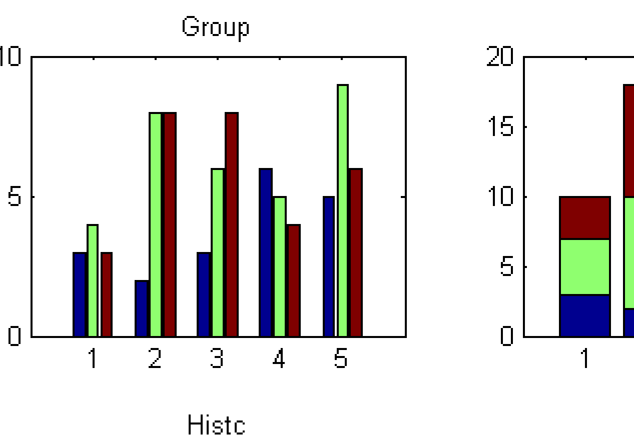
```
y = [75.995,91.972,105.711,123.203,131.669,...
     150.697,179.323,203.212,226.505,249.633,281.422];
figure; bar(y,0.4);
```

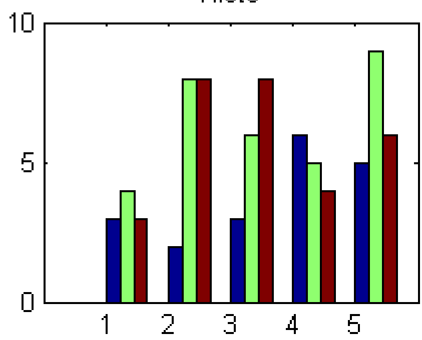


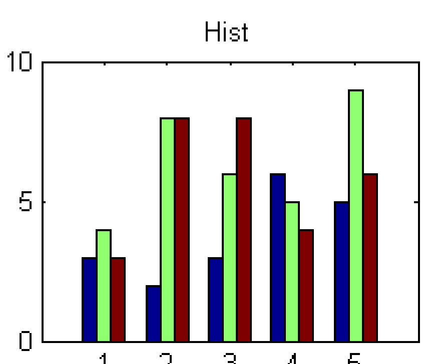
Bar Graph Styles

Create a 2x2 subplot with different styles applied to each bar graph.

```
Y = round(rand(5,3)*10);
figure;
subplot(2,2,1); bar(Y,'grouped'); title('Group')
subplot(2,2,2); bar(Y,'stacked'); title('Stack')
subplot(2,2,3); bar(Y,'histc'); title('Histc')
subplot(2,2,4); bar(Y,'hist'); title('Hist')
```



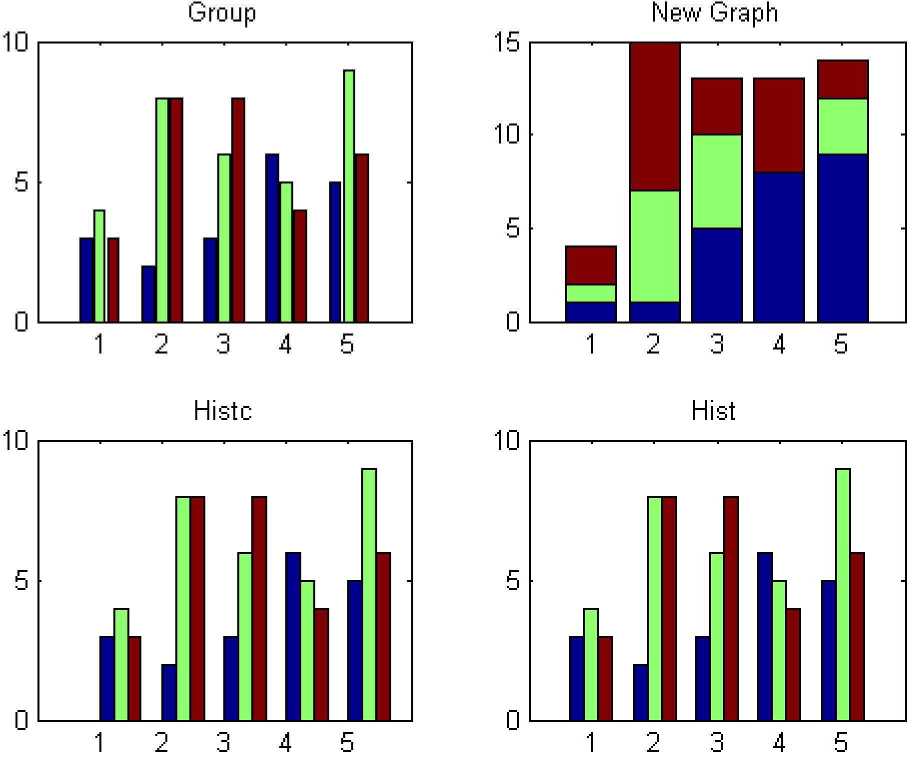




Specify Axes

Specify axes handle in the call to `bar`.

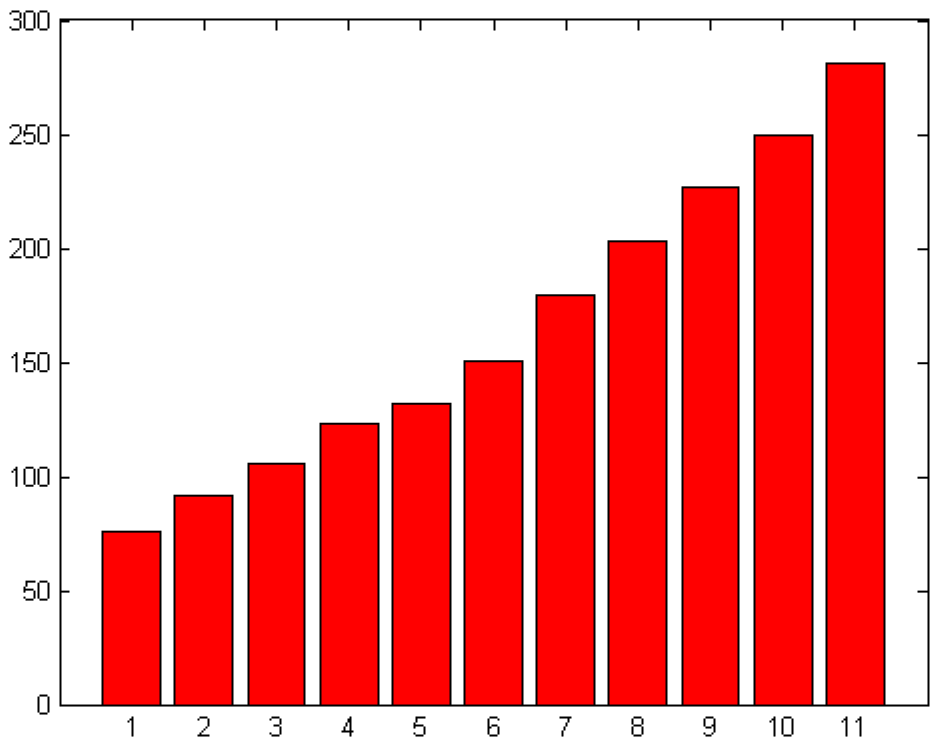
```
newY = round(rand(5,3)*10);
ah = subplot(2,2,2);
bar(ah,newY,'stacked'); title('New Graph')
```



Bar Color

Specify red color for the bar graph.

```
y = [75.995,91.972,105.711,123.203,131.669,...
     150.697,179.323,203.212,226.505,249.633,281.422];
figure; bar(y,'r');
```

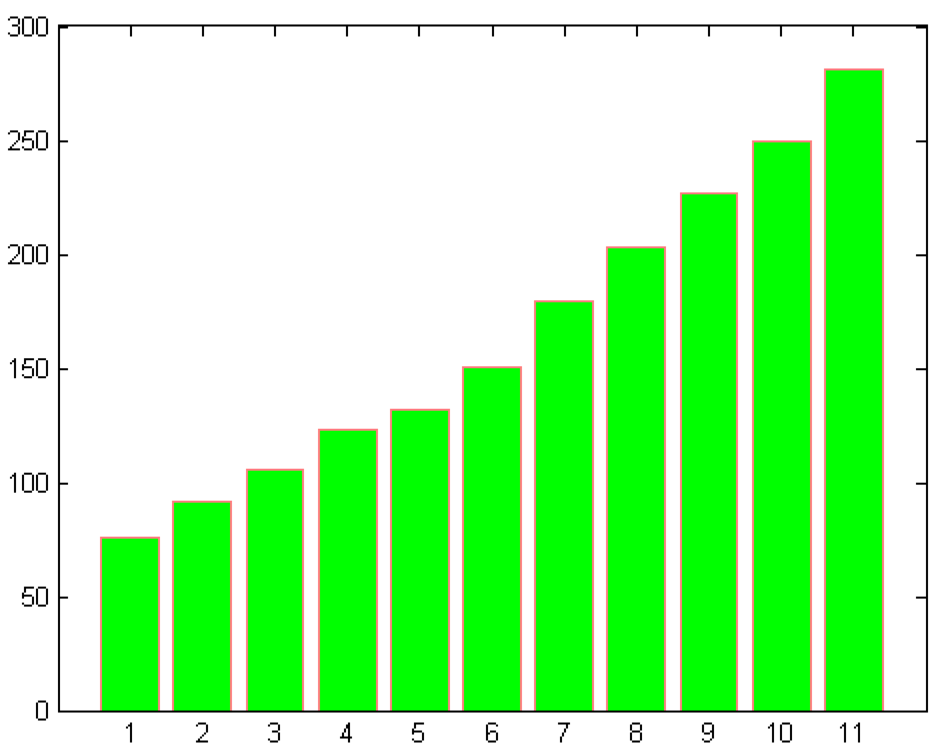


Bar Face and Edge Color

Specify green bars and use an RGB color specification for the bar edge color.

```
y = [75.995,91.972,105.711,123.203,131.669,...
     150.697,179.323,203.212,226.505,249.633,281.422];
```

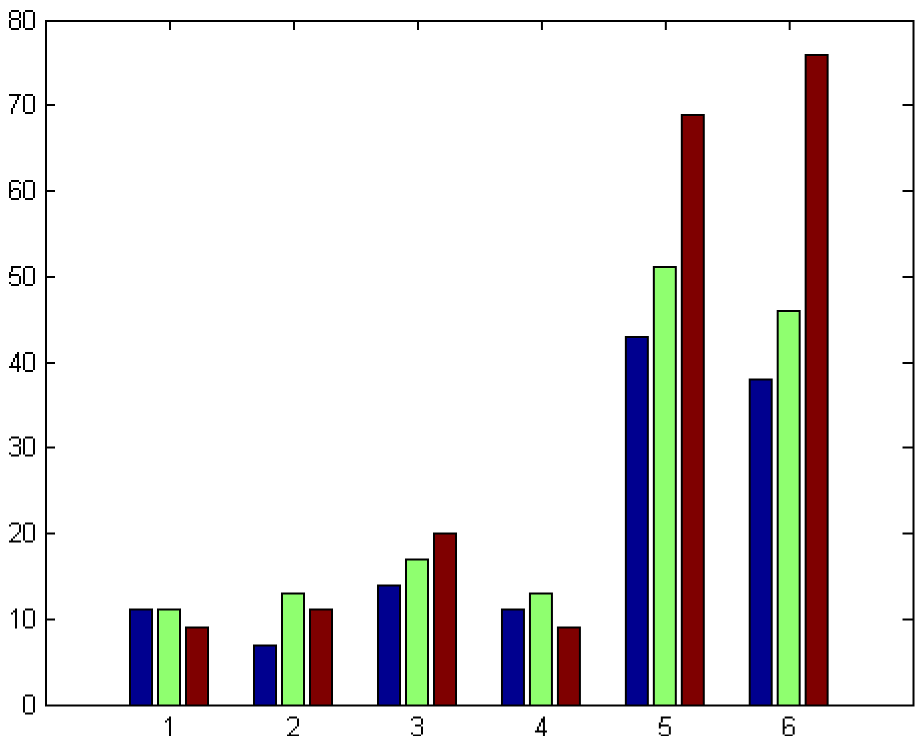
```
figure; bar(y,'g','EdgeColor',[1,0.5,0.5]);
```



Bar Graph of 2–D Array

Plot a 6–by-3 array as six groups with three bars each.

```
c = load('count.dat');
Y = c(1:6,:);
figure; bar(Y);
```



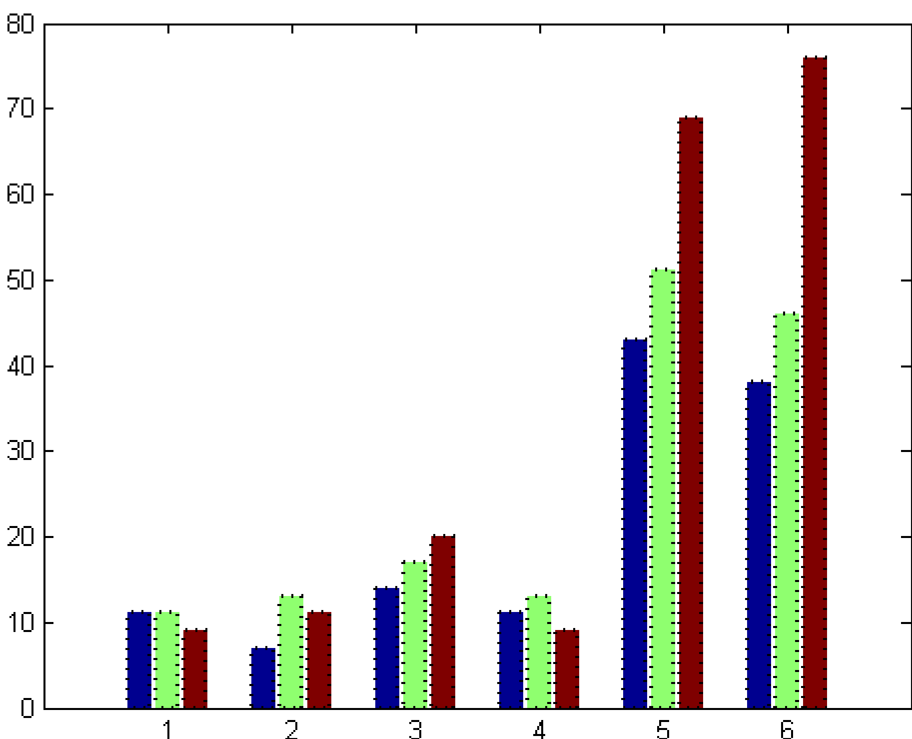
Emphasize Subset of Data

Set appearance of one column of data.

Set `LineWidth` and `EdgeColor` for the bars representing the second column in the data array `y`. Use the handles returned by `bar` and the `set` function to set the `barseries` properties.

```
c = load('count.dat');
Y = c(1:6,:);
hArray = bar(Y);
```

```
set(hArray(2),'LineWidth',2,'EdgeColor','red');
```



Baseline Modifications

Create a graph that displays three groups with five bars `barseries` objects.

All `barseries` objects in a graph share the same baseline. Use the `BaseLine` property of any `barseries` object to change the properties of the baseline. This example uses the first handle returned in `h`.

```
y = sin((-pi:pi).^2);
% Put the baseline at y = -0.2
h = bar(y,'BaseValue',-0.2);
% Get a handle to the baseline
hbl = get(h(1),'BaseLine');
% Change to a red dotted line
set(hbl,'Color','red','LineStyle',':')
```

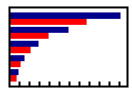
Related Examples

- “Bar and Area Graphs”

barh

Purpose

Plot bar graph horizontally



Syntax

```
barh(Y)
barh(X,Y)
barh(...,width)
barh(...,'style')
barh(...,'bar_color')
barh(...,'PropertyName',PropertyValue,...)
barh(axes_handle,...)
h = barh(...)
```

Description

A `barh` graph displays the values in a vector or matrix as horizontal bars.

`barh(Y)` draws one horizontal bar for each element in `Y`. If `Y` is a matrix, `barh` groups the bars produced by the elements in each row. The *x*-axis scale ranges from 1 up to `length(Y)` when `Y` is a vector, and `1` to `size(Y,1)`, which is the number of rows, when `Y` is a matrix. The default is to assign an appropriate progression of tick values according to the data. If you want the *x*-axis scale to end exactly at the last bar, set the axis limits as,

```
set(gca,'XLim',[1 length(Y)])
```

`barh(X,Y)` draws a bar for each element in `Y` at locations specified in `x`, where `X` is a vector defining the *x*-axis intervals for the vertical bars. The *x*-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `barh` groups the elements of each row in `Y` at corresponding locations in `X`.

`barh(...,width)` sets the relative bar width and controls the separation of bars within a group. The default `width` is `0.8`, so if you do not specify `X`, the bars within a group have a slight separation. If

`width` is `1`, the bars within a group touch one another. The value of `width` must be a scalar.

`barh(...,'style')` specifies the style of the bars. `'style'` is `'grouped'` or `'stacked'`. Default mode of display is `'grouped'`.

- `'grouped'` displays *m* groups of *n* vertical bars, where *m* is the number of rows and *n* is the number of columns in `Y`. The group contains one bar per column in `Y`.
- `'stacked'` displays one bar for each row in `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.
- `'histc'` displays the graph in histogram format, in which bars touch one another.
- `'hist'` also displays the graph in histogram format, but centers each bar over the *x*-ticks, rather than making bars span *x*-ticks as the `histc` option does.

Note When you use either the `hist` or `histc` option, you cannot also use parameter/value syntax. These two options create graphic objects that are patches rather than barseries.

`barh(...,'bar_color')` displays all bars using the color specified by the single-letter abbreviation `'r'`, `'g'`, `'b'`, `'c'`, `'m'`, `'y'`, `'k'`, or `'w'`.

`barh(...,'PropertyName',PropertyValue,...)` sets the named property or properties to the specified values. You cannot specify properties when `hist` or `histc` options are used. See the barseries property descriptions for information on what properties you can set.

`barh(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = barh(...)` returns a vector of handles to barseries graphics objects, one for each created. When `Y` is a matrix, `barh` creates one barseries graphics object per column in `Y`.

Barseries Objects

Creating a bar graph of an *m*-by-*n* matrix creates *m* groups of *n* barseries objects. Each barseries object contains the data for corresponding `x` values of each bar group (as indicated by the coloring of the bars).

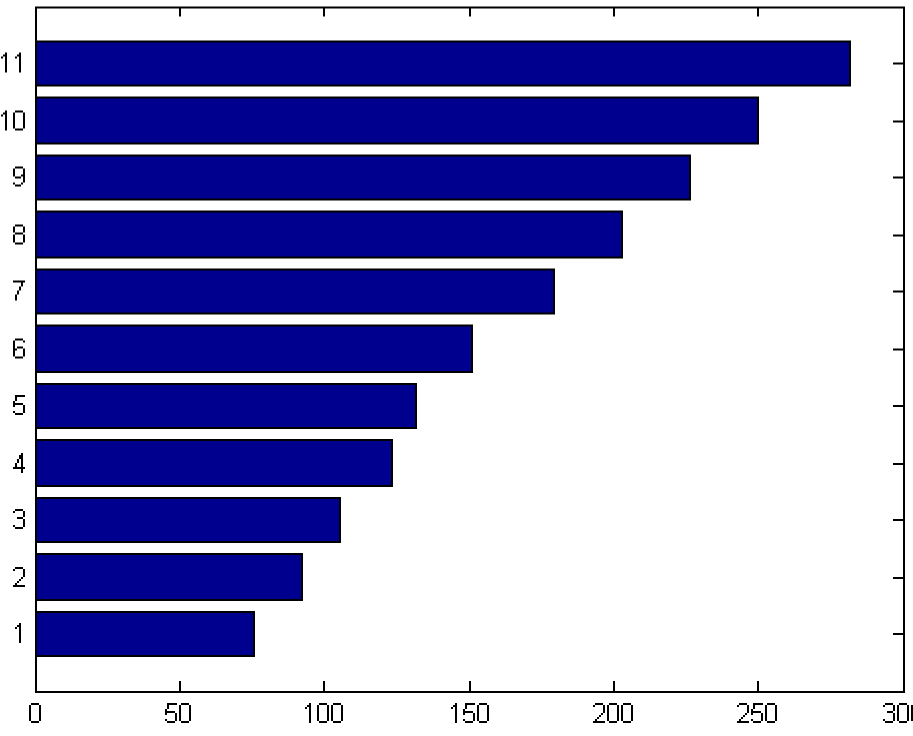
Note some barseries object properties set on an individual barseries object set the values for all barseries objects in the graph. See the barseries property descriptions for information on specific properties.

Examples

Single Series of Data

This example shows how to plot vector data using `barh` .

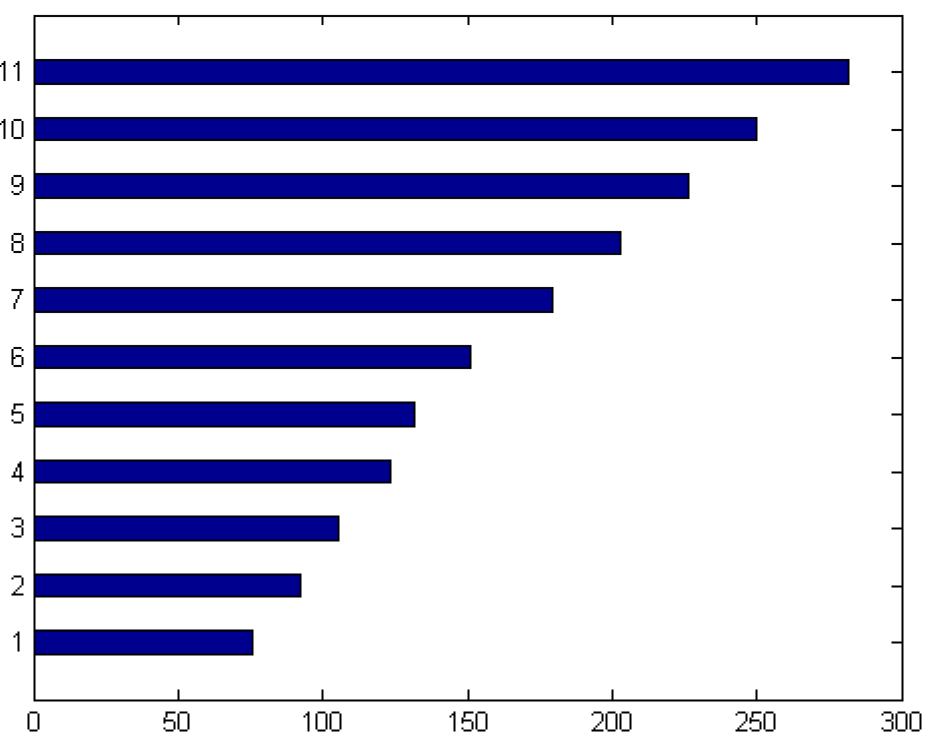
```
y = [75.995 91.972 105.711 123.203 131.669 ...
     150.697 179.323 203.212 226.505 249.633 281.422];
figure; barh(y);
```



Specifying width While Passing Single Variable.

This example shows how to specify width for each bar in the graph. You can specify one or both data inputs.

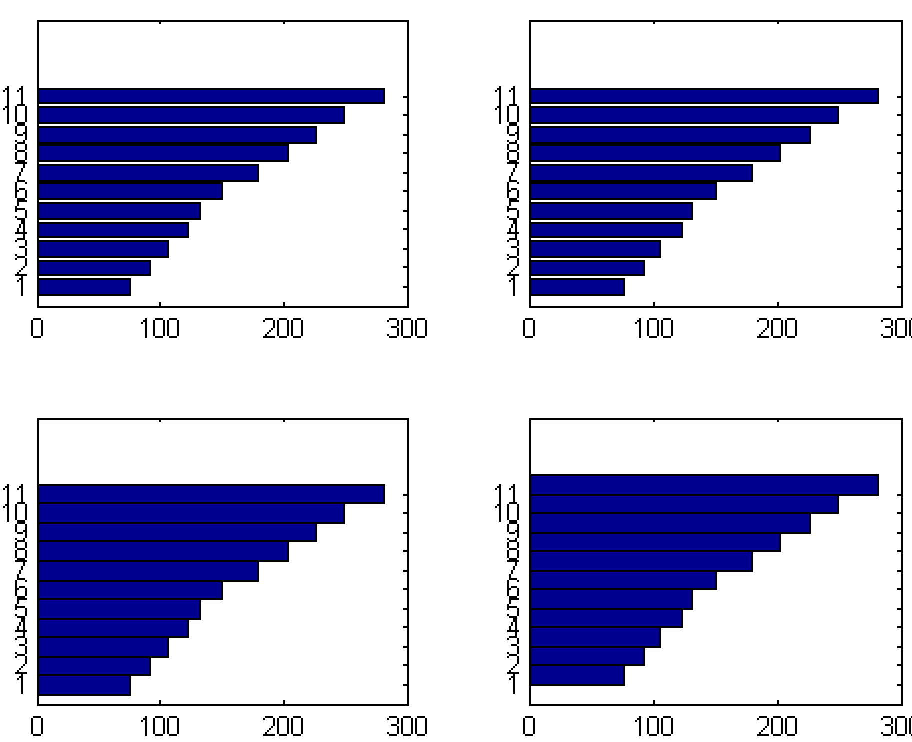
```
figure; barh(y,0.4);
```



Specifying style

This example shows you how to specify `Style` for `bar` graph.

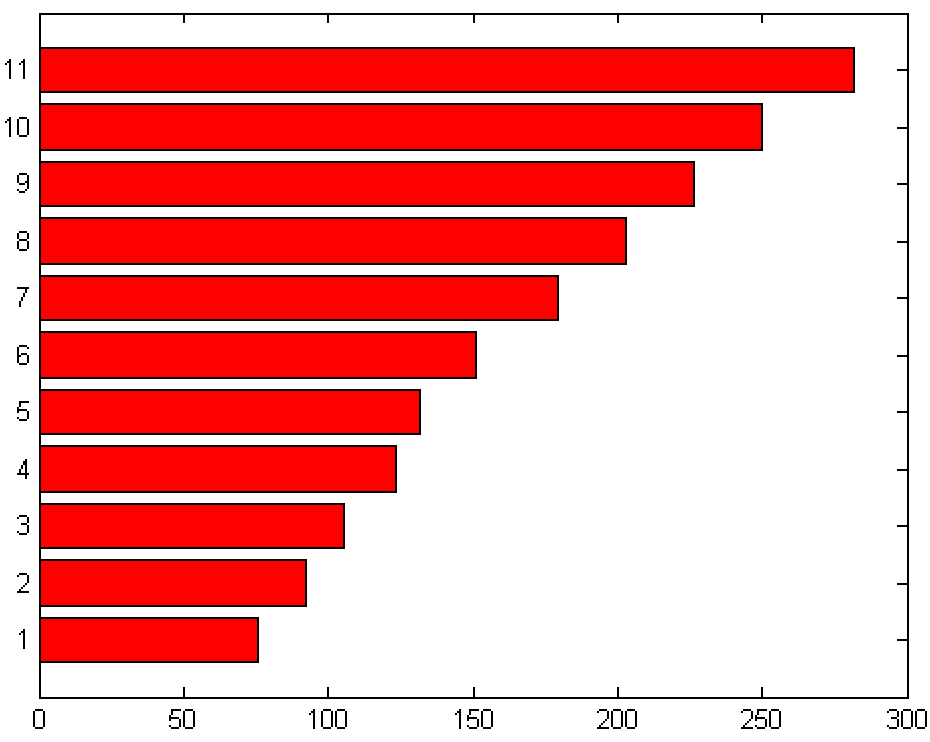
```
figure;
subplot(2,2,1); barh(y,'grouped');
subplot(2,2,2); barh(y,'stacked');
subplot(2,2,3); barh(y,'hist');
subplot(2,2,4); barh(y,'histc');
```



Specifying color

This example shows how to specify color for the graph.

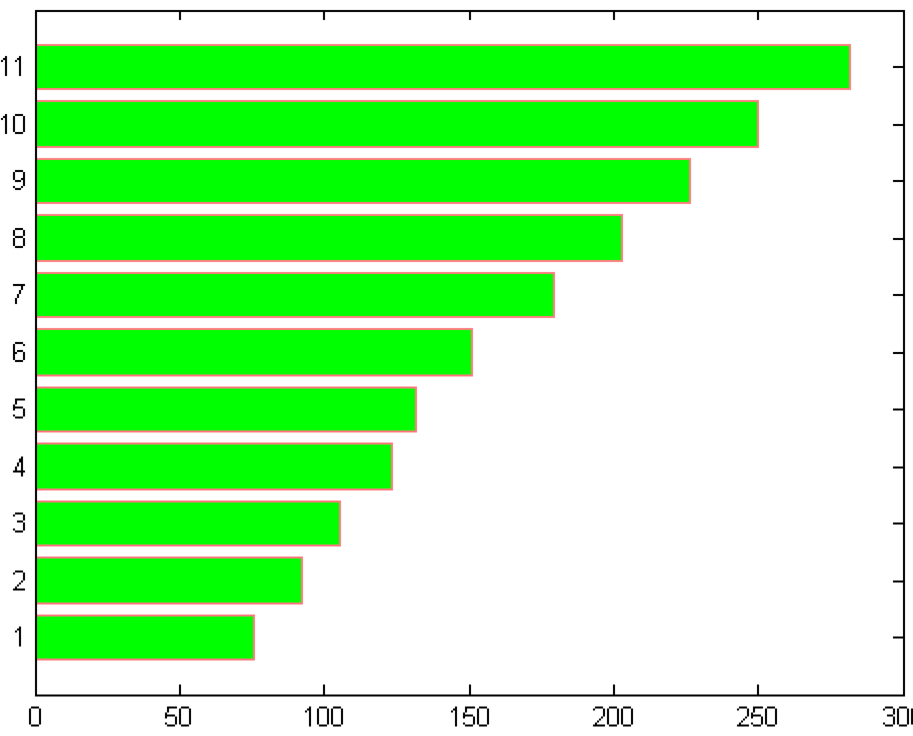
```
figure; barh(y,'r');
```



Specifying Name-Value Pairs

You can instead specify the rgb color instead of using the predefined ones. For example,

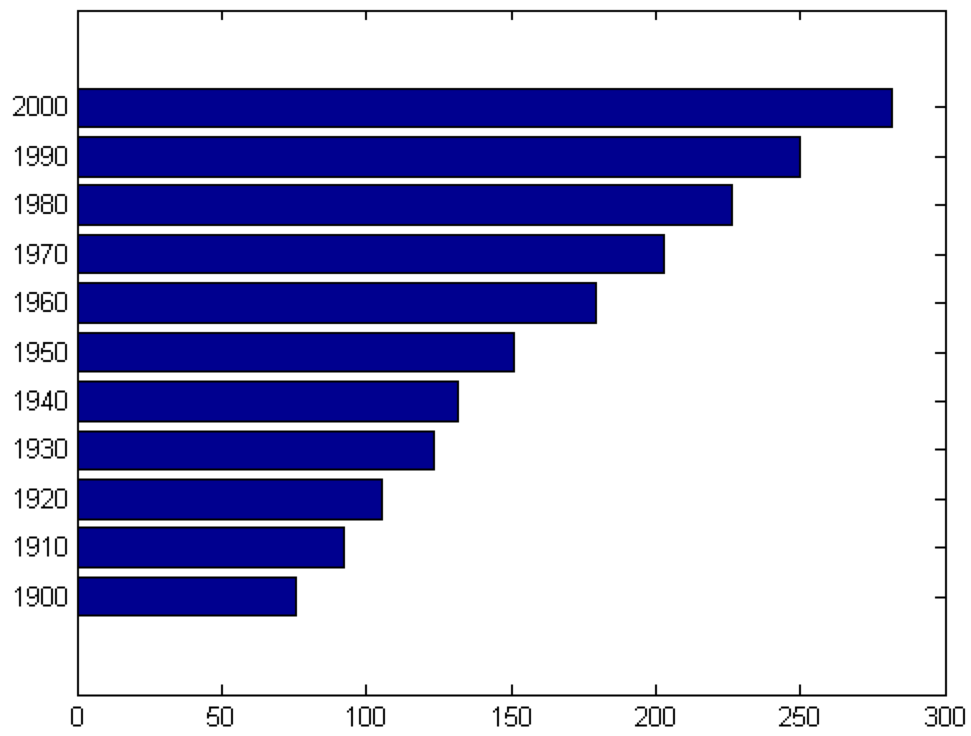
```
figure; barh(y,'g','EdgeColor',[1 0.5 0.5]);
```



Passing Two Variables

This example shows how to plot vector data with two inputs `x` and `y` using `barh` .

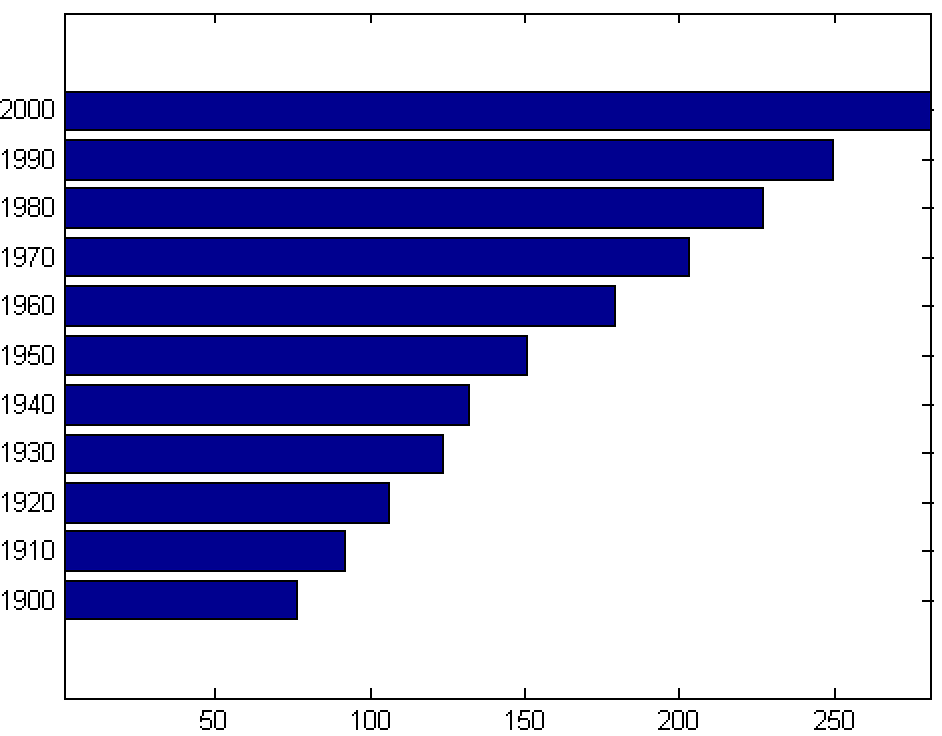
```
x = [1900:10:2000];
figure; barh(x,y);
```



Setting Axis Scale

The default is to assign an appropriate progression of tick values according to the data. If you want the *y*-axis scale to end exactly at the last bar, you can change the axes `YLim` property, which sets the limits of the *y*-axis. See `axes` for more information.

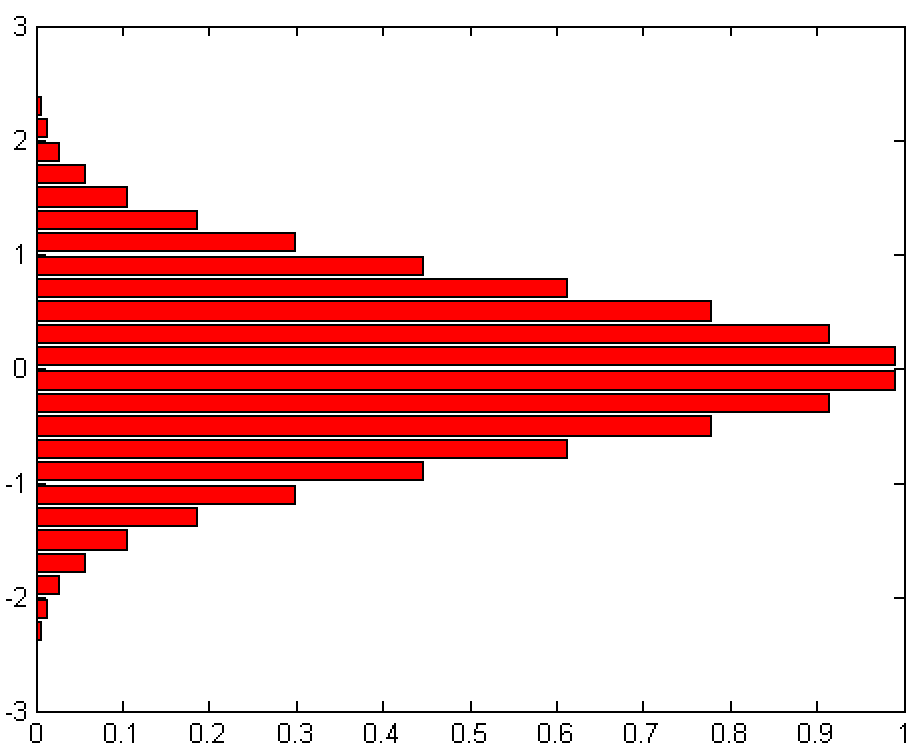
```
x = [1900:10:2000];
figure; barh(x,y);
set(gca,'YLim',[1 max(y)]);
```



Passing an Expression

You can also pass the expression with the `barh` function.

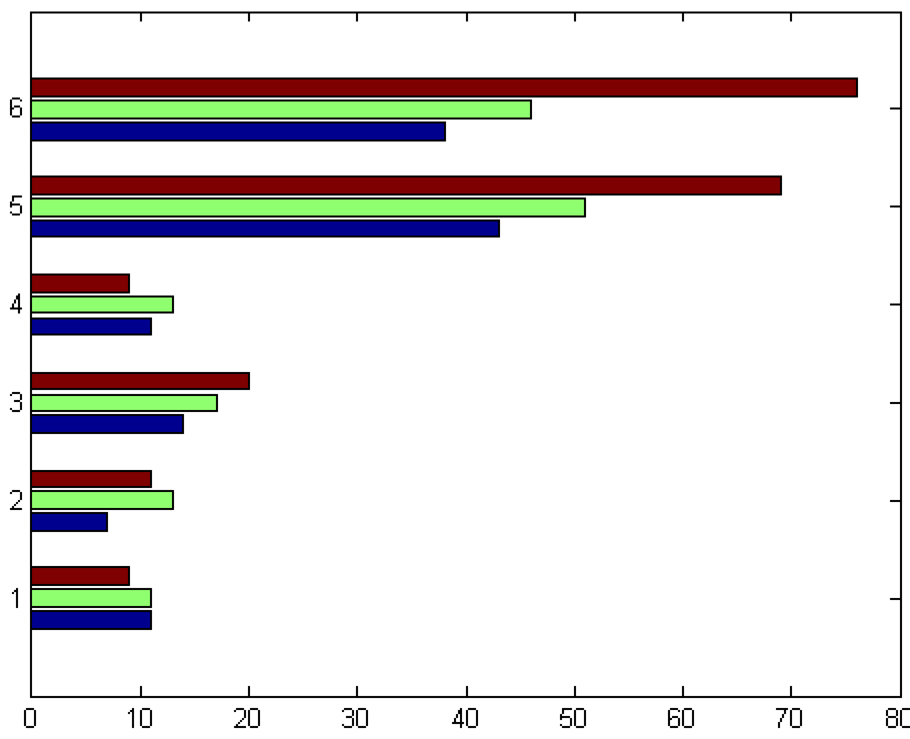
```
a = -2.9:0.2:2.9;
barh(a,exp(-a.*a),'r')
```



Plotting Matrix Data

This example shows how to plot matrix data using `barh`.

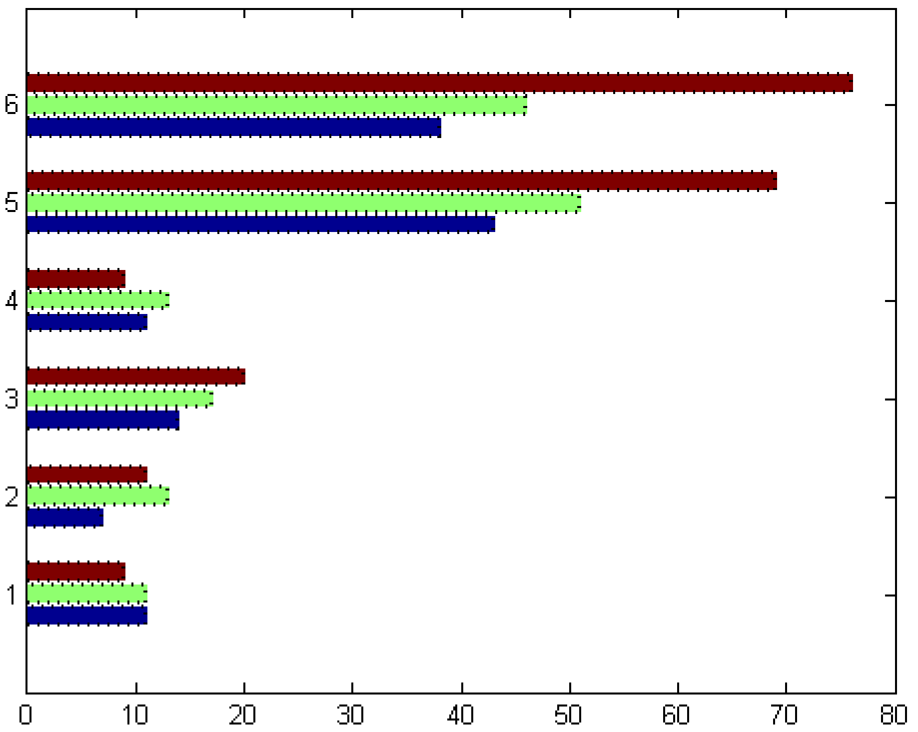
```
load count.dat;
yMat = count(1:6,:);
figure; barh(yMat);
```



Setting Properties with Multiobject Graphs

This example shows how to set `LineWidth` and `LineStyle` for three barseries objects using the handle returned by `barh`.

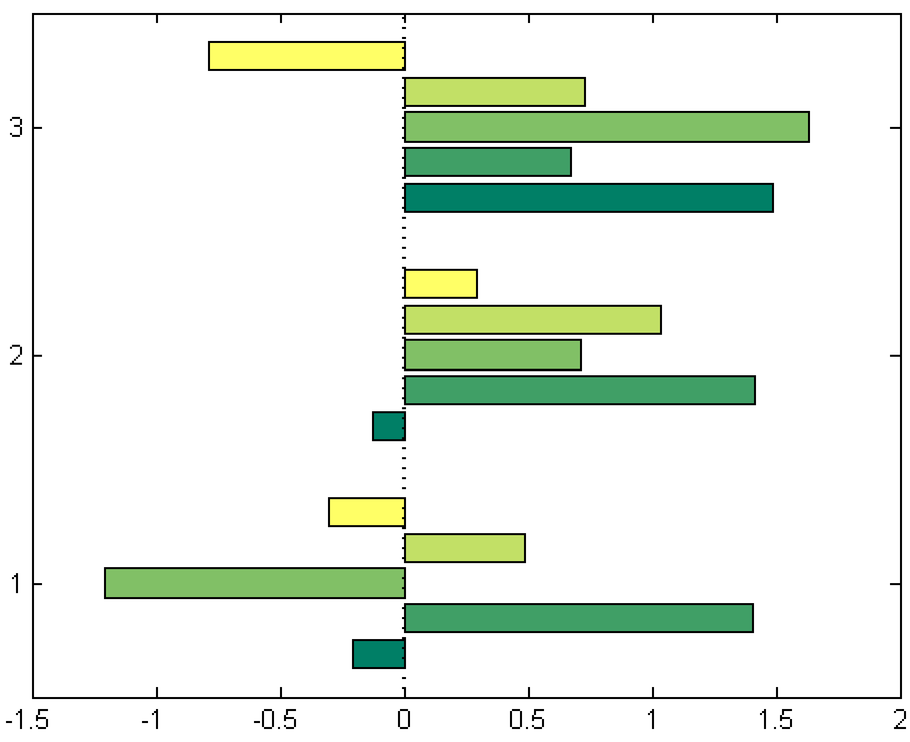
```
hMulti = barh(yMat);
set(hMulti,'LineWidth', 2, 'LineStyle',':');
```



Setting Properties with Multiobject Graphs

This example creates a graph that displays three groups of bars and contains five barseries objects. Since all barseries objects in a graph share the same baseline, you can set values using any barseries object's `BaseLine` property. This example uses the first handle returned in `h`.

```
Y = randn(3,5);
h = barh(Y);
set(get(h(1),'BaseLine'),'LineWidth',2,'LineStyle',':')
colormap summer % Change the color scheme
```



Specifying `colormap` assigns a specific color in the map spectrum to each handle object in the group resulting in one color for each object group.

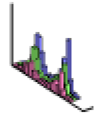
How To

- "Bar and Area Graphs"

bar3

Purpose

Plot 3-D bar graph



Syntax

```
bar3(Y)
bar3(x,Y)
bar3(...,width)
bar3(...,'style')
bar3(...,LineSpec)
bar3(axes_handle,...)
h = bar3(...)
```

Description

`bar3` draws a three-dimensional bar graph.

`bar3(Y)` draws a three-dimensional bar chart, where each element in `Y` corresponds to one bar. When `Y` is a vector, the *x*-axis scale ranges from `1` to `length(Y)`. When `Y` is a matrix, the *x*-axis scale ranges from `1` to `size(Y,1)` and the elements in each row are grouped together.

`bar3(x,Y)` draws a bar chart of the elements in `Y` at the locations specified in `x`, where `x` is a vector defining the *y*-axis intervals for vertical bars. The *x*-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar3` clusters elements from the same row in `Y` at locations corresponding to an element in `x`. Values of elements in each row are grouped together.

`bar3(...,width)` sets the width of the bars and controls the separation of bars within a group. The default `width` is `0.8`, so if you do not specify `x`, bars within a group have a slight separation. If `width` is `1`, the bars within a group touch one another.

`bar3(...,'style')` specifies the style of the bars. `'style'` is `'detached'`, `'grouped'`, or `'stacked'`. Default mode of display is `'detached'`.

- `'detached'` displays the elements of each row in `Y` as separate blocks behind one another in the *x* direction.
- `'grouped'` displays *n* groups of *m* vertical bars, where *n* is the number of rows and *m* is the number of columns in `Y`. The group contains one bar per column in `Y`.
- `'stacked'` displays one bar for each row in `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3(...,LineSpec)` displays all bars using the color specified by `LineSpec`.

`bar3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3(...)` returns a vector of handles to patch graphics objects, one for each created. `bar3` creates one patch object per column in `Y`. When `Y` is a matrix, `bar3` creates one patch graphics object per column in `Y`.

Examples

Compare two 3-D bar graphs where style is specified as `'detached'` and width is varied. This type of graph helps in visualizing trend of each row in the input data.

```
load count.dat;
y = count(1:10,:); % Loading the dataset creates a variable 'count'
figure; subplot(1,2,1);
bar3(y,'detached');
title('Detached');
subplot(1,2,2);
bar3(y,0.5,'detached');
title('Width = 0.5');
```

`bar` | `barh` | `bar3h` | `LineSpec`

How To

- "Bar and Area Graphs"

bar3h

Purpose

Plot horizontal 3-D bar graph

Syntax

```
bar3h(Y)
bar3h(x,Y)
bar3h(...,width)
bar3h(...,'style')
bar3h(...,LineSpec)
bar3h(axes_handle,...)
h = bar3h(...)
```

Description

`bar3h` draws three-dimensional horizontal bar charts.

`bar3h(Y)` draws a three-dimensional bar chart, where each element in `Y` corresponds to one bar. When `Y` is a vector, the *y*-axis scale ranges from `1` to `length(Y)`. When `Y` is a matrix, the *y*-axis scale ranges from `1` to `size(Y,1)` and the elements in each row are grouped together.

`bar3h(x,Y)` draws a bar chart of the elements in `Y` at the locations specified in `x`, where `x` is a vector defining the *y*-axis intervals for horizontal bars. The *x*-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar3` clusters elements from the same row in `Y` at locations corresponding to an element in `x`. Values of elements in each row are grouped together.

`bar3h(...,width)` sets the width of the bars and controls the separation of bars within a group. The default `width` is `0.8`, so if you do not specify `x`, bars within a group have a slight separation. If `width` is `1`, the bars within a group touch one another.

`bar3h(...,'style')` specifies the style of the bars. `'style'` is `'detached'`, `'grouped'`, or `'stacked'`. Default mode of display is `'detached'`.

- `'detached'` displays the elements of each row in `Y` as separate blocks behind one another in the *y* direction.

- `'grouped'` displays *n* groups of *m* vertical bars, where *n* is the number of rows and *m* is the number of columns in `Y`. The group contains one bar per column in `Y`.
- `'stacked'` displays one bar for each row in `Y`. The bar length is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3h(...,LineSpec)` displays all bars using the color specified by `LineSpec`.

`bar3h(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3h(...)` returns a vector of handles to patch graphics objects, one for each created. `bar3` creates one patch object per column in `Y`. When `Y` is a matrix, `bar3h` creates one patch graphics object per column in `Y`.

How To

- “Bar and Area Graphs”

Barseries Properties

Purpose

Define barseries properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default properties for barseries objects.

See "Plot Objects" for more information on barseries objects.

Barseries Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Annotation`

`hg.Annotation` object (read-only)

Control the display of barseries objects in legends. Specifies whether this barseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the barseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
`on`	Include the barseries object in a legend as one entry, but not its children objects
`off`	Do not include the barseries or its children in a legend (default)
`children`	Include only the children of the barseries as separate entries in the legend

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the IconDisplayStyle Property

See "Controlling Legends" for more information and examples.

`BarLayout`

`{grouped} | stacked`

Specify grouped or stacked bars.

- `grouped` — Display *m* groups of *n* vertical bars, where *m* is the number of rows and *n* is the number of columns in the input argument `Y`. The group contains one bar per column in `Y`.
- `stacked` — Display one bar for each row in the input argument `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`BarWidth`

scalar in range `[0 1]`

Width of individual bars. `BarWidth` specifies the relative bar width and controls the separation of bars within a group. The default is `0.8`, so if you do not specify `x`, the bars within a group have a slight separation. If `BarWidth` is `1`, the bars within a group touch one another.

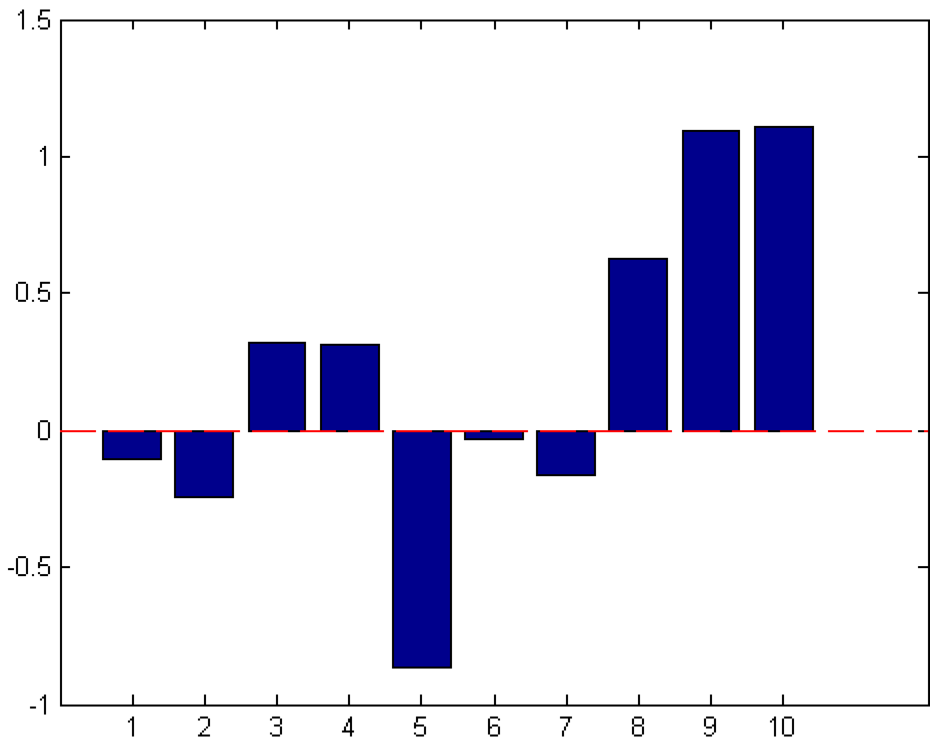
`BaseLine`

handle

Handle of the baseline line object. Handle of the line object used as the baseline. You can set the properties of this line using its handle.

Create a bar graph, obtain the handle of the baseline from the barseries object, and then set line properties that make the baseline a dashed, red line:

```
bar_handle = bar(randn(10,1));
baseline_handle = get(bar_handle,'BaseLine');
set(baseline_handle,'LineStyle','--','Color','red')
```



`BaseValue`

double: y-axis value

Baseline location. You can specify the value along the *y*-axis (vertical bars) or *x*-axis (horizontal bars) at which the MATLAB software draws the baseline. The default is `0`.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`
string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`Children`
array of graphics object handles

Children of the barseries object. The handle of a patch object that is the child of this object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`
`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`CreateFcn`
function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y,'CreateFcn',@CallbackFcn)
```

where *`@CallbackFcn`* is a function handle that references the callback function and *`graphicfcn`* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`

string

String used by legend. The `legend` function uses the `DisplayName` property to label the barseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EdgeColor`
`{[0 0 0]} | none | ColorSpec`

Color of line separating filled areas. You can set the color of the edges of filled areas to a three-element RGB vector or one of the MATLAB predefined names, including the string `none`. The default value is `[0 0 0]` (`black`). See the `ColorSpec` reference page for more information on specifying color.

`EraseMode`
`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However,

the object's color depends on the color of whatever is beneath it on the display.

- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceColor`
`{flat} | none | ColorSpec`

Color of filled areas.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- `none` — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.

- `flat` — The object uses the figure `colormap` to determine the color of the filled areas.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`

`{on} | off`

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the bar graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`

`on | {off}`

Select barseries object on bars or area of extent. This property enables you to select barseries objects in two ways:

- Select by clicking bars (default).

- Select by clicking anywhere in the extent of the bar graph.

When `HitTestArea` is `off`, you must click the bars to select the barseries object. When `HitTestArea` is `on`, you can select the barseries object by clicking anywhere within the extent of the bar graph (that is, anywhere within a rectangle that encloses all the bars).

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`

`{-} | -- | :  | -.  | none`

Line style of barseries object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

`LineWidth`
size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is `0.5` points.

`Parent`
handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Object selection state. When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Object highlighted when selected.

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`ShowBaseLine`
`{on} | off`

Turn baseline display on or off. This property determines whether bar plots display a baseline from which the bars are drawn. By default, the baseline is displayed.

`Tag`

string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create a barseries object and set the `Tag` property:

```
t = bar(Y,'Tag','bar1')
```

To access the barseries object, use `findobj` to find the barseries object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `bar1`.

```
set(findobj('Tag','bar1'),'FaceColor','red')
```

`Type`

string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For barseries objects, `Type` is '`hggroup`'.

The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`

handle of uicontextmenu object

Associate context menu with object. Handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

`UserData`
array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Visibility of object and its children.

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

`XData`
array

Location of bars. The *x*-axis intervals for the vertical bars or *y*-axis intervals for horizontal bars (as specified by the `X` input argument). If `YData` is a vector, `XData` must be the same size. If `YData` is a matrix, the length of `XData` must be equal to the number of rows in `YData`.

`XDataMode`
`{auto} | manual`

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the `X` input

argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

`XDataSource`

MATLAB variable, as a string

Link `XData` *to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h,'XDataSource','xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`

scalar | vector | matrix

Bar plot data. `YData` contains the data plotted as bars (the `Y` input argument). Each value in `YData` is represented by a bar in the bar graph. If `XYData` is a matrix, the `bar` function creates a "group"

or a "stack" of bars for each column in the matrix. See the `bar` reference page for examples of grouped and stacked bar graphs.

The input argument `Y` in the `bar` function calling syntax assigns values to `YData`.

`YDataSource`

MATLAB variable, as a string

Link `YData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h,'YDataSource','Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

TriRep.baryToCart

Purpose

(Will be removed) Convert point coordinates from barycentric to Cartesian

---

Note `baryToCart(TriRep)` will be removed in a future release. Use `barycentricToCartesian(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
XC = baryToCart(TR, SI, B)
```

Description

`XC = baryToCart(TR, SI, B)` returns the Cartesian coordinates `XC` of each point in `B` that represents the barycentric coordinates with respect to its associated simplex `SI`.

Input Arguments

`TR`	Triangulation representation.
`SI`	Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`
`B`	`B` is a matrix that represents the barycentric coordinates of the points to convert with respect to the simplices `SI`. `B` is of size `m`-by-`k`, where `m` = `length(SI)`, the number of points to convert, and `k` is the number of vertices per simplex.

Output Arguments

`XC`	Matrix of cartesian coordinates of the converted points. `XC` is of size `m`-by-`n`, where `n` is the dimension of the space where the triangulation resides. That is, the Cartesian coordinates of the point `B(j)` with respect to simplex `SI(j)` is `XC(j)`.

Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);
tri = dt(:,:);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(dt); hold on;
plot(cc(:,1), cc(:,2), '*r'); hold off;
axis equal;
```

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);
y = [0 0 0 0 16 16 16 16]';
tr = TriRep(tri,x,y)
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(tr); hold on;
plot(xc(:,1), xc(:,2), '*r'); hold off;
axis equal;
```

`cartesianToBarycentric` | `pointLocation` | `delaunayTriangulation` | `triangulation`

Purpose

Convert base N number string to decimal number

Syntax

```
d = base2dec('strn', base)
```

Description

`d = base2dec('strn', base)` converts the string number *`strn`* of the specified `base` into its decimal (base 10) equivalent. `base` must be an integer between 2 and 36. If `'strn'` is a character array, each row is interpreted as a string in the specified `base`.

Examples

The expression `base2dec('212',3)` converts 212_3 to decimal, returning 23.

See Also

`dec2base`

beep

Purpose

Produce beep sound

Syntax

```
beep
beep on
beep off
s = beep
```

Description

`beep` produces your computer's default beep sound.

`beep on` turns the beep on.

`beep off` turns the beep off.

`s = beep` returns the current beep mode (`on` or `off`).

Purpose

Initiate asynchronous .NET delegate call

Syntax

```
result = BeginInvoke(arg1,...,argN,callback,object)
```

Description

`result = BeginInvoke(arg1,...,argN,callback,object)` initiates asynchronous call to a .NET delegate. You must call `EndInvoke` to complete the asynchronous call.

Input Arguments

arg1,...,argN

Input arguments for delegate. The type and number of arguments must agree with the delegate signature.

callback

.NET System.AsyncCallback delegate, or `[]` null value.

object

User-defined object, or `[]` null value.

Output Arguments

result

.NET System.IAsyncResult object. Used to monitor the progress of the asynchronous call. Input argument to `EndInvoke`.

Related Links

- MSDN® Calling Synchronous Methods Asynchronously

bench

Purpose

MATLAB benchmark

Syntax

```
bench
bench(N)
bench(0)
t = bench(N)
```

Description

`bench` times six different MATLAB tasks and compares the execution speed with the speed of several other computers. The six tasks are:

Test	Description	Performance Factors
LU	Perform LU of a full matrix	Floating-point, regular memory access
FFT	Perform FFT of a full vector	Floating-point, irregular memory access
ODE	Solve van der Pol equation with ODE45	Data structures and MATLAB function files
Sparse	Solve a symmetric sparse linear system	Mixed integer and floating-point
2-D	Plot Bernstein polynomial graph	2-D line drawing graphics
3-D	Display animated L-shape membrane logo	3-D animated OpenGL graphics

A final bar chart shows speed, which is inversely proportional to time. The longer bars represent faster machines, and the shorter bars represent the slower ones.

`bench(N)` runs each of the six tasks N times.

`bench(0)` just displays the results from other machines.

`t = bench(N)` returns an N-by-6 array with the execution times.

Tips

Note A benchmark is intended to compare performance of one particular version of MATLAB on different machines. It does not offer direct comparisons between different versions of MATLAB as tasks and problem sizes change from version to version.

The LU and FFT tasks involve large matrices and long vectors. The 2-D and 3-D tasks measure graphics performance, including software or hardware support for OpenGL. The command

```
opengl info
```

describes the OpenGL support available on a particular machine.

Fluctuations of five or ten percent in the measured times of repeated runs on a single machine are not uncommon. Your own mileage may vary.

besselh

Purpose

Bessel function of third kind (Hankel function)

Note The behavior of `besselh` has changed in the following ways:

- The syntax `[H,ierr] = besselh(...)` has been removed.
- `besselh` no longer accepts `nu` and `Z` passed as a combination of row and column vectors.
- `besselh` no longer accepts `nu` and `Z` passed as a combination of non-scalar and empty inputs.

Syntax

```
H = besselh(nu,K,Z)
H = besselh(nu,Z)
H = besselh(nu,K,Z,1)
[H,ierr] = besselh(...)
```

Definitions

The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} + \left(z^2 - \nu^2\right) y = 0,$$

where ν is a nonnegative constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*. $J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν. $Y_\nu(z)$ is a second solution of Bessel's equation—linearly independent of $J_\nu(z)$—defined by

$$Y_\nu(z) = \frac{J_\nu(z)\cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}.$$

The relationship between the Hankel and Bessel functions is

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$
$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z)$$

where $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`.

Description

`H = besselh(nu,K,Z)` computes the Hankel function $H_\nu^{(K)}(z)$ where `K` = 1 or 2, for each element of the complex array `Z`. If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, `besselh` expands it to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

`H = besselh(nu,Z)` uses `K` = 1.

`H = besselh(nu,K,Z,1)` scales $H_\nu{}^{(K)}(z)$ by `exp(-i*Z)` if `K` = 1, and by `exp(+i*Z)` if `K` = 2.

`[H,ierr] = besselh(...)` also returns completion flags in an array the same size as `H`.

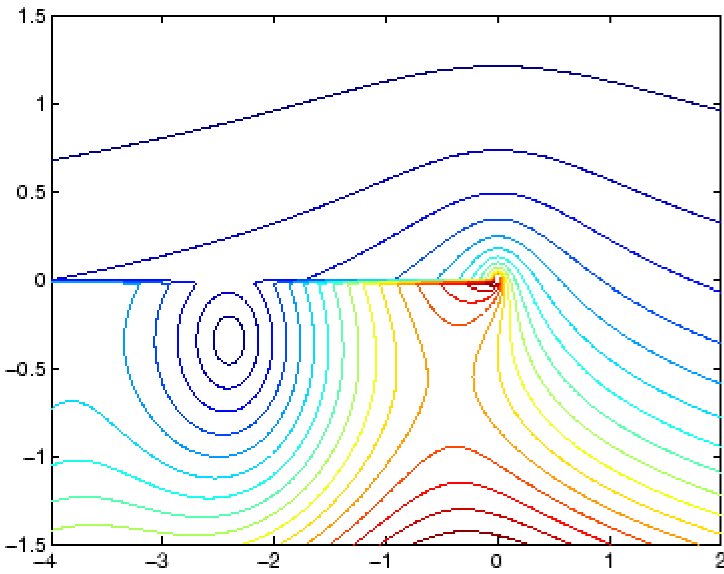
ierr	Description
0	`besselh` successfully computed the Hankel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Examples

This example generates the contour plots of the modulus and phase of the Hankel function $H_0{}^{(1)}(z)$ shown on page 359 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*.

It first generates the modulus contour plot

```
[X,Y] = meshgrid(-4:0.025:2,-1.5:0.025:1.5);
H = besselh(0,1,X+i*Y);
contour(X,Y,abs(H),0:0.2:3.2), hold on
```



then adds the contour plot of the phase of the same function.

```
contour(X,Y,(180/pi)*angle(H),-180:10:180); hold off
```

`besselj` | `bessely` | `besseli` | `besselk`

besseli

Purpose

Modified Bessel function of first kind

Note The behavior of `besseli` has changed in the following ways:

- The syntax `[I,ierr] = besseli(...)` has been removed.
- `besseli` no longer accepts `nu` and `Z` passed as a combination of row and column vectors.
- `besseli` no longer accepts `nu` and `Z` passed as a combination of non-scalar and empty inputs.

Syntax

```
I = besseli(nu,Z)
I = besseli(nu,Z,1)
[I,ierr] = besseli(...)
```

Definitions

The differential equation

$$z^2 \frac{d^2y}{dz^2} + z\frac{dy}{dz} - \left(z^2 + \nu^2\right)y = 0,$$

where ν is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

$I_\nu(z)$ and $I_{-\nu}(z)$ form a fundamental set of solutions of the modified Bessel's equation for noninteger ν. $I_\nu(z)$ is defined by

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{(k=0)}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k!\Gamma(\nu + k + 1)}$$

where $\Gamma(a)$ is the gamma function.

$K_\nu(z)$ is a second solution, independent of $I_\nu(z)$. It can be computed using `besselk`.

Description

`I = besseli(nu,Z)` computes the modified Bessel function of the first kind, $I_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

`I = besseli(nu,Z,1)` computes `besseli(nu,Z).*exp(-abs(real(Z)))`.

`[I,ierr] = besseli(...)` also returns completion flags in an array the same size as `I`.

ierr	Description
0	`besseli` successfully computed the modified Bessel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Examples

Example 1

```
format long
z = (0:0.2:1)';

besseli(1,z)

ans =
                   0
   0.10050083402813
```

```
0.20402675573357
0.31370402560492
0.43286480262064
0.56515910399249
```

Example 2

`besseli(3:9,(0:.2:10)',1)` generates the entire table on page 423 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*

Algorithms

The `besseli` functions use a Fortran MEX-file to call a library developed by D.E. Amos [3] [4].

`airy` | `besselh` | `besselj` | `besselk` | `bessely`

Purpose

Bessel function of first kind

Note The behavior of `besselj` has changed in the following ways:

- The syntax `[J,ierr] = besselj(...)` has been removed.
- `besselj` no longer accepts `nu` and `Z` passed as a combination of row and column vectors.
- `besselj` no longer accepts `nu` and `Z` passed as a combination of non-scalar and empty inputs.

Syntax

```
J = besselj(nu,Z)
J = besselj(nu,Z,1)
[J,ierr] = besselj(nu,Z)
```

Definitions

The differential equation

$$z^2 \frac{d^2y}{dz^2} + z\frac{dy}{dz} + \left(z^2 - \nu^2\right)y = 0,$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

$J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν. $J_\nu(z)$ is defined by

$$J_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{(k=0)}^{\infty} \frac{\left(\frac{-z^2}{4}\right)^k}{k!\,\Gamma(\nu + k + 1)}$$

where $\Gamma(a)$ is the gamma function.

$Y_\nu(z)$ is a second solution of Bessel's equation that is linearly independent of $J_\nu(z)$. It can be computed using `bessely`.

Description

`J = besselj(nu,Z)` computes the Bessel function of the first kind, $J_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

`J = besselj(nu,Z,1)` computes `besselj(nu,Z).*exp(-abs(imag(Z)))`.

`[J,ierr] = besselj(nu,Z)` also returns completion flags in an array the same size as `J`.

ierr	Description
0	`besselj` successfully computed the Bessel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Tips

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind,

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$
$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z)$$

where $H_\nu^{(K)}(z)$ is `besselh`, $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see `besselh`).

Examples

Example 1

```
format long
z = (0:0.2:1)';

besselj(1,z)

ans =
                    0
   0.09950083263924
   0.19602657795532
   0.28670098806392
   0.36884204609417
   0.44005058574493
```

Example 2

`besselj(3:9,(0:.2:10)')` generates the entire table on page 398 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*.

Algorithms

The `besselj` function uses a Fortran MEX-file to call a library developed by D.E. Amos [3] [4].

References

`besselh` | `besseli` | `besselk` | `bessely`

Purpose

Modified Bessel function of second kind

Note The behavior of `besselk` has changed in the following ways:

- The syntax `[K,ierr] = besselk(...)` has been removed.
- `besselk` no longer accepts `nu` and `Z` passed as a combination of row and column vectors.
- `besselk` no longer accepts `nu` and `Z` passed as a combination of non-scalar and empty inputs.

Syntax

```
K = besselk(nu,Z)
K = besselk(nu,Z,1)
[K,ierr] = besselk(...)
```

Definitions

The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} - \left(z^2 + \nu^2\right) y = 0,$$

where ν is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

A solution $K_\nu(z)$ of the second kind can be expressed as:

$$K_\nu(z) = \left(\frac{\pi}{2}\right) \frac{I_{-\nu}(z) - I_\nu(z)}{\sin(\nu\pi)}$$

where $I_\nu(z)$ and $I_{-\nu}(z)$ form a fundamental set of solutions of the modified Bessel's equation for noninteger ν:

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k!\,\Gamma(\nu+k+1)}$$

and $\Gamma(a)$ is the gamma function. $K_\nu(z)$ is independent of $I_\nu(z)$.

$I_\nu(z)$ can be computed using `besseli`.

Description

`K = besselk(nu,Z)` computes the modified Bessel function of the second kind, $K_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

`K = besselk(nu,Z,1)` computes `besselk(nu,Z).*exp(Z)`.

`[K,ierr] = besselk(...)` also returns completion flags in an array the same size as `K`.

ierr	Description
0	`besselk` successfully computed the modified Bessel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Examples

Example 1

```
format long
z = (0:0.2:1)';

besselk(1,z)

ans =
                Inf
   4.77597254322047
   2.18435442473269

`airy` | `besselh` | `besseli` | `besselj` | `bessely`

Purpose

Bessel function of second kind

Note The behavior of `bessely` has changed in the following ways:

- The syntax `[Y,ierr] = bessely(...)` has been removed.
- `bessely` no longer accepts `nu` and `Z` passed as a combination of row and column vectors.
- `bessely` no longer accepts `nu` and `Z` passed as a combination of non-scalar and empty inputs.

Syntax

```
Y = bessely(nu,Z)
Y = bessely(nu,Z,1)
[Y,ierr] = bessely(nu,Z)
```

Definitions

The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} + \left(z^2 - \nu^2\right) y = 0,$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

A solution $Y_\nu(z)$ of the second kind can be expressed as

$$Y_\nu(z) = \frac{J_\nu(z)\cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}$$

where $J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν

$$J_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(-\frac{z^2}{4}\right)^k}{k!\,\Gamma(\nu + k + 1)},$$

and $\Gamma(a)$ is the gamma function. $Y_\nu(z)$ is linearly independent of $J_\nu(z)$.

$J_\nu(z)$ can be computed using `besselj`.

Description

`Y = bessely(nu,Z)` computes Bessel functions of the second kind, $Y_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

`Y = bessely(nu,Z,1)` computes `bessely(nu,Z).*exp(-abs(imag(Z)))`.

`[Y,ierr] = bessely(nu,Z)` also returns completion flags in an array the same size as `Y`.

ierr	Description
0	`bessely` successfully computed the Bessel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Tips

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind,

$$H_\nu^{(1)}(z) = J_\nu(z) + i\,Y_\nu(z)$$
$$H_\nu^{(2)}(z) = J_\nu(z) - i\,Y_\nu(z),$$

where $H_{\nu}^{(K)}(z)$ is `besselh`, $J_{\nu}(z)$ is `besselj`, and $Y_{\nu}(z)$ is `bessely`. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see `besselh`).

Examples

Example 1

```
format long
z = (0:0.2:1)';

bessely(1,z)

ans =
                  -Inf
  -3.32382498811185
  -1.78087204427005
  -1.26039134717739
  -0.97814417668336
  -0.78121282130029
```

Example 2

`bessely(3:9,(0:.2:10)')` generates the entire table on page 399 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*.

Algorithms

The `bessely` function uses a Fortran MEX-file to call a library developed by D. E Amos [3] [4].

Purpose

Beta function

Syntax

```
B = beta(Z,W)
```

Definitions

The beta function is

$$B(z,w) = \int_0^1 t^{z-1}(1-t)^{w-1}\,dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

where $\Gamma(z)$ is the gamma function.

Description

`B = beta(Z,W)` computes the beta function for corresponding elements of arrays `Z` and `W`. The arrays must be real and nonnegative. They must be the same size, or either can be scalar.

Examples

In this example, which uses integer arguments,

```
beta(n,3)
   = (n-1)!*2!/(n+2)!
   = 2/(n*(n+1)*(n+2))
```

is the ratio of fairly small integers, and the rational format is able to recover the exact result.

```
format rat
beta((0:10)',3)

ans =

     1/0
     1/3
     1/12
     1/30
     1/60
     1/105
     1/168
     1/252
```

```
1/360
1/495
1/660
```

Algorithms

```
beta(z,w) = exp(gammaln(z)+gammaln(w)-gammaln(z+w))
```

`betainc` | `betaln` | `gammaln`

Purpose

Incomplete beta function

Syntax

```
I = betainc(X,Z,W)
I = betainc(X,Z,W,tail)
```

Definitions

The incomplete beta function is

$$I_x(z,w) = \frac{1}{B(z,w)} \int_0^x t^{z-1}(1-t)^{w-1} dt$$

where $B(z,w)$, the beta function, is defined as

$$B(z,w) = \int_0^1 t^{z-1}(1-t)^{w-1} dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

and $\Gamma(z)$ is the gamma function.

Description

`I = betainc(X,Z,W)` computes the incomplete beta function for corresponding elements of the arrays `X`, `Z`, and `W`. The elements of `X` must be in the closed interval [0,1]. The arrays `Z` and `W` must be nonnegative and real. All arrays must be the same size, or any of them can be scalar.

`I = betainc(X,Z,W,tail)` specifies the tail of the incomplete beta function. Choices are:

`'lower'` (the default)	Computes the integral from `0` to `x`
`'upper'`	Computes the integral from `x` to `1`

These functions are related as follows:

```
1-betainc(X,Z,W) = betainc(X,Z,W,'upper')
```

Note that especially when the upper tail value is close to `0`, it is more accurate to use the `'upper'` option than to subtract the `'lower'` value from `1`.

Examples

```
format long
betainc(.5,(0:10)',3)

ans =
   1.00000000000000

   0.01928710937500
```

See Also

beta | betaln

betaincinv

Purpose

Beta inverse cumulative distribution function

Syntax

```
x = betaincinv(y,z,w)
x = betaincinv(y,z,w,tail)
```

Description

`x = betaincinv(y,z,w)` computes the inverse incomplete beta function for corresponding elements of `y`, `z`, and `w`, such that `y = betainc(x,z,w)`. The elements of `y` must be in the closed interval [0,1], and those of `z` and `w` must be nonnegative. `y`, `z`, and `w` must all be real and the same size (or any of them can be scalar).

`x = betaincinv(y,z,w,tail)` specifies the tail of the incomplete beta function. Choices are `lower` (the default) to use the integral from 0 to `x`, or `'upper'` to use the integral from `x` to 1. These two choices are related as follows: `betaincinv(y,z,w,'upper') = betaincinv(1-y,z,w,'lower')`. When `y` is close to 0, the `'upper'` option provides a way to compute `x` more accurately than by subtracting from `y` from 1.

Definitions

The incomplete beta function is defined as

$$I_x(z,w) = \frac{1}{\beta(z,w)} \int_0^x t^{(z-1)} (1-t)^{(w-1)} dt$$

`betaincinv` computes the inverse of the incomplete beta function with respect to the integration limit `x` using Newton's method.

`betainc` | `beta` | `betaln`

betaln

Purpose

Logarithm of beta function

Syntax

```
L = betaln(Z,W)
```

Description

`L = betaln(Z,W)` computes the natural logarithm of the `beta` function `log(beta(Z,W))`, for corresponding elements of arrays `Z` and `W`, without computing `beta(Z,W)`. Since the beta function can range over very large or very small values, its logarithm is sometimes more useful.

`Z` and `W` must be real and nonnegative. They must be the same size, or either can be scalar.

Examples

```
x = 510
betaln(x,x)

ans =
      -708.8616
```

`-708.8616` is slightly less than `log(realmin)`. Computing `beta(x,x)` directly would underflow (or be denormal).

Algorithms

```
betaln(z,w) = gammaln(z)+gammaln(w)-gammaln(z+w)
```

See Also

`beta` | `betainc` | `gammaln`

Purpose

Biconjugate gradients method

Syntax

```
x = bicg(A,b)
bicg(A,b,tol)
bicg(A,b,tol,maxit)
bicg(A,b,tol,maxit,M)
bicg(A,b,tol,maxit,M1,M2)
bicg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicg(A,b,...)
[x,flag,relres] = bicg(A,b,...)
[x,flag,relres,iter] = bicg(A,b,...)
[x,flag,relres,iter,resvec] = bicg(A,b,...)
```

Description

`x = bicg(A,b)` attempts to solve the system of linear equations `A*x = b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle, `afun`, such that `afun(x,'notransp')` returns `A*x` and `afun(x,'transp')` returns `A'*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicg` converges, it displays a message to that effect. If `bicg` fails to converge after the maximum number of iterations or halts for any reason, it prints a warning message that includes the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`bicg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicg` uses the default, `1e-6`.

`bicg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicg` uses the default, `min(n,20)`.

`bicg(A,b,tol,maxit,M)` and `bicg(A,b,tol,maxit,M1,M2)` use the preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `bicg` applies

no preconditioner. M can be a function handle mfun, such that mfun(x,'notransp') returns M\x and mfun(x,'transp') returns M'\x.

bicg(A,b,tol,maxit,M1,M2,x0) specifies the initial guess. If x0 is [], then bicg uses the default, an all-zero vector.

[x,flag] = bicg(A,b,...) also returns a convergence flag.

Flag	Convergence
0	bicg converged to the desired tolerance tol within maxit iterations.
1	bicg iterated maxit times but did not converge.
2	Preconditioner M was ill-conditioned.
3	bicg stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during bicg became too small or too large to continue computing.

Whenever flag is not 0, the solution x returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the flag output is specified.

[x,flag,relres] = bicg(A,b,...) also returns the relative residual norm(b-A*x)/norm(b). If flag is 0, relres <= tol.

[x,flag,relres,iter] = bicg(A,b,...) also returns the iteration number at which x was computed, where 0 <= iter <= maxit.

[x,flag,relres,iter,resvec] = bicg(A,b,...) also returns a vector of the residual norms at each iteration including norm(b-A*x0).

Examples

Using bicg with a Matrix Input.

This example shows how to use bicg with a matrix input. bicg. The following code:

```
n = 100;
on = ones(n,1);
```

```
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);

x = bicg(A,b,tol,maxit,M1,M2);
```

displays this message:

```
bicg converged at iteration 9 to a solution with relative
residual 5.3e-009
```

Using bicg with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_bicg` that

- Calls `bicg` with the `@afun` function handle as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_bicg` are available to `afun`.

Place the following into a file called `run_bicg`:

```
function x1 = run_bicg
n = 100;
on = ones(n,1);
b = afun(on,'notransp');
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = bicg(@afun,b,tol,maxit,M1,M2);

    function y = afun(x,transp_flag)
       if strcmp(transp_flag,'transp')      % y = A'*x
          y = 4 * x;
```

```
            y(1:n-1) = y(1:n-1) - 2 * x(2:n);
            y(2:n) = y(2:n) - x(1:n-1);
         elseif strcmp(transp_flag,'notransp') % y = A*x
            y = 4 * x;
            y(2:n) = y(2:n) - 2 * x(1:n-1);
            y(1:n-1) = y(1:n-1) - x(2:n);
         end
      end
   end
```

When you enter

```
x1 = run_bicg;
```

MATLAB software displays the message

```
bicg converged at iteration 9 to a solution with ...
relative residual
5.3e-009
```

Using a Preconditioner

This example demonstrates the use of a preconditioner.

1

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

2

Define `b` so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

3

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

4

Use `bicg` to find a solution at the requested tolerance and number of iterations:

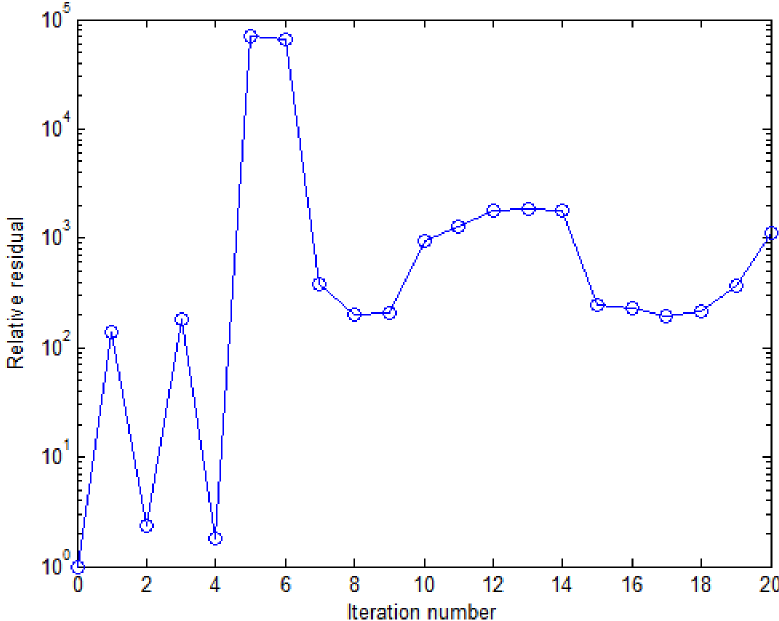
```
[x0,fl0,rr0,it0,rv0] = bicg(A,b,tol,maxit);
```

`fl0` is 1 because `bicg` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. In fact, the behavior of `bicg` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB stores the residual history in `rv0`.

5

Plot the behavior of `bicg`:

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

6

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
Error using ilu
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = bicg(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `bicg` drives the relative residual to `4.1410e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)`, and the output `rv1(7)` is `norm(b-A*x2)`.

8

You can follow the progress of `bicg` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

`bicgstab` | `cgs` | `gmres` | `ilu` | `lsqr` | `luinc` | `minres` | `pcg` | `qmr` | `symmlq` | `function_handle` | `mldivide`

Purpose

Biconjugate gradients stabilized method

Syntax

```
x = bicgstab(A,b)
bicgstab(A,b,tol)
bicgstab(A,b,tol,maxit)
bicgstab(A,b,tol,maxit,M)
bicgstab(A,b,tol,maxit,M1,M2)
bicgstab(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstab(A,b,...)
[x,flag,relres] = bicgstab(A,b,...)
[x,flag,relres,iter] = bicgstab(A,b,...)
[x,flag,relres,iter,resvec] = bicgstab(A,b,...)
```

Description

`x = bicgstab(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle, `afun`, such that `afun(x)` returns `A*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicgstab` converges, a message to that effect is displayed. If `bicgstab` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`bicgstab(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicgstab` uses the default, `1e-6`.

`bicgstab(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicgstab` uses the default, `min(n,20)`.

`bicgstab(A,b,tol,maxit,M)` and `bicgstab(A,b,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `bicgstab` applies no preconditioner. `M` can be a function handle `mfun`, such that `mfun(x)` returns `M\x`.

`bicgstab(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `bicgstab` uses the default, an all zero vector.

`[x,flag] = bicgstab(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	`bicgstab` converged to the desired tolerance `tol` within `maxit` iterations.
1	`bicgstab` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`bicgstab` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `bicgstab` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicgstab(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = bicgstab(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`. `iter` can be an integer + 0.5, indicating convergence halfway through an iteration.

`[x,flag,relres,iter,resvec] = bicgstab(A,b,...)` also returns a vector of the residual norms at each half iteration, including `norm(b-A*x0)`.

Examples

Using bicgstab with a Matrix Input

This example first solves `Ax = b` by providing `A` and the preconditioner `M1` directly as arguments.

The code:

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = bicgstab(A,b,tol,maxit,M1);
```

displays the message:

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

Using bicgstab with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in a file `run_bicgstab` that

- Calls `bicgstab` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_bicgstab` are available to `afun` and `mfun`.

The following shows the code for `run_bicgstab`:

```
function x1 = run_bicgstab
n = 21;
b = afun(ones(n,1));
tol = 1e-12;
maxit = 15;
x1 = bicgstab(@afun,b,tol,maxit,@mfun);

    function y = afun(x)
       y = [0; x(1:n-1)] + ...
           [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
           [x(2:n); 0];
    end
```

```
    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
end
```

When you enter

```
x1 = run_bicgstab;
```

MATLAB software displays the message

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

Using a Preconditioner

This example demonstrates the use of a preconditioner.

1

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

2

Define `b` so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

3

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

4

Use `bicgstab` to find a solution at the requested tolerance and number of iterations:

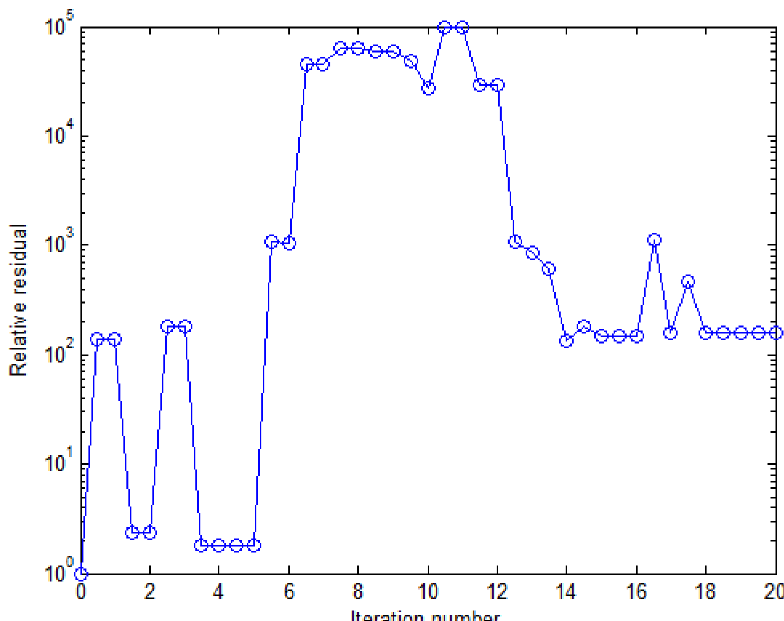
```
[x0,fl0,rr0,it0,rv0] = bicgstab(A,b,tol,maxit);
```

`fl0` is 1 because `bicgstab` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. In fact, the behavior of `bicgstab` is so bad that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB stores the residual history in `rv0`.

5

Plot the behavior of `bicgstab`:

```
semilogy(0:0.5:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

6

Create a preconditioner with `ilu`, since `A` is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
Error using ilu
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = bicgstab(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `bicgstab` drives the relative residual to `5.9829e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the third iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)`and the output `rv1(7)` is `norm(b-A*x2)` since `bicgstab` uses half iterations.

8

You can follow the progress of `bicgstab` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:0.5:it1,rv1/norm(b),'-o');
xlabel('Iteration Number');
ylabel('Relative Residual');
```

bicgstabl

Purpose

Biconjugate gradients stabilized (l) method

Syntax

```
x = bicgstabl(A,b)
x = bicgstabl(afun,b)
x = bicgstabl(A,b,tol)
x = bicgstabl(A,b,tol,maxit)
x = bicgstabl(A,b,tol,maxit,M)
x = bicgstabl(A,b,tol,maxit,M1,M2)
x = bicgstabl(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstabl(A,b,...)
[x,flag,relres] = bicgstabl(A,b,...)
[x,flag,relres,iter] = bicgstabl(A,b,...)
[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)
```

Description

`x = bicgstabl(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and the right-hand side column vector `b` must have length `n`.

`x = bicgstabl(afun,b)` accepts a function handle `afun` instead of the matrix `A`. `afun(x)` accepts a vector input `x` and returns the matrix-vector product `A*x`. In all of the following syntaxes, you can replace `A` by `afun`.

`x = bicgstabl(A,b,tol)` specifies the tolerance of the method. If `tol` is [] then `bicgstabl` uses the default, 1e-6.

`x = bicgstabl(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is [] then `bicgstabl` uses the default, `min(N,20)`.

`x = bicgstabl(A,b,tol,maxit,M)` and `x = bicgstabl(A,b,tol,maxit,M1,M2)` use preconditioner `M` or `M=M1*M2` and effectively solve the system `A*inv(M)*x = b` for x. If `M` is [] then a preconditioner is not applied. `M` may be a function handle returning `M\x`.

`x = bicgstabl(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is [] then `bicgstabl` uses the default, an all zero vector.

`[x,flag] = bicgstabl(A,b,...)` also returns a convergence `flag`:

Flag	Convergence
0	`bicgstabl` converged to the desired tolerance `tol` within `maxit` iterations.
1	`bicgstabl` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`bicgstabl` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `bicgstabl` became too small or too large to continue computing.

`[x,flag,relres] = bicgstabl(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = bicgstabl(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`. `iter` can be `k/4` where `k` is some integer, indicating convergence at a given quarter iteration.

`[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)` also returns a vector of the residual norms at each quarter iteration, including `norm(b-A*x0)`.

Examples

Using bicgstabl with Inputs or with a Function

You can pass inputs directly to `bicgstabl`:

```
n = 21;
A = gallery('wilk',n);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M = diag([10:-1:1 1 1:10]);
x = bicgstabl(A,b,tol,maxit,M);
```

You can also use a matrix-vector product function:

```
function y = afun(x,n)
y = [0; x(1:n-1)] + [((n-1)/2:-1:0)';
(1:(n-1)/2)'].*x+[x(2:n); 0];
```

and a preconditioner backsolve function:

```
function y = mfun(r,n)
y = r ./ [((n-1)/2:-1:1)';
1;
(1:(n-1)/2)'];
```

as inputs to `bicgstabl`:

```
x1 = bicgstabl(@(x)afun(x,n),b,tol,maxit,@(x)mfun(x,n));
```

Using a Preconditioner

This example demonstrates the use of a preconditioner.

1

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

2

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

3

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

4

Use `bicgstabl` to find a solution at the requested tolerance and number of iterations:

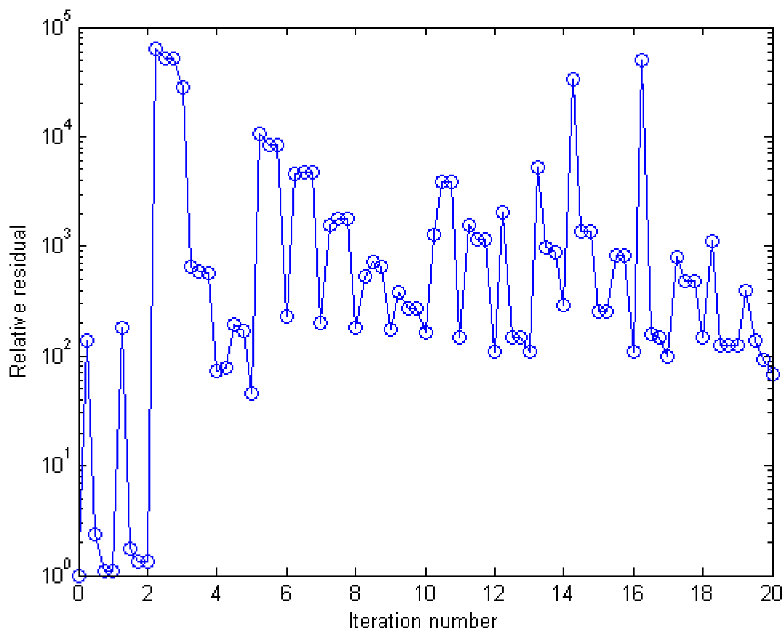
```
[x0,fl0,rr0,it0,rv0] = bicgstabl(A,b,tol,maxit);
```

`fl0` is 1 because `bicgstabl` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. In fact, the behavior of `bicgstabl` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB stores the residual history in `rv0`.

5

Plot the behavior of `bicgstabl`:

```
semilogy(0:0.25:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

6

Create a preconditioner with `ilu`, since `A` is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
Error using ilu
There is a pivot equal to zero.  Consider decreasing the
drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = bicgstabl(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `bicgstabl` drives the relative residual to `1.0257e-015` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)`, and the output `rv1(9)` is `norm(b-A*x2)` since `bicgstabl` uses quarter iterations.

8

You can follow the progress of `bicgstabl` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:0.25:it1,rv1/norm(b),'-o');
set(gca,'XTick',0:0.25:it1);
xlabel('Iteration number');
ylabel('Relative residual');
```

bin2dec

Purpose

Convert binary number string to decimal number

Syntax

```
bin2dec(binarystr)
```

Description

`bin2dec(binarystr)` interprets the binary string *binarystr* and returns the equivalent decimal number.

`bin2dec` ignores any space (`' '`) characters in the input string.

Examples

Binary `010111` converts to decimal `23`:

```
bin2dec('010111')
ans =
    23
```

Because space characters are ignored, this string yields the same result:

```
bin2dec(' 010   111 ')
ans =
    23
```

See Also

`dec2bin`

Purpose

Set FTP transfer type to binary

Syntax

```
binary(ftpobj)
```

Description

`binary(ftpobj)` sets the FTP download and upload mode to binary, which does not convert new line characters. Binary mode is the default for FTP objects. If you previously called the `ascii` method, use this method before transferring a nontext file, such as an executable or ZIP archive.

Input Arguments

ftpobj

FTP object created by `ftp`.

Examples

Connect to the MathWorks FTP server, and set the transfer mode to binary:

```
mw=ftp('ftp.mathworks.com');
binary(mw)
```

See Also

`ascii` | `ftp`

bitand

Purpose

Bit-wise AND

Syntax

```
intout = bitand(integ1,integ2)
intout = bitand(integ1,integ2,assumedtype)

objout = bitand(netobj1,netobj2)
```

Description

`intout = bitand(integ1,integ2)` returns the bit-wise AND of values `integ1` and `integ2`.

`intout = bitand(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitand(netobj1,netobj2)` returns the bit-wise AND of the .NET enumeration objects `netobj1` and `netobj2`.

Input Arguments

integ1, integ2 - Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

Data Types

`double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

assumedtype - Assumed data type of `integ1` and `integ2`

`'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'`

Assumed data type of `integ1` and `integ2`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

Data Types
`char`

netobj1, netobj2 - Input values

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

Output Arguments

intout - Bit-wise AND result

signed integer array | unsigned integer array | double array

Bit-wise AND result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

objout - Bit-wise AND result

.NET enumeration object

Bit-wise AND result, returned as a .NET enumeration objects.

Examples

Truth Table

Create a truth table for the logical AND operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitand(A, B)
```

```
TTable =

     0     0
     0     1
```

`bitand` returns 1 only if both bit-wise inputs are 1.

Negative Values

Explore how `bitand` handles negative values

MATLAB encodes signed integers using two's complement. Thus, the bit-wise AND of 5 (11111010) and 6 (00000110) is 2 (00000010).

```
C = -5;
D = 6;
bitand(C,D,'int8')
```

```
ans =

      2
```

See Also

bitcmp | bitget | bitor | bitshift | bitset | bitxor | intmax

Related Examples

- "Creating .NET Enumeration Bit Flags"

Purpose

Bit-wise complement

Compatibility

`bitcmp(A,N)` will not accept N in a future release. Use `bitcmp(A)` or `bitcmp(A,assumedtype)` instead.

Syntax

```
cmp = bitcmp(A)
cmp = bitcmp(A,assumedtype)

cmp = bitcmp(A,N)
```

Description

`cmp = bitcmp(A)` returns the bit-wise complement of A.

`cmp = bitcmp(A,assumedtype)` assumes that A is of `assumedtype`.

`cmp = bitcmp(A,N)` returns an N-bit complement of A. Elements of A cannot exceed 2^N-1.

Input Arguments

A - Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If A is a double array, and `assumedtype` is not specified, then MATLAB treats A as an unsigned 64-bit integer.
- If `assumedtype` is specified, then all elements in A must have integer values within the range of `assumedtype`.

Data Types

`double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

assumedtype - Assumed data type of A

`'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'`

Assumed data type of `A`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `A` is a double array, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `A` is an integer type array, then `assumedtype` must specify that same integer type.

Data Types
`char`

N - number of returned bits

integer

Number of returned bits, specified as an integer. N cannot exceed the number of bits in the integer type of `A`.

Data Types
`double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

Output Arguments

cmp - Bit-wise complement

signed integer array | unsigned integer array | double array

Bit-wise complement, returned as a signed integer array, unsigned integer array, or double array. `cmp` is the same size and type as `A`.

Examples

Complement of a Negative Integer

```
A = int8(-11);
cmp = bitcmp(A)
```

```
cmp =

   10
```

You can see the complement operation when the numbers are shown in binary.

```
original = bitget(A,8:-1:1)
complement = bitget(bitcmp(A),8:-1:1)

original =

     1     1     1     1     0     1     0     1

complement =

     0     0     0     0     1     0     1     0
```

Complement of Unsigned Integers

```
cmp = bitcmp(64,'uint8')
maxint = intmax('uint8') - 64

cmp =

   191

maxint =

  191
```

The complement of an unsigned integer is equal to itself subtracted from the maximum integer of its data type.

See Also

bitand | bitget | bitor | bitshift | bitset | bitxor | intmax

bitget

Purpose

Get bit at specified position

Syntax

```
b = bitget(A,bit)
b = bitget(A,bit,assumedtype)
```

Description

`b = bitget(A,bit)` returns the bit value at position `bit` in integer array `A`.

`b = bitget(A,bit,assumedtype)` assumes that `A` is of `assumedtype`.

Input Arguments

A - Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If `A` is a double array, and `assumedtype` is not specified, then MATLAB treats `A` as an unsigned 64-bit integer.
- If `assumedtype` is specified, then all elements in `A` must have integer values within the range of `assumedtype`.

Data Types

`double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

bit - Bit position

integer | integer array

Bit position, specified as an integer or integer array. `bit` must be between 1 (the least-significant bit) and the number of bits in the integer class of `A`.

Data Types

`double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

assumedtype - Assumed data type of A

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of A, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If A is a double array, then assumedtype can specify any valid integer type, but defaults to 'uint64'.
- If A is an integer type array, then assumedtype must specify that same integer type.

Data Types
char

Output Arguments

b - Bit value at bit

0 | 1

Bit value at bit, returned as 0 or 1. b is the same data type as A.

Examples

Maximum Integer

Find the difference in the binary representation between the maximum integer of signed and unsigned integers.

```
a1 = intmax('int8');
a2 = intmax('uint8');
b1 = bitget(a1,8:-1:1)
b2 = bitget(a2,8:-1:1)
```

```
b1 =

     0     1     1     1     1     1     1     1

b2 =

     1     1     1     1     1     1     1     1
```

The signed integers require a bit to accommodate negative integers.

Negative Numbers Using Two's Complement

Find the 8-bit representation of a negative number.

```
A = -29;
b = bitget(A,8:-1:1,'int8')

b =

     1     1     1     0     0     0     1     1
```

See Also

bitand | bitcmp | bitor | bitshift | bitset | bitxor | intmax

Purpose

Maximum double-precision floating-point integer

Compatibility

`bitmax` will be removed in a future release. Use `flintmax` instead.

Syntax

```
bitmax
```

Description

`bitmax` returns the maximum unsigned double-precision floating-point integer for your computer. It is the value when all bits are set, namely the value $2^{53} - 1$.

Note Instead of integer-valued double-precision variables, use unsigned integers for bit manipulations and replace `bitmax` with `intmax`.

Examples

Display in different formats the largest floating point integer and the largest 32 bit unsigned integer:

```
format long e
bitmax
ans =
   9.007199254740991e+015

intmax('uint32')
ans =
   4294967295

format hex
bitmax
ans =
   433fffffffffffff

intmax('uint32')
ans =
   ffffffff
```

In the second bitmax statement, the last 13 hex digits of `bitmax` are `f`, corresponding to 52 1's (all 1's) in the mantissa of the binary representation. The first 3 hex digits correspond to the sign bit 0 and the 11 bit biased exponent `10000110011` in binary (`1075` in decimal), and the actual exponent is (`1075-1023`) = `52`. Thus the binary value of `bitmax` is `1.111...111 x 2^52` with 52 trailing 1's, or `2^53-1`.

See Also

`bitand` | `bitcmp` | `bitget` | `bitor` | `bitset` | `bitshift` | `bitxor`

Purpose

Bit-wise NOT

Syntax

```
C = bitnot(A)
```

Description

`C = bitnot(A)` reverses all bits.

Input Arguments

A

.NET enumeration object.

Output Arguments

C

Result of operation, same type as input.

See Also

`bitand` | `bitor` | `bitxor`

bitor

Purpose

Bit-wise OR

Syntax

```
intout = bitor(integ1,integ2)
intout = bitor(integ1,integ2,assumedtype)

objout = bitor(netobj1,netobj2)
```

Description

`intout = bitor(integ1,integ2)` returns the bit-wise OR of `integ1` and `integ2`.

`intout = bitor(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitor(netobj1,netobj2)` returns the bit-wise OR of the .NET enumeration objects `netobj1` and `netobj2`.

Input Arguments

integ1, integ2 - Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

Data Types

`double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

assumedtype - Assumed data type of `integ1` and `integ2`

`'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'`

Assumed data type of `integ1` and `integ2`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

Data Types
`char`

netobj1, netobj2 - Input values

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

Output Arguments

intout - Bit-wise OR result

signed integer array | unsigned integer array | double array

Bit-wise OR result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

objout - Bit-wise OR result

.NET enumeration object

Bit-wise OR result, returned as a .NET enumeration objects.

Examples

Truth Table

Create a truth table for the logical OR operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitor(A, B)
```

```
TTable =

     0     1
     1     1
```

`bitor` returns 1 if either bit-wise input is 1.

Negative Values

Explore how `bitor` handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise OR of -5 (11111010) and 6 (00000110) is -1 (11111110).

```
C = -5;
D = 6;
bitor(C,D,'int8')

ans =

    -1
```

See Also

`bitand` | `bitcmp` | `bitget` | `bitshift` | `bitset` | `bitxor` | `intmax`

Related Examples

- "Creating .NET Enumeration Bit Flags"

Purpose

Set bit at specific location

Syntax

```
intout = bitset(A,bit)
intout = bitset(A,bit,assumedtype)

intout = bitset(A,bit,V)
intout = bitset(A,bit,V,assumedtype)
```

Description

`intout = bitset(A,bit)` returns the value of `A` with position `bit` set to 1 (on).

`intout = bitset(A,bit,assumedtype)` assumes `A` is of type `assumedtype`.

`intout = bitset(A,bit,V)` returns `A` with position `bit` set to the value of `V`.

- If `V` is zero, then the bit position `bit` is set to 0 (off).
- If `V` is nonzero, then the bit position `bit` is set to 1 (on).

`intout = bitset(A,bit,V,assumedtype)` assumes `A` is of type `assumedtype`.

Input Arguments

A - Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If `A` is a double array, and `assumedtype` is not specified, then MATLAB treats `A` as an unsigned 64-bit integer.
- If `assumedtype` is specified, then all elements in `A` must have integer values within the range of `assumedtype`.

Data Types
`double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

bit - Bit position

integer | integer array

Bit position, specified as an integer or integer array. `bit` must be between 1 (the least significant bit) and the number of bits in the integer class of `A`.

Data Types
`double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

assumedtype - Assumed data type of A

`'uint64'` | `'uint32'` | `'uint16'` | `'uint8'` | `'int64'` | `'int32'` | `'int16'` | `'int8'`

Assumed data type of `A`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `A` is a double array, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `A` is an integer type array, then `assumedtype` must specify that same integer type.

Data Types
`char`

V - bit value

scalar | numeric array

Bit value, specified as a scalar or a numeric array. If `V` and `bit` are arrays, they must be the same size.

Data Types
`double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Output Arguments

intout - Adjusted integer

signed integer array | unsigned integer array | double array

Adjusted integer, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same size and type as `A`.

Examples

Set Bits to On

Add powers of 2 onto a number.

```
A = 4;
intout = bitset(A,4:6)

intout =

    12    20    36
```

You can see that `bitset` sequentially turns on bits 4 through 6.

```
c = dec2bin(intout)

c =

001100
010100
100100
```

Out of Range of Integer Type

MATLAB throws an error if you specify an integer outside the range of `assumedtype`.

```
intout = bitset(300,5,'int8')

Error using bitset
Double inputs must have integer values in the range of ASSUMEDTYPE.
```

You can avoid this error by limiting your input to the range of the specified datatype.

Set Bits to Off

Repeatedly subtract powers of 2 from a number.

```
a = intmax('uint8')
for k = 0:7
   a = bitset(a, 8-k, 0);
   b(1,k+1) = a;
end
b
```

```
a =

  255

b =

   127    63    31    15     7     3     1     0
```

Set Multiple Bits

Set multiple bits to different values

```
bits = 2:6;
val = [1 0 0 1 1];
intout = bitset(0,bits,val,'int8')
```

```
intout =

      2     0     0    16    32
```

See Also

bitand | bitcmp | bitget | bitor | bitshift | bitxor | intmax

Purpose

Shift bits specified number of places

Compatibility

`bitshift(A,k,N)` will not accept the argument `N` in a future release. Use `bitshift(A,k)` or `bitcmp(A,k,assumedtype)` instead.

`bitshift` no longer interprets double values as 53-bit unsigned integers by default, but as `unit64` values.

Syntax

```
intout = bitshift(A,k)
intout = bitshift(A,k,assumedtype)

intout = bitshift(A,k,N)
```

Description

`intout = bitshift(A,k)` returns `A` shifted to the left by `k` bits, equivalent to multiplying by 2^k. Negative values of `k` correspond to shifting bits right or dividing by $2^{|k|}$ and rounding to the nearest integer towards negative infinite. Any overflow bits are truncated.

- If `A` is an array of signed integers, then `bitshift` returns the arithmetic shift results, preserving the signed bit when `k` is negative, and not preserving the signed bit when `k` is positive.
- If `k` is positive, MATLAB shifts the bits to the left and inserts `k` 0-bits on the right.
- If `k` is negative and `A` is nonnegative, then MATLAB shifts the bits to the right and inserts `|k|` 0-bits on the left.
- If `k` is negative and `A` is negative, then MATLAB shifts the bits to the right and inserts `|k|` 1-bits on the left.

`intout = bitshift(A,k,assumedtype)` assumes `A` is of type `assumedtype`.

`intout = bitshift(A,k,N)` truncates any bits that overflow `N` bits.

Input Arguments

A - Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If `A` is a double array, and `assumedtype` is not specified, then MATLAB treats `A` as an unsigned 64-bit integer.
- If `assumedtype` is specified, then all elements in `A` must have integer values within the range of `assumedtype`.

Data Types

`double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

k - Number of switched bits

integer | integer array

Number of switched bits, specified as an integer or integer array.

Data Types

`double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

assumedtype - Assumed data type of A

`'uint64'` | `'uint32'` | `'uint16'` | `'uint8'` | `'int64'` | `'int32'` | `'int16'` | `'int8'`

Assumed data type of `A`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `A` is an integer type array, then `assumedtype` must specify that same integer type.
- If `A` is a double array, then `assumedtype` can specify any valid integer type.

Data Types

`char`

N - Number of bits kept

nonnegative integer | nonnegative integer array

Number of bits kept, specified as a nonnegative integer or integer array. N must be less than or equal to the number of bits in the unsigned integer class of A.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output Arguments

intout - Shifted value

signed integer array | unsigned integer array | double array

Shifted value, returned as signed integer array, unsigned integer array, or double array. intout is the same size and type as A.

Examples

Shifted 8-bit Integer

Repeatedly shift the bits of an unsigned 8-bit value to the left until all the nonzero bits overflow.

```
a = intmax('uint8');
s1 = 'Initial uint8 value %5d is %08s in binary\n';
s2 = 'Shifted uint8 value %5d is %08s in binary\n';
fprintf(s1,a,dec2bin(a))
 for i = 1:8
    a = bitshift(a,1);
    fprintf(s2,a,dec2bin(a))
 end
```

```
Initial uint8 value   255 is 11111111 in binary
Shifted uint8 value   254 is 11111110 in binary
Shifted uint8 value   252 is 11111100 in binary
Shifted uint8 value   248 is 11111000 in binary
Shifted uint8 value   240 is 11110000 in binary
Shifted uint8 value   224 is 11100000 in binary
Shifted uint8 value   192 is 11000000 in binary
Shifted uint8 value   128 is 10000000 in binary
```

```
Shifted uint8 value     0 is 00000000 in binary
```

Different Results for Different Integer Types

Find the shift for a number using different assumed integer types.

```
uintout = bitshift(6,5:7,'uint8')
intout = bitshift(6,5:7,'int8')
```

```
uintout =

   192   128     0

intout =

   -64  -128     0
```

See Also

bitand | bitcmp | bitget | bitor | bitset | bitxor | intmax

Purpose

Bit-wise XOR

Syntax

```
intout = bitxor(integ1,integ2)
intout = bitxor(integ1,integ2,assumedtype)

objout = bitxor(netobj1,netobj2)
```

Description

`intout = bitxor(integ1,integ2)` returns the bit-wise XOR of `integ1` and `integ2`.

`intout = bitxor(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitxor(netobj1,netobj2)` returns the bit-wise XOR of the .NET enumeration objects `netobj1` and `netobj2`.

Input Arguments

integ1, integ2 - Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

Data Types

`double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

assumedtype - Assumed data type of integ1 and integ2

`'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'`

Assumed data type of integ1 and integ2, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If integ1 and integ2 are double arrays, then assumedtype can specify any valid integer type, but defaults to 'uint64'.
- If integ1 and integ2 are integer type arrays, then assumedtype must specify that same integer type.

Data Types
char

netobj1, netobj2 - Input values
.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

Output Arguments

intout - Bit-wise XOR result
signed integer array | unsigned integer array | double array

Bit-wise XOR result, returned as a signed integer array, unsigned integer array, or double array. intout is the same data type and size as integ1 and integ2.

- If either integ1 or integ2 is a scalar double, and the other is a non-double integer type, intout is the non-double integer type.

objout - Bit-wise XOR result
.NET enumeration object

Bit-wise XOR result, returned as a .NET enumeration objects.

Examples

Truth Table

Create a truth table for the logical XOR operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitxor(A, B)
```

```
TTable =

     0     1
     1     0
```

`bitxor` returns 0 if both bit-wise inputs are equal.

Negative Values

Explore how `bitxor` handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise XOR of -5 (11111010) and 6 (00000110) is -3 (11111100).

```
C = -5;
D = 6;
bitxor(C,D,'int8')
```

```
ans =

    -3
```

blanks

Purpose

Create string of blank characters

Syntax

```
blanks(n)
```

Description

`blanks(n)` is a string of `n` blanks.

Examples

`blanks` is useful with the `display` function. For example,

```
disp(['xxx' blanks(20) 'yyy'])
```

displays twenty blanks between the strings `'xxx'` and `'yyy'`.

`disp(blanks(n)')` moves the cursor down `n` lines.

See Also

`clc` | `format` | `home`

Purpose

Construct block diagonal matrix from input arguments

Syntax

```
out = blkdiag(a,b,c,d,...)
```

Description

`out = blkdiag(a,b,c,d,...)`, where `a`, `b`, `c`, `d`, `...` are matrices, outputs a block diagonal matrix of the form

$$\begin{bmatrix} a & 0 & 0 & 0 & 0 \\ 0 & b & 0 & 0 & 0 \\ 0 & 0 & c & 0 & 0 \\ 0 & 0 & 0 & d & 0 \\ 0 & 0 & 0 & 0 & \ldots \end{bmatrix}$$

The input matrices do not have to be square, nor do they have to be of equal size.

See Also

`diag` | `horzcat` | `vertcat`

box

Purpose

Axes border

Syntax

```
box on
box off
box
box(axes_handle,...)
```

Description

`box on` displays the boundary of the current axes.

`box off` does not display the boundary of the current axes.

`box` toggles the visible state of the current axes boundary.

`box(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

Algorithms

The `box` function sets the axes `Box` property to `on` or `off`.

See Also

`axes` | `grid`

Purpose

Terminate execution of `for` or `while` loop

Syntax

```
break
```

Description

`break` terminates the execution of a `for` or `while` loop. Statements in the loop that appear after the `break` statement are not executed.

In nested loops, `break` exits only from the loop in which it occurs. Control passes to the statement that follows the `end` of that loop.

Tips

`break` is not defined outside a `for` or `while` loop. Use `return` in this context instead.

Examples

The example below shows a `while` loop that reads the contents of the file `fft.m` into a MATLAB character array. A `break` statement is used to exit the `while` loop when the first empty line is encountered. The resulting character array contains the command line help for the `fft` program.

```
fid = fopen('fft.m','r');
s = '';

while ~feof(fid)
   line = fgetl(fid);
   if isempty(line) || ~ischar(line), break, end
   s = sprintf('%s%s\n', s, line);
end
disp(s);

fclose(fid);
```

See Also

`for` | `while` | `end` | `continue` | `return`

brighten

Purpose Brighten or darken colormap

Syntax

```
brighten(beta)
brighten(h,beta)
newmap = brighten(beta)
newmap = brighten(cmap,beta)
```

Description `brighten(beta)` increases or decreases the color intensities in a colormap by replacing the current colormap with a brighter or darker colormap of essentially the same colors. The modified colormap is brighter if `0 < beta < 1` and darker if `-1 < beta < 0`. `brighten(beta)`, followed by `brighten(-beta)`, where `beta < 1`, restores the original map.

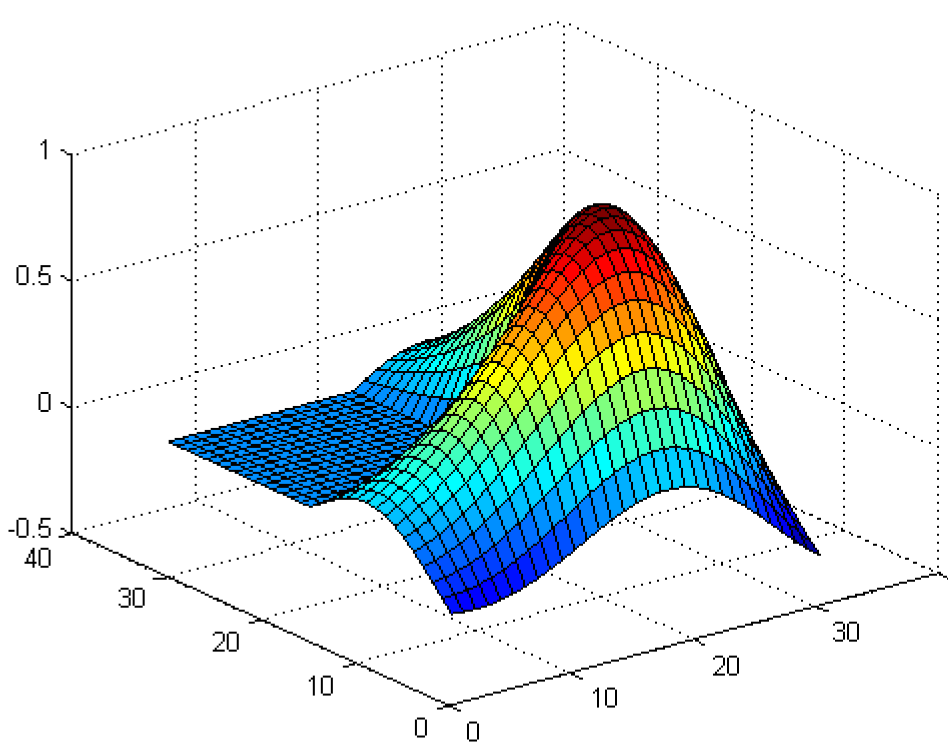
`brighten(h,beta)` brightens all objects that are children of the figure having the handle `h`.

`newmap = brighten(beta)` returns a brighter or darker version of the current colormap without changing the display.

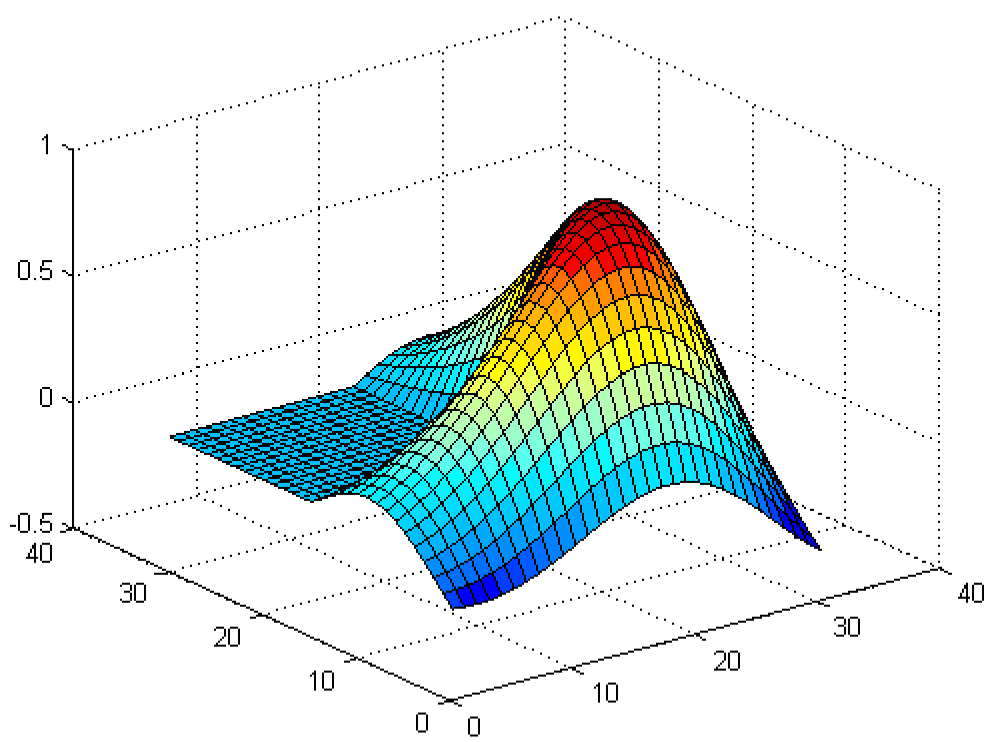
`newmap = brighten(cmap,beta)` returns a brighter or darker version of the colormap `cmap` without changing the display.

Examples Brighten the current colormap:

```
surf(membrane);
```



```
beta = .5;
brighten(beta);
```



Algorithms

`brighten` raises values in the colormap to the power of gamma, where gamma is

$$\gamma = \begin{cases} 1-\beta, & \beta > 0 \\ \dfrac{1}{1+\beta}, & \beta \le 0 \end{cases}$$

`brighten` has no effect on graphics objects defined with true color.

How To

- “Altering Colormaps”

brush

Purpose

Interactively mark, delete, modify, and save observations in graphs

Syntax

```
brush on
brush off
brush
brush color
brush(figure_handle,...)
brushobj = brush(figure_handle)
```

Description

Data brushing is a mode for interacting with graphs in figure windows in which you can click data points or drag a selection rectangle around data points to highlight observations in a color of your choice. Highlighting takes different forms for different types of graphs, and brushing marks persist—even in other interactive modes—until removed by deselecting them.

`brush on` turns on interactive data brushing mode.

`brush off` turns brushing mode off, leaving any brushed observations still highlighted.

`brush` by itself toggles the state of the data brushing tool.

`brush color` sets the current color used for brushing graphics to the specified `ColorSpec`. Changing brush color affects subsequent brushing, but does not change the color of observations already brushed or the brush tool's state.

`brush(figure_handle,...)` applies the function to the specified figure handle.

`brushobj = brush(figure_handle)` returns a *brush mode object* for that figure, useful for controlling and customizing the figure's brushing state. The following properties of such objects can be modified using `get` and `set`:

`Enable 'on' | {'off'}`	Specifies whether this figure mode is currently enabled on the figure.
`FigureHandle`	The associated figure handle. This property supports `get` only.
`Color`	Specifies the color to be used for brushing.

`brush` cannot return a brush mode object at the same time you are calling it to set a brushing option.

Tips

- “Types of Plots You Can Brush” on page 1-547
- “Plot Types You Cannot Brush” on page 1-549
- “Mode Exclusivity and Persistence” on page 1-550
- “How Data Linking Affects Data Brushing” on page 1-551
- “Mouse Gestures for Data Brushing” on page 1-552
- “Brush Mode Callbacks” on page 1-553

Types of Plots You Can Brush

Data brushing places lines and patches on plots to create highlighting, marking different types of graphs as follows (brushing marks are shown in red):

Graph Type	Brushing Annotation	Overlays?	Example
lineseries	Colored lines slightly wider than those in the lineseries with a marker distinct from those on the lineseries (filled circles if none) to identify brushed vertices. Only those line segments that connect brushed vertices are highlighted	Y	
scattergroup	Line with `LineStyle 'none'` and a marker with a color distinct from and slightly larger than the base scattergroup marker.	Y	
stemseries	The brushed stems and stem heads are shaded in the brushing color.	Y	
barseries	The interior of selected bars is filled in the brushing color.	N	
histogram	The bars to which brushed observations contribute are proportionately filled from the bottom up with the brushing color.	N	

Graph Type	Brushing Annotation	Overlays?	Example
areaseries	Patches filling the region between selected points and the *x*-axis in the brushing color.	N	
surfaceplot	Patches with edges slightly wider than the surfaceplot line width and with a marker distinct from that of the surfaceplot (**X** if none) to identify brushed vertices. Patches are plotted only when all four vertices that define them are brushed. The brushed observations are the set of marked vertices, not the patches.	N	

When using the linked plots feature, a graph can become brushed when you brush another graph that displays some of the same data, potentially brushing the same observations more than once. The overlaid brushing marks (whether lines or markers) are slightly wider than the brushing marks that they overlay; this makes multiply brushed observations visually distinct. The wider brushing marks are placed under the narrower ones, so that if they happen to have different colors, you can see all the colors. See the subsection "How Data Linking Affects Data Brushing" on page 1-551 for more information about brushing linked figures.

As the above table indicates, only lineseries, scatterseries, and stemseries brushing marks can be overlaid in this manner. Although you can brush them, you cannot overlay brushing marks on areaseries, barseries, histograms, or surfaceplots.

Plot Types You Cannot Brush

Currently, not all plot types enable data brushing. Graph functions that *do not* support brushing are:

- Line plots created with `line`
- Scatter plots created with `spy`
- Contour plots created with `contour`, `contourf`, or `contour3`
- Pie charts created with `pie` or `pie3`
- Radial graphs created with `polar`, `compass`, or `rose`
- Direction graphs created with `feather`, `quiver`, or `comet`
- Area and image plots created with `fill`, `image`, `imagesc`, or `pcolor`
- Bar graphs created with `pareto` or `errorbar`
- Functional plots created with `ezcontour` or `ezcontourf`
- 3-D plot types *other than* `plot3`, `stem3`, `scatter3`, `mesh`, `meshc`, `surf`, `surfl`, and `surfc`

You can use some of these functions to display base data that do not need to be brushable. For example, use `line` to plot mean *y*-values as horizontal lines that you do not need or want to brush.

Mode Exclusivity and Persistence

Data brushing mode is *exclusive*, like zoom, pan, data cursor, or plot edit mode. However, brush marks created in data brushing mode *persist* through all changes in mode. Brush marks that appear in other graphs while they are linked via `linkdata` also persist even when data linking is subsequently turned off. That is, severing connections to a graph's data sources does not remove brushing marks from it. The only ways to remove brushing marks are (in brushing mode):

- Brush an empty area in a brushed graph.
- Right-click and select **Clear all brushing** from the context menu.

Changing the brushing color for a figure does not recolor brushing marks on it until you brush it again. If you hold down the **Shift** key, all existing brush marks change to the new color. All brush marks that appear on linked plots in the same or different figure also change to the new color if the brushing action affects them. The behavior is the same whether you select a brushing color from the Brush Tool dropdown palette, set

it by calling `brush(colorspec)`, or by setting the `Color` property of a brush mode object (e.g., `set(brushobj,'Color',colorspec)`.

How Data Linking Affects Data Brushing

When you use the Data Linking tool or call the `linkdata` function, brushing marks that you make on one plot appear on other plots that depict the same variable you are brushing—if those plots are also linked. This happens even if the affected plot is not in Brushing mode. That is, brushing marks appear on a linked plot *in any mode* when you brush another plot linked to it via a common variable or brush that variable in the Variables editor. Be aware that the following conditions apply, however:

- The graph type must support data brushing (see "Types of Plots You Can Brush" on page 1-547 and "Plot Types You Cannot Brush" on page 1-549)
- The graphed variable must not be complex; if you can plot a complex variable you can brush it, but such graphs do not respond when you brush the complex variable in another linked plot. For more information about linking complex variables, see Example 3 in the `linkdata` reference page.
- Observations that you brush display in the same color in all linked graphs. The color is the brush color you have selected in the window you are interacting with, and can differ from the brushing colors selected in the other affected figures. When you brush linked plots, the brushing color is associated with the variable(s) you brush

The last bullet implies that brush marks on an unlinked graph can change color when data linking is turned on for that figure. Brushing marks can, in fact, vanish and be replaced by marks in the same or different color when the plot enters a linked state. In the linked state, brushing is tied to variables (data sources), not just the graphics. If different observations for the same variable on a linked figure are brushed, those variables override the brushed graphics on the newly linked plot. In other words, the newly linked graph loses all its previous brush marks when it "joins the club" of common data sources.

Mouse Gestures for Data Brushing

You can brush graphs in several ways. The basic operation is to drag the mouse to highlight all observations within the rectangle you define. The following table lists data brushing gestures and their effects.

Action	Gesture	Result
Select data using a region of interest	ROI mouse drag	Region of interest (ROI) rectangle (or rectangular prism for 3-D axes) appears during the gesture and all brushable observations within the rectangle are highlighted. All other brushing marks in the axes are removed. The ROI rectangle disappears when the mouse button is released.
Select a single point	Single left-click on a graphic object that supports data brushing	Produces an equivalent result to ROI rectangle, brushing where the rectangle encloses only the single vertex on the graphical object closest to the mouse. All other brushing annotations in the figure are removed.
Add a point to the selection or remove a highlighted one	Single left-click on a graphic object that supports data brushing, with the **Shift** key down	Equivalent brushing by dragging an ROI rectangle that encloses only the single vertex on the graphic object closest to the mouse. All other brushed regions in the figure remain brushed.
Select all data associated with a graphic object	Double left-click on a graphic object that supports data brushing	All vertices for the graphic object are brushed.

Action	Gesture	Result
Add to or subtract from region of interest	Click or ROI drag with the **Shift** or **Ctrl** keys down	Region of interest grows; all unbrushed vertices within the rectangle become brushed and all brushed observations in it become unbrushed. All brushed vertices outside the ROI remain brushed.
Copy brushed data to Editor, Command Window, Variables editor, or Workspace Browser	Drag brushed data to another window or to a program/icon on the system desktop	Equivalent to copying brushed data and pasting into other window or an existing/new variable.

Brush Mode Callbacks

You can program the following callbacks for brush mode operations.

- `ActionPreCallback <function_handle>` — Function to execute before brushing

  Use this callback to execute code when a brush operation begins. The function handle should reference a function with two implicit arguments:

  ```
  function myfunction(obj,event_obj)
  % obj         handle to the figure that has been clicked
  % event_obj   object containing struct of event data
  ```

  The event data `struct` has the following field:

`Axes`	The handle of the axes that is being brushed

- `ActionPostCallback <function_handle>` — Function to execute after brushing

  Use this callback to execute code when a brush operation ends. The function handle should reference a function with two implicit arguments:

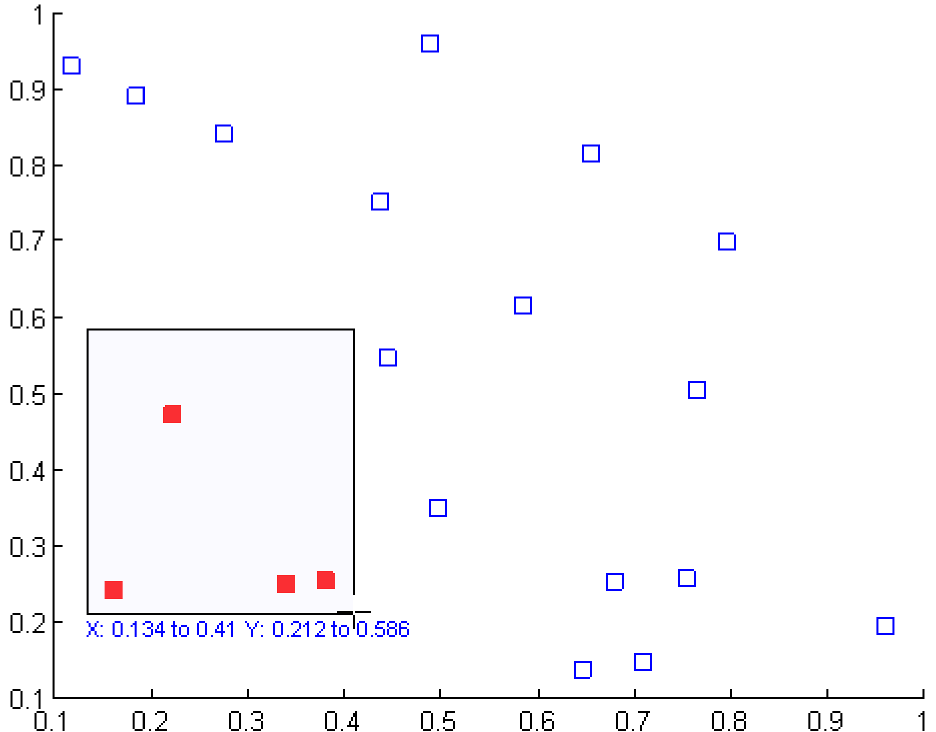
  ```
  function myfunction(obj,event_obj)
  % obj          handle to the figure that has been clicked
  % event_obj    object containing struct of event data (same as the
  %              event data of the 'ActionPreCallback' callback)
  ```

Examples

Example 1

On a scatterplot, drag out a rectangle to brush the graph:

```
x = rand(20,1);
y = rand(20,1);
scatter(x,y,80,'s')
brush on
```



Example 2

Brush observations from -.2 to .2 on a lineseries plot in dark red:

```
x = [-2*pi:.1:2*pi];
y = sin(x);
plot(x,y);
h = brush;
set(h,'Color',[.6 .2 .1],'Enable','on');
```

How To

- "Marking Up Graphs with Data Brushing"

Purpose

Apply element-by-element binary operation to two arrays with singleton expansion enabled

Syntax

```
C = bsxfun(fun,A,B)
```

Description

`C = bsxfun(fun,A,B)` applies the element-by-element binary operation specified by the function handle `fun` to arrays `A` and `B`, with singleton expansion enabled. `fun` can be one of the following built-in functions:

`@plus`	Plus
`@minus`	Minus
`@times`	Array multiply
`@rdivide`	Right array divide
`@ldivide`	Left array divide
`@power`	Array power
`@max`	Binary maximum
`@min`	Binary minimum
`@rem`	Remainder after division
`@mod`	Modulus after division
`@atan2`	Four-quadrant inverse tangent; result in radians
`@atan2d`	Four-quadrant inverse tangent; result in degrees
`@hypot`	Square root of sum of squares
`@eq`	Equal
`@ne`	Not equal
`@lt`	Less than
`@le`	Less than or equal to
`@gt`	Greater than

@ge	Greater than or equal to
@and	Element-wise logical AND
@or	Element-wise logical OR
@xor	Logical exclusive OR

fun can also be a handle to any binary element-wise function not listed above. A binary element-wise function of the form C = fun(A,B) accepts arrays A and B of arbitrary but equal size and returns output of the same size. Each element in the output array C is the result of an operation on the corresponding elements of A and B only. fun must also support scalar expansion, such that if A or B is a scalar, C is the result of applying the scalar to every element in the other input array.

The corresponding dimensions of A and B must be equal to each other or equal to one. Whenever a dimension of A or B is singleton (equal to one), bsxfun virtually replicates the array along that dimension to match the other array. In the case where a dimension of A or B is singleton, and the corresponding dimension in the other array is zero, bsxfun virtually diminishes the singleton dimension to zero.

The size of the output array C is equal to:
max(size(A),size(B)).*(size(A)>0 & size(B)>0).

Examples

In this example, bsxfun is used to subtract the column means from the corresponding columns of matrix A.

```
A = magic(5);
A = bsxfun(@minus, A, mean(A))
A =

     4    11   -12    -5     2
    10    -8    -6     1     3
    -9    -7     0     7     9
    -3    -1     6     8   -10
    -2     5    12   -11    -4
```

`repmat` | `arrayfun`

builddocsearchdb

Purpose

Build searchable documentation database

Syntax

`builddocsearchdb(folder)`

Description

`builddocsearchdb(folder)` builds a searchable database from HTML files in the specified folder. The `builddocsearchdb` function creates a subfolder named `helpsearch` to contain the database files. The database enables MATLAB to search for content within the HTML files, as long as the version of MATLAB is the same as the version used to create the database.

Input Arguments

folder - Full path to folder with HTML files

string

Full path to a folder with HTML files, specified as a string.

To include a particular HTML document in the search database, the `builddocsearchdb` function requires that:

- The document has a title.
- The content is different from the title.

Example: `builddocsearchdb('c:\myfiles\html')`

Examples

Search Custom Help Files

Build a search database for custom help files.

MATLAB includes a set of sample files to demonstrate how to create a custom toolbox and supporting documentation. This sample toolbox is called the *Upslope Area Toolbox*. The `upslope` folder includes a file named `info.xml`, which is required to display custom documentation, and a subfolder named `html`, which contains HTML documentation and supporting files.

Copy the sample files to a temporary folder, and add the copied files to the path.

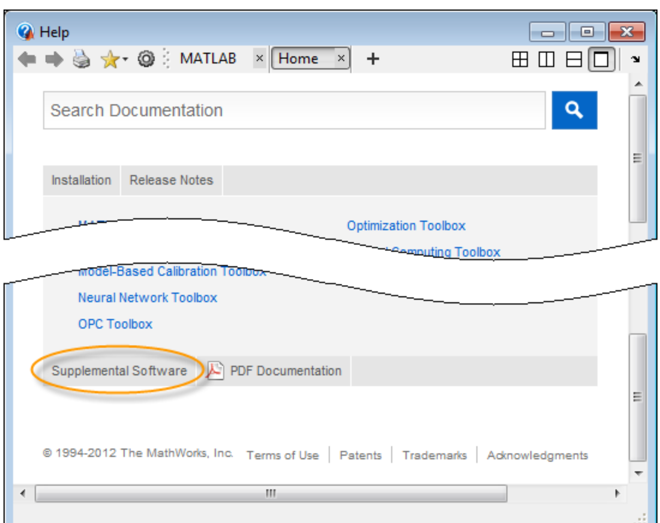
```
sample = fullfile(...
```

```
        matlabroot,'help','techdoc','matlab_env','examples','upslope
tmp = tempname;
mkdir(tmp);
copyfile(sample,tmp);
addpath(tmp);
```

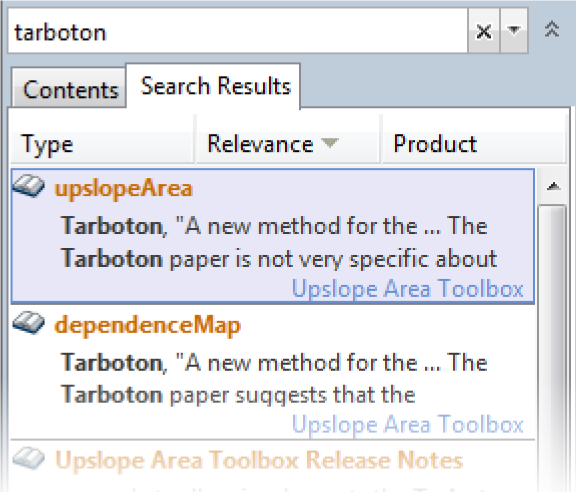
Create a search database.

```
folder = fullfile(tmp,'html');
builddocsearchdb(folder)
```

Open the Supplemental Software documentation browser. There is a link to this browser at the bottom of the documentation home page.



Search the supplemental documentation for the term *tarboton*, which appears in several of the example help files. The search returns several results from the Upslope Area Toolbox.



Remove the temporary example files.

```
rmpath(tmp)
rmdir(tmp,'s')
```

doc | help

Concepts

- “Display Custom Documentation”

Purpose

Execute built-in function from overloaded method

Syntax

```
builtin(function,x1,...,xn)
[y1,...,yn] = builtin(function,x1,...,xn)
```

Description

`builtin(function,x1,...,xn)` executes the built-in `function` with the input arguments `x1` through `xn`. Use `builtin` to execute the original built-in from within a method that overloads the function. To work properly, you must never overload `builtin`.

`[y1,...,yn] = builtin(function,x1,...,xn)` stores any output from `function` in `y1` through `yn`.

Input Arguments

function - Built-in function name
string

Valid built-in function name in the MATLAB path, specified as a string. `function` cannot be a function handle.

x1,...,xn - Valid input arguments for `function`
supported data types

Valid input arguments for `function`, specified by supported data types.

Examples

Run an Overloaded Function within a Class Definition

Execute the built-in functionality from within an overloaded method.

Create a simple class describing the speed of a particle and providing a `disp` method by pasting the following code into a file called `MyParticle.m`.

```
classdef MyParticle
    properties
        velocity;
    end
    methods
        function p = MyParticle(x,y,z)
```

```
            p.velocity.x = x;
            p.velocity.y = y;
            p.velocity.z = z;
        end
        function disp(p)
            builtin('disp',p) %call builtin
            if isscalar(p)
                disp('  Velocity')
                disp(['  x: ',num2str(p.velocity.x)])
                disp(['  y: ',num2str(p.velocity.y)])
                disp(['  z: ',num2str(p.velocity.z)])
            end
        end
    end
end
```

Create an instance MyParticle.

```
p = MyParticle(1,2,4)
```

```
p =

  MyParticle

  Properties:
    velocity: [1x1 struct]

  Methods

  Velocity
  x: 1
  y: 2
  z: 4
```

Definitions

built-in function

A built-in function is part of the MATLAB executable. MATLAB does not implement these functions in the MATLAB language. Although most built-in functions have a `.m` file associated with them, this file only supplies documentation for the function.

You can use the syntax `which` *`function`* to check whether a function is built-in.

See Also

`feval` | `which`

Purpose

Solve boundary value problems for ordinary differential equations

Syntax

```
sol = bvp4c(odefun,bcfun,solinit)
sol = bvp4c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

Arguments

`odefun`	A function handle that evaluates the differential equations $f(x,y)$. It can have the form
	`dydx = odefun(x,y)`
	`dydx = odefun(x,y,parameters)`
	where `x` is a scalar corresponding to x, and `y` is a column vector corresponding to y. `parameters` is a vector of unknown parameters. The output `dydx` is a column vector.

`bcfun`	A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form $bc(y(a),y(b))$, `bcfun` can have the form
	`res = bcfun(ya,yb)`
	`res = bcfun(ya,yb,parameters)`
	where `ya` and `yb` are column vectors corresponding to $y(a)$ and $y(b)$. `parameters` is a vector of unknown parameters. The output `res` is a column vector.
	See “Multipoint Boundary Value Problems” on page 1-569 for a description of `bcfun` for multipoint boundary value problems.

`solinit`	A structure containing the initial guess for a solution. You create `solinit` using the function `bvpinit`. `solinit` has the following fields.

	`x`	Ordered nodes of the initial mesh. Boundary conditions are imposed at a = `solinit.x(1)` and b = `solinit.x(end)`.
	`y`	Initial guess for the solution such that `solinit.y(:,i)` is a guess for the solution at the node `solinit.x(i)`.
	`parameters`	Optional. A vector that provides an initial guess for unknown parameters.
	The structure can have any name, but the fields must be named `x`, `y`, and `parameters`. You can form `solinit` with the helper function `bvpinit`. See `bvpinit` for details.	
`options`	Optional integration argument. A structure you create using the `bvpset` function. See `bvpset` for details.	

Description

`sol = bvp4c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$$y' = f(x,y)$$

on the interval [a,b] subject to two-point boundary value conditions $bc(y(a),y(b)) = 0$.

`odefun` and `bcfun` are function handles. See the `function_handle` reference page for more information.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary.

`bvp4c` can also solve multipoint boundary value problems. See “Multipoint Boundary Value Problems” on page 1-569. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`. See the reference page for `bvpinit` for more information.

The `bvp4c` solver can also find unknown parameters p for problems of the form

$$y' = f(x,y, p)$$

$$0 = bc(y(a),y(b),p)$$

where p corresponds to `parameters`. You provide `bvp4c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp4c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp4c` produces a solution that is continuous on `[a,b]` and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp4c` to evaluate the solution at specific points `xint` in the interval `[a,b]`.

```
sxint = deval(sol,xint)
```

The structure `sol` returned by `bvp4c` has the following fields:

`sol.x`	Mesh selected by `bvp4c`
`sol.y`	Approximation to $y(x)$ at the mesh points of `sol.x`
`sol.yp`	Approximation to $y'(x)$ at the mesh points of `sol.x`
`sol.parameters`	Values returned by `bvp4c` for the unknown parameters, if any
`sol.solver`	'bvp4c'
`sol.stats`	Computational cost statistics (also displayed when the `stats` option is set with `bvpset`).

The structure `sol` can have any name, and `bvp4c` creates the fields `x`, `y`, `yp`, `parameters`, and `solver`.

`sol = bvp4c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

Singular Boundary Value Problems

`bvp4c` solves a class of singular boundary value problems, including problems with unknown parameters `p`, of the form

$$y' = S \cdot y/x + F(x,y,p)$$

$$0 = bc(y(0),y(b),p)$$

The interval is required to be $[0, b]$ with $b > 0$. Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix `S` as the value of the `'SingularTerm'` option of `bvpset`, and `odefun` evaluates only $f(x,y,p)$. The boundary conditions must be consistent with the necessary condition $S \cdot y(0) = 0$ and the initial guess should satisfy this condition.

Multipoint Boundary Value Problems

`bvp4c` can solve multipoint boundary value problems where $a = a_0 < a_1 < a_2 < ...< a_n = b$ are boundary points in the interval $[a,b]$. The points $a_1,a_2,...,a_{n-1}$ represent interfaces that divide $[a,b]$ into regions. `bvp4c` enumerates the regions from left to right (from a to b), with indices starting from 1. In region k, $[a_{k-1},a_k]$, `bvp4c` evaluates the derivative as

```
yp = odefun(x,y,k)
```

In the boundary conditions function

```
bcfun(yleft,yright)
```

`yleft(:,k)` is the solution at the left boundary of $[a_{k-1},a_k]$. Similarly, `yright(:,k)` is the solution at the right boundary of region k. In particular,

```
yleft(:,1) = y(a)
```

and

```
yright(:,end) = y(b)
```

When you create an initial guess with

```
solinit = bvpinit(xinit,yinit),
```

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x,k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bpv4c`, `sol.x` has double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

Note The `bvp5c` function is used exactly like `bvp4c`, with the exception of the meaning of error tolerances between the two solvers. If $S(x)$ approximates the solution $y(x)$, `bvp4c` controls the residual $|S'(x) - f(x,S(x))|$. This controls indirectly the true error $|y(x) - S(x)|$. `bvp5c` controls the true error directly. `bvp5c` is more efficient than `bvp4c` for small error tolerances.

Examples

Example 1

Boundary value problems can have multiple solutions and one purpose of the initial guess is to indicate which solution you want. The second-order differential equation

$$y'' + |y| = 0$$

has exactly two solutions that satisfy the boundary conditions $y(0) = 0$, $y(4) = -2$.

Prior to solving this problem with `bvp4c`, you must write the differential equation as a system of two first-order ODEs

$$y_1' = y_2$$

$$y_2' = -|y_1|.$$

Here $y_1 = y$ and $y_2 = y'$. This system has the required form

$$y' = f(x,y)$$

$$bc(y(a),y(b)) = 0$$

The function f and the boundary conditions bc are coded in MATLAB software as functions `twoode` and `twobc`.

```
function dydx = twoode(x,y)
  dydx = [ y(2)
           -abs(y(1))];

function res = twobc(ya,yb)
  res = [ ya(1)
          yb(1) + 2];
```

Form a guess structure consisting of an initial mesh of five equally spaced points in [0,4] and a guess of constant values

$$y_1(x) \equiv 0$$

and

$$y_2(x) \equiv 0$$

with the command

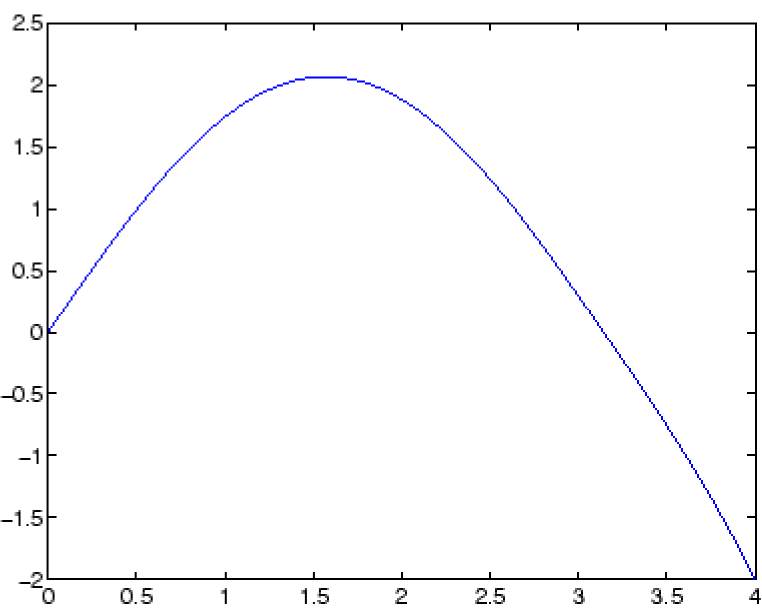
```
solinit = bvpinit(linspace(0,4,5),[1 0]);
```

Now solve the problem with

```
sol = bvp4c(@twoode,@twobc,solinit);
```

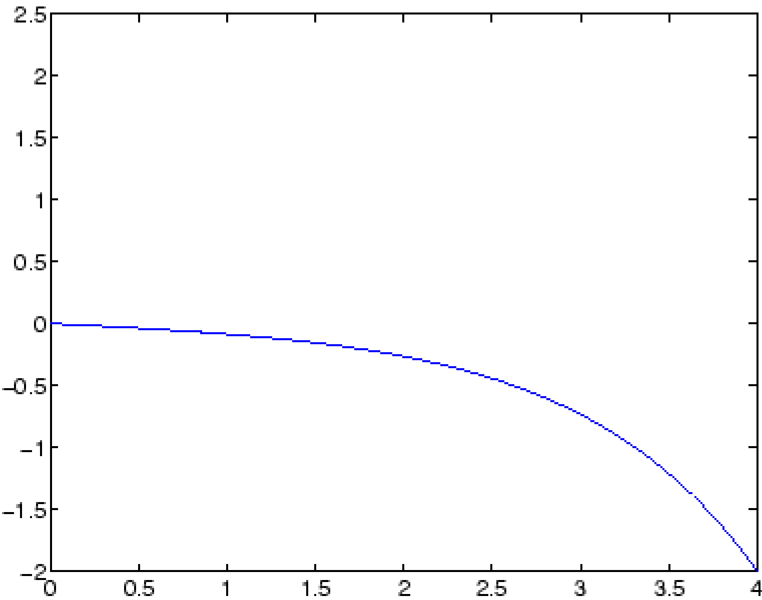
Evaluate the numerical solution at 100 equally spaced points and plot $y(x)$ with

```
x = linspace(0,4);
y = deval(sol,x);
plot(x,y(1,:));
```



You can obtain the other solution of this problem with the initial guess

```
solinit = bvpinit(linspace(0,4,5),[-1 0]);
```



Example 2

This boundary value problem involves an unknown parameter. The task is to compute the fourth ($q = 5$) eigenvalue λ of Mathieu's equation

$$y'' + (\lambda - 2q\cos 2x)y = 0.$$

Because the unknown parameter λ is present, this second-order differential equation is subject to *three* boundary conditions:

$$y'(0) = 0$$

$$y'(\pi) = 0$$

$$y(0) = 1$$

It is convenient to use local functions to place all the functions required by `bvp4c` in a single file.

```
function mat4bvp

lambda = 15;
solinit = bvpinit(linspace(0,pi,10),@mat4init,lambda);
sol = bvp4c(@mat4ode,@mat4bc,solinit);

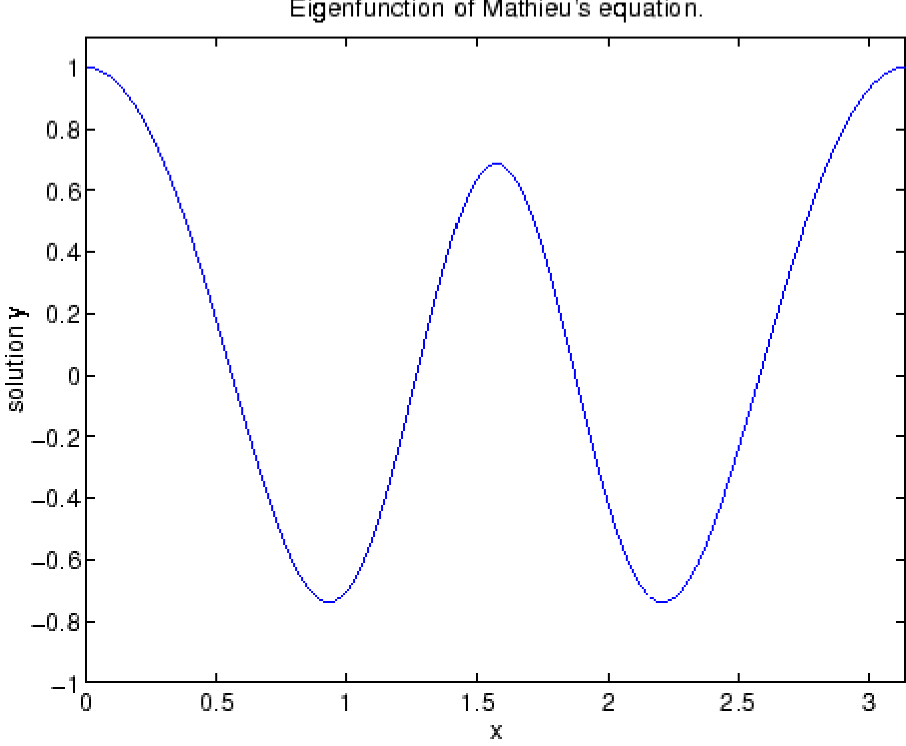
fprintf('The fourth eigenvalue is approximately %7.3f.\n',...
        sol.parameters)

xint = linspace(0,pi);
Sxint = deval(sol,xint);
plot(xint,Sxint(1,:))
axis([0 pi -1 1.1])
title('Eigenfunction of Mathieu''s equation.')
xlabel('x')
ylabel('solution y')
% ------------------------------------------------------------
function dydx = mat4ode(x,y,lambda)
q = 5;
dydx = [  y(2)
         -(lambda - 2*q*cos(2*x))*y(1) ];
% ------------------------------------------------------------
function res = mat4bc(ya,yb,lambda)
res = [  ya(2)
         yb(2)
        ya(1)-1 ];
% ------------------------------------------------------------
function yinit = mat4init(x)
yinit = [  cos(4*x)
          -4*sin(4*x) ];
```

The differential equation (converted to a first-order system) and the boundary conditions are coded as local functions `mat4ode` and `mat4bc`, respectively. Because unknown parameters are present, these functions must accept three input arguments, even though some of the arguments are not used.

The guess structure `solinit` is formed with `bvpinit`. An initial guess for the solution is supplied in the form of a function `mat4init`. We chose $y = \cos 4x$ because it satisfies the boundary conditions and has the correct qualitative behavior (the correct number of sign changes). In the call to `bvpinit`, the third argument (`lambda = 15`) provides an initial guess for the unknown parameter λ.

After the problem is solved with `bvp4c`, the field `sol.parameters` returns the value $\lambda = 17.097$, and the plot shows the eigenfunction associated with this eigenvalue.



Algorithms

`bvp4c` is a finite difference code that implements the three-stage Lobatto IIIa formula. This is a collocation formula and the collocation

polynomial provides a C^1-continuous solution that is fourth-order accurate uniformly in `[a,b]`. Mesh selection and error control are based on the residual of the continuous solution.

`@` | `bvp5c` | `bvpget` | `bvpinit` | `bvpset` | `bvpxtend` | `deval`

Purpose

Solve boundary value problems for ordinary differential equations

Syntax

```
sol = bvp5c(odefun,bcfun,solinit)
sol = bvp5c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

Arguments

`odefun`	A function handle that evaluates the differential equations $f(x,y)$. It can have the form
	
	`dydx = odefun(x,y)`
	`dydx = odefun(x,y,parameters)`
	
	where `x` is a scalar corresponding to x, and `y` is a column vector corresponding to y. `parameters` is a vector of unknown parameters. The output `dydx` is a column vector.	

`bcfun`	A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form $bc(y(a),y(b))$, `bcfun` can have the form
	
	`res = bcfun(ya,yb)`
	`res = bcfun(ya,yb,parameters)`
	
	where `ya` and `yb` are column vectors corresponding to $y(a)$ and $y(b)$. `parameters` is a vector of unknown parameters. The output `res` is a column vector.	

`solinit`	A structure containing the initial guess for a solution. You create `solinit` using the function `bvpinit`. `solinit` has the following fields.	
	`x`	Ordered nodes of the initial mesh. Boundary conditions are imposed at a = `solinit.x(1)` and b = `solinit.x(end)`.

	y	Initial guess for the solution such that `solinit.y(:,i)` is a guess for the solution at the node `solinit.x(i)`.
	parameters	Optional. A vector that provides an initial guess for unknown parameters.
	The structure can have any name, but the fields must be named `x`, `y`, and `parameters`. You can form `solinit` with the helper function `bvpinit`. See `bvpinit` for details.	
options	Optional integration argument. A structure you create using the `bvpset` function. See `bvpset` for details.	

Description

`sol = bvp5c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$$y' = f(x,y)$$

on the interval [a,b] subject to two-point boundary value conditions

$$bc(y(a),y(b)) = 0$$

`odefun` and `bcfun` are function handles. See the `function_handle` reference page for more information.

"Parameterizing Functions" explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`.

The `bvp5c` solver can also find unknown parameters p for problems of the form

$$y' = f(x,y,p)$$

$$0 = bc(y(a),y(b),p)$$

where p corresponds to `parameters`. You provide `bvp5c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp5c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp5c` produces a solution that is continuous on `[a,b]` and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp5c` to evaluate the solution at specific points `xint` in the interval `[a,b]`.

```
sxint = deval(sol,xint)
```

The structure `sol` returned by `bvp5c` has the following fields:

`sol.x`	Mesh selected by `bvp5c`
`sol.y`	Approximation to $y(x)$ at the mesh points of `sol.x`
`sol.parameters`	Values returned by `bvp5c` for the unknown parameters, if any
`sol.solver`	`'bvp5c'`
`sol.stats`	Computational cost statistics (also displayed when the `stats` option is set with `bvpset`).

The structure `sol` can have any name, and `bvp5c` creates the fields `x`, `y`, `parameters`, and `solver`.

`sol = bvp5c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

Singular Boundary Value Problems

`bvp5c` solves a class of singular boundary value problems, including problems with unknown parameters `p`, of the form

$$y' = S \cdot y/x + f(x,y,p)$$

$$0 = bc(y(0),y(b),p)$$

The interval is required to be [0, b] with b > 0. Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix `S` as the value of the `'SingularTerm'` option of `bvpset`, and `odefun` evaluates only $f(x,y,p)$. The boundary conditions must be consistent with the necessary condition $S \cdot y(0) = 0$ and the initial guess should satisfy this condition.

Multipoint Boundary Value Problems

`bvp5c` can solve multipoint boundary value problems where $a = a_0 < a_1 < a_2 < ... < a_n = b$ are boundary points in the interval $[a,b]$. The points $a_1,a_2, ... ,a_{n-1}$ represent interfaces that divide $[a,b]$ into regions. `bvp5c` enumerates the regions from left to right (from a to b), with indices starting from 1. In region k, $[a_{k-1},a_k]$, `bvp5c` evaluates the derivative as

```
yp = odefun(x,y,k)
```

In the boundary conditions function

```
bcfun(yleft,yright)
```

yleft(:, k) is the solution at the left boundary of $[a_{k-1},a_k]$. Similarly, `yright(:,k)` is the solution at the right boundary of region k. In particular,

```
yleft(:,1) = y(a)
```

and

```
yright(:,end) = y(b)
```

When you create an initial guess with

```
solinit = bvpinit(xinit,yinit),
```

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x, k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bvp5c`, `sol.x` has double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example of that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

Algorithms

`bvp5c` is a finite difference code that implements the four-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a C^1-continuous solution that is fifth-order accurate uniformly in `[a,b]`. The formula is implemented as an implicit Runge-Kutta formula. `bvp5c` solves the algebraic equations directly; `bvp4c` uses analytical condensation. `bvp4c` handles unknown parameters directly; while `bvp5c` augments the system with trivial differential equations for unknown parameters.

bvpget

Purpose

Extract properties from options structure created with bvpset

Syntax

```
val = bvpget(options,'name')
val = bvpget(options,'name',default)
```

Description

`val = bvpget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = bvpget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = bvpget(options,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `options`.

See Also

`bvp4c` | `bvp5c` | `bvpinit` | `bvpset` | `deval`

Purpose

Form initial guess for BVP solvers

Syntax

```
solinit = bvpinit(x,yinit)
solinit = bvpinit(x,yinit,parameters)
solinit = bvpinit(sol,[anew bnew])
solinit = bvpinit(sol,[anew bnew],parameters)
```

Description

`solinit = bvpinit(x,yinit)` forms the initial guess for a boundary value problem solver.

`x` is a vector that specifies an initial mesh. If you want to solve the BVP on [a,b], then specify `x(1)` as a and `x(end)` as b. The solver adapts this mesh to the solution, so a guess like `xb=nlinspace(a,b,10)` often suffices. However, in difficult cases, you should place mesh points where the solution changes rapidly. The entries of `x` must be in

- Increasing order if $a<b$
- Decreasing order if $a>b$

For two-point boundary value problems, the entries of `x` must be distinct. That is, if $a<b$, the entries must satisfy `x(1)` < `x(2)` < ... < `x(end)`. If $a>b$, the entries must satisfy `x(1)` > `x(2)` > ... > `x(end)`

For multipoint boundary value problem, you can specify the points in [a,b] at which the boundary conditions apply, other than the endpoints a and b, by repeating their entries in `x`. For example, if you set

```
x = [0, 0.5, 1, 1,  1.5, 2];
```

the boundary conditions apply at three points: the endpoints `0` and `2`, and the repeated entry 1. In general, repeated entries represent boundary points between regions in [a,b]. In the preceding example, the repeated entry 1 divides the interval `[0,2]` into two regions: `[0,1]` and `[1,2]`.

`yinit` is a guess for the solution. It can be either a vector, or a function:

- Vector – For each component of the solution, `bvpinit` replicates the corresponding element of the vector as a constant guess across

all mesh points. That is, `yinit(i)` is a constant guess for the `i`th component `yinit(i,:)` of the solution at all the mesh points in `x`.

- Function – For a given mesh point, the guess function must return a vector whose elements are guesses for the corresponding components of the solution. The function must be of the form

  ```
  y = guess(x)
  ```

  where `x` is a mesh point and `y` is a vector whose length is the same as the number of components in the solution. For example, if the guess function is a function, `bvpinit` calls

  ```
  y(:,j) = guess(x(j))
  ```

  at each mesh point.

  For multipoint boundary value problems, the guess function must be of the form

  ```
  y = guess(x, k)
  ```

  where `y` an initial guess for the solution at `x` in region `k`. The function must accept the input argument `k`, which is provided for flexibility in writing the guess function. However, the function is not required to use `k`.

`solinit = bvpinit(x,yinit,parameters)` indicates that the boundary value problem involves unknown parameters. Use the vector `parameters` to provide a guess for all unknown parameters.

`solinit` is a structure with the following fields. The structure can have any name, but the fields must be named `x`, `y`, and `parameters`.

`x`	Ordered nodes of the initial mesh.
`y`	Initial guess for the solution with `solinit.y(:,i)` a guess for the solution at the node `solinit.x(i)`.
`parameters`	Optional. A vector that provides an initial guess for unknown parameters.

`solinit = bvpinit(sol,[anew bnew])` forms an initial guess on the interval `[anew bnew]` from a solution `sol` on an interval [a,b]. The new interval must be larger than the previous one, so either `anew <=` $a < b$ `<= bnew` or `anew >=` $a > b$ `>= bnew`. The solution `sol` is extrapolated to the new interval. If `sol` contains `parameters`, they are copied to `solinit`.

`solinit = bvpinit(sol,[anew bnew],parameters)` forms `solinit` as described above, but uses `parameters` as a guess for unknown parameters in `solinit`.

`@` | `bvp4c` | `bvp5c` | `bvpget` | `bvpset` | `bvpxtend` | `deval`

bvpset

Purpose

Create or alter options structure of boundary value problem

Syntax

```
options = bvpset('name1',value1,'name2',value2,...)
options = bvpset(oldopts,'name1',value1,...)
options = bvpset(oldopts,newopts)
bvpset
```

Description

`options = bvpset('name1',value1,'name2',value2,...)` creates a structure `options` that you can supply to the boundary value problem solver `bvp4c`, in which the named properties have the specified values. Any unspecified properties retain their default values. For all properties, it is sufficient to type only the leading characters that uniquely identify the property. `bvpset` ignores case for property names.

`options = bvpset(oldopts,'name1',value1,...)` alters an existing options structure `oldopts`. This overwrites any values in `oldopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = bvpset(oldopts,newopts)` combines an existing options structure `oldopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `oldopts`.

`bvpset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `bvpget` to query the `options` structure for the value of a specific property.

BVP Properties

`bvpset` enables you to specify properties for the boundary value problem solver `bvp4c`. There are several categories of properties that you can set:

- "Error Tolerance Properties" on page 1-587
- "Vectorization" on page 1-588
- "Analytical Partial Derivatives" on page 1-589
- "Singular BVPs" on page 1-590
- "Mesh Size Property" on page 1-591

- "Solution Statistic Property" on page 1-592

Error Tolerance Properties

Because `bvp4c` uses a collocation formula, the numerical solution is based on a mesh of points at which the collocation equations are satisfied. Mesh selection and error control are based on the residual of this solution, such that the computed solution $S(x)$ is the exact solution of a perturbed problem $S'(x) = f(x,S(x)) + res(x)$. On each subinterval of the mesh, a norm of the residual in the `i`th component of the solution, `res(i)`, is estimated and is required to be less than or equal to a tolerance. This tolerance is a function of the relative and absolute tolerances, `RelTol` and `AbsTol`, defined by the user.

$$\left\| \left(\mathrm{res}(i) / \max\left(\mathrm{abs}\left(f(i) \right), \mathrm{AbsTol}(i) / \mathrm{RelTol} \right) \right) \right\| \le \mathrm{RelTol}$$

The following table describes the error tolerance properties.

BVP Error Tolerance Properties

Property	Value	Description
`RelTol`	Positive scalar {`1e-3`}	A relative error tolerance that applies to all components of the residual vector. It is a measure of the residual relative to the size of $f(x,y)$. The default, `1e-3`, corresponds to 0.1% accuracy. The computed solution $S(x)$ is the exact solution of $S'(x) = F(x,S(x)) + \mathrm{res}(x)$. On each subinterval of the mesh, the residual $\mathrm{res}(x)$ satisfies $\left\| \left(\mathrm{res}(i) / \max\left(\mathrm{abs}\left(F(i) \right), \mathrm{AbsTol}(i) / \mathrm{RelTol} \right) \right) \right\| \le \mathrm{RelTol}$
`AbsTol`	Positive scalar or vector {`1e-6`}	Absolute error tolerances that apply to the corresponding components of the residual vector. `AbsTol(i)` is a threshold below which the values of the corresponding components are unimportant. If a scalar value is specified, it applies to all components.

Vectorization

The following table describes the BVP vectorization property. Vectorization of the ODE function used by bvp4c differs from the vectorization used by the ODE solvers:

- For bvp4c, the ODE function must be vectorized with respect to the first argument as well as the second one, so that F([x1 x2 ...],[y1 y2 ...]) returns [F(x1,y1) F(x2,y2)...].
- bvp4c benefits from vectorization even when analytical Jacobians are provided. For stiff ODE solvers, vectorization is ignored when analytical Jacobians are used.

Vectorization Properties

Property	Value	Description
Vectorized	on | {off}	Set on to inform bvp4c that you have coded the ODE function F so that F([x1 x2 ...],[y1 y2 ...]) returns [F(x1,y1) F(x2,y2) ...]. That is, your ODE function can pass to the solver a whole array of column vectors at once. This enables the solver to reduce the number of function evaluations and may significantly reduce solution time. With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. In the shockbvp example shown previously, the shockODE function has been vectorized using colon notation into the subscripts and by using the array multiplication (.*) operator. `function dydx = shockODE(x,y,e)`

Vectorization Properties (Continued)

Property	Value	Description

		`pix = pi*x;`
		`dydx = [ y(2,:)...`
		`-x/e.*y(2,:)-pi^2*cos(pix)-`
		`pix/e.*sin(pix)];`

Analytical Partial Derivatives

By default, the `bvp4c` solver approximates all partial derivatives with finite differences. `bvp4c` can be more efficient if you provide analytical partial derivatives $\partial f/\partial y$ of the differential equations, and analytical partial derivatives, $\partial bc/\partial ya$ and $\partial bc/\partial yb$, of the boundary conditions. If the problem involves unknown parameters, you must also provide partial derivatives, $\partial f/\partial p$ and $\partial bc/\partial p$, with respect to the parameters.

The following table describes the analytical partial derivatives properties.

BVP Analytical Partial Derivative Properties

Property	Value	Description
`FJacobian`	Function handle	A function handle that computes the analytical partial derivatives of $f(x,y)$. When solving $y' = f(x,y)$, set this property to `@fjac` if `dfdy = fjac(x,y)` evaluates the Jacobian $\partial f/\partial y$. If the problem involves unknown parameters p, `[dfdy,dfdp] = fjac(x,y,p)` must also return the partial derivative $\partial f/\partial p$. For problems with constant partial derivatives, set

BVP Analytical Partial Derivative Properties (Continued)

Property	Value	Description
		this property to the value of `dfdy` or to a cell array `{dfdy,dfdp}`.
`BCJacobian`	Function handle	A function handle that computes the analytical partial derivatives of *bc*(*ya*,*yb*). For boundary conditions *bc*(*ya*,*yb*), set this property to `@bcjac` if `[dbcdya,dbcdyb] = bcjac(ya,yb)` evaluates the partial derivatives $\partial bc/\partial ya$, and $\partial bc/\partial yb$. If the problem involves unknown parameters *p*, `[dbcdya,dbcdyb,dbcdp] = bcjac(ya,yb,p)` must also return the partial derivative $\partial bc/\partial p$. For problems with constant partial derivatives, set this property to a cell array `{dbcdya,dbcdyb}` or `{dbcdya,dbcdyb,dbcdp}`.

Singular BVPs

`bvp4c` can solve singular problems of the form

$$y' = S\frac{y}{x} + f(x, y, p)$$

posed on the interval [0,*b*] where $b > 0$. For such problems, specify the constant matrix *S* as the value of `SingularTerm`. For equations of this form, `odefun` evaluates only the $f(x,y,p)$ term, where *p* represents unknown parameters, if any.

Singular BVP Property

Property	Value	Description
SingularTerm	Constant matrix	Singular term of singular BVPs. Set to the constant matrix S for equations of the form $$y' = S\frac{y}{x} + f(x, y, p)$$ posed on the interval [0,b] where $b > 0$.

Mesh Size Property

bvp4c solves a system of algebraic equations to determine the numerical solution to a BVP at each of the mesh points. The size of the algebraic system depends on the number of differential equations (n) and the number of mesh points in the current mesh (N). When the allowed number of mesh points is exhausted, the computation stops, bvp4c displays a warning message and returns the solution it found so far. This solution does not satisfy the error tolerance, but it may provide an excellent initial guess for computations restarted with relaxed error tolerances or an increased value of NMax.

The following table describes the mesh size property.

BVP Mesh Size Property

Property	Value	Description
NMax	positive integer {floor(1000/n)}	Maximum number of mesh points allowed when solving the BVP, where n is the number of differential equations in the problem. The default value of NMax limits the size of the algebraic system to about 1000 equations. For systems of a few differential equations, the default value of NMax should be sufficient to obtain an accurate solution.

Solution Statistic Property

The Stats property lets you view solution statistics.

The following table describes the solution statistics property.

BVP Solution Statistic Property

Property	Value	Description
Stats	on | {off}	Specifies whether statistics about the computations are displayed. If the stats property is on, after solving the problem, bvp4c displays: • The number of points in the mesh • The maximum residual of the solution • The number of times it called the differential equation function odefun to evaluate $f(x,y)$

BVP Solution Statistic Property (Continued)

Property	Value	Description
		• The number of times it called the boundary condition function `bcfun` to evaluate $bc(y(a),y(b))$

Examples

To create an options structure that changes the relative error tolerance of `bvp4c` from the default value of `1e-3` to `1e-4`, enter

```
options = bvpset('RelTol',1e-4);
```

To recover the value of `'RelTol'` from `options`, enter

```
bvpget(options,'RelTol')

ans =

  1.0000e-004
```

See Also

`function_handle` | `bvp4c` | `bvp5c` | `bvpget` | `bvpinit` | `deval`

bvpxtend

Purpose

Form guess structure for extending boundary value solutions

Syntax

```
solinit = bvpxtend(sol,xnew,ynew)
solinit = bvpxtend(sol,xnew,extrap)
solinit = bvpxtend(sol,xnew)
solinit = bvpxtend(sol,xnew,ynew,pnew)
solinit = bvpxtend(sol,xnew,extrap,pnew)
```

Description

`solinit = bvpxtend(sol,xnew,ynew)` uses solution `sol` computed on `[a,b]` to form a solution guess for the interval extended to `xnew`. The extension point `xnew` must be outside the interval `[a,b]`, but on either side. The vector `ynew` provides an initial guess for the solution at `xnew`.

`solinit = bvpxtend(sol,xnew,extrap)` forms the guess at `xnew` by extrapolating the solution `sol`. `extrap` is a string that determines the extrapolation method. `extrap` has three possible values:

- `'constant'` — `ynew` is a value nearer to end point of solution in `sol`.
- `'linear'` — `ynew` is a value at `xnew` of linear interpolant to the value and slope at the nearer end point of solution in `sol`.
- `'solution'` — `ynew` is the value of (cubic) solution in `sol` at `xnew`.

The value of `extrap` is case-insensitive and only the leading, unique portion needs to be specified.

`solinit = bvpxtend(sol,xnew)` uses the extrapolating solution where `extrap` is `'constant'`. If there are unknown parameters, values present in `sol` are used as the initial guess for parameters in `solinit`.

`solinit = bvpxtend(sol,xnew,ynew,pnew)` specifies a different guess `pnew`. `pnew` can be used with extrapolation, using the syntax `solinit = bvpxtend(sol,xnew,extrap,pnew)`. To modify parameters without changing the interval, use `[]` as place holder for `xnew` and `ynew`.

`bvp4c` | `bvp5c` | `bvpinit`

Purpose

Calendar for specified month

Syntax

```
c = calendar
c = calendar(d)
c = calendar(y, m)
```

Description

`c = calendar` returns a 6-by-7 matrix containing a calendar for the current month. The calendar runs Sunday (first column) to Saturday.

`c = calendar(d)`, where `d` is a serial date number or a date string, returns a calendar for the specified month.

`c = calendar(y, m)`, where `y` and `m` are integers, returns a calendar for the specified month of the specified year.

Examples

The command

```
calendar(1957,10)
```

reveals that the Space Age began on a Friday (on October 4, 1957, when Sputnik 1 was launched).

```
                          Oct 1957
     S      M     Tu      W     Th      F      S
     0      0      1      2      3      4      5
     6      7      8      9     10     11     12
    13     14     15     16     17     18     19
    20     21     22     23     24     25     26
    27     28     29     30     31      0      0
     0      0      0      0      0      0      0
```

`datenum`

calllib

Purpose

Call function in shared library

Syntax

```
[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)
```

Description

`[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)` calls function, `funcname`, in library, `libname`, passing input arguments, `arg1,...,argN`, and returns output values obtained from `funcname` in `x1,...,xN`.

Input Arguments

libname - Name of shared library

string

Name of shared library, specified as a string. If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types

`char`

funcname - Name of function in library

string

Name of function in library, specified as a string.

Data Types

`char`

arg1,...,argN - Input arguments

any type

Input arguments, 1 through N, required by `funcname` (if any), specified by any type. The argument type is specified by the `funcname` argument list.

Output Arguments

x1,...,xN - Output arguments

any type

Output arguments, 1 through N, from `funcname` (if any), returned as any type. The argument type is specified by the `funcname` argument list.

Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

Examples

Call addStructByRef Function

Load the library.

```
if ~libisloaded('shrlibsample')
   addpath(fullfile(matlabroot,'extern','examples','shrlib'))
   loadlibrary('shrlibsample')
end
```

Display function signature.

```
libfunctionsview shrlibsample
```

```
[double, c_structPtr] addStructByRef(c_structPtr)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `struct`:

```
struct.p1 = 4; struct.p2 = 7.3; struct.p3 = -290;
```

Call the function.

```
[res,st] = calllib('shrlibsample','addStructByRef',struct);
```

Display the results.

```
res
```

```
res =
        -279
```

Clean up.

```
unloadlibrary shrlibsample
```

Concepts

- Passing Arguments
- “MATLAB Crashes Making a Function Call to a Shared Library”

Purpose

Send SOAP message to endpoint

Syntax

```
response = callSoapService(endpoint,soapAction,message)
```

Description

`response = callSoapService(endpoint,soapAction,message)` sends `message`, a Java® document object model (DOM), to the `soapAction` service at `endpoint`. Create `message` using `createSoapMessage`, and extract results from `response` using `parseSoapResponse`.

Examples

This example uses `callSoapService` in conjunction with other SOAP functions to retrieve information about books from a library database, specifically, the author's name for a given book title.

Note The example does not use an actual endpoint; therefore, you cannot run it. The example only illustrates how to use the SOAP functions.

```
% Create the message:
message = createSoapMessage(...
'urn:LibraryCatalog',...
'getAuthor',...
{'In the Fall'},...
{'nameToLookUp'},...
{'{http://www.w3.org/2001/XMLSchema}string'},...
'rpc');
%
% Send the message to the service and get the response:
response = callSoapService(...
'http://test/soap/services/LibraryCatalog',...
'urn:LibraryCatalog#getAuthor',...
message)
%
% Extract MATLAB data from the response
```

```
author = parseSoapResponse(response)
```

MATLAB returns:

```
author = Kate Alvin
```

where author is a char class (type).

How To

- "Access Web Services Using MATLAB SOAP Functions"

Purpose

Move camera position and target

Syntax

```
camdolly(dx,dy,dz)
camdolly(dx,dy,dz,'targetmode')
camdolly(dx,dy,dz,'targetmode','coordsys')
camdolly(axes_handle,...)
```

Description

`camdolly(dx,dy,dz)` moves the camera position and the camera target by the specified amounts `dx`, `dy`, and `dz`.

`camdolly(dx,dy,dz,'targetmode')` uses the `targetmode` argument to determine how the camera moves:

- `movetarget` (default) — Move both the camera and the target.
- `fixtarget` — Move only the camera.

`camdolly(dx,dy,dz,'targetmode','coordsys')` uses the `coordsys` argument to determine how MATLAB interprets `dx`, `dy`, and `dz`:

- `camera` (default) — Move in the coordinate system of the camera. `dx` moves left/right, `dy` moves down/up, and `dz` moves along the viewing axis. MATLAB normalizes the units to the scene.

  For example, setting `dx` to 1 moves the camera to the right, which pushes the scene to the left edge of the box formed by the axes position rectangle. A negative value moves the scene in the other direction. Setting `dz` to 0.5 moves the camera to a position halfway between the camera position and the camera target.

- `pixels` — Interpret `dx` and `dy` as pixel offsets and ignore `dz`.
- `data` — Interpret `dx`, `dy`, and `dz` as offsets in axes data coordinates.

`camdolly(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camdolly` operates on the current axes.

`camdolly` sets the axes `CameraPosition` and `CameraTarget` properties, which in turn sets the `CameraPositionMode` and `CameraTargetMode` properties to `manual`.

Examples

Move the camera along the *x*- and *y*-axes in a series of steps:

```
surf(peaks)
axis vis3d
t = 0:pi/20:2*pi;
dx = sin(t)./40;
dy = cos(t)./40;
for i = 1:length(t);
    camdolly(dx(i),dy(i),0)
    drawnow
end
```

How To

- "Defining Scenes with Cameras"

Purpose

Control camera toolbar programmatically

Syntax

```
cameratoolbar
cameratoolbar('NoReset')
cameratoolbar('SetMode',mode)
cameratoolbar('SetCoordSys',coordsys)
cameratoolbar('Show')
cameratoolbar('Hide')
cameratoolbar('Toggle')
cameratoolbar('ResetCameraAndSceneLight')
cameratoolbar('ResetCamera')
cameratoolbar('ResetSceneLight')
cameratoolbar('ResetTarget')
mode = cameratoolbar('GetMode')
paxis = cameratoolbar('GetCoordsys')
vis = cameratoolbar('GetVisible')
cameratoolbar(fig,...)
h = cameratoolbar
cameratoolbar('Close')
```

Description

`cameratoolbar` creates a toolbar that enables interactive manipulation of the axes camera and light when you drag the mouse on the figure window. Several axes camera properties are set when the toolbar is initialized.

`cameratoolbar('NoReset')` creates the toolbar without setting any camera properties.

`cameratoolbar('SetMode',mode)` sets the toolbar mode (depressed button). `mode` can be `'orbit'`, `'orbitscenelight'`, `'pan'`, `'dollyhv'`, `'dollyfb'`, `'zoom'`, `'roll'`, `'nomode'`. For descriptions of the various modes, see “Camera Toolbar”. You can also set these modes using the toolbar, by clicking the respective buttons.

`cameratoolbar('SetCoordSys',coordsys)` sets the principal axis of the camera motion. `coordsys` can be: `'x'`, `'y'`, `'z'`, `'none'`.

`cameratoolbar('Show')` shows the toolbar on the current figure.

`cameratoolbar('Hide')` hides the toolbar on the current figure.

`cameratoolbar('Toggle')` toggles the visibility of the toolbar.

`cameratoolbar('ResetCameraAndSceneLight')` resets the current camera and scenelight.

`cameratoolbar('ResetCamera')` resets the current camera.

`cameratoolbar('ResetSceneLight')` resets the current scenelight.

`cameratoolbar('ResetTarget')` resets the current camera target.

`mode = cameratoolbar('GetMode')` returns the current mode.

`paxis = cameratoolbar('GetCoordsys')` returns the current principal axis.

`vis = cameratoolbar('GetVisible')` returns the visibility of the toolbar (`1` if visible, `0` if not visible).

`cameratoolbar(fig,...)` specifies the figure to operate on by passing the figure handle as the first argument.

`h = cameratoolbar` returns the handle to the toolbar.

`cameratoolbar('Close')` removes the toolbar from the current figure.

In general, the use of OpenGL hardware improves rendering performance.

Alternatives

Display the toolbar by selecting **Camera Toolbar** from the figure window's **View** menu.

`rotate3d` | `zoom`

How To

- "Camera Toolbar"

Purpose

Create or move light object in camera coordinates

Syntax

```
camlight('headlight')
camlight('right')
camlight('left')
camlight
camlight(az,el)
camlight(...,'style')
camlight(light_handle,...)
light_handle = camlight(...)
```

Description

`camlight('headlight')` creates a light at the camera position.

`camlight('right')` creates a light right and up from camera.

`camlight('left')` creates a light left and up from camera.

`camlight` with no arguments is the same as `camlight('right')`.

`camlight(az,el)` creates a light at the specified azimuth (`az`) and elevation (`el`) with respect to the camera position. The camera target is the center of rotation and `az` and `el` are in degrees.

`camlight(...,'style')` defines the style argument using one of two values:

- `local` (default) — The light is a point source that radiates from the location in all directions.
- `infinite` — The light shines in parallel rays.

`camlight(light_handle,...)` uses the light specified in `light_handle`.

`light_handle = camlight(...)` returns the light object handle.

`camlight` sets the light object `Position` and `Style` properties. A light created with `camlight` does not track the camera. In order for the light to stay in a constant position relative to the camera, call `camlight` whenever you move the camera.

Examples

Create a light positioned to the left of the camera and then reposition the light each time the camera moves:

```
surf(peaks)
axis vis3d
h = camlight('left');
for i = 1:20;
 camorbit(10,0)
 camlight(h,'left')
 drawnow;
end
```

See Also

`lightangle` | `light`

How To

- “Lighting Overview”

Purpose

Position camera to view object or group of objects

Syntax

```
camlookat(object_handles)
camlookat(axes_handle)
camlookat
```

Description

`camlookat(object_handles)` views the objects identified in the vector `object_handles`. The vector can contain the handles of axes children.

`camlookat(axes_handle)` views the objects that are children of the axes identified by `axes_handle`.

`camlookat` views the objects that are in the current axes by moving the camera position and camera target while preserving the relative view direction and camera view angle. The viewed object (or objects) roughly fill the axes position rectangle. To change the view, `camlookat` sets the axes `CameraPosition` and `CameraTarget` properties.

Examples

Create three spheres at different locations and then progressively position the camera so that the scene composes around each sphere individually:

```
% Create three spheres using the sphere function:
[x y z] = sphere;
s1 = surf(x,y,z);
hold on
s2 = surf(x+3,y,z+3);
s3 = surf(x,y,z+6);
% Set the data aspect ratio using daspect:
daspect([1 1 1])
% Set the view:
view(30,10)
% Set the projection type using camproj:
camproj perspective
% Compose the scene around the current axes
camlookat(gca)
pause(2)
% Compose the scene around sphere s1
```

```
camlookat(s1)
pause(2)
% Compose the scene around sphere s2
camlookat(s2)
pause(2)
% Compose the scene around sphere s3
camlookat(s3)
pause(2)
camlookat(gca)
```

campos | camtarget

How To

- "Defining Scenes with Cameras"

Purpose

Rotate camera position around camera target

Syntax

```
camorbit(dtheta,dphi)
camorbit(dtheta,dphi,'coordsys')
camorbit(dtheta,dphi,'coordsys','direction')
camorbit(axes_handle,...)
```

Description

`camorbit(dtheta,dphi)` rotates the camera position around the camera target by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`camorbit(dtheta,dphi,'`*`coordsys`*`')` rotates the camera position around the camera target, using the *`coordsys`* argument to determine the center of rotation. *`coordsys`* can take on two values:

- `data` (default) — Rotate the camera around an axis defined by the camera target and the `direction` (default is the positive *z* direction).
- `camera` — Rotate the camera about the point defined by the camera target.

`camorbit(dtheta,dphi,'`*`coordsys`*`','direction')` defines the axis of rotation for the data coordinate system using the `direction` argument in conjunction with the camera target. Specify `direction` as a three-element vector containing the *x*-, *y*-, and *z*-components of the direction or one of the characters, `x`, `y`, or `z`, to indicate `[1 0 0]`, `[0 1 0]`, or `[0 0 1]` respectively.

`camorbit(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camorbit` operates on the current axes.

The behavior of `camorbit` differs from the `rotate3d` function in that while the `rotate3d` tool modifies the `View` property of the axes, the `camorbit` function fixes the aspect ratio and modifies the `CameraTarget`, `CameraPosition` and `CameraUpVector` properties of the axes. See `Axes Properties` for more information.

Examples

Rotate the camera horizontally about a line defined by the camera target point and a direction that is parallel to the *y*-axis. Visualize this rotation as a cone formed with the camera target at the apex and the camera position forming the base:

```
surf(peaks)
axis vis3d
for i=1:36
   camorbit(10,0,'data',[0 1 0])
   drawnow
end
```

Rotate in the `camera` coordinate system to orbit the camera around the axes along a circle while keeping the center of a circle at the camera target:

```
surf(peaks)
axis vis3d
for i=1:36
   camorbit(10,0,'camera')
   drawnow
end
```

Alternatives

Enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

See Also

`axes` | `axis` | `camdolly` | `campan` | `camzoom` | `camroll`

How To

- “Defining Scenes with Cameras”

Purpose

Rotate camera target around camera position

Syntax

```
campan(dtheta,dphi)
campan(dtheta,dphi,coordsys)
campan(dtheta,dphi,coordsys,direction)
campan(axes_handle,...)
```

Description

`campan(dtheta,dphi)` rotates the camera target of the current axes around the camera position by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`campan(dtheta,dphi,coordsys)` determine the center of rotation using the `coordsys` argument. It can take on two values:

- `'data'` (default) — Rotate the camera target around an axis defined by the camera position and the `direction` (default is the positive *z* direction)
- `'camera'` — Rotate the camera about the point defined by the camera target.

`campan(dtheta,dphi,coordsys,direction)` defines the axis of rotation for the data coordinate system using the `direction` argument with the camera position. Specify `direction` as a three-element vector containing the *x*-, *y*-, and *z*-components of the direction or one of the characters, `'x'`, `'y'`, or `'z'`, to indicate `[1 0 0]`, `[0 1 0]`, or `[0 0 1]` respectively.

`campan(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campan` operates on the current axes.

Examples

Move the camera target to pan the object in a circular motion.

```
sphere;
axis vis3d
hPan = sin(-pi:1:pi);
vPan = cos(-pi:1:pi);
```

```
for k=1:length(hPan)
   campan(hPan(k),vPan(k))
   drawnow
   pause(.1)
end
```

How To

- "Defining Scenes with Cameras"

Purpose

Set or query camera position

Syntax

```
campos
campos([camera_position])
campos('mode')
campos('auto')
campos('manual')
campos(axes_handle,...)
```

Description

`campos` returns the camera position in the current axes.

`campos([camera_position])` sets the position of the camera in the current axes to the specified value. Specify the position as a three-element vector containing the *x*-, *y*-, and *z*-coordinates of the desired location in the data units of the axes.

`campos('mode')` returns the value of the camera position mode, which can be either `auto` (the default) or `manual`.

`campos('auto')` sets the camera position mode to `auto`.

`campos('manual')` sets the camera position mode to `manual`.

`campos(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campos` operates on the current axes.

`campos` sets or queries values of the axes `CameraPosition` and `CameraPositionMode` properties. The camera position is the point in the Cartesian coordinate system of the axes from which you view the scene.

Examples

Move the camera along the *x*-axis in a series of steps:

```
surf(peaks)
axis vis3d off
for x = -200:5:200
    campos([x,5,10])
    drawnow
end
```

See Also

`axis` | `camproj` | `camtarget` | `camup` | `camva` | Axes: `CameraPosition` | Axes: `CameraTarget` | Axes: `CameraUpVector` | Axes: `CameraViewAngle` | Axes: `Projection`

How To

- "Defining Scenes with Cameras"

Purpose

Set or query projection type

Syntax

```
camproj
camproj('projection_type')
camproj(axes_handle,...)
```

Description

`camproj` returns the projection type setting in the current axes. The projection type determines whether MATLAB 3-D views use a perspective or orthographic projection.

`camproj('projection_type')` sets the projection type in the current axes to the specified value. Possible values for *`projection_type`* are `orthographic` and `perspective`.

`camproj(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camproj` operates on the current axes.

`camproj` sets or queries values of the axes object `Projection` property.

Examples

Compare the different `camproj` settings using `subplot`:

```
subplot(1,2,1); surf(membrane); camproj('perspective')
subplot(1,2,2); surf(membrane); camproj('orthographic')
```

How To

- "Defining Scenes with Cameras"

Purpose

Rotate camera about view axis

Syntax

```
camroll(dtheta)
camroll(axes_handle,dtheta)
```

Description

`camroll(dtheta)` rotates the camera around the camera viewing axis by the amounts specified in `dtheta` (in degrees). The viewing axis is the line passing through the camera position and the camera target.

`camroll(axes_handle,dtheta)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camroll` operates on the current axes.

`camroll` sets the axes `CameraUpVector` property and also sets the `CameraUpVectorMode` property to `manual`.

Examples

Rotate the camera around the viewing axis:

```
surf(peaks)
axis vis3d
for i=1:36
 camroll(10)
 drawnow
end
```

How To

- “Defining Scenes with Cameras”

camtarget

Purpose

Set or query location of camera target

Syntax

```
camtarget
camtarget([camera_target])
camtarget('mode')
camtarget('auto')
camtarget('manual')
camtarget(axes_handle,...)
```

Description

`camtarget` returns the location of the camera target in the current axes. The camera target is the location in the axes that the camera points to. The camera remains oriented toward this point regardless of its position.

`camtarget([camera_target])` sets the camera target in the current axes to the specified value. Specify the target as a three-element vector containing the *x*-, *y*-, and *z*-coordinates of the desired location in the data units of the axes.

`camtarget('mode')` returns the value of the camera target mode, which can be either `auto` (default) or `manual`.

`camtarget('auto')` sets the camera target mode to `auto`. When the camera target mode is `auto`, the camera target is the center of the axes plot box.

`camtarget('manual')` sets the camera target mode to `manual`.

`camtarget(axes_handle,...)` performs the set or query on the axes identified by `axes_handle`. When you do not specify an axes handle, `camtarget` operates on the current axes.

`camtarget` sets or queries values of the axes object `CameraTarget` and `CameraTargetMode` properties.

Examples

Move the camera position and the camera target along the *x*-axis in a series of steps:

```
surf(peaks);
axis vis3d
```

```
xp = linspace(-150,40,50);
xt = linspace(25,50,50);
for i=1:50
     campos([xp(i),25,5]);
     camtarget([xt(i),30,0])
     drawnow
end
```

axis | campos | camup | camva | Axes: CameraPosition | Axes: CameraTarget | Axes: CameraUpVector | Axes: CameraViewAngle | Axes: Projection

How To

- "Defining Scenes with Cameras"

camup

Purpose

Set or query camera up vector

Syntax

```
camup
camup([up_vector])
camup('mode')
camup('auto')
camup('manual')
camup(axes_handle,...)
```

Description

`camup` returns the camera up vector setting in the current axes. The camera up vector specifies the direction that is oriented up in the scene.

`camup([up_vector])` sets the up vector in the current axes to the specified value. Specify the up vector as *x*, *y*, and *z* components.

`camup('mode')` returns the current value of the camera up vector mode, which can be either `auto` (default) or `manual`.

`camup('auto')` sets the camera up vector mode to `auto`. In `auto` mode, `[0 1 0]` is the up vector of for 2-D views. This means the *y*-axis points up. For 3-D views, the up vector is `[0 0 1]`, meaning the *z*-axis points up.

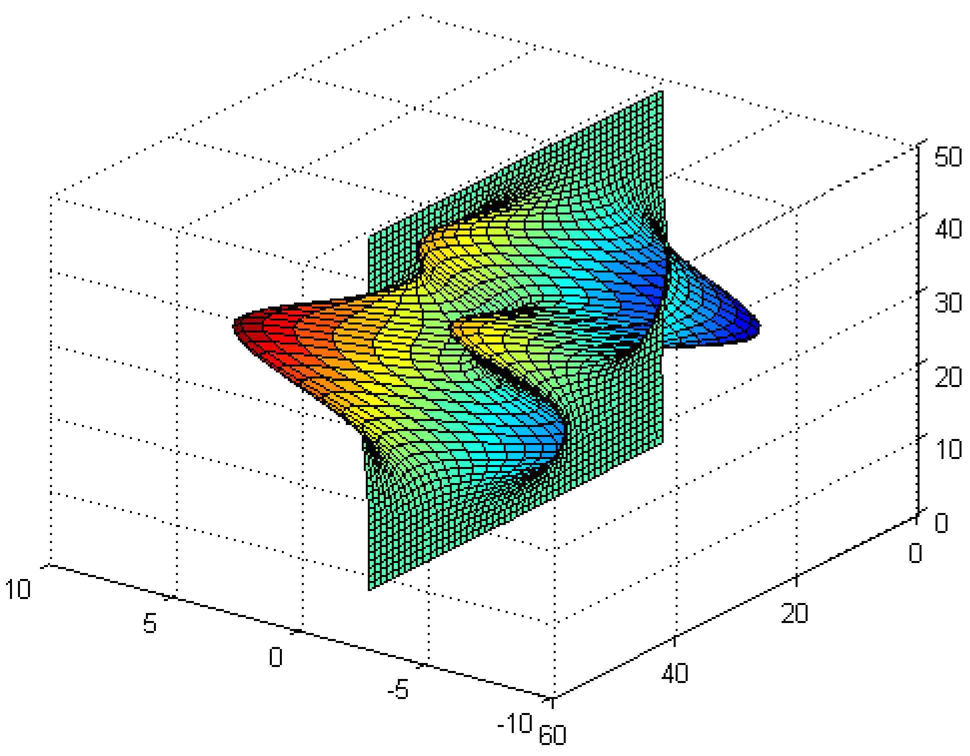
`camup('manual')` sets the camera up vector mode to `manual`. In `manual` mode, the value of the camera up vector does not change unless you set it.

`camup(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camup` operates on the current axes.

Examples

Set the *x*-axis to be the up axis:

```
surf(peaks)
camup([1 0 0]);
```



See Also

axis | campos | camup | camtarget | Axes: CameraPosition | Axes: CameraTarget | Axes: CameraUpVector | Axes: CameraViewAngle | Axes: Projection

How To

- “Defining Scenes with Cameras”

Purpose

Set or query camera view angle

Syntax

```
camva
camva(view_angle)
camva('mode')
camva('auto')
camva('manual')
camva(axes_handle,...)
```

Description

`camva` returns the camera view angle setting in the current axes. The camera view angle determines the field of view of the camera. Larger angles produce a smaller view of the scene. Implement zooming by changing the camera view angle.

`camva(view_angle)` sets the view angle in the current axes to the specified value. Specify the view angle in degrees.

`camva('mode')` returns the current value of the camera view angle mode, which can be either `auto` (the default) or `manual`.

`camva('auto')` sets the camera view angle mode to `auto`.

`camva('manual')` sets the camera view angle mode to `manual`.

`camva(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camva` operates on the current axes.

Tips

The `camva` function sets or queries values of the axes object `CameraViewAngle` and `CameraViewAngleMode` properties.

When the camera view angle mode is `auto`, the camera view angle adjusts so that the scene fills the available space in the window. If you move the camera to a different position, the camera view angle changes to maintain a view of the scene that fills the available area in the window.

Setting a camera view angle or setting the camera view angle to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes

to fit the window). This means setting the camera view angle to its current value,

```
camva(camva)
```

can cause a change in the way the graph looks. See `axes` for more information.

Examples

Create two pushbuttons, one that zooms in and another that zooms out:

```
% Set the range checking in the callback statements to keep
% the values for the camera view angle in the range greater
% than zero and less than 180.
uicontrol('Style','pushbutton',...
  'String','Zoom In',...
  'Position',[20 20 60 20],...
  'Callback','if camva <= 1;return;else;camva(camva-1);end');
uicontrol('Style','pushbutton',...
  'String','Zoom Out',...
  'Position',[100 20 60 20],...
  'Callback','if camva >= 179;return;else;camva(camva+1);end');
% Now create a graph to zoom in and out on:
surf(peaks);
```

How To

- "Defining Scenes with Cameras"

Purpose

Zoom in and out on scene

Syntax

```
camzoom(zoom_factor)
camzoom(axes_handle,...)
```

Description

`camzoom(zoom_factor)` zooms in or out on the scene depending on the value specified by `zoom_factor`. If `zoom_factor` is greater than 1, the scene appears larger; if `zoom_factor` is greater than zero and less than 1, the scene appears smaller.

`camzoom(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camzoom` operates on the current axes.

Tips

`camzoom` sets the axes `CameraViewAngle` property, which in turn causes the `CameraViewAngleMode` property to be set to `manual`. Note that setting the `CameraViewAngle` property disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This may result in a change to the aspect ratio of your graph. See the `axes` function for more information on this behavior.

How To

- "Defining Scenes with Cameras"

Purpose

(Will be removed) Convert point coordinates from cartesian to barycentric

Note `cartToBary(TriRep)` will be removed in a future release. Use `cartesianToBarycentric(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
B = cartToBary(TR, SI, XC)
```

Description

`B = cartToBary(TR, SI, XC)` returns the barycentric coordinates of each point in `XC` with respect to its associated simplex `SI`.

Input Arguments

`TR`	Triangulation representation.
`SI`	Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`.
`XC`	Matrix that represents the Cartesian coordinates of the points to be converted. `XC` is of size `m`-by-`n`, where `m` is of `length(SI)`, the number of points to convert, and `n` is the dimension of the space where the triangulation resides.

Output Arguments

`B`	Matrix of dimension `m`-by-`k` where `k` is the number of vertices per simplex.

Definitions

A simplex is a triangle/tetrahedron or higher dimensional equivalent.

Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';
```

```
y = [0 0 0 0 8 8 8 8]';
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);
tri = dt(:,:);
```

Plot the original triangulation and reference points.

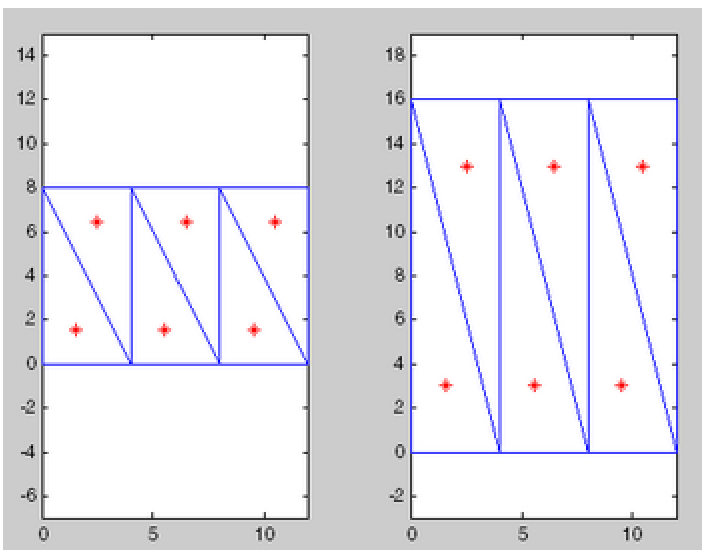
```
figure
subplot(1,2,1);
triplot(dt); hold on;
plot(cc(:,1), cc(:,2), '*r');
hold off;
axis equal;
```

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);
y = [0 0 0 0 16 16 16 16]';
tr = TriRep(tri,x,y)
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(tr);
hold on;
plot(xc(:,1), xc(:,2), '*r');
hold off;
axis equal;
```



See Also

barycentricToCartesian | pointLocation | delaunayTriangulation | triangulation

cart2pol

Purpose

Transform Cartesian coordinates to polar or cylindrical

Syntax

```
[THETA,RHO,Z] = cart2pol(X,Y,Z)
[THETA,RHO] = cart2pol(X,Y)
```

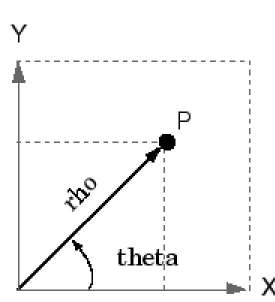
Description

`[THETA,RHO,Z] = cart2pol(X,Y,Z)` transforms three-dimensional Cartesian coordinates stored in corresponding elements of arrays `X`, `Y`, and `Z`, into cylindrical coordinates. `THETA` is a counterclockwise angular displacement in radians from the positive *x*-axis, `RHO` is the distance from the origin to a point in the *x*-*y* plane, and `Z` is the height above the *x*-*y* plane. Arrays `X`, `Y`, and `Z` must be the same size (or any can be scalar).

`[THETA,RHO] = cart2pol(X,Y)` transforms two-dimensional Cartesian coordinates stored in corresponding elements of arrays `X` and `Y` into polar coordinates.

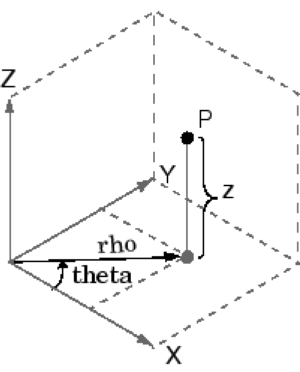
Algorithms

The mapping from two-dimensional Cartesian coordinates to polar coordinates, and from three-dimensional Cartesian coordinates to cylindrical coordinates is



Two-Dimensional Mapping

```
theta = atan2(y,x)
rho = sqrt(x.^2 + y.^2)
```



Three-Dimensional Mapping

```
theta = atan2(y,x)
rho = sqrt(x.^2 + y.^2)
z = z
```

See Also

`cart2sph` | `pol2cart` | `sph2cart`

cart2sph

Purpose

Transform Cartesian coordinates to spherical

Syntax

```
[azimuth,elevation,r] = cart2sph(X,Y,Z)
```

Description

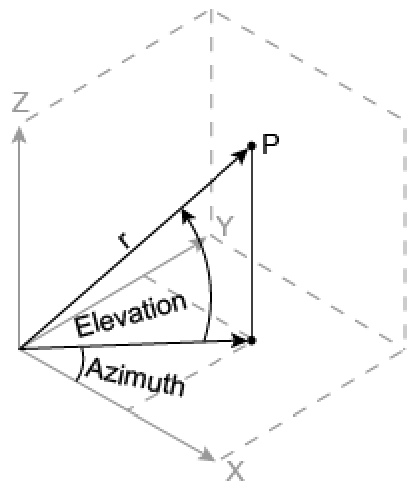
`[azimuth,elevation,r] = cart2sph(X,Y,Z)` transforms Cartesian coordinates stored in corresponding elements of arrays `X`, `Y`, and `Z` into spherical coordinates. `azimuth` and `elevation` are angular displacements in radians measured from the positive *x*-axis, and the *x*-*y* plane, respectively; and `r` is the distance from the origin to a point.

Arrays `X`, `Y`, and `Z` must be the same size (or any of them can be scalar).

Algorithms

The mapping from three-dimensional Cartesian coordinates to spherical coordinates is

```
azimuth = atan2(y,x)
elevation = atan2(z,sqrt(x.^2 + y.^2))
r = sqrt(x.^2 + y.^2 + z.^2)
```



The notation for spherical coordinates is not standard. For the `cart2sph` function, `elevation` is measured from the *x*-*y* plane. Notice that if

`elevation = 0`, the point is in the *x*-*y* plane. If `elevation = pi/2`, then the point is on the positive *z*-axis.

See Also

`cart2pol` | `pol2cart` | `sph2cart`

case

Purpose

Optional keyword in switch statement

Syntax

```
switch switch_expression
   case case_expression
      statements
   case case_expression
      statements
    :
   otherwise
      statements
end
```

Description

A `switch` block conditionally executes one set of statements from several choices. Each choice is a `case`.

An evaluated *`switch_expression`* is a scalar or string. An evaluated *`case_expression`* is a scalar, a string, or a cell array of scalars or strings. The `switch` block tests each case until one of the cases is `true`. A case is `true` when:

- For numbers, `eq(`*`case_expression`*`,`*`switch_expression`*`)`.
- For strings, `strcmp(`*`case_expression`*`,`*`switch_expression`*`)`.
- For objects that support the `eq` function, `eq(`*`case_expression`*`,`*`switch_expression`*`)`.
- For a cell array *`case_expression`*, at least one of the elements of the cell array matches *`switch_expression`*, as defined above for numbers, strings, and objects.

When a case is true, MATLAB executes the corresponding statements, and then exits the `switch` block.

`otherwise` is optional, and executes only when no case is true.

For more information, see the `switch` reference page.

Examples

Decide which plot to create based on the value of the string `plottype`:

```
x = [12, 64, 24];
plottype = 'pie3';

switch plottype
    case 'bar'
        bar(x)
        title('Bar Graph')
    case {'pie','pie3'}
        pie3(x)
        title('Pie Chart')
        legend('First','Second','Third')
    otherwise
        warning('Unexpected plot type. No plot created.');
end
```

See Also

`switch` | `end` | `if` | `for` | `while`

Purpose

Cast variable to different data type

Syntax

```
B = cast(A,newclass)
B = cast(A,'like',p)
```

Description

`B = cast(A,newclass)` converts `A` to class `newclass`, where `newclass` is the name of a built-in data type compatible with `A`. The `cast` function truncates any values in `A` that are too large to map into `newclass`.

`B = cast(A,'like',p)` converts `A` to the same data type and sparsity as the variable `p`. If `A` and `p` are both real, then `B` is also real. Otherwise, `B` is complex.

Examples

Convert Numeric Data Type

Convert an `int8` value to `uint8`.

Define a scalar 8-bit integer.

```
a = int8(5);
```

Convert `a` to an unsigned 8-bit integer.

```
b = cast(a,'uint8');
class(b)
```

```
ans =
uint8
```

Match Data Type and Complex Nature of `p`

Define a single precision vector `p` that is complex valued.

```
p = single([1+i 2]);
```

Define a 2-by-3 matrix of ones.

```
A = ones(2,3);
```

Convert `A` to the same data type and complexity (real or complex) as `p`.

```
B = cast(A,'like',p)
```

```
B =

   1.0000 + 0.0000i   1.0000 + 0.0000i   1.0000 + 0.0000i
   1.0000 + 0.0000i   1.0000 + 0.0000i   1.0000 + 0.0000i
```

```
class(B)
```

```
ans =

single
```

See Also

`class` | `typecast`

Purpose

Concatenate arrays along specified dimension

Syntax

```
C = cat(dim, A, B)
C = cat(dim, A1, A2, A3, A4, ...)
```

Description

`C = cat(dim, A, B)`concatenates the arrays `A` and `B` along array dimension `dim`.

`C = cat(dim, A1, A2, A3, A4, ...)` concatenates all the input arrays (`A1`, `A2`, `A3`, `A4`, and so on) along array dimension `dim`.

For nonempty arrays, `cat(2, A, B)` is the same as `[A, B]`, and `cat(1, A, B)` is the same as `[A; B]`.

Tips

When used with comma-separated list syntax, `cat(dim, C{:})` or `cat(dim, C.field)` is a convenient way to concatenate a cell or structure array containing numeric matrices into a single matrix.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see "Valid Combinations of Unlike Classes"

Examples

Given

```
A =                     B =
      1     2                          5     6
      3     4                          7     8
```

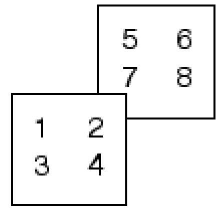
concatenating along different dimensions produces

1 2
3 4
5 6
7 8

`C = cat(1,A,B)`

1 2 5 6
3 4 7 8

`C = cat(2,A,B)`



`C = cat(3,A,B)`

The commands

```
A = magic(3); B = pascal(3);
C = cat(4, A, B);
```

produce a 3-by-3-by-1-by-2 array.

`vertcat` | `horzcat` | `strcat` | `char` | `num2cell` | `reshape` | `squeeze` | `strjoin` | `shiftdim` | `special character`

catch

Purpose

Handle error detected in try statement

Syntax

```
try
   statements
catch exception
   statements
end
```

Description

`try` and `catch` blocks allow you to override the default error behavior for a set of program statements. If any statement in a `try` block generates an error, program control goes immediately to the `catch` block, which contains your error handling statements.

`exception` is an optional `MException` object input to the `catch` block that allows you to identify the error.

Both `try` and `catch` blocks can contain nested `try/catch` statements.

Examples

Provide more information about a dimension mismatch error:

```
A = rand(3);
B = ones(5);

try
   C = [A; B];
catch err

   % Give more information for mismatch.
   if (strcmp(err.identifier,'MATLAB:catenate:dimensionMismatch'))

      msg = sprintf('%s', ...
            'Dimension mismatch occured: First argument has ', ...
             num2str(size(A,2)), ' columns while second has ', ...
             num2str(size(B,2)), ' columns.');
      error('MATLAB:myCode:dimensions', msg);

   % Display any other errors as usual.
   else
```

```
      rethrow(err);
   end

end  % end try/catch
```

See Also

error | assert | try | MException

caxis

Purpose

Color axis scaling

Syntax

```
caxis([cmin cmax])
caxis auto
caxis manual
caxis(caxis) freeze
v = caxis
caxis(axes_handle,...)
```

Description

`caxis` controls the mapping of data values to the colormap. It affects any surfaces, patches, and images with indexed `CData` and `CDataMapping` set to scaled. It does not affect surfaces, patches, or images with true color `CData` or with `CDataMapping` set to `direct`.

`caxis([cmin cmax])` sets the color limits to specified minimum and maximum values. Data values less than `cmin` or greater than `cmax` map to `cmin` and `cmax`, respectively. Values between `cmin` and `cmax` linearly map to the current colormap.

`caxis auto` computes the color limits automatically using the minimum and maximum data values. This is the default behavior. Color values set to `Inf` map to the maximum color, and values set to `-Inf` map to the minimum color. Faces or edges with color values set to `NaN` are not drawn.

`caxis manual` and `caxis(caxis) freeze` the color axis scaling at the current limits. This enables subsequent plots to use the same limits when `hold` is `on`.

`v = caxis` returns a two-element row vector containing the `[cmin cmax]` currently in use.

`caxis(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

`caxis` changes the `CLim` and `CLimMode` properties of axes graphics objects.

Tips

How Color Axis Scaling Works

Surface, patch, and image graphics objects having indexed `CData` and `CDataMapping` set to `scaled` map `CData` values to colors in the figure colormap each time they render. `CData` values equal to or less than `cmin` map to the first color value in the colormap, and `CData` values equal to or greater than `cmax` map to the last color value in the colormap. The following linear transformation is performed on the intermediate values (referred to as `C` below) to map them to an entry in the colormap (whose length is `m`, and whose row index is referred to as `index` below).

```
index = fix((C-cmin)/(cmax-cmin)*m)+1;
%Clamp values outside the range [1 m]
index(index<1) = 1;
index(index>m) = m;
```

Examples

Create `(X,Y,Z)` data for a sphere and view the data as a surface.

```
[X,Y,Z] = sphere;
C = Z;
surf(X,Y,Z,C)
```

Values of `C` have the range [-1 1]. Values of `C` near -1 are assigned the lowest values in the colormap; values of `C` near 1 are assigned the highest values in the colormap.

To map the top half of the surface to the highest value in the color table, use

```
caxis([-1 0])
```

To use only the bottom half of the color table, enter

```
caxis([-1 3])
```

which maps the lowest `CData` values to the bottom of the colormap, and the highest values to the middle of the colormap (by specifying a `cmax` whose value is equal to `cmin` plus twice the range of the `CData`).

The command

```
caxis auto
```

resets axis scaling back to autoranging and you see all the colors in the surface. In this case, entering

```
caxis
```

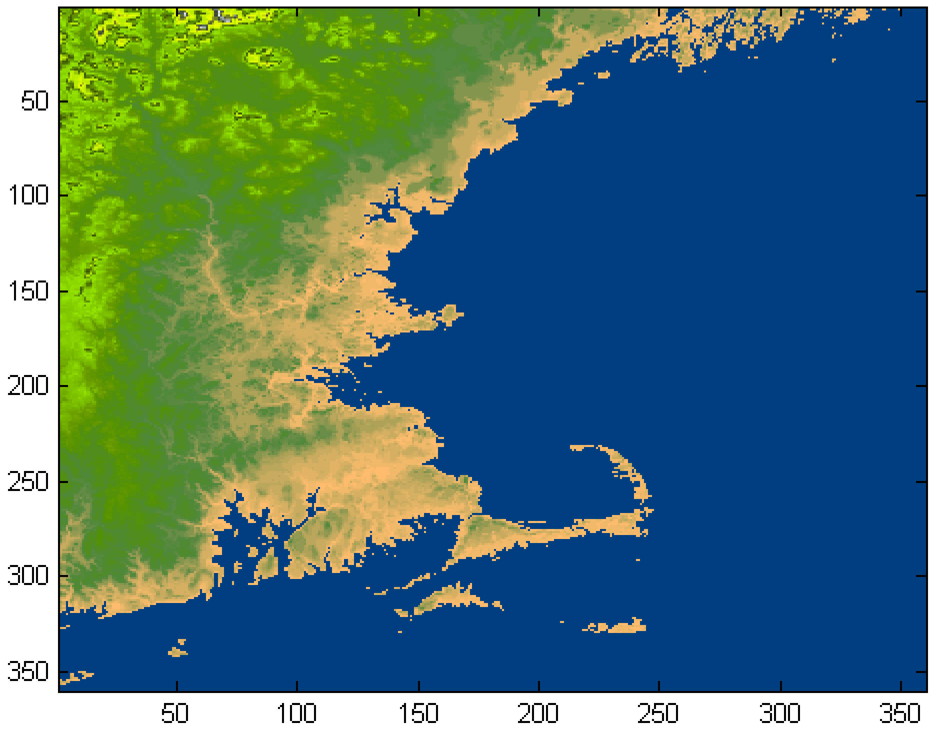
returns

```
[-1 1]
```

Using caxis with Image Data

Adjusting the color axis can be useful when using images with scaled color data. For example, load the image data and colormap for Cape Cod, Massachusetts. This command loads the image's data `X` and the image's colormap `map` into the workspace.

```
load cape
% Display the image with CDataMapping set to scaled and
%  install the image's colormap.
image(X,'CDataMapping','scaled')
colormap(map)
% This adjusts the color limits to span the range
% of the image data, which is 1 to 192:
caxis
ans =
     1   192
```



The blue color of the ocean is the first color in the colormap and is mapped to the lowest data value (1). You can effectively move sea level by changing the lower color limit value. For example, The following code compares four settings:

```
figure
load cape
colormap(map)
subplot(2,2,1)
image(X,'CDataMapping','scaled')
```

```
axis image
title('Caxis = [1 192]')
subplot(2,2,2)
image(X,'CDataMapping','scaled')
axis image
title('Caxis = [3 192]')

Purpose

Change current folder

Syntax

```
cd(newFolder)
oldFolder = cd(newFolder)
cd
```

Description

`cd(newFolder)` changes the current folder to `newFolder`.

`oldFolder = cd(newFolder)` returns the existing current folder as a string to `oldFolder`, and then changes the current folder to `newFolder`.

`cd` displays the current folder.

Tips

- When using the command syntax (`cd newfolder`), if the `newFolder` string contains spaces, enclose the string in single quotation marks.
- On UNIX platforms, use the ~ (tilde) character to represent the user home directory.
- If you use `cd` within a local function, the folder change persists after program control returns from the function. That is, the scope of the folder change is global.

Input Arguments

newFolder

A string specifying the folder to which you want to change the current folder. Valid values can be any one of the following:

- A full or relative path.
- `../`, which indicates one level up from the current folder.
- Multiple strings of `../`, which indicates multiple levels up from the current folder.
- `./`, which indicates a path relative to the current folder, although without the `./`, `cd` assumes that the path is relative to the current folder.

Output Arguments

oldFolder

A string specifying the current folder that was in place when you issued the `cd` command.

Definitions

The current folder is a reference location that MATLAB uses to find files. See "The Current Folder".

Examples

Use `cd` with the `matlabroot` function to change the current folder to the examples directory for the currently running version of MATLAB:

```
cd(fullfile(matlabroot, '/help/techdoc/matlab_env/examples'))
```

On a Microsoft Windows platform, specify the full path to change the current folder from any location to the examples directory for MATLAB Version 7.11 (R2010b), assuming that version is installed on your `C:` drive:

```
cd('C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples')

% Change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples to
% C:/Program Files/MATLAB/R2010b/help/techdoc:

cd ../..

% Use a relative path to change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc back to
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples:

cd matlab_env/examples

% Change the current folder from its current location to a new locatio
% but save its previous location. Later, change the current folder to
% previous location.
```

```
% This returns C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/exa
% to oldFolder, and then changes the current folder to C:/Program Files:

oldFolder = cd('C:/Program Files')

% Display current folder:

pwd

% Change the current folder to the previous location:
cd(oldFolder)

pwd
```

On a UNIX platform, change the current folder to the examples directory for the currently running version of MATLAB, assuming it is installed in your home location:

```
cd('~/help/techdoc/matlab_env/examples')
```

How To

- "Path Names in MATLAB"
- "Files and Folders that MATLAB Accesses"

Purpose

(Will be removed) Convex hull

Note `convexHull(DelaunayTri)` will be removed in a future release. Use `convexHull(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Syntax

```
K = convexHull(DT)
[K AV] = convexHull(DT)
```

Description

`K = convexHull(DT)` returns the indices into the array of points `DT.X` that correspond to the vertices of the convex hull.

`[K AV] = convexHull(DT)` returns the convex hull and the area or volume bounded by the convex hull.

Input Arguments

`DT`	Delaunay triangulation.

Output Arguments

`K`	If the points lie in 2-D space, `K` is a column vector of length `numf`. Otherwise `K` is a matrix of size `numf`-by-`ndim`, `numf` being the number of facets in the convex hull, and `ndim` the dimension of the space where the points reside.
`AV`	The area or volume of the convex hull.

Definitions

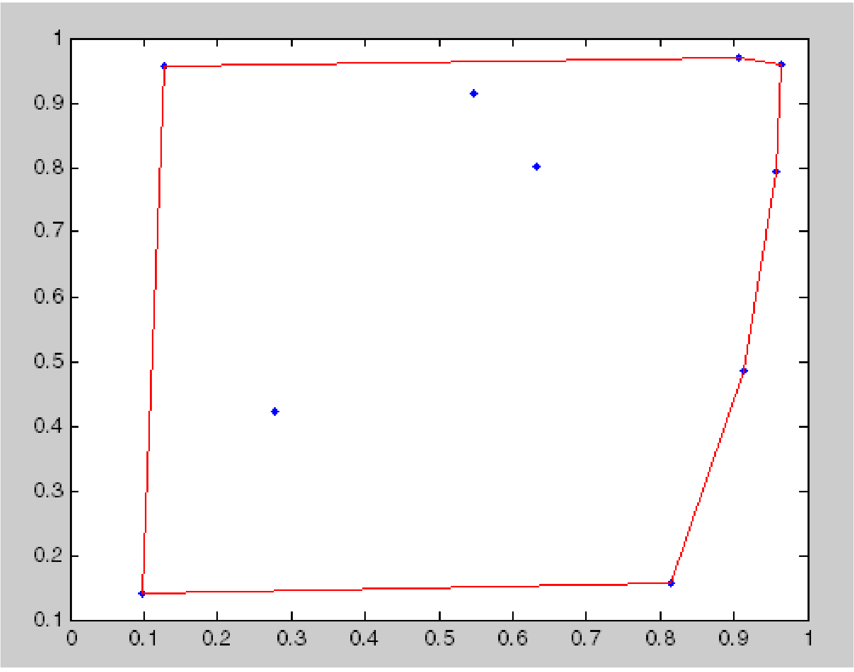
The convex hull of a set of points `X` is the smallest convex region containing all of the points of `X`.

Examples

Example 1

Compute the convex hull of a set of random points located within a unit square in 2-D space.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
k = convexHull(dt)
plot(dt.X(:,1),dt.X(:,2), '.', 'markersize',10); hold on;
plot(dt.X(k,1),dt.X(k,2), 'r'); hold off;
```



Example 2

Compute the convex hull of a set of random points located within a unit cube in 3-D space, and the volume bounded by the convex hull.

```
X = rand(25,3)
dt = DelaunayTri(X)
[ch v] = convexHull(dt)
trisurf(ch, dt.X(:,1),dt.X(:,2),dt.X(:,3), 'FaceColor', 'cyan')
```

Purpose

Change or view current folder on FTP server

Syntax

```
cd(ftpobj,folder)
cd(ftpobj)
```

Description

`cd(ftpobj,folder)` changes the current folder on the FTP server.

`cd(ftpobj)` displays the current folder on the server.

Input Arguments

ftpobj

FTP object created by `ftp`.

folder

String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use `'..'`.

Examples

Connect to the MathWorks FTP server, change to the `pub` folder, and view its contents:

```
mw=ftp('ftp.mathworks.com');
cd(mw,'pub');
dir(mw)
```

See Also

`dir` | `ftp`

Purpose

Convert complex diagonal form to real block diagonal form

Syntax

```
[V,D] = cdf2rdf(V,D)
[V,D] = cdf2rdf(V,D)
```

Description

If the eigensystem `[V,D] = eig(X)` has complex eigenvalues appearing in complex-conjugate pairs, `cdf2rdf` transforms the system so `D` is in real diagonal form, with 2-by-2 real blocks along the diagonal replacing the complex pairs originally there. The eigenvectors are transformed so that

```
X = V*D/V
```

continues to hold. The individual columns of `V` are no longer eigenvectors, but each pair of vectors associated with a 2-by-2 block in `D` spans the corresponding invariant vectors.

Examples

The matrix

```
X =
    1      2      3
    0      4      5
    0     -5      4
```

has a pair of complex eigenvalues.

```
[V,D] = eig(X)

V =

    1.0000      -0.0191 - 0.4002i     -0.0191 + 0.4002i
         0            0 - 0.6479i           0 + 0.6479i
         0       0.6479                0.6479

D =

    1.0000            0                     0
```

```
         0        4.0000 + 5.0000i          0
         0             0                4.0000 - 5.0000i
```

Converting this to real block diagonal form produces

```
[V,D] = cdf2rdf(V,D)

V =

    1.0000   -0.0191   -0.4002
         0         0   -0.6479
         0    0.6479         0

D =

    1.0000         0         0
         0    4.0000    5.0000
         0   -5.0000    4.0000
```

Algorithms

The real diagonal form for the eigenvalues is obtained from the complex form using a specially constructed similarity transformation.

`eig` | `rsf2csf`

Purpose

Convert MATLAB formatted dates to CDF formatted dates

Syntax

```
E = cdfepoch(date)
```

Description

`E = cdfepoch(date)` converts the date, specified by `date`, into a `cdfepoch` object. `date` must be a valid date string, returned by `datestr`, or a serial date number, returned by `datenum`. `date` can also be a `cdfepoch` object.

When writing data to a CDF file using `cdfwrite`, use `cdfepoch` to convert MATLAB formatted dates to CDF formatted dates. The MATLAB `cdfepoch` object simulates the `CDFEPOCH` data type in CDF files.

To convert a `cdfepoch` object into a MATLAB serial date number, use the `todatenum` function.

Definitions

The MATLAB serial date number calculates dates differently than CDF epochs.

A MATLAB serial date number represents the whole and fractional number of days from 1-Jan-0000 to a specific date. The year 0000 is merely a reference point and is not intended to be interpreted as a real year in time.

A CDF epoch is the number of milliseconds since 1-Jan-0000.

Examples

Convert the current time in serial date number format into a CDF epoch object.

```
% NOW function returns current time as serial date number
dateobj = cdfepoch(now)

dateobj =

     cdfepoch object:
     11-Mar-2009 15:09:25
```

Convert the current time in date string format into a CDF epoch object.

```
% DATESTR function returns date as string
dateobj2 = cdfepoch(datestr(now))

dateobj2 =

     cdfepoch object:
     11-Mar-2009 15:09:25
```

Convert the CDF epoch object into a serial date number.

```
dateobj = cdfepoch(now);
mydatenum = todatenum(dateobj)

mydatenum =

     7.3384e+005
```

See Also

`datenum` | `datestr` | `todatenum` | `cdfinfo` | `cdfread`

Purpose

Information about Common Data Format (CDF) file

Syntax

```
info = cdfinfo(filename)
```

Description

`info = cdfinfo(filename)` returns information about the Common Data Format (CDF) file specified in the string `filename`.

Note Because `cdfinfo` creates temporary files, the current working directory must be writeable.

The following table lists the fields returned in the structure, `info`. The table lists the fields in the order that they appear in the structure.

Field	Description
`Filename`	Text string specifying the name of the file
`FileModDate`	Text string indicating the date the file was last modified
`FileSize`	Double scalar specifying the size of the file, in bytes
`Format`	Text string specifying the file format
`FormatVersion`	Text string specifying the version of the CDF library used to create the file
`FileSettings`	Structure array containing library settings used to create the file
`Subfiles`	Filenames containing the CDF file's data, if it is a multi-file format CDF

<table>
<tr><th>Field</th><th colspan="2">Description</th></tr>
<tr><td rowspan="6"><code>Variables</code></td><td colspan="2">N-by-6 cell array, where N is the number of variables, containing information about the variables in the file. The columns present the following information:</td></tr>
<tr><td>Column 1</td><td>Text string specifying name of variable</td></tr>
<tr><td>Column 2</td><td>Double array specifying the dimensions of the variable, as returned by the <code>size</code> function</td></tr>
<tr><td>Column 3</td><td>Double scalar specifying the number of records assigned for the variable</td></tr>
<tr><td>Column 4</td><td>Text string specifying the data type of the variable, as stored in the CDF file</td></tr>
<tr><td>Column 5</td><td>Text string specifying the record and dimension variance settings for the variable. The single <code>T</code> or <code>F</code> to the left of the slash designates whether values vary by record. The zero or more <code>T</code> or <code>F</code> letters to the right of the slash designate whether values vary at each dimension. Here are some examples.

<code>T/ (scalar variable</code>
<code>F/T (one-dimensional variable)</code>

T/TFF (three-dimensional variable)</td></tr>
</table>

Field	Description
`GlobalAttributes`	Structure array that contains one field for each global attribute. The name of each field corresponds to the name of an attribute. The data in each field, contained in a cell array, represents the entry values for that attribute.
`VariableAttributes`	Structure array that contains one field for each variable attribute. The name of each field corresponds to the name of an attribute. The data in each field is contained in a *n*-by-2 cell array, where *n* is the number of variables. The first column of this cell array contains the variable names associated with the entries. The second column contains the entry values.

Note Attribute names returned by `cdfinfo` might not match the names of the attributes in the CDF file exactly. Attribute names can contain characters that are illegal in MATLAB field names. `cdfinfo` removes illegal characters that appear at the beginning of attributes and replaces other illegal characters with underscores ('_'). When `cdfinfo` modifies an attribute name, it appends the attribute's internal number to the end of the field name. For example, the attribute name `Variable%Attribute` becomes `Variable_Attribute_013`.

Note To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see `cdflib.setValidate`.

Examples

```
info = cdfinfo('example.cdf')
info =
              Filename: 'example.cdf'
```

```
             FileModDate: '09-Mar-2001 15:45:22'
                FileSize: 1240
                  Format: 'CDF'
           FormatVersion: '2.7.0'
            FileSettings: [1x1 struct]
                Subfiles: {}
               Variables: {5x6 cell}
        GlobalAttributes: [1x1 struct]
      VariableAttributes: [1x1 struct]

info.Variables
ans =
  'Time'         [1x2 double] [24] 'epoch'  'T/'     'Full'
  'Longitude'    [1x2 double] [ 1] 'int8'   'F/FT'   'Full'
  'Latitude'     [1x2 double] [ 1] 'int8'   'F/TF'   'Full'
  'Data'         [1x3 double] [ 1] 'double' 'T/TTT'  'Full'
  'multidim'     [1x4 double] [ 1] 'uint8'  'T/TTTT' 'Full'
```

Purpose

Summary of Common Data Format (CDF) capabilities

Description

The MATLAB product provides both high-level and low-level access to Common Data Format (CDF) files. The high-level access functions make it easy to read data from a CDF file or write data from the workspace to a CDF file. The low-level interface provides you with more control over the import and export operations.

Note For information about MATLAB support for the Network Common Data Form (netCDF), which is a completely separate, incompatible format, see `netcdf`.

High-Level Functions

MATLAB includes functions that provide high-level access to CDF files:

- `cdfinfo`
- `cdfread`

In addition, MATLAB provides functions that convert time data to and from the CDF epoch data type: `cdfepoch` and `todatenum`.

Low-Level Functions

MATLAB provides direct access to dozens of functions in the CDF library. Using these functions, you can read and write data, create variables, attributes, and entries, and take advantage of other features of the CDF library. To use these functions, you must be familiar with the CDF C interface. Documentation about CDF, version 3.3.0, is available at the `CDF Web site`.

The MATLAB functions correspond to functions in the CDF library new Standard Interface. In most cases, the syntax of a MATLAB function is similar to the syntax of the corresponding CDF library function. To use these functions, you must prefix the function name with the package name, `cdflib`. For example, to use the CDF library function to open an existing CDF file, you would use this syntax:

```
cdfid = cdflib.open('example.cdf');
```

The following tables list all of the functions in the MATLAB CDF library package, grouped by category.

Library Information

cdflib	Summary of Common Data Format (CDF) capabilities
cdflib.getConstantNames	Names of Common Data Format (CDF) library constants
cdflib.getConstantValue	Numeric value corresponding to Common Data Format (CDF) library constant
cdflib.getFileBackward	Return current backward compatibility mode setting
cdflib.getLibraryCopyright	Copyright notice of Common Data Format (CDF) library
cdflib.getLibraryVersion	Library version and release information
cdflib.getValidate	Library validation mode
cdflib.setFileBackward	Set backward compatibility mode
cdflib.setValidate	Specify library validation mode

File Operations

cdflib.close	Close Common Data Format (CDF) file
cdflib.create	Create Common Data Format (CDF) file
cdflib.delete	Delete existing Common Data Format (CDF) file
cdflib.getCacheSize	Number of cache buffers used
cdflib.getChecksum	Checksum mode

cdflib.getCompression	Compression settings
cdflib.getCompressionCacheSize	Number of compression cache buffers
cdflib.getCopyright	Copyright notice in Common Data Format (CDF) file
cdflib.getFormat	Format of Common Data Format (CDF) file
cdflib.getMajority	Majority of variables
cdflib.getName	Name of Common Data Format (CDF) file
cdflib.getReadOnlyMode	Read-only mode
cdflib.getStageCacheSize	Number of cache buffers for staging
cdflib.getVersion	Common Data Format (CDF) library version and release information
cdflib.inquire	Basic characteristics of Common Data Format (CDF) file
cdflib.open	Open existing Common Data Format (CDF) file
cdflib.setCacheSize	Specify number of dotCDF cache buffers
cdflib.setChecksum	Specify checksum mode
cdflib.setCompression	Specify compression settings
cdflib.setCompressionCacheSize	Specify number of compression cache buffers
cdflib.setFormat	Specify format of Common Data Format (CDF) file
cdflib.setMajority	Specify majority of variables

cdflib.setReadOnlyMode	Specify read-only mode
cdflib.setStageCacheSize	Specify number of staging cache buffers for Common Data Format (CDF) file

Variables

cdflib.closeVar	Close specified variable from multifile format Common Data Format (CDF) file
cdflib.createVar	Create new variable
cdflib.deleteVar	Delete variable
cdflib.deleteVarRecords	Delete range of records from variable
cdflib.getVarAllocRecords	Number of records allocated for variable
cdflib.getVarBlockingFactor	Blocking factor for variable
cdflib.getVarCacheSize	Number of multifile cache buffers
cdflib.getVarCompression	Information about compression used by variable
cdflib.getVarData	Single value from record in variable
cdflib.getVarMaxAllocRecNum	Maximum allocated record number for variable
cdflib.getVarMaxWrittenRecNum	Maximum written record number for variable
cdflib.getVarName	Variable name, given variable number
cdflib.getVarNum	Variable number, given variable name

cdflib.getVarNumRecsWritten	Number of records written to variable
cdflib.getVarPadValue	Pad value for variable
cdflib.getVarRecordData	Entire record for variable
cdflib.getVarReservePercent	Compression reserve percentage for variable
cdflib.getVarsMaxWrittenRecNum	Maximum written record number for CDF file
cdflib.getVarSparseRecords	Information about how variable handles sparse records
cdflib.hyperGetVarData	Read hyperslab of data from variable
cdflib.hyperPutVarData	Write hyperslab of data to variable
cdflib.inquireVar	Information about variable
cdflib.putVarData	Write single value to variable
cdflib.putVarRecordData	Write entire record to variable
cdflib.renameVar	Rename existing variable
cdflib.setVarAllocBlockRecords	Specify range of records to be allocated for variable
cdflib.setVarBlockingFactor	Specify blocking factor for variable
cdflib.setVarCacheSize	Specify number of multi-file cache buffers for variable
cdflib.setVarCompression	Specify compression settings used with variable
cdflib.setVarInitialRecs	Specify initial number of records written to variable

cdflib.setVarPadValue	Specify pad value used with variable
cdflib.SetVarReservePercent	Specify reserve percentage for variable
cdflib.setVarsCacheSize	Specify number of cache buffers used for all variables
cdflib.setVarSparseRecords	Specify how variable handles sparse records

Attributes

cdflib.createAttr	Create attribute
cdflib.deleteAttr	Delete attribute
cdflib.deleteAttrEntry	Delete attribute entry
cdflib.deleteAttrgEntry	Delete entry in global attribute
cdflib.getAttrEntry	Value of entry in attribute with variable scope
cdflib.getAttrgEntry	Value of entry in global attribute
cdflib.getAttrMaxEntry	Number of last entry for variable attribute
cdflib.getAttrMaxgEntry	Number of last entry for global attribute
cdflib.getAttrName	Name of attribute, given attribute number
cdflib.getAttrNum	Attribute number, given attribute name
cdflib.getAttrScope	Scope of attribute
cdflib.getNumAttrEntries	Number of entries for attribute with variable scope
cdflib.getNumAttrgEntries	Number of entries for attribute with global scope

cdflib.getNumAttributes	Number of attributes with variable scope
cdflib.getNumgAttributes	Number of attributes with global scope
cdflib.inquireAttr	Information about attribute
cdflib.inquireAttrEntry	Information about entry in attribute with variable scope
cdflib.inquireAttrgEntry	Information about entry in attribute with global scope
cdflib.putAttrEntry	Write value to entry in attribute with variable scope
cdflib.putAttrgEntry	Write value to entry in attribute with global scope
cdflib.renameAttr	Rename existing attribute

Utility Functions

cdflib.computeEpoch	Convert time value to `CDF_EPOCH` value
cdflib.computeEpoch16	Convert time value to `CDF_EPOCH16` value
cdflib.epoch16Breakdown	Convert `CDF_EPOCH16` value to time value
cdflib.epochBreakdown	Convert `CDF_EPOCH` value into time value

- "Exporting to Common Data File Format (CDF) Files"

cdflib.close

Purpose

Close Common Data Format (CDF) file

Syntax

`cdflib.close(cdfId)`

Description

`cdflib.close(cdfId)` closes the specified CDF file. `cdfId` identifies the CDF file.

You must close a CDF to guarantee that all modifications you made since opening the CDF are actually written to the file.

Examples

Open the example CDF file and then close it.

```
cdfid = cdflib.open('example.cdf');
cdflib.close(cdfid)
```

References

This function corresponds to the CDF library C API routine `CDFcloseCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.open` | `cdflib.create`

Tutorials

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

Purpose

Close specified variable from multifile format Common Data Format (CDF) file

Syntax

```
cdflib.closeVar(cdfId,varNum)
```

Description

`cdflib.closeVar(cdfId,varNum)` closes a variable in a multifile format CDF.

`cdfId` identifies the CDF file and `varNum` is a numeric value that specifies the variable. Variable identifiers (variable numbers) are zero-based.

For multifile CDFs, you must close all open variable files to guarantee that all modifications you have made are actually written to the CDF file(s). You do not need to call this function for variables in a single-file format CDF.

Examples

Create a multifile CDF, create a variable, and then close the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_multifile.cdf');

% Make it a multifile format CDF
cdflib.setFormat(cdfid,'MULTI_FILE')

% Create a variable in the CDF.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

%  Close the variable.
cdflib.closeVar(cdfid, varnum)

% Clean up
cdflib.delete(cdfid)
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFclosezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Convert time value to CDF_EPOCH value

Syntax

```
epoch = cdflib.computeEpoch(timeval)
```

Description

`epoch = cdflib.computeEpoch(timeval)` converts the time value specified by `timeval` into a `CDF_EPOCH` value.

Input Arguments

timeval

7-by-1 time vector. The following table describes the time components.

Component	Description
year	AD e.g. 1994
month	1 12
day	1 31
hour	0 23
minute	0 59
second	0 59
millisecond	0 999

Output Arguments

epoch

MATLAB `double` representing a `CDF_EPOCH` time value.

Examples

Convert a time value into a `CDF_EPOCH` value.

```
timeval = [1999 12 31 23 59 59 0];
epoch = cdflib.computeEpoch(timeval);
```

References

This function corresponds to the CDF library C API routine `computeEPOCH`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.computeEpoch16` | `cdflib.epochBreakdown` | `cdflib.epoch16Breakdown`

Tutorials

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

Purpose Convert time value to `CDF_EPOCH16` value

Syntax

```
epoch16 = cdflib.computeEpoch16(timeval)
```

Description `epoch16 = cdflib.computeEpoch16(timeval)` converts the time value specified by `timeval` into a `CDF_EPOCH16` value.

Input Arguments

timeval

10-by-1 time vector. The following table describes the time components. To specify multiple time values, use additional columns.

Component	Description
year	AD e.g. 1994
month	1 12
day	1 31
hour	0 23
minute	0 59
second	0 59
millisecond	0 999
microsecond	0 999
nanosecond	0 999
picosecond	0 999

Output Arguments

epoch16

CDF Epoch16 time value. If the input argument `timeval` has `m-by-10` elements, the return value `epoch16` will have size `2-by-m`

Examples Convert the time value into an `CDF_EPOCH16` value:

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];
```

```
epoch16 = cdflib.computeEpoch16(timeval);
```

References

This function corresponds to the CDF library C API routine `computeEPOCH16`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Create Common Data Format (CDF) file

Syntax

`cdfId = cdflib.create(filename)`

Description

`cdfId = cdflib.create(filename)` creates a new CDF file with the name specified by the text string *`filename`*. Returns the CDF file identifier `cdfId`.

Examples

Create a CDF file. To run this example, you must have write permission in your current directory.

```
cdfId = cdflib.create('myfile.cdf');

% Clean up
cdflib.delete(cdfId);

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFcreateCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

- “Exporting to Common Data File Format (CDF) Files”

Purpose

Create attribute

Syntax

```
attrnum = cdflib.createAttr(cdfId,attrName,scope)
```

Description

`attrnum = cdflib.createAttr(cdfId,attrName,scope)` creates an attribute in a CDF file with the specified scope.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrName

Text string that specifies the name you want to assign to the attribute.

scope

One of the following text strings, or its numeric equivalent, that specifies the scope of the attribute.

Text String	Description
`'global_scope'`	Attribute applies to the CDF as a whole.
`'variable_scope'`	Attribute applies only to the variable

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

Output Arguments

attrNum

Numeric value identifying the attribute. Attribute numbers are zero-based.

Examples

Create a CDF, and then create an attribute in the CDF. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create attribute
attrNum = cdflib.createAttr(cdfId,'Purpose','global_scope');

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFcreateAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

cdflib.createVar

Purpose Create new variable

Syntax

```
varnum = cdflib.createVar(cdfId, varname, datatype,
   numElements, dims, recVariance, dimVariance)
```

Description

`varnum = cdflib.createVar(cdfId, varname, datatype, numElements, dims, recVariance, dimVariance)` creates a new variable in the Common Data Format (CDF) file with the specified characteristics.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varname

Text string that specifies the name you want to assign to the variable.

datatype

Data type of the variable. One of the following text strings, or its numeric equivalent, that specifies a valid CDF data type.

CDF Data Type	Description
`CDF_BYTE`	1-byte, signed integer
`CDF_CHAR`	1 byte, signed character data type that maps to the MATLAB `char` class
`CDF_INT1`	1-byte, signed integer
`CDF_UCHAR`	1 byte, unsigned character data type that maps to the MATLAB `uint8` class
`CDF_UINT1`	1-byte, unsigned integer
`CDF_INT2`	2-byte, signed integer
`CDF_UINT2`	2-byte, unsigned integer

CDF Data Type	Description
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

numElements

Number of elements per datum. Value should be 1 for all data types, except `CDF_CHAR` and `CDF_UCHAR`.

dims

A vector of the dimensions extents; empty if there are no dimension extents.

recVariance

Specifies record variance: `true` or `false`.

dimVariance

A vector of logicals; empty if there are no dimensions.

Output Arguments

varNum

The numeric identifier for the variable. Variable numbers are zero-based.

Examples

Create a CDF file and then create a variable named `'Time'` in the CDF. The variable has no dimensions and varies across records. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no variables.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Retrieve info about the file again to verify variable was created.
% Note value of numVars field is now 1.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 1
    numvAttrs: 0
    numgAttrs: 0

% Clean up
cdflib.delete(cdfid);
```

```
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFcreatezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

cdflib.delete

Purpose

Delete existing Common Data Format (CDF) file

Syntax

```
cdflib.delete(cdfId)
```

Description

`cdflib.delete(cdfId)` deletes the existing CDF file specified by the identifier `cdfId`. If the CDF file is a multi-file format CDF, the `cdflib.delete` function also deletes the variable files (having file extensions of `.z0`, `.z1`, etc.).

Examples

Create a CDF file, and then delete it. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('mytempfile.cdf');

% Verify that the file was created.
ls *.cdf

mytempfile.cdf

% Delete the file.
cdflib.delete(cdfId)

% Verify that the file no longer exists.
ls *.cdf
```

References

This function corresponds to the CDF library C API routine `CDFdeleteCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

Purpose

Delete attribute

Syntax

`cdflib.deleteAttr(cdfId,attrNum)`

Description

`cdflib.deleteAttr(cdfId,attrNum)` deletes the specified attribute from the CDF file.

`cdfId` identifies the Common Data Format (CDF) file.`attrNum` is a numeric identifier that specifies the attribute. Attribute numbers are zero-based.

Examples

Create a CDF file, and then create an attribute in the file. Then delete the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create attribute.
attrNum = cdflib.createAttr(cdfId,'Purpose','global_scope');

% Prove it exists.
anum = cdflib.getAttrNum(cdfid,'Purpose')

anum =

     0

% Delete the attribute.
cdflib.deleteAttr(cdfid,attrNum);

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

Tutorials

- "Importing Common Data File Format (CDF) Files"
- "Exporting to Common Data File Format (CDF) Files"

Purpose

Delete attribute entry

Syntax

`cdflib.deleteAttrEntry(cdfId,attrNum,entryNum)`

Description

`cdflib.deleteAttrEntry(cdfId,attrNum,entryNum)` deletes an entry from an attribute in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

entryNum

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

Examples

Create a CDF, and then create an attribute in the file. Write a value to an entry for the attribute, and then delete the entry. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
```

```
    numgAttrs: 0

% Create an attribute with variable scope in the file.
attrNum = cdflib.createAttr(cdfid,'my_var_scope_attr','variable_scope');

% Write a value to an entry for the attribute
cdflib.putAttrEntry(cdfid,attrNum,0,'CDF_CHAR','My attr value');

% Get the value of the attribute entry
value = cdflib.getAttrEntry(cdfid,attrNum,0)

value =

My attr value

% Delete the entry
cdflib.deleteAttrEntry(cdfid,attrNum,0);

% Now try to view the value of the entry
% Should return NO_SUCH_ENTRY failure.
value = cdflib.getAttrEntry(cdfid,attrNum,0)  % Should fail

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

cdflib.deleteAttrgEntry

Purpose Delete entry in global attribute

Syntax `cdflib.deleteAttrgEntry(cdfId,attrNum,entryNum)`

Description `cdflib.deleteAttrgEntry(cdfId,attrNum,entryNum)` deletes an entry from a global attribute in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

entryNum

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

Examples Create a CDF and create a global attribute in the file. Write a value to an entry for the attribute and then delete the entry. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
```

```
    numgAttrs: 0

% Create an attribute with global scope in the file.
attrNum = cdflib.createAttr(cdfid,'my_global_attr','global_scope');

% Write a value to an entry for the attribute
cdflib.putAttrgEntry(cdfid,attrNum,0,'CDF_CHAR','My global attr');

% Get the value of the global attribute entry
value = cdflib.getAttrgEntry(cdfid,attrNum,0)

value =

My global attr

% Delete the entry
cdflib.deleteAttrgEntry(cdfid,attrNum,0);

% Now try to view the value of the entry
% Should return NO_SUCH_ENTRY failure.
value = cdflib.getAttrgEntry(cdfid,attrNum,0)  % Should fail

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

Purpose Delete variable

Syntax

```
cdflib.deleteVar(cdfId,varNum)
```

Description

`cdflib.deleteVar(cdfId,varNum)` deletes a variable from a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that specifies the variable. Variable numbers are zero-based.

Examples

Create a CDF, create a variable in the CDF, and then delete it.

```
cdfid = cdflib.create('mycdf.cdf');

% Initially the file contains no variables.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create a variable in the CDF.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Retrieve info about the variable in the CDF.

info = cdflib.inquireVar(cdfid, 0)

info =

           name: 'Time'
       datatype: 'cdf_int1'
```

```
    numElements: 1
           dims: []
    recVariance: 1
    dimVariance: []

% Delete the variable from the CDF

cdflib.deleteVar(cdfid,0);

% Check to see if the variable was deleted from the CDF.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

cdflib.deleteVarRecords

Purpose

Delete range of records from variable

Syntax

`cdflib.deleteVarRecords(cdfId,varNum,startRec,endRec)`

Description

`cdflib.deleteVarRecords(cdfId,varNum,startRec,endRec)` deletes a range of records from a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value that identifies the variable. Variable numbers are zero-based.

startRec

Numeric value that specifies the record at which to start deleting records. Record numbers are zero-based.

endRec

Numeric value that specifies the record at which to stop deleting records. Record numbers are zero-based.

Examples

Make a writable copy of the example CDF, get the number of a variable in the CDF, and delete specific records in the variable. To run this example, you must be in a writable folder.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.cdf');
copyfile(srcFile,'myfile.cdf');
fileattrib('myfile.cdf','+w');
cdfid = cdflib.open('myfile.cdf');
varnum = cdflib.getVarNum(cdfid,'Temperature');
cdflib.deleteVarRecords(cdfid,varnum,1,2);
cdflib.close(cdfid);
```

References

This function corresponds to the CDF library C API routine `CDFdeletezVarRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

cdflib.epoch16Breakdown

Purpose

Convert `CDF_EPOCH16` value to time value

Syntax

```
timeVec = cdflib.epoch16Breakdown(epoch16Time)
```

Description

`timeVec = cdflib.epoch16Breakdown(epoch16Time)` convert a `CDF_EPOCH16` value into a time vector. `timeVec` will have 10-by-*n* elements, where *n* is the number of CDF_EPOCH16 values.

The following table describes the time value components.

timeVec Element	Description	Valid Values
`timeVec(1,:)`	Year AD	e.g. `1994`
`timeVec(2,:)`	Month	`1 12`
`timeVec(3,:)`	Day	`1 31`
`timeVec(4,:)`	Hour	`0 23`
`timeVec(5,:)`	Minute	`0 59`
`timeVec(6,:)`	Second	`0 59`
`timeVec(7,:)`	Millisecond	`0 999`
`timeVec(8,:)`	Microsecond	`0 999`
`timeVec(9,:)`	Nanosecond	`0 999`
`timeVec(10,:)`	Picosecond	`0 999`

Examples

Convert `CDF_EPOCH16` value into time value.

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];
epoch16 = cdflib.computeEpoch16(timeval);

timevec = cdflib.epoch16Breakdown(epoch16)

timevec =

        1999
```

```
    12
    31
    23
    59
    59
    50
   100
   500
   999
```

References

This function corresponds to the CDF library C API routine `EPOCH16breakdown`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.epochBreakdown

Purpose

Convert CDF_EPOCH value into time value

Syntax

```
timeVec = cdflib.epochBreakdown(epochTime)
```

Description

`timeVec = cdflib.epochBreakdown(epochTime)` decomposes the `CDF_EPOCH` value, `epochTime` value into individual time components. `timeVec` will have 7-by-*n* elements, where *n* is the number of `CDF_EPOCH` values in `epochTime`.

The return value `timeVec` has the following elements:

timeVec Element	Description	Valid Values
`timeVec(1,:)`	Year AD	e.g. `1994`
`timeVec(2,:)`	Month	`1 12`
`timeVec(3,:)`	Day	`1 31`
`timeVec(4,:)`	Hour	`0 23`
`timeVec(5,:)`	Minute	`0 59`
`timeVec(6,:)`	Second	`0 59`
`timeVec(7,:)`	Millisecond	`0 999`

Examples

Convert a `CDP_EPOCH` value into a time vector.

```
% First convert a time vector into a CDF_EPOCH value
timeval = [1999 12 31 23 59 59 0];
epoch = cdflib.computeEpoch(timeval);

% Convert the CDF_EPOCH value into a time vector
timevec = cdflib.epochBreakdown(epoch)

timevec =

        1999
          12
          31
```

```
23
59
59
 0
```

References

cdflib.getAttrEntry

Purpose

Value of entry in attribute with variable scope

Syntax

```
value = cdflib.getAttrEntry(cdfId,attrNum,entryNum)
```

Description

`value = cdflib.getAttrEntry(cdfId,attrNum,entryNum)` returns the value of an attribute entry in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

entryNum

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

Output Arguments

Value

Value of the entry.

Examples

Open the example CDF and get the value of an entry associated with an attribute with variable scope in the file.

```
cdfid = cdflib.open('example.cdf');

% The fourth attribute is of variable scope.
attrscope = cdflib.getAttrScope(cdfid,3)

attrscope =

VARIABLE_SCOPE
```

```
% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrEntry(cdfid,3,0)

dtype =

cdf_char

numel =

    10

% Get the value of the entry for this attribute.
% Note that it's a character string, 10 characters in length
value = cdflib.getAttrEntry(cdfid,3,0)

value =

Time value

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Value of entry in global attribute

Syntax

```
value = cdflib.getAttrgEntry(cdfId,attrNum,entryNum)
```

Description

`value = cdflib.getAttrgEntry(cdfId,attrNum,entryNum)` returns the value of a global attribute entry in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

entryNum

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

Output Arguments

Value

Value of the entry.

Examples

Open the example CDF, and then get the value of an entry associated with a global attribute in the file:

```
cdfid = cdflib.open('example.cdf');

% Any of the first three attributes have global scope.
attrscope = cdflib.getAttrScope(cdfid,0)

attrscope =

GLOBAL_SCOPE
```

```
% Get information about the first entry for global attribute
[dtype numel] = cdflib.inquireAttrgEntry(cdfid,0,0)

dtype =

cdf_char

numel =

    23

% Get the value of the first entry for this global attribute.
value = cdflib.getAttrgEntry(cdfid,0,0)

value =

This is a sample entry.

% Clean up
cdflib.close(cdfid);

clear cdfid
```

cdflib.getAttrMaxEntry

Purpose

Number of last entry for variable attribute

Syntax

```
maxEntry = cdflib.getAttrMaxEntry(cdfId,attrNum)
```

Description

`maxEntry = cdflib.getAttrMaxEntry(cdfId,attrNum)` returns the number of the last entry for an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

Output Arguments

maxEntry

Entry number of the last entry in the attribute. Entry numbers are zero-based.

Examples

Open the example CDF and get the number of the last entry associated with an attribute with variable scope in the file:

```
cdfid = cdflib.open('example.cdf');

% The fourth attribute is of variable scope.
attrscope = cdflib.getAttrScope(cdfid,3)

attrscope =

VARIABLE_SCOPE
```

```
% Get the number of the last entry for this attribute.
entrynum = cdflib.getAttrMaxEntry(cdfid,3)

entrynum =

     3

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrMaxzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

cdflib.getAttrMaxgEntry

Purpose

Number of last entry for global attribute

Syntax

```
maxEntry = cdflib.getAttrMaxgEntry(cdfId,attrNum)
```

Description

`maxEntry = cdflib.getAttrMaxgEntry(cdfId,attrNum)` returns the last entry number of a global attribute in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

Output Arguments

maxEntry

Entry number of the last entry in the attribute. Entry numbers are zero-based.

Examples

Open the example CDF and get the number of the last entry associated with a global attribute in the file:

```
cdfid = cdflib.open('example.cdf');

% Any of the first three attribute are of global scope.
attrscope = cdflib.getAttrScope(cdfid,0)

attrscope =

GLOBAL_SCOPE

% Get the number of the last entry for this attribute.
entrynum = cdflib.getAttrMaxgEntry(cdfid,0)
```

```
entrynum =

     4

% Clean up
cdflib.close(cdfid);

clear cdfid
```

cdflib.getAttrName

Purpose

Name of attribute, given attribute number

Syntax

```
name = cdflib.getAttrName(cdfId,attrNum)
```

Description

`name = cdflib.getAttrName(cdfId,attrNum)` returns the name of an attribute in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that identifies the attribute. Attribute numbers are zero-based.

Output Arguments

name

Text string specifying the name of the attribute.

Examples

Open the example CDF and get name of an attribute.

```
cdfid = cdflib.open('example.cdf');

% Get name of the first attribute in the file.
attrName = cdflib.getAttrName(cdfId,0)

attrName =

SampleAttribute

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrName`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getAttrNum

Purpose

Attribute number, given attribute name

Syntax

```
attrNum = cdflib.getAttrNum(cdfId,attrName)
```

Description

`attrNum = cdflib.getAttrNum(cdfId,attrName)` returns the number of an attribute in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrName

Text string specifying the name of an attribute.

Output Arguments

attrNum

Numeric value that identifies the attribute. Attribute numbers are zero-based.

Examples

Open the example CDF and get the attribute number associated with the `SampleAttribute` attribute.

```
cdfid = cdflib.open('example.cdf');

attrNum = cdflib.getAttrNum(cdfid,'SampleAttribute')

attrNum =

     0

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getAttrScope

Purpose

Scope of attribute

Syntax

```
scope = cdflib.getAttrScope(cdfId,attrNum)
```

Description

`scope = cdflib.getAttrScope(cdfId,attrNum)` returns the scope of an attribute in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that specifies the attribute. Attribute numbers are zero-based.

Output Arguments

scope

Either of the following text strings, or its numeric equivalent.

Text String	Description
`'GLOBAL_SCOPE'`	Attribute applies to the CDF as a whole.
`'VARIABLE_SCOPE'`	Attribute applies only to the variable.

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

Examples

Open example CDF and get the scope of the first attribute in the file:

```
cdfid = cdflib.open('example.cdf');

attrScope = cdflib.getAttrScope(cdfid,0)

attrScope =
```

```
GLOBAL_SCOPE

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrScope`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getCacheSize

Purpose Number of cache buffers used

Syntax

```
numBuffers = cdflib.getCacheSize(cdfId)
```

Description `numBuffers = cdflib.getCacheSize(cdfId)` returns the number of cache buffers used for the Common Data Format (CDF) file identified by `cdfId`. For a discussion of cache schemes, see the *CDF User's Guide*.

Examples Open the example CDF file and get the cache size:

```
cdfid = cdflib.open('example.cdf');

numBuf = cdflib.getCacheSize(cdfid)

numBuf =

   300

% Clean up
cdflib.close(cdfid)
clear cdfid
```

References This function corresponds to the CDF library C API routine `CDFgetCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

Purpose

Checksum mode

Syntax

```
mode = cdflib.getChecksum(cdfId)
```

Description

`mode = cdflib.getChecksum(cdfId)` returns the checksum mode of the Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

mode

Either of the following text strings or its numeric equivalent.

'MD5_CHECKSUM'	File uses MD5 checksum.
'NO_CHECKSUM'	File does not use a checksum.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Open the example CDF file, and then get the checksum mode of the file:

```
cdfid = cdflib.open('example.cdf');

checksummode = cdflib.getChecksum(cdfid)

checksummode =

NO_CHECKSUM

% Clean up
cdflib.close(cdfid);
clear cdfid;
```

References

This function corresponds to the CDF library C API routine `CDFgetChecksum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

Purpose

Compression settings

Syntax

`[ctype,cparms,cpercentage] = cdflib.getCompression(cdfId)`

Description

`[ctype,cparms,cpercentage] = cdflib.getCompression(cdfId)` returns information about the compression settings of a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

ctype

Text string specifying compression type, such as `'HUFF_COMPRESSION'`. If the CDF does not use compression, the function returns the string `'NO_COMPRESSION'`. For a list of supported compression types, see `cdflib.setCompression`.

cparms

The value of the parameter associated with the type of compression. For example, for the `'RLE_COMPRESSION'` compression type, the parameter specifies the style of run-length encoding. For a list of parameters supported by each compression type, see `cdflib.setCompression`.

cpercentage

The rate of compression, expressed as a percentage.

Examples

Open the example CDF file and check the compression settings in the file.

```
cdfId = cdflib.open('example.cdf');

[ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)
```

```
ctype =

GZIP_COMPRESSION

cparms =

     7

cper =

    26

% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Number of compression cache buffers

Syntax

```
numBuffers = cdflib.getCompressionCacheSize(cdfId)
```

Description

`numBuffers = cdflib.getCompressionCacheSize(cdfId)` returns the number of cache buffers used for the compression scratch Common Data Format (CDF) file. `cdfId` identifies the CDF file. For a discussion of cache schemes, see the *CDF User's Guide*.

Examples

Open the example CDF file and check the compression cache size of the file:

```
cdfId = cdflib.open('example.cdf');

numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

    80

% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetCompressionCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

cdflib.getConstantNames

Purpose

Names of Common Data Format (CDF) library constants

Syntax

```
names = cdflib.getConstantNames()
```

Description

`names = cdflib.getConstantNames()` returns a cell array of text strings, where each text string is the name of a constant known to the Common Data Format (CDF) library.

Examples

Get a list of the names of CDF library constants.

```
names  = cdflib.getConstantNames()

names =

    'AHUFF_COMPRESSION'
    'ALPHAMVSD_ENCODING'
    'ALPHAMVSG_ENCODING'
    'ALPHAMVSI_ENCODING'
    'ALPHAOSF1_ENCODING'
    'CDF_BYTE'
    'CDF_CHAR'
      .
      .
      .
```

Purpose

Numeric value corresponding to Common Data Format (CDF) library constant

Syntax

`value = cdflib.getConstantValue(constantName)`

Description

`value = cdflib.getConstantValue(constantName)` returns the numeric value of the CDF library constant specified by the text string *`constantName`*. To see a list of constant names, use `cdflib.getConstantNames`.

Examples

View the list of CDF library constants and get the numeric value corresponding to one of the constants.

```
% Retrieve a list of library constants
names = cdflib.getConstantNames();

value  = cdflib.getConstantValue(names{1})

value =

   3
```

cdflib.getCopyright

Purpose

Copyright notice in Common Data Format (CDF) file

Syntax

```
copyright = cdflib.getCopyright(cdfId)
```

Description

`copyright = cdflib.getCopyright(cdfId)` returns the copyright notice in the CDF file identified by `cdfId`.

Examples

Create a CDF file, and then get the copyright notice in the file. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');

copyright  = cdflib.getCopyright(cdfId)

copyright =

Common Data Format (CDF)
(C) Copyright 1990-2009 NASA/GSFC
Space Physics Data Facility

cdflib.getFileBackward

Purpose

Return current backward compatibility mode setting

Syntax

```
mode = cdflib.getFileBackward()
```

Description

`mode = cdflib.getFileBackward()` returns the backward compatibility mode.

Output Arguments

mode

One of the following text strings:

`BACKWARDFILEon`	Backward compatibility mode is on.
`BACKWARDFILEoff`	Backward compatibility mode is off.

For more information about backward compatibility mode, see `cdflib.setFileBackward`.

Examples

```
mode = cdflib.getFileBackward

mode =

BACKWARDFILEoff
```

References

This function corresponds to the CDF library C API routine `CDFgetFileBackward`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

-

Purpose

Format of Common Data Format (CDF) file

Syntax

format = cdflib.setFormat(cdfId)

Description

format = cdflib.setFormat(cdfId) returns the format of the CDF file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to cdflib.create or cdflib.open.

Output Arguments

format

Either of the following text strings, or its numeric equivalent.

'SINGLE_FILE'	The CDF is stored in a single file.
'MULTI_FILE'	The CDF is made up of multiple files.

To get the numeric equivalent of these text strings, use cdflib.getConstantValue.

Examples

Open the example CDF file and determine its file format:

```
cdfId = cdflib.open('example.cdf');

format = cdflib.getFormat(cdfId)

format =

   'SINGLE_FILE'

% Clean up.
cdflib.close(cdfId)
clear cdfId
```

References

cdflib.getLibraryVersion

Purpose

Library version and release information

Syntax

```
[version,release,increment] = cdflib.getLibraryVersion()
```

Description

`[version,release,increment] = cdflib.getLibraryVersion()` returns information about the Common Data Format (CDF) library.

Output Arguments

version

Numeric value indicating the version number of the CDF library.

release

Numeric value indicating the release number of the CDF library.

increment

Numeric value indicating the increment number of the CDF library.

Examples

Get the version information of the CDF library:

```
[version, release, increment] = cdflib.getLibraryVersion()

version =

     3

release =

     3

increment =

     0
```

References

This function corresponds to the CDF library C API routine `CDFgetLibraryVersion`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getMajority

Purpose

Majority of variables

Syntax

```
majority = cdflib.getMajority(cdfId)
```

Description

majority = `cdflib.getMajority(cdfId)` returns the majority of variables in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

majority

Either of the following text strings, or its numeric equivalent.

'ROW_MAJOR'	C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default.
'COLUMN_MAJOR'	Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Open the example CDF file, and then determine the majority of variables in the file:

```
cdfId = cdflib.open('example.cdf');

majority = cdflib.getMajority(cdfId)

majority =

ROW_MAJOR
```

```
% Clean up
cdflib.close(cdfId)

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetMajority`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getName

Purpose

Name of Common Data Format (CDF) file

Syntax

```
name = cdflib.getName(cdfId)
```

Description

`name = cdflib.getName(cdfId)` returns the name of the CDF file identified by `cdfId`.

Examples

Open the example CDF file and get the name of the file. The path name returned for your installation will be different.

```
cdfId = cdflib.open('example.cdf');

name = cdflib.getName(cdfId)

name =

yourinstallation\matlab\toolbox\matlab\demos\example

% Clean up
cdflib.close(cdfId)

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetName`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Tutorials

- "Importing Common Data File Format (CDF) Files"
- "Exporting to Common Data File Format (CDF) Files"

Purpose

Number of entries for attribute with variable scope

Syntax

```
nentries = cdflib.getNumAttrEntries(cdfId,attrNum)
```

Description

`nentries = cdflib.getNumAttrEntries(cdfId,attrNum)` returns the number of entries for the specified attribute in the Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

Examples

Open the example CDF, find an attribute with variable scope, and determine how many entries are associated with the attribute:

```
cdfid = cdflib.open('example.cdf');

% Get the number of an attribute
% with variable scope
attrNum = cdflib.getAttrNum(cdfid,'Description');

% Check that scope of attribute is variable
attrScope = cdflib.getAttrScope(cdfid,attrNum)

VARIABLE_SCOPE

% Detemine the number of entries for the attribute
attrEntries = cdflib.getNumAttrEntries(cdfid,attrNum)

attrEntries =

    4

% Clean up
cdflib.close(cdfid);
```

References

This function corresponds to the CDF library C API routine `CDFgetNumAttrzEntries`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

cdflib.getNumAttrgEntries

Purpose

Number of entries for attribute with global scope

Syntax

```
nentries = cdflib.getNumAttrgEntries(cdfId,attrNum)
```

Description

`nentries = cdflib.getNumAttrgEntries(cdfId,attrNum)` returns the number of entries written for the specified global attribute in the Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `attrNum` is a numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

Examples

Open the example CDF and find out how many entries are associated with a global attribute in the file.

```
cdfid = cdflib.open('example.cdf');

% The first attribute is a global attribute.
attrgEntries = cdflib.getNumAttrgEntries(cdfid,0)

attrgEntries =

     3

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetNumAttrgEntries`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose Number of attributes with variable scope

Syntax

```
numAtts = cdflib.getNumAttributes(cdfId)
```

Description `numAtts = cdflib.getNumAttributes(cdfId)` returns the total number of attributes with variable scope in a Common Data Format (CDF) file. `cdfId` identifies the CDF file.

Examples Open the example CDF and find out how many attributes in the file have variable scope:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of attributes with variable scope
numAttrs = cdflib.getNumAttributes(cdfid)

numAttrs =

     1

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References This function corresponds to the CDF library C API routine `CDFgetNumvAttributes`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getNumgAttributes

Purpose

Number of attributes with global scope

Syntax

```
ngatts = cdflib.getNumgAttributes(cdfId)
```

Description

`ngatts = cdflib.getNumgAttributes(cdfId)` returns the total number of global attributes in a Common Data Format (CDF) file. `cdfId` identifies the CDF file.

Examples

Open the example CDF and find out how many global attributes are in the file:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of global attributes in the file.
numgAttrs = cdflib.getNumgAttributes(cdfid)

numgAttrs =

     3

% Clean up
cdflib.close(cdfid);
```

References

This function corresponds to the CDF library C API routine `CDFgetNumgAttributes`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

Purpose Read-only mode

Syntax

```
mode = cdflib.getReadOnlyMode(cdfId)
```

Description

`mode = cdflib.getReadOnlyMode(cdfId)` returns the read-only mode of a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

mode

Either of the following text strings or its numeric equivalent.

'READONLYon'	CDF is in read-only mode
'READONLYoff'	CDF can be modified.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Open the example CDF file and determine its current read-only status:

```
cdfId = cdflib.open('example.cdf');

mode = cdflib.getReadOnlyMode(cdfId)

mode =

READONLYoff

% Clean up.
cdflib.close(cdfId);
clear cdfId
```

cdflib.getReadOnlyMode

References

This function corresponds to the CDF library C API routine `CDFgetReadOnlyMode`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

cdflib.getStageCacheSize

Purpose

Number of cache buffers for staging

Syntax

```
numBuffers = cdflib.getStageCacheSize(cdfId)
```

Description

`numBuffers = cdflib.getStageCacheSize(cdfId)` returns the number of cache buffers used for the staging scratch file of the Common Data Format (CDF) file. For more information about cache buffers, see the *CDF User's Guide*.

`cdfId` identifies the CDF file.

Examples

Open the example CDF file and determine the number of cache buffers used for staging:

```
cdfId = cdflib.open('example.cdf');

numBuf = cdflib.getStageCacheSize(cdfId)

numBuf =

   125

% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetStageCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

Purpose

Library validation mode

Syntax

```
mode = cdflib.getValidate()
```

Description

`mode = cdflib.getValidate()` returns the validation mode of the Common Data Format (CDF) library.

Output Arguments

mode

Either of the following text strings or its numeric equivalent.

'VALIDATEFILEon'	Validation mode is on. For information about validation mode, see `cdflib.setValidate`.
'VALIDATEFILEoff'	Validation mode is off.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Determine the current validation mode of the CDF library.

```
mode = cdflib.getValidate()

mode =

'VALIDATEFILEon'
```

References

This function corresponds to the CDF library C API routine `CDFgetValidate`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Number of records allocated for variable

Syntax

```
numrecs = cdflib.getVarAllocRecords(cdfId, varNum)
```

Description

`numrecs = cdflib.getVarAllocRecords(cdfId, varNum)` returns the number of records allocated for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

Examples

Open example CDF and get the number of records allocated for a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of records allocated for the
% first variable in the file.
numrecs = cdflib.getVarAllocRecords(cdfid,0)

numrecs =

    64

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarAllocRecords`.

Purpose

Blocking factor for variable

Syntax

```
blockingFactor = cdflib.getVarBlockingFactor(cdfId,varNum)
```

Description

`blockingFactor = cdflib.getVarBlockingFactor(cdfId,varNum)` returns the blocking factor for a variable in a Common Data Format (CDF) file. A variable's *blocking factor* specifies the minimum number of records the library allocates when you write to an unallocated record.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

Examples

Open the example CDF and determine the blocking factor of a variable.

```
cdfid = cdflib.open('example.cdf');

cdflib.getVarBlockingFactor(cdfid,0)

ans =

     0

%  Clean up
cdflib.close(cdfid)
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarBlockingFactor`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Number of multifile cache buffers

Syntax

```
numBuffers = cdflib.getVarCacheSize(cdfId,varNum)
```

Description

`numBuffers = cdflib.getVarCacheSize(cdfId,varNum)` returns the number of cache buffers used for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable identifiers are zero-based.

This function applies only to multifile format CDFs. For more information about caching, see the *CDF User's Guide*.

Examples

Create a multifile CDF and retrieve the number of buffers being used for a variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*

your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     1

%  Clean up
```

```
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarCacheSize`.

Purpose

Information about compression used by variable

Syntax

```
[ctype,cparams,percent] = cdflib.getVarCompression(cdfId,
   varNum)
```

Description

`[ctype,cparams,percent] = cdflib.getVarCompression(cdfId, varNum)` returns information about the compression used for a variable in a Common Data Format (CDF) File.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

ctype

Text string identifying the type of compression. For a list of compression types, see `cdflib.setCompression`.

cparams

Any additional parameter required by the compression type.

percent

Numeric value indicating the level of compression, expressed as a percentage.

Examples

Open the example CDF file and check the compression settings of any variable.

```
cdfid = cdflib.open('example.cdf');

% Check the compression setting of any variable in the file
% The example checks the first variable (variable numbers are zero-bas
[ctype params percent] = cdflib.getVarCompression(cdfid,0)

ctype =
```

```
NO_COMPRESSION

params =

     []

percent =

   100

% Clean up
cdflib.close(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarCompression`.

- “Exporting to Common Data File Format (CDF) Files”

Purpose

Single value from record in variable

Syntax

```
datum = cdflib.getVarData(cdfId,varNum,recNum,indices)
```

Description

`datum = cdflib.getVarData(cdfId,varNum,recNum,indices)` returns a single value from a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying the variable containing the datum. Variable numbers are zero-based.

recNum

Numeric value identifying the location of the datum in the variable. In CDF terminology, this is called the *record number*. Record numbers are zero-based.

indices

Array of dimension indices within the record. Dimension indices are zero-based. If the variable has no dimensions, you can omit this parameter.

Output Arguments

datum

Value of the specified record.

Examples

Open the example CDF file and retrieve data associated with a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine how many variables are in the file.
```

```
info = cdflib.inquire(cdfid);

info.numVars

ans =

  5

% Determine if the first variable has dimensions.
varinfo = cdflib.inquireVar(cdfid,0);
vardims = varinfo.dims
vardims =

  []

% Get data from variable, without specifying dimensions.
datum = cdflib.getVarData(cdfid, varnum, recnum)

datum =

  6.3146e+013

% Get dimensions of another variable in file.
varinfo = cdflib.inquireVar(cdfid,3);
vardims = varinfo.dims
vardims =

  [4 2 2]

% Retrieve the first datum in the record. Indices are zero-based.
datum = cdflib.getVarData(cdfId,3,0,[0 0 0])

info =

    30

% Clean up.
```

```
cdflib.close(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarData`.

cdflib.getVarMaxAllocRecNum

Purpose

Maximum allocated record number for variable

Syntax

```
maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)
```

Description

`maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)` returns the record number of the maximum allocated record for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers and record numbers are zero-based.

Examples

Open example CDF and get the maximum allocated record number for a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine maximum record number for variable in file.
maxRecNum = cdflib.getVarMaxAllocRecNum(cdfid,0)

maxRecNum =

    63

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarMaxAllocRecNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getVarMaxWrittenRecNum

Purpose

Maximum written record number for variable

Syntax

```
maxrec = cdflib.getVarMaxwrittenRecNum(cdfId,varNum)
```

Description

`maxrec = cdflib.getVarMaxwrittenRecNum(cdfId,varNum)` returns the record number of the maximum record written for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers and record numbers are zero-based.

Examples

Open the example CDF, and then determine the maximum number of records written to a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number records written to variable.
numRecs = cdflib.getVarNumRecsWritten(cdfid,0)

numRecs =

    24

% Determine the maximum record number of the records written
maxRecNum = cdflib.getVarMaxWrittenRecNum(cdfid,0)

maxRecNum =

    23

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarMaxWrittenRecNum`.

cdflib.getVarsMaxWrittenRecNum

Purpose

Maximum written record number for CDF file

Syntax

```
maxrec = cdflib.getVarsMaxwrittenRecNum(cdfId)
```

Description

`maxrec = cdflib.getVarsMaxwrittenRecNum(cdfId)` returns the maximum record number written for all variables in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. Record numbers are zero-based.

Examples

Open the example CDF, and then determine the maximum number of records written to the file:

```
cdfid = cdflib.open('example.cdf');

% Determine the maximum record number of the records written
maxRecNum = cdflib.getVarsMaxWrittenRecNum(cdfid)

maxRecNum =

    0

%  Clean up
cdflib.close(cdfid)
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarsMaxWrittenRecNum`.

Purpose

Variable name, given variable number

Syntax

```
name = cdflib.getVarName(cdfId,varNum)
```

Description

`name = cdflib.getVarName(cdfId,varNum)` returns the name of the variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.`name` is a text string specifying the name.

Examples

Open the example CDF, and then get the name of a variable in the file:

```
cdfid = cdflib.open('example.cdf');

name = cdflib.getVarName(cdfid,1)

name =

Longitude

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

Purpose

Variable number, given variable name

Syntax

```
varNum = cdflib.getVarNum(cdfId,varname)
```

Description

`varNum = cdflib.getVarNum(cdfId,varname)` returns the identifier (variable number) for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. *varname* is a text string that identifies the variable. Variable names are case-sensitive.

Examples

Open example CDF, and then get the number of a variable named `Longitude`:

```
cdfid = cdflib.open('example.cdf');

varNum = cdflib.getVarNum(cdfid,'Longitude')

varNum =

     1

%  Clean up
cdflib.close(cdfid);

clear cdfid

data = cdflib.getVarRecordData(cdfId,varNum,recNum)
```

Description

`data = cdflib.getVarRecordData(cdfId,varNum,recNum)` returns the data in a record associated with a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value that identifies the variable in the CDF file. Variable numbers are zero-based.

recNum

Numeric value that identifies the record in the variable. Record numbers are zero-based.

Output Arguments

data

Data in the record.

Examples

Open the example CDF, and then get the data associated with a record in a variable:

```
cdfid = cdflib.open('example.cdf');

% Get data in first record in first variable in file.
recData = cdflib.getVarRecordData(cdfid,0,0)

recData =

    6.3146e+013
```

```

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Compression reserve percentage for variable

Syntax

```
percent = cdflib.getVarReservePercent(cdfId,varNum)
```

Description

`percent = cdflib.getVarReservePercent(cdfId,varNum)` returns the compression reserve percentage for a variable in a Common Data Format (CDF) file. This operation only applies to compressed variables.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

Definitions

reserve percentage

Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space.

By default, the reserve percent is `0` (no extra space is reserved). You can specify any percentage between `1` and `100` and values greater than `100`. The value specifies the percentage of the uncompressed size of the variable.

Examples

Open the example CDF file, get the number of a compressed variable, and then determine the reserve percent for the variable.

```
cdfid = cdflib.open('example.cdf');
varnum = cdflib.getVarNum(cdfid,'Temperature');
percent = cdflib.getVarReservePercent(cdfid,varnum);
cdflib.close(cdfid);
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarReservePercent`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Information about how variable handles sparse records

Syntax

`stype = cdflib.getVarSparseRecords(cdfId,varNum)`

Description

`stype = cdflib.getVarSparseRecords(cdfId,varNum)` returns information about how a variable in the Common Data Format (CDF) file handles sparse records.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value that identifies the variable. Variable numbers are zero-based.

Output Arguments

stype

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

Text String	Description
'NO_SPARSERECORDS'	No sparse records.
'PAD_SPARSERECORDS'	For sparse records, the library uses the variable's pad value when reading values from a missing record.
'PREV_SPARSERECORDS'	For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Open the example CDF, and then get the sparse record type of a variable in the file:

```
cdfid = cdflib.open('example.cdf');

stype = cdflib.getVarSparseRecords(cdfid,0)

stype =

NO_SPARSERECORDS

%Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarSparseRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

- “Exporting to Common Data File Format (CDF) Files”

Purpose

Common Data Format (CDF) library version and release information

Syntax

```
[version,release,increment] = cdflib.getVersion(cdfId)
```

Description

`[version,release,increment] = cdflib.getVersion(cdfId)` returns information about the version of the Common Data Format (CDF) library used to create a CDF file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

version

Numeric value indicating the version number of the CDF library.

release

Numeric value indicating the release number of the CDF library.

increment

Numeric value indicating the increment number of the CDF library.

Examples

Open the example CDF file, and then find out the version of the CDF library used to create it:

```
cdfId = cdflib.open('example.cdf');

[version, release, increment] = cdflib.getVersion(cdfId)

version =

     2

release =
```

```
     7

increment =

     8

% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetVersion`.

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Read hyperslab of data from variable

Syntax

```
data = cdflib.hyperGetVarData(cdfId,varNum,recSpec,dimSpec)
```

Description

`data = cdflib.hyperGetVarData(cdfId,varNum,recSpec,dimSpec)` reads a hyperslab of data from a variable in the Common Data Format (CDF) file. Hyper access allows more than one value to be read from or written to a variable with a single call to the CDF library.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Number identifying the variable containing the datum.

recSpec

Three-element array, `[RSTART RCOUNT RSTRIDE]`, where `RSTART`, `RCOUNT`, and `RSTRIDE` are scalar values specifying the starting record, number of records to read, and the sampling interval or stride between records. Record numbers are zero-based.

dimSpec

Three-element cell array, `{DSTART DCOUNT DSTRIDE}`, where `DSTART`, `DCOUNT`, and `DSTRIDE` are *n*-element vectors that describe the start, number of values along each dimension, and sampling interval along each dimension. If the hyperslab has zero dimensions, you can omit this parameter. Dimension indices are zero-based.

Examples

Open the example CDF file, and then get all the data associated with a variable:

```
cdfid = cdflib.open('example.cdf');
```

```
% Determine the number of records allocated for the first variable in the
maxRecNum = cdflib.getVarMaxWrittenRecNum(cdfid,0);

% Retrieve all data in records for variable.
data = cdflib.hyperGetVarData(cdfid,0,[0 maxRecNum 1]);

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFhyperGetzVarData`.

Purpose

Write hyperslab of data to variable

Syntax

`cdflib.hyperPutVarData(cdfId,varNum,recSpec,dimSpec,data)`

Description

`cdflib.hyperPutVarData(cdfId,varNum,recSpec,dimSpec,data)` writes a hyperslab of data to a variable in a Common Data Format (CDF) file. Hyper access allows more than one value to be read from or written to a variable with a single call to the CDF library.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Specifies the variable containing the datum.

recSpec

Three-element array described by `[RSTART RCOUNT RSTRIDE]`, where `RSTART`, `RCOUNT`, and `RSTRIDE` are scalar values giving the start, number of records, and sampling interval (or stride) between records. Record indices are zero-based.

dimSpec

Three-element cell array described by `{DSTART DCOUNT DSTRIDE}`, where `DSTART`, `DCOUNT`, and `DSTRIDE` are n-element vectors that describe the start, number of values along each dimension, and sampling interval along each dimension. If the hyperslab has zero dimensions, you can omit this parameter. Dimension indices are zero-based.

data

Data to write to the variable.

Examples

Create a CDF, create a variable, and then write a slab of data to the variable. To run this example, you must be in a writable folder.

cdflib.hyperPutVarData

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);

% Write data to the variable
cdflib.hyperPutVarData(cdfid,varNum,0,[],int8(98))

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFhyperzPutVarData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Basic characteristics of Common Data Format (CDF) file

Syntax

```
info = cdflib.inquire(cdfId)
```

Description

`info = cdflib.inquire(cdfId)` returns basic information about a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

info

A structure containing the following fields:

Field	Description
`encoding`	Encoding of the variable data and attribute entry data
`majority`	Majority of the variable data
`maxRec`	Maximum record number written to a CDF variable
`numVars`	Number of CDF variables
`numvAttrs`	Number of attributes with variable scope
`numgAttrs`	Number of attributes with global scope

Examples

Open the example CDF file, and then get basic information about the file:

```
cdfId = cdflib.open('example.cdf');

info = cdflib.inquire(cdfId)

info =
```

```
      encoding: 'IBMPC_ENCODING'
      majority: 'ROW_MAJOR'
        maxRec: 23
       numVars: 5
     numvAttrs: 1
     numgAttrs: 3
```

References

```
info = cdflib.inquireAttr(cdfId,attrNum)
```

Description

`info = cdflib.inquireAttr(cdfId,attrNum)` returns information about an attribute in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that identifies the attribute in the file. Attribute numbers are zero-based.

Output Arguments

info

Structure containing the following fields.

Field	Description
`name`	Attribute's name
`scope`	Either `'GLOBAL_SCOPE'` or `'VARIABLE_SCOPE'`
`maxgEntry`	The maximum entry number used for global attributes.
`maxEntry`	The maximum entry number used for attributes with variable scope.

Examples

Open the example CDF, and then get information about the first attribute in the file.

```
cdfid = cdflib.open('example.cdf');
```

```
% Get information about an attribute
info = cdflib.inquireAttr(cdfid,0)

info =

         name: 'SampleAttribute'
        scope: 'GLOBAL_SCOPE'
    maxgEntry: 4
     maxEntry: -1

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFinquireAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Tutorials

- "Importing Common Data File Format (CDF) Files"
- "Exporting to Common Data File Format (CDF) Files"

Purpose

Information about entry in attribute with variable scope

Syntax

```
[datatype,numElements] = cdflib.inquireAttrEntry(cdfId,
   attrNum,entryNum)
```

Description

`[datatype,numElements] = cdflib.inquireAttrEntry(cdfId,attrNum,entryNum)` returns the data type and the number of elements for an attribute entry in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value identifying an attribute in the file. Attribute numbers are zero-based. The attribute must have variable scope.

entryNum

Numeric value identifying the entry in the attribute. Entry number are zero-based.

Output Arguments

datatype

Text string identifying a CDF data type. For a list of CDF data types, see `cdflib.putAttrEntry`

numElements

Numeric value indicating the number of elements in the entry.

Examples

Open example CDF, and then get information about entries associated with an attribute in the file:

```
cdfid = cdflib.open('example.cdf');
```

```
% The fourth attribute is of variable scope.
attrscope = cdflib.getAttrScope(cdfid,3)

attrscope =

VARIABLE_SCOPE

% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrEntry(cdfid,3,0)

dtype =

cdf_char

numel =

    10

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFinquireAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Information about entry in attribute with global scope

Syntax

```
[datatype,numElements] = cdflib.inquireAttrgEntry(cdfId,
   attrNum,entryNum)
```

Description

`[datatype,numElements] = cdflib.inquireAttrgEntry(cdfId,attrNum,entryNum)` returns the data type and the number of elements for a global attribute entry in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value identifying an attribute in the file. Attribute numbers are zero-based. The attribute must have global scope.

entryNum

Numeric value identifying the entry in the attribute. Entry number are zero-based.

Output Arguments

datatype

Text string identifying a CDF data type. For a list of CDF data types, see `cdflib.putAttrgEntry`

numElements

Numeric value indicating the number of elements in the entry.

Examples

Open the example CDF, and then get information about entries associated with a global attribute in the file.

```
cdfid = cdflib.open('example.cdf');
```

```
% Any of the first three attributes have global scope.
attrscope = cdflib.getAttrScope(cdfid,0)

attrscope =

GLOBAL_SCOPE

% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrgEntry(cdfid,0,0)

dtype =

cdf_char

numel =

    23

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFinquireAttrgEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Tutorials

- "Importing Common Data File Format (CDF) Files"
- "Exporting to Common Data File Format (CDF) Files"

Purpose

Information about variable

Syntax

```
info = cdflib.inquireVar(cdfId,varNum)
```

Description

`info = cdflib.inquireVar(cdfId,varNum)` returns information about a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value that identifies the variable. Variable numbers are zero-based.

Output Arguments

info

Structure containing the following fields.

Field	Description
`name`	Name of the variable
`datatype`	Data type
`numElements`	Number of elements of the datatype
`dims`	Sizes of the dimensions
`recVariance`	Record variance
`dimVariance`	Dimension variances

Record and dimension variances affect how the library physically stores variable data. For example, if a variable has a record variance of `VARY`, the library physically stores each record. If the record variance is `NOVARY`, the library only stores one record.

Examples

Open the example CDF file and get information about a variable.

```
cdfid = cdflib.open('example.cdf');

% Determine if the file contains variables
info  = cdflib.inquireVar(cdfid,1)

info =

           name: 'Longitude'
       datatype: 'cdf_int1'
    numElements: 1
           dims: [2 2]
    recVariance: 0
    dimVariance: [1 0]
```

`cdflib.inquire`

Tutorials

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

Purpose

Open existing Common Data Format (CDF) file

Syntax

`cdfId = cdflib.open(filename)`

Description

`cdfId = cdflib.open(filename)` opens an existing Common Data Format (CDF) file. *`filename`* is a text string that identifies the file.

This function returns a CDF file identifier, `cdfId`.

All CDF files opened this way have the `zMode` set to `zModeon2`. Refer to the *CDF User's Guide* for information about `zModes`.

Examples

Open the example CDF file:

```
cdfId = cdflib.open('example.cdf');

% Clean up
cdflib.close(cdfId)

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFopenCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

cdflib.putAttrEntry

Purpose

Write value to entry in attribute with variable scope

Syntax

```
cdflib.putAttrEntry(cdfId,attrNum,entryNum,CDFDataType,
   entryVal)
```

Description

`cdflib.putAttrEntry(cdfId,attrNum,entryNum,CDFDataType,entryVal)` writes a value to an attribute entry in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Number identifying attribute. The attribute must have variable scope. Attribute numbers are zero-based.

entryNum

Number identifying entry. Entry numbers are zero-based.

CDFdatatype

One of the following text strings, or its numeric equivalent, that specify the data type of the attribute entry.

CDF Data Type	MATLAB Equivalent
`CDF_BYTE`	1-byte, signed integer
`CDF_CHAR`	1 byte, signed character data type that maps to the MATLAB `char` class
`CDF_INT1`	1-byte, signed integer.
`CDF_UCHAR`	1 byte, unsigned character data type that maps to the MATLAB `uint8` class
`CDF_UINT1`	1-byte, unsigned integer

CDF Data Type	MATLAB Equivalent
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer.
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

entryVal

Data to be written to attribute entry.

Examples

Create a CDF and create an attribute with variable scope in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
```

```
    numgAttrs: 0

% Create an attribute of variable scope in the file.
attrNum = cdflib.createAttr(cdfid,'Another Attribute','variable_scope');

% Write a value to an entry for the attribute
cdflib.putAttrEntry(cdfid,attrNum,0,'CDF_CHAR','My Variable Attribute Tes

% Get the value of the global attribute entry
value = cdflib.getAttrEntry(cdfid,attrNum,0)

value =

My Variable Attribute Test

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFputAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Write value to entry in attribute with global scope

Syntax

```
cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,
   entryVal)
```

Description

`cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,entryVal)` writes a value to a global attribute entry in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Number identifying attribute. Attribute numbers are zero-based. The attribute must have global scope.

entryNum

Number identifying entry. Entry numbers are zero-based.

CDFdatatype

One of the following text strings that specify the data type of the attribute entry, or its numeric equivalent.

CDF Data Type	MATLAB Equivalent
`CDF_BYTE`	1-byte, signed integer
`CDF_CHAR`	1 byte, signed character data type that maps to the MATLAB `char` class
`CDF_INT1`	1-byte, signed integer.
`CDF_UCHAR`	1 byte, unsigned character data type that maps to the MATLAB `uint8` class
`CDF_UINT1`	1-byte, unsigned integer

CDF Data Type	MATLAB Equivalent
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer.
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

entryVal

Data to be written to global attribute entry.

Examples

Create a CDF and create a global attribute in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

cdflib.putVarData

Purpose

Write single value to variable

Syntax

```
cdflib.putVarData(cdfId,varNum,recNum,indices,datum)
```

Description

`cdflib.putVarData(cdfId,varNum,recNum,indices,datum)` writes a single value to a variable in a Common Data File (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.

recNum

Numeric value that identifies the record to which you want to write the datum. Record numbers are zero-based.

dims

Dimension indices within the record. Dimension indices are zero-based.

datum

Data to be written to the variable.

Examples

Create a CDF, create a variable in the CDF and write data to the variable. To run this example, you must have write permission in the current folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);
```

```
% Write some data to the variable
cdflib.putVarData(cdfid,varNum,0,[],int8(98))

% Read the value from the variable.
datum = cdflib.getVarData(cdfid,varNum,0)

datum =

   98

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFputzVarData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.putVarRecordData

Purpose

Write entire record to variable

Syntax

```
cdflib.putVarRecordData(cdfId,varNum,recNum,recordData)
```

Description

`cdflib.putVarRecordData(cdfId,varNum,recNum,recordData)` writes data to a record in a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.

recNum

Numeric value identifying the location of the datum in the variable. Record numbers are zero-based.

recordData

Data to be written to the variable.

Examples

Create a CDF, create a variable, and write an entire record of data to the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);

% Write some data to the variable
cdflib.putVarRecordData(cdfid,varNum,0,int8(98))
```

```
% Read the value from the variable.
datum = cdflib.getVarData(cdfid,varNum,0)

datum =

   98

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

cdflib.renameAttr

Purpose Rename existing attribute

Syntax

```
cdflib.renameAttr(cdfId,attrNum,newName)
```

Description `cdflib.renameAttr(cdfId,attrNum,newName)` renames an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `attrNum` is a numeric value that identifies the attribute. Attribute numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the attribute.

Examples Create a CDF, create an attribute in the CDF, and then rename the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create an attribute
attrNum = cdflib.createAttr(cdfid,'Purpose','global_scope');

% Rename the attribute
cdflib.renameAttr(cdfid, attrNum, 'NewPurpose');

% Check the name of the attribute
attrName = cdflib.getAttrName(cdfid,anum)

attrName =

NewPurpose

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References This function corresponds to the CDF library C API routine `CDFrenameAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.renameVar

Purpose

Rename existing variable

Syntax

```
cdflib.renameVar(cdfId,varNum,newName)
```

Description

`cdflib.renameVar(cdfId,varNum,newName)` renames a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the variable.

Examples

Create a CDF, create a variable in the CDF, and then rename the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Get the name of the variable.
name = cdflib.getVarName(cdfid,varNum)

name =

Time

% Rename the variable
cdflib.renameVar(cdfid,varNum,'NewName');

% Check the new name.
name = cdflib.getVarName(cdfid,varNum)

name =

NewName

%  Clean up
```

```
cdflib.delete(cdfid)

clear cdfid
```

References

cdflib.setCacheSize

Purpose

Specify number of dotCDF cache buffers

Syntax

`cdflib.setCacheSize(cdfId,numBuffers)`

Description

`cdflib.setCacheSize(cdfId,numBuffers)` specifies the number of cache buffers the CDF library uses for an open dotCDF file. A *dotCDF* file is a file with the `.cdf` file extension.

`cdfId` identifies an open CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

For information about cache schemes, see the *CDF User's Guide*.

Examples

Create a CDF file and set the cache size. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf');

% Get the default cache size
numBuf = cdflib.getCacheSize(cdfid)

numBuf =

   300

% Specify a cache size
cdflib.setCacheSize(cdfid,150)

% Check the cache size again
numBuf =  cdflib.getCacheSize(cdfid)

numBuf =

   150

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.setChecksum

Purpose

Specify checksum mode

Syntax

`cdflib.setChecksum(cdfId,mode)`

Description

`cdflib.setChecksum(cdfId,mode)` specifies the checksum mode of a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

mode

Either of the following text strings, or its numeric equivalent. To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

'MD5_CHECKSUM'	Sets file checksum to MD5 checksum.
'NO_CHECKSUM'	File does not use a checksum.

Examples

Create a CDF file and set the checksum mode. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('mycdf.cdf');

% Check initial value of checksum.
mode = cdflib.getChecksum(cdfid)

NO_CHECKSUM

cdflib.setChecksum(cdfid,'MD5_CHECKSUM')

% Verify the setting
mode = cdflib.getChecksum(cdfid)

MD5_CHECKSUM
```

References

This function corresponds to the CDF library C API routine `CDFsetChecksum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

cdflib.setCompression

Purpose

Specify compression settings

Syntax

`cdflib.setCompression(cdfId,ctype,cparms)`

Description

`cdflib.setCompression(cdfId,ctype,cparms)` specifies compression settings of a Common Data Format (CDF) file.

This function sets the compression for the CDF file itself, not that of any variables in the file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

ctype

One of the following text strings, or its numeric equivalent, specifying compression type.

Text String	Compression Type
`'NO_COMPRESSION'`	No compression
`'RLE_COMPRESSION'`	Run-length encoding compression
`'HUFF_COMPRESSION'`	Huffman compression
`'AHUFF_COMPRESSION'`	Adaptive Huffman compression
`'GZIP_COMPRESSION'`	GNU's zip compression

To get the numeric equivalent, use `cdflib.getConstantValue`.

cparms

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is `'GZIP_COMPRESSION'`. For this compression type, use `cparms` to specify the level of compression as a numeric value between 1 and 9.

Examples

Create a CDF file and set the compression setting of the file. To run this example, your current folder must be writable.

```
cdfId = cdflib.create('your_file.cdf');

% Determine the file's default compression setting
[ctype, cparms, cpercent ] = cdflib.getCompression(cdfId)

ctype =

NO_COMPRESSION

cparms =

     []

cpercent =

   100

% Specify new compression setting
cdflib.setCompression(cdfId,'HUFF_COMPRESSION');

% Check the file's compression setting.
[ctype, cparms, cpercent ] = cdflib.getCompression(cdfId)

ctype =

HUFF_COMPRESSION

cparms =

OPTIMAL_ENCODING_TREES

cpercent =
```

```
     0

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

See Also

`cdflib.getCompression` | `cdflib.getConstantValue`

Tutorials

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

Purpose

Specify number of compression cache buffers

Syntax

`cdflib.setCompressionCacheSize(cdfId,numBuffers)`

Description

`cdflib.setCompressionCacheSize(cdfId,numBuffers)` specifies the number of cache buffers used for the compression scratch CDF file. For more information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` specifies the number of buffers.

Examples

Create a CDF file and specify the number of compression cache buffers used. To run this example you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');

% Get the current number of compression cache buffers
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

    80

% Set a new value
cdflib.setCompressionCacheSize(cdfId,100)

% Check the new value
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

   100

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

cdflib.setCompressionCacheSize

References

This function corresponds to the CDF library C API routine `CDFsetCompressionCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Set backward compatibility mode

Syntax

```
cdflib.getFileBackward(mode)
```

Description

`cdflib.getFileBackward(mode)` sets the backward compatibility mode to the value specified by `mode`.

Tips

- Setting backward compatibility mode affects only your current MATLAB session, or until you call `cdflib.setFileBackward` again.

Input Arguments

mode

One of the following text strings:

BACKWARDFILEon	Set backward compatibility mode on.
BACKWARDFILEoff	Set backward compatibility mode off.

Default: `BACKWARDFILEoff`

Definitions

backward compatibility mode

When specified, ensures that any new CDF file created using CDF V3.0 (or later) will be readable by clients using version 2.7 of the CDF library. CDF 3.0 and later releases use a 64-bit file offset to allow for files greater than 2G bytes in size. CDF library versions released before CDF 3.0 use a 32-bit file offset.

Examples

Set backward compatibility mode and then check the value.

```
cdflib.setFileBackward('BACKWARDFILEon');

mode = cdflib.getFileBackward

mode =

BACKWARDFILEon
```

- "Exporting to Common Data File Format (CDF) Files"
-

Purpose

Specify format of Common Data Format (CDF) file

Syntax

`cdflib.setFormat(cdfId,format)`

Description

`cdflib.setFormat(cdfId,format)` specifies the format of a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

format

Either of the following text strings, or its numeric equivalent.

'SINGLE_FILE'	The CDF consists of only one file. This is the default file format
'MULTI_FILE'	The CDF consists of one header file for control and attribute data and one additional file for each variable in the CDF.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Create a CDF file and specify its format. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('mycdffile.cdf');

% Specify multifile format.
cdflib.setFormat(cdfId, 'MULTI_FILE');

% Check format.
 format = cdflib.getFormat(cdfId)

format =
```

```
MULTI_FILE

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetFormat`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Specify majority of variables

Syntax

`cdflib.setMajority(cdfId,majority)`

Description

`cdflib.setMajority(cdfId,majority)` specifies the majority of variables in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

majority

Either of the following text strings, or its numeric equivalent.

'ROW_MAJOR'	C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default.
'COLUMN_MAJOR'	Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Create a CDF file and specify the majority used by variables in the file. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf')

% Specify the majority used by variables in the file
cdflib.setMajority(cdfId,'COLUMN_MAJOR');

% Check the majority value
majority = cdflib.getMajority(cdfId)
```

```
majority =

COLUMN_MAJOR

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetMajority`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Specify read-only mode

Syntax

`cdflib.setReadOnlyMode(cdfId,mode)`

Description

`cdflib.setReadOnlyMode(cdfId,mode)` specifies the read-only mode of a Common Data Format (CDF) file.

After you open a CDF file, you can put the file into read-only mode to prevent accidental modification.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

mode

Either of the following text strings or its numeric equivalent.

'READONLYon'	CDF file is read-only
'READONLYoff'	CDF file is modifiable.

To get the numeric equivalent of these mode values, use `cdflib.getConstantValue`.

Examples

Open the example CDF file and set the file to read-only mode.

```
cdfId = cdflib.open('example.cdf');

% Set the  file to READONLY mode
cdflib.setReadOnlyMode(cdfId,'READONLYon')

% Check read-only status of file again.
mode = cdflib.getReadOnlyMode(cdfId)

mode =

READONLYon
```

```
% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetReadOnlyMode`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

- "Exporting to Common Data File Format (CDF) Files"

Purpose Specify number of staging cache buffers for Common Data Format (CDF) file

Syntax

```
cdflib.setStageCacheSize(cdfId,numBuffers)
```

Description `cdflib.setStageCacheSize(cdfId,numBuffers)` specifies the number of staging cache buffers for a Common Data Format (CDF) file. For information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

Examples Open the example CDF file and specify the number of cache buffers used.

```
cdfId = cdflib.open('example.cdf');

% Get current number of staging cache buffers
size = cdflib.getStageCacheSize(cdfId)

size =

   125

% Specify new cache size value.
cdflib.setStageCacheSize(cdfId, 200)

% Get size again.
size = cdflib.getStageCacheSize(cdfId)

size =

   200

% Clean up
cdflib.close(cdfId)
```

```
clear cdfId
```

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Specify library validation mode

Syntax

`cdflib.setValidate(mode)`

Description

`cdflib.setValidate(mode)` specifies the validation mode of the Common Data Format (CDF) library. Specify the validation mode before opening any files.

Input Arguments

mode

Either of the following text strings, or its numeric equivalent:

'VALIDATEFILEon'	Turns validation mode on. With validation mode on, the library performs sanity checks on the data fields in the CDF' file's internal data structures to make sure that the values are within valid ranges and consistent with the defined values/types/entries. This mode also ensures that variable and attribute associations within the file are valid. Note, however, that enabling this mode will, in most cases, slow down the file opening process, especially for large or very fragmented files.
'VALIDATEFILEoff'	Turns validation mode off.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Set the validation mode of the CDF library.

```
cdflib.setValidate('VALIDATEFILEon');
```

References

This function corresponds to the CDF library C API routine `CDFsetValidate`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Specify range of records to be allocated for variable

Syntax

```
cdflib.setVarAllocBlockRecords(cdfId,varNum,firstrec,lastrec)
```

Description

`cdflib.setVarAllocBlockRecords(cdfId,varNum,firstrec,lastrec)` specifies a range of records you want to allocate (but not write) for a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

firstRec

Numeric value identifying the record at which to start allocating. Record numbers are zero-based.

lastRec

Numeric value identifying the record at which to stop allocating. Record numbers are zero-based.

Examples

Create a CDF, create a variable in the CDF, and then specify the number of records to allocate for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);

% Specify the number of records to allocate.
```

```
cdflib.setVarAllocBlockRecords(cdfid,varNum,1,10);

%  Clean up
cdflib.delete(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarAllocBlockRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Specify blocking factor for variable

Syntax

```
cdflib.setVarBlockingFactor(cdfId,varNum,blockingFactor)
```

Description

`cdflib.setVarBlockingFactor(cdfId,varNum,blockingFactor)` specifies the blocking factor for a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable numbers are zero-based.

blockingFactor

Numeric value that specifies the number of records to allocate when writing to an unallocated record.

Definitions

blocking factor

A variable's *blocking factor* specifies the minimum number of records the library allocates when you write to an unallocated record. If you specify a fractional blocking factor, the library rounds the value down.

Examples

Create a CDF, create a variable in the CDF, and then set the blocking factor used with the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);
```

```
% Get the current blocking factor used with the variable
bFactor = cdflib.getVarBlockingFactor(cdfid,varNum)

bFactor =

    0

% Change the blocking factor for the variable
cdflib.setVarBlockingFactor(cdfid,varNum,10);

% Check the new blocking factor .
bFactor = cdflib.getVarBlockingFactor(cdfid,varNum)

bFactor =

    10

%  Clean up
cdflib.delete(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarBlockingFactor`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

- "Exporting to Common Data File Format (CDF) Files"

Purpose

Specify number of multi-file cache buffers for variable

Syntax

`cdflib.setVarCacheSize(cdfId,varNum,numBuffers)`

Description

`cdflib.setVarCacheSize(cdfId,varNum,numBuffers)` specifies the number of cache buffers the CDF library uses for a variable in a Common Data Format (CDF) file.

This function is only used with multifile format CDF files. It does not apply to single-file format CDFs. For more information about caching, see the *CDF User's Guide*.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

numBuffers

Numeric value identifying the number of cache buffers to use.

Examples

Create a multifile CDF, and then retrieve the number of buffers being used for a variable:

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
```

```
ls your_file.*

your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     1

% Increase the number of cache buffers used.
cdflib.setVarCacheSize(cdfid,varNum,5)

% Check the number of cache buffers used with the variable.
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     5

%  Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

cdflib.setVarCompression

Purpose

Specify compression settings used with variable

Syntax

```
cdflib.setVarCompression(cdfId,varNum,ctype,cparams)
```

Description

`cdflib.setVarCompression(cdfId,varNum,ctype,cparams)` configures the compression setting for a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

ctype

One of the following text strings, or its numeric equivalent, specifying the compression type.

Text String	Compression Type
'NO_COMPRESSION'	No compression.
'RLE_COMPRESSION'	Run-length encoding compression
'HUFF_COMPRESSION'	Huffman compression
'AHUFF_COMPRESSION'	Adaptive Huffman compression
'GZIP_COMPRESSION'	GNU's zip compression

cparams

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is `'GZIP_COMPRESSION'`. For this compression type,

you use `cparms` to specify the level of compression as a numeric value between 1 and 9.

Examples

Create a CDF, create a variable, and then set the compression used by the variable. To run this example, you must be in a folder with execute permission.

```
cdfid = cdflib.create('mycdf.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Specify the compression used by the variable.
cdflib.setVarCompression(cdfid,0,'GZIP_COMPRESSION',8)

% Check the compression setting of the variable
[ctype params percent] = cdflib.getVarCompression(cdfid,0)

ctype =

GZIP_COMPRESSION

params =

     8

percent =

     0

% Clean up
cdflib.delete(cdfid);
clear cdfid
```

Purpose

Specify initial number of records written to variable

Syntax

`cdflib.setVarInitialRecs(cdfId,varNum,numrecs)`

Description

`cdflib.setVarInitialRecs(cdfId,varNum,numrecs)` specifies the initial number of records to write to a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable numbers are zero-based.

numRecs

Numeric value specifying the number of records to write.

Examples

Create a CDF, create a variable, and then specify the number of records to write for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);

% Specify the number of records to write for the variable
cdflib.setVarInitialRecs(cdfid,varNum,100);

recsWritten = cdflib.getVarNumRecsWritten(cdfid,varNum)

recsWritten =
```

```
   100

%  Clean up
cdflib.delete(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarInitialRecs`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Purpose

Specify pad value used with variable

Syntax

```
cdflib.setVarPadValue(cdfId,varNum,padvalue)
```

Description

`cdflib.setVarPadValue(cdfId,varNum,padvalue)` specifies the pad value used with a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable numbers are zero-based.

padValue

Value to use a pad value for the variable. The data type of the pad value must match the data type of the variable.

Examples

Create a CDF, create a variable in the CDF, and then set the pad value used with the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Get the current pad value used with the variable
padval = cdflib.getVarPadValue(cdfid,varNum)

padval =

    0
```

```
% Change the pad value for the variable
cdflib.setVarPadValue(cdfid,varNum,int8(1));

% Check the new pad value.
padval = cdflib.getVarPadValue(cdfid,varNum)

padval =

    1

%  Clean up
cdflib.delete(cdfid)

clear cdfid
```

cdflib.SetVarReservePercent

Purpose

Specify reserve percentage for variable

Syntax

```
cdflib.setVarReservePercent(cdfId,varNum,percent)
```

Description

`cdflib.setVarReservePercent(cdfId,varNum,percent)` specifies the compression reserve percentage for a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

percent

Numeric value specifying the amount of extra space to allocate for a compressed variable, experssed as a percentage. You can specify values between`0` (no extra space is reserved) and `100`, or values greater than `100`. The value specifies the percentage of the uncompressed size of the variable. If you specify a fractional reserve percentages, the library rounds the value down.

Definitions

reserve percentage

Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space.

Examples

Create a CDF, create a variable, set the compression of the variable, and then set the reserve percent for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Set the compression of the variable.
cdflib.setVarCompression(cdfid,varNum,'GZIP_COMPRESSION',8);

% Set the compression reserver percentage
cdflib.setVarReservePercent(cdfid,varNum, 80);

cdflib.close(cdfid);
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarReservePercent`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

For copyright information, see the `cdfcopyright.txt` file.

- “Exporting to Common Data File Format (CDF) Files”

Purpose

Specify number of cache buffers used for all variables

Syntax

`cdflib.setVarsCacheSize(cdfId,varNum,numBuffers)`

Description

`cdflib.setVarsCacheSize(cdfId,varNum,numBuffers)` specifies the number of cache buffers the CDF library uses for all the variables in the multifile format Common Data Format (CDF) file.

This function is not applicable to single-file CDFs. For more information about caching, see the *CDF User's Guide*.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

numBuffers

Numeric value specifying the cache buffers.

Examples

Create a multifile CDF and specify the number of buffers used for all variables. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*
```

```
your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     1

% Specify the number of cache buffers used by all variables in CDF.
cdflib.setVarsCacheSize(cdfid,6)

% Check the number of cache buffers used with the variable.
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     6

%  Clean up
cdflib.delete(cdfid);

clear cdfid
```

Tutorials

- "Importing Common Data File Format (CDF) Files"
- "Exporting to Common Data File Format (CDF) Files"

Purpose

Specify how variable handles sparse records

Syntax

`cdflib.getVarSparseRecords(cdfId,varNum,stype)`

Description

`cdflib.getVarSparseRecords(cdfId,varNum,stype)` specifies the sparse records type of a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Number that identifies the variable to be set. Variable numbers are zero-based.

stype

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

Text String	Description
'NO_SPARSERECORDS'	No sparse records
'PAD_SPARSERECORDS'	For sparse records, the library uses the variable's pad value when reading values from a missing record.
'PREV_SPARSERECORDS'	For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value.

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

Examples

Open a multifile CDF and close a variable.

Create a CDF, create a variable, and set the sparse records type of the variable. To run this example you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Set the sparse records type of the variable
cdflib.setVarSparseRecords(cdfid,varNum,'PAD_SPARSERECORDS');

% Check the sparse records type of the variable
stype = cdflib.getVarSparseRecords(cdfid,varNum)

stype =

PAD_SPARSERECORDS

%Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarSparseRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the `CDF Web site`.

Tutorials

- "Importing Common Data File Format (CDF) Files"
- "Exporting to Common Data File Format (CDF) Files"

Purpose

Read data from Common Data Format (CDF) file

Syntax

```
data = cdfread(filename)
data = cdfread(filename, param1, val1, param2, val2, ...)
[data, info] = cdfread(filename, ...)
```

Description

`data = cdfread(filename)` reads all the data from the Common Data Format (CDF) file specified in the string `filename`. CDF data sets typically contain a set of variables, of a specific data type, each with an associated set of records. The variable might represent time values with each record representing a specific time that an observation was recorded. `cdfread` returns all the data in a cell array where each column represents a variable and each row represents a record associated with a variable. If the variables have varying numbers of associated records, `cdfread` pads the rows to create a rectangular cell array, using pad values defined in the CDF file.

Note Because `cdfread` creates temporary files, the current working directory must be writeable.

`data = cdfread(filename, param1, val1, param2, val2, ...)` reads data from the file, where *param1*, *param2*, and so on, can be any of the parameters listed in the following table.

`[data, info] = cdfread(filename, ...)` returns details about the CDF file in the `info` structure.

Parameter	Value
'Records'	A vector specifying which records to read. Record numbers are zero-based. `cdfread` returns a cell array with the same number of rows as the number of records read and as many columns as there are variables.
'Variables'	A 1-by-*n* or *n*-by-1 cell array specifying the names of the variables to read from the file. *n* must be less than or equal to the total number of variables in the file. `cdfread` returns a cell array with the same number of columns as the number of variables read, and a row for each record read.
'Slices'	An *m*-by-3 array, where each row specifies where to start reading along a particular dimension of a variable, the skip interval to use on that dimension (every item, every other item, etc.), and the total number of values to read on that dimension. *m* must be less than or equal to the number of dimensions of the variable. If *m* is less than the total number of dimensions, `cdfread` reads every value from the unspecified dimensions (`[0 1 n]`, where *n* is the total number of elements in the dimension. Note: Because the `'Slices'` parameter describes how to process a single variable, it must be used in conjunction with the `'Variables'` parameter.
'ConvertEpochToDatenum'	A Boolean value that determines whether `cdfread` automatically converts CDF epoch data types to MATLAB serial date numbers. If set to `false` (the default), `cdfread` wraps epoch values in MATLAB `cdfepoch` objects. Note: For better performance when reading large data sets, set this parameter to `true`.
'CombineRecords'	A Boolean value that determines how `cdfread` returns the CDF data sets read from the file. If set to `false` (the default), `cdfread` stores the data in an *m*-by-*n* cell array, where *m* is the number of records and *n* is the number of variables requested. If set to `true`, `cdfread` combines

Parameter	Value
	all records for a particular variable into one cell in the output cell array. In this cell, `cdfread` stores scalar data as a column array. `cdfread` extends the dimensionality of nonscalar and string data. For example, instead of creating 1000 elements containing 20-by-30 arrays for each record, `cdfread` stores all the records in one cell as a 1000-by-20-by-30 array Note: If you use the `'Records'` parameter to specify which records to read, you cannot use the `'CombineRecords'` parameter. Note: When using the `'Variable'` parameter to read one variable, if the `'CombineRecords'` parameter is `true`, `cdfread` returns the data as an M-by-N numeric or character array; it does not put the data into a cell array.

Note To improve performance when working with large data files, use the `'ConvertEpochToDatenum'` and `'CombineRecords'` options.

Note To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see `cdflib.setValidate`.

Examples

Read all the data from a CDF file.

```
data = cdfread('example.cdf');
```

Read the data from the variable `'Time'`.

```
data = cdfread('example.cdf', 'Variable', {'Time'});
```

Read the first value in the first dimension, the second value in the second dimension, the first and third values in the third dimension, and all values in the remaining dimension of the variable `'multidimensional'`.

```
data = cdfread('example.cdf', ...
               'Variable', {'multidimensional'}, ...
               'Slices', [0 1 1; 1 1 1; 0 2 2]);
```

This is similar to reading the whole variable into `data` and then using matrix indexing, as in the following.

```
data{1}(1, 2, [1 3], :)
```

Collapse the records from a data set and convert CDF epoch data types to MATLAB serial date numbers.

```
data = cdfread('example.cdf', ...
               'CombineRecords', true, ...
               'ConvertEpochToDatenum', true);
```

How To

- "Importing Common Data File Format (CDF) Files"

Purpose

Write data to Common Data Format (CDF) file

Note `cdfwrite` is not recommended. Use the `cdflib` low-level functions instead.

Syntax

```
cdfwrite(filename,variablelist)
cdfwrite(...,'PadValues',padvals)
cdfwrite(...,'GlobalAttributes',gattrib)
cdfwrite(..., 'VariableAttributes', vattrib)
cdfwrite(...,'WriteMode',mode)
cdfwrite(...,'Format',format)
```

Description

`cdfwrite(filename,variablelist)` writes out a Common Data Format (CDF) file, specified in `filename`. The `filename` input is a string enclosed in single quotes. The `variablelist` argument is a cell array of ordered pairs, each of which comprises a CDF variable name (a string) and the corresponding CDF variable value. To write out multiple records for a variable, put the values in a cell array where each element in the cell array represents a record.

Note Because `cdfwrite` creates temporary files, both the destination directory for the file and the current working directory must be writeable.

`cdfwrite(...,'PadValues',padvals)` writes out pad values for given variable names. `padvals` is a cell array of ordered pairs, each of which comprises a variable name (a string) and a corresponding pad value. Pad values are the default values associated with the variable when an out-of-bounds record is accessed. Variable names that appear in `padvals` must appear in `variablelist`.

`cdfwrite(...,'GlobalAttributes',gattrib)` writes the structure `gattrib` as global metadata for the CDF file. Each field of the structure

is the name of a global attribute. The value of each field contains the value of the attribute. To write out multiple values for an attribute, put the values in a cell array where each element in the cell array represents a record.

Note To specify a global attribute name that is invalid in your MATLAB application, create a field called `'CDFAttributeRename'` in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `GlobalAttributes` structure, and the corresponding name of the attribute to be written to the CDF file.

`cdfwrite(..., 'VariableAttributes', vattrib)` writes the structure `vattrib` as variable metadata for the CDF. Each field of the struct is the name of a variable attribute. The value of each field should be an M-by-2 cell array where M is the number of variables with attributes. The first element in the cell array should be the name of the variable and the second element should be the value of the attribute for that variable.

Note To specify a variable attribute name that is illegal in MATLAB, create a field called `'CDFAttributeRename'` in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `VariableAttributes` struct, and the corresponding name of the attribute to be written to the CDF file. If you are specifying a variable attribute of a CDF variable that you are renaming, the name of the variable in the `VariableAttributes` structure must be the same as the renamed variable.

`cdfwrite(...,'WriteMode',`*`mode`*`)`, where *`mode`* is either `'overwrite'` or `'append'`, indicates whether or not the specified variables should be

appended to the CDF file if the file already exists. By default, `cdfwrite` overwrites existing variables and attributes.

`cdfwrite(...,'Format',`*`format`*`)`, where *`format`* is either `'multifile'` or `'singlefile'`, indicates whether or not the data is written out as a multifile CDF. In a multifile CDF, each variable is stored in a separate file with the name `*.vN`, where `N` is the number of the variable that is written out to the CDF. By default, `cdfwrite` writes out a single file CDF. When `'WriteMode'` is set to `'Append'`, the `'Format'` option is ignored, and the format of the preexisting CDF is used.

Examples

Write out a file `'example.cdf'` containing a variable `'Longitude'` with the value `[0:360]`.

```
cdfwrite('example', {'Longitude', 0:360});
```

Write out a file `'example.cdf'` containing variables `'Longitude'` and `'Latitude'` with the variable `'Latitude'` having a pad value of 10 for all out-of-bounds records that are accessed.

```
cdfwrite('example', {'Longitude', 0:360, 'Latitude', 10:20}, ...
        'PadValues', {'Latitude', 10});
```

Write out a file `'example.cdf'`, containing a variable `'Longitude'` with the value `[0:360]`, and with a variable attribute of `'validmin'` with the value 10.

```
varAttribStruct.validmin = {'Longitude' [10]};
cdfwrite('example', {'Longitude' 0:360}, 'VariableAttributes', ...
        varAttribStruct);
```

`cdfread` | `cdfinfo` | `cdfepoch`

ceil

Purpose

Round toward positive infinity

Syntax

```
B = ceil(A)
```

Description

`B = ceil(A)` rounds the elements of `A` to the nearest integers greater than or equal to `A`. For complex `A`, the imaginary and real parts are rounded independently.

Examples

```
a = [-1.9, -0.2, 3.4, 5.6, 7, 2.4+3.6i]

a =
  Columns 1 through 4
  -1.9000        -0.2000        3.4000        5.6000

  Columns 5 through 6
   7.0000        2.4000 + 3.6000i

ceil(a)

ans =
  Columns 1 through 4
  -1.0000        0              4.0000        6.0000

  Columns 5 through 6
   7.0000        3.0000 + 4.0000i
```

See Also

`fix` | `floor` | `round`

Purpose

Create cell array

Syntax

```
C = cell(dim)
C = cell(dim1,...,dimN)
D = cell(obj)
```

Description

`C = cell(dim)` creates a cell array of empty matrices. If `dim` is a scalar, `C` is `dim`-by-`dim`. If `dim` is a vector, `C` is `dim(1)`-by-...-`dim(N)`, where `N` is the number of elements of `dim`.

`C = cell(dim1,...,dimN)` creates cell array `C`, where `C` is `dim1`-by-...-`dimN`.

`D = cell(obj)` converts a Java array or .NET array of `System.String` or `System.Object` into a MATLAB cell array.

Tips

Creating an empty array with the `cell` function, such as

```
C = cell(3,4,2);
```

is exactly equivalent to assigning an empty array to the last index of a new cell array:

```
C{3,4,2} = [];
```

Input Arguments

dim

Scalar integer or vector of integers that specifies the dimensions of cell array `C`.

dim1,...,dimN

Scalar integers that specify the dimensions of `C`.

obj

One of the following:

- Java array or object
- .NET array of type `System.String` or `System.Object`

Output Arguments

C

Cell array. Each cell contains an empty, 0-by-0 array of type `double`.

D

Cell array. Each cell contains a MATLAB type closest to the Java or .NET type. For more information, see:

- “Conversion of Java Return Types”
- “.NET Type to MATLAB Type Mapping”

Examples

Create an empty 3-by-4-by-2 cell array.

```
mycell = cell(3,4,2);
```

Create a cell array that is the same size as `mycell`, created in the previous example.

```
similar = cell(size(mycell));
```

Convert an array of `java.lang.String` objects into a MATLAB cell array.

```
strArray = java_array('java.lang.String', 3);
strArray(1) = java.lang.String('one');
strArray(2) = java.lang.String('two');
strArray(3) = java.lang.String('three');

cellArray = cell(strArray)
```

This code returns

```
cellArray =
    'one'
    'two'
```

```
    'three'
```

Create a cell array of folders in the `c:\work` folder, using the .NET Framework `System.IO.Directory` class :

```
myList = cell(System.IO.Directory.GetDirectories('c:\work'));
celldisp(myList)
```

`num2cell` | `ones` | `rand` | `randn` | `zeros`

How To

- "Access Data in a Cell Array"

cell2mat

Purpose Convert cell array to numeric array

Syntax

```
A= cell2mat(C)
```

Description

`A= cell2mat(C)` converts cell array `C` with contents of the same data type into a single array, `A`.

Input Arguments

C

Cell array, where each cell contains the same type of data. The `cell2mat` function accepts numeric or character data within cells of `C`, but not structs, objects, or nested cells.

The contents of `C` must support concatenation into a hyperrectangle. Otherwise, the results are undefined. For example, the contents of cells in the same column must have the same number of columns, although they need not have the same number of rows.

10x25 10x25
20x25 20x25
30x25 30x25
cell2mat
60x50

Output Arguments

A

Array of the same type as the contents of the cells of `C`. The number of dimensions of `A` matches the highest number of dimensions of arrays within `C`.

Examples

Combine matrices in the four cells of cell array `c` into matrix `m`.

```
c = {[1],    [2, 3, 4];
     [5; 9], [6, 7, 8; 10, 11, 12]};

m = cell2mat(c)
```

`m` is a 3-by-4 matrix:

```
m =
     1     2     3     4
     5     6     7     8
     9    10    11    12
```

See Also

`mat2cell` | `num2cell`

cell2struct

Purpose

Convert cell array to structure array

Syntax

`structArray = cell2struct(cellArray, fields, dim)`

Description

`structArray = cell2struct(cellArray, fields, dim)` creates a structure array, `structArray`, from the information contained within cell array `cellArray`.

The `fields` argument specifies field names for the structure array. This argument is an array of strings or a cell array of strings.

The `dim` argument tells MATLAB which axis of the cell array to use in creating the structure array. Use a numeric `double` to specify `dim`.

To create a structure array with fields derived from `N` rows of a cell array, specify `N` field names in the `fields` argument, and the number 1 in the `dim` argument. To create a structure array with fields derived from `M` columns of a cell array, specify `M` field names in the `fields` argument and the number 2 in the `dim` argument.

The `structArray` output is a structure array with `N` fields, where `N` is equal to the number of fields in the `fields` input argument. The number of fields in the resulting structure must equal the number of cells along dimension `dim` that you want to convert.

Examples

Create the following table for use with the examples in this section. The table lists information about the employees of a small Engineering company. Reading the table by rows shows the names of employees by department. Reading the table by columns shows the number of years each employee has worked at the company.

	5 Years	10 Years	15 Years
Development	Lee, Reed, Hill	Dean, Frye	Lane, Fox, King
Sales	Howe, Burns	Kirby, Ford	Hall
Management	Price	Clark, Shea	Sims

	5 Years	10 Years	15 Years
Quality	Bates, Gray	Nash	Kay, Chase
Documentation	Lloyd, Young	Ryan, Hart, Roy	Marsh

Enter the following commands to create the initial cell array `employees`:

```
devel = {{'Lee','Reed','Hill'}, {'Dean','Frye'}, ...
   {'Lane','Fox','King'}};
sales = {{'Howe','Burns'}, {'Kirby','Ford'}, {'Hall'}};
mgmt = {{'Price'}, {'Clark','Shea'}, {'Sims'}};
qual = {{'Bates','Gray'}, {'Nash'}, {'Kay','Chase'}};
docu = {{'Lloyd','Young'}, {'Ryan','Hart','Roy'}, {'Marsh'}};

employees = [devel; sales; mgmt; qual; docu]
employees =
    {1x3 cell}    {1x2 cell}    {1x3 cell}
    {1x2 cell}    {1x2 cell}    {1x1 cell}
    {1x1 cell}    {1x2 cell}    {1x1 cell}
    {1x2 cell}    {1x2 cell}    {1x2 cell}
    {1x2 cell}    {1x2 cell}    {1x1 cell}
```

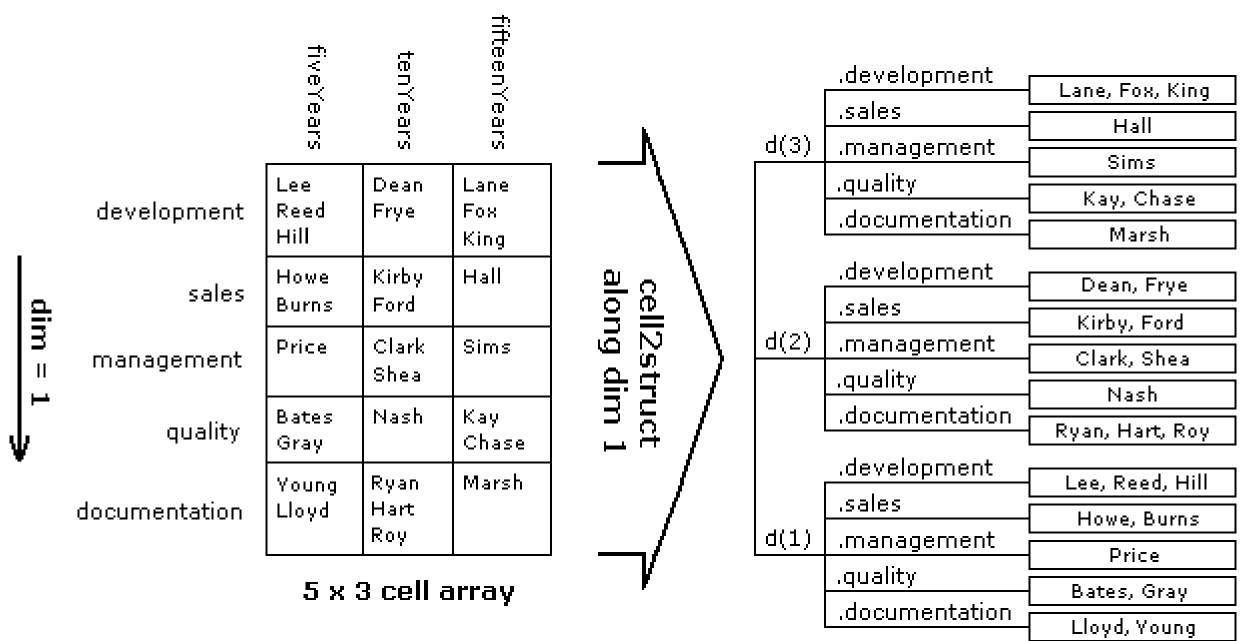
This is the resulting cell array:

	fiveYears	tenYears	fifteenYears
development	Lee Reed Hill	Dean Frye	Lane Fox King
sales	Howe Burns	Kirby Ford	Hall
management	Price	Clark Shea	Sims
quality	Bates Gray	Nash	Kay Chase
documentation	Young Lloyd	Ryan Hart Roy	Marsh

5 x 3 cell array

Convert the cell array to a struct along dimension 1:

1. Convert the 5-by-3 cell array along its first dimension to construct a 3-by-1 struct array with 5 fields. Each of the rows along dimension 1 of the cell array becomes a field in the struct array:



Traversing the first (i.e., vertical) dimension, there are 5 rows with row headings that read as follows:

```
rowHeadings = {'development', 'sales', 'management', ...
   'quality', 'documentation'};
```

2 Convert the cell array to a struct array, `depts`, in reference to this dimension:

```
depts = cell2struct(employees, rowHeadings, 1)
depts =
3x1 struct array with fields:
    development
    sales
```

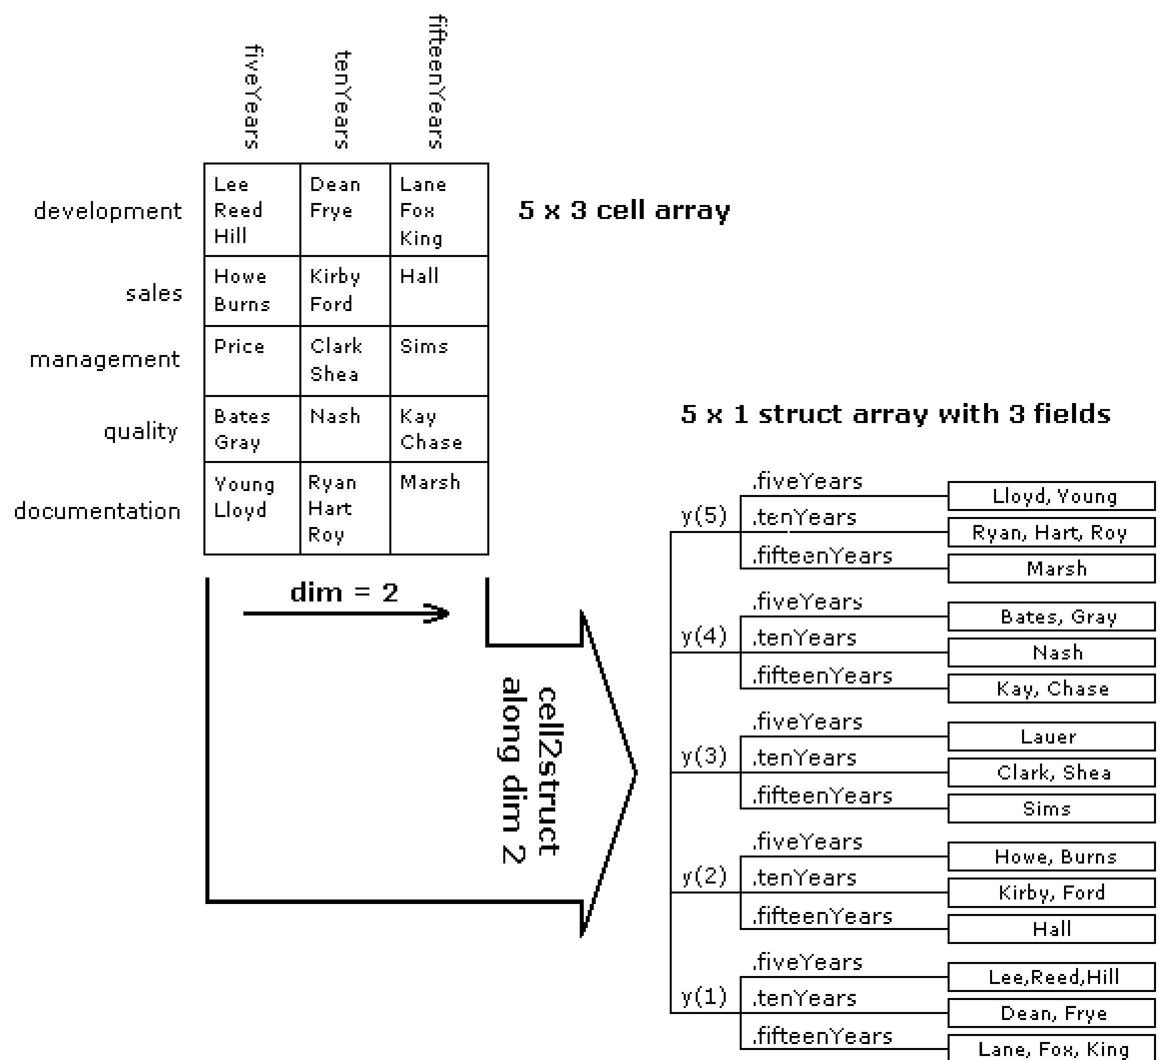
```
management
quality
documentation
```

3 Use this row-oriented structure to find the names of the Development staff who have been with the company for up to 10 years:

```
depts(1:2).development
ans =
    'Lee'    'Reed'    'Hill'
ans =
    'Dean'    'Frye'
```

Convert the same cell array to a struct along dimension 2:

1 Convert the 5-by-3 cell array along its second dimension to construct a 5-by-1 struct array with 3 fields. Each of the columns along dimension 2 of the cell array becomes a field in the struct array:



fiveYears
tenYears
fifteenYears
development
sales
management
quality
documentation
Lee
Reed
Hill
Dean
Frye
Lane
Fox
King
Howe
Burns
Kirby
Ford
Hall
Price
Clark
Shea
Sims
Bates
Gray
Nash
Kay
Chase
Young
Lloyd
Ryan
Hart
Roy
Marsh
5 x 3 cell array
dim = 2
cell2struct
along dim 2
5 x 1 struct array with 3 fields
y(5)
y(4)
y(3)
y(2)
y(1)
.fiveYears
.tenYears
.fifteenYears
Lloyd, Young
Ryan, Hart, Roy
Marsh
Bates, Gray
Nash
Kay, Chase
Lauer
Clark, Shea
Sims
Howe, Burns
Kirby, Ford
Hall
Lee,Reed,Hill
Dean, Frye
Lane, Fox, King

2 Traverse the cell array along the second (or horizontal) dimension. The column headings become fields of the resulting structure:

```
colHeadings = {'fiveYears' 'tenYears' 'fifteenYears'};

years = cell2struct(employees, colHeadings, 2)
years =
5x1 struct array with fields:
    fiveYears
    tenYears
    fifteenYears
```

3 Using the column-oriented structure, show how many employees from the Sales and Documentation departments have worked for the company for at least 5 years:

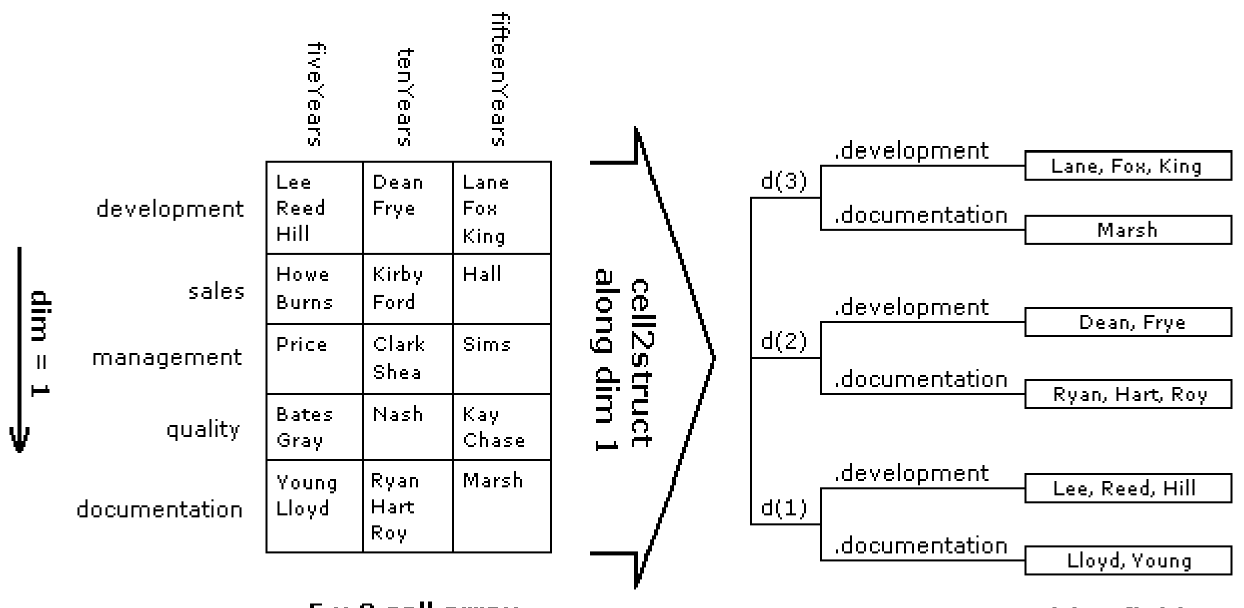
```
[~, sales_5years, ~, ~, docu_5years] = years.fiveYears
sales_5years =
    'Howe'    'Burns'
docu_5years =
    'Lloyd'    'Young'
```

Convert only part of the cell array to a struct:

1 Convert only the first and last rows of the cell array. This results in a 3-by-1 struct array with 2 fields:

```
rowHeadings = {'development', 'documentation'};

depts = cell2struct(employees([1,5],:), rowHeadings, 1)
depts =
3x1 struct array with fields:
    development
    documentation
```



2 Display those employees who belong to these departments for all three periods of time:

```
for k=1:3
   depts(k,:)
end

ans =
      development: {'Lee'   'Reed'   'Hill'}
    documentation: {'Lloyd'   'Young'}
ans =
      development: {'Dean'   'Frye'}
    documentation: {'Ryan'   'Hart'   'Roy'}
ans =
      development: {'Lane'   'Fox'   'King'}
```

```
documentation: {'Marsh'}
```

`struct2cell` | `cell` | `iscell` | `struct` | `isstruct` | `fieldnames`

How To

- dynamic field names

celldisp

Purpose

Cell array contents

Syntax

```
celldisp(C)
celldisp(C, name)
```

Description

`celldisp(C)` recursively displays the contents of a cell array.

`celldisp(C, name)` uses the string *name* for the display instead of the name of the first input (or `ans`).

Examples

Use `celldisp` to display the contents of a 2-by-3 cell array:

```
C = {[1 2] 'Tony' 3+4i; [1 2;3 4] -5 'abc'};
celldisp(C)

C{1,1} =
     1     2

C{2,1} =
     1     2
     3     4

C{1,2} =
Tony

C{2,2} =
    -5

C{1,3} =
   3.0000+ 4.0000i

C{2,3} =
abc
```

See Also

`cellplot`

How To

- "Exporting a Cell Array to a Text File"

Purpose

Apply function to each cell in cell array

Syntax

```
[A1,...,Am] = cellfun(func,C1,...,Cn)
[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)
```

Description

`[A1,...,Am] = cellfun(func,C1,...,Cn)` calls the function specified by function handle `func` and passes elements from cell arrays `C1,...,Cn`, where `n` is the number of inputs to function `func`. Output arrays `A1,...,Am`, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The `i`th iteration corresponds to the syntax `[A1(i),...,Am(i)] = func(C{i},...,Cn{i})`. The `cellfun` function does not perform the calls to function `func` in a specific order.

`[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

Input Arguments

func

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

Backward Compatibility

`cellfun` accepts function name strings for function `func`, rather than a function handle, for these function names: `isempty`, `islogical`, `isreal`, `length`, `ndims`, `prodofsize`, `size`, `isclass`. Enclose the function name in single quotes.

If you specify a function name string rather than a function handle:

- `cellfun` does not call any overloaded versions of the function.

- The `size` and `isclass` functions require additional inputs to the `cellfun` function:

  `A = cellfun('size', C, k)` returns the size along the `k`th dimension of each element of `C`.

  `A = cellfun('isclass', C, classname)` returns logical `1` (`true`) for each element of `C` that matches the `classname` string. This syntax returns logical 0 (`false`) for objects that are a subclass of `classname`.

C1,...,Cn

Cell arrays that contain the `n` inputs required for function `func`. Each cell array must have the same dimensions.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'UniformOutput'

Logical value, as follows:

`true (1)`	Indicates that for all inputs, each output from function `func` is a cell array or a scalar value that is always of the same type. The `cellfun` function combines the outputs in arrays `A1,...,Am`, where `m` is the number of function outputs. Each output array is of the same type as the individual function outputs.
`false (0)`	Requests that the `cellfun` function combine the outputs into cell arrays `A1,...,Am`. The outputs of function `func` can be of any size or type.

Default: `true`

'ErrorHandler'

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

`identifier`	Error identifier.
`message`	Error message text.
`index`	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

Output Arguments

A1,...,Am

Arrays that collect the `m` outputs from function `func`. Each array `A` is the same size as each of the inputs `C1,...,Cn`.

Function `func` can return output arguments of different classes. However, if `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

Examples

Compute the mean of each vector in cell array `C`.

```
C = {1:10, [2; 4; 6], []};

averages = cellfun(@mean, C)
```

This code returns

```
averages =
    5.5000    4.0000       NaN
```

Compute the size of each array in `C`, created in the previous example.

```
[nrows, ncols] = cellfun(@size, C)
```

This code returns

```
nrows =
     1     3     0
ncols =
    10     1     0
```

Create a cell array that contains strings, and abbreviate those strings to the first three characters. Because the output strings are nonscalar, set `UniformOutput` to `false`.

```
days = {'Monday', 'Tuesday', 'Wednesday', 'Thursday', 'Friday'};

abbrev = cellfun(@(x) x(1:3), days, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
abbrev =
    'Mon'    'Tue'    'Wed'    'Thu'    'Fri'
```

Compute the covariance between arrays in two cell arrays `C` and `D`. Because the covariance output is nonscalar, set `UniformOutput` to `false`.

```
c1 = rand(5,1);  c2 = rand(10,1);  c3 = rand(15,1);
d1 = rand(5,1);  d2 = rand(10,1);  d3 = rand(15,1);
```

```
C = {c1, c2, c3};
D = {d1, d2, d3};

covCD = cellfun(@cov, C, D, 'UniformOutput', false)
```

This code returns

```
covCD =
    [2x2 double]    [2x2 double]    [2x2 double]
```

Define and call a custom error handling function.

```
function result = errorfun(S, varargin)
   warning(S.identifier, S.message);
   result = NaN;
end

A = {rand(3)};
B = {rand(5)};
AgtB = cellfun(@(x,y) x > y, A, B, 'ErrorHandler', @errorfun, ...
               'UniformOutput', false)
```

See Also

arrayfun | spfun | function_handle | cell2mat

Tutorials

- “Anonymous Functions”

Purpose

Graphically display structure of cell array

Syntax

```
cellplot(c)
cellplot(c, 'legend')
handles = cellplot(c)
```

Description

`cellplot(c)` displays a figure window that graphically represents the contents of `c`. Filled rectangles represent elements of vectors and arrays, while scalars and short text strings are displayed as text.

`cellplot(c, 'legend')` places a colorbar next to the plot labelled to identify the data types in `c`.

`handles = cellplot(c)` displays a figure window and returns a vector of surface handles.

Limitations

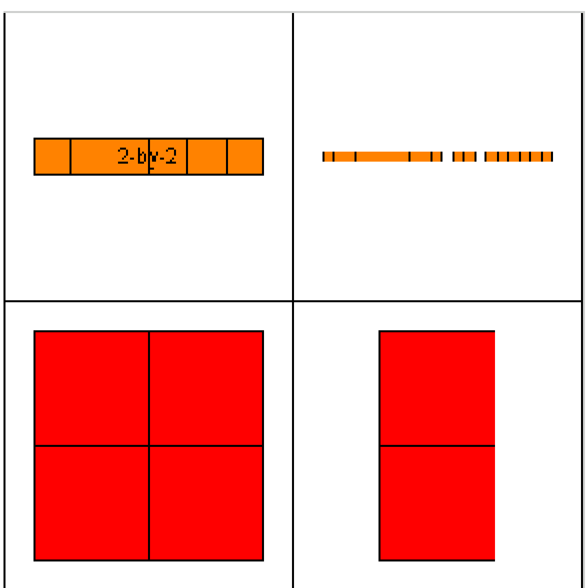
The `cellplot` function can display only two-dimensional cell arrays.

Examples

Consider a 2-by-2 cell array containing a matrix, a vector, and two text strings:

```
c{1,1} = '2-by-2';
c{1,2} = 'eigenvalues of eye(2)';
c{2,1} = eye(2);
c{2,2} = eig(eye(2));
```

The command `cellplot(c)` produces



See Also

`celldisp`

How To

- "Editing Plots"
- "Exporting a Cell Array to a Text File"

Purpose

Create cell array of strings from character array

Syntax

```
c = cellstr(S)
```

Description

`c = cellstr(S)` places each row of the character array `S` into separate cells of `c`. Any trailing spaces in the rows of `S` are removed.

Use the `char` function to convert back to a string matrix.

Examples

Given the string matrix

```
S = ['abc '; 'defg'; 'hi  ']

S =
    abc
    defg
    hi

whos S
  Name      Size         Bytes  Class
  S         3x4             24  char array
```

The following command returns a 3-by-1 cell array.

```
c = cellstr(S)

c =
    'abc'
    'defg'
    'hi'

whos c
  Name      Size         Bytes  Class
  c         3x1            198  cell array
```

See Also

`iscellstr` | `strings` | `char` | `isstrprop` | `strsplit`

Purpose

Conjugate gradients squared method

Syntax

```
x = cgs(A,b)
cgs(A,b,tol)
cgs(A,b,tol,maxit)
cgs(A,b,tol,maxit,M)
cgs(A,b,tol,maxit,M1,M2)
cgs(A,b,tol,maxit,M1,M2,x0)
[x,flag] = cgs(A,b,...)
[x,flag,relres] = cgs(A,b,...)
[x,flag,relres,iter] = cgs(A,b,...)
[x,flag,relres,iter,resvec] = cgs(A,b,...)
```

Description

`x = cgs(A,b)` attempts to solve the system of linear equations `A*x = b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. You can specify `A` as a function handle, `afun`, such that `afun(x)` returns `A*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `cgs` converges, a message to that effect is displayed. If `cgs` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`cgs(A,b,tol)` specifies the tolerance of the method, `tol`. If `tol` is `[]`, then `cgs` uses the default, `1e-6`.

`cgs(A,b,tol,maxit)` specifies the maximum number of iterations, `maxit`. If `maxit` is `[]` then `cgs` uses the default, `min(n,20)`.

`cgs(A,b,tol,maxit,M)` and `cgs(A,b,tol,maxit,M1,M2)` use the preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `cgs` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`cgs(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess `x0`. If `x0` is `[]`, then `cgs` uses the default, an all-zero vector.

`[x,flag] = cgs(A,b,...)` returns a solution `x` and a flag that describes the convergence of `cgs`.

Flag	Convergence
0	`cgs` converged to the desired tolerance `tol` within `maxit`iterations.
1	`cgs` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`cgs` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `cgs` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = cgs(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, then `relres <= tol`.

`[x,flag,relres,iter] = cgs(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = cgs(A,b,...)` also returns a vector of the residual norms at each iteration, including `norm(b-A*x0)`.

Examples

Using cgs with a Matrix Input

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;  maxit = 15;
M1 = diag([10:-1:1 1 1:10]);
x = cgs(A,b,tol,maxit,M1);
```

displays the message

```
cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.
```

Using cgs with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in the file `run_cgs` that

- Calls `cgs` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_cgs` are available to `afun` and `myfun`.

The following shows the code for `run_cgs`:

```
function x1 = run_cgs
n = 21;
b = afun(ones(n,1));
tol = 1e-12;  maxit = 15;
x1 = cgs(@afun,b,tol,maxit,@mfun);

    function y = afun(x)
        y = [0; x(1:n-1)] + ...
              [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
              [x(2:n); 0];
    end

    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
end
```

When you enter

```
x1 = run_cgs
```

MATLAB software returns

```
cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.
```

Using a Preconditioner

This example demonstrates the use of a preconditioner.

1

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

2

Define `b` so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

3

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

4

Use `cgs` to find a solution at the requested tolerance and number of iterations:

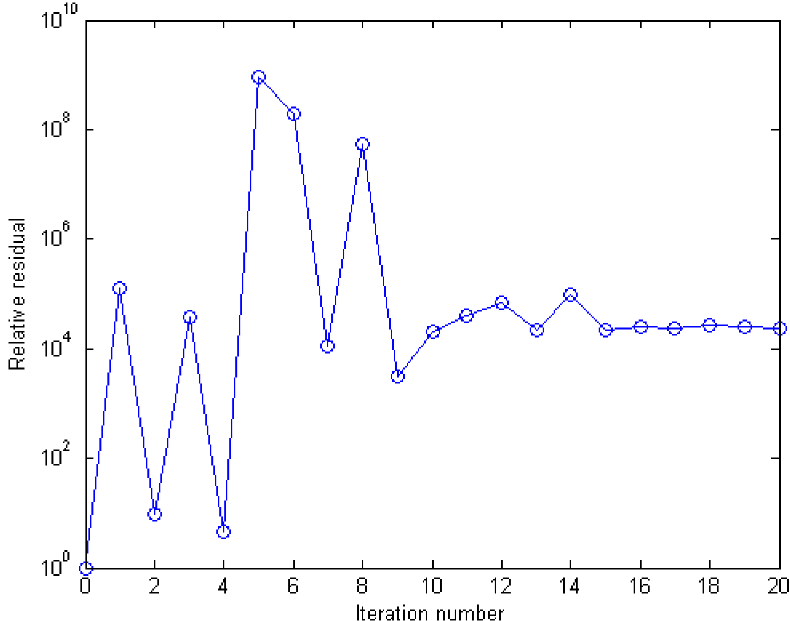
```
[x0,fl0,rr0,it0,rv0] = cgs(A,b,tol,maxit);
```

`fl0` is 1 because `cgs` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. In fact, the behavior of `cgs` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB stores the residual history in `rv0`.

5

Plot the behavior of cgs:

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

6

Create a preconditioner with ilu, since A is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
Error using ilu
There is a pivot equal to zero.  Consider decreasing the
```

```
drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = cgs(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `cgs` drives the relative residual to `4.3851e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the third iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)`and the output `rv1(14)` is `norm(b-A*x2)`.

8

You can follow the progress of `cgs` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0)

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

Purpose

Convert to character array (string)

Syntax

```
S = char(X)
S = char(C)
S = char(T1,T2,...,TN)
```

Description

`S = char(X)` converts array `X` of nonnegative integer codes into a character array. Valid codes range from 0 to 65535, where codes 0 through 127 correspond to 7-bit ASCII characters. The characters that MATLAB can process (other than 7-bit ASCII characters) depend upon your current locale setting. To convert characters into a numeric array, use the `double` function.

`S = char(C)`, when `C` is a cell array of strings, places each element of `C` into the rows of the character array `s`. Use `cellstr` to convert back.

`S = char(T1,T2,...,TN)` forms the character array `S` containing the text strings `T1`, `T2`, `...`, `TN` as rows, automatically padding each string with blanks to form a valid matrix. Each text parameter, `Ti`, can itself be a character array. This allows the creation of arbitrarily large character arrays. Empty strings are significant.

Examples

Convert Integers to Characters

Create a 3-by-32 array of the printable ASCII characters.

```
asc = char(reshape(32:127,32,3)')
```

```
asc =

 !"#$%&'()*+,-./0123456789:;<=>?
@ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_
`abcdefghijklmnopqrstuvwxyz{|}~
```

- “How the MATLAB Process Uses Locale Settings”

checkcode

Purpose

Check MATLAB code files for possible problems

Alternatives

For information on using the graphical user interface for checking code, see “Check Code for Errors and Warnings”.

Syntax

```
checkcode('filename')
checkcode('filename','-config=settings.txt')
checkcode('filename','-config=factory')
inform=checkcode('filename','-struct')
msg=checkcode('filename','-string')
[inform,filepaths]=checkcode('filename')
inform=checkcode('filename','-id')
inform=checkcode('filename','-fullpath')
inform=checkcode('filename','-notok')
checkcode('filename','-cyc')
checkcode('filename','-codegen')
checkcode('filename','-eml')
```

Description

`checkcode('filename')` displays messages, sometimes referred to as Code Analyzer messages, about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `checkcode(F1,F2,F3,...)`, where each input is a character array, MATLAB software displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `checkcode` messages is subject to some change between versions.

`checkcode('filename','-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

Note If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

For information about creating a `settings.txt` file, see "Save and Reuse Code Analyzer Message Settings". If you specify an invalid file, `checkcode` returns a message indicating that it cannot open or read the file you specified. In that case, `checkcode` uses the factory default settings.

`checkcode('filename','-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=checkcode('filename','-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

Field	Description
`message`	Message describing the suspicious construct that code analysis caught.
`line`	Vector of file line numbers to which the message refers.
`column`	Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message.

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=checkcode('filename','-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as input, `msg` contains a string where each file's information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the **`-struct`** or **`-string`** argument and you specify an output argument, the default behavior is **`-struct`**. If you omit the argument

and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepaths]=checkcode('filename')` additionally returns `filepaths`, the absolute paths to the file names, in the same order as you specified them.

`inform=checkcode('filename','-id')` requests the message ID, where ID is a string of the form `ABC...`. When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=checkcode('filename','-fullpath')` assumes that the input file names are absolute paths, so that `checkcode` does not try to locate them.

`inform=checkcode('filename','-notok')` runs `checkcode` for all lines in `filename`, even those lines that end with the `checkcode` suppression directive, `%#ok`.

`checkcode('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`checkcode('filename','-codegen')` enables code generation messages for display in the Command Window.

`checkcode('filename','-eml')` `'-eml'` is not recommended. Use `'-codegen'` instead.

Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in *`matlabroot`*`/help/techdoc/matlab_env/examples`. If you want to run

the examples, save a copy of `lengthofline.m` to a location on your MATLAB path.

Running checkcode on a File with No Options

To run `checkcode` on the example file, `lengthofline.m`, run

```
checkcode('lengthofline')
```

MATLAB displays the Code Analyzer messages for `lengthofline.m` in the Command Window:

```
L 22 (C 1-9): The value assigned here to variable 'nothandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMPI(str1,str2) instead of using LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
                Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop.Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

Running checkcode with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=checkcode('lengthofline', '-id')
```

MATLAB returns

```
inform =

19x1 struct array with fields:
    message
    line
    column
    id
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =

    message: 'The value assigned here to variable 'nothandle' might never be used.'
       line: 22
     column: [1 9]
         id: 'NASGU'
```

Here, the message is for the value that appears on line 22 that extends from column 1–9 in the file.`NASGU` is the ID for the message `'The value assigned here to variable 'nothandle' might never be used.'`.

Displaying McCabe Complexity with checkcode

To display the McCabe complexity of a MATLAB code file, run `checkcode` with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
checkcode lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the Code Analyzer messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 22 (C 1-9): The value assigned here to variable 'nothandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMPI(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for mo
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary.  Use parentheses to group, if needed.
```

How To

- For information on the suppression directive, `%#ok`, and suppressing messages from within your program, see "Adjust Code Analyzer Message Indicators and Messages".

checkin

Purpose

Check files into source control system (UNIX platforms)

Syntax

```
checkin('filename','comments','comment_text')
checkin({'filename1','filename2'},'comments','comment_text')
checkin('filename','comments', 'comment_text','option',
   'value')
```

Description

`checkin('filename','comments','comment_text')` checks in the file named `filename` to the source control system. Use the full path for `filename` and include the file extension. You must save the file before checking it in, but the file can be open or closed. The `comment_text` is a MATLAB string containing checkin comments for the source control system. You must supply **`comments`** and `comment_text`.

`checkin({'filename1','filename2'},'comments','comment_text')` checks in the files `filename1` through `filenamen` to the source control system. Use the full paths for the files and include file extensions. Comments apply to all files checked in.

`checkin('filename','comments', 'comment_text','option','value')` provides additional `checkin` options. For multiple file names, use an array of strings instead of `filename`, that is, `{'filename1','filename2',...}`. Options apply to all file names. The *`option`* and *`value`* arguments are shown in the following table.

option Argument	value Argument	Purpose
`'force'`	`'on'`	`filename` is checked in even if the file has not changed since it was checked out.
`'force'`	`'off'` (default)	`filename` is not checked in if there were no changes since checkout.

option Argument	value Argument	Purpose
'lock'	'on'	filename is checked in with comments, and is automatically checked out.
'lock'	'off' (default)	filename is checked in with comments but does not remain checked out.

Examples

Check In a File

Check the file /myserver/myfiles/clock.m into the source control system, with the comment Adjustment for leapyear:

```
checkin('/myserver/myfiles/clock.m','comments',...
'Adjustment for leapyear')
```

Check In Multiple Files

Check two files into the source control system, using the same comment for each:

```
checkin({'/myserver/myfiles/clock.m', ...
'/myserver/myfiles/calendar.m'},'comments',...
'Adjustment for leapyear')
```

Check In a File and Keep It Checked Out

Check the file /myserver/myfiles/clock.m into the source control system and keep the file checked out:

```
checkin('/myserver/myfiles/clock.m','comments',...
'Adjustment for leapyear','lock','on')
```

See Also

checkout | cmopts | undocheckout | verctrl

How To

- "Check In Files (UNIX Platforms)"

checkout

Purpose

Check files out of source control system (UNIX platforms)

Syntax

```
checkout('filename')
checkout({'filename1','filename2', ...})
checkout('filename','option','value',...)
```

Description

`checkout('filename')` checks out the file named `filename` from the source control system. Use the full path for `filename` and include the file extension. The file can be open or closed when you use `checkout`.

`checkout({'filename1','filename2', ...})` checks out the files named `filename1` through `filenamen` from the source control system. Use the full paths for the files and include the file extensions.

`checkout('filename','option','value',...)` provides additional `checkout` options. For multiple file names, use an array of strings instead of `filename`, that is, `{'filename1','filename2', ...}`. Options apply to all file names. The *`option`* and *`value`* arguments are shown in the following table.

option Argument	value Argument	Purpose
`'force'`	`'on'`	The checkout is forced, even if you already have the file checked out. This is effectively an `undocheckout` followed by a `checkout`.
`'force'`	`'off'` (default)	Prevents you from checking out the file if you already have it checked out.

option Argument	value Argument	Purpose
'lock'	'on' (default)	The checkout gets the file, allows you to write to it, and locks the file so that access to the file for others is read only.
'lock'	'off'	The checkout gets a read-only version of the file, allowing another user to check out the file for updating. You do not have to check the file in after checking it out with this option.
'revision'	'version_num'	Checks out the specified revision of the file.

If you end the MATLAB session, the file remains checked out. You can check in the file from within the MATLAB desktop during a later session, or directly from your source control system.

Examples

Check Out a File

Check out the file /myserver/myfiles/clock.m from the source control system:

```
checkout('/myserver/myfiles/clock.m')
```

Check Out Multiple Files

Check out /matlab/myfiles/clock.m and /matlab/myfiles/calendar.m from the source control system:

```
checkout({'/myserver/myfiles/clock.m',...
```

```
'/myserver/myfiles/calendar.m'})
```

Force a Checkout, Even If File Is Already Checked Out

Check out `/matlab/myfiles/clock.m` even if `clock.m` is already checked out to you:

```
checkout('/myserver/myfiles/clock.m','force','on')
```

Check Out Specified Revision of File

Check out revision `1.1` of `clock.m`:

```
checkout('/matlab/myfiles/clock.m','revision','1.1')
```

See Also

`checkin` | `cmopts` | `undocheckout` | `customverctrl` | `verctrl`

How To

- "Check Out Files (UNIX Platforms)"

Purpose

Cholesky factorization

Syntax

```
R = chol(A)
L = chol(A,'lower')
R = chol(A,'upper')
[R,p] = chol(A)
[L,p] = chol(A,'lower')
[R,p] = chol(A,'upper')
[R,p,S] = chol(A)
[R,p,s] = chol(A,'vector')
[L,p,s] = chol(A,'lower','vector')
[R,p,s] = chol(A,'upper','vector')
```

Description

`R = chol(A)` produces an upper triangular matrix `R` from the diagonal and upper triangle of matrix `A`, satisfying the equation `R'*R=A`. The `chol` function assumes that `A` is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the upper triangle as the lower triangle. Matrix `A` must be positive definite.

`L = chol(A,'lower')` produces a lower triangular matrix `L` from the diagonal and lower triangle of matrix `A`, satisfying the equation `L*L'=A`. The `chol` function assumes that `A` is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the lower triangle as the upper triangle. When `A` is sparse, this syntax of `chol` is typically faster. Matrix `A` must be positive definite. `R = chol(A,'upper')` is the same as `R = chol(A)`.

`[R,p] = chol(A)` for positive definite `A`, produces an upper triangular matrix `R` from the diagonal and upper triangle of matrix `A`, satisfying the equation `R'*R=A` and `p` is zero. If `A` is not positive definite, then `p` is a positive integer and MATLAB does not generate an error. When `A` is full, `R` is an upper triangular matrix of order `q=p-1` such that `R'*R=A(1:q,1:q)`. When `A` is sparse, `R` is an upper triangular matrix of size `q`-by-`n` so that the `L`-shaped region of the first `q` rows and first `q` columns of `R'*R` agree with those of `A`.

`[L,p] = chol(A,'lower')` for positive definite `A`, produces a lower triangular matrix `L` from the diagonal and lower triangle of matrix `A`,

satisfying the equation `L*L'=A` and `p` is zero. If `A` is not positive definite, then `p` is a positive integer and MATLAB does not generate an error. When `A` is full, `L` is a lower triangular matrix of order `q=p-1` such that `L*L'=A(1:q,1:q)`. When `A` is sparse, `L` is a lower triangular matrix of size `q`-by-`n` so that the `L`-shaped region of the first `q` rows and first `q` columns of `L*L'` agree with those of `A`. `[R,p] = chol(A,'upper')` is the same as `[R,p] = chol(A)`.

The following three-output syntaxes require sparse input `A`.

`[R,p,S] = chol(A)`, when `A` is sparse, returns a permutation matrix `S`. Note that the preordering `S` may differ from that obtained from `amd` since `chol` will slightly change the ordering for increased performance. When `p=0`, `R` is an upper triangular matrix such that `R'*R=S'*A*S`. When `p` is not zero, `R` is an upper triangular matrix of size `q`-by-`n` so that the `L`-shaped region of the first `q` rows and first `q` columns of `R'*R` agree with those of `S'*A*S`. The factor of `S'*A*S` tends to be sparser than the factor of `A`.

`[R,p,s] = chol(A,'vector')`, when `A` is sparse, returns the permutation information as a vector `s` such that `A(s,s)=R'*R`, when `p=0`. You can use the `'matrix'` option in place of `'vector'` to obtain the default behavior.

`[L,p,s] = chol(A,'lower','vector')`, when `A` is sparse, uses only the diagonal and the lower triangle of `A` and returns a lower triangular matrix `L` and a permutation vector `s` such that `A(s,s)=L*L'`, when `p=0`. As above, you can use the `'matrix'` option in place of `'vector'` to obtain a permutation matrix. `[R,p,s] = chol(A,'upper','vector')` is the same as `[R,p,s] = chol(A,'vector')`.

Note Using `chol` is preferable to using `eig` for determining positive definiteness.

Examples

Example 1

The `gallery` function provides several symmetric, positive, definite matrices.

```
A=gallery('moler',5)

A =

     1    -1    -1    -1    -1
    -1     2     0     0     0
    -1     0     3     1     1
    -1     0     1     4     2
    -1     0     1     2     5

C=chol(A)

ans =

     1    -1    -1    -1    -1
     0     1    -1    -1    -1
     0     0     1    -1    -1
     0     0     0     1    -1
     0     0     0     0     1
isequal(C'*C,A)

ans =

     1
```

For sparse input matrices, `chol` returns the Cholesky factor.

```
N = 100;
A = gallery('poisson', N);
```

`N` represents the number of grid points in one direction of a square `N`-by-`N` grid. Therefore, `A` is N^2 by N^2.

```
L = chol(A, 'lower');
D = norm(A - L*L', 'fro');
```

The value of D will vary somewhat among different versions of MATLAB but will be on order of 10^{-14}.

Example 2

The binomial coefficients arranged in a symmetric array create a positive definite matrix.

```
n = 5;
X = pascal(n)
X =
     1     1     1     1     1
     1     2     3     4     5
     1     3     6    10    15
     1     4    10    20    35
     1     5    15    35    70
```

This matrix is interesting because its Cholesky factor consists of the same coefficients, arranged in an upper triangular matrix.

```
R = chol(X)
R =
     1     1     1     1     1
     0     1     2     3     4
     0     0     1     3     6
     0     0     0     1     4
     0     0     0     0     1
```

Destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element.

```
X(n,n) = X(n,n)-1

X =
     1     1     1     1     1
     1     2     3     4     5
```

```
     1     3     6    10    15
     1     4    10    20    35
     1     5    15    35    69
```

Now an attempt to find the Cholesky factorization of X fails.

```
chol(X)
Error using chol
Matrix must be positive definite.
```

cholinc | cholupdate

cholinc

Purpose

Sparse incomplete Cholesky and Cholesky-Infinity factorizations

---

Note `cholinc` has been removed.

- You can replace most instances of `cholinc` with `ichol`. Note that `cholinc` returned upper triangular factors, while `ichol` returns lower triangular factors by default.
- Remove any instances that use the syntax `cholinc(X,'inf')`. There is no replacement for this syntax.

Syntax

```
R = cholinc(X,droptol)
R = cholinc(X,options)
R = cholinc(X,'0')
[R,p] = cholinc(X,'0')
R = cholinc(X,'inf')
```

Description

`cholinc` produces two different kinds of incomplete Cholesky factorizations: the drop tolerance and the 0 level of fill-in factorizations. These factors may be useful as preconditioners for a symmetric positive definite system of linear equations being solved by an iterative method such as `pcg` (Preconditioned Conjugate Gradients). `cholinc` works only for sparse matrices.

`R = cholinc(X,droptol)` performs the incomplete Cholesky factorization of `X`, with drop tolerance `droptol`.

`R = cholinc(X,options)` allows additional options to the incomplete Cholesky factorization. `options` is a structure with up to three fields:

`droptol`	Drop tolerance of the incomplete factorization
`michol`	Modified incomplete Cholesky
`rdiag`	Replace zeros on the diagonal of `R`

Only the fields of interest need to be set.

`droptol` is a non-negative scalar used as the drop tolerance for the incomplete Cholesky factorization. This factorization is computed by performing the incomplete LU factorization with the pivot threshold option set to `0` (which forces diagonal pivoting) and then scaling the rows of the incomplete upper triangular factor, `U`, by the square root of the diagonal entries in that column. Since the nonzero entries `U(i,j)` are bounded below by `droptol*norm(X(:,j))` (see `luinc`), the nonzero entries `R(i,j)` are bounded below by the local drop tolerance `droptol*norm(X(:,j))/R(i,i)`.

Setting `droptol = 0` produces the complete Cholesky factorization, which is the default.

`michol` stands for modified incomplete Cholesky factorization. Its value is either `0` (unmodified, the default) or `1` (modified). This performs the modified incomplete LU factorization of `X` and scales the returned upper triangular factor as described above.

`rdiag` is either `0` or `1`. If it is `1`, any zero diagonal entries of the upper triangular factor R are replaced by the square root of the local drop tolerance in an attempt to avoid a singular factor. The default is `0`.

`R = cholinc(X,'0')` produces the incomplete Cholesky factor of a real sparse matrix that is symmetric and positive definite using no fill-in. The upper triangular `R` has the same sparsity pattern as `triu(X)`, although `R` may be zero in some positions where `X` is nonzero due to cancellation. The lower triangle of `X` is assumed to be the transpose of the upper. Note that the positive definiteness of `X` does not guarantee the existence of a factor with the required sparsity. An error message results if the factorization is not possible. If the factorization is successful, `R'*R` agrees with `X` over its sparsity pattern.

`[R,p] = cholinc(X,'0')` with two output arguments, never produces an error message. If `R` exists, `p` is `0`. If `R` does not exist, then `p` is a positive integer and `R` is an upper triangular matrix of size `q`-by-`n` where `q = p-1`. In this latter case, the sparsity pattern of `R` is that of the `q`-by-`n` upper triangle of `X`. `R'*R` agrees with `X` over the sparsity pattern of its first `q` rows and first `q` columns.

`R = cholinc(X,'inf')` produces the Cholesky-Infinity factorization. This factorization is based on the Cholesky factorization, and additionally handles real positive semi-definite matrices. It may be useful for finding a solution to systems which arise in interior-point methods. When a zero pivot is encountered in the ordinary Cholesky factorization, the diagonal of the Cholesky-Infinity factor is set to `Inf` and the rest of that row is set to `0`. This forces a `0` in the corresponding entry of the solution vector in the associated system of linear equations. In practice, `X` is assumed to be positive semi-definite so even negative pivots are replaced with a value of `Inf`.

Tips

The incomplete factorizations may be useful as preconditioners for solving large sparse systems of linear equations. A single `0` on the diagonal of the upper triangular factor makes it singular. The incomplete factorization with a drop tolerance prints a warning message if the upper triangular factor has zeros on the diagonal. Similarly, using the `rdiag` option to replace a zero diagonal only gets rid of the symptoms of the problem, but it does not solve it. The preconditioner may not be singular, but it probably is not useful, and a warning message is printed.

The Cholesky-Infinity factorization is meant to be used within interior-point methods. Otherwise, its use is not recommended.

Examples

Example 1

Start with a symmetric positive definite matrix, `S`.

```
S = delsq(numgrid('C',15));
```

S is the two-dimensional, five-point discrete negative Lapacian on the grid generated by numgrid('C',15).

Compute the Cholesky factorization and the incomplete Cholesky factorization of level 0 to compare the fill-in. Make `S` singular by zeroing out a diagonal entry and compute the (partial) incomplete Cholesky factorization of level `0`.

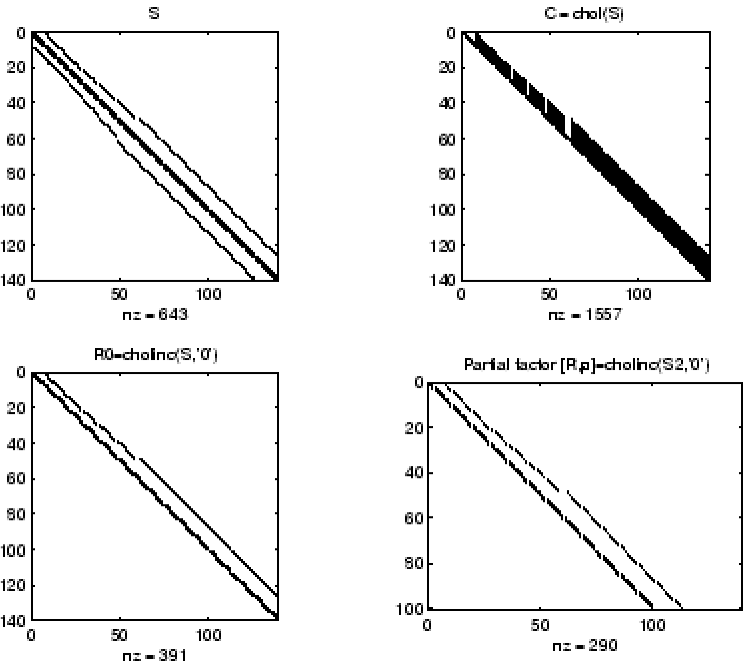
```
C = chol(S);
R0 = cholinc(S,'0');
```

```
S2 = S; S2(101,101) = 0;
[R,p] = cholinc(S2,'0');
```

Fill-in occurs within the bands of `S` in the complete Cholesky factor, but none in the incomplete Cholesky factor. The incomplete factorization of the singular `S2` stopped at row `p = 101` resulting in a 100-by-139 partial factor.

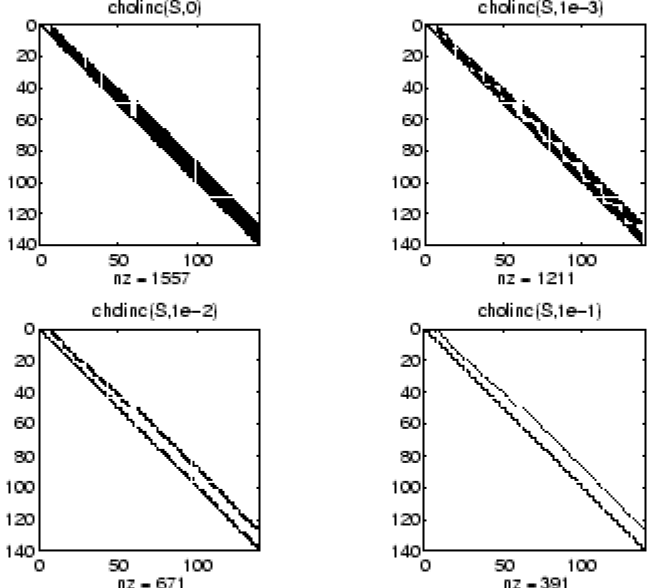
```
D1 = (R0'*R0).*spones(S)-S;
D2 = (R'*R).*spones(S2)-S2;
```

`D1` has elements of the order of `eps`, showing that `R0'*R0` agrees with `S` over its sparsity pattern. `D2` has elements of the order of `eps` over its first 100 rows and first 100 columns, `D2(1:100,:)` and `D2(:,1:100)`.

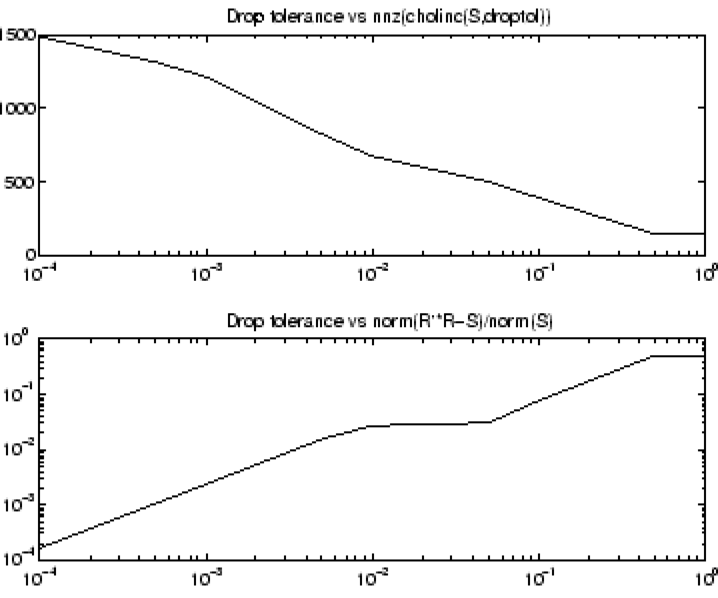


Example 2

The first subplot below shows that `cholinc(S,0)`, the incomplete Cholesky factor with a drop tolerance of `0`, is the same as the Cholesky factor of `S`. Increasing the drop tolerance increases the sparsity of the incomplete factors, as seen below.



Unfortunately, the sparser factors are poor approximations, as is seen by the plot of drop tolerance versus `norm(R'*R-S,1)/norm(S,1)` in the next figure.



Example 3

The Hilbert matrices have (i,j) entries 1/(i+j-1) and are theoretically positive definite:

```
H3 = hilb(3)
H3 =
    1.0000    0.5000    0.3333
    0.5000    0.3333    0.2500
    0.3333    0.2500    0.2000
R3 = chol(H3)
R3 =
    1.0000    0.5000    0.3333
         0    0.2887    0.2887
         0         0    0.0745
```

In practice, the Cholesky factorization breaks down for larger matrices:

```
H20 = sparse(hilb(20));
```

```
[R,p] = chol(H20);
p =
    14
```

For `hilb(20)`, the Cholesky factorization failed in the computation of row 14 because of a numerically zero pivot. You can use the Cholesky-Infinity factorization to avoid this error. When a zero pivot is encountered, `cholinc` places an `Inf` on the main diagonal, zeros out the rest of the row, and continues with the computation:

```
Rinf = cholinc(H20,'inf');
```

In this case, all subsequent pivots are also too small, so the remainder of the upper triangular factor is:

```
full(Rinf(14:end,14:end))
ans =
   Inf     0     0     0     0     0     0
     0   Inf     0     0     0     0     0
     0     0   Inf     0     0     0     0
     0     0     0   Inf     0     0     0
     0     0     0     0   Inf     0     0
     0     0     0     0     0   Inf     0
     0     0     0     0     0     0   Inf
```

Limitations

`cholinc` works on square sparse matrices only. For `cholinc(X,'0')` and `cholinc(X,'inf')`, `X` must be real.

Algorithms

`R = cholinc(X,droptol)` is obtained from `[L,U] = luinc(X,options)`, where `options.droptol = droptol` and `options.thresh = 0`. The rows of the uppertriangular `U` are scaled by the square root of the diagonal in that row, and this scaled factor becomes `R`.

`R = cholinc(X,options)` is produced in a similar manner, except the `rdiag` option translates into the `udiag` option and the `milu` option takes the value of the `michol` option.

`R = cholinc(X,'0')` is based on the "KJI" variant of the Cholesky factorization. Updates are made only to positions which are nonzero in the upper triangle of `X`.

`R = cholinc(X,'inf')` is based on the algorithm in Zhang [2].

`chol` | `ilu` | `luinc` | `pcg`

cholupdate

Purpose

Rank 1 update to Cholesky factorization

Syntax

```
R1 = cholupdate(R,x)
R1 = cholupdate(R,x,'+')
R1 = cholupdate(R,x,'-')
[R1,p] = cholupdate(R,x,'-')
```

Description

`R1 = cholupdate(R,x)` where `R = chol(A)` is the original Cholesky factorization of `A`, returns the upper triangular Cholesky factor of `A + x*x'`, where `x` is a column vector of appropriate length. `cholupdate` uses only the diagonal and upper triangle of `R`. The lower triangle of `R` is ignored.

`R1 = cholupdate(R,x,'+')` is the same as `R1 = cholupdate(R,x)`.

`R1 = cholupdate(R,x,'-')` returns the Cholesky factor of `A - x*x'`. An error message reports when R is not a valid Cholesky factor or when the downdated matrix is not positive definite and so does not have a Cholesky factorization.

`[R1,p] = cholupdate(R,x,'-')` will not return an error message. If `p` is `0`, `R1` is the Cholesky factor of `A - x*x'`. If `p` is greater than `0`, `R1` is the Cholesky factor of the original `A`. If `p` is `1`, `cholupdate` failed because the downdated matrix is not positive definite. If `p` is `2`, `cholupdate` failed because the upper triangle of `R` was not a valid Cholesky factor.

Tips

`cholupdate` works only for full matrices.

Examples

```
A = pascal(4)
A =

     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    20

R = chol(A)
R =
```

```
     1     1     1     1
     0     1     2     3
     0     0     1     3
     0     0     0     1
x = [0 0 0 1]';
```

This is called a rank one update to `A` since `rank(x*x')` is `1`:

```
A + x*x'
ans =

     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    21
```

Instead of computing the Cholesky factor with `R1 = chol(A + x*x')`, we can use `cholupdate`:

```
R1 = cholupdate(R,x)
R1 =

    1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    1.4142
```

Next destroy the positive definiteness (and actually make the matrix singular) by subtracting `1` from the last element of `A`. The downdated matrix is:

```
A - x*x'
ans =

     1     1     1     1
     1     2     3     4
```

```
     1     3     6    10
     1     4    10    19
```

Compare `chol` with `cholupdate`:

```
R1 = chol(A-x*x')
Error using chol
Matrix must be positive definite.
R1 = cholupdate(R,x,'-')
Error using cholupdate
Downdated matrix must be positive definite.
```

However, subtracting `0.5` from the last element of `A` produces a positive definite matrix, and we can use `cholupdate` to compute its Cholesky factor:

```
x = [0 0 0 1/sqrt(2)]';
R1 = cholupdate(R,x,'-')
R1 =
    1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    0.7071
```

Algorithms

`cholupdate` uses the algorithms from the LINPACK subroutines `ZCHUD` and `ZCHDD`. `cholupdate` is useful since computing the new Cholesky factor from scratch is an $O(N^3)$ algorithm, while simply updating the existing factor in this way is an $O(N^2)$ algorithm.

See Also

`chol` | `qrupdate`

Purpose

Shift array circularly

Syntax

```
B = circshift(A,shiftsize)
```

Description

`B = circshift(A,shiftsize)` circularly shifts the values in the array, `A`, by `shiftsize` elements. `shiftsize` is a vector of integer scalars where the `n`-th element specifies the shift amount for the `n`-th dimension of array `A`. If an element in `shiftsize` is positive, the values of `A` are shifted down (or to the right). If it is negative, the values of `A` are shifted up (or to the left). If it is `0`, the values in that dimension are not shifted.

Examples

Circularly shift first dimension values down by 1.

```
A = [ 1 2 3;4 5 6; 7 8 9]
A =
     1     2     3
     4     5     6
     7     8     9

B = circshift(A,1)
B =
     7     8     9
     1     2     3
     4     5     6
```

Circularly shift first dimension values down by 1 and second dimension values to the left by 1.

```
B = circshift(A,[1 -1]);
B =
    8     9     7
    2     3     1
    5     6     4
```

TriRep.circumcenters

Purpose

(Will be removed) Circumcenters of specified simplices

Note `circumcenters(TriRep)` will be removed in a future release. Use `circumcenter(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
CC = circumcenters(TR, SI)
[CC RCC] = circumcenters(TR, SI)
```

Description

`CC = circumcenters(TR, SI)` returns the coordinates of the circumcenter of each specified simplex `SI`. `CC` is an `m`-by-`n` matrix, where `m` is of length `length(SI)`, the number of specified simplices, and `n` is the dimension of the space where the triangulation resides.

`[CC RCC] = circumcenters(TR, SI)` returns the circumcenters and the corresponding radii of the circumscribed circles or spheres.

Input Arguments

`TR`	Triangulation object.
`SI`	Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`. If `SI` is not specified the circumcenter information for the entire triangulation is returned, where the circumcenter associated with simplex `i` is the `i`'th row of `CC`.

Output Arguments

`CC`	`m`-by-`n` matrix. `m` is the number of specified simplices and `n` is the dimension of the space where the triangulation resides. Each row `CC(i,:)` represents the coordinates of the circumcenter of simplex `SI(i)`.
`RCC`	Vector of length `length(SI)`, the number of specified simplices containing radii of the circumscribed circles or spheres.

Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

Examples

Example 1

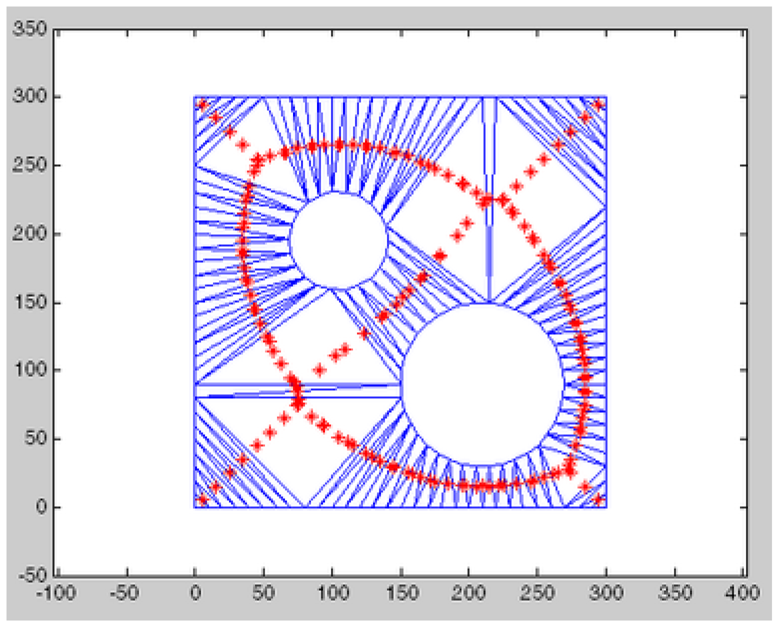
Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y)
```

Compute the circumcenters.

```
cc = circumcenters(trep);
triplot(trep);
axis([-50 350 -50 350]);
axis equal;
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
```

The circumcenters represent points on the medial axis of the polygon.



Example 2

Query a 3-D triangulation created with `DelaunayTri`. Compute the circumcenters of the first five tetrahedra.

```
X = rand(10,3);
dt = DelaunayTri(X);
cc = circumcenters(dt, [1:5]')
```

See Also

`incenter` | `delaunayTriangulation` | `triangulation`

Purpose

Clear current axes

Syntax

```
cla
cla reset
cla(ax)
cla(ax,'reset')
```

Description

`cla` deletes from the current axes all graphics objects whose handles are not hidden (i.e., their `HandleVisibility` property is set to `on`).

`cla reset` deletes from the current axes all graphics objects regardless of the setting of their `HandleVisibility` property and resets all axes properties, except `Position` and `Units`, to their default values.

`cla(ax)` or `cla(ax,'reset')` clears the single axes with handle `ax`.

Tips

The `cla` command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the `HandleVisibility` setting of `callback`. This means that when issued from within a callback routine, `cla` deletes only those objects whose `HandleVisibility` property is set to `on`.

Alternatives

Remove axes and clear objects from them in *plot edit* mode. For details, see "Working in Plot Edit Mode".

See Also

`clf` | `hold` | `newplot` | `reset`

clabel

Purpose

Contour plot elevation labels

Syntax

```
clabel(C)
clabel(C,h)
clabel(C,v)
clabel(C,h,v)
clabel( ___ ,Name,Value)

clabel(C,'manual')
clabel(C,h,'manual')

text_handles = clabel( ___ )
```

Description

`clabel(C)` labels all contours displayed in the current contour plot. Labels are upright and displayed with `'+'` symbols. `clabel` randomly selects label positions.

`clabel(C,h)` rotates the labels and inserts them in the contour lines. This syntax inserts only those labels that fit within the contour, depending on the size of the contour.

`clabel(C,v)` labels only the contour levels specified by the vector, `v`.

`clabel(C,h,v)` labels only the contour levels specified by vector `v`, rotates the labels, and inserts them in the contour lines.

`clabel( ___ ,Name,Value)` specifies the text object properties and the `'LabelSpacing'` contourgroup property, using one or more `Name,Value` pair arguments, in addition to any of the input arguments in previous syntaxes.

`clabel(C,'manual')` places contour labels at locations you select with a mouse. Click the mouse or press the space bar to label the contour

closest to the center of the crosshair. Press the **Return** key while the cursor is within the figure window to terminate labeling.

`clabel(C,h,'manual')` places contour labels at locations you select with a mouse. Press the **Return** key while the cursor is within the figure window to terminate labeling. The labels are rotated and inserted in the contour lines.

`text_handles = clabel(___)` additionally returns an array containing the handles of the text objects created, using any of the input arguments in the previous syntaxes. If you call `clabel` without the `h` argument, `text_handles` also contains the handles of line objects used to create the `'+'` symbols.

Input Arguments

C - Contour matrix

2-by-`n` matrix

Contour matrix containing the data that defines the contour lines. `C` is returned by the `contour`, `contour3`, or `contourf` function.

h - Handle to the contourgroup object

Handle to the contourgroup object returned by the `contour`, `contour3`, or `contourf` function.

v - Contour level values

vector

Contour level values, specified as a row or column vector of individual values.

Example: `[0,10,20]`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can

specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Color','red','Rotation',45` adds red labels to a contour plot, where each label is rotated 45 degrees.

In addition to the following, you can specify other text object properties using `Name,Value` pair arguments. See Text Properties.

'Color' - Text color

`[0 0 0]` (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`.

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
`[1 1 0]`	`y`	`yellow`
`[1 0 1]`	`m`	`magenta`
`[0 1 1]`	`c`	`cyan`
`[1 0 0]`	`r`	`red`
`[0 1 0]`	`g`	`green`
`[0 0 1]`	`b`	`blue`
`[1 1 1]`	`w`	`white`
`[0 0 0]`	`k`	`black`

Example: `'Color',[0 1 0]`

Example: `'Color','green'`

'FontName' - Font name

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

Example: 'FontName','Courier'

'FontSize' - Font size

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

Example: 'FontSize',12.5

'FontUnits' - Font size units

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize

accordingly. `points`, `inches`, `centimeters`, and `pixels` are absolute units. 1 point = $^1/_{72}$ inch

---

Note When setting both the `FontSize` and the `FontUnits`, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`. For example, to set the font size to 0.3 inches, call `'FontUnits','inches','FontSize',0.3` in the argument list.

'FontWeight' - Weight of text characters

`'normal'` (default) | `'bold'` | `'light'` | `'demi'`

Weight of text characters, specified as the comma-separated pair consisting of `'FontWeight'` and one of the following strings:

- `'normal'`
- `'bold'`
- `'light'`
- `'demi'`

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to `'bold'` or `'demi'` causes MATLAB to use a bold font.

Example: `'FontWeight','bold'`

'LabelSpacing' - Spacing between labels

144 (default) | scalar

Spacing between labels on each contour line, specified as the comma-separated pair consisting of `'LabelSpacing'` and a scalar. Specify the label spacing in points, where 1 point = $^1/_{72}$ inch.

Example: `'LabelSpacing',72`

'Rotation' - Text orientation

0 (default) | scalar

Text orientation, specified as the comma-separated pair consisting of 'Rotation' and a scalar. Specify values of rotation in degrees. Positive values result in counterclockwise rotation.

Example: 'Rotation',45

Output Arguments

text_handles - Handles of text objects

Handles of the text objects that clabel creates. The UserData properties of the text objects contain the contour values displayed.

If you call clabel without the h argument, text_handles also contains the handles of line objects used to create the '+' symbols.

Examples

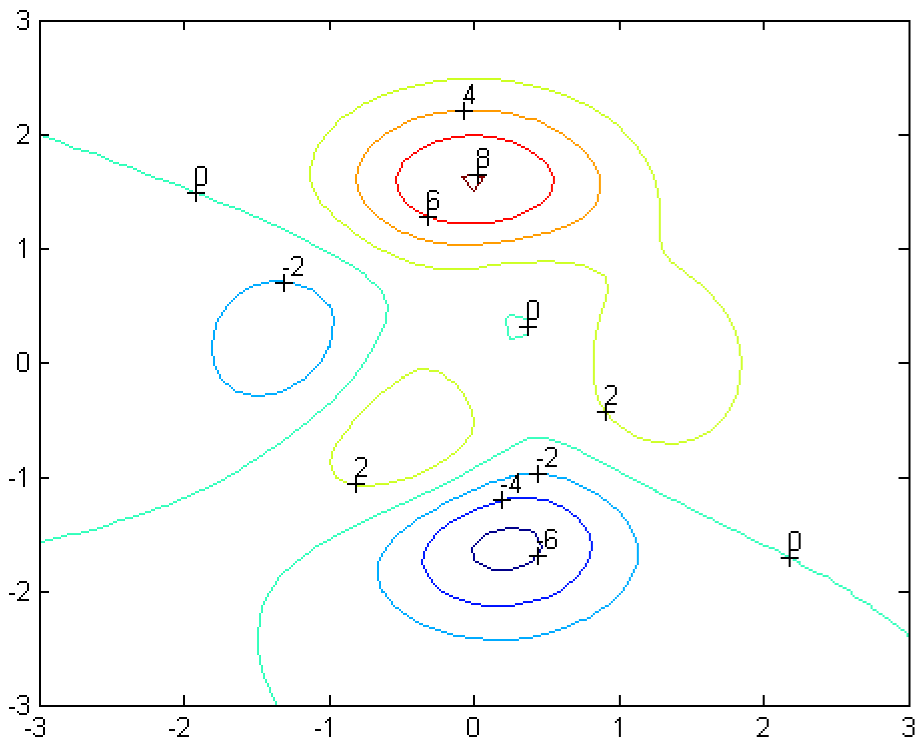
Label Contour Plot with Vertical Text and '+' Symbols

Generate a contour plot and obtain the contour matrix, C.

```
[x,y,z] = peaks;
figure
C = contour(x,y,z);
```

Label the contour plot.

```
clabel(C)
```



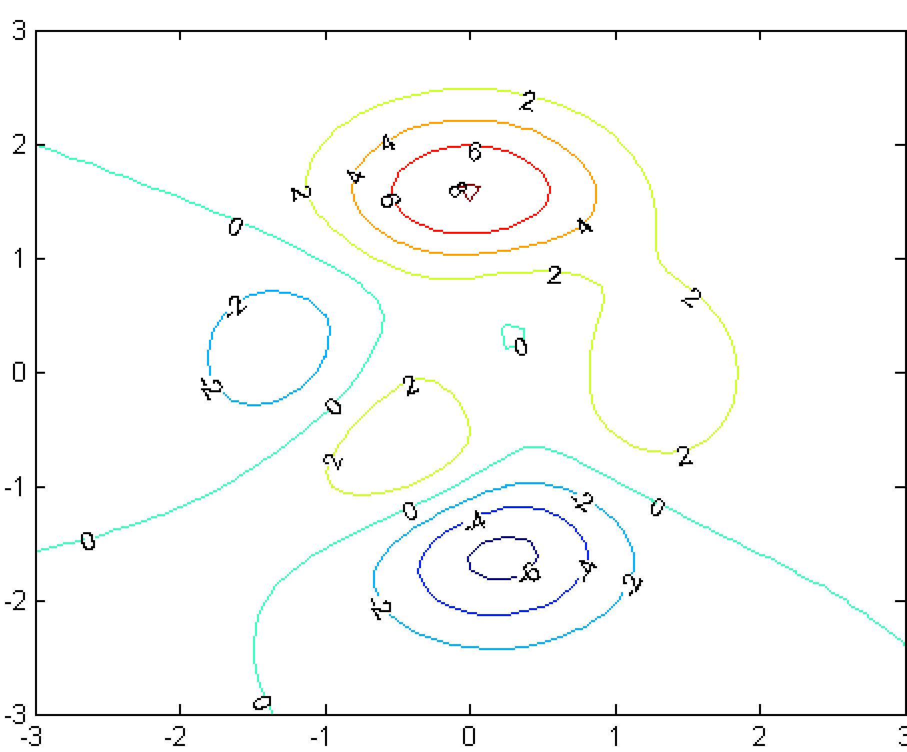
Label Contour Plot with Rotated Text Inserted in Contour Lines

Generate a contour plot and obtain the contour matrix, C, and the handle to the contourgroup object, h.

```
[x,y,z] = peaks;
figure
[C,h] = contour(x,y,z);
```

Label the contour plot.

```
clabel(C,h);
```

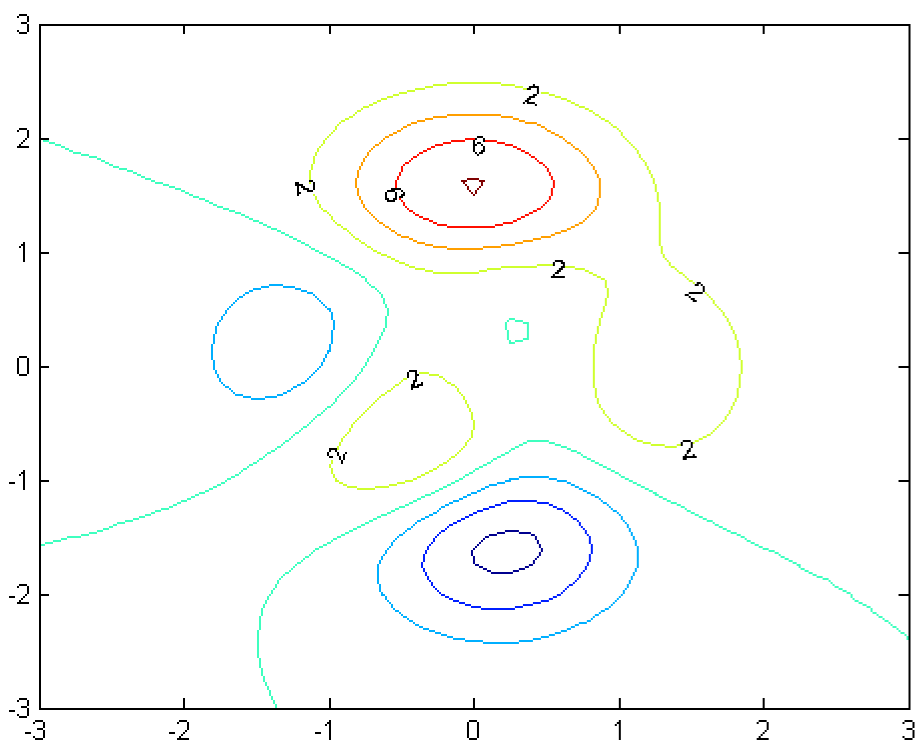


Label Specific Contour Levels

Label only the contours with contour levels 2 or 6.

```
[x,y,z] = peaks;
figure
[C,h] = contour(x,y,z);
```

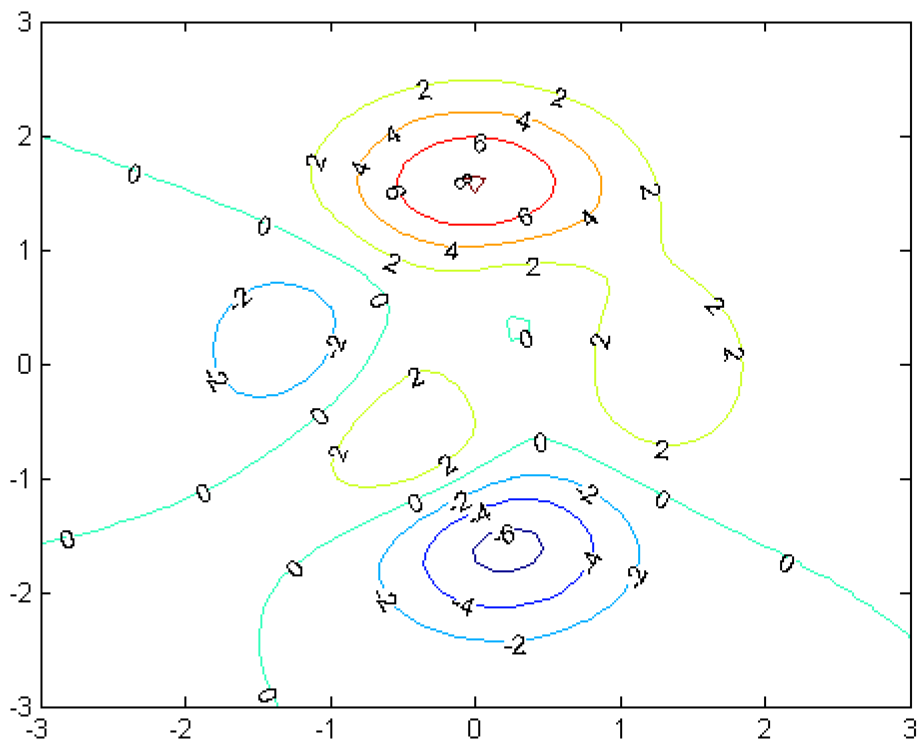
```
v = [2,6];
clabel(C,h,v)
```



Set Label Spacing

Set the label spacing to 72 points (1 inch).

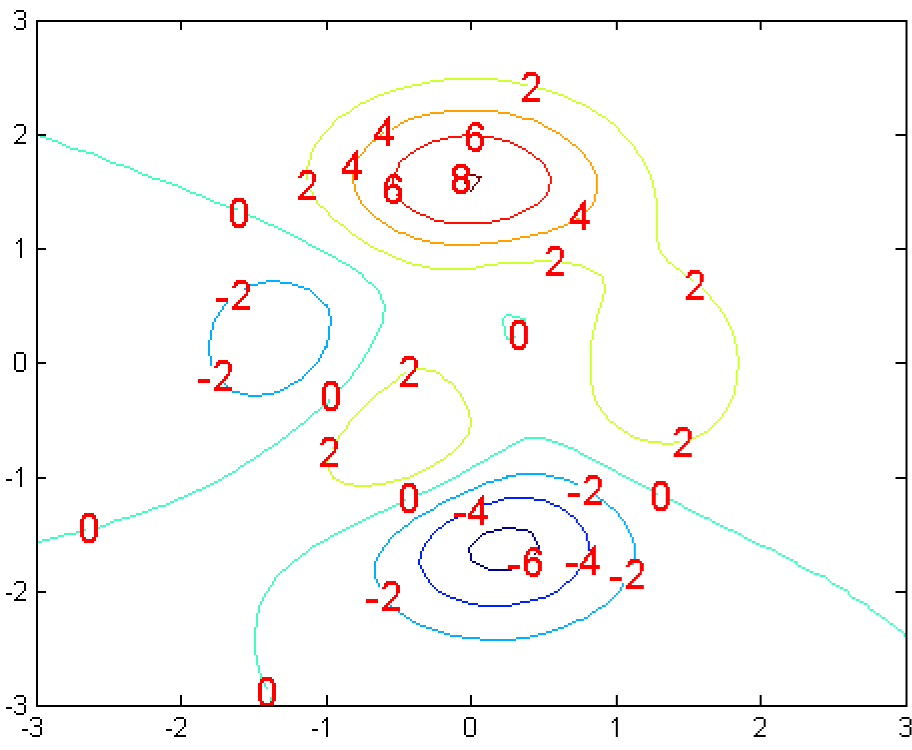
```
[x,y,z] = peaks;
figure
[C,h] = contour(x,y,z);
clabel(C,h,'LabelSpacing',72)
```



Label Contour Plot and Set Text Properties

Use `Name,Value` arguments to set the font size, font color, and text orientation of the labels.

```
[x,y,z] = peaks;
figure
[C,h] = contour(x,y,z);
clabel(C,h,'FontSize',15,'Color','r','Rotation',0)
```



`'FontSize',15,'Color','r'` adds 15-point red labels to the contour plot. `'Rotation',0` makes the text upright.

Label Contour Plot and Return Object Handles

Label a contour plot and return the handles of the objects created.

```
[x,y,z] = peaks;
figure
[C,h] = contour(x,y,z);
text_handles = clabel(C,h);
```

MATLAB returns an array containing the handles of the text objects created.

Set the color of the labels to blue, using the handle to the text objects.

```
set(text_handles,'Color','blue')
```

Related Examples

- "Drawing Text in a Box"

Concepts

Text Properties

class

Purpose

Determine class of object

Syntax

```
ClassName = class(object)
obj = class(s,'class_name')
obj = class(s,'class_name',parent1,parent2,...)
obj = class(struct([]),'class_name',parent1,parent2,...)
obj_struct = class(struct_array,'class_name',parent_array)
```

Description

`ClassName = class(object)` returns a string specifying the class of `object`. See "Fundamental MATLAB Classes" for more information on MATLAB classes.

Note Before MATLAB 7.6 (classes defined without a `classdef` statement), class constructors called the `class` function to create the object. The following `class` function syntaxes apply only within classes defined before Version 7.6.

`obj = class(s,'class_name')` creates an array of class *`class_name`* objects using the `struct` `s` as a pattern to determine the size of `obj`.

`obj = class(s,'class_name',parent1,parent2,...)` inherits the methods and fields of the parent objects `parent1`, `parent2`, and so on. The size of the parent objects must match the size of `s` or be a scalar (1–by-1), in which case, MATLAB performs scalar expansion.

`obj = class(struct([]),'class_name',parent1,parent2,...)` constructs object containing only fields that it inherits from the parent objects. All parents must have the same, nonzero size, which determines the size of the returned object `obj`.

`obj_struct = class(struct_array,'class_name',parent_array)` maps every element of the `parent_array` to a corresponding element in the `struct_array` to produce the output array of objects, `obj_struct`.

All arrays must be of the same size. If either the `struct_array` or the `parent_array` is of size 1–by–1, then MATLAB performs scalar expansion to match the array sizes.

To create an object array of size 0–by-0, set the size of the `struct_array` and `parent_array` to 0–by-0.

Examples

Return the class of Java object `obj`:

```
import java.lang.*;
obj = String('mystring');
class(obj)

ans =

java.lang.String
```

Return class of any MATLAB variable:

```
h = @sin;
class(h)

ans =

function_handle
```

- "Class Syntax Fundamentals"

classdef

Purpose

Class definition keywords

Syntax

```
classdef classname
   properties
      PropName
   end
   methods
      methodName
   end
   events
      EventName
   end
   enumeration
      EnumName (arg)
   end
end
```

Description

`classdef` *`classname`* begins the class definition and an `end` keyword terminates the `classdef` block. Only blank lines and comments can precede `classdef`. Enter a class definition in a file having the same name as the class, with a filename extension of `.m`. Class definition files can be in folders on the MATLAB path or in @ folders whose parent folder is on the MATLAB path. See "Class Files" for more information. See "Classdef Block" and "Class Definition" for more information on classes.

`properties` begins a property definition block, an `end` keyword terminates the `properties` block. Class definitions can contain multiple property definition blocks, each specifying different attribute settings that apply to the properties in that particular block. See "Defining Properties" for more information.

`methods` begins a methods definition block, an `end` keyword terminates the `methods` block. This block contains functions that implement class methods. Class definitions can contain multiple method blocks, each specifying different attribute settings that apply to the methods in that particular block. It is possible to define method functions in separate files. See "How to Use Methods" for more information.

events begins an events definition block, an end keyword terminates the events block. This block contains event names defined by the class. Class definitions can contain multiple event blocks, each specifying different attribute settings that apply to the events in that particular block. See "Events and Listeners — Syntax and Techniques" for more information.

enumeration begins an enumeration definition block, an end keyword terminates the enumeration block. See "Enumerations" for more information.

properties, methods, events, and enumeration are also the names of MATLAB functions used to query the respective class members for a given object or class name.

To see the attributes of all class components in a popup window, click this link: Attribute Tables

Examples

Use these keywords to define classes.

```
classdef (Attributes) class_name
   properties (Attributes)
      PropertyName
   end
   methods (Attributes)
      function obj = methodName(obj,arg2,...)
         ...
      end
   end
   events (Attributes)
      EventName
   end
   enumeration
      EnumName
   end
end
```

- “Class Syntax Fundamentals”
-

clc

Purpose

Clear Command Window

Syntax

```
clc
```

Description

`clc` clears all input and output from the Command Window display, giving you a "clean screen."

After using `clc`, you cannot use the scroll bar to see the history of functions, but you still can use the up arrow to recall statements from the command history.

Examples

Use `clc` in a MATLAB code file to always display output in the same starting position on the screen.

See Also

`clear` | `clf` | `close` | `home`

clear

Purpose

Remove items from workspace, freeing up system memory

Syntax

```
clear
clear name1 ... nameN
clear -regexp expr1 ... exprN
clear ItemType
```

Description

`clear` removes all variables from the current workspace, releasing them from system memory. When called from within a function with persistent variables, `clear` reinitializes the persistent variables.

`clear name1 ...  nameN` removes the variables, scripts, functions, or MEX-functions `name1 ...  nameN` from memory. `clear` removes debugging breakpoints in MATLAB files.

- If function `name` is locked by `mlock`, then it remains in memory.
- If variable `name` is global, then `clear` removes it from the current workspace, but it remains in the global workspace.

`clear -regexp expr1 ...  exprN` clears all variables that match any of the regular expressions listed. This option only clears variables.

`clear ItemType` clears the types of items indicated by `ItemType`, such as `all`, `functions`, or `classes`.

Input Arguments

name1 ... nameN - Names of variables, scripts, functions, or MEX-functions to clear

string

Names of variables, scripts, functions, or MEX-functions to clear, specified as strings.

Use a partial path to distinguish between different overloaded versions of a function. For example, `clear polynom/display` clears only the `display` method for `polynom` objects, leaving any other implementations in memory.

expr1 ... exprN - Regular expressions matching names of variables to clear

string

Regular expressions matching names of variables to clear, specified as strings.

ItemType - Type of items to clear

`all` | `classes` | `functions` | `global` | `import` | `java` | `mex` | `variables`

Type of items to clear, specified as one of the following strings.

ItemType	Items Cleared
`all`	Removes all variables from the base workspace, and all compiled scripts, functions, and MEX-functions from memory. If called from a function, `clear all` clears the function workspace instead of the base workspace. `clear all` removes debugging breakpoints in MATLAB files and reinitializes persistent variables. When issued from the Command Window prompt, `clear all` also removes the Java packages import list.
`classes`	The same as `clear all`, but also clears MATLAB class definitions. `clear classes` issues a warning and does not remove class definitions for objects outside the workspace (for example, in user data or persistent variables in a locked file). Call `clear classes` whenever you change a class definition, including when the number or names of properties, methods, or events or any of their attributes change.

ItemType	Items Cleared
`functions`	Clears all the currently compiled functions, scripts, and MEX-functions from memory. If called from a function, `clear functions` removes all functions from memory. It also removes debugging breakpoints in the code file and reinitializes persistent variables.
`global`	Removes all global variables in the base and global workspaces. If called from a function, `clear global` also removes all global variables in the function workspace. Use `clear global  regexp expr1 ...  exprN` to clear all variables that match any of the regular expressions listed.
`import`	Removes the packages import list. Use this keyword only from the command prompt. Using this keyword in a function returns an error.
`java`	The same as `clear all`, but also clears the definitions of all Java classes defined by files on the Java dynamic class path. If any Java objects exist outside the workspace (for example, in user data or persistent variables in a locked code file), `clear` issues a warning and does not remove the Java class definition. Issue a `clear java` command after modifying any files on the Java dynamic class path.
`mex`	Clears all MEX-functions from memory, except for locked functions or functions that are currently in use. `clear mex` also clears breakpoints and persistent variables.
`variables`	Clears all variables from the workspace.

If you name a variable `all`, `classes`, `functions`, `java`, `import`, or `variables`, calling `clear` followed by that name deletes the variable with that name. `clear` does not interpret the name as a keyword in this context. For example, if the workspace contains variables `a`, `all`, `b`, and `ball`, `clear all` removes the variable `all` only.

Tips

- The `clear` function can remove variables that you specify. To remove all but some specified variables, use `clearvars` instead.
- You can clear the handle of a figure or graphics object, but the object itself is not removed. Use `delete` to remove objects. Deleting an object does not delete the variable (if any) used for storing its handle.
- The `clear` function does not clear Simulink® models. Use `bdclose` instead.
- On UNIX systems, `clear` does not affect the amount of memory allocated to the MATLAB process.

Examples

Clear a Single Variable

Define two variables `a` and `b`, and then clear `a`.

```
a=1;
b=2;
clear a
whos
```

```
Name      Size            Bytes  Class     Attributes

b         1x1                 8  double
```

Only variable `b` remains in the workspace.

Clear Specific Variables

Using regular expressions, clear those variables with names that begin with `Mon`, `Tue`, or `Wed`.

```
clear -regexp ^Mon ^Tue ^Wed;
```

Clear All Variables and Functions

```
clear all
```

Clear All Compiled Scripts, Functions, and MEX-functions

```
clear functions
```

If a function is locked, it will not be cleared from memory.

See Also

`clc` | `clearvars` | `close` | `delete` | `import` | `inmem` | `load` | `mlock` | `persistent` | `whos` | `workspace`

Concepts

- "Base and Function Workspaces"
- "Strategies for Efficient Use of Memory"
- "Modifying and Reloading Classes"
- "The Java Class Path"
- "Regular Expressions"

Purpose

Clear variables from memory

Alternatives

As an alternative to the `clearvars` function, in the Workspace browser, select variables to clear and then press **Delete**.

Syntax

```
clearvars v1 v2 ...
clearvars -global
clearvars -global v1 v2 ...
clearvars -regexp p1 p2 ...
clearvars -except v1 v2 ...
clearvars -except -regexp p1 p2 ...
clearvars v1 v2 ... -except -regexp p1 p2 ...
clearvars -regexp p1 p2 ... -except v1 v2 ...
```

Description

`clearvars v1 v2 ...` clears variables `v1`, `v2`, and so on from the currently active workspace. Each input must be an unquoted string specifying the variable to be cleared. This string may include the wildcard character (`*`) to clear all variables that match a pattern. For example, `clearvars X*` clears all the variables in the current workspace that start with the letter `X`.

If any of the variables `v1`, `v2`, and so on, are global, `clearvars` removes these variables from the current workspace only, leaving them accessible to any functions that declare them as global.

`clearvars -global` removes all global variables, including those made global within functions.

`clearvars -global v1 v2 ...` completely removes the specified global variables.

The `-global` flag may be used with any of the following syntaxes. When used in this way, it must immediately follow the function name.

`clearvars -regexp p1 p2 ...` clears all variables that match regular expression patterns `p1`, `p2`, and so on.

`clearvars -except v1 v2 ...` clears all variables except for those specified following the `-except` flag. Use the wildcard character '*'

in a variable name to exclude variables that match a pattern from being cleared. `clearvars -except X*` clears all the variables in the current workspace, except for those that start with `X`, for instance. Use `clearvars -except` to keep the variables you want and remove all others.

`clearvars -except -regexp p1 p2 ...` clears all variables except those that regular expression patterns `p1`, `p2`. If used in this way, the `-regexp` flag must immediately follow the `-except` flag.

`clearvars v1 v2 ...  -except -regexp p1 p2 ...` can be used to specify variables to clear that do not match specified regular expression patterns.

`clearvars -regexp p1 p2 ...  -except v1 v2 ...` clears variables that match `p1`, `p2`, ..., except for variables `v1`, `v2`, ...

Examples

Clear variables starting with `a`, except for the variable `ab`:

```
clearvars a* -except ab
```

Clear all global variables except those starting with `x`:

```
clearvars -global -except x*
```

Clear variables that start with `b` and are followed by 3 digits, for the variable `b106`:

```
clearvars -regexp ^b\d{3}$ -except b106
```

Clear variables that start with `a`, except those ending with `a`:

```
clearvars a* -except -regexp a$
```

`clear` | `exist` | `global` | `persistent` | `save` | `who` | `whos`

How To

- “What Is the MATLAB Workspace?”

Purpose

Remove serial port object from MATLAB workspace

Syntax

`clear obj`

Description

`clear obj` removes `obj` from the MATLAB workspace, where `obj` is a serial port object or an array of serial port objects.

Tips

If `obj` is connected to the device and it is cleared from the workspace, then `obj` remains connected to the device. You can restore `obj` to the workspace with the `instrfind` function. A serial port object connected to the device has a `Status` property value of `open`.

To disconnect `obj` from the device, use the `fclose` function. To remove `obj` from memory, use the `delete` function. You should remove invalid serial port objects from the workspace with `clear`.

Examples

This example creates the serial port object `s` on a Windows platform, copies `s` to a new variable `scopy`, and clears `s` from the MATLAB workspace. `s` is then restored to the workspace with `instrfind` and is shown to be identical to `scopy`.

```
s = serial('COM1');
scopy = s;
clear s
s = instrfind;
isequal(scopy,s)
ans =
     1
```

See Also

`delete` | `fclose` | `instrfind` | `isvalid` | `Status`

clf

Purpose

Clear current figure window

Syntax

```
clf
clf('reset')
clf(fig)
clf(fig,'reset')
figure_handle = clf(...)
```

Description

`clf` deletes from the current figure all graphics objects whose handles are not hidden (i.e., their `HandleVisibility` property is set to `on`).

`clf('reset')` deletes from the current figure all graphics objects regardless of the setting of their `HandleVisibility` property and resets all figure properties except `Position`, `Units`, `PaperPosition`, and `PaperUnits` to their default values.

`clf(fig)` or `clf(fig,'reset')` clears the single figure with handle `fig`.

`figure_handle = clf(...)` returns the handle of the figure. This is useful when the figure `IntegerHandle` property is `off` because the noninteger handle becomes invalid when the reset option is used (i.e., `IntegerHandle` is reset to `on`, which is the default).

Tips

The `clf` command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the `HandleVisibility` setting of `callback`. This means that when issued from within a callback routine, `clf` deletes only those objects whose `HandleVisibility` property is set to `on`.

Alternatives

Use **Clear Figure** from the figure window's **Edit** menu to clear the contents of a figure. You can also create a *desktop shortcut* to clear the current figure with one mouse click. See "Create Shortcuts to Rerun Commands".

See Also

`cla` | `clc` | `hold` | `reset`

Purpose

Copy and paste strings to and from system clipboard

Syntax

```
clipboard('copy', data)
str = clipboard('paste')
data = clipboard('pastespecial')
```

Description

`clipboard('copy', data)` sets the clipboard contents to `data`. If `data` is not a character array, the clipboard uses `mat2str` to convert `data` to a string.

`str = clipboard('paste')` returns the current contents of the clipboard as a string or, if MATLAB cannot convert the current clipboard contents to a string, as an empty string (`' '`).

`data = clipboard('pastespecial')` returns the current contents of the clipboard as an array by using `uiimport`.

Definitions

The `clipboard` function requires Oracle® Java software.

See Also

`load` | `mat2str` | `uiimport`

clock

Purpose

Current date and time as date vector

Syntax

```
c = clock
```

Description

`c = clock` returns a six-element date vector containing the current date and time in decimal form:

```
[year month day hour minute seconds]
```

Examples

Round clock Output to Integer Display

Use `clock` to return the current date and time.

```
format shortg
c = clock

c =
        2012           3          27          13          58
```

The sixth element of the date vector output (seconds) is accurate to several digits beyond the decimal point.

Use the `fix` function to round to integer display format.

```
fix(c)

ans =
        2012           3          27          13          58           9
```

Tips

- To time the duration of an event, use the `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.

See Also

`date` | `now` | `tic` | `toc` | `cputime` | `etime` | `fix`

Purpose

Remove specified figure

Syntax

```
close
close(h)
close name
close all
close all hidden
close all force
status = close(...)
```

Description

`close` deletes the current figure or the specified figure(s). It optionally returns the status of the close operation.

`close` deletes the current figure (equivalent to `close(gcf)`).

`close(h)` deletes the figure identified by `h`. If `h` is a vector or matrix, `close` deletes all figures identified by `h`.

`close name` deletes the figure with the specified name.

`close all` deletes all figures whose handles are not hidden.

`close all hidden` deletes all figures including those with hidden handles.

`close all force` deletes all figures, including GUIs for which `CloseRequestFcn` has been altered to not close the window.

`status = close(...)` returns `1` if the specified windows have been deleted and `0` otherwise.

Algorithms

The `close` function works by evaluating the specified figure's `CloseRequestFcn` property with the statement

```
eval(get(h,'CloseRequestFcn'))
```

The default `CloseRequestFcn`, `closereq`, deletes the current figure using `delete(get(0,'CurrentFigure'))`. If you specify multiple figure handles, `close` executes each figure's `CloseRequestFcn` in turn. If an error that terminates the execution of a `CloseRequestFcn` occurs, the

figure is not deleted. Note that using your computer's window manager (i.e., the **Close** menu item) also calls the figure's `CloseRequestFcn`.

If a figure's handle is hidden (i.e., the figure's `HandleVisibility` property is set to `callback` or `off` and the root `ShowHiddenHandles` property is set to `on`), you must specify the `hidden` option when trying to access a figure using the `all` option.

To delete all figures unconditionally, use the statements

```
set(0,'ShowHiddenHandles','on')
delete(get(0,'Children'))
```

The figure `CloseRequestFcn` allows you to either delay or abort the closing of a figure once the `close` function has been issued. For example, you can display a dialog box to see if the user really wants to delete the figure or save and clean up before closing.

When coding a `CloseRequestFcn` callback, make sure that it does not call `close`, because this sets up a recursion that results in a MATLAB warning. Instead, the callback should destroy the figure with `delete`. The `delete` function does not execute the figure's `CloseRequestFcn`; it simply deletes the specified figure.

Purpose

Close Tiff object

Syntax

`tiffobj.close()`

Description

`tiffobj.close()` closes a Tiff object.

Examples

Open a Tiff object and then close it.

```
% Replace 'myfile.tif' with a TIFF file on your MATLAB path.
t = Tiff('myfile.tif', 'w');
%
% Close Tiff object.
t.close();
```

References

This method corresponds to the `TIFFClose` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTiff - TIFF Library and Utilities`.

Tutorials

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

close (avifile)

Purpose

Close Audio/Video Interleaved (AVI) file

Syntax

`aviobj = close(aviobj)`

Description

`aviobj = close(aviobj)` finishes writing and closes the AVI file associated with `aviobj`, which is an AVI file object created using the `avifile` function.

To close all open AVI files, use the `clear mex` command.

See Also

`avifile` | `addframe (avifile)` | `movie2avi`

Purpose

Close connection to FTP server

Syntax

```
close(ftpobj)
```

Description

`close(ftpobj)` closes the connection to the FTP server.

Tips

- If you do not run `close` at the end of your session, the connection either times out automatically or terminates when you exit MATLAB.
- After calling `close`, calling any other FTP method on the same object automatically reopens the connection.
- `close` does not return any output to indicate success or failure.

Input Arguments

ftpobj

FTP object created by `ftp`.

Examples

Connect to the MathWorks FTP server, and then disconnect:

```
mw=ftp('ftp.mathworks.com');
close(mw)
```

See Also

`ftp`

VideoWriter.close

Purpose

Close file after writing video data

Syntax

```
close(writerObj)
```

Description

`close(writerObj)` closes the file associated with object `writerObj`. The object remains in the workspace. If you call the `open` method after closing, `open` discards any existing contents of the file.

Input Arguments

writerObj

`VideoWriter` object created by the `VideoWriter` function.

Examples

AVI File from Animation

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);
axis tight
set(gca,'nextplot','replacechildren');
set(gcf,'Renderer','zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL® renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20
   surf(sin(2*pi*k/20)*Z,Z)
   frame = getframe;
   writeVideo(writerObj,frame);
```

```
end

close(writerObj);
```

See Also

writeVideo | VideoWriter | open

closereq

Purpose

Default figure close request function

Syntax

```
closereq
```

Description

`closereq` deletes the current figure.

See Also

| CloseRequestFcn

Purpose

Name of source control system

Syntax

```
cmopts
```

Description

`cmopts` returns the name of your version control system.

Output Arguments

Value Returned by cmopts	Description	Platform Supported On
`clearcase`	ClearCase® software from IBM® Rational®	UNIX platforms
`customverctrl`	Custom interface created using `customverctrl` function	UNIX platforms
`cvs`	Concurrent Version System (CVS)	UNIX platforms
`none`	No source control system selected	
`pvcs`	PVCS® and ChangeMan® software	UNIX platforms
`rcs`	Revision Control System (RCS)	UNIX platforms
Any SCC-compliant source control system, for example, `Microsoft Visual SourceSafe`	Varies	Windows platforms

Alternatives

To view the currently selected source control system, click the **Preferences** button on the **Home** tab, and select **General > Source Control**.

`checkin` | `checkout` | `customverctrl` | `undocheckout` | `verctrl`

How To

- "Source Control Interface on Microsoft Windows"
- "Source Control Interface on UNIX Platforms"

Purpose

Rearrange colors in colormap

Syntax

```
[Y,newmap] = cmpermute(X,map)
[Y,newmap] = cmpermute(X,map,index)
```

Description

`[Y,newmap] = cmpermute(X,map)` randomly reorders the colors in `map` to produce a new colormap, `newmap`. The `cmpermute` function also modifies the values in `X` to maintain correspondence between the indices and the colormap, and returns the result in `Y`. The image `Y` and associated colormap, `newmap`, produce the same image as `X` and `map`.

`[Y,newmap] = cmpermute(X,map,index)` uses an ordering matrix (such as the second output of `sort`) to define the order of colors in the new colormap.

Class Support

The input image `X` can be of class `uint8` or `double`. `Y` is returned as an array of the same class as `X`.

Examples

Randomly reorder a colormap and compare the two images:

```
load trees
image(X)
[Y, newmap] = cmpermute(X,map);
figure
image(Y)
```

See Also

`randperm` | `sort`

cmunique

Purpose

Eliminate duplicate colors in colormap; convert grayscale or truecolor image to indexed image

Syntax

```
[Y,newmap] = cmunique(X,map)
[Y,newmap] = cmunique(RGB)
[Y,newmap] = cmunique(I)
```

Description

`[Y,newmap] = cmunique(X,map)` returns the indexed image `Y` and associated colormap, `newmap`, that produce the same image as `(X,map)` but with the smallest possible colormap. The `cmunique` function removes duplicate rows from the colormap and adjusts the indices in the image matrix accordingly.

`[Y,newmap] = cmunique(RGB)` converts the truecolor image `RGB` to the indexed image `Y` and its associated colormap, `newmap`. The return value `newmap` is the smallest possible colormap for the image, containing one entry for each unique color in `RGB`.

Note `newmap` might be very large, because the number of entries can be as many as the number of pixels in `RGB`.

`[Y,newmap] = cmunique(I)` converts the grayscale image `I` to an indexed image `Y` and its associated colormap, `newmap`. The return value, `newmap`, is the smallest possible colormap for the image, containing one entry for each unique intensity level in `I`.

Class Support

The input image can be of class `uint8`, `uint16`, or `double`. The class of the output image `Y` is `uint8` if the length of `newmap` is less than or equal to 256. If the length of `newmap` is greater than 256, `Y` is of class `double`.

Examples

1. Use the magic function to create a sample 4-by-4 image that uses every value in the range between 1 and 16.

   ```
   X = magic(4)
   ```

```
X =

    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

2 Concatenate two 8-entry grayscale colormaps created using the `gray` function. The resultant colormap, `map`, has 16 entries. Entries 9 through 16 are duplicates of entries 1 through 8.

```
map = [gray(8); gray(8)]
size(map)

ans =

    16     3
```

3 Use `cmunique` to eliminate duplicate entries in the colormap.

```
[Y, newmap] = cmunique(X, map);
size(newmap)

ans =

     8     3
```

`cmunique` adjusts the values in the original image `X` to index the new colormap.

```
Y =

     7     1     2     4
     4     2     1     7
     0     6     5     3
     3     5     6     0
```

4 View both images to verify that their appearance is the same.

```
figure, imshow(X, map, 'InitialMagnification', 'fit')
figure, imshow(Y, newmap, 'InitialMagnification', 'fit')
```

See Also

`rgb2ind`

Purpose

Column approximate minimum degree permutation

Syntax

```
p = colamd(S)
```

Description

`p = colamd(S)` returns the column approximate minimum degree permutation vector for the sparse matrix `S`. For a non-symmetric matrix `S`, `S(:,p)` tends to have sparser LU factors than `S`. The Cholesky factorization of `S(:,p)' * S(:,p)` also tends to be sparser than that of `S'*S`.

`knobs` is a two-element vector. If S is `m`-by-`n`, then rows with more than `(knobs(1))*n` entries are ignored. Columns with more than `(knobs(2))*m` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs(1)` = `knobs(2) = spparms('wh_frac')`.

`stats` is an optional vector that provides data about the ordering and the validity of the matrix `S`.

`stats(1)`	Number of dense or empty rows ignored by `colamd`
`stats(2)`	Number of dense or empty columns ignored by `colamd`
`stats(3)`	Number of garbage collections performed on the internal data structure used by `colamd` (roughly of size `2.2*nnz(S) + 4*m + 7*n` integers)
`stats(4)`	`0` if the matrix is valid, or `1` if invalid
`stats(5)`	Rightmost column index that is unsorted or contains duplicate entries, or `0` if no such column exists

`stats(6)`	Last seen duplicate or out-of-order row index in the column index given by `stats(5)`, or `0` if no such row index exists
`stats(7)`	Number of duplicate and out-of-order row indices

Although MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `colamd`. For this reason, `colamd` verifies that `S` is valid:

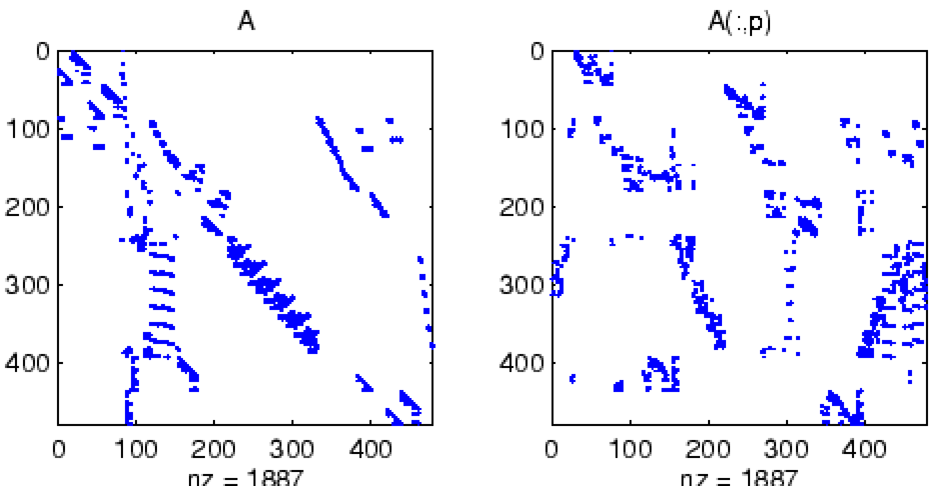
- If a row index appears two or more times in the same column, `colamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `colamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `colamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`) .

The ordering is followed by a column elimination tree post-ordering.

Examples

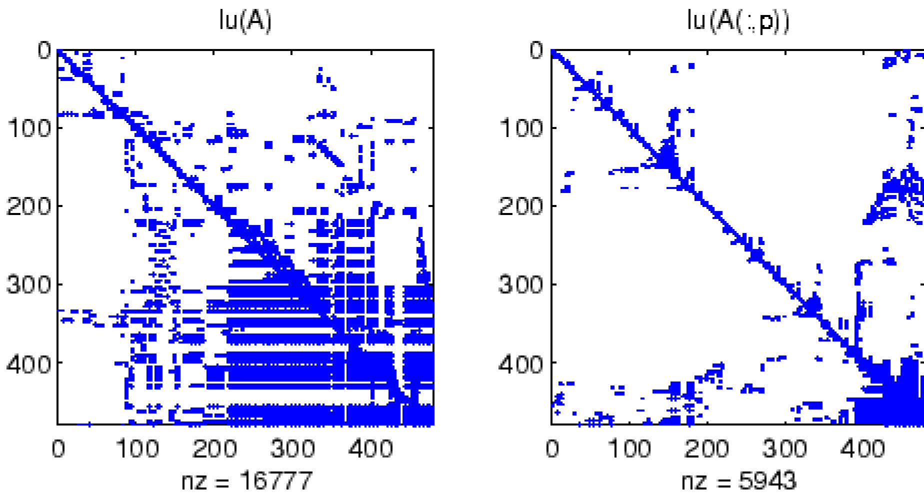
The Harwell-Boeing collection of sparse matrices and the MATLAB demos directory include a test matrix `west0479`. It is a matrix of order 479 resulting from a model due to Westerberg of an eight-stage chemical distillation column. The spy plot shows evidence of the eight stages. The `colamd` ordering scrambles this structure.

```
load west0479
A = west0479;
p = colamd(A);
subplot(1,2,1), spy(A,4), title('A')
subplot(1,2,2), spy(A(:,p),4), title('A(:,p)')
```



Comparing the spy plot of the LU factorization of the original matrix with that of the reordered matrix shows that minimum degree reduces the time and storage requirements by better than a factor of 2.8. The nonzero counts are 16777 and 5904, respectively.

```
spy(lu(A),4)
spy(lu(A(:,p)),4)
```



References

See Also

`colperm` | `spparms` | `symamd` | `symrcm`

Purpose

Colorbar showing color scale

Syntax

```
colorbar
colorbar('off')
colorbar('hide')
colorbar('delete')
colorbar(...,'peer',axes_handle)
colorbar(...,'location')
colorbar(...,'PropertyName',propertyvalue)
cbar_axes = colorbar(...)
colorbar('option')
colorbar(cbar_handle,'option')
```

Description

The `colorbar` function displays the current colormap in the current figure and resizes the current axes to accommodate the colorbar.

`colorbar` adds a new vertical colorbar on the right side of the current axes. If a colorbar exists in that location, `colorbar` replaces it with a new one. If a colorbar exists at a nondefault location, it is retained along with the new colorbar.

`colorbar('off')`, `colorbar('hide')`, and `colorbar('delete')` delete all colorbars associated with the current axes.

`colorbar(...,'peer',axes_handle)` creates a colorbar associated with the axes `axes_handle` instead of the current axes.

`colorbar(...,'location')` adds a colorbar in the specified orientation with respect to the axes. If a colorbar exists at the location specified, it is replaced. Any colorbars not occupying the specified location are retained. Possible values for *location* are

North	Inside plot box near top
South	Inside bottom
East	Inside right
West	Inside left

`NorthOutside`	Outside plot box near top
`SouthOutside`	Outside bottom
`EastOutside`	Outside right
`WestOutside`	Outside left

Using one of the `...Outside` values for *`location`* ensures that the colorbar does not overlap the plot, whereas overlaps can occur when you specify any of the other four values.

`colorbar(...,'`*`PropertyName`*`',propertyvalue)` specifies property names and values for the axes object used to create the colorbar. See Axes Properties for a description of the properties you can set. The *`location`* property applies only to colorbars and legends, not to axes.

`cbar_axes = colorbar(...)` returns a handle to a new colorbar object, which is a child of the current figure. If a colorbar exists, a new one is still created.

`colorbar('`*`option`*`')` specifies options for colorbar visibility. '*`option`*' is one of `'off'`, `` `hide' `` or `` `delete' ``. All of the options delete the colorbar in the current axes.

`colorbar(cbar_handle,'`*`option`*`')` specifies options for colorbar visibility. `'`*`option`*`'` is one of `'off'`, `` `hide' `` or `` `delete' ``. All of the options delete the colorbar specified by the `cbar_handle`.

You can use `colorbar` with 2-D and 3-D plots.

Tips

To obtain the handle to an existing colorbar, use the command

```
cbar_handle = findobj(figure_handle,'tag','Colorbar')
```

where `figure_handle` is the handle of the figure containing the colorbar you want to modify. If the figure contains more than one colorbar, `cbar_handle` is returned as a vector, and you must choose which of the handles to specify to `colorbar`.

Examples

Display a colorbar beside the axes and use descriptive text strings as *y*-tick labels. Labels repeat cyclically when the number of *y*-ticks is greater than the number of labels, and not all labels will appear if there are fewer *y*-ticks than labels you have specified. Also note that when colorbars are horizontal, their ticks and labels are governed by the `XTick` property rather than the `YTick` property. For more information, see "Labeling Colorbar Ticks".

```
surf(peaks(30))
colorbar('YTickLabel',...
    {'Freezing','Cold','Cool','Neutral',...
     'Warm','Hot','Burning','Nuclear'})
```

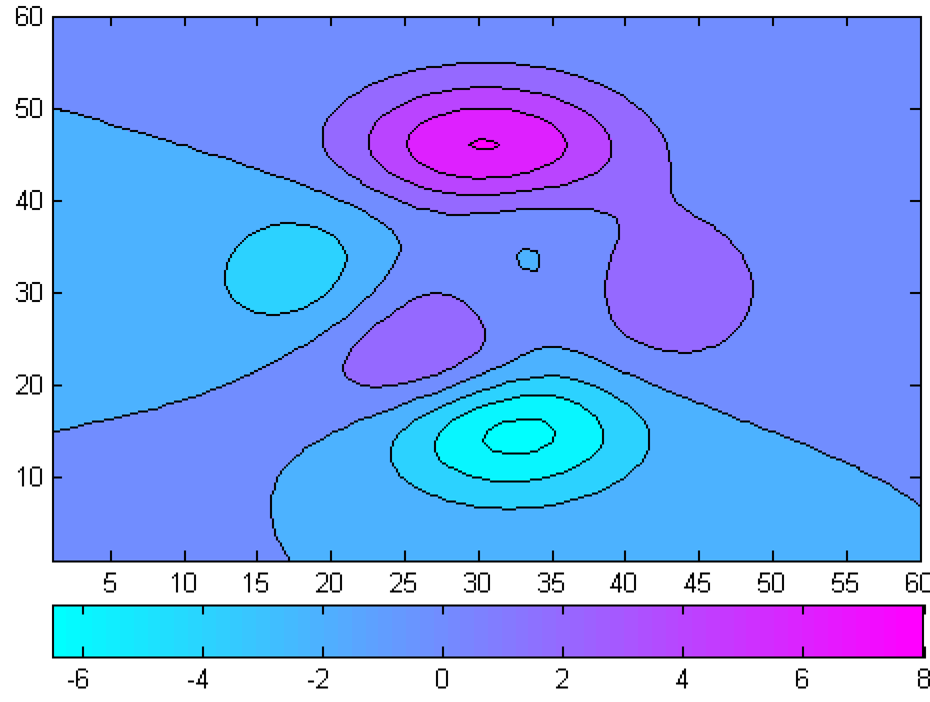
Display a horizontal colorbar beneath the axes of a filled contour plot:

```
contourf(peaks(60))
colormap cool
colorbar('location','southoutside')
```



Alternatives

Add a colorbar to a plot with the colorbar tool on the figure toolbar, or use **Insert > Colorbar** from the figure menu. Use the Property

Editor to modify the position, font and other properties of a legend. .
For details, see “Working in Plot Edit Mode”.

See Also

`colormap`

Purpose

Set default property values to display different color schemes

Syntax

```
colordef white
colordef black
colordef none
colordef(fig,color_option)
h = colordef('new',color_option)
```

Description

`colordef` enables you to select either a white or black background for graphics display. It sets axis lines and labels so that they contrast with the background color.

`colordef white` sets the axis background color to white, the axis lines and labels to black, and the figure background color to light gray.

`colordef black` sets the axis background color to black, the axis lines and labels to white, and the figure background color to dark gray.

`colordef none` sets the figure coloring to that used by MATLAB Version 4. The most noticeable difference is that the axis background is set to `'none'`, making the axis background and figure background colors the same. The figure background color is set to black.

`colordef(fig,`*`color_option`*`)` sets the color scheme of the figure identified by the handle `fig` to one of the color options `'white'`, `'black'`, or `'none'`. When you use this syntax to apply `colordef` to an existing figure, the figure must have no graphic content. If it does, you should first clear it (via `clf`) before using this form of the command.

`h = colordef('new',`*`color_option`*`)` returns the handle to a new figure created with the specified color options (i.e., `'white'`, `'black'`, or `'none'`). This form of the command is useful for creating GUIs when you may want to control the default environment. The figure is created with `'visible','off'` to prevent flashing.

Tips

`colordef` affects only subsequently drawn figures, not those currently on the display. This is because `colordef` works by setting default property values (on the root or figure level). You can list the currently set default values on the root level with the statement

```
get(0,'defaults')
```

You can remove all default values using the `reset` command:

```
reset(0)
```

See the `get` and `reset` references pages for more information.

See Also

`whitebg` | `clf`

Purpose

Set and get current colormap

Syntax

```
colormap(map)
colormap('default')
cmap = colormap
colormap(ax,...)
```

Description

A colormap is an m-by-3 matrix of real numbers between 0.0 and 1.0. Each row is an RGB vector that defines one color. The kth row of the colormap defines the kth color, where `map(k,:) = [r(k) g(k) b(k)])` specifies the intensity of red, green, and blue.

`colormap(map)` sets the colormap to the matrix `map`. If any values in `map` are outside the interval [0 1], you receive the error `Colormap must have values in [0,1]`.

`colormap('default')` sets the current colormap to the default colormap.

`cmap = colormap` retrieves the current colormap. The values returned are in the interval [0 1].

`colormap(ax,...)` uses the figure corresponding to axes `ax` instead of the current figure.

Specifying Colormaps

Files in the `color` folder generate a number of colormaps. Each file accepts the colormap size as an argument. For example,

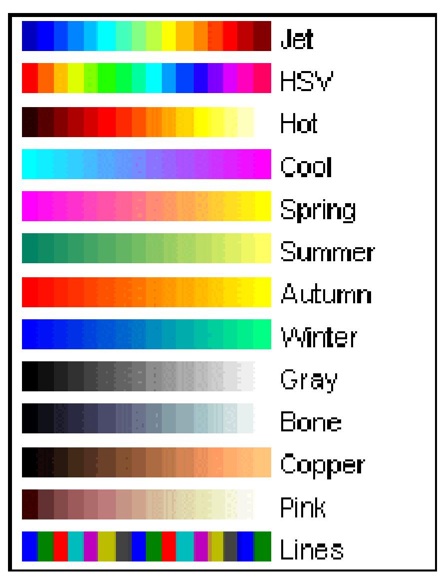
```
colormap(hsv(128))
```

creates an `hsv` colormap with 128 colors. If you do not specify a size, a colormap the same size as the current colormap is created.

Supported Colormaps

The built-in MATLAB colormaps are illustrated and described below. In addition to specifying built-in colormaps programmatically, you can use the **Colormap** menu in the **Figure Properties** pane of the Plot Tools GUI to select one interactively.

The named built-in colormaps are the following:



- `autumn` varies smoothly from red, through orange, to yellow.
- `bone` is a grayscale colormap with a higher value for the blue component. This colormap is useful for adding an "electronic" look to grayscale images.
- `colorcube` contains as many regularly spaced colors in RGB color space as possible, while attempting to provide more steps of gray, pure red, pure green, and pure blue.
- `cool` consists of colors that are shades of cyan and magenta. It varies smoothly from cyan to magenta.
- `copper` varies smoothly from black to bright copper.
- `flag` consists of the colors red, white, blue, and black. This colormap completely changes color with each index increment.
- `gray` returns a linear grayscale colormap.

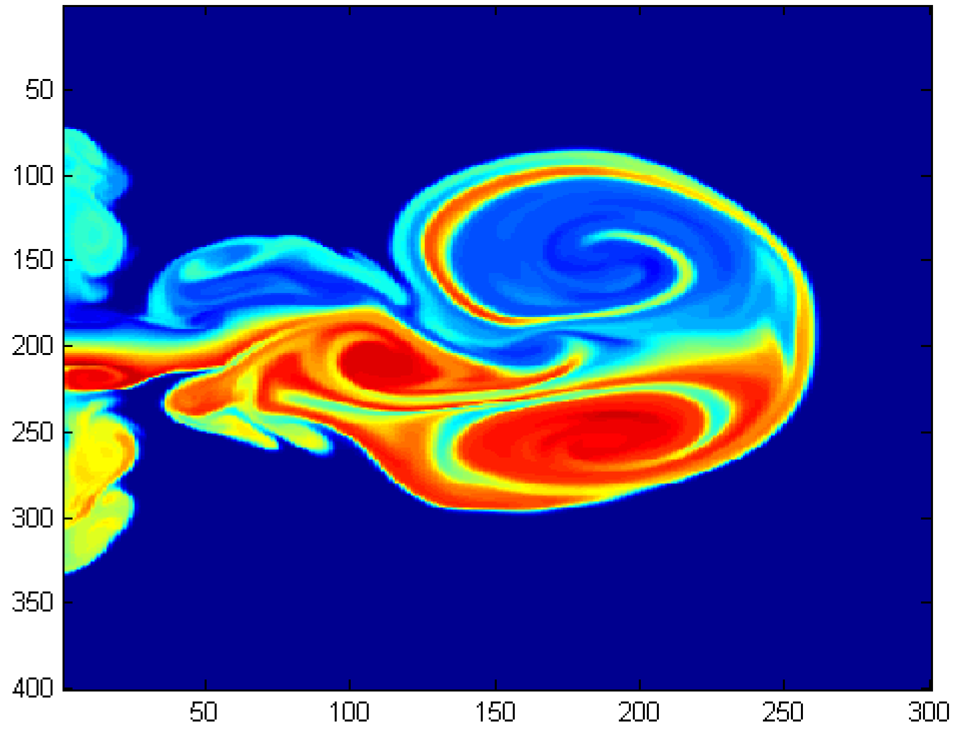
- `hot` varies smoothly from black through shades of red, orange, and yellow, to white.
- `hsv` varies the hue component of the hue-saturation-value color model. The colors begin with red, pass through yellow, green, cyan, blue, magenta, and return to red. The colormap is particularly appropriate for displaying periodic functions. `hsv(m)` is the same as `hsv2rgb([h ones(m,2)])` where `h` is the linear ramp, `h = (0:m 1)'/m`.
- `jet` ranges from blue to red, and passes through the colors cyan, yellow, and orange. It is a variation of the `hsv` colormap. The `jet` colormap is associated with an astrophysical fluid jet simulation from the National Center for Supercomputer Applications. See "Examples" on page 1-977.
- `lines` produces a colormap of colors specified by the axes `ColorOrder` property and a shade of gray.
- `pink` contains pastel shades of pink. The pink colormap provides sepia tone colorization of grayscale photographs.
- `prism` repeats the six colors red, orange, yellow, green, blue, and violet.
- `spring` consists of colors that are shades of magenta and yellow.
- `summer` consists of colors that are shades of green and yellow.
- `white` is an all white monochrome colormap.
- `winter` consists of colors that are shades of blue and green.

Examples

The `rgbplot` function plots colormap values. Try `rgbplot(hsv)`, `rgbplot(gray)`, and `rgbplot(hot)`.

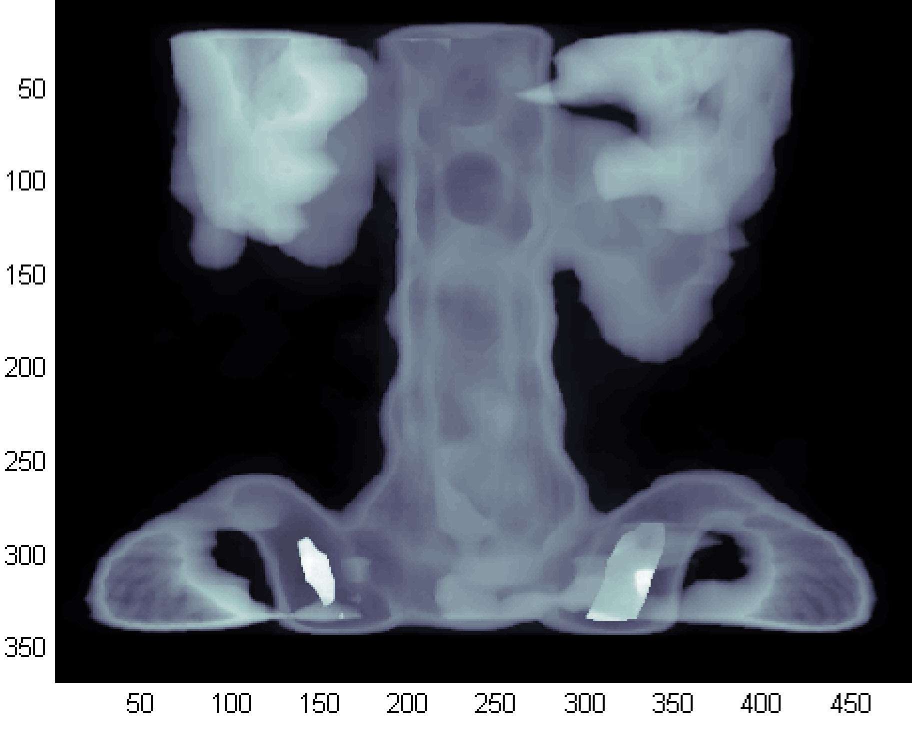
The following commands display the `flujet` data using the `jet` colormap:

```
load flujet
image(X)
colormap(jet)
```



The `demos` folder contains a CAT scan image of a human spine. Use the `image` function to view the data:

```
load spine
image(X)
colormap bone
```



Algorithms

Each figure has its own `colormap` property. `colormap` is a function that sets and gets this property.

Alternatives

Select a built-in colormap with the Property Editor. To modify the current colormap, use the Colormap Editor, accessible from **Edit > Colormap** on the figure menu.

See Also

`brighten` | `caxis` | `colorbar` | `colormapeditor` | `contrast` | `hsv2rgb` | `pcolor` | `rgbplot` | `rgb2hsv` | `Colormap`

How To

- “Coloring Mesh and Surface Plots”

Purpose

Open colormap editor

Syntax

```
colormapeditor
```

Description

`colormapeditor` displays the current figure's colormap as a strip of rectangular cells in the colormap editor. Node pointers are colored cells below the colormap strip that indicate points in the colormap where the rate of the variation of R, G, and B values changes. You can also work in the HSV colorspace by setting the **Interpolating Colorspace** selector to HSV.

You can also start the colormap editor by selecting **Colormap** from the **Edit** menu.

Node Pointer Operations

You can select and move node pointers to change a range of colors in the colormap. The color of a node pointer remains constant as you move it, but the colormap changes by linearly interpolating the RGB values between nodes.

Change the color at a node by double-clicking the node pointer. A color picker box appears, from which you can select a new color. After you select a new color at a node, the colors between nodes are reinterpolated.

You can select a different color map using the **Standard Colormaps** submenu of the GUI **Tools** menu. The Plotting Tools Property Editor has a dropdown menu that also lets you select from standard colormaps, but does not help you to modify a colormap.

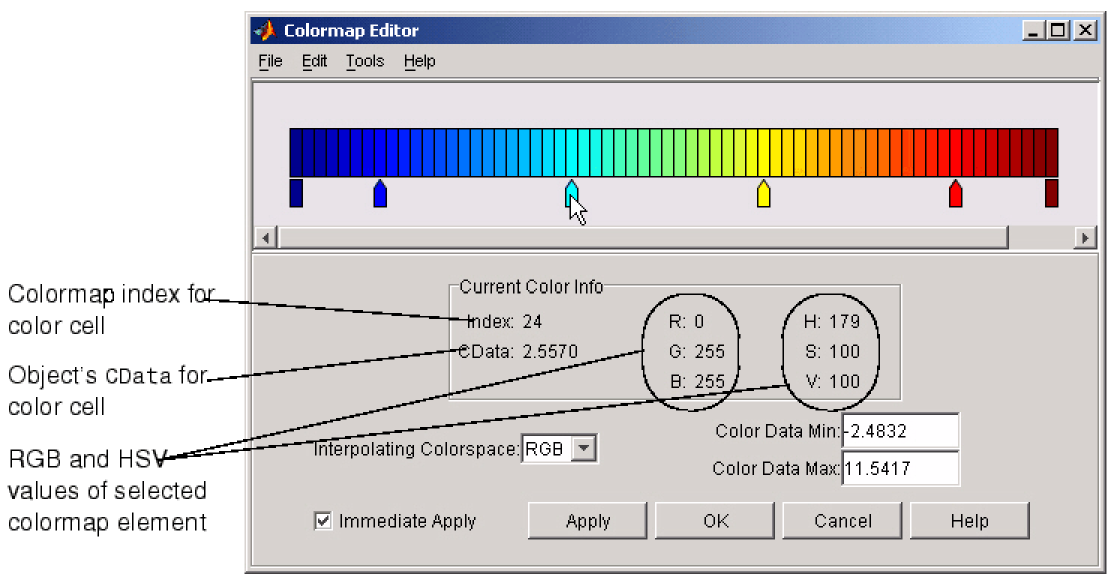
Operation	How to Perform
Select a built-in colormap	**Tools > Standard Colormaps**
Add a node	Click below the corresponding cell in the colormap strip.
Select a node	Left-click the node.

Operation	How to Perform
Select multiple nodes	Adjacent: left-click first node, **Shift+click** the last node. Nonadjacent: left-click first node, **Ctrl+click** subsequent nodes.
Move a node	Select and drag with the mouse or select and use the left and right arrow keys.
Move multiple nodes	Select multiple nodes and use the left and right arrow keys to move nodes as a group. Movement stops when one of the selected nodes hits an unselected node or an end node.
Delete a node	Select the node and then press the **Delete** key, or select **Delete** from the **Edit** menu, or type **Ctrl+x**.
Delete multiple nodes	Select the nodes and then press the **Delete** key, or select **Delete** from the **Edit** menu, or type **Ctrl+x**.
Display color picker for a node	Double-click the node pointer.

Current Color Info

When you put the mouse over a color cell or node pointer, the colormap editor displays the following information about that colormap element:

- The element's index in the colormap
- The value from the graphics object color data that is mapped to the node's color (i.e., data from the `CData` property of any image, patch, or surface objects in the figure)
- The color's RGB and HSV color value



Interpolating Colorspace

The colorspace determines what values are used to calculate the colors of cells between nodes. For example, in the RGB colorspace, internode colors are calculated by linearly interpolating the red, green, and blue intensity values from one node to the next. Switching to the HSV colorspace causes the colormap editor to recalculate the colors between nodes using the hue, saturation, and value components of the color definition.

Note that when you switch from one colorspace to another, the color editor preserves the number, color, and location of the node pointers, which can cause the colormap to change.

Interpolating in HSV. Since hue is conceptually mapped about a color circle, the interpolation between hue values can be ambiguous. To minimize this ambiguity, the interpolation uses the shortest distance around the circle. For example, interpolating between two nodes, one with hue of 2 (slightly orange red) and another with a hue of 356 (slightly magenta red), does not result in hues 3,4,5...353,354,355 (orange/red-yellow-green-cyan-blue-magenta/red). Taking the shortest distance around the circle gives 357,358,1,2 (orange/red-red-magenta/red).

Color Data Min and Max

The **Color Data Min** and **Color Data Max** text fields enable you to specify values for the axes `CLim` property. These values change the mapping of object color data (the `CData` property of images, patches, and surfaces) to the colormap. See "Axes Color Limits — the CLim Property" for discussion and examples of how to use this property.

Examples

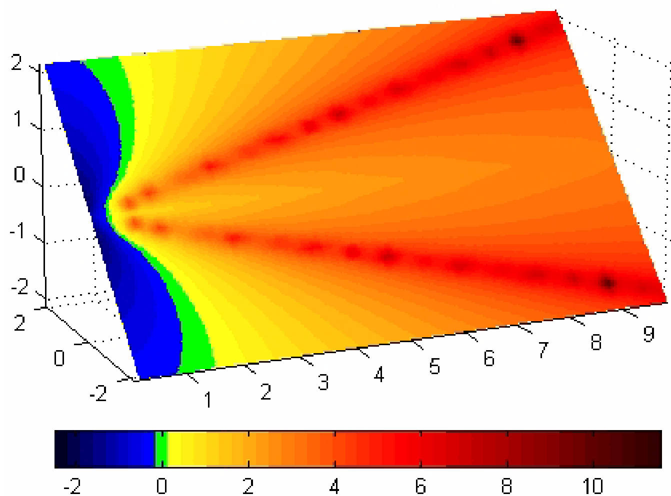
This example modifies a default MATLAB colormap so that ranges of data values are displayed in specific ranges of color. The graph is a slice plane illustrating a cross section of fluid flow through a jet nozzle. See the `slice` reference page for more information on this type of graph.

Example Objectives

The objectives are as follows:

- Regions of flow from left to right (positive data) are mapped to colors from yellow through orange to dark red. Yellow is slowest and dark red is the fastest moving fluid.
- Regions that have a speed close to zero are colored green.
- Regions where the fluid is actually moving right to left (negative data) are shades of blue (darker blue is faster).

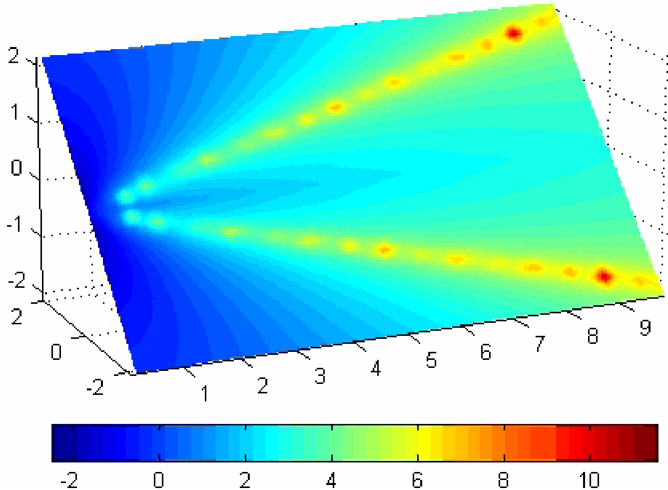
The following picture shows the desired coloring of the slice plane. The colorbar shows the data to color mapping.



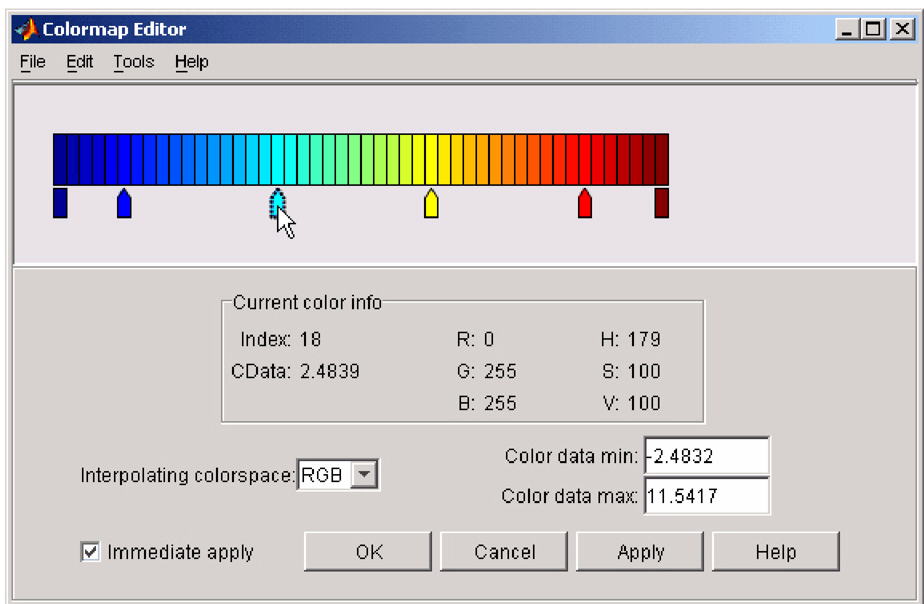
Running the Example

Note If you are viewing this documentation in the MATLAB help browser, you can display the graph used in this example by running this file from the MATLAB editor (select **Run** from the **Debug** menu).

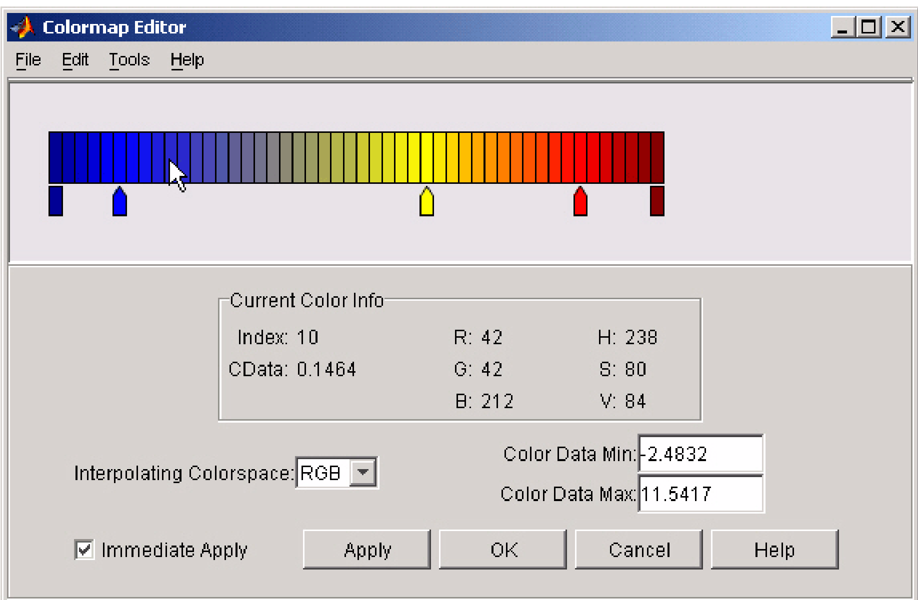
Initially, the default colormap (`jet`) colored the slice plane, as illustrated in the following picture. Note that this example uses a colormap that is 48 elements to display wider bands of color (the default is 64 elements).



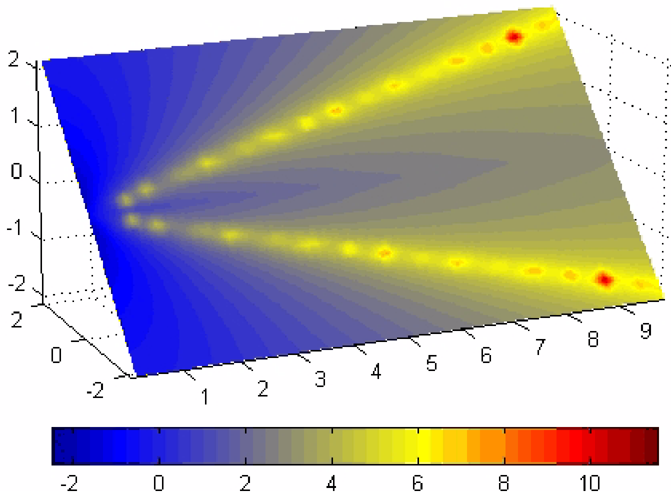
1 Start the colormap editor using the `colormapeditor` command. The color map editor displays the current figure' s colormap, as shown in the following picture.



2 Since we want the regions of left-to-right flow (positive speed) to range from yellow to dark red, we can delete the cyan node pointer. To do this, first select it by clicking with the left mouse button and press **Delete**. The colormap now looks like this.

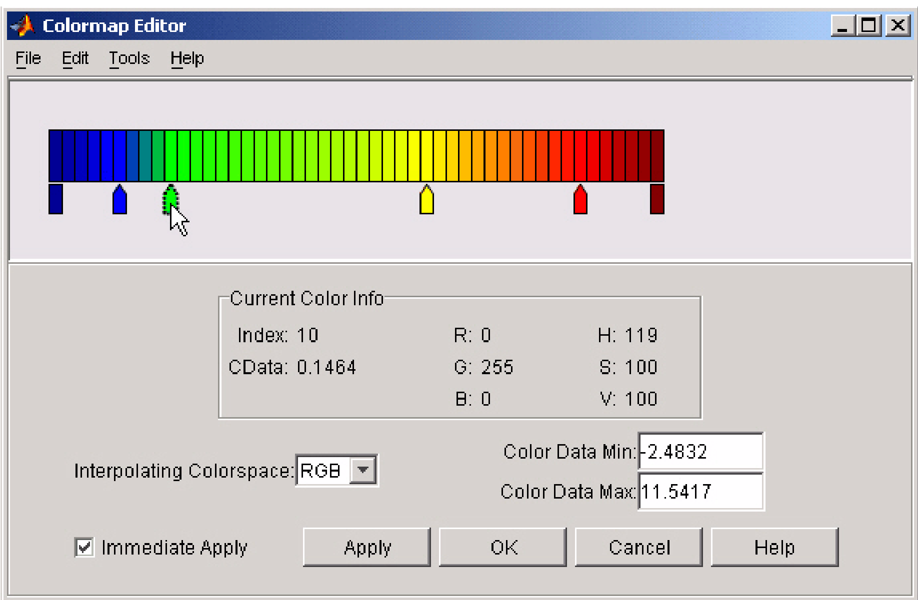


The **Immediate Apply** box is checked, so the graph displays the results of the changes made to the colormap.

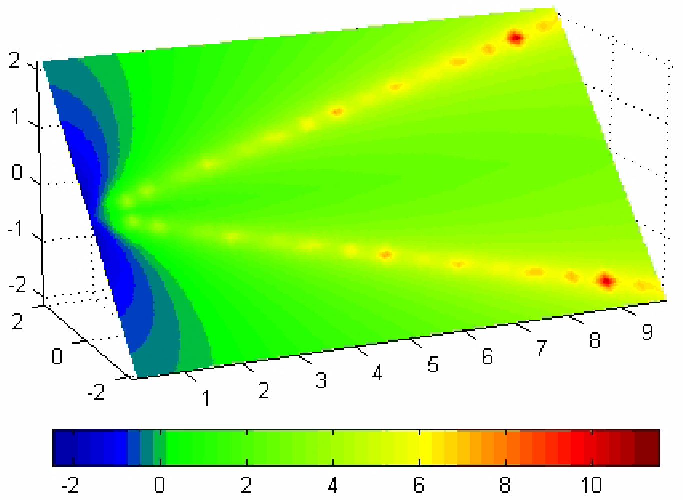


3 We want the fluid speed values around zero to stand out, so we need to find the color cell where the negative-to-positive transition occurs. Dragging the cursor over the color strip enables you to read the data values in the **Current Color Info** panel.

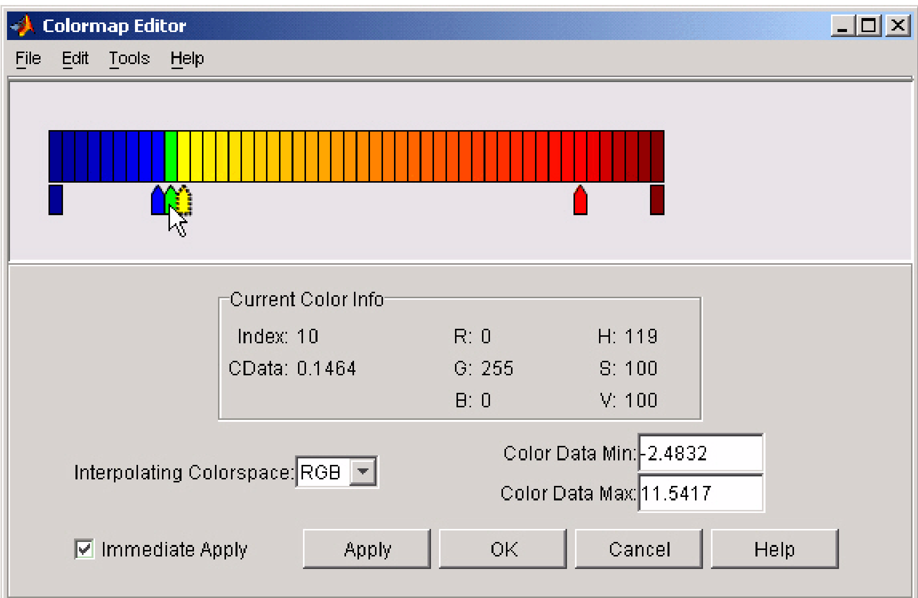
In this case, cell 10 is the first positive value, so we click below that cell and create a node pointer. Double-clicking the node pointer displays the color picker. Set the color of this node to green.



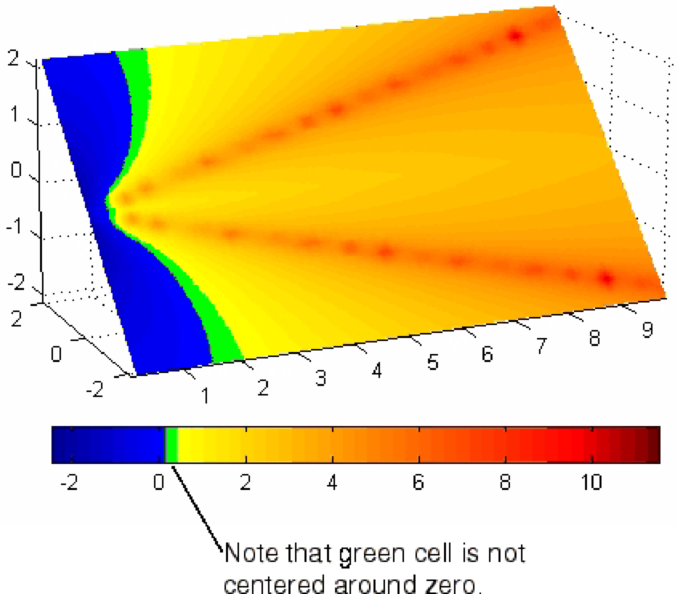
The graph continues to update to the modified colormap.



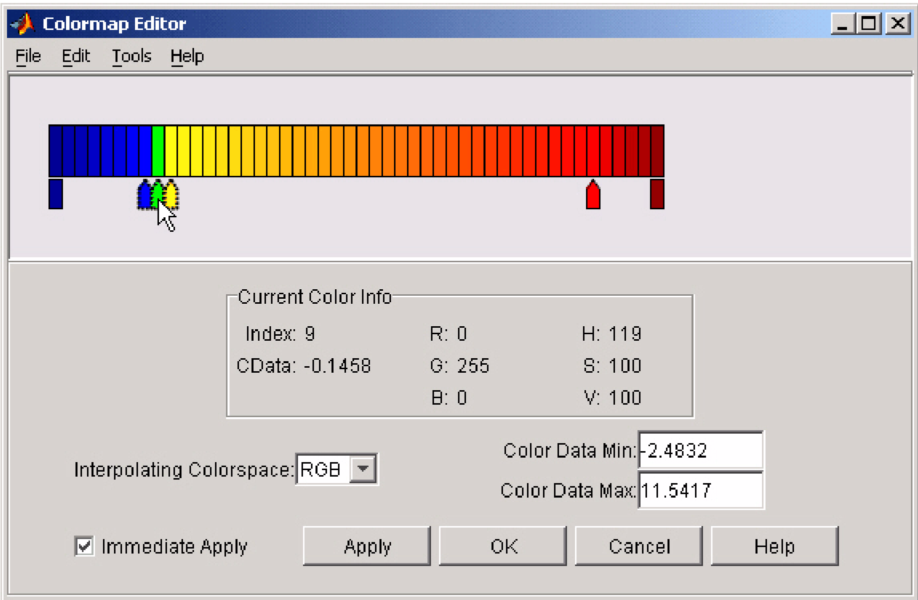
4 In the current state, the colormap colors are interpolated from the green node to the yellowish node about 20 cells away. We actually want only the single cell that is centered around zero to be colored green. To limit the color green to one cell, move the blue and yellow node pointers next to the green pointer.



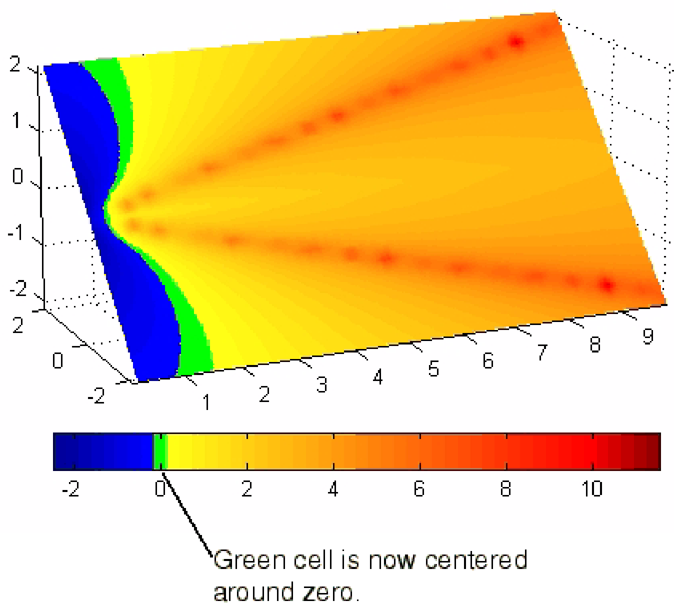
5 Before making further adjustments to the colormap, we need to move the green cell so that it is centered around zero. Use the colorbar to locate the green cell.



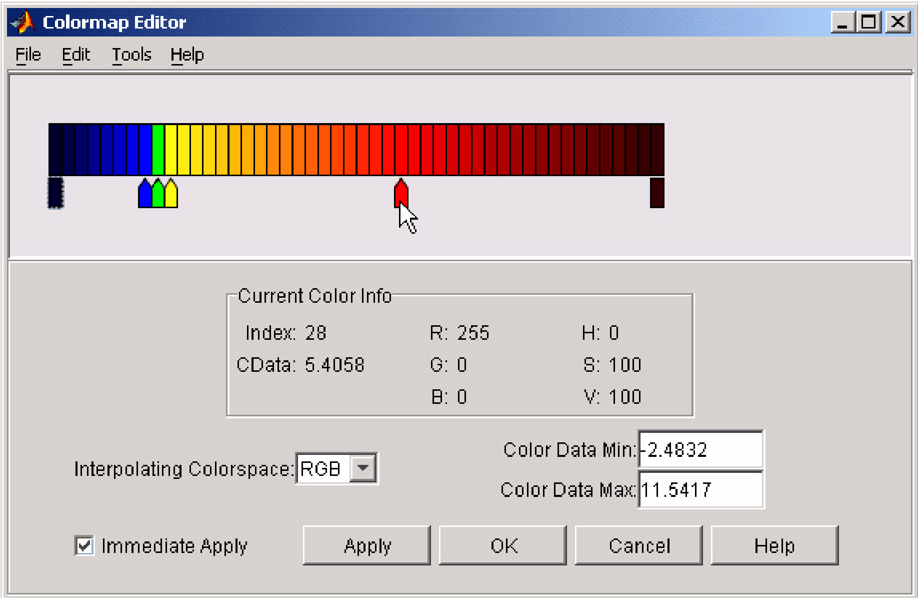
To recenter the green cell around zero, select the blue, green, and yellow node pointers (left-click blue, **Shift+click** yellow) and move them as a group using the left arrow key. Watch the colorbar in the figure window to see when the green color is centered around zero.



The slice plane now has the desired range of colors for negative, zero, and positive data.

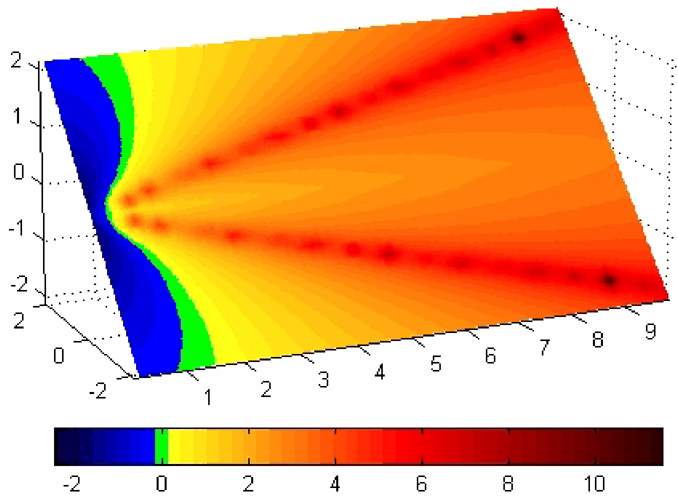


6 Increase the orange-red coloring in the slice by moving the red node pointer toward the yellow node.



7 Darken the endpoints to bring out more detail in the extremes of the data. Double-click the end nodes to display the color picker. Set the red endpoint to the RGB value [50 0 0] and set the blue endpoint to the RGB value [0 0 50].

The slice plane coloring now matches the example objectives.



Saving the Modified Colormap

You can save the modified colormap using the `colormap` function or the figure `Colormap` property.

After you have applied your changes, save the current figure colormap in a variable:

```
mycmap = get(fig,'Colormap'); % fig is figure
handle or use gcf
```

To use this colormap in another figure, set that figure's `Colormap` property:

```
set(new_fig,'Colormap',mycmap)
```

To save your modified colormap in a MAT-file, use the `save` command to save the `mycmap` workspace variable:

```
save('MyColormaps','mycmap')
```

To use your saved colormap in another MATLAB session, `load` the variable into the workspace and assign the colormap to the figure:

```
load('MyColormaps','mycmap')
set(fig,'Colormap',mycmap)
```

`colormap` | `get` | `load` | `propertyeditor` | `save` | `set`

How To

- "Colormaps"

Purpose

Color specification

Description

`ColorSpec` is not a function; it refers to the three ways in which you specify color for MATLAB graphics:

- RGB triple
- Short name
- Long name

The short names and long names are MATLAB strings that specify one of eight predefined colors. The RGB triple is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color; the intensities must be in the range [0 1]. The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
`[1 1 0]`	`y`	`yellow`
`[1 0 1]`	`m`	`magenta`
`[0 1 1]`	`c`	`cyan`
`[1 0 0]`	`r`	`red`
`[0 1 0]`	`g`	`green`
`[0 0 1]`	`b`	`blue`
`[1 1 1]`	`w`	`white`
`[0 0 0]`	`k`	`black`

Tips

The eight predefined colors and any colors you specify as RGB values are not part of a figure's colormap, nor are they affected by changes to the figure's colormap. They are referred to as *fixed* colors, as opposed to *colormap* colors.

Some high-level functions (for example, `scatter`) accept a colorspec as an input argument and use it to set the `CData` of graphic objects they create. When using such functions, take care not to specify a colorspec

in a property/value pair that sets CData; values for CData are always n-length vectors or n-by-3 matrices, where n is the length of XData and YData, never strings.

Examples

To change the background color of a figure to green, specify the color with a short name, a long name, or an RGB triple. These statements generate equivalent results:

```
whitebg('g')
whitebg('green')
whitebg([0 1 0]);
```

You can use ColorSpec anywhere you need to define a color. For example, this statement changes the figure background color to pink:

```
set(gcf,'Color',[1,0.4,0.6])
```

See Also

bar | bar3 | colordef | colormap | fill | fill3 | whitebg

Purpose Sparse column permutation based on nonzero count

Syntax

```
j = colperm(S)
```

Description `j = colperm(S)` generates a permutation vector `j` such that the columns of `S(:,j)` are ordered according to increasing count of nonzero entries. This is sometimes useful as a preordering for LU factorization; in this case use `lu(S(:,j))`.

If `S` is symmetric, then `j = colperm(S)` generates a permutation `j` so that both the rows and columns of `S(j,j)` are ordered according to increasing count of nonzero entries. If `S` is positive definite, this is sometimes useful as a preordering for Cholesky factorization; in this case use `chol(S(j,j))`.

Algorithms The algorithm involves a sort on the counts of nonzeros in each column.

Examples The `n`-by-`n` *arrowhead* matrix

```
A = [ones(1,n); ones(n-1,1) speye(n-1,n-1)]
```

has a full first row and column. Its LU factorization, `lu(A)`, is almost completely full. The statement

```
j = colperm(A)
```

returns `j = [2:n 1]`. So `A(j,j)` sends the full row and column to the bottom and the rear, and `lu(A(j,j))` has the same nonzero structure as `A` itself.

On the other hand, the Bucky ball example,

```
B = bucky
```

has exactly three nonzero elements in each row and column, so `j = colperm(B)` is the identity permutation and is no help at all for reducing fill-in with subsequent factorizations.

Purpose

Convenience function for static .NET System.Delegate Combine method

Syntax

```
result = Combine(delegateA,delegateB)
```

Description

`result = Combine(delegateA,delegateB)` combines two delegates into a new delegate.

Input Arguments

delegateA

.NET `System.Delegate` object. The first delegate in the new delegate.

delegateB

.NET `System.Delegate` object. The last delegate in the new delegate.

Output Arguments

result

.NET `System.Delegate` object. A new delegate that delegates to the input delegate `delegateA`, then `delegateB`

Alternatives

Use the static `Combine` method of the `System.Delegate` class.

comet

Purpose

2-D comet plot

Syntax

```
comet(y)
comet(x,y)
comet(x,y,p)
comet(axes_handle,...)
```

Description

`comet(y)` displays a comet graph of the vector `y`. A comet graph is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet(x,y)` displays a comet graph of vector `y` versus vector `x`.

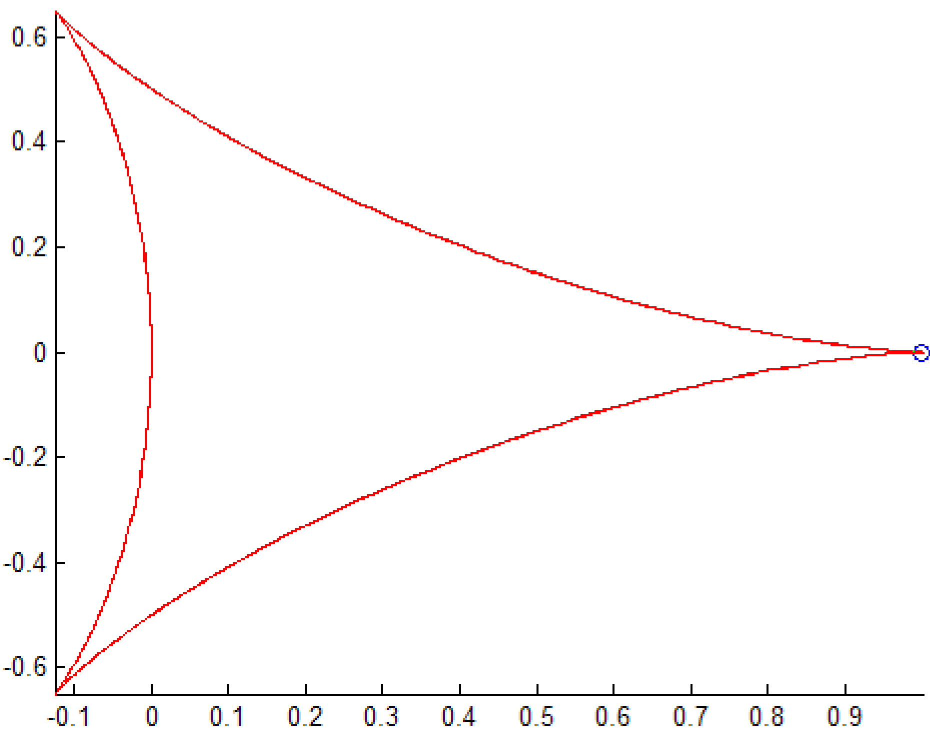
`comet(x,y,p)` specifies a comet body of length `p*length(y)`. `p` defaults to `0.1`.

`comet(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

Examples

Create a simple comet graph:

```
t = 0:.01:2*pi;
x = cos(2*t).*(cos(t).^2);
y = sin(2*t).*(sin(t).^2);
comet(x,y);
```



See Also

`comet3`

Purpose

3-D comet plot

Syntax

```
comet3(z)
comet3(x,y,z)
comet3(x,y,z,p)
comet3(axes_handle,...)
```

Description

A comet plot is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet3(z)` displays a 3-D comet graph of the vector `z`.

`comet3(x,y,z)` displays a comet graph of the curve through the points `[x(i),y(i),z(i)]`.

`comet3(x,y,z,p)` specifies a comet body of length `p*length(y)`. `p` must be between `0` and `1`.

`comet3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

Tips

The trace left by `comet3` is created by using an `EraseMode` of `none`, which means you cannot print the graph (you get only the comet head), and it disappears if you cause a redraw (for example, by resizing the window).

Examples

Create a 3-D comet graph.

```
t = -10*pi:pi/250:10*pi;
comet3((cos(2*t).^2).*sin(t),(sin(2*t).^2).*cos(t),t);
```

`comet`

commandhistory

Purpose

Open Command History window, or select it if already open

Syntax

```
commandhistory
```

Description

`commandhistory` opens the MATLAB Command History window when it is closed, and selects the Command History window when it is open. The Command History window presents a log of the statements most recently run in the Command Window.

See Also

`diary` | `prefdir` | `startup`

How To

- "Command History"

Purpose

Open Command Window, or select it if already open

Syntax

```
commandwindow
```

Description

`commandwindow` opens the MATLAB Command Window when it is closed, and selects the Command Window when it is open.

Tips

To determine the number of columns and rows that display in the Command Window, given its current size, use

```
get(0,'CommandWindowSize')
```

The number of columns is based on the width of the Command Window. With the matrix display width preference set to 80 columns, the number of columns is always 80.

See Also

`commandhistory` | `input` | `inputdlg`

How To

- "Optimize Desktop Layout for Limited Screen Space"
- "Set Command Window Preferences"

Purpose

Companion matrix

Syntax

```
A = compan(u)
```

Description

`A = compan(u)` returns the corresponding companion matrix whose first row is `-u(2:n)/u(1)`, where `u` is a vector of polynomial coefficients. The eigenvalues of `compan(u)` are the roots of the polynomial.

Examples

The polynomial $(x-1)(x-2)(x+3) = x^3 - 7x + 6$ has a companion matrix given by

```
u = [1  0  -7  6]
A = compan(u)
A =
     0     7    -6
     1     0     0
     0     1     0
```

The eigenvalues are the polynomial roots:

```
eig(compan(u))

ans =
    -3.0000
     2.0000
     1.0000
```

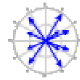
This is also `roots(u)`.

See Also

`eig` | `poly` | `polyval` | `roots`

Purpose

Plot arrows emanating from origin



Syntax

```
compass(U,V)
compass(Z)
compass(...,LineSpec)
compass(axes_handle,...)
h = compass(...)
```

Description

A compass graph displays the vectors with components `(U,V)` as arrows emanating from the origin. `U`, `V`, and `Z` are in Cartesian coordinates and plotted on a circular grid.

`compass(U,V)` displays a compass graph having *n* arrows, where *n* is the number of elements in `U` or `V`. The location of the base of each arrow is the origin. The location of the tip of each arrow is a point relative to the base and determined by `[U(i),V(i)]`.

`compass(Z)` displays a compass graph having *n* arrows, where *n* is the number of elements in `Z`. The location of the base of each arrow is the origin. The location of the tip of each arrow is relative to the base as determined by the real and imaginary components of `Z`. This syntax is equivalent to `compass(real(Z),imag(Z))`.

`compass(...,LineSpec)` draws a compass graph using the line type, marker symbol, and color specified by `LineSpec`.

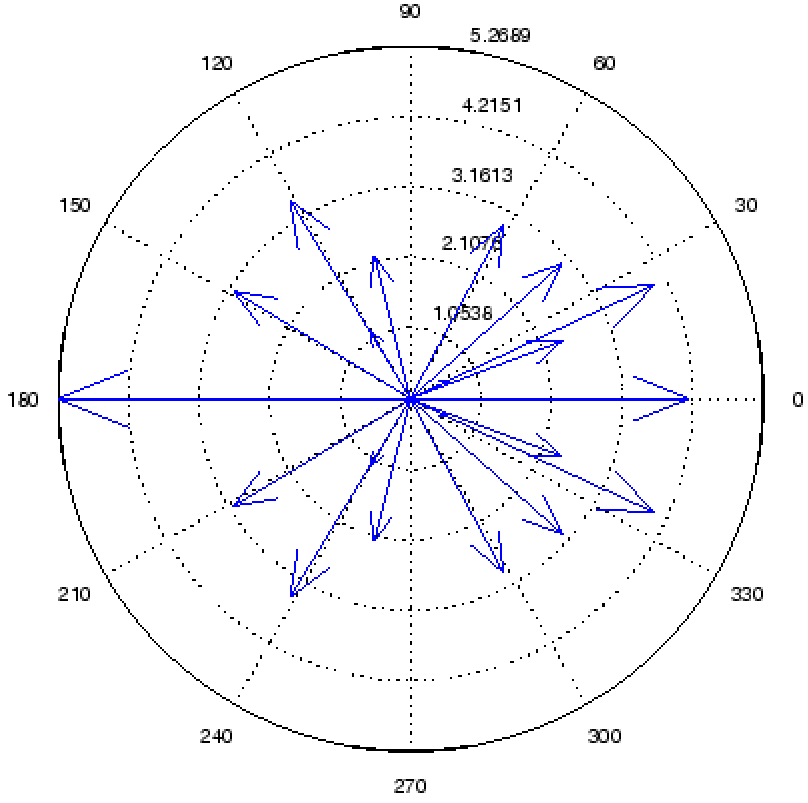
`compass(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = compass(...)` returns handles to line objects.

Examples

Draw a compass graph of the eigenvalues of a matrix.

```
Z = eig(randn(20,20));
compass(Z)
```



See Also

`feather` | `polar` | `LineSpec` | `quiver` | `rose`

How To

- "Compass Plots"

complex

Purpose

Construct complex data from real and imaginary components

Syntax

```
c = complex(a,b)
```

Description

`c = complex(a,b)` creates a complex output, `c`, from the two real inputs.

```
c = a + bi
```

The output is the same size as the inputs, which must be scalars or equally sized vectors, matrices, or multi-dimensional arrays.

Note If `b` is all zeros, `c` is complex and the value of all its imaginary components is `0`. In contrast, the result of the addition `a+0i` returns a strictly real result.

The following describes when `a` and `b` can have different data types, and the resulting data type of the output `c`:

- If either of `a` or `b` has type `single`, `c` has type `single`.
- If either of `a` or `b` has an integer data type, the other must have the same integer data type or type scalar `double`, and `c` has the same integer data type.

`c = complex(a)` for real `a` returns the complex result `c` with real part `a` and `0` as the value of all imaginary components. Even though the value of all imaginary components is `0`, `c` is complex and `isreal(c)` returns false.

The `complex` function provides a useful substitute for expressions such as

```
a + i*b   or   a + j*b
```

in cases when the names "i" and "j" may be used for other variables (and do not equal $\sqrt{-1}$), when a and b are not single or double, or when b is all zero.

Examples

Create complex uint8 vector from two real uint8 vectors.

```
a = uint8([1;2;3;4])
b = uint8([2;2;7;7])
c = complex(a,b)
c =
   1.0000 + 2.0000i
   2.0000 + 2.0000i
   3.0000 + 7.0000i
   4.0000 + 7.0000i
```

Tiff.computeStrip

Purpose

Index number of strip containing specified coordinate

Syntax

```
stripNumber = tiffobj.computeStrip(row)
stripNumber = tiffobj.computeStrip(row, plane)
```

Description

`stripNumber = tiffobj.computeStrip(row)` returns the index number of the strip containing the given row. The value of `row` must be one-based.

`stripNumber = tiffobj.computeStrip(row, plane)` returns the index number of the strip containing the given row in the specified plane, if the value of the `PlanarConfiguration` tag is `Tiff.PlanarConfiguration.Separate`.. The values of row and plane must be one-based.

`computeStrip` clamps out-of-range coordinate values to the bounds of the image.

Examples

Open a `Tiff` object and get the index number of the strip containing the middle row. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path:

```
t = Tiff('myfile.tif','r');
% Get the number of rows in the image.
numRows = t.getTag('ImageLength');
% Get the number of the strip containing the middle row
stripNum = t.computeStrip(numRows/2);
```

References

This method corresponds to the `TIFFComputeStrip` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

See Also

`Tiff.computeTile`

Tutorials

- "Reading Image Data and Metadata from TIFF Files"

Purpose

Index number of tile containing specified coordinates

Syntax

```
tileNumber = tiffobj.computeTile([row col])
tileNumber = tiffobj.computeTile([row col], plane)
```

Description

`tileNumber = tiffobj.computeTile([row col])` returns the index number of the tile containing the row and column pixel coordinates. The row and column coordinate values are one-based.

`tileNumber = tiffobj.computeTile([row col], plane)` returns the index number of the tile containing the row and column pixel coordinates in the specified plane, if the value of the `PlanarConfiguration` tag is `Tiff.PlanarConfiguration.Separate`. The row, column, and plane coordinate values are one-based.

`computeTile` clamps out-of-range coordinate values to the bounds of the image.

Examples

Open a `Tiff` object and get the index number of the tile containing the last pixel. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif','r');
% Get the dimensions of the image to calculate coordinates.
numRows = t.getTag('ImageLength');
numCols = t.getTag('ImageWidth');
% Get the ID number of the tile containing the coordinates.
tileNum = t.computeTile([numRows numCols]);
```

References

This method corresponds to the `TIFFComputeTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTiff - TIFF Library and Utilities`.

`Tiff.computeStrip`

Tutorials

- "Exporting Image Data and Metadata to TIFF Files"

- “Reading Image Data and Metadata from TIFF Files”

Purpose

Information about computer on which MATLAB software is running

Syntax

```
str = computer
archstr = computer('arch')
[str,maxsize] = computer
[str,maxsize,endian] = computer
```

Description

`str = computer` returns the string `str` with the computer type on which MATLAB is running.

`archstr = computer('arch')` returns the string `archstr` which is used by the `mex` command `-arch` switch.

`[str,maxsize] = computer` returns the integer `maxsize`, the maximum number of elements allowed in an array with this version of MATLAB.

`[str,maxsize,endian] = computer` returns either 'L' for little-endian byte ordering or 'B' for big-endian byte ordering.

Platform	Word Size	str	archstr	maxsize	endian	ispc	isunix	ismac
Microsoft Windows	32-bit	PCWIN	win32	2^31 - 1	L	1	0	0
	64-bit	PCWIN64	win64	2^48 - 1	L	1	0	0
Linux	64-bit	GLNXA64	glnxa64	2^48 - 1	L	0	1	0
Apple Macintosh	64-bit	MACI64	maci64	2^48 - 1	L	0	1	1

Tips

In some cases, both 32-bit and 64-bit versions of MATLAB can run on the same platform. In this case, the value returned by `computer` reflects which of these is running. For example, if you run a 32-bit version of MATLAB on a Windows x64 platform, `computer` returns `PCWIN`, indicating that the 32-bit version is running. You can get this information and the value of `archstr` from the **Help** menu, as described

in “Information About your Installation” in the Desktop Tools and Development Environment documentation.

See Also

`getenv` | `setenv` | `ispc` | `isunix` | `ismac`

Purpose

Condition number with respect to inversion

Syntax

```
c = cond(X)
c = cond(X,p)
```

Description

The *condition number* of a matrix measures the sensitivity of the solution of a system of linear equations to errors in the data. It gives an indication of the accuracy of the results from matrix inversion and the linear equation solution. Values of `cond(X)` and `cond(X,p)` near 1 indicate a well-conditioned matrix.

`c = cond(X)` returns the 2-norm condition number, the ratio of the largest singular value of `X` to the smallest.

`c = cond(X,p)` returns the matrix condition number in `p`-norm:

```
norm(X,p) * norm(inv(X),p)
```

If p is...	Then cond(X,p) returns the...
1	1-norm condition number
2	2-norm condition number
'fro'	Frobenius norm condition number
inf	Infinity norm condition number

Algorithms

The algorithm for `cond` (when `p = 2`) uses the singular value decomposition, `svd`. When the input matrix is sparse, `cond` ignores any specified `p` value and calls `condest`.

See Also

`condeig` | `condest` | `norm` | `normest` | `rank` | `rcond` | `svd`

Purpose

Condition number with respect to eigenvalues

Syntax

```
c = condeig(A)
[V,D,s] = condeig(A)
```

Description

`c = condeig(A)` returns a vector of condition numbers for the eigenvalues of `A`. These condition numbers are the reciprocals of the cosines of the angles between the left and right eigenvectors.

`[V,D,s] = condeig(A)` is equivalent to

```
[V,D] = eig(A);
s = condeig(A);
```

Large condition numbers imply that `A` is near a matrix with multiple eigenvalues.

See Also

`balance` | `cond` | `eig`

Purpose

1-norm condition number estimate

Syntax

```
c = condest(A)
c = condest(A,t)
[c,v] = condest(A)
```

Description

`c = condest(A)` computes a lower bound `c` for the 1-norm condition number of a square matrix `A`.

`c = condest(A,t)` changes `t`, a positive integer parameter equal to the number of columns in an underlying iteration matrix. Increasing the number of columns usually gives a better condition estimate but increases the cost. The default is `t = 2`, which almost always gives an estimate correct to within a factor 2.

`[c,v] = condest(A)` also computes a vector `v` which is an approximate null vector if `c` is large. `v` satisfies `norm(A*v,1) = norm(A,1)*norm(v,1)/c`.

Note `condest` invokes `rand`. If repeatable results are required then use `rng` to set the random number generator to its startup settings before using `condest`.

```
rng('default')
```

Tips

This function is particularly useful for sparse matrices.

Algorithms

`condest` is based on the 1-norm condition estimator of Hager [1] and a block-oriented generalization of Hager's estimator given by Higham and Tisseur [2]. The heart of the algorithm involves an iterative search to estimate $\left\|A^{-1}\right\|_1$ without computing A^{-1}. This is posed as the convex but nondifferentiable optimization problem $\max\left\|A^{-1}\mathbf{x}\right\|_1$ subject to $\|\mathbf{x}\|_1 = 1$

`cond` | `norm` | `normest`

Purpose

Plot velocity vectors as cones in 3-D vector field

Syntax

```
coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)
coneplot(U,V,W,Cx,Cy,Cz)
coneplot(...,s)
coneplot(...,color)
coneplot(...,'quiver')
coneplot(...,'method')
coneplot(X,Y,Z,U,V,W,'nointerp')
coneplot(axes_handle,...)
h = coneplot(...)
```

Description

`coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)` plots velocity vectors as cones pointing in the direction of the velocity vector and having a length proportional to the magnitude of the velocity vector. `X`, `Y`, `Z` define the coordinates for the vector field. `U`, `V`, `W` define the vector field. These arrays must be the same size, monotonic, and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). `Cx`, `Cy`, `Cz` define the location of the cones in the vector field. The section "Specifying Starting Points for Stream Plots" in Visualization Techniques provides more information on defining starting points.

`coneplot(U,V,W,Cx,Cy,Cz)` (omitting the `X`, `Y`, and `Z` arguments) assumes `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p]= size(U)`.

`coneplot(...,s)` automatically scales the cones to fit the graph and then stretches them by the scale factor `s`. If you do not specify a value for `s`, `coneplot` uses a value of 1. Use `s = 0` to plot the cones without automatic scaling.

`coneplot(...,color)` interpolates the array `color` onto the vector field and then colors the cones according to the interpolated values. The size of the `color` array must be the same size as the `U`, `V`, `W` arrays. This option works only with cones (that is, not with the `quiver` option).

`coneplot(...,'quiver')` draws arrows instead of cones (see `quiver3` for an illustration of a quiver plot).

`coneplot(...,'method')` specifies the interpolation method to use. *`method`* can be `linear`, `cubic`, or `nearest`. `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`coneplot(X,Y,Z,U,V,W,'nointerp')` does not interpolate the positions of the cones into the volume. The cones are drawn at positions defined by `X`, `Y`, `Z` and are oriented according to `U`, `V`, `W`. Arrays `X`, `Y`, `Z`, `U`, `V`, `W` must all be the same size.

`coneplot(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = coneplot(...)` returns the handle to the `patch` object used to draw the cones. You can use the `set` command to change the properties of the cones.

`coneplot` automatically scales the cones to fit the graph, while keeping them in proportion to the respective velocity vectors.

Examples

Plot the velocity vector cones for vector volume data representing the motion of air through a rectangular region of space:

```
% Load the data. The winds data set contains six 3-D arrays: u, v, and w specify
% the vector components at each of the coordinates specified in x, y, and z. The
% coordinates define a lattice grid structure where the data is sampled within the
% volume.
load wind

% Now establish the range of the data to place the slice planes and to specify
% where you want the cone plots (min, max):
xmin = min(x(:));
xmax = max(x(:));
ymin = min(y(:));
ymax = max(y(:));
zmin = min(z(:));

% Use daspect to set the data aspect ratio of the axes before calling coneplot.
daspect([2,2,1])
```

```
% Decide where in data space you want to plot cones. This example selects the
% full range of x and y in eight steps and the range 3 to 15 in four steps in z
% using linspace and meshgrid.
xrange = linspace(xmin,xmax,8);
yrange = linspace(ymin,ymax,8);
zrange = 3:4:15;
[cx cy cz] = meshgrid(xrange,yrange,zrange);

% Draw the cones, setting the scale factor to 5 to make the cones larger than
% the default size:
hcones = coneplot(x,y,z,u,v,w,cx,cy,cz,5);
% Set the coloring of each cone using FaceColor and EdgeColor:
set(hcones,'FaceColor','red','EdgeColor','none')

% Calculate the magnitude of the vector field (which represents wind speed) to
% generate scalar data for the slice command:
hold on
wind_speed = sqrt(u.^2 + v.^2 + w.^2);
% Create slice planes along the x-axis at xmin and xmax, along the y-axis at
% ymax, and along the z-axis at zmin:
hsurfaces = slice(x,y,z,wind_speed,[xmin,xmax],ymax,zmin);
% Specify interpolated face color so the slice coloring indicates wind speed,
% and do not draw edges (hold, slice, FaceColor, EdgeColor):
set(hsurfaces,'FaceColor','interp','EdgeColor','none')
hold off

% Use the axis command to set the axis limits equal to the range of the data.

Tutorials

- “Overview of Volume Visualization”

conj

Purpose

Complex conjugate

Syntax

```
ZC = conj(Z)
```

Description

`ZC = conj(Z)` returns the complex conjugate of the elements of `Z`.

Algorithms

If `Z` is a complex array:

```
conj(Z) = real(Z) - i*imag(Z)
```

See Also

`i` | `j` | `imag` | `real`

Purpose

Pass control to next iteration of `for` or `while` loop

Syntax

```
continue
```

Description

`continue` temporarily interrupts the execution of a program loop, skipping any remaining statements in the body of the loop for the current pass. The `continue` statement does not cause an immediate exit from the loop as a `break` or `return` statement would do, but instead continues within the loop for as long as the stated `for` or `while` condition holds true.

A `continue` statement in a *nested* loop behaves in the same manner. Execution resumes at the `for` or `while` statement of the loop in which the `continue` statement was encountered, and reenters the loop if the stated condition evaluates to `true`.

Examples

Count the number of lines of code in the file `magic.m`, skipping all blank lines and comments:

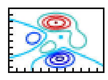
```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) || strncmp(line,'%',1) || ~ischar(line)
        continue
    end
    count = count + 1;
end
fprintf('%d lines\n',count);
fclose(fid);
```

See Also

`for` | `while` | `end` | `break` | `return`

Purpose

Contour plot of matrix



Syntax

```
contour(Z)
contour(Z,n)
contour(Z,v)
contour(X,Y,Z)
contour(X,Y,Z,n)
contour(X,Y,Z,v)
contour(...,LineSpec)
contour(axes_handle,...)
[C,h] = contour(...)
```

Description

A contour plot displays isolines of matrix `Z`. Label the contour lines using `clabel`.

`contour(Z)` draws a contour plot of matrix `Z`, where `Z` is interpreted as heights with respect to the *x*-*y* plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The number of contour lines and the values of the contour lines are chosen automatically based on the minimum and maximum values of `Z`. The ranges of the *x*- and *y*-axis are `[1:n]` and `[1:m]`, where `[m,n] = size(Z)`.

`contour(Z,n)` draws a contour plot of matrix `Z` with `n` contour levels where `n` is a scalar.

`contour(Z,v)` draws a contour plot of matrix `Z` with contour lines at the data values specified in the monotonically increasing vector `v`. The number of contour levels is equal to `length(v)`. To draw a single contour of level `i`, use `contour(Z,[i i])`. Specifying the vector v sets the `LevelListMode` to manual to allow user control over contour levels. See `contourgroup properties` for more information.

`contour(X,Y,Z)`, `contour(X,Y,Z,n)`, and `contour(X,Y,Z,v)` draw contour plots of `Z` using `X` and `Y` to determine the *x*- and *y*-axis limits.

When X and Y are matrices, they must be the same size as Z and must be monotonically increasing.

contour(...,LineSpec) draws the contours using the line type and color specified by LineSpec. contour ignores marker symbols.

contour(axes_handle,...) plots into axes axes_handle instead of gca.

[C,h] = contour(...) returns a contour matrix, C, that contains the data that defines the contour lines, and a handle, h, to a contourgroup object. The clabel function uses contour matrix C to label the contour lines. ContourMatrix is also a read-only contourgroup property that you can obtain from the returned handle.

Use contourgroup object properties to control the contour plot appearance.

If X or Y is irregularly spaced, contour calculates contours using a regularly spaced contour grid, and then transforms the data to X or Y.

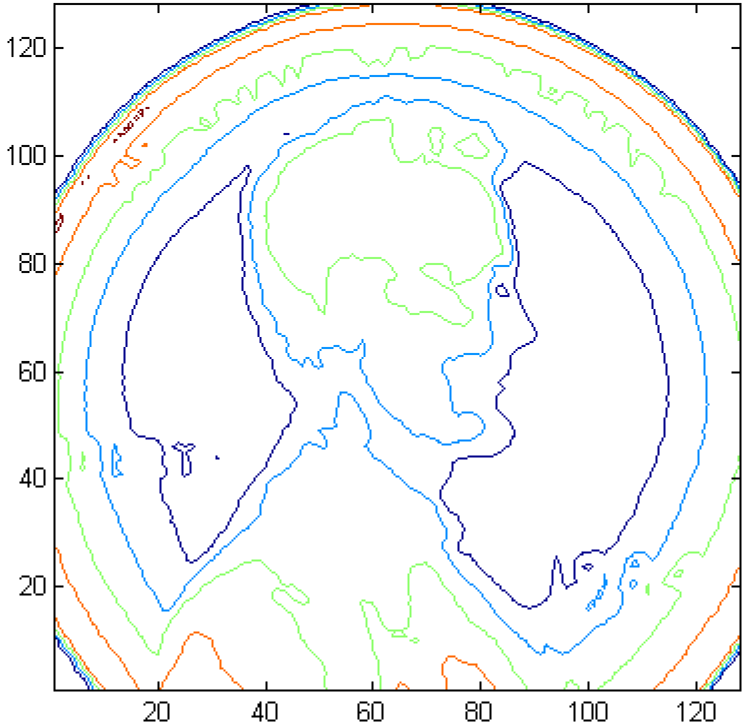
Examples

Contour Graph of a Data Set

Load the penny data set, which is a 128x128 grid of the surface relief of a U.S. penny. It generates a variable *P*. To contour this data, pass the matrix into the contour function. You have to flip the graph using flipud to see the actual contour of the image on the penny:

```
load penny;
figure;
contour(flipud(P));
axis square;
```

The figure output is as:

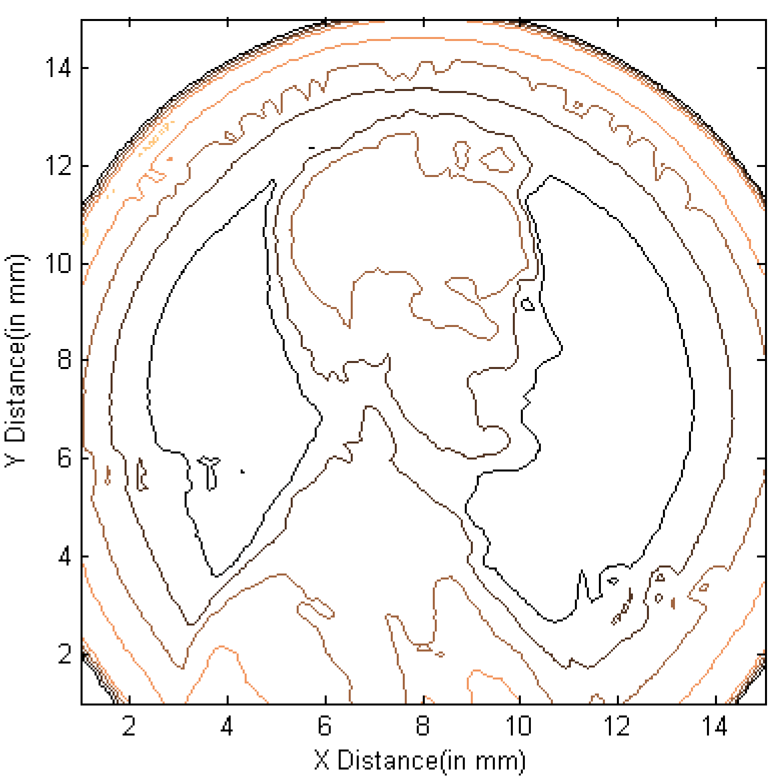


Contour Graph of a Matrix

Consider plotting the `penny` dataset with respect to the diameter distance. Assume the starting point to be `1mm` and ending at around `15mm`, we need 128 data points on both x and y axes because the dataset is a `128x128 double`. To generate 128 elements for both axes, we use `linspace` function here.

```
x = linspace(1,15,128);
y = linspace(1,15,128);
figure;
```

```
contour(x,y,flipud(P));
axis square;
colormap('Copper');
xlabel('X Distance(in mm)');
ylabel('Y Distance(in mm)');
```



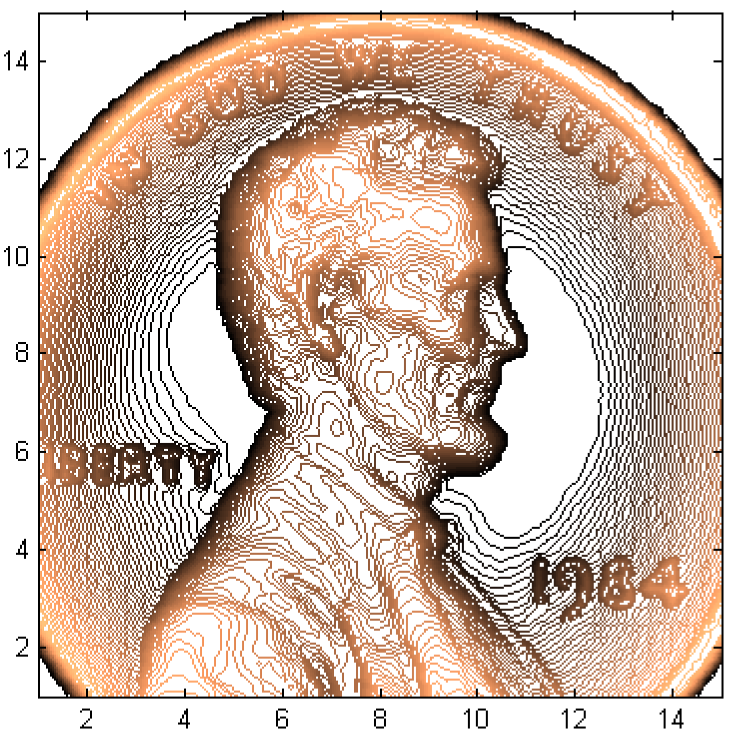
Contour Graph with Specified Number of Contour Lines

To plot a contour with more levels,

```
figure;
```

```
contour(x,y,flipud(P),50);
axis square;
colormap('Copper');
```

The figure looks like this.



Contour Graph of a Function

Create a contour plot of the function:

$z = xe^{(-x_2 - y_2)}$

over the range $-2 \le x \le 2$, $-2 \le y \le 3$.

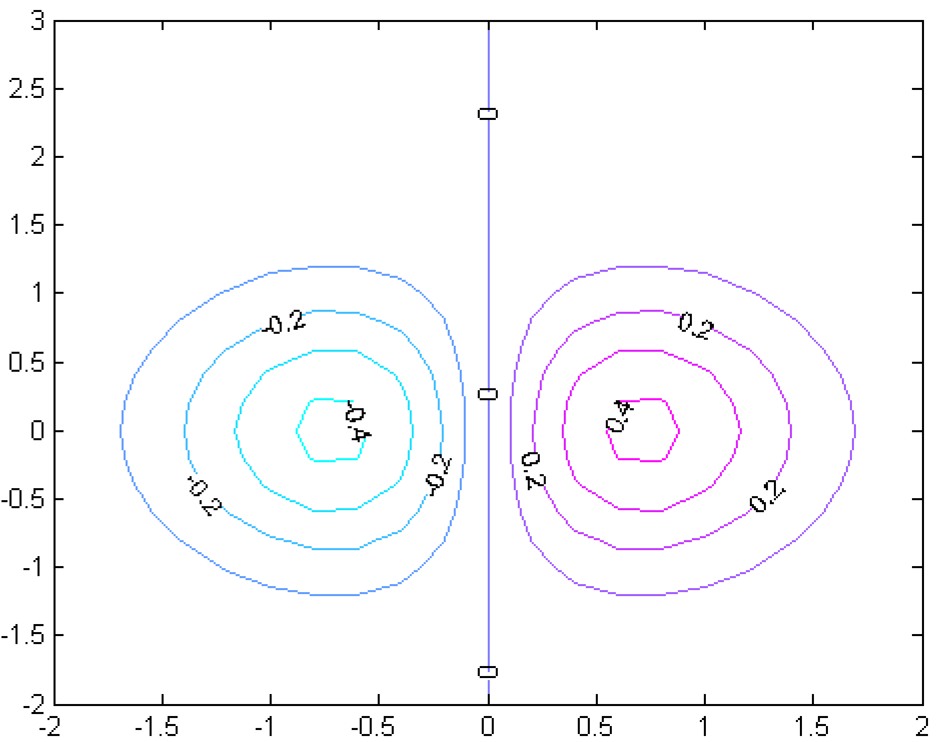
Evaluate the function to create matrix, Z. Use the meshgrid function to generate the values used to evaluate the function within the specified range:

```
[X,Y] = meshgrid(-2:.2:2,-2:.2:3);
Z = X.*exp(-X.^2-Y.^2);
```

Generate the contour plot of Z:

- Display contour labels by setting the ShowText property to on.
- Label every other contour line by setting the TextStep property to twice the contour interval (that is, two times the LevelStep property).
- Use a smoothly varying colormap.

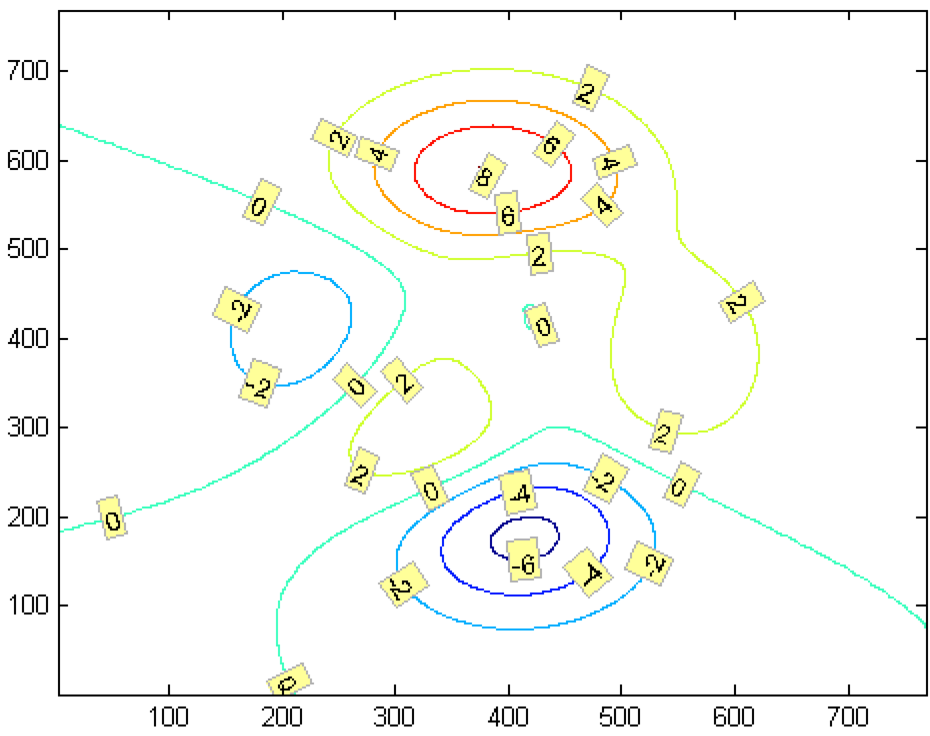
```
[C,h] = contour(X,Y,Z);
set(h,'ShowText','on','TextStep',get(h,'LevelStep')*2)
colormap cool
```



Smoothing Contour Data

Use `interp2` to smooth contour lines. Also set the contour label text `BackgroundColor` to a light yellow and the `EdgeColor` to light gray.

```
Z = peaks;
[C,h] = contour(interp2(Z,4));
text_handle = clabel(C,h);
set(text_handle,'BackgroundColor',[1 1 .6],...
    'Edgecolor',[.7 .7 .7])
```



For more examples using `contour`, see “Contour Plots”.

Data With Discontinuities

The `contour` function cannot determine if there are discontinuities in the input data. You can add `NaN`s to the data to prevent drawing the contour lines in those regions. For example, add `NaN` to the `y` data where `y == 0` and `x < 0`:

```
[x,y] = meshgrid(-2.05:.1:2.05,[-2.05:.1:-0.05,0,0.05:.1:2.05]);
y(y==0 & x<0) = NaN; % Explicitly add NaNs to data
```

```
contour(x,y,atan2(y,x))
```

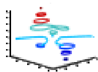
How To

- "Contour Plots"

Purpose

3-D contour plot



Syntax

```
contour3(Z)
contour3(Z,n)
contour3(Z,v)
contour3(X,Y,Z)
contour3(X,Y,Z,n)
contour3(X,Y,Z,v)
contour3(...,LineSpec)
contour3(axes_handle,...)
[C,h] = contour3(...)
```

Description

`contour3` creates a 3-D contour plot of a surface defined on a rectangular grid.

`contour3(Z)` draws a contour plot of matrix `Z` in a 3-D view. `Z` is interpreted as heights with respect to the *x*-*y* plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The number of contour levels and the values of contour levels are chosen automatically based on the minimum and maximum values of `Z`. The ranges of the *x*- and *y*-axis are `[1:n]` and `[1:m]`, where `[m,n] = size(Z)`.

`contour3(Z,n)` draws a contour plot of matrix `Z` with `n` contour levels in a 3-D view.

`contour3(Z,v)` draws a contour plot of matrix `Z` with contour lines at the values specified in vector `v`. The number of contour levels is equal to `length(v)`. To draw a single contour of level `i`, use `contour(Z,[i i])`. Specifying the vector v sets the `LevelListMode` to manual to allow user control over contour levels. See `contourgroup properties` for more information.

`contour3(X,Y,Z)`, `contour3(X,Y,Z,n)`, and `contour3(X,Y,Z,v)` draw contour plots of `Z` using `X` and `Y` to determine the *x*- and *y*-axis limits. If `X` is a matrix, `X(1,:)` defines the *x*-axis. If `Y` is a matrix, `Y(:,1)` defines

the *y*-axis. When X and Y are matrices, they must be the same size as Z and must be monotonically increasing.

`contour3(...,LineSpec)` draws the contour lines using the line type and color specified by `LineSpec`. `contour3` ignores marker symbols.

`contour3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`[C,h] = contour3(...)` returns a contour matrix, `C`, that contains the data that defines the contour lines, and a handle, `h`, to an array of handles to graphics objects. The `clabel` function uses contour matrix `C` to label the contour lines. The graphic objects that `contour3` creates are `patch` objects, or if you specify a `LineSpec` argument, `line` objects.

Tips

If `X` or `Y` is irregularly spaced, `contour3` calculates contours using a regularly spaced contour grid, and then transforms the data to `X` or `Y`.

If you do not specify `LineSpec`, the functions `colormap` and `caxis` control the color.

Label the contour lines using `clabel`.

`contour3(...)` works the same as `contour(...)` with these exceptions:

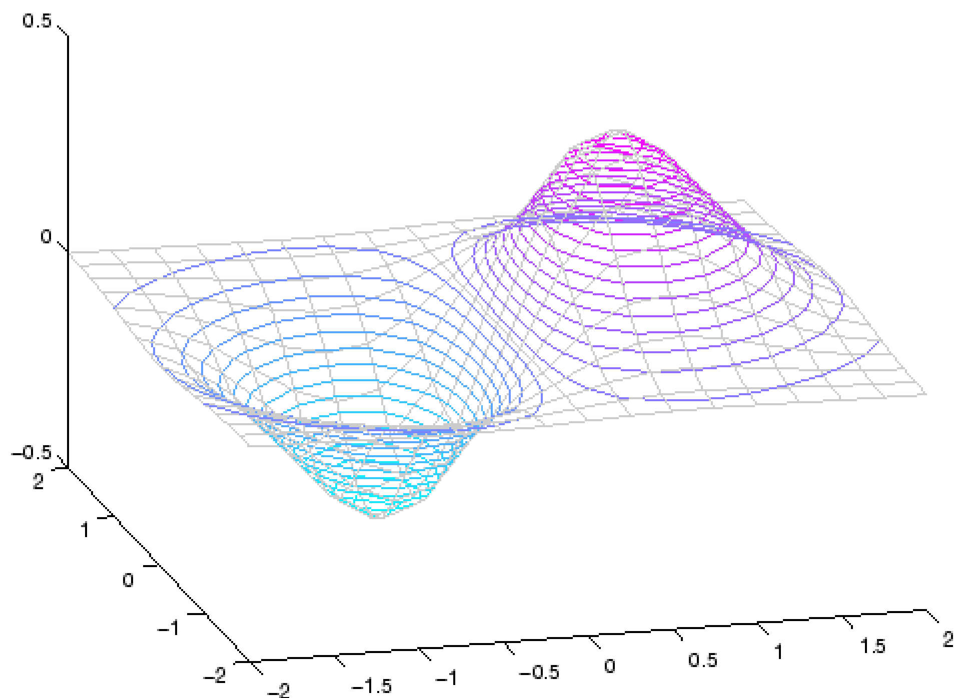
- The contours are drawn at their corresponding Z level.
- Multiple `patch` or `line` objects are created instead of a `contourgroup`.
- Calling `contour3` with trailing property-value pairs is not allowed.

Examples

Plot the three-dimensional contour of a function and superimpose a surface plot to enhance visualization of the function.

```
[X,Y] = meshgrid([-2:.25:2]);
Z = X.*exp(-X.^2-Y.^2);
contour3(X,Y,Z,30)
surface(X,Y,Z,'EdgeColor',[.8 .8 .8],'FaceColor','none')
grid off
view(-15,25)
```

```
colormap cool
```



For more examples using `contour3`, see “Contour Plots”.

`contour` | `contourc` | `contourf` | `meshc` | `meshgrid` | `surfc` | `contourgroup properties`

How To

- “Contour Plots”

contourc

Purpose

Low-level contour plot computation

Syntax

```
C = contourc(Z)
C = contourc(Z,n)
C = contourc(Z,v)
C = contourc(x,y,Z)
C = contourc(x,y,Z,n)
C = contourc(x,y,Z,v)
```

Description

`contourc` calculates the contour matrix `C` used by `contour`, `contour3`, and `contourf`. The values in `Z` determine the heights of the contour lines with respect to a plane. The contour calculations use a regularly spaced grid determined by the dimensions of `Z`.

`C = contourc(Z)` computes the contour matrix from data in matrix `Z`, where `Z` must be at least a 2-by-2 matrix. The contours are isolines in the units of `Z`. The number of contour lines and the corresponding values of the contour lines are chosen automatically.

`C = contourc(Z,n)` computes contours of matrix `Z` with `n` contour levels.

`C = contourc(Z,v)` computes contours of matrix `Z` with contour lines at the values specified in vector `v`. The length of `v` determines the number of contour levels. To compute a single contour of level `i`, use `contourc(Z,[i i])`.

`C = contourc(x,y,Z)`, `C = contourc(x,y,Z,n)`, and `C = contourc(x,y,Z,v)` compute contours of `Z` using vectors `x` and `y` to determine the *x*- and *y*-axis limits. `x` and `y` must be monotonically increasing.

Tips

`C` is a two-row matrix specifying all the contour lines. Each contour line defined in matrix `C` begins with a column that contains the value of the contour (specified by `v` and used by `clabel`), and the number of `(x,y)` vertices in the contour line. The remaining columns contain the data for the `(x,y)` pairs.

```
C = [value1 xdata(1) xdata(2) ... xdata(dim1) value2 xdata(1) xdata(2) ..
```

```
dim1 ydata(1) ydata(2) ... ydata(dim1) dim2 ydata(1) ydata(2) ... y
```

Specifying irregularly spaced `x` and `y` vectors is not the same as contouring irregularly spaced data. If `x` or `y` is irregularly spaced, `contourc` calculates contours using a regularly spaced contour grid, then transforms the data to `x` or `y`.

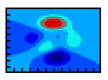
`clabel` | `contour` | `contour3` | `contourf`

How To

- "The Contouring Algorithm"

Purpose

Filled 2-D contour plot



Syntax

```
contourf(Z)
contourf(Z,n)
contourf(Z,v)
contourf(X,Y,Z)
contourf(X,Y,Z,n)
contourf(X,Y,Z,v)
contourf(...,LineSpec)
contourf(axes_handle,...)
contour(axes_handle,...)
[C,h] = contourf(...)
```

Description

A filled `contour` plot displays isolines calculated from matrix `Z` and fills the areas between the isolines using constant colors corresponding to the current figure's colormap.

`contourf(Z)` draws a filled contour plot of matrix `Z`, where `Z` is interpreted as heights with respect to the *x*-*y* plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The number of contour lines and the values of the contour lines are chosen automatically based on the minimum and maximum values of `Z`. The ranges of the *x*- and *y*-axis are `[1:n]` and `[1:m]`, where `[m,n] = size(Z)`.

`contourf(Z,n)` draws a filled contour plot of matrix `Z` with `n` contour levels.

`contourf(Z,v)` draws a filled contour plot of matrix `Z` with contour lines at the data values specified in the monotonically increasing vector `v`. The number of contour levels is equal to `length(v)`. To draw a single contour of level `i`, use `contour(Z,[i i])`. Specifying the vector v sets the `LevelListMode` to manual to allow user control over contour levels. See `contourgroup properties` for more information.

`contourf(X,Y,Z)`, `contourf(X,Y,Z,n)`, and `contourf(X,Y,Z,v)` draw filled contour plots of `Z` using `X` and `Y` to determine the *x*- and *y*-axis limits. When `X` and `Y` are matrices, they must be the same size as `Z` and must be monotonically increasing.

`contourf(...,LineSpec)` draws the contour lines using the line type and color specified by `LineSpec`. `contourf` ignores marker symbols.

`contourf(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`contour(axes_handle,...)` plots into axes `gerkaxes_handle` instead of `gca`.

`[C,h] = contourf(...)` returns a contour matrix, `C`, that contains the data that defines the contour lines, and a handle, `h`, to a contourgroup object containing the filled contours. The `clabel` function uses contour matrix `C` to label the contour lines. `ContourMatrix` is also a read-only Contourgroup property that you can obtain from the returned handle.

Tips

Use `contourgroup` object properties to control the filled contour plot appearance.

Label the contour lines using `clabel`.

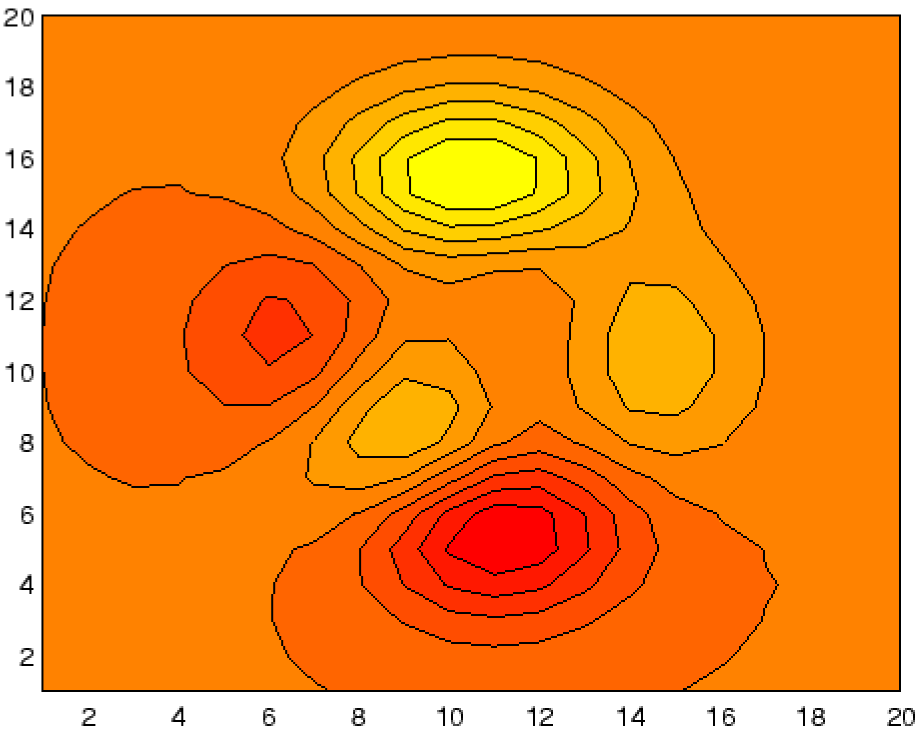
`NaN`s in the Z-data leave white holes with black borders in the contour plot.

If `X` or `Y` is irregularly spaced, `contourf` calculates contours using a regularly spaced contour grid, and then transforms the data to `X` or `Y`.

Examples

Create a filled contour plot of the `peaks` function with contour matrix and `contourgroup` object handle as output and `autumn` colormap.

```
[C,h] = contourf(peaks(20),10);
colormap autumn
```



For more examples using `contourf`, see "Contour Plots".

`clabel` | `contour` | `contour3` | `contourc` | `quiver` | `contourgroup properties`

How To

- "Contour Plots"

Purpose

Define contourgroup properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default properties for contourgroup objects.

See "Plot Objects" for more information on contourgroup objects.

Contourgroup Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Annotation`

`hg.Annotation` object (read-only)

Control the display of contourgroup objects in legends. Specifies whether this contourgroup object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the contourgroup object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
`on`	Include the contourgroup object in a legend as one entry, but not its children objects
`off`	Do not include the contourgroup or its children in a legend (default)
`children`	Include only the children of the contourgroup as separate entries in the legend

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the IconDisplayStyle Property

See "Controlling Legends" for more information and examples.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

running callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`Children`

array of graphics object handles

Children of the contourgroup object. An array containing the handles of all line objects parented to the contourgroup object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`

`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`ContourMatrix`

`2`-by-`n` matrix (read-only)

Two-row matrix specifying all contour lines. Each contour line defined in the `ContourMatrix` begins with a column that contains the value of the contour (specified by the `LevelList` property and is used by `clabel`), and the number of `(x,y)` vertices in the contour line. The remaining columns contain the data for the `(x,y)` pairs.

For example:

```
C = [value1 xdata(1) xdata(2)...value2 xdata(1) xdata(2)...;
       dim1 ydata(1) ydata(2)...  dim2 ydata(1) ydata(2)...]
```

That is:

```
C = [C(1) C(2)...C(I)...C(N)]
```

where N is the number of contour levels, and:

```
C(i) = [ level(i) x(1) x(2)...x(  numel(i));
         numel(i) y(1) y(2)...y(  numel(i))];
```

For further information, see `contour` and The Contouring Algorithm.

`CreateFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y,'CreateFcn',@CallbackFcn)
```

where *`@CallbackFcn`* is a function handle that references the callback function and *`graphicfcn`* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`

string

String used by legend. The `legend` function uses the `DisplayName` property to label the contourgroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EraseMode`
`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode` `none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`Fill`
`{off} | on`

Color spaces between contour lines.

- `on` — Default when using `contourf` or `ezcontourf`.
- `off` — Default when using `contour` or `ezcontour`.

By default, `contour` draws only the contour lines of the surface. If you set `Fill` to `on`, `contour` colors the regions in between the contour lines according to the Z-value of the region and changes the contour lines to black.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- on — Handles are always visible.
- callback — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- off — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes get, findobj, gca, gcf, gco, newplot, cla, clf, and close.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using callback or off, the object's handle does not appear in its parent's Children property, figures do not appear in the root's CurrentFigure property, objects do not appear in the root's CallbackObject property or in the figure's CurrentObject property, and axes do not appear in their parent's CurrentAxes property.

Overriding Handle Visibility

You can set the root ShowHiddenHandles property to on to make all handles visible regardless of their HandleVisibility settings. This does not affect the values of the HandleVisibility properties. See also findall.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`
: `{on} | off`

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the contour plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`
: `on | {off}`

Select the object by clicking lines or area of extent. Select plot objects by:

- Clicking contour lines(default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the contour lines (excluding the baseline) to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the contour lines).

`Interruptible`
: `off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

`LabelSpacing`
distance in points (default = `144`)

Spacing between labels on each contour line. When you display contour line labels using either the `ShowText` property or the `clabel` command, the labels are spaced `144` points (2 inches) apart on each line. You can specify the spacing by setting the `LabelSpacing` property to a value in points. If the length of an individual contour line is less than the specified value, MATLAB displays only one contour label on that line.

`LevelList`
vector of `ZData`-values

Values at which contour lines are drawn. When the `LevelListMode` property is `auto`, the `contour` function automatically chooses contour values that span the range of values in `ZData` (the input argument `Z`). You can set this property to the values at which you want contour lines drawn.

To specify the contour interval (space between contour lines) use the `LevelStep` property.

`LevelListMode`
`{auto} | manual`

User-specified or autogenerated `LevelList` values. By default, the `contour` function automatically generates the values at which contours are drawn. If you set this property to `manual`, contour does not change the values in `LevelList` as you change the values of `ZData`.

`LevelStep`
scalar

Spacing of contour lines. The `contour` function draws contour lines at regular intervals determined by the value of `LevelStep`. When the `LevelStepMode` property is `auto`, `contour` determines the contour interval automatically based on the `ZData`.

`LevelStepMode`
`{auto} | manual`

User-specified or autogenerated `LevelStep` values. By default, the `contour` function automatically determines a value for the `LevelStep` property. If you set this property to `manual`, `contour` does not change the value of `LevelStep` as you change the values of `ZData`.

`LineColor`
`{auto} | ColorSpec | none`

Color of the contour lines. This property determines how MATLAB colors the contour lines.

- `auto` — Each contour line is a single color determined by its contour value, the figure colormap, and the color axis (`caxis`).
- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is `[0 0 0]` (`black`). See `ColorSpec` for more information on specifying color.
- `none` — No contour lines are drawn.

`LineStyle`

`{-} | -- | :  | -.  | none`

Line style of contourgroup object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

`LineWidth`

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is `0.5` points.

`Parent`

handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`

`on | {off}`

Object selection state. When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You

can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Object highlighted when selected.

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`ShowText`
`on | {off}`

Display labels on contour lines. When you set this property to `on`, MATLAB displays text labels on each contour line indicating the contour value. See also `LevelList`, `clabel`, and the example “Contour Graph of a Function” on page 1-1034.

`Tag`
string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an areaseries object and set the `Tag` property.

```
t = area(Y,'Tag','area1')
```

When you want to access objects of a given type, use `findobj` to find the object’s handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

`TextList`
vector

Contour values to label. This property contains the contour values where text labels are placed. By default, these values are the same as those contained in the `LevelList` property, which define where the contour lines are drawn. Note that there must be an equivalent contour line to display a text label.

For example, the following statements create and label a contour plot:

```
[c,h]=contour(peaks);
clabel(c,h)
```

You can get the `LevelList` property to see the contour line values:

```
get(h,'LevelList')
```

Suppose you want to view the contour value `4.375` instead of the value of `4` that the contour function used. To do this, you need to set both the `LevelList` and `TextList` properties:

```
set(h,'LevelList',[-6 -4 -2 0 2 4.375 6 8],...
 'TextList',[-6 -4 -2 0 2 4.375 6 8])
```

See the example "Contour Graph of a Function" on page 1-1034 for additional information.

`TextListMode`
`{auto} | manual`

User-specified or auto `TextList` values. When this property is `auto`, MATLAB sets the `TextList` property equal to the values of the `LevelList` property (i.e., a text label for each contour line). When this property is `manual`, MATLAB does not set the values of the `TextList` property. Note that specifying values for the

`TextList` property causes the `TextListMode` property to be set to `manual`.

`TextStep`
scalar

Determines which contour line have numeric labels. The `contour` function labels contour lines at regular intervals which are determined by the value of the `TextStep` property. When the `TextStepMode` property is `auto`, `contour` labels every contour line when the `ShowText` property is `on`. See "Contour Graph of a Function" on page 1-1034 for an example that uses the `TextStep` property.

`TextStepMode`
`{auto} | manual`

User-specified or autogenerated `TextStep` values. By default, the `contour` function automatically determines a value for the `TextStep` property. If you set this property to `manual`, `contour` does not change the value of `TextStep` as you change the values of `ZData`.

`Type`
string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For contourgroup objects, `Type` is '`hggroup`'. This statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`
handle of uicontextmenu object

Associate context menu with object. Handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu`

function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

`UserData`
array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Visibility of object and its children.

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

`XData`
vector | matrix

x-axis values for graph. The *x*-axis values for graphs are specified by the `X` input argument. If `XData` is a vector, `length(XData)` must equal `length(YData)` and must be monotonic. If `XData` is a matrix, `size(XData)` must equal `size(YData)` and each column must be monotonic.

You can use `XData` to define meaningful coordinates for an underlying surface whose topography is being mapped. See "Changing the Offset of a Contour" for more information.

`XDataMode`
`{auto} | manual`

Use automatic or user-specified x-axis values. If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to manual and uses the specified values to label the *x*-axis.

If you set XDataMode to auto after having specified XData, MATLAB resets the *x*-axis ticks to the column indices of the ZData, overwriting any previous values for XData.

XDataSource

MATLAB variable, as a string

Link XData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h,'XDataSource','xdatavariablename')
```

MATLAB requires a call to refreshdata when you set this property. Changing workspace variables used as an object's XDataSource does not change the object's XData values, but you can use refreshdata to force an update of the object's data. refreshdata also lets you specify that the data source variable be evaluated in the workspace of a function from which you call refreshdata.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

YData

scalar | vector | matrix

Y-axis limits. This property determines the *y*-axis limits used in the contour plot. If you do not specify a Y argument, the contour

function calculates *y*-axis limits based on the size of the input argument Z.

YData can be either a matrix equal in size to ZData or a vector equal in length to the number of columns in ZData.

Use YData to define meaningful coordinates for the underlying surface whose topography is being mapped. See "Changing the Offset of a Contour" for more information.

YDataMode
{auto} | manual

Use automatic or user-specified y-axis values. In auto mode (the default) the contour function automatically determines the *y*-axis limits. If you set this property to manual, specify a value for YData, or specify a Y argument, then contour sets this property to manual and does not change the axis limits.

If you set YDataMode to auto after having specified YData, MATLAB resets the *y*-axis ticks to the row indices of the ZData, overwriting any previous values for YData.

YDataSource
MATLAB variable, as a string

Link YData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h,'YDataSource','Ydatavariablename')
```

MATLAB requires a call to refreshdata when you set this property. Changing workspace variables used as an object's YDataSource does not change the object's YData values, but you can use refreshdata to force an update of the object's data. refreshdata also lets you specify that the data source variable

be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`ZData`
matrix

Contour data. This property contains the data from which the contour lines are generated (specified as the input argument `Z`). `ZData` must be at least a `2`-by-`2` matrix. The number of contour levels and the values of the contour levels are chosen automatically based on the minimum and maximum values of `ZData`. The limits of the *x*- and *y*-axis are `[1:n]` and `[1:m]`, where `[m,n] = size(ZData)`.

`ZDataSource`
MATLAB variable, as a string

Link `ZData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`. The default value is an empty array.

```
set(h,'ZDataSource','zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

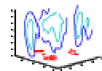
Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

How To

- "Contour Plots"
- "Core Graphics Objects"
- "Setting Default Property Values"
- "The Property Editor"

Purpose

Draw contours in volume slice planes



Syntax

```
contourslice(X,Y,Z,V,Sx,Sy,Sz)
contourslice(X,Y,Z,V,Xi,Yi,Zi)
contourslice(V,Sx,Sy,Sz)
contourslice(V,Xi,Yi,Zi)
contourslice(...,n)
contourslice(...,cvals)
contourslice(...,[cv cv])
contourslice(...,'method')
contourslice(axes_handle,...)
h = contourslice(...)
```

Description

`contourslice(X,Y,Z,V,Sx,Sy,Sz)` draws contours in the *x*-, *y*-, and *z*-axis aligned planes at the points in the vectors `Sx`, `Sy`, `Sz`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V` and must be monotonic and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). The color at each contour is determined by the volume `V`, which must be an m-by-n-by-p volume array.

`contourslice(X,Y,Z,V,Xi,Yi,Zi)` draws contours through the volume `V` along the surface defined by the 2-D arrays `Xi,Yi,Zi`. The surface should lie within the bounds of the volume.

`contourslice(V,Sx,Sy,Sz)` and `contourslice(V,Xi,Yi,Zi)` (omitting the `X`, `Y`, and `Z` arguments) assume `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p]= size(v)`.

`contourslice(...,n)` draws `n` contour lines per plane, overriding the automatic value.

`contourslice(...,cvals)` draws `length(cval)` contour lines per plane at the values specified in vector `cvals`.

`contourslice(...,[cv cv])` computes a single contour per plane at the level `cv`.

`contourslice(...,'method')` specifies the interpolation method to use. *method* can be `linear`, `cubic`, or `nearest`. `nearest` is the default except when the contours are being drawn along the surface defined by `Xi`, `Yi`, `Zi`, in which case `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`contourslice(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

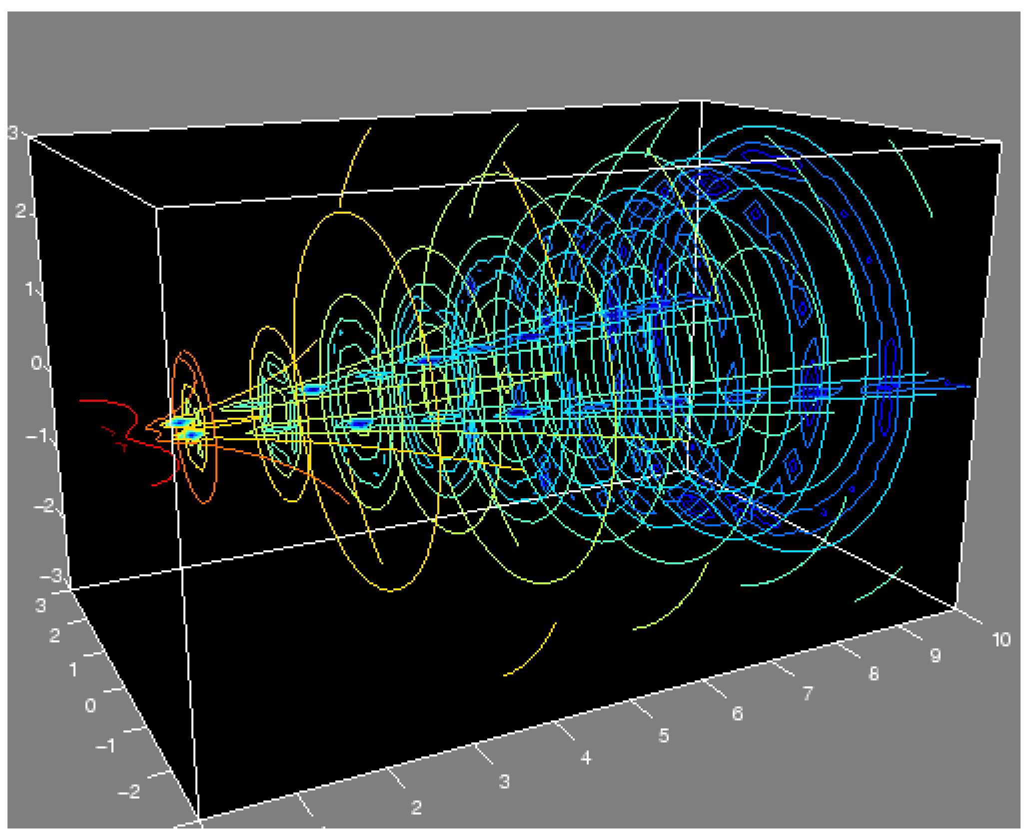
`h = contourslice(...)` returns a vector of handles to `patch` objects that are used to implement the contour lines.

Examples

This example uses the `flow` data set to illustrate the use of contoured slice planes. (Type `doc flow` for more information on this data set.) Notice that this example

- Specifies a vector of `length = 9` for `Sx`, an empty vector for the `Sy`, and a scalar value (0) for `Sz`. This creates nine contour plots along the x direction in the y-z plane, and one in the x-y plane at z = 0.
- Uses `linspace` to define a 10-element vector of linearly spaced values from -8 to 2. This vector specifies that 10 contour lines be drawn, one at each element of the vector.
- Defines the view and projection type (`camva`, `camproj`, `campos`).
- Sets figure (`gcf`) and axes (`gca`) characteristics.

```
[x y z v] = flow;
h = contourslice(x,y,z,v,[1:9],[],[0],linspace(-8,2,10));
axis([0,10,-3,3,-3,3]); daspect([1,1,1])
camva(24); camproj perspective;
campos([-3,-15,5])
set(gcf,'Color',[.5,.5,.5],'Renderer','zbuffer')
set(gca,'Color','black','XColor','white', ...
 'YColor','white','ZColor','white')
box on
```



This example draws contour slices along a spherical surface within the volume.

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);
v = x.*exp(-x.^2-y.^2-z.^2); % Create volume data
[xi,yi,zi] = sphere; % Plane to contour
contourslice(x,y,z,v,xi,yi,zi)
view(3)
```

See Also

isosurface | slice | smooth3 | subvolume | reducevolume

Purpose

Grayscale colormap for contrast enhancement

Syntax

```
cmap = contrast(X)
cmap = contrast(X,m)
```

Description

The `contrast` function enhances the contrast of an `image`. It creates a new gray colormap, `cmap`, that has an approximately equal intensity distribution. All three elements in each row are identical.

`cmap = contrast(X)` returns a gray colormap that is the same length as the current colormap. If there are `NaN` or `Inf` elements in `X` the length of the colormap increases.

`cmap = contrast(X,m)` returns an `m`-by-3 gray colormap.

Examples

Add contrast to the clown image defined by `X`.

```
load clown;
cmap = contrast(X);
image(X);
colormap(cmap);
```

See Also

`brighten` | `colormap` | `image`

Purpose

Convolution and polynomial multiplication

Syntax

```
w = conv(u,v)
w = conv(...,'shape')
```

Description

`w = conv(u,v)` convolves vectors `u` and `v`. Algebraically, convolution is the same operation as multiplying the polynomials whose coefficients are the elements of `u` and `v`.

`w = conv(...,'shape')` returns a subsection of the convolution, as specified by the `shape` parameter:

`full`	Returns the full convolution (default).
`same`	Returns the central part of the convolution of the same size as `u`.
`valid`	Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, `length(w)` is `max(length(u)-max(0,length(v)-1),0)`.

Definitions

Let `m = length(u)` and `n = length(v)` . Then `w` is the vector of length `m+n-1` whose `k`th element is

$$w(k) = \sum_j u(j)v(k-j+1)$$

The sum is over all the values of `j` which lead to legal subscripts for `u(j)` and `v(k+1-j)`, specifically `j = max(1,k+1-n): min(k,m)`. When `m = n`, this gives

```
w(1) = u(1)*v(1)
w(2) = u(1)*v(2)+u(2)*v(1)
w(3) = u(1)*v(3)+u(2)*v(2)+u(3)*v(1)
...
w(n) = u(1)*v(n)+u(2)*v(n-1)+ ... +u(n)*v(1)
...
```

```
w(2*n-1) = u(n)*v(n)
```

See Also

conv2 | convn | deconv | filter | convmtx | xcorr

Purpose

2-D convolution

Syntax

```
C = conv2(A,B)
C = conv2(h1,h2,A)
C = conv2(...,shape)
```

Description

`C = conv2(A,B)` computes the two-dimensional convolution of matrices `A` and `B`. If one of these matrices describes a two-dimensional finite impulse response (FIR) filter, the other matrix is filtered in two dimensions. The size of `C` is determined as follows: if `[ma,na] = size(A)`, `[mb,nb] = size(B)`, and `[mc,nc] = size(C)`, then `mc = max([ma+mb-1,ma,mb])` and `nc = max([na+nb-1,na,nb])`.

`C = conv2(h1,h2,A)` first convolves `A` with the vector `h1` along the rows and then with the vector `h2` along the columns. The size of `C` is determined as follows: if `n1 = length(h1)` and `n2 = length(h2)`, then `mc = max([ma+n1-1,ma,n1])` and `nc = max([na+n2-1,na,n2])`.

`C = conv2(...,shape)` returns a subsection of the two-dimensional convolution, as specified by the `shape` parameter:

`'full'`	Returns the full two-dimensional convolution (default).
`'same'`	Returns the central part of the convolution of the same size as `A`.
`'valid'`	Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, `size(C) = max([ma-max(0,mb-1),na-max(0,nb-1)],0)`.

Note All numeric inputs to `conv2` must be of type `double` or `single`.

Algorithms

`conv2` uses a straightforward formal implementation of the two-dimensional convolution equation in spatial form. If a and b are

functions of two discrete variables, n_1 and n_2, then the formula for the two-dimensional convolution of a and b is

$$c(n_1,n_2) = \sum_{k_1=-\infty}^{\infty} \sum_{k_2=-\infty}^{\infty} a(k_1,k_2) b(n_1-k_1,n_2-k_2)$$

In practice however, `conv2` computes the convolution for finite intervals.

Note that matrix indices in MATLAB software always start at 1 rather than 0. Therefore, matrix elements `A(1,1)`, `B(1,1)`, and `C(1,1)` correspond to mathematical quantities $a(0,0)$, $b(0,0)$, and $c(0,0)$.

Examples

Example 1

For the `'same'` case, `conv2` returns the central part of the convolution. If there are an odd number of rows or columns, the "center" leaves one more at the beginning than the end.

This example first computes the convolution of A using the default (`'full'`) shape, then computes the convolution using the `'same'` shape. Note that the array returned using `'same'` corresponds to the red highlighted elements of the array returned using the default shape.

```
A = rand(3);
B = rand(4);
C = conv2(A,B)   % C is 6-by-6

C =
   0.1838   0.2374   0.9727   1.2644   0.7890   0.3750
   0.6929   1.2019   1.5499   2.1733   1.3325   0.3096
   0.5627   1.5150   2.3576   3.1553   2.5373   1.0602
   0.9986   2.3811   3.4302   3.5128   2.4489   0.8462
   0.3089   1.1419   1.8229   2.1561   1.6364   0.6841
   0.3287   0.9347   1.6464   1.7928   1.2422   0.5423

Cs = conv2(A,B,'same')   % Cs is the same size as A: 3-by-3
Cs =
   2.3576   3.1553   2.5373
```

```
    3.4302   3.5128   2.4489
    1.8229   2.1561   1.6364
```

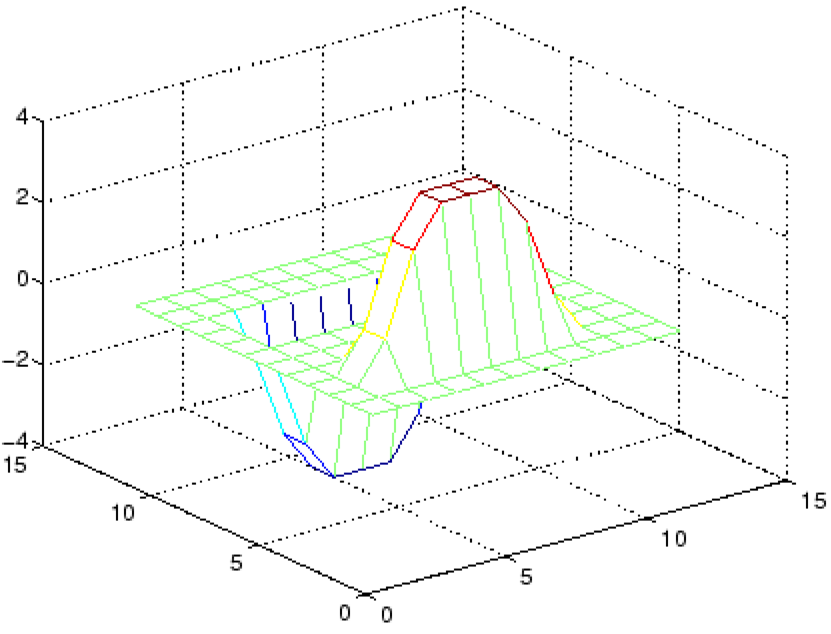
Example 2

In image processing, the Sobel edge finding operation is a two-dimensional convolution of an input array with the special matrix

```
s = [1 2 1; 0 0 0; -1 -2 -1];
```

These commands extract the horizontal edges from a raised pedestal.

```
A = zeros(10);
A(3:7,3:7) = ones(5);
H = conv2(A,s);
mesh(H)
```

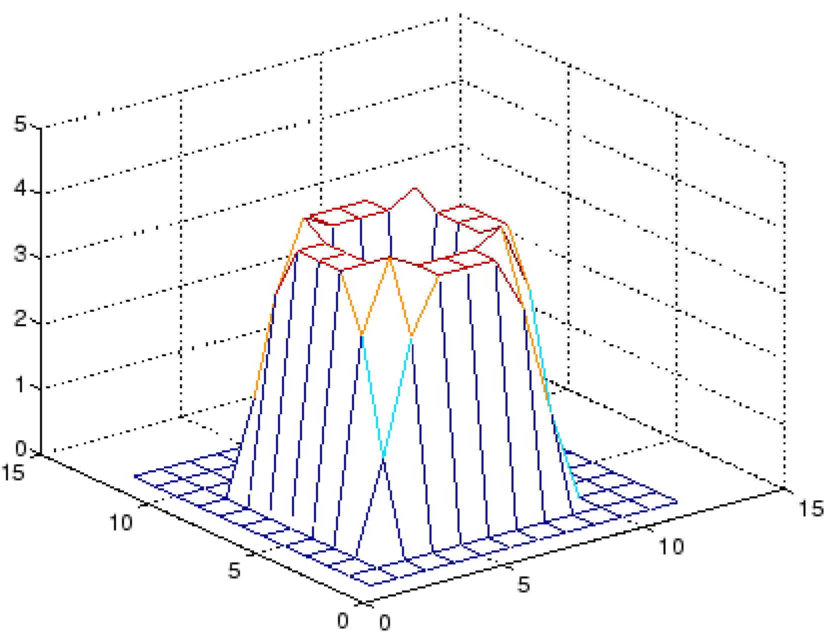


Transposing the filter s extracts the vertical edges of A.

```
V = conv2(A,s');
figure, mesh(V)
```

This figure combines both horizontal and vertical edges.

```
figure
mesh(sqrt(H.^2 + V.^2))
```



See Also

`conv` | `convn` | `filter2` | `xcorr2`

convhull

Purpose

Convex hull

Note Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `convhull`.

Syntax

```
K = convhull(X,Y)
K = convhull(X,Y,Z)
K = convhull(X)
K = convhull(...,'simplify', logicalvar)
[K,V] = convhull(...)
```

Definitions

`convhull` returns the convex hull of a set of points in 2-D or 3-D space.

Description

`K = convhull(X,Y)` returns the 2-D convex hull of the points (`X`,`Y`), where `X` and `Y` are column vectors. The convex hull `K` is expressed in terms of a vector of point indices arranged in a counterclockwise cycle around the hull.

`K = convhull(X,Y,Z)` returns the 3-D convex hull of the points (`X`,`Y`,`Z`), where `X`, `Y`, and `Z` are column vectors. `K` is a triangulation representing the boundary of the convex hull. `K` is of size `mtri`-by-3, where `mtri` is the number of triangular facets. That is, each row of `K` is a triangle defined in terms of the point indices.

`K = convhull(X)` returns the 2-D or 3-D convex hull of the points `X`. This variant supports the definition of points in matrix format. `X` is of size `mpts`-by-`ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, $2 \leqq$ `ndim` $\leqq 3$. The output facets are equivalent to those generated by the 2-input or 3-input calling syntax.

`K = convhull(...,'simplify', logicalvar)` provides the option of removing vertices that do not contribute to the area/volume of the convex hull, the default is false. Setting `'simplify'` to true returns the topology in a more concise form.

`[K,V] = convhull(...)` returns the convex hull `K` and the corresponding area/volume `V` bounded by `K`.

Visualization

Use `plot` to plot the output of `convhull` in 2-D. Use `trisurf` or `trimesh` to plot the output of convhull in 3-D.

Examples

Example 1

```
xx = -1:.05:1; yy = abs(sqrt(xx));
[x,y] = pol2cart(xx,yy);
k = convhull(x,y);
plot(x(k),y(k),'r-',x,y,'b+')
```

`convexHull` | `voronoiDiagram` | `convhulln` | `delaunay` | `polyarea` | `voronoi`

convhulln

Purpose

N-D convex hull

Syntax

```
K = convhulln(X)
K = convhulln(X, options)
[K, v] = convhulln(...)
```

Description

`K = convhulln(X)` returns the indices `K` of the points in `X` that comprise the facets of the convex hull of `X`. `X` is an `m`-by-`n` array representing `m` points in N-dimensional space. If the convex hull has `p` facets then `K` is `p`-by-`n`.

`convhulln` uses Qhull.

`K = convhulln(X, options)` specifies a cell array of strings `options` to be used as options in Qhull. The default options are:

- `{'Qt'}` for 2-, 3-. and 4-dimensional input
- `{'Qt','Qx'}` for 5-dimensional input and higher.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options are used, not even the default. For more information on Qhull and its options, see `http://www.qhull.org/`.

`[K, v] = convhulln(...)` also returns the volume `v` of the convex hull.

Visualization

Plotting the output of `convhulln` depends on the value of `n`:

- For `n = 2`, use `plot` as you would for `convhull`.
- For `n = 3`, you can use `trisurf` to plot the output. The calling sequence is

  ```
  K = convhulln(X);
  trisurf(K,X(:,1),X(:,2),X(:,3))
  ```

- You cannot plot `convhulln` output for `n > 3`.

Examples

The following example illustrates the `options` input for `convhulln`. The following commands

```
X = [0 0; 0 1e-10; 0 0; 1 1];
K = convhulln(X)
```

return a warning.

```
Warning: qhull precision warning:
The initial hull is narrow
(cosine of min. angle is 0.9999999999999998).
A coplanar point may lead to a wide facet.
Options 'QbB' (scale to unit box) or 'Qbb'
(scale last coordinate) may remove this warning.
Use 'Pp' to skip this warning.
```

To suppress the warning, use the option `'Pp'`. The following command passes the option `'Pp'`, along with the default `'Qt'`, to `convhulln`.

```
K = convhulln(X,{'Qt','Pp'})

K =

     1     4
     1     2
     4     2
```

Algorithms

`convhulln` is based on Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

convn

Purpose

N-D convolution

Syntax

```
C = convn(A,B)
C = convn(A,B,'shape')
```

Description

`C = convn(A,B)` computes the N-dimensional convolution of the arrays `A` and `B`. The size of the result is `size(A)+size(B)-1`.

`C = convn(A,B,'shape')` returns a subsection of the N-dimensional convolution, as specified by the `shape` parameter:

`'full'`	Returns the full N-dimensional convolution (default).
`'same'`	Returns the central part of the result that is the same size as `A`.
`'valid'`	Returns only those parts of the convolution that can be computed without assuming that the array A is zero-padded. The size of the result is `max(size(A)-size(B) + 1, 0)`

Purpose

Superclass providing copy functionality for handle objects

Description

The `matlab.mixin.Copyable` class is an abstract handle class that provides a `copy` method for copying handle objects. The `copy` method makes a shallow copy of the object (that is, it shallow copies all non-dependent properties from the source to the destination object). In making a shallow copy, MATLAB does not call `copy` recursively on any handles contained in property values.

Subclass `matlab.mixin.Copyable` when you want to define handles classes that inherit a `copy` method. The `copy` method:

- Copies data without calling class constructors or property set functions and therefore produces no side effects.
- Enables subclasses to customize the copy behavior

Customizing Subclass Copy Behavior

The `copy` method provides the public, non-overrideable interface to copy behavior. `copy` takes an array of objects as input and returns an array of the same shape and dimensions.

`copyElement` is a protected method that the `copy` method uses to perform the copy operation on each object in the input array. `copyElement` is not `Sealed` so you can override it in your subclass to customize the behavior of the inherited `copy` method.

Implementing a Selective Deep Copy

This example overrides the `copyElement` method in a subclass of `matlab.mixin.Copyable` to implement a deep copy of a specific class of `handle` objects.

Consider the following classes:

- `ContainsHandles` — subclass of `matlab.mixin.Copyable` that contains `handle` objects in two properties
- `DeepCp` — subclass of `matlab.mixin.Copyable`
- `ShallowCp` — subclass of `handle`

Here are the simplified class definitions:

```
classdef ContainsHandles < matlab.mixin.Copyable
   properties
      Prop1
      Prop2
      DeepObj     % Contains a DeepCp object
      ShallowObj  % Contains a ShallowCp object
   end
   methods
      function obj = ContainsHandles(val1, val2, deepobj, shallowobj)
         if nargin > 0
            obj.Prop1 = val1;
            obj.Prop2 = val2;
            obj.DeepObj = deepobj;
            obj.ShallowObj = shallowobj;
          end
      end
   end
      methods(Access = protected)
       % Override copyElement method:
      function cpObj = copyElement(obj)
         % Make a shallow copy of all four properties
         cpObj = copyElement@matlab.mixin.Copyable(obj);
         % Make a deep copy of the DeepCp object
         cpObj.DeepObj = copy(obj.DeepObj);
      end
   end
end
```

The `DeepCp` class derives from `matlab.mixin.Copyable`:

```
classdef DeepCp < matlab.mixin.Copyable
   properties
      DpProp
   end
   methods
      function obj = DeepCp(val)
```

```
      ...
      end
   end
end
```

The handle class ShallowCp does not derive from matlab.mixin.Copyable and, therefore, has no copy method:

```
classdef ShallowCp < handle
   properties
      ShProp
   end
   methods
      function obj = ShallowCp(val)
       ...
      end
   end
end
```

Create a ContainsHandles object, which contains the two handle objects in its DpProp and ShProp properties:

```
>> sc = ShallowCp(7);
>> dc = DeepCp(7);
>> a = ContainsHandles(4,5,dc,sc);
>> a.DeepObj
ans =

  DeepCp with properties:

    DpProp: 7
>> a.ShallowObj.ShProp
ans =

  ShallowCp with properties:

    ShProp: 7
```

Make a copy of the `ContainsHandles` object:

```
>> b = copy(a);
```

The returned copy `b` contains a shallow copy of object `sc`, and a deep copy of object `dc`. That is, the `dc` object passed to `ContainsHandles` constructor is now a new, independent objects as a result of the copy operation. You can now change the `dc` object without affecting the copy. This is not the case for the shallow copied object, `sc`:

```
% Change the property values of the handle objects:
>> sc.ShProp = 5;
>> dc.DpProp = 5;
% Note that the deep copied object is not affected:
>> b.DeepObj

ans =

  DeepCp with properties:

    DpProp: 7
% The shallow copied object is still referencing the same data:
>> b.ShallowObj

ans =

  ShallowCp with properties:

    ShProp: 5
```

Overriding Copy Behavior in Hierarchies

The `copyElement` method in a superclass cannot access the private data in a subclass.

If you override `copyElement` in a subclass of `matlab.mixin.Copyable`, and then use this subclass as a superclass, you need to override `copyElement` in all subclasses that contain private properties. The

override of `copyElement` in subclasses should call the `copyElement` in the respective superclass, as in the previous example.

The following simplified code demonstrates this approach:

```
classdef SuperClass < matlab.mixin.Copyable
   properties(Access = private)
      super_prop
   end
   methods
        ...

      function cpObj = copyElement(obj)
            ...
         cpObj = copyElement@mixin.matlab.Copyable(obj);
            ...
      end
   end
end

classdef SubClass1 < SuperClass
   properties(Access=private)
      sub_prop1
   end
   methods
      function cpObj = copyElement(obj)
         % Copy super_prop
         cpObj = copyElement@SuperClass(obj);
         % Copy sub_prop1 in subclass
         % Assignment can introduce side effects
         cpObj.sub_prop1 = obj.sub_prop1;
      end
   end
end
```

The override of `copyElement` in `SubClass1` copies the private subclass property because the superclass cannot access private data in the subclass.

Note The assignment of `sub_prop1` in the override of `copyElement` in `SubClass1` calls the property set method, if one exists, possibly introducing side effects to the copy operation.

Copy Behaviors for Specific Inputs

Given a call to the `matlab.mixin.Copyable` `copy` method of the form:

```
B = copy(A);
```

Under the following conditions, produces the described results:

- `A` has dynamic properties — `copy` does not copy dynamic properties. You can implement dynamic-property copying in the subclass if needed.
- `A` has no non-Dependent properties — `copy` creates a new object with no property values without calling the class constructor to avoid introducing side effects.
- `A` contains deleted handles — `copy` creates deleted handles of the same class in the output array.
- `A` has attached listeners — `copy` does not copy listeners.
- `A` contains objects of enumeration classes — Enumeration classes cannot subclass `matlab.mixin.Copyable`.
- A `delete` method calls `copy` — `copy` creates a legitimate copy, obeying all the behaviors that apply in any other usage.

Note You cannot derive an enumeration class from `matlab.mixin.Copyable` because the number of instances you can create are limited to the ones defined inside the enumeration block. See "Working with Enumerations" for more information about enumeration classes.

Methods

copy	Copy array of handle objects

Definitions

Deep Copy

Copy each property value and assign it to the new (copied) property. Recursively copy property values that reference handle objects to copy all of the underlying data.

Shallow Copy

Copy each property value and assign it to the new (copied) property. If a property value is a handle, copy the handle but not the underlying data.

Attributes

`ConstructOnLoad`	`true`

To learn about attributes of classes, see Class Attributes in the MATLAB Object-Oriented Programming documentation.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

See Also

`handle`

How To

- Class Attributes

matlab.mixin.Copyable.copy

Purpose

Copy array of handle objects

Syntax

`B = copy(A)`

Description

`B = copy(A)` copies each element in the array of handles `A` to the new array of handles `B`.

The `copy` method performs a copy according to the following rules:

- The `copy` method does not copy `Dependent` properties
- MATLAB does not call the `copy` method recursively on any handles contained in property values
- MATLAB does not call the class constructor or property set methods during the copy operation.
- `B` has the same number of elements and same size as `A`.
- `B` is the same class as `A`.
- If `A` is empty, `B` is also empty.
- If `A` is heterogeneous, `B` is also heterogeneous.
- If `A` contains deleted handle objects, copy creates deleted handles of the same class in `B`.
- Dynamic properties and listeners associated with objects in `A` are not copied to objects in `B`.
- You can call `copy` inside your class `delete` method.

Input Arguments

A

Handle object array

Output Arguments

B

Handle object array containing copies of the objects in `A`.

Attributes

Sealed	true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

copyfile

Purpose

Copy file or folder

Syntax

```
copyfile('source','destination')
copyfile('source','destination','f')
[status] = copyfile( ___ )
[status, message] = copyfile( ___ )
[status,message,messageid] = copyfile( ___ )
```

Description

`copyfile('source','destination')` copies the file or folder named `source` to the file or folder `destination`. The values for `source` and `destination` are 1 x n strings. Use full path names or path names relative to the current folder. To copy multiple files or folders, use one or more wildcard characters (`*`) after the last file separator in `source`. You cannot use a wildcard character in `destination`.

`copyfile('source','destination','f')` copies `source` to `destination`, even when `destination` is not writable. The state of the read-write attribute for `destination` does not change. You can use `f` with any syntax for `copyfile`.

`[status] = copyfile( ___ )` reports the outcome as a logical scalar, `status`. The value is `1` for success and `0` for failure.

`[status, message] = copyfile( ___ )` returns any warning or error message as a string to `message`. When `copyfile` succeeds, `message` is an empty string.

`[status,message,messageid] = copyfile( ___ )` returns any warning or error identifier as a string to `messageId`. When `copyfile` succeeds, `messageId` is an empty string.

Tips

- The timestamp for `destination` is the same as the timestamp for `source`.
- When `source` is a folder, `destination` must be a folder.
  - When `source` is a folder and `destination` does not exist, `copyfile` creates `destination` and copies the contents of `source` into `destination`.

- When `source` is a folder and `destination` is an existing folder, `copyfile` copies the contents of `source` into `destination`.
- When `source` is multiple files and `destination` does not exist, `copyfile` creates `destination`.

Examples

Copy File to Another Folder

Copy `myFun.m` from the current folder to `d:/work/Projects/`.

```
copyfile('myFun.m','d:/work/Projects/')
```

Copy File to Its Current Folder

Copy `myFun.m` in the current folder, assigning it the name `myFun2.m`.

```
copyfile('myFun.m','myFun2.m')
```

Copy Files and Folders to a New Folder Using Wildcards

Copy files and subfolders whose names begin with `my`, from the `Projects` subfolder within the current folder to the folder `newProjects`, which is at the same level as the current folder:

```
copyfile('Projects/my*','../newProjects/')
```

Copy Files to a New, Nonexistent Folder

Copy the contents of the `Projects` subfolder within the current folder to the `I:/work/newProjects` folder, where `newProjects` does not exist.

```
copyfile('Projects','I:/work/newProjects')
```

Copy File that Overwrites a Read-Only File

Copy the contents of `myFun.m` from the current folder to `d:/work/restricted/myFun2.m`, where `myFun2.m` is read-only.

```
[status,message,messageId]=copyfile('myFun.m', ...
'd:/work/restricted/myFun2.m','f')
```

```
status =
     1

message =
     ''

messageId =
     ''
```

The `status` of 1 and empty `message` and `messageId` strings confirm the copy was successful.

How To

- "Path Names in MATLAB"
- "Creating, Opening, Changing, and Deleting Files and Folders"

Purpose

Copy graphics objects and their descendants

Syntax

```
new_handle = copyobj(h,p)
```

Description

`copyobj` creates copies of graphics objects. The copies are identical to the original objects except the copies have different values for their `Parent` property and a new handle. The new parent must be appropriate for the copied object (e.g., you can copy a line object only to another axes object).

`new_handle = copyobj(h,p)` copies one or more graphics objects identified by `h` and returns the handle of the new object or a vector of handles to new objects. The new graphics objects are children of the graphics objects specified by `p`.

Tips

`h` and `p` can be scalars or vectors. When both are vectors, they must be the same length, and the output argument, `new_handle,` is a vector of the same length. In this case, `new_handle(i)` is a copy of `h(i)` with its `Parent` property set to `p(i)`.

When `h` is a scalar and `p` is a vector, `h` is copied once to each of the parents in `p`. Each `new_handle(i)` is a copy of `h` with its `Parent` property set to `p(i)`, and `length(new_handle)` equals `length(p)`.

When `h` is a vector and `p` is a scalar, each `new_handle(i)` is a copy of `h(i)` with its `Parent` property set to `p`. The length of `new_handle` equals `length(h)`.

When programming a GUI, do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

Examples

Copy a surface to a new axes within a different figure.

```
h = surf(peaks);
colormap hot
figure    % Create a new figure
```

```
axes    % Create an axes object in the figure
new_handle = copyobj(h,gca);
colormap hot
view(3)
grid on
```

Note that while the surface is copied, the `colormap` (`figure` property), `view`, and `grid` (`axes` properties) are not copied.

Purpose

Correlation coefficients

Syntax

```
R = corrcoef(X)
R = corrcoef(x,y)
[R,P]=corrcoef(...)
[R,P,RLO,RUP]=corrcoef(...)
[...]=corrcoef(...,'param1',val1,'param2',val2,...)
```

Description

`R = corrcoef(X)` returns a matrix `R` of correlation coefficients calculated from an input matrix `X` whose rows are observations and whose columns are variables. The matrix `R = corrcoef(X)` is related to the covariance matrix `C = cov(X)` by

$$R(i,j) = \frac{C(i,j)}{\sqrt{C(i,i)C(j,j)}}.$$

`corrcoef(X)` is the zeroth lag of the normalized covariance function, that is, the zeroth lag of `xcov(x,'coeff')` packed into a square array.

`R = corrcoef(x,y)` where `x` and `y` are column vectors is the same as `corrcoef([x y])`. If `x` and `y` are not column vectors, `corrcoef` converts them to column vectors. For example, in this case `R=corrcoef(x,y)` is equivalent to `R=corrcoef([x(:) y(:)])`.

`[R,P]=corrcoef(...)` also returns `P`, a matrix of p-values for testing the hypothesis of no correlation. Each p-value is the probability of getting a correlation as large as the observed value by random chance, when the true correlation is zero. If `P(i,j)` is small, say less than `0.05`, then the correlation `R(i,j)` is significant.

`[R,P,RLO,RUP]=corrcoef(...)` also returns matrices `RLO` and `RUP`, of the same size as `R`, containing lower and upper bounds for a 95% confidence interval for each coefficient.

`[...]=corrcoef(...,'param1',val1,'param2',val2,...)` specifies additional parameters and their values. Valid parameters are the following.

'alpha'	A number between 0 and 1 to specify a confidence level of 100*(1 – alpha)%. Default is 0.05 for 95% confidence intervals.
'rows'	Either 'all' (default) to use all rows, 'complete' to use rows with no NaN values, or 'pairwise' to compute R(i,j) using rows with no NaN values in either column i or j.

The p-value is computed by transforming the correlation to create a t statistic having n-2 degrees of freedom, where n is the number of rows of X. The confidence bounds are based on an asymptotic normal distribution of 0.5*log((1+R)/(1-R)), with an approximate variance equal to 1/(n-3). These bounds are accurate for large samples when X has a multivariate normal distribution. The 'pairwise' option can produce an R matrix that is not positive definite.

Examples

Generate random data having correlation between column 4 and the other columns.

```
x = randn(30,4);     % Uncorrelated data
x(:,4) = sum(x,2);   % Introduce correlation.
[r,p] = corrcoef(x)  % Compute sample correlation and p-values.
[i,j] = find(p<0.05);  % Find significant correlations.
[i,j]                % Display their (row,col) indices.

r =
    1.0000   -0.3566    0.1929    0.3457

```

See Also

cov | mean | median | std | var | xcorr | xcov

Purpose

Cosine of argument in radians

Syntax

```
Y = cos(X)
```

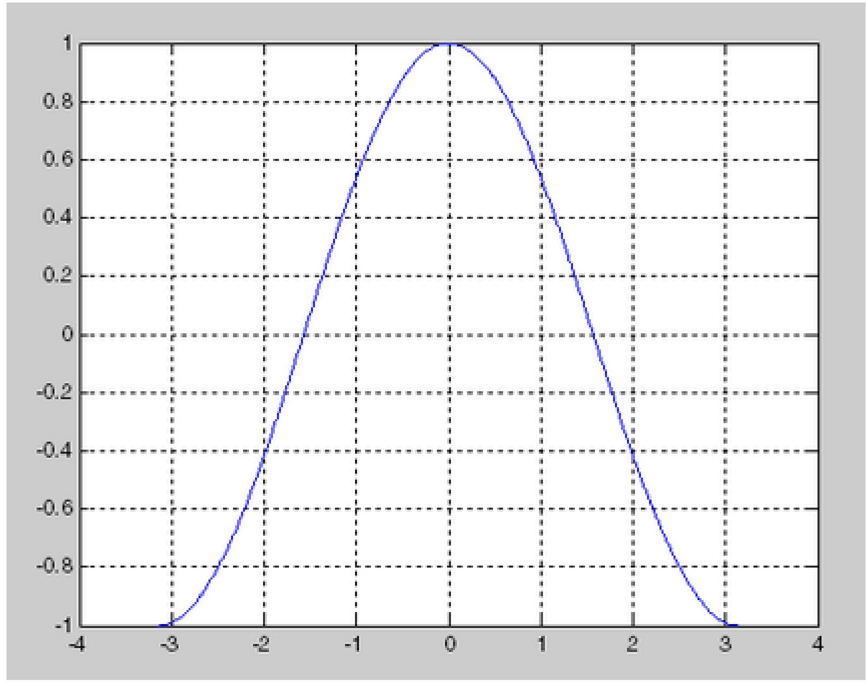
Description

`Y = cos(X)` returns the cosine for each element of `X`. The `cos` function operates element-wise on arrays. All angles are in radians.

Examples

Graph the cosine function over the domain $-\pi \le x \le \pi$:

```
x = -pi:0.01:pi;
plot(x,cos(x)), grid on
```



See Also

`cosd` | `acos` | `acosd` | `cosh`

Purpose

Cosine of argument in degrees

Syntax

```
Y = cosd(X)
```

Description

`Y = cosd(X)` returns the cosine of the elements of `X`, which are expressed in degrees.

Input Arguments

X - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cosd` operation is element-wise when `X` is nonscalar.

Data Types
`single | double`
Complex Number Support: Yes

Output Arguments

Y - Cosine of angle

scalar value | vector | matrix | N-D array

Cosine of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Cosine of 90 degrees compared to cosine of /2 radians

```
cosd(90)

ans =

     0

cos(pi/2)

ans =

   6.1232e-17
```

Cosine of complex angles specified in degrees

Create an array of three complex angles and compute the cosine.

```
z = [180+i 45+2i 10+3i];
y = cosd(z)

y =

  -1.0002          0.7075 - 0.0247i   0.9862 - 0.0091i
```

See Also

`cos` | `acos` | `acosd`

Purpose

Hyperbolic cosine

Syntax

```
Y = cosh(X)
```

Description

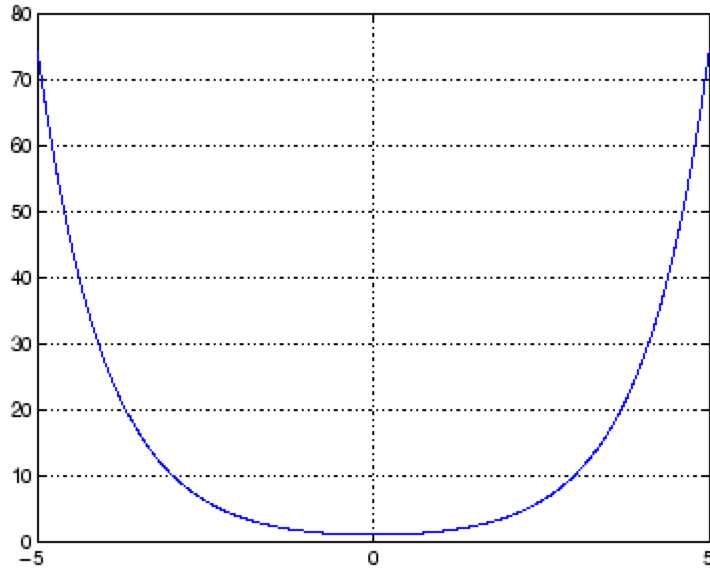
The `cosh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = cosh(X)` returns the hyperbolic cosine for each element of `X`.

Examples

Graph the hyperbolic cosine function over the domain $-5 \le x \le 5$.

```
x = -5:0.01:5;
plot(x,cosh(x)), grid on
```



See Also

`acosh` | `cos` | `sinh` | `tanh`

Purpose

Cotangent of argument in radians

Syntax

```
Y = cot(X)
```

Description

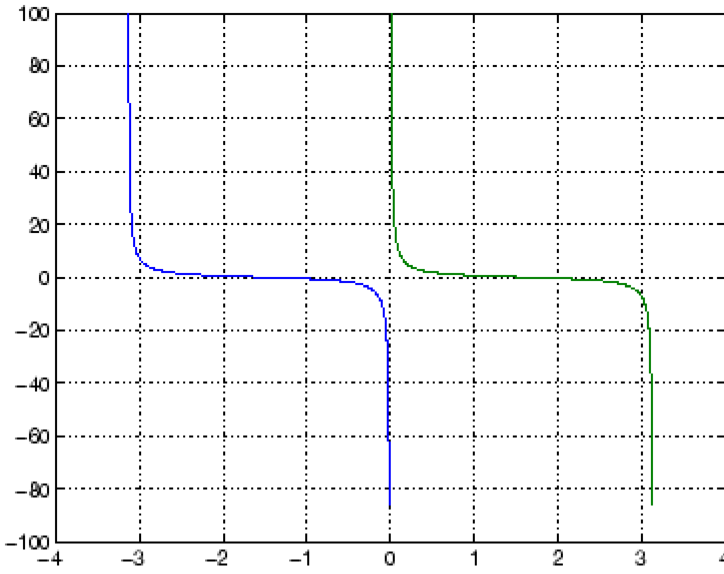
The `cot` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = cot(X)` returns the cotangent for each element of `X`.

Examples

Graph the cotangent the domains $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,cot(x1),x2,cot(x2)), grid on
```



See Also

`cotd` | `coth` | `acot` | `acotd` | `acoth`

Purpose

Cotangent of argument in degrees

Syntax

```
Y = cotd(X)
```

Description

`Y = cotd(X)` returns the cotangent of the elements of `X`, which are expressed in degrees.

Input Arguments

X - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cotd` operation is element-wise when `X` is nonscalar.

Data Types

`single` | `double`

Complex Number Support: Yes

Output Arguments

Y - Cotangent of angle

scalar value | vector | matrix | N-D array

Cotangent of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Cotangent of angles approaching 90 and 180 degrees

Create a vector of input angles consisting of 90° and the next smaller and larger double precision numbers. Then compute the cotangent.

```
x1 = [90-eps(90) 90 90+eps(90)];
y1 = cotd(x1)
```

```
y1 =

   1.0e-15 *

    0.2480         0   -0.2480
```

`cotd` returns zero when the input angle is exactly 90°. Evaluation at the next smaller double-precision angle returns a slightly positive result. Likewise, the cotangent is slightly negative when the input angle is the next double-precision number larger than 90.

The behavior is similar for input angles near 180°.

```
x2 = [180-eps(180) 180 180+eps(180)];
y2 = cotd(x2)

y2 =

   1.0e+15 *

   -2.0159       Inf    2.0159
```

Cotangent of complex angle, specified in degrees

```
x = 35+5i;
y = cotd(x)

y =

   1.3958 - 0.2606i
```

`acotd` | `cot` | `acot`

Purpose

Hyperbolic cotangent

Syntax

```
Y = coth(X)
```

Description

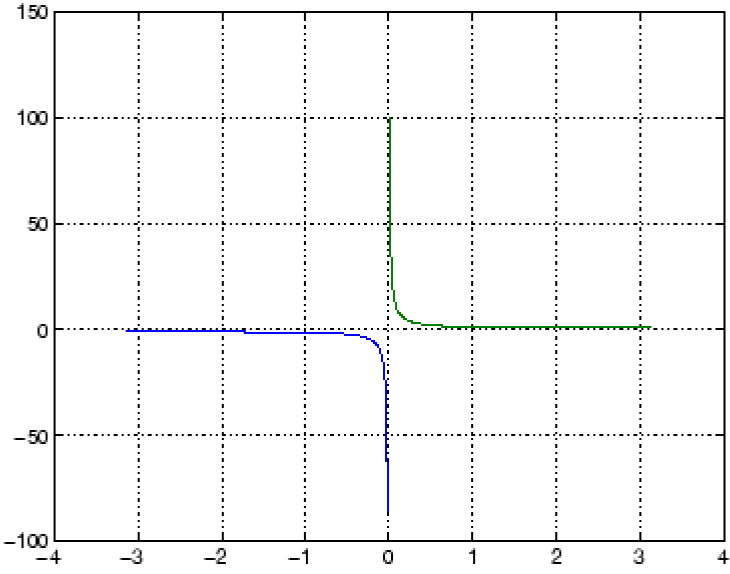
The `coth` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = coth(X)` returns the hyperbolic cotangent for each element of `X`.

Examples

Graph the hyperbolic cotangent over the domains $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,coth(x1),x2,coth(x2)), grid on
```



See Also

`acoth` | `cot` | `sinh` | `cosh` | `tanh`

Purpose

Covariance matrix

Syntax

```
cov(x)
cov(X)
cov(X,Y)
cov(x) or cov(x,y)
cov(x,1)
cov(x,y,1)
```

Description

`cov(x)`, if `x` is a vector, returns the variance of `x`. For matrix input `X`, where each row is an observation, and each column is a variable, `cov(X)` is the covariance matrix. `diag(cov(X))` is a vector of variances for each column, and `sqrt(diag(cov(X)))` is a vector of standard deviations. `cov(X,Y)`, where `X` and `Y` are matrices with the same number of elements, is equivalent to `cov([X(:)  Y(:)])`.

`cov(x) or cov(x,y)` normalizes by `N` – 1, if `N` > 1, where `N` is the number of observations. This makes `cov(X)` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For `N` = 1, cov normalizes by `N`.

`cov(x,1)` or `cov(x,y,1)` normalizes by `N` and produces the second moment matrix of the observations about their mean. `cov(X,Y,0)` is the same as `cov(X,Y)` and `cov(X,0)` is the same as `cov(X)`.

Tips

`cov` removes the mean from each column before calculating the result.

The *covariance* between two random variables is:

$$\mathrm{cov}(x_1, x_2) = E\left[(x_1 - \mu_1)^*(x_2 - \mu_2)\right]$$

where E is the mathematical expectation and $\mu_i = Ex_i$.

Examples

Consider `A = [-1 1 2 ; -2 3 1 ; 4 0 3]`. To obtain a vector of variances for each column of `A`:

```
v = diag(cov(A))'
v =
```

```
   10.3333    2.3333    1.0000
```

Compare vector v with covariance matrix C of A:

```
C = cov(A)
C =
   10.3333   -4.1667    3.0000
   -4.1667    2.3333   -1.5000
    3.0000   -1.5000    1.0000
```

The diagonal elements C(i,i) represent the variances for the columns of A. The off-diagonal elements C(i,j) represent the covariances of columns i and j.

See Also

corrcoef | mean | median | std | var | xcorr | xcov

Purpose

Sort complex numbers into complex conjugate pairs

Syntax

```
B = cplxpair(A)
B = cplxpair(A,tol)
B = cplxpair(A,[],dim)
B = cplxpair(A,tol,dim)
```

Description

`B = cplxpair(A)` sorts the elements along different dimensions of a complex array, grouping together complex conjugate pairs.

The conjugate pairs are ordered by increasing real part. Within a pair, the element with negative imaginary part comes first. The purely real values are returned following all the complex pairs. The complex conjugate pairs are forced to be exact complex conjugates. A default tolerance of `100*eps` relative to `abs(A(i))` determines which numbers are real and which elements are paired complex conjugates.

If `A` is a vector, `cplxpair(A)` returns `A` with complex conjugate pairs grouped together.

If `A` is a matrix, `cplxpair(A)` returns `A` with its columns sorted and complex conjugates paired.

If `A` is a multidimensional array, `cplxpair(A)` treats the values along the first non-singleton dimension as vectors, returning an array of sorted elements.

`B = cplxpair(A,tol)` overrides the default tolerance.

`B = cplxpair(A,[],dim)` sorts `A` along the dimension specified by scalar dim.

`B = cplxpair(A,tol,dim)` sorts `A` along the specified dimension and overrides the default tolerance.

Diagnostics

If there are an odd number of complex numbers, or if the complex numbers cannot be grouped into complex conjugate pairs within the tolerance, `cplxpair` generates the error message

```
Complex numbers can't be paired.
```

Purpose

Elapsed CPU time

Syntax

```
cputime
```

Description

`cputime` returns the total CPU time (in seconds) used by your MATLAB application from the time it was started. This number can overflow the internal representation and wrap around.

Tips

Although it is possible to measure performance using the `cputime` function, it is recommended that you use the `tic` and `toc` functions for this purpose exclusively. See Using tic and toc Versus the cputime Function in the MATLAB Programming Fundamentals documentation for more information.

Examples

The following code returns the CPU time used to run `surf(peaks(40))`.

```
t = cputime; surf(peaks(40)); e = cputime-t

e =
    0.4667
```

See Also

`clock` | `etime` | `tic` | `toc`

RandStream.create

Purpose Create random number streams

Class `RandStream`

Syntax

```
[s1,s2,...] = RandStream.create('gentype','NumStreams',n)
s = RandStream.create('gentype')
[ ... ] = RandStream.create('gentype', Name, Value,...)
```

Description

`[s1,s2,...]  = RandStream.create('gentype','NumStreams',n)` creates `n` random number streams that use the uniform pseudorandom number generator algorithm specified by `gentype`. The streams are independent in a pseudorandom sense. The streams are not necessarily independent from streams created at other times. `RandStream.list` returns all possible values for `gentype` or see "Choosing a Random Number Generator" in the MATLAB Mathematics documentation for details on generator algorithms.

Note Multiple streams are not supported by all generator types. Use either the multiplicative lagged Fibonacci generator (`mlfg6331_64`) or the combined multiple recursive generator (`mrg32k3a`) to create multiple streams.

`s = RandStream.create('gentype')` creates a single random stream. The `RandStream` constructor is a more concise alternative when you need to create a single stream.

`[ ...  ]  = RandStream.create('gentype', Name, Value,...)` allows you to specify optional Name, Value pairs to control creation of the stream. The parameters are:

NumStreams	Total number of streams of this type that will be created across sessions or labs. Default is 1.
StreamIndices	Stream indices that should be created in this call. Default is `1:N`, where `N` is the value given with the `'NumStreams'` parameter.
Seed	Nonnegative scalar integer with which to initialize all streams. Default is 0. Seeds must be an integer between 0 and $2^{32} - 1$ or `'shuffle'` to create a seed based on the current time.
NormalTransform	Transformation algorithm used by `randn(S, ...)` to generate normal pseudorandom values. Options are `'Ziggurat'`, `'Polar'`, or `'Inversion'`.
RandnAlg	`RandnAlg` has been removed. Use `NormalTransform` instead. Transformation algorithm used by `randn(S, ...)` to generate normal pseudorandom values. Options are `'Ziggurat'`, `'Polar'`, or `'Inversion'`.
CellOutput	Logical flag indicating whether or not to return the stream objects as elements of a cell array. Default is false.

Examples

Create three independent streams.

```
[s1,s2,s3] = RandStream.create('mrg32k3a','NumStreams',3);
r1 = rand(s1,100000,1);
```

```
r2 = rand(s2,100000,1);
r3 = rand(s3,100000,1);
corrcoef([r1,r2,r3])
```

Create one stream from a set of three independent streams and designate it as the global stream.

```
s2 = RandStream.create('mrg32k3a','NumStreams',3,'StreamIndices',2);
RandStream.setGlobalStream(s2);
```

See Also

`RandStream` | `RandStream.list`

Purpose

Create MATLAB class based on WSDL document

Syntax

```
createClassFromWsdl(source)
```

Description

`createClassFromWsdl(source)` creates a MATLAB class, `servicename`, based on a service name defined in `source`. The `source` argument is a string that specifies a URL, full path, or relative path to a Web Services Description Language (WSDL) document located on a server. `createClassFromWsdl` creates a class folder, `@servicename`, in the current folder. The class folder contains a method file for each Web service operation, and the display method (`display.m`) and constructor (`servicename.m`) for the class.

Examples

Get the methods from the `myWebService` WSDL document, which specifies two methods. The example does not use an actual WSDL document; therefore, you cannot run it. The example only illustrates how to use the function.

Create the class:

```
createClassFromWsdl('pathto_myWebService')
```

MATLAB creates the following in the current folder:

```
@myWebService
@myWebService/method1.m
@myWebService/method2.m
@myWebService/display.m
@myWebService/myWebService.m
```

Retrieve a student name, given the WSDL document for `TestScoreWebService`, at `http://examplestandardtests.com/scoreswebservice?WSDL`. The example does not use an actual WSDL document; therefore, you cannot run it. The example only illustrates how to use the function.

```
url = 'http://examplestandardtests.com/scoreswebservice?WSDL';
```

```
createClassFromWsdl(url);
obj = TestScoreWebService;
% Show the methods
methods(obj)
% Retrieve the first student name
students = StudentNames(obj);
students.StudentInfo(1)
```

MATLAB returns

```
StudentNameLast: 'Benjamin'
StudentNameFirst: 'Ali'
```

Display the endpoint and WSDL document location:

```
display('TestScoreWebService')
```

MATLAB returns

```
endpoint: 'http://examplestandardtests.com/scoreswebservice'
    wsdl: 'http://examplestandardtests.com/scoreswebservice?WSDL'
```

`callSoapService` | `createSoapMessage` | `parseSoapResponse` | `xmlread`

How To

- “Access Web Services That Use WSDL Documents”
- “Specify Proxy Server Settings for Connecting to the Internet”

Purpose Create copy of `inputParser` object (to be removed)

Compatibility The `createCopy` method will be removed in a future release. Use `copy` instead.

Syntax `pNew = createCopy(p)`

Description `pNew = createCopy(p)` creates a copy of `inputParser` object `p`.

Tips

- Using `createCopy` is not the same as copying by assignment, such as `pNew = p`, which creates a new handle to the same object `p`.

Input Arguments

p

Object of class `inputParser`.

Output Arguments

pNew

`inputParser` object with the same properties as object `p`.

Examples

Copy Input Parser Scheme

Create a copy of an existing `inputParser` object, and add an optional input to the copy.

```
p = inputParser;
default = 0;

addRequired(p,'first');
addOptional(p,'second',default);

pNew = createCopy(p);
addOptional(pNew,'third',default);
```

Object `p` has two inputs in the scheme, `first` and `second`. Object `pNew` has an additional input, `third`.

Parse each object.

```
input1 = 1; input2 = 2; input3 = 3;

parse(p,input1);
p.Results

ans =
     first: 1
    second: 0

parse(pNew,input1,input2,input3);
pNew.Results

ans =
     first: 1
    second: 2
     third: 3
```

See Also `inputParser` |

Purpose

Create SOAP message to send to server

Syntax

```
message = createSoapMessage(namespace,method,values,names,
   types,style)
```

Description

`message = createSoapMessage(namespace,method,values,names,types,style)` creates a SOAP message based on the values you provide for the arguments. `message` is a Java document object model (DOM). To send `message` to the Web service, use it with `callSoapService`.

Argument	Description
`namespace`	Location of the Web service in the form of a valid Uniform Resource Identifier (URI).
`method`	Name of the Web service operation you want to run.
`values`	Cell array of input you need to provide for the `method`.
`names`	Cell array of parameters for `method`.
`types`	Cell array defining the XML data types for `values`. Specifying `style` is optional; when you do not include the argument, MATLAB uses unspecified.
`style`	Style for structuring the SOAP message, either `'document'` or `'rpc'`. Specifying `style` is optional; when you do not include the argument, MATLAB uses `rpc`. Use a style supported by the service you specified in `namespace`.

Examples

This example uses `createSoapMessage` in conjunction with other SOAP functions to retrieve information about books from a library database, specifically, the author's name for a given book title.

Note The example is not based on an actual endpoint; therefore, you cannot run it. The example only illustrates how to use the SOAP functions.

```
% Create the message:
message = createSoapMessage(...
'urn:LibraryCatalog',...
'getAuthor',...
{'In the Fall'},...
{'nameToLookUp'},...
{'{http://www.w3.org/2001/XMLSchema}string'},...
'rpc');
%
% Send the message to the service and get the response:
response = callSoapService(...
'http://test/soap/services/LibraryCatalog',...
'urn:LibraryCatalog#getAuthor',...
message)
%
% Extract MATLAB data from the response
author = parseSoapResponse(response)
```

MATLAB returns:

```
author = Kate Alvin
```

where author is a char class (type).

`callSoapService` | `createClassFromWsdl` | `parseSoapResponse` | `urlread` | `xmlread`

How To

- "Access Web Services Using MATLAB SOAP Functions"

Purpose

Vector cross product

Syntax

```
C = cross(A,B)
C = cross(A,B,dim)
```

Description

`C = cross(A,B)` returns the cross product of the vectors `A` and `B`. That is, `C = A x B`. `A` and `B` must be 3-element vectors. If `A` and `B` are multidimensional arrays, `cross` returns the cross product of `A` and `B` along the first dimension of length 3.

`C = cross(A,B,dim)` where `A` and `B` are multidimensional arrays, returns the cross product of `A` and `B` in dimension `dim`. `A` and `B` must have the same size, and both `size(A,dim)` and `size(B,dim)` must be 3.

Tips

To perform a dot (scalar) product of two vectors of the same size, use `c = dot(a,b)`.

Examples

The cross and dot products of two vectors are calculated as shown:

```
a = [1 2 3];
b = [4 5 6];
c = cross(a,b)

c =
      -3     6    -3

d = dot(a,b)

d =
      32
```

See Also

`dot`

Purpose

Cosecant of argument in radians

Syntax

```
Y = csc(x)
```

Description

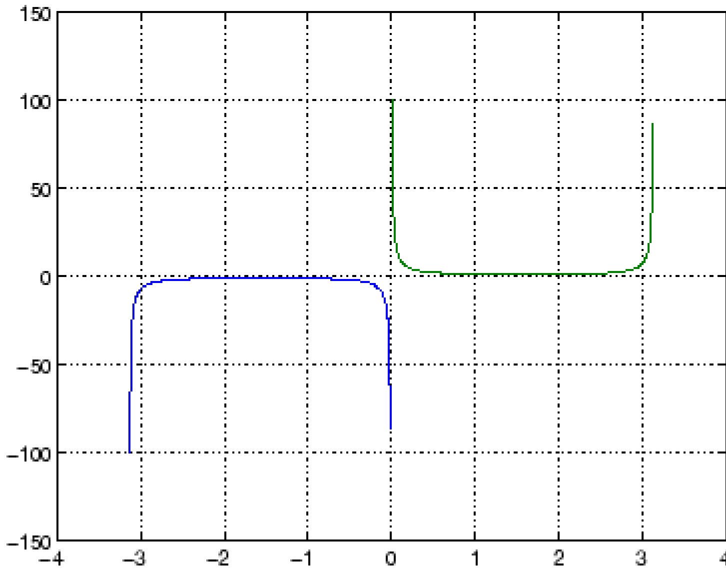
The `csc` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = csc(x)` returns the cosecant for each element of `x`.

Examples

Graph the cosecant over the domains $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,csc(x1),x2,csc(x2)), grid on
```



See Also

`cscd` | `csch` | `acsc` | `acscd` | `acsch`

Purpose

Cosecant of argument in degrees

Syntax

```
Y = cscd(X)
```

Description

`Y = cscd(X)` returns the cosecant of the elements of `X`, which are expressed in degrees.

Input Arguments

X - Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cscd` operation is element-wise when `X` is nonscalar.

Data Types
`single | double`
Complex Number Support: Yes

Output Arguments

Y - Cosecant of angle

scalar value | vector | matrix | N-D array

Cosecant of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Examples

Cosecant of 180 degrees compared to cosecant of radians

`cscd(180)` is infinite, whereas `csc(pi)` is large but finite.

```
cscd(180)

ans =

   Inf

csc(pi)

ans =
```

```
   8.1656e+15
```

Cosecant of vector of complex angles, specified in degrees

```
z = [35+i 15+2i 10+3i];
y = cscd(z)

y =

   1.7421 - 0.0434i   3.7970 - 0.4944i   5.2857 - 1.5681i
```

See Also

acscd | csc | acsc

Purpose

Hyperbolic cosecant

Syntax

```
Y = csch(x)
```

Description

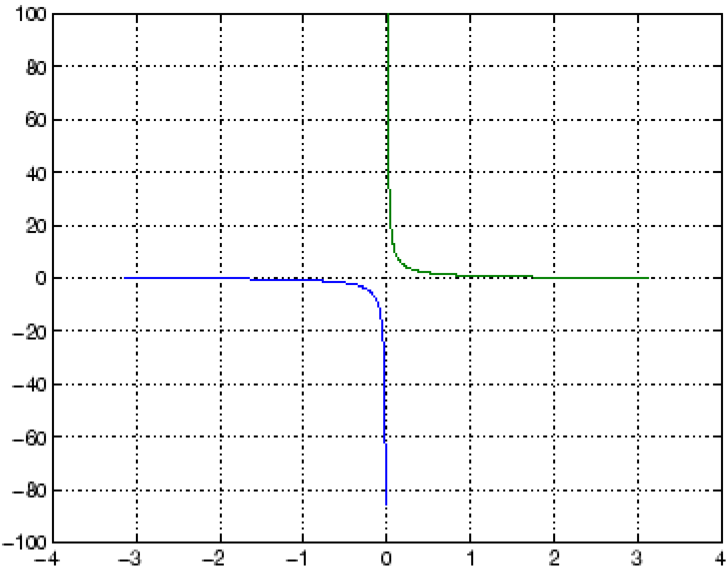
The `csch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = csch(x)` returns the hyperbolic cosecant for each element of `x`.

Examples

Graph the hyperbolic cosecant over the domains $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,csch(x1),x2,csch(x2)), grid on
```



See Also

`acsch` | `csc` | `sinh` | `cosh`

csvread

Purpose

Read comma-separated value file

Syntax

```
M = csvread(filename)
M = csvread(filename,row,col)
M = csvread(filename,row,col,csvRange)
```

Description

`M = csvread(filename)` reads a comma-separated value formatted file, `filename`. The file can only contain numeric values.

`M = csvread(filename,row,col)` reads data from the file starting at the specified row and column. The row and column arguments are zero based, so that `row = 0` and `col = 0` specify the first value in the file.

`M = csvread(filename,row,col,csvRange)` reads only the range specified by `csvRange`.

Input Arguments

filename - Name of file to read

string

Name of the file to read, specified as a string.

Example: `'myFile.dat'`

Data Types

`char`

row - Row of first value to read

0 (default) | positive integer

Row of the first value to read, specified as a positive integer. `row` is zero based, so that `row = 0` specifies the first row of data.

Data Types

`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

col - Column of first value to read

0 (default) | positive integer

Column of the first value to read, specified as a positive integer. `col` is zero based, so that `col = 0` specifies the first column of data.

Data Types
`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

csvRange - Range of data to read

4-element vector | string

Range of the data to read, specified as a 4-element vector or a string.

- If `csvRange` is a 4-element vector, then it must have the form `[R1,C1,R2,C2]`, where (`R1,C1`) is the upper left corner of the data to be read and (`R2,C2`) is the lower right corner. The range is zero based, so that `R1 = 0` specifies the first row of data, and `C1 = 0` specifies the first column of data.
- If `csvRange` is a string, then it should be specified using spreadsheet notation, as in `csvRange = 'A1..B7'`.

Data Types
`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char`

Output Arguments

M - Numeric data

matrix

Numeric data, returned as a matrix of `double` values.

Examples

Read File Containing Comma-Separated Values

Create a file, `csvlist.dat`, that contains these comma-separated values.

```
02, 04, 06, 08
03, 06, 09, 12
05, 10, 15, 20
07, 14, 21, 28
```

Read the entire file.

```
filename = 'csvlist.dat';
M = csvread(filename)

M =

     2     4     6     8
     3     6     9    12
     5    10    15    20
     7    14    21    28
```

`csvread` returns the numeric data in `M`.

Read Data Starting at Specific Row and Column

Read data from the file, `csvlist.dat`, of the previous example, starting at zero-based row 2, column 0.

```
M = csvread('csvlist.dat',2,0)

M =

     5    10    15    20
     7    14    21    28
```

Read a Specific Range of Data

Read a specific range of data from the file, `csvlist.dat`, of the first example.

Read the matrix bounded by zero-based (1,0) and (2,2).

```
M = csvread('csvlist.dat',1,0,[1,0,2,2])

M =

     3     6     9
     5    10    15
```

Algorithms

`csvread` fills empty delimited fields with zero. When `csvread` reads data files with lines that end with a nonspace delimiter, such as a semicolon, it returns a matrix, `M`, that has an additional last column of zeros.

`csvread` imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type. The table shows valid forms for a complex number.

<table>
<tr><th>Form</th><th>Example</th></tr>
<tr><td>–<real>–<imag>i|j</td><td>5.7-3.1i</td></tr>
<tr><td>–<imag>i|j</td><td>-7j</td></tr>
</table>

Embedded white-space in a complex number is invalid and is regarded as a field delimiter.

See Also

`csvwrite` | `dlmread` | `textscan` | `importdata` | `uiimport`

ctranspose

Purpose

Complex conjugate transpose

Syntax

```
b = a'
b = ctranspose(a)
```

Description

`b = a'` computes the complex conjugate transpose of matrix `a` and returns the result in `b`.

`b = ctranspose(a)` is called for the syntax `a'` (complex conjugate transpose) when `a` is an object.

See Also

`transpose`

Purpose

Write comma-separated value file

Syntax

```
csvwrite(filename,M)
csvwrite(filename,M,row,col)
```

Description

`csvwrite(filename,M)` writes matrix `M` into `filename` as comma-separated values. The `filename` input is a string enclosed in single quotes.

`csvwrite(filename,M,row,col)` writes matrix `M` into `filename` starting at the specified row and column offset. The row and column arguments are zero based, so that `row=0` and `C=0` specify the first value in the file.

Tips

- `csvwrite` terminates each line with a line feed character and no carriage return.
- `csvwrite` writes a maximum of five significant digits. If you need greater precision, use `dlmwrite` with a precision argument.
- `csvwrite` does not accept cell arrays for the input matrix `M`. To export a cell array that contains only numeric data, use `cell2mat` to convert the cell array to a numeric matrix before calling `csvwrite`. To export cell arrays with mixed alphabetic and numeric data, where each cell contains a single element, you can create an Excel spreadsheet (if your system has Excel installed) using `xlswrite`. For all other cases, you must use low-level export functions to write your data. For more information, see "Exporting a Cell Array to a Text File" in the MATLAB Data Import and Export documentation.

Examples

The following example creates a comma-separated value file from the matrix `m`.

```
m = [3 6 9 12 15; 5 10 15 20 25; ...
     7 14 21 28 35; 11 22 33 44 55];

csvwrite('csvlist.dat',m)
type csvlist.dat
```

```
3,6,9,12,15
5,10,15,20,25
7,14,21,28,35
11,22,33,44,55
```

The next example writes the matrix to the file, starting at a column offset of 2.

```
csvwrite('csvlist.dat',m,0,2)
type csvlist.dat

,,3,6,9,12,15
,,5,10,15,20,25
,,7,14,21,28,35
,,11,22,33,44,55
```

See Also

csvread | dlmwrite | xlswrite | importdata | uiimport

Purpose

Cumulative product

Syntax

```
B = cumprod(A)
B = cumprod(A,dim)
```

Description

`B = cumprod(A)` returns an array the same size as the array `A` containing the cumulative product.

- If `A` is a vector, then `cumprod(A)` returns a vector containing the cumulative product of the elements of `A`.
- If `A` is a matrix, then `cumprod(A)` returns a matrix containing the cumulative products for each column of `A`.
- If `A` is a multidimensional array, then `cumprod(A)` acts along the first nonsingleton dimension.

`B = cumprod(A,dim)` returns the cumulative product along dimension `dim`. For example, if `A` is a matrix, then `cumprod(A,2)` returns the cumulative product of each row.

Input Arguments

A - Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types
`double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`
Complex Number Support: Yes

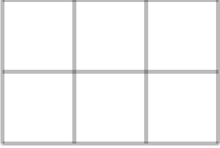
dim - Dimension to operate along

positive integer scalar

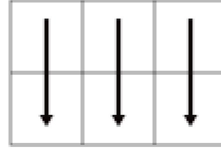
Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first nonsingleton dimension.

Consider a two-dimensional input array, `A`.

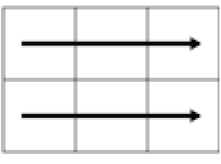
- `cumprod(A,1)` works along the rows of `A` and returns the cumulative product of each column.
- `cumprod(A,2)` works along the columns of `A` and returns the cumulative product of each row.



A



cumprod(A,1)



cumprod(A,2)

`cumprod` returns `A` if `dim` is greater than `ndims(A)`.

Data Types
`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

B - Cumulative product array

vector | matrix | multidimensional array

Cumulative product array, returned as a vector, matrix, or multidimensional array of the same size as the input array `A`.

The class of `B` is the same as the class of `A` except if `A` is `logical`, in which case `B` is `double`.

Definitions

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to `1`.

For example:

- If `X` is a 1-by-n row vector, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-0-by-n empty array, then the second dimension is the first nonsingleton dimension of `X`.

- If `X` is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of `X`.

Examples

Cumulative Product of Vector

Find the cumulative product of the integers from `1` to `5`.

```
A = [1:5];
B = cumprod(A)

B =

     1     2     6    24   120
```

`B(2)` is the product of `A(1)` and `A(2)`, while `B(5)` is the product of elements `A(1)` through `A(5)`.

Cumulative Product of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]

A =

     1     4     7
     2     5     8
     3     6     9
```

Find the cumulative product of the columns of `A`.

```
B = cumprod(A)

B =

     1     4     7
     2    20    56
     6   120   504
```

B(5) is the product of A(4) and A(5), while B(9) is the product of A(7) , A(8), and A(9).

Cumulative Product of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]
```

```
A =

     1     3     5
     2     4     6
```

Find the cumulative product of the rows of A.

```
B = cumprod(A,2)
```

```
B =

     1     3    15
     2     8    48
```

B(3) is the product of A(1) and A(3), while B(5) is the product of A(1), A(3), and A(5) .

Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]
```

```
A =

     1     0     1
     1     1     0
```

Find the cumulative product of the rows of A.

```
B = cumprod(A,2)

B =

     1     0     0
     1     1     0
```

The output is `double`.

```
class(B)

ans =

double
```

See Also

`cumsum` | `prod` | `sum`

Purpose

Cumulative sum

Syntax

```
B = cumsum(A)
B = cumsum(A,dim)
```

Description

`B = cumsum(A)` returns an array `A` containing the cumulative sum.

- If `A` is a vector, then `cumsum(A)` returns a vector containing the cumulative sum of the elements of `A`.
- If `A` is a matrix, then `cumsum(A)` returns a matrix containing the cumulative sums for each column of `A`.
- If `A` is a multidimensional array, then `cumsum(A)` acts along the first nonsingleton dimension.

`B = cumsum(A,dim)` returns the cumulative sum of the elements along dimension `dim`. For example, if `A` is a matrix, then `cumsum(A,2)` returns the cumulative sum of each row.

Input Arguments

A - Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types
`double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`
Complex Number Support: Yes

dim - Dimension to operate along

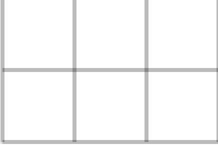
positive integer scalar

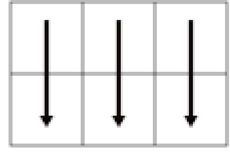
Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first nonsingleton dimension.

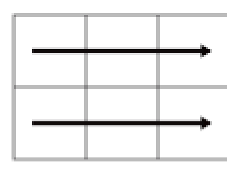
Consider a two-dimensional input array, `A`:

- `cumsum(A,1)` works along the rows of `A` and returns the cumulative sum of each column.

- `cumsum(A,2)` works along the columns of `A` and returns the cumulative sum of each row.







`cumsum` returns `A` if `dim` is greater than `ndims(A)`.

Data Types
`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

B - Cumulative sum array

vector | matrix | multidimensional array

Cumulative sum array, returned as a vector, matrix, or multidimensional array of the same size as the input array `A`.

The class of `B` is the same as the class of `A` except if `A` is `logical`, in which case `B` is `double`.

Definitions

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to `1`.

For example:

- If `X` is a 1-by-n row vector, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-0-by-n empty array, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of `X`.

Examples

Cumulative Sum of Vector

Find the cumulative sum of the integers from `1` to `5`.

```
A = [1:5];
B = cumsum(A)
```

```
B =

     1     3     6    10    15
```

`B(2)` is the sum of `A(1)` and `A(2)`, while `B(5)` is the sum of elements `A(1)` through `A(5)`.

Cumulative Sum of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

```
A =

     1     4     7
     2     5     8
     3     6     9
```

Find the cumulative sum of the columns of `A`.

```
B = cumsum(A)
```

```
B =

     1     4     7
     3     9    15
     6    15    24
```

`B(5)` is the sum of `A(4)` and `A(5)`, while `B(9)` is the sum of `A(7)` , `A(8)`, and `A(9)`.

Cumulative Sum of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]
```

```
A =

     1     3     5
     2     4     6
```

Find the cumulative sum of the rows of A.

```
B = cumsum(A,2)
```

```
B =

     1     4     9
     2     6    12
```

`B(3)` is the sum of `A(1)` and `A(3)`, while `B(5)` is the sum of `A(1)`, `A(3)`, and `A(5)` .

Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]
```

```
A =

     1     0     1
     1     1     0
```

Find the cumulative sum of the rows of A.

```
B = cumsum(A,2)
```

```
B =

     1     1     2
     1     2     2
```

The output is `double`.

```
class(B)
```

```
ans =

double
```

See Also

`cumprod` | `prod` | `sum` | `diff`

Purpose

Cumulative trapezoidal numerical integration

Syntax

```
Z = cumtrapz(Y)
Z = cumtrapz(X,Y)
Z = cumtrapz(X,Y,dim) or cumtrapz(Y,dim)
```

Description

`Z = cumtrapz(Y)` computes an approximation of the cumulative integral of `Y` via the trapezoidal method with unit spacing. To compute the integral with other than unit spacing, multiply `Z` by the spacing increment. Input `Y` can be complex.

For vectors, `cumtrapz(Y)` is a vector containing the cumulative integral of `Y`.

For matrices, `cumtrapz(Y)` is a matrix the same size as `Y` with the cumulative integral over each column.

For multidimensional arrays, `cumtrapz(Y)` works across the first nonsingleton dimension.

`Z = cumtrapz(X,Y)` computes the cumulative integral of `Y` with respect to `X` using trapezoidal integration. `X` and `Y` must be vectors of the same length, or `X` must be a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`. `cumtrapz` operates across this dimension. Inputs `X` and `Y` can be complex.

If `X` is a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`, `cumtrapz(X,Y)` operates across this dimension.

`Z = cumtrapz(X,Y,dim) or cumtrapz(Y,dim)` integrates across the dimension of `Y` specified by scalar `dim`. The length of `X` must be the same as `size(Y,dim)`.

Examples

Example 1

```
Y = [0 1 2; 3 4 5];

cumtrapz(Y,1)
ans =
0         0         0
```

```
    1.5000   2.5000    3.5000

cumtrapz(Y,2)
ans =
0    0.5000    2.0000
        0    3.5000    8.0000
```

Example 2

This example uses two complex inputs:

```
z = exp(1i*pi*(0:100)/100);

ct = cumtrapz(z,1./z);
ct(end)
ans =
   0.0000 + 3.1411i
```

See Also

cumsum | trapz

curl

Purpose

Compute curl and angular velocity of vector field

Syntax

```
[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)
[curlx,curly,curlz,cav] = curl(U,V,W)
[curlz,cav]= curl(X,Y,U,V)
[curlz,cav]= curl(U,V)
[curlx,curly,curlz] = curl(...), [curlx,curly] = curl(...)
cav = curl(...)
```

Description

`[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)` computes the curl (`curlx`, `curly`, `curlz`) and angular velocity (`cav`) perpendicular to the flow (in radians per time unit) of a 3-D vector field `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`[curlx,curly,curlz,cav] = curl(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`[curlz,cav]= curl(X,Y,U,V)` computes the curl `z`-component and the angular velocity perpendicular to `z` (in radians per time unit) of a 2-D vector field `U`, and `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`[curlz,cav]= curl(U,V)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[m,n] = size(U)`.

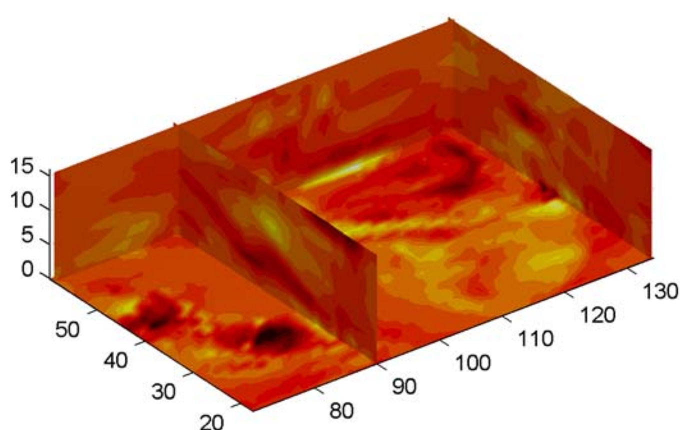
`[curlx,curly,curlz] = curl(...)`, `[curlx,curly] = curl(...)` returns only the curl.

`cav = curl(...)` returns only the curl angular velocity.

Examples

This example uses colored slice planes to display the curl angular velocity at specified locations in the vector field.

```
figure
load wind
cav = curl(x,y,z,u,v,w);
h = slice(x,y,z,cav,[90 134],59,0);
shading interp
daspect([1 1 1]);
axis tight
colormap hot(16)
camlight
set([h(1),h(2)],'ambientstrength',.6)
```



This example views the curl angular velocity in one plane of the volume and plots the velocity vectors (quiver) in the same plane.

```
load wind
k = 4;
x = x(:,:,k); y = y(:,:,k); u = u(:,:,k); v = v(:,:,k);
cav = curl(x,y,u,v);
pcolor(x,y,cav); shading interp
hold on;
quiver(x,y,u,v,'y')
hold off
colormap copper
```

- “Displaying Curl with Stream Ribbons”

Tiff.currentDirectory

Purpose

Index of current IFD

Syntax

```
dirNum = tiffobj.currentDirectory()
```

Description

`dirNum = tiffobj.currentDirectory()` returns the index of the current image file directory (IFD). Index values are one-based. Use this index value with the `setDirectory` member function.

Examples

Open a `Tiff` object and determine which IFD is the current IFD. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path:

```
t = Tiff('myfile.tif', 'r');
dnum = t.currentDirectory();
```

References

This method corresponds to the `TIFFCurrentDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTiff - TIFF Library and Utilities`.

See Also

`Tiff.setDirectory`

Tutorials

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

Purpose

Allow custom source control system (UNIX platforms)

Syntax

`customverctrl`

Description

`customverctrl` function is for customers who want to integrate a source control system that is not supported for use with MATLAB software. When using this function, conform to the structure of one of the supported version control systems, for example, RCS. For examples, see the files `clearcase.m`, `cvs.m`, `pvcs.m`, and `rcs.m` in *`matlabroot`*`\toolbox\matlab\verctrl`.

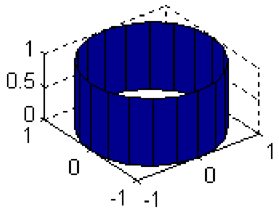
See Also

`checkin` | `checkout` | `cmopts` | `undocheckout` | `verctrl`

cylinder

Purpose

Generate cylinder



Syntax

```
[X,Y,Z] = cylinder
[X,Y,Z] = cylinder(r)
[X,Y,Z] = cylinder(r,n)
cylinder(axes_handle,...)
cylinder(...)
```

Description

`cylinder` generates *x*-, *y*-, and *z*-coordinates of a unit cylinder. You can draw the cylindrical object using `surf` or `mesh`, or draw it immediately by not providing output arguments.

`[X,Y,Z] = cylinder` returns the *x*-, *y*-, and *z*-coordinates of a cylinder with a radius equal to `1`. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r)` returns the *x*-, *y*-, and *z*-coordinates of a cylinder using `r` to define a profile curve. `cylinder` treats each element in `r` as a radius at equally spaced heights along the unit height of the cylinder. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r,n)` returns the *x*-, *y*-, and *z*-coordinates of a cylinder based on the profile curve defined by vector `r`. The cylinder has `n` equally spaced points around its circumference.

`cylinder(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`cylinder(...)`, with no output arguments, plots the cylinder using `surf`.

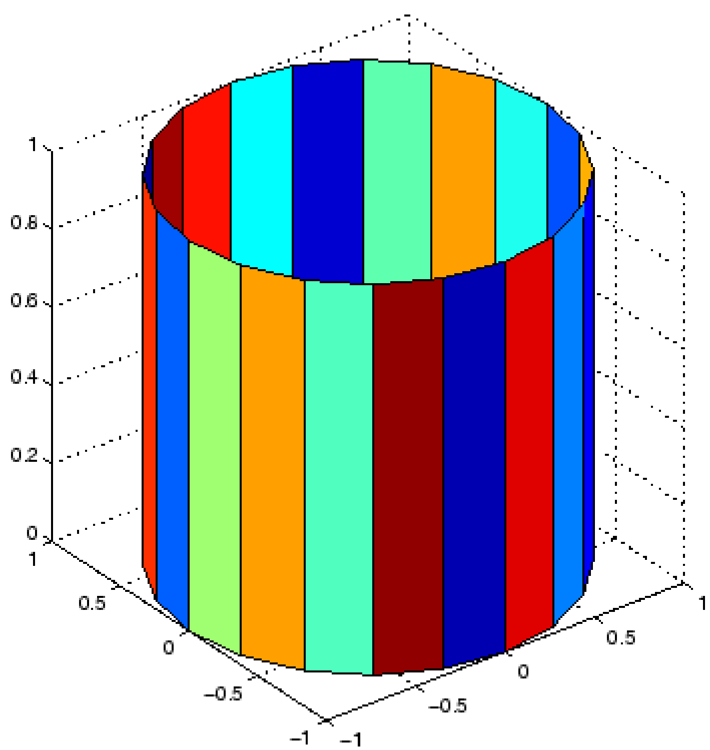
Tips

`cylinder` treats its first argument as a profile curve. The resulting surface graphics object is generated by rotating the curve about the *x*-axis, and then aligning it with the *z*-axis.

Examples

Create a cylinder with randomly colored faces.

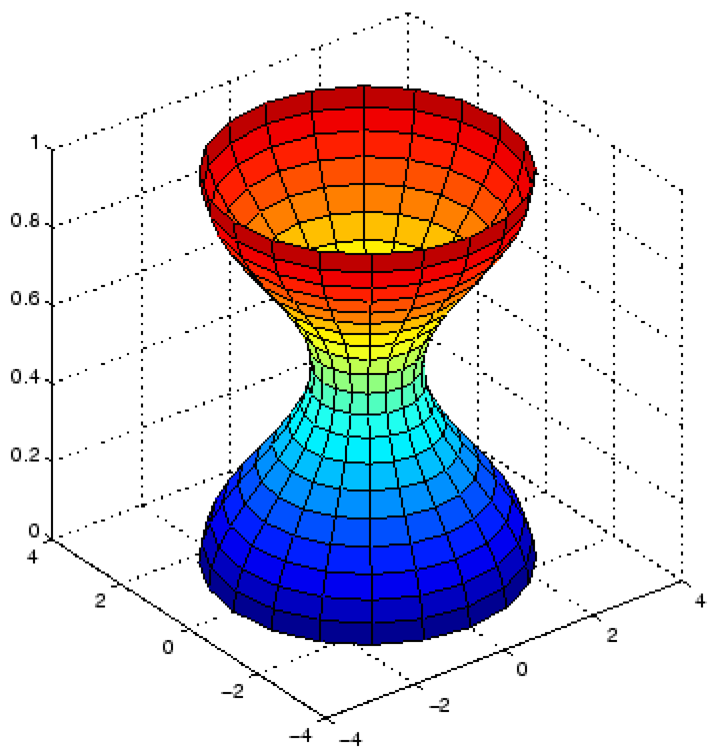
```
cylinder
axis square
h = findobj('Type','surface');
set(h,'CData',rand(size(get(h,'CData'))))
```



Generate a cylinder defined by the profile function `2+sin(t)`.

```
t = 0:pi/10:2*pi;
```

```
[X,Y,Z] = cylinder(2+cos(t));
surf(X,Y,Z)
axis square
```



See Also

sphere | surf

Purpose

Read Data Acquisition Toolbox (.daq) file

Syntax

```
data = daqread('filename')
[data, time] = daqread(...)
[data, time, abstime] = daqread(...)
[data, time, abstime, events] = daqread(...)
[data, time, abstime, events, daqinfo] = daqread(...)
data = daqread(...,'Param1', Val1,...)
daqinfo = daqread('filename','info')
```

Description

`data = daqread('filename')` reads all the data from the Data Acquisition Toolbox™ (`.daq`) file specified by `filename`. `daqread` returns `data`, an *m*-by-*n* data matrix, where *m* is the number of samples and *n* is the number of channels. If `data` includes data from multiple triggers, the data from each trigger is separated by a `NaN`. If you set the `OutputFormat` property to `tscollection`, `daqread` returns a time series collection object. See below for more information.

`[data, time] = daqread(...)` returns time/value pairs. `time` is an *m*-by-1 vector, the same length as `data`, that contains the relative time for each sample. Relative time is measured with respect to the first trigger that occurs.

`[data, time, abstime] = daqread(...)` returns the absolute time of the first trigger. `abstime` is returned as a `clock` vector.

`[data, time, abstime, events] = daqread(...)` returns a log of events. `events` is a structure containing event information. If you specify either the`Samples`, `Time`, or `Triggers` parameters (see below), the events structure contains only the specified events.

`[data, time, abstime, events, daqinfo] = daqread(...)` returns a structure, `daqinfo`, that contains two fields: `ObjInfo` and `HwInfo`. `ObjInfo` is a structure containing property name/property value pairs and `HwInfo` is a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

`data = daqread(...,'Param1', Val1,...)` specifies the amount of data returned and the format of the data, using the following parameters.

Parameter	Description
`Samples`	Specify the sample range.
`Time`	Specify the relative time range.
`Triggers`	Specify the trigger range.
`Channels`	Specify the channel range. Channel names can be specified as a cell array.
`DataFormat`	Specify the data format as `doubles` (default) or `native`.
`TimeFormat`	Specify the time format as `vector` (default) or `matrix`.
`OutputFormat`	Specify the output format as `matrix` (the default) or `tscollection`. When you specify `tscollection`, `daqread` only returns `data`.

The `Samples`, `Time`, and `Triggers` properties are mutually exclusive; that is, either `Samples`, `Triggers` or `Time` can be defined at once.

`daqinfo = daqread('filename','`**`info`**`')` returns metadata from the file in the `daqinfo` structure, without incurring the overhead of reading the data from the file as well. The `daqinfo` structure contains two fields:

`daqinfo.ObjInfo`
: a structure containing parameter/value pairs for the data acquisition object used to create the file, `filename`. Note: The `UserData` property value is not restored.

`daqinfo.HwInfo`
: a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

Tips

More About .daq Files

- The format used by `daqread` to return data, relative time, absolute time, and event information is identical to the format used by the `getdata` function that is part of Data Acquisition Toolbox. For more information, see the Data Acquisition Toolbox documentation.
- If data from multiple triggers is read, then the size of the resulting data array is increased by the number of triggers issued because each trigger is separated by a `NaN`.
- `ObjInfo.EventLog` always contains the entire event log regardless of the value specified by `Samples`, `Time`, or `Triggers`.
- The `UserData` property value is not restored when you return device object (`ObjInfo`) information.
- When reading a `.daq` file, the `daqread` function does not return property values that were specified as a cell array.
- Data Acquisition Toolbox (`.daq`) files are created by specifying a value for the `LogFileName` property (or accepting the default value), and configuring the `LoggingMode` property to `Disk` or `Disk&Memory`.

More About Time Series Collection Object Returned

When `OutputFormat` is set to `tscollection`, `daqread` returns a time series collection object. This times series collection object contains an absolute time series object for each channel in the file. The following describes how `daqread` sets some of the properties of the times series collection object and the time series objects.

- The `time` property of the time series collection object is set to the value of the `InitialTriggerTime` property specified in the file.
- The `name` property of each time series object is set to the value of the `Name` property of a channel in the file. If this name cannot be used as a time series object name, `daqread` sets the name to `'Channel'` with the `HwChannel` property of the channel appended.
- The value of the `Units` property of the time series object depends on the value of the `DataFormat` parameter. If the `DataFormat` parameter

is set to 'double', daqread sets the DataInfo property of each time series object in the collection to the value of the Units property of the corresponding channel in the file. If the DataFormat parameter is set to 'native', daqread sets the Units property to 'native'. See the Data Acquisition Toolbox documentation for more information on these properties.

- Each time series object will have tsdata.event objects attached corresponding to the log of events associated with the channel.

If daqread returns data from multiple triggers, the data from each trigger is separated by a NaN in the time series data. This increases the length of data and time vectors in the time series object by the number of triggers.

Examples

Use Data Acquisition Toolbox to acquire data. The analog input object, ai, acquires one second of data for four channels, and saves the data to the output file data.daq.

```
ai = analoginput('nidaq','Dev1');
chans = addchannel(ai,0:3);
set(ai,'SampleRate',1000)
ActualRate = get(ai,'SampleRate');
set(ai,'SamplesPerTrigger, ActualRate)
set(ai,'LoggingMode','Disk&Memory')
set(ai,'LogFileName','data.daq')
start(ai)
```

After the data has been collected and saved to a disk file, you can retrieve the data and other acquisition-related information using daqread. To read all the sample-time pairs from data.daq:

```
[data,time] = daqread('data.daq');
```

To read samples 500 to 1000 for all channels from data.daq:

```
data = daqread('data.daq','Samples',[500 1000]);
```

To read only samples 1000 to 2000 of channel indices 2, 4 and 7 in native format from the file, `data.daq`:

```
data = daqread('data.daq', 'Samples', [1000 2000],...
               'Channels', [2 4 7], 'DataFormat', 'native');
```

To read only the data which represents the first and second triggers on all channels from the file, `data.daq`:

```
[data, time] = daqread('data.daq', 'Triggers', [1 2]);
```

To obtain the channel property information from `data.daq`:

```
daqinfo = daqread('data.daq','info');
chaninfo = daqinfo.ObjInfo.Channel;
```

To obtain a list of event types and event data contained by `data.daq`:

```
daqinfo = daqread('data.daq','info');
events = daqinfo.ObjInfo.EventLog;
event_type = {events.Type};
event_data = {events.Data};
```

To read all the data from the file `data.daq` and return it as a time series collection object:

```
data = daqread('data.daq','OutputFormat','tscollection');
```

`timeseries` | `tscollection`

daspect

Purpose

Set or query axes data aspect ratio

Syntax

```
daspect
daspect([aspect_ratio])
daspect('mode')
daspect('auto')
daspect('manual')
daspect(axes_handle,...)
```

Description

The data aspect ratio determines the relative scaling of the data units along the *x*-, *y*-, and *z*-axes.

`daspect` with no arguments returns the data aspect ratio of the current axes.

`daspect([aspect_ratio])` sets the data aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the *x*-, *y*-, and *z*-axis scaling (e.g., `[1 1 3]` means one unit in *x* is equal in length to one unit in *y* and three units in *z*).

`daspect('mode')` returns the current value of the data aspect ratio mode, which can be either `auto` (the default) or `manual`. See TipsRemarks.

`daspect('auto')` sets the data aspect ratio mode to `auto`.

`daspect('manual')` sets the data aspect ratio mode to `manual`.

`daspect(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `daspect` operates on the current axes.

Tips

`daspect` sets or queries values of the axes object `DataAspectRatio` and `DataAspectRatioMode` properties.

When the data aspect ratio mode is `auto`, the data aspect ratio adjusts so that each axis spans the space available in the figure window. If you are displaying a representation of a real-life object, you should set the data aspect ratio to `[1 1 1]` to produce the correct proportions.

Setting a value for data aspect ratio or setting the data aspect ratio mode to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the data aspect ratio to a value, including its current value,

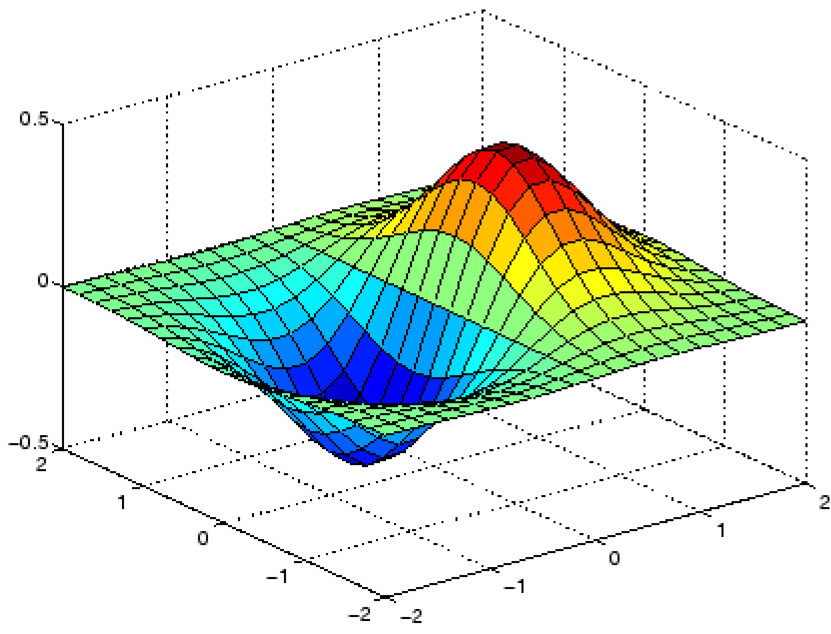
```
daspect(daspect)
```

can cause a change in the way the graphs look. See the Remarks section of the `axes` description for more information.

Examples

The following surface plot of the function $z = xe^{(-x^2 - y^2)}$ is useful to illustrate the data aspect ratio. First plot the function over the range $-2 \le x \le 2$, $-2 \le y \le 2$,

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2 - y.^2);
surf(x,y,z)
```



Querying the data aspect ratio shows how the surface is drawn.

```
daspect
ans =
     4   4   1
```

Setting the data aspect ratio to [1 1 1] produces a surface plot with equal scaling along each axis.

```
daspect([1 1 1])
```

datacursormode

Purpose

Enable, disable, and manage interactive data cursor mode

Syntax

```
datacursormode on
datacursormode off
datacursormode
datacursormode toggle
datacursormode(figure_handle)
dcm_obj = datacursormode(figure_handle)
```

Description

`datacursormode on` enables data cursor mode on the current figure.

`datacursormode off` disables data cursor mode on the current figure.

`datacursormode` or `datacursormode toggle` toggles data cursor mode in the current figure.

`datacursormode(figure_handle)` enables or disables data cursor mode on the specified figure.

`dcm_obj = datacursormode(figure_handle)` returns the data cursor mode object for the figure. The object enables you to customize the data cursor. For more information on data cursor mode objects, see "Output Arguments" on page 1-1165. You cannot change the state of data cursor mode in a call to `datacursormode` that returns a mode object.

A *data cursor* is a small black square with a white border that you interactively position on a graph in data cursor mode. When you click a graphic object such as a line on a graph, a *data tip* appears. Data tips are small text boxes or windows that float within an axes that display data values at data cursor locations. The default style is a text box. Data tips list *x*-, *y*- and (where appropriate) *z*-values for one data point at a time. See "Examples" on page 1-1169 for an illustration of these two styles.

Tips

- Most types of graphs and 3-D plots support data cursor mode, but several do not (`pareto`, for example).
- Polar plots support data tips, but display Cartesian rather than polar coordinates on them.

- Histograms created with `hist` display specialized data tips that itemize the observation counts, lower and upper limits and center point for histogram bins.
- You place data tips only by clicking data objects on graphs. You cannot place them programmatically (by executing code to position a data cursor).
- When `DisplayStyle` is `datatip`, you can place multiple data tips on a graph. When `DisplayStyle` is `window`, it reports only the most recent data tip.
- `datacursormode off` exits data cursor mode but does not remove displayed data tips. However, if the `DisplayStyle` is `window`, the data tip window goes away.

Input Arguments

figure_handle

Optional handle of figure window

Default: The current figure

state

`''`, `'toggle'`, `'on'`, or `'off'`

Default: `'toggle'`

Output Arguments

dcm_obj

Use the object returned by `datacursormode` to control aspects of data cursor behavior. You can use the `set` and `get` commands to set and query object property values. You can customize how data cursor mode presents information by coding callback functions for these objects.

Parameter Name/Value Pairs for Data Cursor Mode Objects

The following parameters apply to objects returned by calls to `datacursormode`, not to the function itself.

'DisplayStyle'

`datatip | window`

Determines how the data cursor displays.

- `datatip` displays data cursor information in a small yellow text box attached to a black square marker at a data point you interactively select.
- `window` displays data cursor information for the data point you interactively select in a floating window within the figure.

Default: `datatip`

'Enable'

`on | off`

Specifies whether data cursor mode is currently enabled for the figure.

Default: `off`

'Figure'

handle

Handle of the figure associated with the data cursor mode object.

'SnapToDataVertex'

`on | off`

Specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position.

Default: `on`

'UpdateFcn'

function handle

Reference to a function that formats the text appearing in the data cursor. You can supply your own function to customize data tip display. Your function must include at least two arguments. The first argument is unused, and can be a variable name or tilde (~). The second argument passes the data cursor event object to your update function. The event object encapsulates the state of the data cursor. The following function definition illustrates the update function:

```
function output_txt = myfunction(~,event_obj)
% ~            Currently not used (empty)
% event_obj    Object containing event data structure
% output_txt   Data cursor text (string or cell array of strings)
```

`event_obj` is an object that has the following properties.

`Target`	Handle of the object the data cursor is referencing (the object which you click, for example, a line or a bar from a series)
`Position`	An array specifying the *x*, *y* (and *z* for 3-D graphs) coordinates of the cursor

You can query these properties within your function. For example,

```
pos = get(event_obj,'Position');
```

returns the coordinates of the cursor. Another way of accessing that data is to obtain the struct and query its `Position` field:

```
eventdata = get(event_obj);
pos = eventdata.Position;
```

You can also obtain the position directly from the object:

```
pos = event_obj.Position;
```

You can redefine the data cursor `Updatefcn` at run time. For example:

```
set(dcm_obj,'UpdateFcn',@myupdatefcn)
```

applies the function `myupdatefcn` to the current data tip or tips. When you set an update function in this way, the function must be on the MATLAB path. If instead you select the data cursor mode context menu item **Select text update function**, you can interactively select a function that is not on the path.

Do not redefine figure window callbacks, such as `ButtonDownFcn`, `KeyPpressFcn`, or `CloseRequestFcn` *while in data cursor mode.* If you attempt to change any *figure* callbacks when you are in an interactive mode, you receive a warning and the attempt fails. MATLAB interactive modes are:

- `brush`
- `datacursormode`
- `pan`
- `rotate3d`
- `zoom`

This restriction does not apply to changing the figure `WindowButtonMotionFcn` callback or `uicontrol` callbacks.

Querying Data Cursor Mode

Use the `getCursorInfo` function to query the data cursor mode object (`dcm_obj` in the update function syntax) to obtain information about the data cursor. For example,

```
info_struct = getCursorInfo(dcm_obj);
```

returns a vector of structures, one for each data cursor on the graph. Each structure has the following fields.

`Target`	The handle of the graphics object containing the data point
`Position`	An array specifying the x, y, (and z) coordinates of the cursor

Line and lineseries objects have an additional field.

`DataIndex`	A scalar index into the data arrays that correspond to the nearest data point. The value is the same for each array.

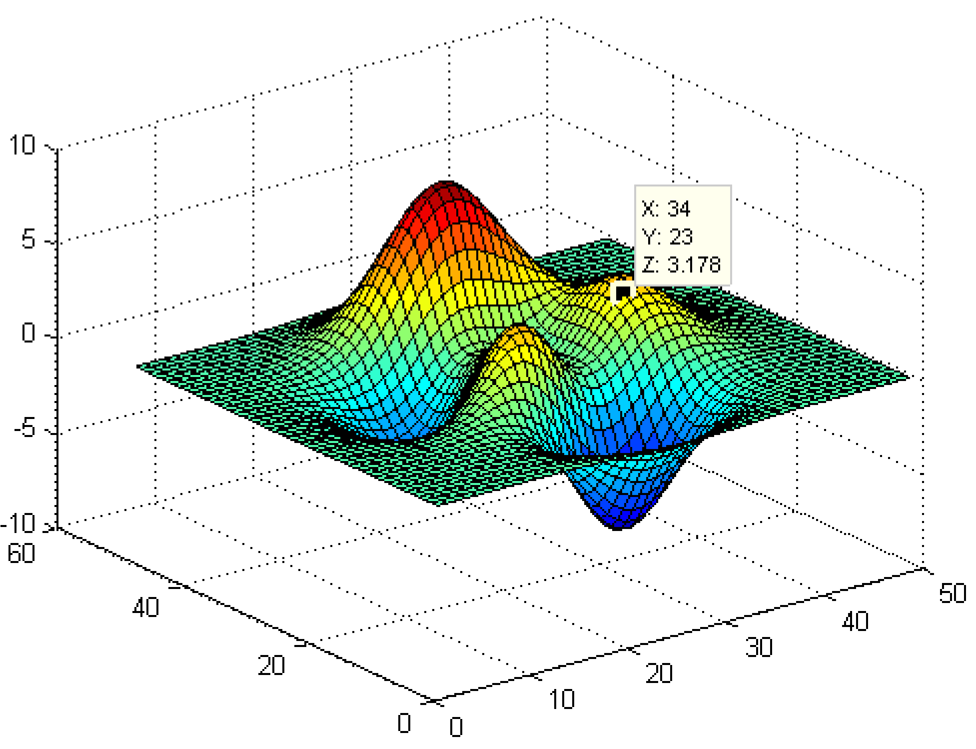
See "Output Arguments" on page 1-1165 for more details on data cursor mode objects.

Examples

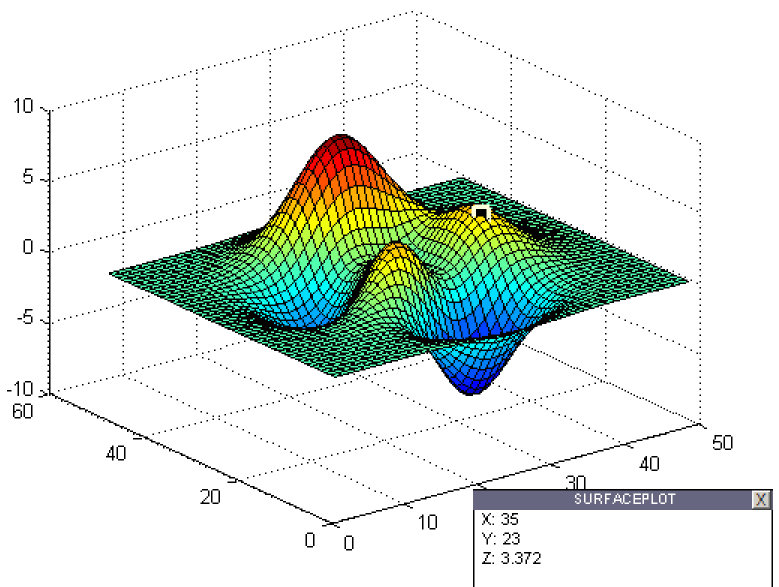
This example creates a plot and enables data cursor mode from the command line.

```
surf(peaks)
datacursormode on
% Click mouse on surface to display data cursor
```

Selecting a point on the surface opens a data tip displaying its *x*-, *y*-, and z-coordinates.



You change the data tip display style to be a window instead of a text box using the **Tools > Options > Display cursor in window** , or use the context menu **Display Style > Window inside figure** to view the data tip in a floating window that you can move around inside the axes.



You can position multiple text box data tips on the same graph, the window style of data tip displays only one value at a time. For more information on interacting with data cursors, including point selection options and exporting data tips to the workspace, see "Data Cursor — Displaying Data Values Interactively".

This example enables data cursor mode on the current figure and sets data cursor mode options. The following statements

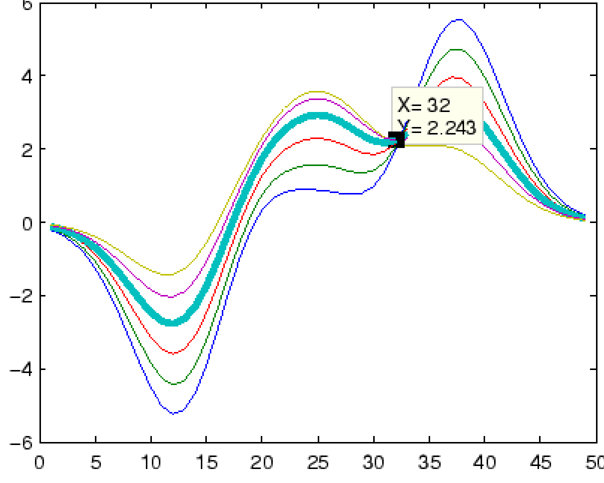
- Create a graph
- Toggle data cursor mode to on
- Obtain the data cursor mode object, specify data tip options, and get the handle of the line the data tip occupies:

```
fig = figure;
z = peaks;
plot(z(:,30:35))
```

```
dcm_obj = datacursormode(fig);
set(dcm_obj,'DisplayStyle','datatip',...
    'SnapToDataVertex','off','Enable','on')

disp('Click on a line to display a data tip, then press Return.')
pause                             % Wait while the user does this.

c_info = getCursorInfo(dcm_obj);
set(c_info.Target,'LineWidth',2)  % Make selected line wider
```



This example shows you how to customize the text that the data cursor displays. For example, you can replace the text displayed in the data tip and data window (`x:` and `y:`) with `Time:` and `Amplitude:` by creating a simple update function.

Save the following functions in your current directory or any writable directory on the MATLAB path before running them. As they are functions, you cannot highlight them and then evaluate the selection to make them work.

Save this code as `doc_datacursormode.m`:

```
function doc_datacursormode
% Plots graph and sets up a custom data tip update function
fig = figure;
a = -16; t = 0:60;
plot(t,sin(a*t))
dcm_obj = datacursormode(fig);
set(dcm_obj,'UpdateFcn',@myupdatefcn)
```

Save the following code as `myupdatefcn.m` on the MATLAB path:

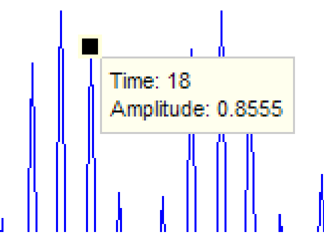
```
function txt = myupdatefcn(empt,event_obj)
% Customizes text of data tips

pos = get(event_obj,'Position');
txt = {['Time: ',num2str(pos(1))],...
       ['Amplitude: ',num2str(pos(2))]};
```

To set up and use the update function, type:

```
doc_datacursormode
```

When you place a data tip using this update function, it looks like the one in the following figure.



Alternatives

Use the Data Cursor tool to label *x*, *y*, and *z* values on graphs and surfaces. You can control how data tips display by right-clicking and selecting items from the context menu.

Tutorials

- “Data Cursor — Displaying Data Values Interactively”

How To

- “Example — Visually Exploring Demographic Statistics”
- “Using Data Cursors with Histograms”

Purpose

Produce short description of input variable

Syntax

```
datatipinfo(var)
```

Description

`datatipinfo(var)` displays a short description of a variable, similar to what is displayed in a datatip in the MATLAB debugger.

Examples

Get datatip information for a 5-by-5 matrix:

```
A = rand(5);

datatipinfo(A)
A: 5x5 double =
    0.4445    0.3567    0.7458    0.0767    0.4400
    0.7962    0.6575    0.3918    0.8289    0.9746
    0.5641    0.9808    0.0265    0.4838    0.6722
    0.9099    0.9653    0.2508    0.4859    0.4054
    0.2857    0.5198    0.7383    0.9301    0.9604
```

Get datatip information for a 50-by-50 matrix. For this larger matrix, `datatipinfo` displays just the size and data type:

```
A = rand(50);

datatipinfo(A)
A: 50x50 double
```

Also for multidimensional matrices, `datatipinfo` displays just the size and data type:

```
A = rand(5);
A(:,:,2) = A(:,:,1);

datatipinfo(A)
A: 5x5x2 double
```

`inputname` | `narginchk` | `nargin` | `varargin` | `inputParser`

date

Purpose Current date string

Syntax

```
str = date
```

Description `str = date` returns a string containing the date in `dd-mmm-yyyy` format.

See Also `clock` | `datestr` | `datenum` | `now`

Purpose

Convert date and time to serial date number

Syntax

```
DateNumber = datenum(DateString)
DateNumber = datenum(DateString,formatIn)
DateNumber = datenum(DateString,PivotYear)
DateNumber = datenum(DateString,formatIn,PivotYear)

DateNumber = datenum(DateVector)
DateNumber = datenum(Y,M,D)
DateNumber = datenum(Y,M,D,H,MN,S)
```

Description

`DateNumber = datenum(DateString)` converts date strings to serial date numbers. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000).

`DateNumber = datenum(DateString,formatIn)` uses `formatIn` to interpret each date string.

`DateNumber = datenum(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateNumber = datenum(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

`DateNumber = datenum(DateVector)` converts date vectors to serial date numbers, and returns a column vector of `m` date numbers, where `m` is the total number of date vectors in `DateVector`.

`DateNumber = datenum(Y,M,D)` returns the serial date numbers for corresponding elements of the `Y`, `M`, and `D` (year, month, day) arrays. The arrays must be of the same size (or any can be a scalar). You can also specify the input arguments as a date vector, `[Y,M,D]`.

`DateNumber = datenum(Y,M,D,H,MN,S)` additionally returns the serial date numbers for corresponding elements of the `H`, `MN`, and `S` (hour, minute, and second) arrays. The arrays must be of the same size (or any can be a scalar). You can also specify the input arguments as a date vector, `[Y,M,D,H,MN,S]`.

Input Arguments

DateVector - Date vectors

matrix

Date vectors, specified as an `m`-by-6 or `m`-by-3 matrix containing `m` full or partial date vectors, respectively. A full date vector has six elements, specifying year, month, day, hour, minute, and second, in that order. A partial date vector has three elements, specifying year, month, and day, in that order. Each element of `DateVector` must be a positive double-precision array.

Example: `[2003,10,24,12,45,07]`

Data Types
`double`

DateString - Date strings

string | cell array of strings

Date strings, specified as a single string or a cell array of strings, where each row corresponds to one date string. All of the date strings must have the same format.

Example: `'24 Oct-2003 12:45:07'`

Example: `{'15-Oct-2010';'20-Nov-2012'}`

If the date string format is known, you should also specify `formatIn`. If you do not specify `formatIn`, `DateString` must be in one of the following formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00
'mm/dd'	03/01
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. MATLAB considers two-character date string years (e.g., `'79'`) to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (`mm`), the month value must not be greater than 12.
- However, for the format `'mm/dd/yy'`, if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, MATLAB considers the date string to be in `'yy/mm/dd'` format.

formatIn - Format of the input date string

string

Format of the input date string, specified as a string of symbolic identifiers.

Example: `'dddd, mmm dd, yyyy'`

The following table shows symbolic identifiers you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

Symbolic Identifier	Description	Example
`yyyy`	Year in full	1990, 2002
`yy`	Year in two digits	90, 02
`QQ`	Quarter year using letter `Q` and one digit	`Q1`
`mmmm`	Month using full name	`March`, `December`
`mmm`	Month using first three letters	`Mar`, `Dec`
`mm`	Month in two digits	03, 12
`m`	Month using capitalized first letter	`M`, `D`
`dddd`	Day using full name	`Monday`, `Tuesday`
`ddd`	Day using first three letters	`Mon`, `Tue`
`dd`	Day in two digits	05, 20
`d`	Day using capitalized first letter	`M`, `T`

Symbolic Identifier	Description	Example
`HH`	Hour in two digits (no leading zeros when symbolic identifier `AM` or `PM` is used)	`05`, `5 AM`
`MM`	Minute in two digits	`12`, `02`
`SS`	Second in two digits	`07`, `59`
`FFF`	Millisecond in three digits	`057`
`AM or PM`	`AM` or `PM` inserted in date string	`3:45:02 PM`

The `formatIn` string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use `'yy-mmm-dd-m'` because it has two month identifiers. The one exception to this is that you can combine one instance of `dd` with one instance of any of the other day identifiers. For example, `'dddd mmm dd yyyy'` is a valid input.
- When you use `AM` or `PM`, the `HH` field is also required.
- You only can use `QQ` alone or with a year specifier.

PivotYear - Start year of 100-year date range

current year minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

Example: `2000`

Data Types

`double`

Y,M,D - Year, month, and day arrays

scalar | vector

Year, month, and day arrays, specified as scalars or vectors. The arrays must be of the same size (or any can be a scalar).

You can also specify the input arguments as a date vector, `[Y,M,D]`.

Example: `2003,10,24`

Data Types
`double`

Y,M,D,H,MN,S - Year, month, day, hour, minute and second arrays

scalar | vector

Year, month, day, hour, minute and second arrays, specified as scalars or vectors. The arrays must be of the same size (or any can be a scalar).`datenum` does not accept milliseconds as a separate input, but as a fractional part of the seconds input, `s`.

You can also specify the input arguments as a date vector, `[Y,M,D,H,MN,S]`.

Example: `2003,10,24,12,45,07.451`

Data Types
`double`

Output Arguments

DateNumber - Serial date numbers

scalar | vector

Serial date numbers, returned as a column vector of length `m`, where `m` is the total number of input date vectors or date strings.

Examples

Convert Date String to Date Number

```
DateString = '19-May-2001';
formatIn = 'dd-mmm-yyyy';
datenum(DateString,formatIn)
```

```
ans =
      730990
```

`datenum` returns a date number for the date string with the format `'dd-mmm-yyyy'` .

Convert Multiple Date Strings to Date Numbers

Pass multiple date strings in a cell array. All input date strings must use the same format.

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};
formatIn = 'mm/dd/yyyy';
datenum(DateString,formatIn)
```

```
ans =
    733301
    729159
    734471
```

Convert Date String to Date Number Using Pivot Year

Convert a date string to a serial date number using the default pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy')
```

```
n =
      736858
```

The corresponding date string to this date number is 12-Jun-2017.

Convert the same date string to a serial date number using 1400 as the pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy',1400)
```

```
n =
      517712
```

The corresponding date string to this date number is 12-Jun-1417.

Convert Date Vector to Date Number

```
datenum([2009,4,2,11,7,18])

ans =
   7.3387e+05
```

Convert Year, Month, and Day to Date Number

Convert a date specified by year, month and day values to a serial date number.

```
n = datenum(2001,12,19)

n =
      731204
```

See Also

datestr | datevec

Concepts

- “Represent Dates and Times in MATLAB”
- “Carryover in Date Vectors and Strings”

Purpose

Convert date and time to string format

Syntax

```
DateString = datestr(DateVector)
DateString = datestr(DateNumber)

DateString = datestr( ___ ,formatOut)

DateString = datestr(DateStringIn)
DateString = datestr(DateStringIn,formatOut,PivotYear)

DateString = datestr( ___ ,'local')
```

Description

`DateString = datestr(DateVector)` converts date vectors to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date vectors in `DateVector`. `datestr` returns date strings in the default date string format `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second).

`DateString = datestr(DateNumber)` converts serial date numbers to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date numbers in `DateNumber`.

`DateString = datestr( ___ ,formatOut)` specifies the format of the output date strings using `formatOut`. You can use `formatOut` with any of the input arguments in the above syntaxes.

`DateString = datestr(DateStringIn)` converts `DateStringIn` to date strings in the default date string format `dd-mmm-yyyy HH:MM:SS`. All date strings in `DateStringIn` must have the same format.

`DateString = datestr(DateStringIn,formatOut,PivotYear)` converts `DateStringIn` to `DateString`, in the format specified by `formatOut`, and using optional `PivotYear` to interpret date strings that specify the year as two characters.

DateString = datestr(___ ,'local') returns the date string in the language of the current locale. This is the language you select by means of your computer's operating system. If you leave local out of the argument list, datestr returns the date string in the default language, which is US English. Use local with any of the previous syntaxes. The local argument must be last in the argument sequence.

Input Arguments

DateVector - Date vectors

matrix

Date vectors, specified as an m-by-6 matrix, where m is the number of full (six-element) date vectors. Each element of DateVector must be a positive double-precision number.

Example: [2003,10,24,12,45,07]

Data Types
double

DateNumber - Serial date numbers

scalar | vector | multidimensional array

Serial date numbers, specified as a scalar, vector, or multidimensional array of positive double-precision numbers.

Example: 731878

Data Types
double

formatOut - Format of the date string output

0 (default) | string | integer

Format of the date string output, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format. If you do not specify formatOut, datestr returns a date string in the default date string format dd-mmm-yyyy HH:MM:SS.

The following table shows symbolic identifiers you can use to construct the formatOut string. You can include characters such as a hyphen, space, or colon to separate the fields.

Symbolic Identifier	Description	Example
`yyyy`	Year in full	`1990`, `2002`
`yy`	Year in two digits	`90`, `02`
`QQ`	Quarter year using letter `Q` and one digit	`Q1`
`mmmm`	Month using full name	`March`, `December`
`mmm`	Month using first three letters	`Mar`, `Dec`
`mm`	Month in two digits	`03`, `12`
`m`	Month using capitalized first letter	`M`, `D`
`dddd`	Day using full name	`Monday`, `Tuesday`
`ddd`	Day using first three letters	`Mon`, `Tue`
`dd`	Day in two digits	`05`, `20`
`d`	Day using capitalized first letter	`M`, `T`
`HH`	Hour in two digits (no leading zeros when symbolic identifier `AM` or `PM` is used)	`05`, `5 AM`
`MM`	Minute in two digits	`12`, `02`
`SS`	Second in two digits	`07`, `59`
`FFF`	Millisecond in three digits	`057`
`AM or PM`	`AM` or `PM` inserted in date string	`3:45:02 PM`

The `formatOut` string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use 'yy-mmm-dd-m' because it has two month identifiers. The one exception to this is that you can combine one instance of dd with one instance of any of the other day identifiers. For example, 'dddd mmm dd yyyy' is a valid input.
- When you use AM or PM, the HH field is also required.
- You only can use QQ alone or with a year specifier.

The following table lists predefined MATLAB date formats.

Numeric Identifier	Date String Format	Example
0 or -1 (default)	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M
5	'mm'	03
6	'mm/dd'	03/01
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45

Numeric Identifier	Date String Format	Example
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1-01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd,yyyy'	Mar.01,2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01
26	'yyyy/mm/dd'	2000/03/01
27	'QQ-YYYY'	Q1-2001
28	'mmmyyyy'	Mar2000
29	'yyyy-mm-dd' (ISO 8601)	2000-03-01
30	'yyyymmddTHHMMSS' (ISO 8601)	20000301T154517
31	'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17

DateStringIn - Date strings to convert
string | cell array

Date strings to convert, specified as a single string or a cell array of strings, where each row corresponds to one date string.

MATLAB considers two-character date string years (for example, `'79'`) to fall within the 100-year range centered around the current year.

All date strings must have the same date format, and they must be in one of the following MATLAB date formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00
'mm/dd'	03/01
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Note When converting from one date string format to another, you should first pass the strings to the `datenum` function, so that you can specify the format of the input date strings. This ensures that the format of the input date strings is correctly interpreted. For example, see "Convert Date String from Custom Format" on page 1-1193.

PivotYear - Start year of 100-year date range

current year minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

Example: 2000

Data Types
`double`

Output Arguments

DateString - Date strings

string | two-dimensional character array

Date strings, returned as a character array with `m` rows, where `m` is the total number of input date vectors, serial date numbers, or date strings. The default output date string format is `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second).

Tips

- To convert a date string not in a predefined MATLAB date format, first convert the date string to a date number, using either `datenum` or `datevec`.

Examples

Convert Date Vector to Date String

```
DateVector = [2009,4,2,11,7,18];

datestr(DateVector)
```

```
ans =
   02-Apr-2009 11:07:18
```

`datestr` returns a date string in the default date string format.

Convert Date and Time to Specific Format

Format the current date in the `mm/dd/yy` format.

You can specify this format using a string of symbolic identifiers.

```
formatOut = 'mm/dd/yy';
datestr(now,formatOut)
```

```
ans =
   09/07/12
```

Alternatively, you can specify this format using a numeric identifier.

```
formatOut = 2;
datestr(now,formatOut)
```

```
ans =
   09/07/12
```

You can reformat the date and time, and also show milliseconds.

```
dt = datestr(now,'mmmm dd, yyyy HH:MM:SS.FFF AM')
```

```
dt =
January 05, 2012  2:44:48.753 PM
```

Convert 12-Hour Time String to 24-Hour Equivalent

Convert the 12-hour time 05:32 p.m. to its 24-hour equivalent.

```
datestr('05:32 PM','HH:MM')
```

```
ans =

17:32
```

Convert the 24-hour time 05:32 to its 12-hour equivalent.

```
datestr('05:32','HH:MM PM')
```

```
ans =

5:32 AM
```

The use of `AM` or `PM` in the `formatOut` string does not influence which characters actually become part of the date string; they only determine

whether or not to include them in the date string. MATLAB selects AM or PM based on the time entered.

Convert Date String from Custom Format

Call datenum inside of datestr to specify the format of the input date string.

```
formatOut = 'dd mmm yyyy';
datestr(datenum('16-04-55','dd-mm-yy',1900),formatOut)

ans =
16 Apr 1955
```

Convert Multiple Date Strings

Convert more than one date string input by passing the multiple date strings in a cell array.

All input date strings must use the same format. For example, the following command passes three dates that all use the mm/dd/yyyy format.

```
datestr(datenum({'09/16/2007';'05/14/1996';'11/29/2010'}, ...
    'mm/dd/yyyy'))

ans =
    16-Sep-2007
    14-May-1996
    29-Nov-2010
```

datestr returns a character array of converted date strings in the default date string format.

Convert Date String with Values Outside Normal Range

Call datenum inside of datestr to return the expected value, because the date below uses a value outside its normal range (month=13).

```
datestr(datenum('13/24/88','mm/dd/yy'))
```

```
ans =
   24-Jan-1989
```

Use a Pivot Year

Change the pivot year to change the year range.

Use a pivot year of 1900.

```
DateStringIn = '4/16/55';
formatOut = 1;
PivotYear = 1900;
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =
   16-Apr-1955
```

For the same date string, use a pivot year of 2000.

```
PivotYear = 2000;
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =
   16-Apr-2055
```

Return Date String in Local Language

Convert a date number to a date string in the language of the current locale.

Use the `local` argument in a French locale.

```
DateNumber = 725935;
formatOut = 'mmmm-dd-yyyy';
str = datestr(DateNumber,formatOut,'local')
```

```
str =
Juillet-17-1987
```

You can make the same call without specifying `` `local' ``.

```
str = datestr(DateNumber,formatOut)

str =
July-17-1987
```

In this case, the output defaults to the English language.

datetick

Purpose

Date formatted tick labels

Syntax

```
datetick(tickaxis)
datetick(tickaxis,dateFormat)

datetick( ___ ,'keeplimits')

datetick( ___ ,'keepticks')

datetick(axes_handle, ___ )
```

Description

`datetick(tickaxis)` labels the tick lines of the axis specified by `tickaxis` using dates, replacing the default numeric labels. `datetick` selects a label format based on the minimum and maximum limits of the specified axis. The axis data values should be serial date numbers, as returned by the `datenum` function.

`datetick(tickaxis,dateFormat)` formats the labels according to the string `dateFormat`.

`datetick( ___ ,'keeplimits')` changes the tick labels to date-based labels while preserving the axis limits. Append `'keeplimits'` to any of the previous syntaxes.

`datetick( ___ ,'keepticks')` changes the tick labels to date-based labels while preserving their locations. Append `'keepticks'` to any of the previous syntaxes.

`datetick(axes_handle, ___ )` labels the tick lines of an axis on the axes specified by `axes_handle`. The `axes_handle` argument can precede any of the input argument combinations in the previous syntaxes.

Input Arguments

tickaxis - Axis to label

'x' (default) | 'y' | 'z'

Axis to label with dates, specified as 'x', 'y', or 'z'.

dateFormat - Format of tick line labels

string | integer

Format of the tick line labels, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format.

The following table shows symbolic identifiers you can use to construct the dateFormat string. You can include characters such as a hyphen, space, or colon to separate the fields. For example, to display the day of the month followed by the three-letter abbreviation of the day of the week in parentheses, use dateFormat = 'dd (ddd)'.

Symbolic Identifier	Description	Example
yyyy	Year in full	1990, 2002
yy	Year in two digits	90, 02
QQ	Quarter year using letter Q and one digit	Q1
mmmm	Month using full name	March, December
mmm	Month using first three letters	Mar, Dec
mm	Month in two digits	03, 12
m	Month using capitalized first letter	M, D
dddd	Day using full name	Monday, Tuesday
ddd	Day using first three letters	Mon, Tue
dd	Day in two digits	05, 20

Symbolic Identifier	Description	Example
d	Day using capitalized first letter	M, T
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The following table lists predefined MATLAB date formats.

Numeric Identifier	Date String Format	Example
0 or -1 (default)	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M
5	'mm'	03
6	'mm/dd'	03/01
7	'dd'	01
8	'ddd'	Wed
9	'd'	W

Numeric Identifier	Date String Format	Example
10	'yyyy'	2000
11	'yy'	00
12	'mmmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1-01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd,yyyy'	Mar.01,2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01
26	'yyyy/mm/dd'	2000/03/01
27	'QQ-YYYY'	Q1-2001
28	'mmmyyyy'	Mar2000
29	'yyyy-mm-dd' (ISO 8601)	2000-03-01
30	'yyyymmddTHHMMSS' (ISO 8601)	20000301T154517
31	'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17

Examples

Label x-Axis Ticks with 2-digit Years

Graph population data for the 20th Century taken from the 1990 US census and label *x*-axis ticks with 2-digit years.

Create time data by decade.

```
t = (1900:10:1990)';
```

Enter total population counts for the USA.

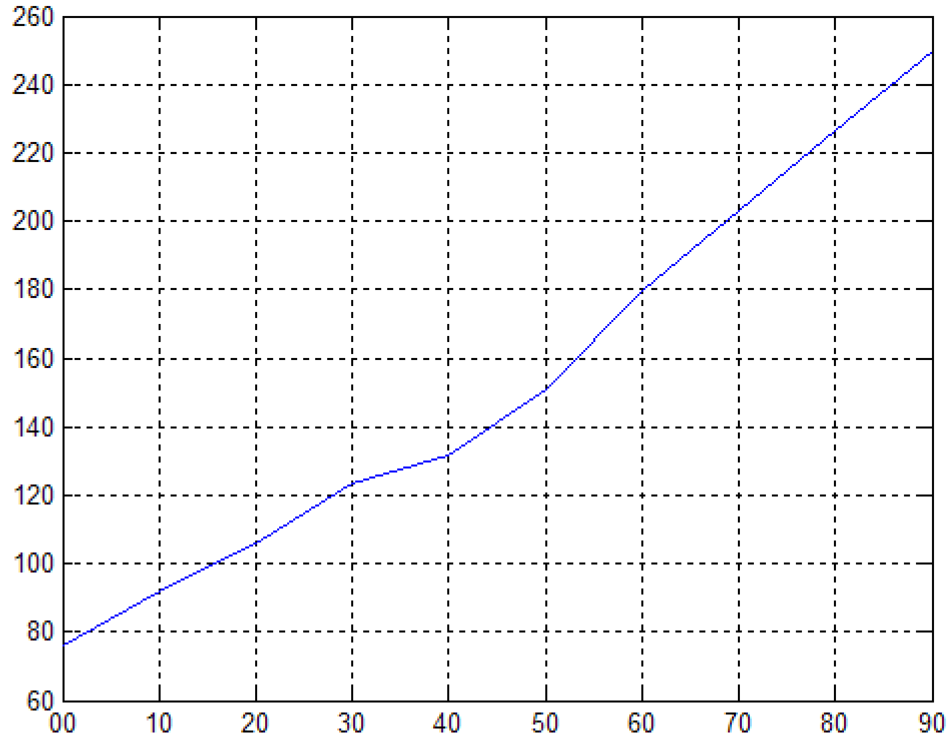
```
p = [75.995 91.972 105.711 123.203 131.669 ...
 150.697 179.323 203.212 226.505 249.633]';
```

Convert years to serial date numbers using the `datenum` function, and then plot the data.

```
figure
plot(datenum(t,1,1),p)
grid on
```

Replace *x*-axis ticks with 2-digit years. The numeric identifier `11` corresponds to the predefined MATLAB date format `'yy'`.

```
dateFormat = 11;
datetick('x',dateFormat)
```



Label x-Axis Ticks with Hours of the Day

Plot traffic count data against date ticks for hours of the day showing AM and PM.

Get traffic count data.

```
load count.dat
```

Create arrays for an arbitrary date, for example, April 18, 1995

```
n = length(count);
year = 1990 * ones(1,n);
month = 4 * ones(1,n);
```

```
day = 18 * ones(1,n);
```

Create arrays for each of 24 hours.

```
hour = 1:n;
minutes = zeros(1,n);
```

Get the serial date numbers for the date arrays.

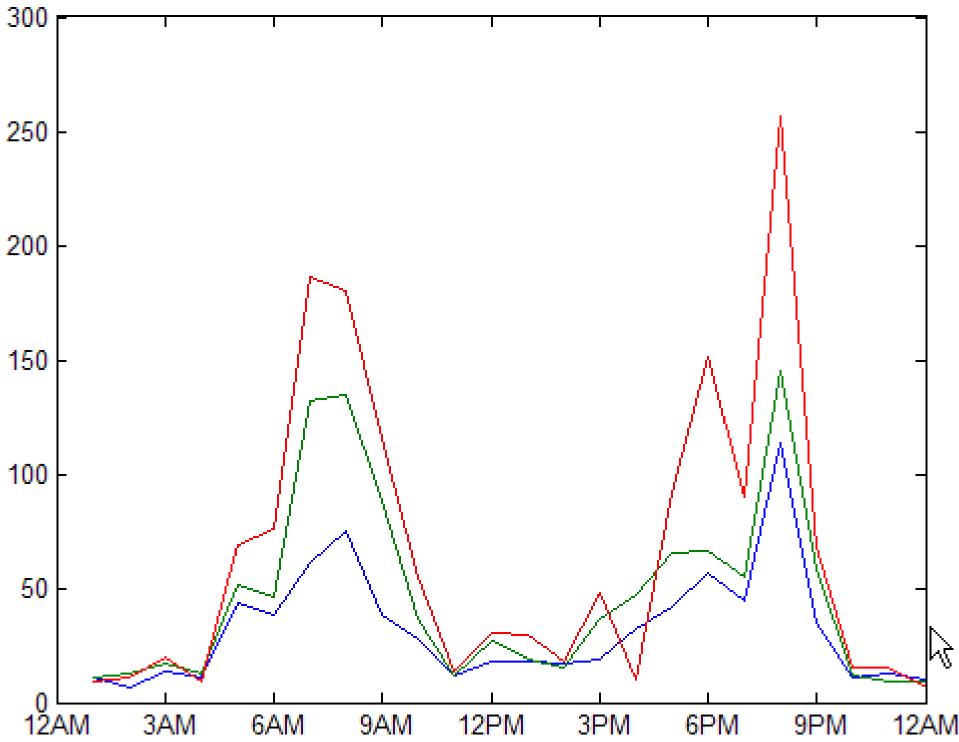
```
xdate = datenum(year,month,day,hour,minutes,minutes);
```

Plot the traffic data against the serial date numbers.

```
figure
plot(xdate,count)
```

Label the tick lines of the graph's *x*-axis with the hours of the day.

```
datetick('x','HHPM')
```



Label x-Axis and Preserve Axis Limits

Select a starting date.

```
startDate = datenum('02-01-1962');
```

Select an ending date.

```
endDate = datenum('11-15-2012');
```

Create a variable, `xdata`, that corresponds to the number of years between the start and end dates.

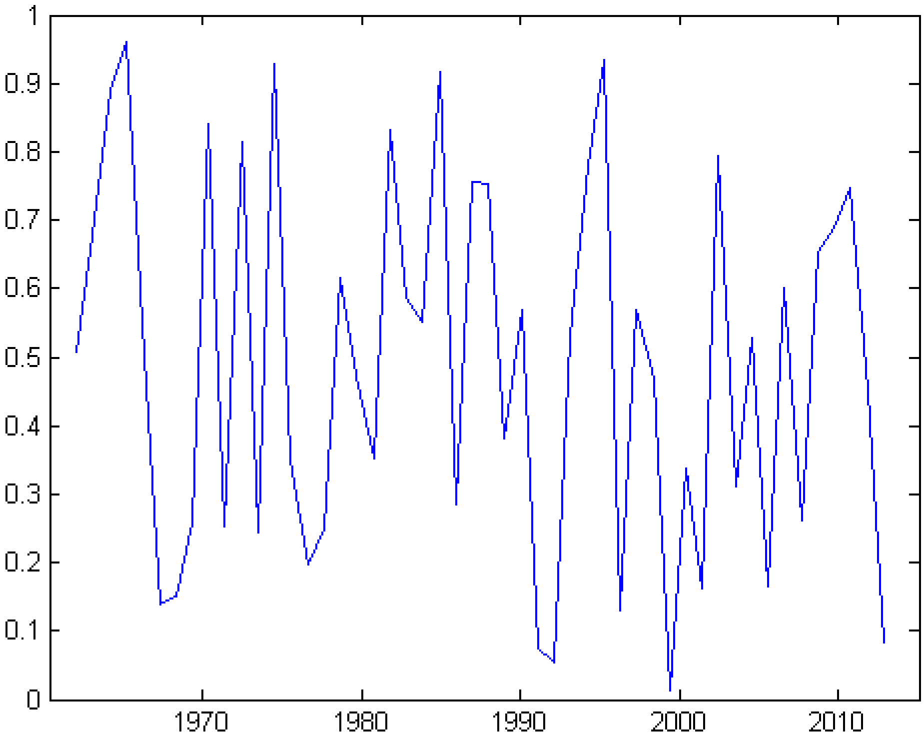
```
xData = linspace(startDate,endDate,50);
```

For this example, plot random data.

```
figure
plot(xData,rand(1,50))
```

Label the x-axis with 4-digit years, preserving the x-axis limits by using the `'keeplimits'` option.

```
datetick('x','yyyy','keeplimits')
```



Add Month Labels to a Plot and Preserve Number of Ticks

Select a starting date.

```
startDate = datenum('01-01-2009');
```

Select an ending date.

```
endDate = datenum('12-31-2009');
```

Create a variable, `xdata`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate,endDate,12);
```

For this example, plot random data.

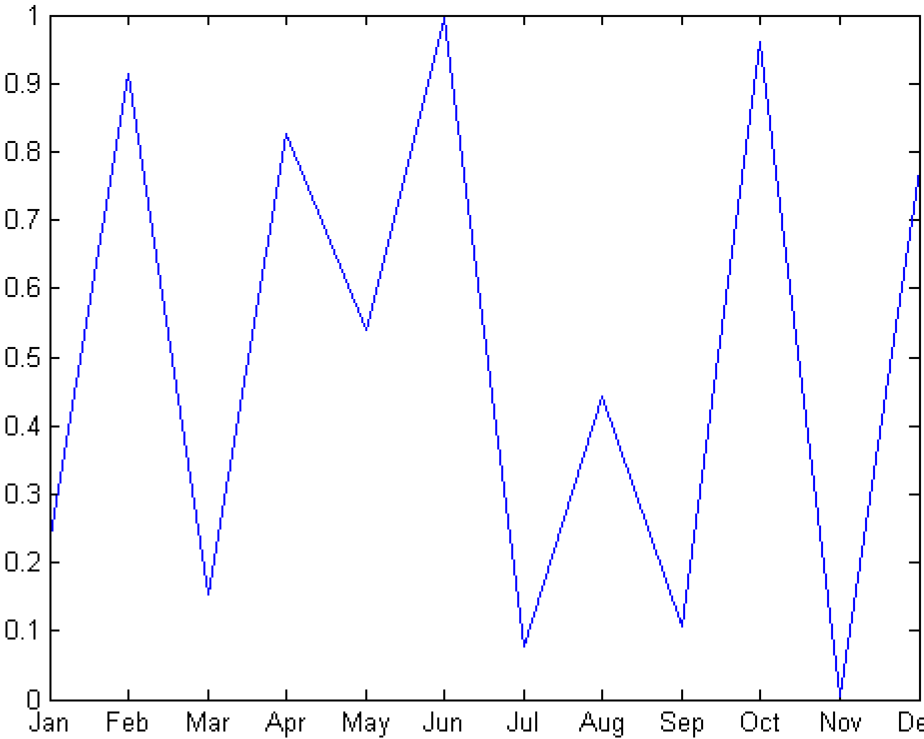
```
figure
plot(xData,rand(1,12))
```

Set the number of `XTicks` to the number of points in `xData`.

```
set(gca,'XTick',xData)
```

Label the *x*-axis with month names, preserving the total number of ticks by using the `'keepticks'` option.

```
datetick('x','mmm','keepticks')
```



Create Multiple Plots Within One Figure and Label Axis with Month Names

Select a starting date and an ending date.

```
startDate = datenum('01-01-2009');
endDate = datenum('12-31-2009');
```

Create a variable, `xdata`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate,endDate,12);
```

For this example, plot random data.

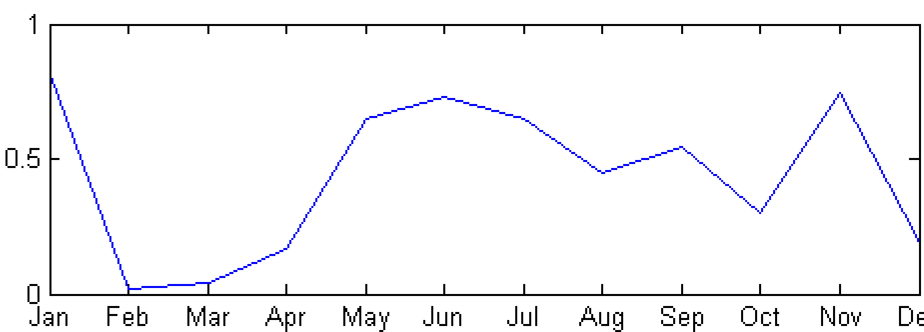
```
figure
s(1)=subplot(2,1,1);
plot(xData,rand(1,12))
s(2) = subplot(2,1,2);
plot(xData,rand(1,12))
```

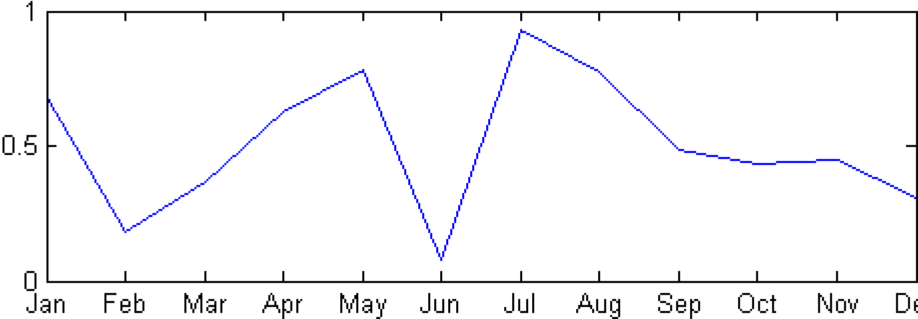
Set the number of `XTicks` to the number of points in `xData`.

```
set(s,'XTick',xData)
```

Label the *x*-axis of each subplot with month names, referring to each subplot using its axes handle. Preserve the total number of ticks by using the `'keepticks'` option.

```
for i = 1:2
 datetick(s(i),'x','mmm','keepticks')
end
```





Algorithms

`datetick` calls the `datestr` function to convert date numbers to date strings.

Tips

- To change the tick spacing and locations, set the appropriate axes property (i.e., `XTick`, `YTick`, or `ZTick`) before calling `datetick`.
- Calling `datetick` sets the `TickMode` of the specified axis to `'manual'`. This means that after zooming, panning or otherwise changing axis limits, you should call `datetick` again to update the ticks and labels.

See Also XTick | YTick | ZTick | datenum | datestr

Purpose

Convert date and time to vector of components

Syntax

```
DateVector = datevec(DateNumber)

DateVector = datevec(DateString)
DateVector = datevec(DateString,formatIn)
DateVector = datevec(DateString,PivotYear)
DateVector = datevec(DateString,formatIn,PivotYear)

[Y, M, D, H, MN, S] = datevec(___)
```

Description

`DateVector = datevec(DateNumber)` converts one or more date numbers to date vectors. `datevec` returns an `m`-by-6 matrix containing `m` date vectors, where `m` is the total number of date numbers in `DateNumber`.

`DateVector = datevec(DateString)` converts date strings to date vectors. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector = datevec(DateString,formatIn)` uses `formatIn` to interpret each date string.

`DateVector = datevec(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector = datevec(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

[Y, M, D, H, MN, S] = datevec(___) returns the components of the date vector as individual variables Y, M, D, H, MN, and S (year, month, day, hour, minutes and seconds). datevec returns milliseconds as a fractional part of the seconds (S) output.

Input Arguments

DateNumber - Serial date number

scalar | vector | multidimensional array

Serial date number, specified as a scalar, vector, or multidimensional array of positive double-precision numbers.

Example: 731878

Data Types

double

DateString - Date strings

string | cell array of strings

Date strings, specified as a single string or a cell array of strings, where each row corresponds to one date string. All of the date strings must have the same format.

Example: '24 Oct-2003 12:45:07'

Example: {'15-Oct-2010';'20-Nov-2012'}

If the date string format is known, you should also specify formatIn. If you do not specify formatIn, DateString must be in one of the following formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00
'mm/dd'	03/01

Date String Format	Example
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. MATLAB considers two-character date string years (e.g., `'79'`) to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (`mm`), the month value must not be greater than 12.
- However, for the format `'mm/dd/yy'`, if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, MATLAB considers the date string to be in `'yy/mm/dd'` format.

formatIn - Format of the input date string

string

Format of the input date string, specified as a string of symbolic identifiers.

The following table shows symbolic identifiers you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

Symbolic Identifier	Description	Example
`yyyy`	Year in full	1990, 2002
`yy`	Year in two digits	90, 02
`QQ`	Quarter year using letter `Q` and one digit	Q1
`mmmm`	Month using full name	March, December
`mmm`	Month using first three letters	Mar, Dec
`mm`	Month in two digits	03, 12
`m`	Month using capitalized first letter	M, D
`dddd`	Day using full name	Monday, Tuesday
`ddd`	Day using first three letters	Mon, Tue
`dd`	Day in two digits	05, 20
`d`	Day using capitalized first letter	M, T
`HH`	Hour in two digits (no leading zeros when symbolic identifier `AM` or `PM` is used)	05, 5 AM
`MM`	Minute in two digits	12, 02
`SS`	Second in two digits	07, 59
`FFF`	Millisecond in three digits	057
`AM` or `PM`	`AM` or `PM` inserted in date string	3:45:02 PM

The `formatIn` string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use `'yy-mmm-dd-m'` because it has two month identifiers. The one exception to this is that you can combine one instance of `dd` with one instance of any of the other day identifiers. For example, `'dddd mmm dd yyyy'` is a valid input.
- When you use `AM` or `PM`, the `HH` field is also required.
- `datevec` does not accept formats that include `'QQ'`

PivotYear - Start year of 100-year date range
current year minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

Example: 2000

Data Types
`double`

Output Arguments

DateVector - Date vectors
vector | matrix

Date vectors, returned as an `m`-by-6 matrix, where each row corresponds to one date vector, and `m` is the total number of input date numbers or date strings.

[Y, M, D, H, MN, S] - Components of the date vector
scalar

Components of the date vector (year, month, day, hour, minute, and second), returned as individual scalar variables. Milliseconds are a fractional part of the seconds output.

Examples

Convert Date Number to Date Vector

```
format short g
```

```
n = 733779.651;
datevec(n)

ans =
        2009            1            5           15           37
```

Convert Date String to Date Vector

```
DateString = '28.03.2005';
formatIn = 'dd.mm.yyyy';
datevec(DateString,formatIn)

ans =
        2005            3           28            0            0            0
```

datevec returns a date vector for the date string with the format 'dd.mm.yyyy'.

Convert Multiple Date Strings to Date Vectors

Pass multiple date strings in a cell array. All input date strings must use the same format.

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};
formatIn = 'mm/dd/yyyy';
datevec(DateString,formatIn)

ans =
        2007            9           16            0            0            0
        1996            5           14            0            0            0
        2010           11           29            0            0            0
```

Convert Date with Milliseconds to Date Vector

```
datevec('11:21:02.647','HH:MM:SS.FFF')

ans =
   1.0e+03 *
    2.0120    0.0010    0.0010    0.0110    0.0210    0.0026
```

In the output date vector, milliseconds are a fractional part of the seconds field.

Convert Date String to Date Vector Using Pivot Year

Convert a date string to a date vector using the default pivot year.

```
DateString = '12-jun-17';
formatIn = 'dd-mmm-yy';
DateVector = datevec(DateString,formatIn)

DateVector =

        2017           6          12           0           0
```

Convert the same date string to a date vector using 1800 as the pivot year.

```
DateVector = datevec(DateString,formatIn,1800)

DateVector =

        1817           6          12           0           0
```

Assign Elements of Returned Date Vector

Convert a date string to a date vector and return the components of the date vector.

```
[y, m, d, h, mn, s] = datevec('01.02.12','dd.mm.yy')

y =
        2012
m =
     2
d =
     1
h =
     0
mn =
```

```
s =

     0
```

Limitations

- When computing date vectors, MATLAB sets month values less than 1 to 1. Day values, D, less than 1 are set to the last day of the previous month minus |D|. However, if $0 \leq$ `DateNumber` < 1, then `datevec(DateNumber)` returns a date vector of the form `[0 0 0 H MN S]`, where `H`, `MN`, and `S` are hours, minutes, and seconds, respectively.

Tips

- The vectorized calling syntax can offer significant performance improvement for large arrays.

Purpose

Clear breakpoints

Syntax

```
dbclear all
dbclear in file ...
dbclear in file ... -completenames
dbclear if error ...
dbclear if warning ...
dbclear if naninf
dbclear if infnan
```

Description

`dbclear all` removes all breakpoints in all MATLAB code files, as well as breakpoints set for errors, caught errors, caught error identifiers, warnings, warning identifiers, and `naninf`/`infnan`.

`dbclear in file ...` and `dbclear in file ... -completenames` formats are listed here:

Format	Action
`dbclear in file`	Removes all breakpoints in `file`. `file` must be the name of a MATLAB program file, and can include a MATLAB partial path.
`dbclear in file -completenames`	If the command includes the `-completenames` option, then `file` need not be on the path, as long as it is a fully qualified file name. (On Microsoft Windows platforms, this is a file name that begins with `\\` or with a drive letter followed by a colon. On UNIX platforms, this is a file name that begins with `/` or `~`.) `file` can include a `>` to specify the path to a particular local function or to a nested function within a code file.
`dbclear in file at lineno`	Removes the breakpoint set at line number `lineno` in `file`.
`dbclear in file at lineno@`	Removes the breakpoint set in the anonymous function at line number `lineno` in `file`.

Format	Action
`dbclear in file at lineno@n`	Removes the breakpoint set in the nth anonymous function at line number `lineno` in `file`.
`dbclear in file at locfun`	Removes all breakpoints in local function `locfun` in `file`.

`dbclear if error ...` formats are listed here:

Format	Action
`dbclear if error`	Removes the breakpoints set using the `dbstop if error` and `dbstop if error identifier` statements.
`dbclear if error identifier`	Removes the breakpoint set using `dbstop if error identifier` for the specified `identifier`. Running this produces an error if `dbstop if error` or `dbstop if error all` is set.
`dbclear if caught error`	Removes the breakpoints set using the `dbstop if caught error` and `dbstop if caught error identifier` statements.
`dbclear if caught error identifier`	Removes the breakpoints set using the `dbstop if caught error identifier` statement for the specified identifier. Running this produces an error if `dbstop if caught error` or `dbstop if caught error all` is set.

`dbclear if warning ...` formats are listed here:

`dbclear if warning`	Removes the breakpoints set using the `dbstop if warning` and `dbstop if warning identifier` statements.
`dbclear if warning identifier`	Removes the breakpoint set using `dbstop if warning identifier` for the specified `identifier`. Running this produces an error if `dbstop if warning` or `dbstop if warning all` is set.

`dbclear if naninf` removes the breakpoint set by `dbstop if naninf` or `dbstop if infnan`.

`dbclear` **`if infnan`** removes the breakpoint set by `dbstop` **`if infnan`** or `dbstop` **`if naninf`**.

Tips

The **`at`** and **`in`** keywords are optional.

In the syntax, `file` can be a MATLAB program file, or the path to a function within a file. For example

```
dbclear in foo>myfun
```

clears the breakpoint at the `myfun` function in the file `foo.m`.

Related Examples

- “Disable and Clear Breakpoints”

dbcont

Purpose

Resume execution

Syntax

```
dbcont
```

Description

`dbcont` resumes execution of a MATLAB code file from a breakpoint. Execution continues until another breakpoint is encountered, a pause condition is met, an error occurs, or MATLAB software returns to the base workspace prompt.

Note If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

See Also

`dbclear` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstop` | `dbstep` | `dbtype` | `dbup`

Related Examples

- "Step Through a File"

Purpose

Reverse workspace shift performed by `dbup`, while in debug mode

Syntax

```
dbdown
```

Description

`dbdown` changes the current workspace context to the workspace of the called MATLAB code file when a breakpoint is encountered. You must have issued the `dbup` function at least once before you issue this function. `dbdown` is the opposite of `dbup`.

Multiple `dbdown` functions change the workspace context to each successively executed MATLAB code file on the stack until the current workspace context is the current breakpoint. It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.

dblquad

Purpose

Numerically evaluate double integral over rectangle

Compatibility

`dblquad` will be removed in a future release. Use `integral2` instead.

Syntax

```
q = dblquad(fun,xmin,xmax,ymin,ymax)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)
```

Description

`q = dblquad(fun,xmin,xmax,ymin,ymax)` calls the `quad` function to evaluate the double integral `fun(x,y)` over the rectangle `xmin <= x <= xmax`, `ymin <= y <= ymax`. The input argument, `fun`, is a function handle that accepts a vector `x`, a scalar `y`, and returns a vector of integrand values.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol)` uses a tolerance `tol` instead of the default, which is `1.0e-6`.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quadl` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quadl`.

Examples

Pass function handle `@integrnd` to `dblquad`:

```
Q = dblquad(@integrnd,pi,2*pi,0,pi);
```

where the function `integrnd.m` is:

```
function z = integrnd(x, y)
z = y*sin(x)+x*cos(y);
```

Pass anonymous function handle `F` to `dblquad`:

```
F = @(x,y)y*sin(x)+x*cos(y);
Q = dblquad(F,pi,2*pi,0,pi);
```

The `integrnd` function integrates `y*sin(x)+x*cos(y)` over the square `pi <= x <= 2*pi`, `0 <= y <= pi`. Note that the integrand can be evaluated with a vector `x` and a scalar `y`.

Nonsquare regions can be handled by setting the integrand to zero outside of the region. For example, the volume of a hemisphere is:

```
dblquad(@(x,y)sqrt(max(1-(x.^2+y.^2),0)), -1, 1, -1, 1)
```

or

```
dblquad(@(x,y)sqrt(1-(x.^2+y.^2)).*(x.^2+y.^2<=1), -1, 1, -1, 1)
```

How To

- "Anonymous Functions"

dbmex

Purpose

Enable MEX-file debugging (on UNIX platforms)

Syntax

```
dbmex on
dbmex off
dbmex stop
```

Description

`dbmex on` enables MEX-file debugging for UNIX platforms.

To use this option, first start the MATLAB software from a debugger by typing `matlab -D`*`debugger`*, where `debugger` is the name of the debugger program. You must invoke `dbmex on` before calling your MEX-file. If you have already loaded the MEX-file, remove it from memory using the `clear` function.

`dbmex off` disables MEX-file debugging.

`dbmex stop` returns to the debugger prompt.

Tips

For more information about debugging MEX-files, see "Debug C/C++ Language MEX-Files".

See Also

`dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstep` | `dbstop` | `dbtype` | `dbup`

Purpose

Quit debug mode

Syntax

```
dbquit
dbquit('all')
dbquit all
```

Description

`dbquit` terminates debug mode. The Command Window then displays the standard prompt (>>). The file being processed is *not* completed and no results are returned. All breakpoints remain in effect, unless your file contains (and MATLAB has processed) one or more of the following commands: `clear all`, `clear function`, `clear classes`.

If you debug `file1` and step into `file2`, running `dbquit` terminates debugging for both files. However, if you debug `file3` and also debug `file4`, running `dbquit` terminates debugging for `file4`, but `file3` remains in debug mode until you run `dbquit` again.

`dbquit('all')` or the command form, `dbquit all`, ends debugging for all files at once.

Examples

This example illustrates the use of `dbquit` relative to `dbquit('all')`. Set breakpoints in and run `file1` and `file2`:

```
>> dbstop in file1
>> dbstop in file2
>> file1
K>> file2
K>> dbstack
```

MATLAB software returns

```
K>> dbstack
  In file1 at 11
  In file2 at 22
```

If you use the `dbquit` syntax

```
K>> dbquit
```

MATLAB ends debugging for `file2` but `file1` is still in debug mode as shown here

```
K>> dbstack
    in file1 at 11
```

Run `dbquit` again to exit debug mode for `file1`.

Alternatively, `dbquit('all')` ends debugging for both files at once:

```
K>> dbstack
  In file1 at 11
  In file2 at 22
dbquit('all')
dbstack
```

returns no result.

`clear` | `dbcont` | `dbclear` | `dbdown` | `dbstack` | `dbstatus` | `dbstop` | `dbstep` | `dbtype` | `dbup`

Related Examples

- "Correct Problems and End Debugging"

Purpose

Function call stack

Syntax

```
dbstack
dbstack(n)
dbstack('-completenames')
[ST,I] = dbstack(...)
```

Description

`dbstack` displays the line numbers and file names of the function calls that led to the current breakpoint, listed in the order in which they were executed. The display lists the line number of the most recently executed function call (at which the current breakpoint occurred) first, followed by its calling function, which is followed by its calling function, and so on. This continues until the topmost MATLAB function is reached. Each line number is a hyperlink you can click to go directly to that line in the Editor. The notation `functionname>localfunctionname` is used to describe the location of the local function.

`dbstack(n)` omits the first `n` frames from the display. This is useful when issuing a `dbstack` from within an error handler, for example.

`dbstack('`**`-completenames`**`')` outputs the “complete name“ (the absolute file name and the entire sequence of functions that nests the function in the stack frame) of each function in the stack.

Either none, one, or both `n` and `'`**`-completenames`**`'` can appear. If both appear, the order is irrelevant.

`[ST,I] = dbstack(...)` returns the stack trace information in an `m`-by-`1` structure, `ST`, with the fields:

`file`	The file in which the function appears. This field is the empty string if there is no file.
`name`	Function name within the file.
`line`	Function line number.

The current workspace index is returned in `I`.

If you step past the end of a file, dbstack returns a negative line number value to identify that special case. For example, if the last line to be executed is line 15, then the dbstack line number is 15 before you execute that line and -15 afterwards.

Tips

In addition to using dbstack while debugging, you can also use dbstack within a MATLAB code file outside the context of debugging. In this case, to get and analyze information about the current file stack. For example, to get the name of the calling file, use dbstack with an output argument within the file being called. For example:

```
st=dbstack;
```

Examples

This example shows the information returned when you issue dbstack while debugging a MATLAB code file:

```
dbstack

In /usr/local/matlab/toolbox/matlab/cond.m at line 13
In test1.m at line 2
In test.m at line 3
```

This example shows the information returned when you issue dbstack while debugging lengthofline.m to get the complete name of the file, the function name, and line number in which the function appears:

```
[ST,I] = dbstack('-completenames')
ST =
    file: 'I:\MATLABFiles\mymfiles\lengthofline.m'
    name: 'lengthofline'
    line: 28
I =
     1
```

See Also

dbcont | dbclear | dbdown | dbquit | dbstatus | dbstop | dbstep | dbtype | dbup | evalin | mfilename | whos

Related Examples

- “Examine Values”

dbstatus

Purpose

List all breakpoints

Syntax

```
dbstatus
dbstatus file
dbstatus('-completenames')
s = dbstatus(...)
```

Description

`dbstatus` lists all the breakpoints in effect including errors, caught errors, warnings, and `naninfs`.

`dbstatus file` displays a list of the line numbers for which breakpoints are set in the specified file, where `file` is a MATLAB code file function name or a MATLAB relative partial path. Each line number is a hyperlink you can click to go directly to that line in the Editor.

`dbstatus('-completenames')` displays, for each breakpoint, the absolute file name and the sequence of functions that nest the function containing the breakpoint.

`s = dbstatus(...)` returns breakpoint information in an `m`-by-`1` structure with the fields listed in the following table. Use this syntax to save breakpoint status and restore it at a later time using `dbstop(s)`—see `dbstop` for an example.

`name`	Function name.
`file`	Full path for file containing breakpoints.
`line`	Vector of breakpoint line numbers.
`anonymous`	Vector of integers representing the anonymous functions in the `line` field. For example, `2` means the second anonymous function in that line. A value of `0` means the breakpoint is at the start of the line, not in an anonymous function.
`expression`	Cell vector of breakpoint conditional expression strings corresponding to lines in the `line` field.

`cond`	Condition string (`'error'`, `'caught error'`, `'warning'`, or `'naninf'`).
`identifier`	When `cond` is `'error'`, `'caught error'`, or `'warning'`, a cell vector of MATLAB message identifier strings for which the particular `cond` state is set.

Use `dbstatus class/function`, `dbstatus private/function`, or `dbstatus class/private/function` to determine the status for methods, private functions, or private methods (for a class named `class`).

In all forms you can further qualify the function name with a local function name, as in `dbstatus function>localfunction`.

Tips

In the syntax, `file` can be a file, or the path to a function within a file. For example

```
Breakpoint for foo>myfun is on line 9
```

means there is a breakpoint at the `myfun` local function, which is line 9 in the file `foo.m`.

dbstep

Purpose

Execute one or more lines from current breakpoint

Syntax

```
dbstep
dbstep nlines
dbstep in
dbstep out
```

Description

This function allows you to debug a MATLAB code file by following its execution from the current breakpoint. At a breakpoint, the `dbstep` function steps through execution of the current file one line at a time or at the rate specified by `nlines`.

`dbstep` executes the next executable line of the current file. `dbstep` steps over the current line, skipping any breakpoints set in functions called by that line.

`dbstep nlines` executes the specified number of executable lines.

`dbstep in` steps to the next executable line. If that line contains a call to another MATLAB code file function, execution will step to the first executable line of the called function. If there is no call to a MATLAB code file on that line, `dbstep in` is the same as `dbstep`.

`dbstep out` runs the rest of the function and stops just after leaving the function.

For all forms, MATLAB software also stops execution at any breakpoint it encounters.

Note If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

dbstop

Purpose

Set breakpoints for debugging

Syntax

```
dbstop in file
dbstop in file at location
dbstop in file if expression
dbstop in file at location if expression
dbstop if condition
dbstop(s)
```

Description

`dbstop in file` sets a breakpoint at the first executable line in `file`. When you run `file`, MATLAB enters debug mode and pauses execution at the first executable line.

`dbstop in file at location` sets a breakpoint at the specified location. MATLAB execution pauses immediately before that location, unless the location is an anonymous function. If the location is an anonymous function, then execution pauses just after the breakpoint.

`dbstop in file if expression` sets a breakpoint at the line containing the `expression`. Execution pauses only if that expression evaluates to `1` (true).

`dbstop in file at location if expression` sets a breakpoint at the specified location. Execution pauses at or just before that location only if the `expression` evaluates to true.

`dbstop if condition` pauses execution at the line that meets the specified `condition`.

`dbstop(s)` restores breakpoints you previously saved to `s`. The files containing the saved breakpoints must be on the search path or in the current folder. MATLAB assigns breakpoints by line number; therefore, the lines in the file must be the same as when you saved the breakpoints, or the results are unpredictable.

Tips

- Use `dbcont` or `dbstep` to resume execution after a breakpoint pauses execution. Use `dbquit` to exit debug mode.

- If you debug a file that MATLAB uses when running and debugging files, and that file is not a MATLAB code file, then some debugging features do not operate as expected. For instance, typing `help functionname` at the debug (`K>>`) prompt will not return help.
- MATLAB can become unresponsive when it stops at a breakpoint while displaying a modal dialog box or figure created by your program. Use **Ctrl+C** to exit debug mode and return to the MATLAB prompt (`>>`).
- If MATLAB pauses and displays a hyperlinked line number in the Command Window, click the hyperlink, The file opens in the Editor at the line where MATLAB paused execution. For an example of such a link, see the image in "Stop at File That Is Not a MATLAB Code File" on page 1-1242
- You can set breakpoints only at executable lines in saved files that are in the current folder or in folders on the search path.
- `dbstop` **`if warning`** has no effect when you disable warnings using `warning off all`. Similarly, `dbstop` **`if warning`** `identifier` has no effect when you disable warnings for the specified message identifier. See `warning` for more information about `off`, `all`, and `warning off identifier`

Input Arguments

file

File specification, typically for a MATLAB function, specified as a string. The file specification can include a partial path, but must be in a folder on the search path, or in the current folder.

If the command includes the `-completenames` option, then the file need not be on the search path, as long as the file specification is a "fully qualified name" on page 1-1239. In addition, `filespec` can include a filemarker (`>`) to specify the path to a particular local function or to a nested function within the file.

If `file` is not a MATLAB code file (for instance, it is a built-in or MDL-file), then MATLAB issues a warning. MATLAB cannot stop *in* the file, so it pauses before executing the file.

location

Location in `file` where you want to set a breakpoint, specified as one of the following:

- lineno

  Line number in `file` specified as a string. The default is `1`.

- lineno@n

  `n`th anonymous function on line number, `lineno`, specified as a string. The default value of `n` is `1`.

- subfun

  Name of a local function in `file`, specified as a string.

expression

Code that evaluates (as if by `eval`) to a scalar logical value of `1` or `0`, (true or false, respectively).

condition

Condition that causes execution to pause when that condition evaluates to true. Specify `condition` as one of the following:

- `error`— Run-time error that occurs outside a `try/catch` block. You cannot resume execution after an uncaught run-time error.

  If you want execution to pause only if a specific error occurs, specify the message id. For example:

  - `dbstop if error` stops execution at the first run-time error that occurs outside a `try/catch` block.
  - `dbstop if error MATLAB:ls:InputsMustBeStrings` pauses execution at the first run-time error outside a `try/catch` block that has a message ID of `MATLAB:ls:InputsMustBeStrings`.

- `caught error` — Run-time error that occurs within the `try` portion of a `try/catch` block. If you want execution to stop only if a specific

error occurs, specify the message id. See the `error` condition for an example of specifying a message id.

- `warning`— Run-time warning occurs. If you want execution to pause only if a specific warning occurs, specify the message id. See the `error` condition for an example of specifying a message id.

  This condition has no effect if you disabled warnings with the `warning off all` command or if you disabled warnings for the specified `id`. For more information about disabling warnings, see `warning`.

- `naninf` and `infnan`

  The code returns an infinite value (`Inf`) or a value that is not a number (`NaN`) as a result of an operator, function call, or scalar assignment. The `naninf` and `infnan` conditions have identical effects.

s

Breakpoints previously saved to a structure using `s=dbstatus`.

Definitions

fully qualified name

- On Microsoft Windows platforms, a file name that begins with two back slashes (`\\`) or with a drive letter followed by a colon (`:`).
- On UNIX platforms, a file name that begins with a slash (`/`) or a tilde (`~`).

Examples

Stop at First Executable Line

This example shows how to set a breakpoint and pause execution at the first executable line in `buggy.m`.

1. Create a file, `buggy.m`, which contains these statements.

   ```
   function z = buggy(x)
   n = length(x);
   z = (1:n)./x;
   ```

2. Issue the `dbstop` command.

```
dbstop in buggy
```

3. Run buggy.

```
buggy(2:5)
```

MATLAB displays the line where it pauses and enters debug mode.

```
2   n = length(x);
K>>
```

4. Advance to the next line in the file.

```
dbstep
```

5. Examine the value of `n` in the Variable Editor.

```
openvar('n')
```

6. Quit debug mode.

```
dbquit
```

Stop if Error

This example shows how to set a breakpoint and pause execution if a run-time error occurs.

1. Create a file, `buggy.m`, which contains these statements.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

2. Issue these statements in the Command Window:

```
dbstop if error
buggy(magic(3))
```

Because buggy.m works on vectors only, the input in step 2 results in a run-time error. MATLAB goes into debug mode, paused at line 3 in buggy.m.

```
Error using  ./
Matrix dimensions must agree.

Error in buggy at 3
z = (1:n)./x;
3   z = (1:n)./x;
```

3 Quit debug mode.

```
dbquit
```

Stop if InfNaN

This example shows how to set a breakpoint and pause execution if the code returns a NaN value.

1 Create a file, buggy.m, containing these statements.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

2 Issue these commands.

```
dbstop if naninf
buggy(0:2)
```

If any of the elements of the input, x, is zero, a division by zero occurs in buggy.m. Therefore, MATLAB returns the following message.

```
NaN/Inf breakpoint hit for buggy on line 3.
```

MATLAB is in debug mode, paused at line 3.

Stop at Function in File

This example shows how to set a breakpoint in the `collatzall` program file at the first executable line in the `collatzplot_new` function.

1. Copy `collatzall.m` from the MATLAB examples folder to your current folder.

   ```
   copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
   'examples','collatzall.m'),'.','f')
   ```

2. Open `collatzall.m` in the Editor.

   ```
   open collatzall.m
   ```

3. Set the breakpoint.

   ```
    dbstop in collatzall>collatzplot_new
   ```

Stop at File That Is Not a MATLAB Code File

This example shows how to set a breakpoint at the built-in function `clear` when you run `myfile.m`.

1. Create a file, `myfile.m`, in the Editor, containing these statements.

   ```
   function myfile(x)
   n = length(x);
   if n < 10
       disp('length is less than 10')
   else
       disp('length is 10 or greater')
   end
   clear
   disp('Value of n is cleared')
   ```

2. Issue these commands to set the breakpoint.

   ```
   x = [1 2 3 4 5 6 7 8 9 10]
   ```

```
dbstop in clear; myfile(x)
```

MATLAB issues a warning, and pauses before the call to the clear function. The warning appears as shown in this image.

```
Warning: MATLAB debugger can only stop in MATLAB code files, a
"m_interpreter>clear" is not a MATLAB code file.
         Instead, the debugger will stop at the point right be
         "m_interpreter>clear" is called.
length is 10 or greater
8    clear
K>>
```

Restore Saved Breakpoints

This example shows how to save, and then restore, saved breakpoints.

1 Copy `collatzall.m` from the MATLAB examples folder to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc','matlab_env','examples
'collatzall.m'),'.','f')
```

2 Open `collatzall.m` in the Editor.

```
open collatzall.m
```

3 Set breakpoints from the Command Window.

```
dbstop at 12 in collatzall
dbstop if error
```

4 Run `dbstatus`.

```
dbstatus
```

MATLAB describes the breakpoints you set.

```
Breakpoint for collatzall>collatzplot_new is on line 12.
Stop if error.
```

5. Save the breakpoints to the structure, `s`, and then save `s` to the MAT-file, `myfilebrkpnts`.

   ```
   s=dbstatus('-completenames');
   save myfilebrkpnts s
   ```

   Using `s=dbstatus('-completenames')` saves absolute paths and the breakpoint function nesting sequence.

6. Clear all breakpoints.

   ```
   dbclear collatzall
   ```

7. Restore the breakpoints by loading the MAT-file.

   ```
   load myfilebrkpnts
   dbstop(s)
   ```

   The file (or files) containing the breakpoints must be on the search path or in the current folder.

8. Verify the breakpoints.

   ```
   dbstatus collatzall
   ```

Related Examples

- “Set Breakpoints”

Purpose

List text file with line numbers

Syntax

```
dbtype filename
dbtype filename start:end
```

Description

The `dbtype` command is used to list a text file with line numbers, which is helpful when setting breakpoints in a MATLAB code file with `dbstop`.

`dbtype filename` displays the contents of the specified text file, with the line number preceding each line. `filename` must be the full path name of a file, or a MATLAB relative partial path.

`dbtype filename start:end` displays the portion of the file specified by a range of line numbers from `start` to `end`.

You cannot use `dbtype` for built-in functions.

Examples

To see only the input and output arguments for a function, that is, the first line of the file, use the syntax

```
dbtype filename 1
```

For example,

```
dbtype addpath 1
```

returns

```
1     function oldpath = addpath(varargin)
```

See Also

`dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstep` | `dbstop` | `dbup`

dbup

Purpose

Shift current workspace to workspace of caller, while in debug mode

Syntax

```
dbup
```

Description

This function allows you to examine the calling MATLAB code file to determine what caused the arguments to be passed to the called function.

`dbup` changes the current workspace context, while the user is in the debug mode, to the workspace of the calling file.

Multiple `dbup` functions change the workspace context to each previous calling file on the stack until the base workspace context is reached. (It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.)

Tips

If your receive an error message such as the following, it means that the parent workspace is under construction so that the value of `x` is unavailable:

```
??? Reference to a called function result under construction x
```

See Also

`dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstep` | `dbstop` | `dbtype`

Concepts

- "Problems Viewing Variable Values from the Parent Workspace"

Purpose

Solve delay differential equations (DDEs) with constant delays

Syntax

```
sol = dde23(ddefun,lags,history,tspan)
sol = dde23(ddefun,lags,history,tspan,options)
```

Arguments

`ddefun` — Function handle that evaluates the right side of the differential equations $y'(t) = f\left(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k)\right)$. The function must have the form

```
dydt = ddefun(t,y,Z)
```

where `t` corresponds to the current t, `y` is a column vector that approximates $y(t)$, and `Z(:,j)` approximates $y(t - \tau_j)$ for delay τ_j = `lags(j)`. The output is a column vector corresponding to $f\left(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k)\right)$.

`lags` — Vector of constant, positive delays $\tau_1, \ldots, \tau_k$.

`history` — Specify `history` in one of three ways:

- A function of t such that `y = history(t)` returns the solution $y(t)$ for $t \le t_0$ as a column vector
- A constant column vector, if $y(t)$ is constant
- The solution `sol` from a previous integration, if this call continues that integration

`tspan`	Interval of integration from `t0=tspan(1)` to `tf=tspan(end)` with `t0 < tf`.
`options`	Optional integration argument. A structure you create using the `ddeset` function. See `ddeset` for details.

Description

`sol = dde23(ddefun,lags,history,tspan)` integrates the system of DDEs

$$y'(t) = f\left(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k)\right)$$

on the interval $[t_0, t_f]$, where τ_1, ..., τ_k are constant, positive delays and t_0, t_f. The input argument, `ddefun`, is a function handle.

"Parameterizing Functions" explains how to provide additional parameters to the function `ddefun`, if necessary.

`dde23` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0,tf]`.

```
yint = deval(sol,tint)
```

The structure `sol` returned by `dde23` has the following fields.

`sol.x`	Mesh selected by `dde23`
`sol.y`	Approximation to $y(x)$ at the mesh points in `sol.x`.
`sol.yp`	Approximation to $y'(x)$ at the mesh points in `sol.x`
`sol.solver`	Solver name, `'dde23'`

`sol = dde23(ddefun,lags,history,tspan,options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and "Types of DDEs" in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance `'RelTol'` (`1e-3` by default) and vector of absolute error tolerances `'AbsTol'` (all components are `1e-6` by default).

Use the `'Jumps'` option to solve problems with discontinuities in the history or solution. Set this option to a vector that contains the locations of discontinuities in the solution prior to `t0` (the history) or in coefficients of the equations at known values of t after `t0`.

Use the `'Events'` option to specify a function that `dde23` calls to find where functions $g\left(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k)\right)$ vanish. This function must be of the form

```
[value,isterminal,direction] = events(t,y,Z)
```

and contain an event function for each event to be tested. For the `k`th event function in `events`:

- `value(k)` is the value of the `k`th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and `0` otherwise.
- `direction(k) = 0` if you want `dde23` to compute all zeros of this event function, `+1` if only zeros where the event function increases, and `-1` if only zeros where the event function decreases.

If you specify the `'Events'` option and events are detected, the output structure `sol` also includes fields:

`sol.xe`	Row vector of locations of all events, i.e., times when an event function vanished
`sol.ye`	Matrix whose columns are the solution values corresponding to times in `sol.xe`
`sol.ie`	Vector containing indices that specify which event occurred at the corresponding time in `sol.xe`

Examples

This example solves a DDE on the interval [0, 5] with lags 1 and 0.2. The function `ddex1de` computes the delay differential equations, and `ddex1hist` computes the history for `t <= 0`.

Note The file, `ddex1.m`, contains the complete code for this example. To see the code in an editor, type `edit ddex1` at the command line. To run it, type `ddex1` at the command line.

```
sol = dde23(@ddex1de,[1, 0.2],@ddex1hist,[0, 5]);
```

This code evaluates the solution at 100 equally spaced points in the interval `[0,5]`, then plots the result.

```
tint = linspace(0,5);
yint = deval(sol,tint);
plot(tint,yint);
```

`ddex1` shows how you can code this problem using local functions. For more examples see `ddex2`.

Algorithms

`dde23` tracks discontinuities and integrates with the explicit Runge-Kutta (2,3) pair and interpolant of `ode23`. It uses iteration to take steps longer than the lags.

See Also

`ddesd` | `ddensd` | `ddeget` | `ddeset` | `deval` | `function_handle`

Purpose

Extract properties from delay differential equations options structure

Syntax

```
val = ddeget(options,'name')
val = ddeget(options,'name',default)
```

Description

`val = ddeget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = ddeget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = ddeget(opts,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `opts`.

See Also

`dde23` | `ddesd` | `ddensd` | `ddeset`

Purpose

Solve delay differential equations (DDEs) of neutral type

Syntax

```
sol = ddensd(ddefun,dely,delyp,history,tspan)
sol = ddensd(ddefun,dely,delyp,history,tspan,options)
```

Description

`sol = ddensd(ddefun,dely,delyp,history,tspan)` integrates a system of delay differential equations of neutral type, that has the form

$$y'(t) = f(t, y(t), y(dy_1),..., y(dy_p), y'(dyp_1),..., y'(dyp_q)) \quad \textbf{(1-1)}$$

where

- t is the independent variable representing time.
- dy_i is any of p solution delays.
- dyp_j is any of q derivative delays.

`sol = ddensd(ddefun,dely,delyp,history,tspan,options)` replaces default integration parameters with those specified in `options`, a structure created with the `ddeset` function.

Input Arguments

ddefun - Derivative function

function handle

Derivative function, specified as a function handle whose syntax is `yp = ddefun(t,y,ydel,ypdel)`. The arguments for `ddefun` are described in the table below.

ddefun Argument	Description
`t`	A scalar value representing the current value of time, t.
`y`	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is `n`-by-`1`, where `n` is the number of equations in the system you want to solve.

ddefun Argument	Description
`ydel`	A matrix whose columns, `ydel(:,i)`, represent $y(dy_i)$. The size of this matrix is `n`-by-`p`, where `n` is the number of equations in the system you want to solve, and `p` is the number of $y(dy)$ terms in Equation 1-1.
`ypdel`	A matrix whose columns, `ypdel(:,j)` represent $y'(dyp_j)$. The size of this matrix is `n`-by-`q`, where `n` is the number of equations in the system you want to solve, and `q` is the number of $y'(dyp)$ terms in Equation 1-1.
`yp`	The result returned by `ddefun`. It is an `n`-by-`1` vector whose elements represent the right side of Equation 1-1.

dely - Solution delays
function handle | vector

Solution delays, specified as a function handle, which returns $dy_1,..., dy_p$ in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If you specify `dely` as a function handle, the syntax must be `dy = dely(t,y)`. The arguments for this function are described in the table below.

dely Argument	Description
`t`	A scalar value representing the current value of time, t.
`y`	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is `n`-by-`1`, where `n` is the number of equations in the system you want to solve.
`dy`	A vector returned by the `dely` function whose values are the solution delays, dy_i , in Equation 1-1. The size of this vector is `p`-by-`1`, where `p` is the number of solution delays in the equation. Each element must be less than or equal to t.

If you want to specify constant solution delays having the form $dy_i = t - \tau_i$, then `dely` must be a vector, where `dely(i)` = τ_i. Each value in this vector must be greater than or equal to zero.

If dy is not present in the problem, set `dely` to `[]`.

Data Types

`function_handle | single | double`

delyp - Derivative delays

function handle | vector

Derivative delays, specified as a function handle, which returns dyp_1,..., dyp_q in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If `delyp` is a function handle, its syntax must be `dyp = delyp(t,y)`. The arguments for this function are described in the table below.

delyp Argument	Description
t	A scalar value representing the current value of time, t.
y	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is n-by-1, where n is the number of equations in the system you want to solve.
dyp	A vector returned by the delyp function whose values are the derivative delays, dyp_j, in Equation 1-1. The size of this vector must be q-by-1, where q is the number of solution delays, dyp_j, in the equation. Each element of dyp must be less than t. There is one exception to this restriction: if you are solving an initial value DDE, the value of dyp can equal t at $t = t_0$. For more information, see "Initial Value Neutral Delay Differential Equations" on page 1-1257.

If you want specify constant derivative delays having the form $dyp_j = t - \tau_j$, then delyp must be a vector, where delyp(j) = τ_j. Each value in this vector must be greater than zero. An exception to this restriction occurs when you solve initial value problems for DDEs of neutral type. In such cases, a value in delyp can equal zero at $t = t_0$. See "Initial Value Neutral Delay Differential Equations" on page 1-1257 for more information.

If dyp is not present in the problem, set delyp to [].

Data Types

function_handle | single | double

history - Solution history

function handle | column vector | structure (sol, from previous integration) | 1-by-2 cell array

Solution history, specified as a function handle, column vector, `sol` structure (from a previous integration), or a cell array. This is the solution at $t \leq t_0$.

- If the history varies with time, specify the solution history as a function handle whose syntax is `y = history(t)`. This function returns an `n`-by-`1` vector that approximates the solution, $y(t)$, for $t <= t_0$. The length of this vector, `n`, is the number of equations in the system you want to solve.
- If $y(t)$ is constant, you can specify `history` as an `n`-by-`1` vector of the constant values.
- If you are calling `ddensd` to continue a previous integration to t_0, you can specify history as the output, `sol`, from the previous integration.
- If you are solving an initial value DDE, specify history as a cell array, `{y0, yp0}`. The first element, `y0`, is a column vector of initial values, $y(t_0)$. The second element, yp_0, is a column vector whose elements are the initial derivatives, $y'(t_0)$. These vectors must be consistent, meaning that they satisfy Equation 1-1 at t_0. See "Initial Value Neutral Delay Differential Equations" on page 1-1257 for more information.

Data Types
`function_handle | single | double | struct | cell`

tspan - Interval of integration

1-by-2 vector

Interval of integration, specified as the vector `[t0 tf]`. The first element, `t0`, is the initial value of t. The second element, `tf`, is the final value of t. The value of `t0` must be less than `tf`.

Data Types
`single | double`

options - Optional integration parameters

structure returned by `ddeset`

Optional integration parameters, specified as a structure created and returned by the `ddeset` function. Some commonly used properties are: `'RelTol'`, `'AbsTol'`, and `'Events'`. See the `ddeset` reference page for more information about specifying `options`.

Output Arguments

sol - Solution

structure

Solution, returned as a structure containing the following fields.

`sol.x`	Mesh selected by `ddensd`.
`sol.y`	An approximation to $y(t)$ at the mesh points.
`sol.yp`	An approximation to $y'(t)$ at the mesh points.
`sol.solver`	A string identifying the solver, `'ddensd'`.

You can pass `sol` to the `deval` function to evaluate the solution at specific points. For example, `y = deval(sol, 0.5*(sol.x(1) + sol.x(end)))` evaluates the solution at the midpoint of the interval of integration.

Definitions

Initial Value Neutral Delay Differential Equations

An initial value DDE has $dy_i \geq t_0$ and $dyp_j \geq t_0$, for all i and j. At $t = t_0$, all delayed terms reduce to $y(dy_i) = y(t_0)$ and $y'(dyp_j) = y'(t_0)$:

$$y'(t_0) = f(t_0, y(t_0), y(t_0),..., y(t_0), y'(t_0),..., y'(t_0)) \quad \textbf{(1-2)}$$

For $t > t_0$, all derivative delays must satisfy $dyp < t$.

When you solve initial value neutral DDEs, you must supply $y'(t_0)$ to `ddensd`. To do this, specify `history` as a cell array `{Y0,YP0}`. Here, `Y0` is the column vector of initial values, $y(t_0)$, and `YP0` is a column vector of initial derivatives, $y'(t_0)$. These vectors must be consistent, meaning that they satisfy Equation 1-2 at t_0.

Examples

Neutral DDE with Two Delays

Solve the following neutral DDE, presented by Paul [1], for $0 \le t \le \pi$:

$$y'(t) = 1 + y(t) - 2y(t/2)^2 - y'(t - \pi)$$

with history: $y(t) = \cos(t)$ for $t \le 0$.

Create a new program file in the editor. This file will contain a main function and four local functions.

Define the first-order DDE as a local function.

```
function yp = ddefun(t,y,ydel,ypdel)
    yp = 1 + y - 2*ydel^2 - ypdel;
end
```

Define the solution delay as a local function.

```
function dy = dely(t,y)
    dy = t/2;
end
```

Define the derivative delay as a local function.

```
function dyp = delyp(t,y)
    dyp = t-pi;
end
```

Define the solution history as a local function.

```
function y = history(t)
    y = cos(t);
end
```

Define the interval of integration and solve the DDE using the `ddensd` function. Add this code to the main function.

```
tspan = [0 pi];
sol = ddensd(@ddefun,@dely,@delyp,@history,tspan);
```

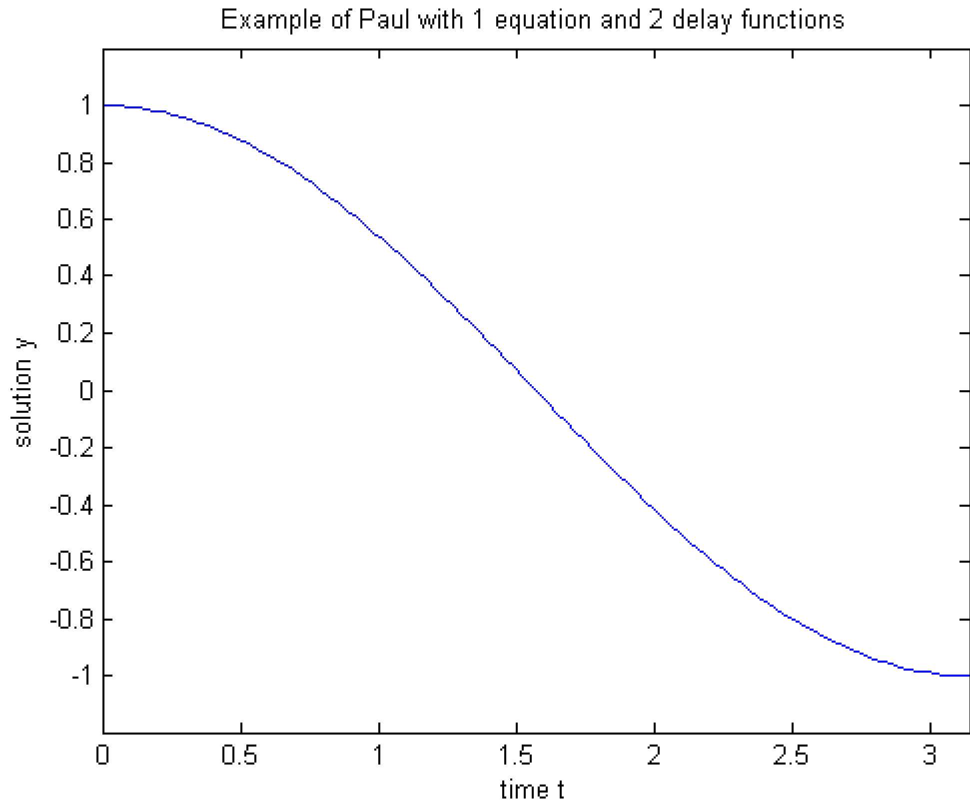
Evaluate the solution at 100 equally spaced points between 0 and π. Add this code to the main function.

```
tn = linspace(0,pi);
yn = deval(sol,tn);
```

Plot the results. Add this code to the main function.

```
plot(tn,yn);
xlim([0 pi]);
ylim([-1.2 1.2]);
xlabel('time t');
ylabel('solution y');
```

Run your program to calculate the solution and display the plot.



Note The file, `ddex4.m`, contains the complete code for this example. To see the code in an editor, type `edit ddex4` at the command line.

Algorithms

For information about the algorithm used in this solver, see Shampine [2].

ddesd

Purpose

Solve delay differential equations (DDEs) with general delays

Syntax

```
sol = ddesd(ddefun,delays,history,tspan)
sol = ddesd(ddefun,delays,history,tspan,options)
```

Arguments

`ddefun`

Function handle that evaluates the right side of the differential equations $y'(t) = f(t,y(t),y(d(1),...,y(d(k)))$. The function must have the form

```
dydt = ddefun(t,y,Z)
```

where `t` corresponds to the current t, `y` is a column vector that approximates $y(t)$, and `Z(:,j)` approximates $y(d(j))$ for delay $d(j)$ given as component j of `delays(t,y)`. The output is a column vector corresponding to $f(t,y(t),y(d(1),...,y(d(k)))$.

`delays`

Function handle that returns a column vector of delays $d(j)$. The delays can depend on both t and $y(t)$. `ddesd` imposes the requirement that $d(j) \leq t$ by using `min`$(d(j),t)$.

If all the delay functions have the form $d(j) = t - \tau_j$, you can set the argument `delays` to a constant vector `delays`(j) = τ_j. With delay functions of this form, `ddesd` is used exactly like `dde23`.

`history`	Specify `history` in one of three ways: • A function of t such that `y = history(t)` returns the solution $y(t)$ for $t \le t_0$ as a column vector • A constant column vector, if $y(t)$ is constant • The solution `sol` from a previous integration, if this call continues that integration
`tspan`	Interval of integration from `t0=tspan(1)` to `tf=tspan(end)` with `t0 < tf`.
`options`	Optional integration argument. A structure you create using the `ddeset` function. See `ddeset` for details.

Description

`sol = ddesd(ddefun,delays,history,tspan)` integrates the system of DDEs

$$y'(t) = f\left(t, y(t), y(d(1)), \ldots, y(d(k))\right)$$

on the interval $[t_0, t_f]$, where delays $d(j)$ can depend on both t and $y(t)$, and $t_0 < t_f$. Inputs `ddefun` and `delays` are function handles. See the `function_handle` reference page for more information.

"Parameterizing Functions" explains how to provide additional parameters to the functions `ddefun`, `delays`, and `history`, if necessary.

`ddesd` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0,tf]`.

```
yint = deval(sol,tint)
```

The structure `sol` returned by `ddesd` has the following fields.

`sol.x`	Mesh selected by `ddesd`
`sol.y`	Approximation to $y(x)$ at the mesh points in `sol.x`.
`sol.yp`	Approximation to $y'(x)$ at the mesh points in `sol.x`
`sol.solver`	Solver name, `'ddesd'`

`sol = ddesd(ddefun,delays,history,tspan,options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and "Types of DDEs" in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance `'RelTol'` (`1e-3` by default) and vector of absolute error tolerances `'AbsTol'` (all components are `1e-6` by default).

Use the `'Events'` option to specify a function that `ddesd` calls to find where functions $g(t,y(t),y(d(1)),...,y(d(k)))$ vanish. This function must be of the form

```
[value,isterminal,direction] = events(t,y,Z)
```

and contain an event function for each event to be tested. For the `k`th event function in `events`:

- `value(k)` is the value of the `k`th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and `0` otherwise.
- `direction(k) = 0` if you want `ddesd` to compute all zeros of this event function, `+1` if only zeros where the event function increases, and `-1` if only zeros where the event function decreases.

If you specify the `'Events'` option and events are detected, the output structure `sol` also includes fields:

`sol.xe`	Row vector of locations of all events, i.e., times when an event function vanished
`sol.ye`	Matrix whose columns are the solution values corresponding to times in `sol.xe`
`sol.ie`	Vector containing indices that specify which event occurred at the corresponding time in `sol.xe`

Examples

The equation

```
sol = ddesd(@ddex1de,@ddex1delays,@ddex1hist,[0,5]);
```

solves a DDE on the interval `[0,5]` with delays specified by the function `ddex1delays` and differential equations computed by `ddex1de`. The history is evaluated for $t \leq 0$ by the function `ddex1hist`. The solution is evaluated at 100 equally spaced points in `[0,5]`:

```
tint = linspace(0,5);
yint = deval(sol,tint);
```

and plotted with

```
plot(tint,yint);
```

This problem involves constant delays. The `delay` function has the form

```
function d = ddex1delays(t,y)
%DDEX1DELAYS  Delays for using with DDEX1DE.
d = [ t - 1
      t - 0.2];
```

The problem can also be solved with the syntax corresponding to constant delays

```
delays = [1, 0.2];
sol = ddesd(@ddex1de,delays,@ddex1hist,[0, 5]);
```

or using `dde23`:

```
sol = dde23(@ddex1de,delays,@ddex1hist,[0, 5]);
```

For more examples of solving delay differential equations see `ddex2` and `ddex3`.

See Also

`dde23` | `ddeget` | `ddensd` | `ddeset` | `deval` | `function_handle`

Purpose

Create or alter delay differential equations options structure

Syntax

```
options = ddeset('name1',value1,'name2',value2,...)
options = ddeset(oldopts,'name1',value1,...)
options = ddeset(oldopts,newopts)
ddeset
```

Description

`options = ddeset('name1',value1,'name2',value2,...)` creates an integrator options structure `options` in which the named properties have the specified values. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify the property. `ddeset` ignores case for property names.

`options = ddeset(oldopts,'name1',value1,...)` alters an existing options structure `oldopts`. This overwrites any values in `oldopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = ddeset(oldopts,newopts)` combines an existing options structure `oldopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `oldopts`.

`ddeset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `ddeget` to query the `options` structure for the value of a specific property.

DDE Properties

The following sections describe the properties that you can set using `ddeset`. There are several categories of properties:

- Error control
- Solver output
- Step size
- Event location
- Discontinuities

Error Control Properties

At each step, the DDE solvers estimate an error `e`. The `dde23` function estimates the local truncation error, and the other solvers estimate the residual. In either case, this error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

```
|e(i)|*max(RelTol*abs(y(i)),AbsTol(i))
```

For routine problems, the solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For the absolute error tolerance, the scaling of the solution components is important: if `|y|` is somewhat smaller than `AbsTol`, the solver is not constrained to obtain any correct digits in `y`. You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. Even if you are not interested in a component `y(i)` when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in `y(i)` so that you can accurately compute more interesting components.

The following table describes the error control properties.

DDE Error Control Properties

<table>
<tr><th>Property</th><th>Value</th><th>Description</th></tr>
<tr><td>RelTol</td><td>Positive scalar {1e-3}</td><td>A relative error tolerance that applies to all components of the solution vector y. It is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components except those smaller than thresholds AbsTol(i). The default, 1e-3, corresponds to 0.1% accuracy.

The estimated error in each integration step satisfies |e(i)|max(RelTol*abs(y(i)),AbsTol(i)).</td></tr>
<tr><td>AbsTol</td><td>Positive scalar or vector {1e-6}</td><td>Absolute error tolerances that apply to the individual components of the solution vector. AbsTol(i) is a threshold below which the value of the ith solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero. Even if you are not interested in a component y(i) when it is small, you may have to specify AbsTol(i) small enough to get some correct digits in y(i) so that you can accurately compute more interesting components.

If AbsTol is a vector, the length of AbsTol must be the same as the length of the solution vector y. If AbsTol is a scalar, the value applies to all components of y.</td></tr>
<tr><td>NormControl</td><td>on | {off}</td><td>Control error relative to norm of solution. Set this property on to request that the solvers control the error in each integration step with norm(e)<= max(RelTol*norm(y),AbsTol). By default, the solvers use a more stringent component-wise error control.</td></tr>
</table>

Solver Output Properties

You can use the solver output properties to control the output that the solvers generate.

DDE Solver Output Properties

Property	Value	Description

OutputFcn	Function handle {@odeplot}	The output function is a function that the solver calls after every successful integration step. To specify an output function, set 'OutputFcn' to a function handle. For example,
		
		`options = ddeset('OutputFcn',...`
		`@myfun)`
		
		sets 'OutputFcn' to @myfun, a handle to the function myfun. See the function_handle reference page for more information.
		
		The output function must be of the form
		
		`status = myfun(t,y,flag)`
		
		"Parameterizing Functions" explains how to provide additional parameters to myfun, if necessary.
		
		The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:
		
		• init — The solver calls myfun(tspan,y0,'init') before beginning the integration to allow the output function to initialize. tspan is the input argument to the solvers. y0 is the initial value of the solution, either from history(t0) or specified in the initialY option.
		
		• {none} — The solver calls status = myfun(t,y) after each integration step on which output is requested. t contains points where output was

DDE Solver Output Properties (Continued)

Property	Value	Description
		generated during the step, and `y` is the numerical solution at the points in `t`. If `t` is a vector, the `i`th column of `y` corresponds to the `i`th element of `t`. `myfun` must return a `status` output value of `0` or `1`. If literal > `status`, the solver halts integration. You can use this mechanism, for instance, to implement a **Stop** button. • done — The solver calls `myfun([],[],'done')` when integration is complete to allow the output function to perform any cleanup chores. You can use these general purpose output functions or you can edit them to create your own. Type `help functionname` at the command line for more information. • `odeplot` – time series plotting (default when you call the solver with no output argument and you have not specified an output function) • `odephas2` – two-dimensional phase plane plotting • `odephas3` – three-dimensional phase plane plotting • `odeprint` – print solution as the solver computes it

`OutputSel`	Vector of indices	Vector of indices specifying which components of the solution vector the solvers pass to the output function. For example, if you want to use the `odeplot` output function, but you want to plot only the first and third components of the solution, you can do this using
		
		`options = ddeset...`
		`('OutputFcn',@odeplot,...`

DDE Solver Output Properties (Continued)

Property	Value	Description
		`'OutputSel',[1 3]);` By default, the solver passes all components of the solution to the output function.
`Stats`	`on` | `{off}`	Specifies whether the solver should display statistics about its computations. By default, `Stats` is `off`. If it is `on`, after solving the problem the solver displays: • The number of successful steps • The number of failed attempts • The number of times the DDE function was called

Step Size Properties

The step size properties let you specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step size properties.

DDE Step Size Properties

Property	Value	Description
`InitialStep`	Positive scalar	Suggested initial step size. `InitialStep` sets an upper bound on the magnitude of the first step size the solver tries. If you do not set `InitialStep`, the solver bases the initial step size on the slope of the solution at the initial time `tspan(1)`. The initial step size is limited by the shortest delay. If the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know

DDE Step Size Properties (Continued)

Property	Value	Description
		this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable `InitialStep`.
`MaxStep`	Positive scalar {`0.1* abs(t0-tf)`}	Upper bound on solver step size. If the differential equation has periodic coefficients or solutions, it may be a good idea to set `MaxStep` to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do *not* reduce `MaxStep`: • When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance `RelTol`, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector `AbsTol`. (See "Error Control Properties" on page 1-1268 for a description of the error tolerance properties.) • To make sure that the solver doesn't step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances `RelTol` and `AbsTol`. Use `MaxStep` as a last resort.

Event Location Property

In some DDE problems, the times of specific events are important. While solving a problem, the solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the `Events` property.

DDE Events Property

String	Value	Description

`Events`	Function handle	A function handle that includes one or more event functions. For `dde23` and `ddesd`, this function has the following syntax:
		`[value,isterminal,direction] = events(t,y,YDEL)`
		For `ddensd`, the syntax is:
		`[value,isterminal,direction] = events(t,y,YDEL,YPDEL)`
		The output arguments, `value`, `isterminal`, and `direction`, are vectors for which the `i`th element corresponds to the `i`th event function:
		• `value(i)` is the value of the `i`th event function.
		• `isterminal(i) = 1` if you want the integration to terminate at a zero of this event function, and `0` otherwise.
		• `direction(i) = 0` if you want the solver to locate all zeros (the default), `+1` if only zeros where the event function is increasing, and `-1` if only zeros where the event function is decreasing.
		If you specify an events function and events are detected, the solver returns three additional fields in the solution structure `sol`:
		• `sol.xe` is a row vector of times at which events occur.
		• `sol.ye` is a matrix whose columns are the solution values corresponding to times in `sol.xe`.
		• `sol.ie` is a vector containing indices that specify which event occurred at the corresponding time in `sol.xe`.

DDE Events Property (Continued)

String	Value	Description
		For examples that use an event function while solving ordinary differential equation problems, see “Event Location” (`ballode`) and “Advanced Event Location” (`orbitode`), in the MATLAB Mathematics documentation.

Discontinuity Properties

The solver functions can solve problems with discontinuities in the history or in the coefficients of the equations. The following properties enable you to provide these solvers with a different initial value, and, for `dde23`, locations of known discontinuities. For more information, see “Discontinuities in DDEs”.

The following table describes the discontinuity properties.

DDE Discontinuity Properties

String	Value	Description
`Jumps`	Vector	Location of discontinuities. Points t where the history or solution may have a jump discontinuity in a low-order derivative. This applies only to the `dde23` solver.
`InitialY`	Vector	Initial value of solution. By default the initial value of the solution is the value returned by `history` at the initial point. Supply a different initial value as the value of the `InitialY` property.

Examples

To create an options structure that changes the relative error tolerance of the solver from the default value of `1e-3` to `1e-4`, enter

```
options = ddeset('RelTol',1e-4);
```

To recover the value of 'RelTol' from options, enter

```
ddeget(options,'RelTol')

ans =

  1.0000e-004
```

Purpose

Distribute inputs to outputs

Note Beginning with MATLAB Version 7.0 software, you can access the contents of cell arrays and structure fields without using the `deal` function. See Example 3, below.

Syntax

```
[Y1, Y2, Y3, ...] = deal(X)
[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)
[S.field] = deal(X)
[X{:}] = deal(A.field)
[Y1, Y2, Y3, ...] = deal(X{:})
[Y1, Y2, Y3, ...] = deal(S.field)
```

Description

`[Y1, Y2, Y3, ...]  = deal(X)` copies the single input to all the requested outputs. It is the same as `Y1 = X`, `Y2 = X`, `Y3 = X`, `...`

`[Y1, Y2, Y3, ...]  = deal(X1, X2, X3, ...)` is the same as `Y1 = X1`; `Y2 = X2`; `Y3 = X3`; `...`

Tips

`deal` is most useful when used with cell arrays and structures via comma-separated list expansion. Here are some useful constructions:

`[S.field] = deal(X)` sets all the fields with the name `field` in the structure array `S` to the value `X`. If `S` doesn't exist, use `[S(1:m).field] = deal(X)`.

`[X{:}] = deal(A.field)` copies the values of the field with name `field` to the cell array `X`. If `X` doesn't exist, use `[X{1:m}] = deal(A.field)`.

`[Y1, Y2, Y3, ...]  = deal(X{:})` copies the contents of the cell array `X` to the separate variables `Y1, Y2, Y3, ...`

`[Y1, Y2, Y3, ...]  = deal(S.field)` copies the contents of the fields with the name `field` to separate variables `Y1, Y2, Y3, ...`

Examples

Example 1 — Assign Data From a Cell Array

Use `deal` to copy the contents of a 4-element cell array into four separate output variables.

```
C = {rand(3) ones(3,1) eye(3) zeros(3,1)};
[a,b,c,d] = deal(C{:})

a =
    0.9501    0.4860    0.4565
    0.2311    0.8913    0.0185
    0.6068    0.7621    0.8214

b =
    1
    1
    1

c =
    1    0    0
    0    1    0
    0    0    1

d =
    0
    0
    0
```

Example 2 — Assign Data From Structure Fields

Use `deal` to obtain the contents of all the name fields in a structure array:

```
A.name = 'Pat'; A.number = 176554;
A(2).name = 'Tony'; A(2).number = 901325;
[name1,name2] = deal(A(:).name)

name1 =
   Pat
```

```
name2 =
   Tony
```

Example 3 — Doing the Same Without deal

Beginning with MATLAB Version 7.0 software, you can, in most cases, access the contents of cell arrays and structure fields without using the `deal` function. The two commands shown below perform the same operation as those used in the previous two examples, except that these commands do not require `deal`.

```
[a,b,c,d] = C{:}
[name1,name2] = A(:).name
```

`cell` | `iscell` | `celldisp` | `struct` | `isstruct` | `fieldnames` | `isfield` | `orderfields` | `rmfield` | `cell2struct` | `struct2cell`

deblank

Purpose

Strip trailing blanks from end of string

Syntax

```
str = deblank(str)
c = deblank(c)
```

Description

`str = deblank(str)` removes all trailing whitespace and null characters from the end of character string `str`. A whitespace is any character for which the `isspace` function returns logical 1 (`true`).

`c = deblank(c)` when `c` is a cell array of strings, applies `deblank` to each element of `c`.

The `deblank` function is useful for cleaning up the rows of a character array.

Examples

Example 1 – Removing Trailing Blanks From a String

Compose a string `str` that contains space, tab, and null characters:

```
NL = char(0);    TAB = char(9);
str = [NL 32 TAB NL 'AB' 32 NL 'CD' NL 32 TAB NL 32];
```

Display all characters of the string between | symbols:

```
['|' str '|']
ans =
    |    AB  CD       |
```

Remove trailing whitespace and null characters, and redisplay the string:

```
newstr = deblank(str);

['|' newstr '|']
ans =
    |    AB  CD|
```

Example 2– Removing Trailing Blanks From a Cell Array of Strings

Create a 2-by-2 cell array in which each cell contains a word with trailing blanks:

```
A{1,1} = 'MATLAB    ';
A{1,2} = 'SIMULINK    ';
A{2,1} = 'Toolboxes    ';
A{2,2} = 'MathWorks    '
A =
    'MATLAB    '        'SIMULINK    '
    'Toolboxes    '    'MathWorks    '
```

Remove the trailing blanks and redisplay the cell array:

```
deblank(A);
A
A =
    'MATLAB'       'SIMULINK'
    'Toolboxes'    'MathWorks'
```

See Also

strjust | strtrim

Purpose

Convert decimal to base N number in string

Syntax

```
str = dec2base(d, base)
str = dec2base(d, base, n)
```

Description

`str = dec2base(d, base)` converts the nonnegative integer `d` to the specified `base`. `d` must be a nonnegative integer smaller than 2^52, and `base` must be an integer between 2 and 36. The returned argument `str` is a string.

`str = dec2base(d, base, n)` produces a representation with at least `n` digits.

Examples

The expression `dec2base(23, 2)` converts 23_{10} to base 2, returning the string `'10111'`.

See Also

`base2dec`

Purpose

Convert decimal to binary number in string

Syntax

```
str = dec2bin(d)
str = dec2bin(d,n)
```

Description

returns the

`str = dec2bin(d)` binary representation of `d` as a string. `d` must be a nonnegative integer smaller than 2^52.

`str = dec2bin(d,n)` produces a binary representation with at least `n` bits.

The output of `dec2bin` is independent of the endian settings of the computer you are using.

Examples

Decimal 23 converts to binary 010111:

```
dec2bin(23)
ans =
    10111
```

See Also

`bin2dec` | `dec2hex`

dec2hex

Purpose

Convert decimal to hexadecimal number in string

Syntax

```
str = dec2hex(d)
str = dec2hex(d, n)
```

Description

`str = dec2hex(d)` converts the decimal integer `d` to its hexadecimal representation stored in a MATLAB string. `d` must be a nonnegative integer smaller than 2^52. MATLAB converts noninteger inputs, such as those of class `double` or `char`, to their integer equivalents before converting to hexadecimal.

`str = dec2hex(d, n)` produces a hexadecimal representation with at least `n` digits.

Examples

To convert decimal 1023 to hexadecimal,

```
dec2hex(1023)
ans =
    3FF

dec2hex(1023, 6)
ans =
0003FF
```

Convert 2-by-5 array `A` to hexadecimal:

```
A = [3487,    125,  8997,  1433,  189; ...
      771,  84832,   118,  9366,  212];

 A(:)                        dec2hex(A)
ans =                        ans =
     3487                       00D9F
      771                       00303
      125                       0007D
    84832                       14B60
     8997                       02325
      118                       00076
     1433                       00599
```

```
    9366                  02496
     189                  000BD
     212                  000D4
```

See Also

dec2bin | format | hex2dec | hex2num

Purpose

Compute consistent initial conditions for ode15i

Syntax

```
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,
   options)
[y0mod,yp0mod,resnrm] = decic(odefun,t0,y0,fixed_y0,yp0,
   fixed_yp0...)
```

Description

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)` uses the inputs `y0` and `yp0` as initial guesses for an iteration to find output values that satisfy the requirement $f(t0, y0\,\mathrm{mod}, yp0\,\mathrm{mod}) = 0$, i.e., `y0mod` and `yp0mod` are consistent initial conditions. `odefun` is a function handle. The function `decic` changes as few components of the guesses as possible. You can specify that `decic` holds certain components fixed by setting `fixed_y0(i) = 1` if no change is permitted in the guess for `y0(i)` and 0 otherwise. `decic` interprets `fixed_y0 = []` as allowing changes in all entries. `fixed_yp0` is handled similarly.

"Parameterizing Functions" explains how to provide additional parameters to the function `odefun`, if necessary.

You cannot fix more than `length(y0)` components. Depending on the problem, it may not be possible to fix this many. It also may not be possible to fix certain components of `y0` or `yp0`. It is recommended that you fix no more components than necessary.

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,options)` computes as above with default tolerances for consistent initial conditions, `AbsTol` and `RelTol`, replaced by the values in options, a structure you create with the `odeset` function.

`[y0mod,yp0mod,resnrm] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0...)` returns the norm of `odefun(t0,y0mod,yp0mod)` as `resnrm`. If the norm seems unduly large, use `options` to decrease `RelTol` (`1e-3` by default).

Examples

The files, `ihb1dae.m` and `iburgersode.m`, provide examples which use `decic` to solve implicit ODEs.

See Also

`ode15i` | `odeget` | `odeset` | `function_handle`

deconv

Purpose

Deconvolution and polynomial division

Syntax

```
[q,r] = deconv(v,u)
```

Description

`[q,r] = deconv(v,u)` deconvolves vector `u` out of vector `v`, using long division. The quotient is returned in vector `q` and the remainder in vector `r` such that `v = conv(u,q)+r` .

If `u` and `v` are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials, and deconvolution is polynomial division. The result of dividing `v` by `u` is quotient `q` and remainder `r`.

Examples

If

```
u = [1   2   3   4]
v = [10   20   30]
```

the convolution is

```
c = conv(u,v)
c =
    10     40     100     160     170     120
```

Use deconvolution to recover `u`:

```
[q,r] = deconv(c,u)
q =
    10    20    30
r =
    0     0     0     0     0     0
```

This gives a quotient equal to `v` and a zero remainder.

Algorithms

`deconv` uses the `filter` primitive.

See Also

`conv` | `residue`

Purpose

Discrete Laplacian

Syntax

```
L = del2(U)
L = del2(U,h)
L = del2(U,hx,hy)
L = del2(U,hx,hy,hz,...)
```

Definitions

If the matrix `U` is regarded as a function *u(x,y)* evaluated at the point on a square grid, then `4*del2(U)` is a finite difference approximation of Laplace's differential operator applied to u, that is:

$$l = \frac{\nabla^2 u}{4} = \frac{1}{4}\left(\frac{d^2 u}{dx^2} + \frac{d^2 u}{dy^2}\right)$$

where:

$$l_{ij} = \frac{1}{4}\left(u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1}\right) - u_{i,j}$$

in the interior. On the edges, the same formula is applied to a cubic extrapolation.

For functions of more variables *u(x,y,z,...)*, `del2(U)` is an approximation,

$$l = \frac{\nabla^2 u}{2N} = \frac{1}{2N}\left(\frac{d^2 u}{dx^2} + \frac{d^2 u}{dy^2} + \frac{d^2 u}{dz^2} + \ldots\right)$$

where N is the number of variables in u.

Description

`L = del2(U)` where `U` is a rectangular array is a discrete approximation of

$$l = \frac{\nabla^2 u}{4} = \frac{1}{4}\left(\frac{d^2 u}{dx^2} + \frac{d^2 u}{dy^2}\right)$$

The matrix `L` is the same size as `U` with each element equal to the difference between an element of `U` and the average of its four neighbors.

`L = del2(U)` when `U` is an multidimensional array, returns an approximation of

$$\frac{\nabla^2 u}{2N}$$

where N is `ndims(u)`.

`L = del2(U,h)` where `H` is a scalar uses `H` as the spacing between points in each direction (`h=1` by default).

`L = del2(U,hx,hy)` when `U` is a rectangular array, uses the spacing specified by `hx` and `hy`. If `hx` is a scalar, it gives the spacing between points in the x-direction. If `hx` is a vector, it must be of length `size(u,2)` and specifies the x-coordinates of the points. Similarly, if `hy` is a scalar, it gives the spacing between points in the y-direction. If `hy` is a vector, it must be of length `size(u,1)` and specifies the y-coordinates of the points.

`L = del2(U,hx,hy,hz,...)` where `U` is multidimensional uses the spacing given by `hx`, `hy`, `hz`, ...

Tips

MATLAB software computes the boundaries of the grid by extrapolating the second differences from the interior. The algorithm used for this computation can be seen in the `del2` program file code. To view this code, type:

```
type del2
```

Examples

The function:

$$u(x, y) = x^2 + y^2$$

has:

$$\nabla^2 u = 4$$

For this function, `4*del2(U)` is also `4`.

```
[x,y] = meshgrid(-4:4,-3:3);
U = x.*x+y.*y
U =
    25    18    13    10     9    10    13    18    25
    20    13     8     5     4     5     8    13    20
    17    10     5     2     1     2     5    10    17
    16     9     4     1     0     1     4     9    16
    17    10     5     2     1     2     5    10    17
    20    13     8     5     4     5     8    13    20
    25    18    13    10     9    10    13    18    25

V = 4*del2(U)
V =
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
```

DelaunayTri

Superclasses

TriRep

Purpose

(Will be removed) Delaunay triangulation in 2-D and 3-D

Note `DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Description

`DelaunayTri` creates a Delaunay triangulation object from a set of points. You can incrementally modify the triangulation by adding or removing points. In 2-D triangulations you can impose edge constraints. You can perform topological and geometric queries, and compute the Voronoi diagram and convex hull.

Definitions

The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

Construction

DelaunayTri	(Will be removed) Construct Delaunay triangulation

Methods

convexHull	(Will be removed) Convex hull
inOutStatus	(Will be removed) Status of triangles in 2-D constrained Delaunay triangulation
nearestNeighbor	(Will be removed) Point closest to specified location

pointLocation	(Will be removed) Simplex containing specified location
voronoiDiagram	(Will be removed) Voronoi diagram

Inherited methods

baryToCart	(Will be removed) Convert point coordinates from barycentric to Cartesian
cartToBary	(Will be removed) Convert point coordinates from cartesian to barycentric
circumcenters	(Will be removed) Circumcenters of specified simplices
edgeAttachments	(Will be removed) Simplices attached to specified edges
edges	(Will be removed) Triangulation edges
faceNormals	(Will be removed) Unit normals to specified triangles
featureEdges	(Will be removed) Sharp edges of surface triangulation
freeBoundary	(Will be removed) Facets referenced by only one simplex
incenters	(Will be removed) Incenters of specified simplices
isEdge	(Will be removed) Test if vertices are joined by edge
neighbors	(Will be removed) Simplex neighbor information

size	(Will be removed) Size of triangulation matrix
vertexAttachments	(Will be removed) Return simplices attached to specified vertices

Properties

`Constraints`	`Constraints` is a `numc`-by-2 matrix that defines the constrained edge data in the triangulation, where `numc` is the number of constrained edges. Each constrained edge is defined in terms of its endpoint indices into `X`. The constraints can be specified when the triangulation is constructed or can be imposed afterwards by directly editing the constraints data. This feature is only supported for 2-D triangulations.
`X`	The dimension of `X` is `mpts`-by-`ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside. If column vectors of `x`,`y` or `x`,`y`,`z` coordinates are used to construct the triangulation, the data is consolidated into a single matrix `X`.
`Triangulation`	Triangulation is a matrix representing the set of simplices (triangles or tetrahedra etc.) that make up the triangulation. The matrix is of size `mtri`-by-`nv`, where `mtri` is the number of simplices and `nv` is the number of vertices per simplex. The triangulation is represented by standard simplex-vertex format; each row specifies a simplex defined by indices into `X`, where `X` is the array of point coordinates.

Instance Hierarchy

`DelaunayTri` is a subclass of `TriRep`.

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

DelaunayTri

Purpose

(Will be removed) Construct Delaunay triangulation

Note `DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Syntax

```
DT = DelaunayTri()
DT = DelaunayTri(X)
DT = DelaunayTri(x,y)
DT = DelaunayTri(x,y,z)
DT = DelaunayTri(..., C)
```

Description

`DT = DelaunayTri()` creates an empty Delaunay triangulation.

`DT = DelaunayTri(X)`, `DT = DelaunayTri(x,y)` and `DT = DelaunayTri(x,y,z)` create a Delaunay triangulation from a set of points. The points can be specified as an `mpts`-by-`ndim` matrix `X`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, where `ndim` is 2 or 3. Alternatively, the points can be specified as column vectors `(x,y)` or `(x,y,z)` for 2-D and 3-D input.

`DT = DelaunayTri(..., C)` creates a constrained Delaunay triangulation. The edge constraints `C` are defined by an `numc`-by-2 matrix, `numc` being the number of constrained edges. Each row of `C` defines a constrained edge in terms of its endpoint indices into the point set `X`. This feature is only supported for 2-D triangulations.

Definitions

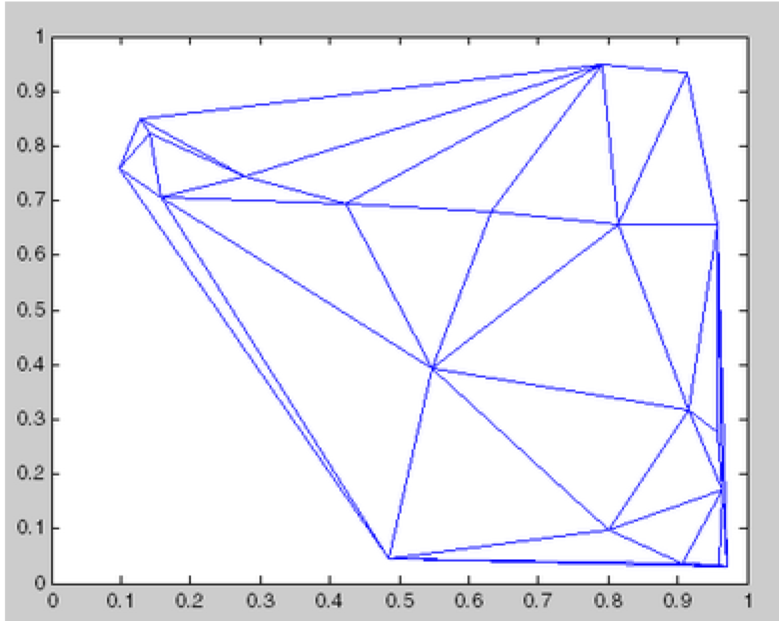
The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

Examples

Compute the Delaunay triangulation of twenty random points located within a unit square.

```
x = rand(20,1);
```

```
y = rand(20,1);
dt = DelaunayTri(x,y)
triplot(dt);
```



For more examples, type `help demoDelaunayTri` at the MATLAB command-line prompt.

delaunay

Purpose

Delaunay triangulation

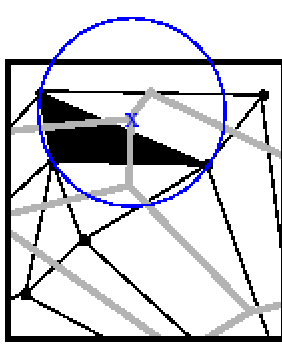
Note Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `delaunay`.

Syntax

```
TRI = delaunay(X,Y)
TRI = delaunay(X,Y,Z)
TRI = delaunay(X)
```

Definitions

`delaunay` creates a Delaunay triangulation of a set of points in 2-D or 3-D space. A 2-D Delaunay triangulation ensures that the circumcircle associated with each triangle contains no other point in its interior. This definition extends naturally to higher dimensions.



Description

`TRI = delaunay(X,Y)`creates a 2-D Delaunay triangulation of the points (`X`,`Y`), where `X` and `Y` are column-vectors. `TRI` is a matrix representing the set of triangles that make up the triangulation. The matrix is of size `mtri`-by-3, where `mtri` is the number of triangles. Each row of `TRI` specifies a triangle defined by indices with respect to the points.

`TRI = delaunay(X,Y,Z)` creates a 3-D Delaunay triangulation of the points (`X`,`Y`,`Z`), where `X`, `Y`, and `Z` are column-vectors. `TRI` is a matrix

representing the set of tetrahedra that make up the triangulation. The matrix is of size mtri-by-4, where mtri is the number of tetrahedra. Each row of TRI specifies a tetrahedron defined by indices with respect to the points.

TRI = delaunay(X) creates a 2-D or 3-D Delaunay triangulation from the point coordinates X. This variant supports the definition of points in matrix format. X is of size mpts-by-ndim, where mpts is the number of points and ndim is the dimension of the space where the points reside, $2 \leqq$ ndim $\leqq 3$. The output triangulation is equivalent to that of the dedicated functions supporting the 2-input or 3-input calling syntax.

delaunay produces an isolated triangulation, useful for applications like plotting surfaces via the trisurf function. If you wish to query the triangulation; for example, to perform nearest neighbor, point location, or topology queries, use delaunayTriangulation instead.

Visualization

Use one of these functions to plot the output of delaunay:

triplot	Displays the triangles defined in the m-by-3 matrix TRI.
trisurf	Displays each triangle defined in the m-by-3 matrix TRI as a surface in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example `trisurf(TRI,x,y,zeros(size(x)))`

`trimesh`	Displays each triangle defined in the m-by-3 matrix TRI as a mesh in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example, `trimesh(TRI,x,y,zeros(size(x)))` produces almost the same result as `triplot`, except in 3-D space.
`tetramesh`	Plots a triangulation composed of tetrahedra.

Examples

Example

Plot the Delaunay triangulation of a large dataset:

```
load seamount
tri = delaunay(x,y);
trisurf(tri,x,y,z);
```

`delaunayTriangulation` | `scatteredInterpolant` | `plot` | `triplot` | `trimesh` | `trisurf`

delaunayn

Purpose

N-D Delaunay triangulation

Syntax

```
T = delaunayn(X)
T = delaunayn(X, options)
```

Description

`T = delaunayn(X)` computes a set of simplices such that no data points of `X` are contained in any circumspheres of the simplices. The set of simplices forms the Delaunay triangulation. `X` is an `m`-by-`n` array representing m points in n-dimensional space. `T` is a `numt`-by-(`n+1`) array where each row contains the indices into `X` of the vertices of the corresponding simplex.

`T = delaunayn(X, options)` specifies a cell array of strings `options`. The default options are:

- `{'Qt','Qbb','Qc'}` for 2- and 3-dimensional input
- `{'Qt','Qbb','Qc','Qx'}` for 4 and higher-dimensional input

If `options` is `[]`, the default options used. If `options` is `{''}`, no options are used, not even the default.

Visualization

Plotting the output of `delaunayn` depends of the value of `n`:

- For `n = 2`, use `triplot`, `trisurf`, or `trimesh` as you would for `delaunay`.
- For `n = 3`, use `tetramesh`.

  For more control over the color of the facets, use `patch` to plot the output.
- You cannot plot `delaunayn` output for `n > 3`.

Examples

Example 1

This example generates an n-dimensional Delaunay triangulation, where `n = 3`.

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d);  % A cube
```

```
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x,y,z] are corners of a cube plus the center.
X = [x(:) y(:) z(:)];
Tes = delaunayn(X)

Tes =

     4     3     9     1
     4     9     2     1
     7     9     3     1
     7     5     9     1
     7     9     4     3
     7     8     4     9
     6     2     9     1
     6     9     5     1
     6     4     9     2
     6     4     8     9
     6     9     7     5
     6     8     7     9
```

You can use `tetramesh` to visualize the tetrahedrons that form the corresponding simplex. `camorbit` rotates the camera position to provide a meaningful view of the figure.

```
tetramesh(Tes,X);camorbit(20,0)
```

Superclasses triangulation

Purpose Delaunay triangulation in 2-D and 3-D

Description

Use the `delaunayTriangulation` class to create a 2-D or 3-D triangulation from a set of points. When your points are in 2-D, you can specify edge constraints .

You can perform a variety of topological and geometric queries on a `delaunayTriangulation`, including any `triangulation` query. For example, locate a facet that contains a specific point, find the vertices of the convex hull, or compute the Voronoi Diagram.

Construction

`DT = delaunayTriangulation(P)` creates a Delaunay triangulation from the points in `P`. Matrix `P` has 2 or 3 columns, depending on whether your points are in 2-D or 3-D space.

`DT = delaunayTriangulation(P,C)` specifies the edge constraints in matrix `C`. In this case, `P` specifies points in 2-D. Each row of `C` defines the start and end vertex IDs of a constrained edge.

`DT = delaunayTriangulation(x,y)` creates a 2-D Delaunay triangulation from the point coordinates in the column vectors, `x` and `y`.

`DT = delaunayTriangulation(x,y,C)` specifies the edge constraints in matrix `C`.

`DT = delaunayTriangulation(x,y,z)` creates a 3-D Delaunay triangulation from the point coordinates in the column vectors, `x`, `y`, and `z`.

`DT = delaunayTriangulation()` creates an empty Delaunay triangulation.

Input Arguments

P

Input points, specified as a matrix whose columns are the *x*, *y*, (and possibly *z*) coordinates of the triangulation points. The row numbers of `P` are the vertex IDs in the triangulation.

x

x-coordinates vector, specified as a column vector containing the *x*-coordinates of the triangulation points.

y

y-coordinates vector, specified as a column vector containing the *y*-coordinates of the triangulation points.

z

z-coordinates vector, specified as a column vector containing the *z*-coordinates of the triangulation points.

C

Vertex IDs of constrained edges, specified as a 2-column matrix. Each row of `C` corresponds to a constrained edge and contains two IDs:

- `C(j,1)` is the ID of the vertex at the start of an edge.
- `C(j,2)` is the ID of the vertex at end of the edge.

You can specify edge constraints for 2-D triangulations only.

Properties

Points

Points in the triangulation, represented as a matrix containing the following information:

- Each row in `DT.Points` contains the coordinates of a vertex.
- Each row number of `DT.Points` is a vertex ID.

ConnectivityList

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `DT.ConnectivityList` is a "Triangle or Tetrahedron ID" on page 1-1309.
- Each element is a vertex ID.

Constraints

Constrained edges, represented as a two-column matrix of vertex IDs. Each row of `DT.Constraints` corresponds to a constrained edge and contains two IDs:

- `DT.Constraints(j,1)` is the ID of the vertex at the start of an edge.
- `DT.Constraints(j,2)` is the ID of the vertex at end of the edge.

`DT.Constraints` is an empty matrix when the triangulation has no constrained edges.

Methods

convexHull	Convex hull
isInterior	Test if triangle is in interior of 2-D constrained Delaunay triangulation
nearestNeighbor	Vertex closest to specified location
pointLocation	Triangle or tetrahedron containing specified location
voronoiDiagram	Voronoi diagram

Inherited Methods

barycentricToCartesian	Converts point coordinates from barycentric to Cartesian
cartesianToBarycentric	Converts point coordinates from Cartesian to barycentric
circumcenter	Circumcenter of triangle or tetrahedron
edgeAttachments	Triangles or tetrahedra attached to specified edge
edges	Triangulation edges
faceNormal	Triangulation face normal
featureEdges	Triangulation sharp edges
freeBoundary	Triangulation facets referenced by only one triangle or tetrahedron
incenter	Incenter of triangle or tetrahedron
isConnected	Test if two vertices are connected by edge
neighbors	Neighbors to specified triangle or tetrahedron
size	Size of triangulation connectivity list
vertexAttachments	Triangles or tetrahedra attached to specified vertex
vertexNormal	Triangulation vertex normal

Definitions

Delaunay Triangulation

In a 2-D Delaunay triangulation, the circumcircle associated with each triangle does not contain any points in its interior. Similarly, a 3-D Delaunay triangulation does not have any points in the interior of the circumsphere associated with each tetrahedron. This definition extends to N-D, although `delaunayTriangulation` supports only 2-D and 3-D.

Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

Triangle or Tetrahedron ID

A row number of the matrix, `DT.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

2-D Delaunay Triangulation

Create a 2-D `delaunayTriangulation` for 30 random points.

```
P = gallery('uniformdata',[30 2],0);
DT = delaunayTriangulation(P)
```

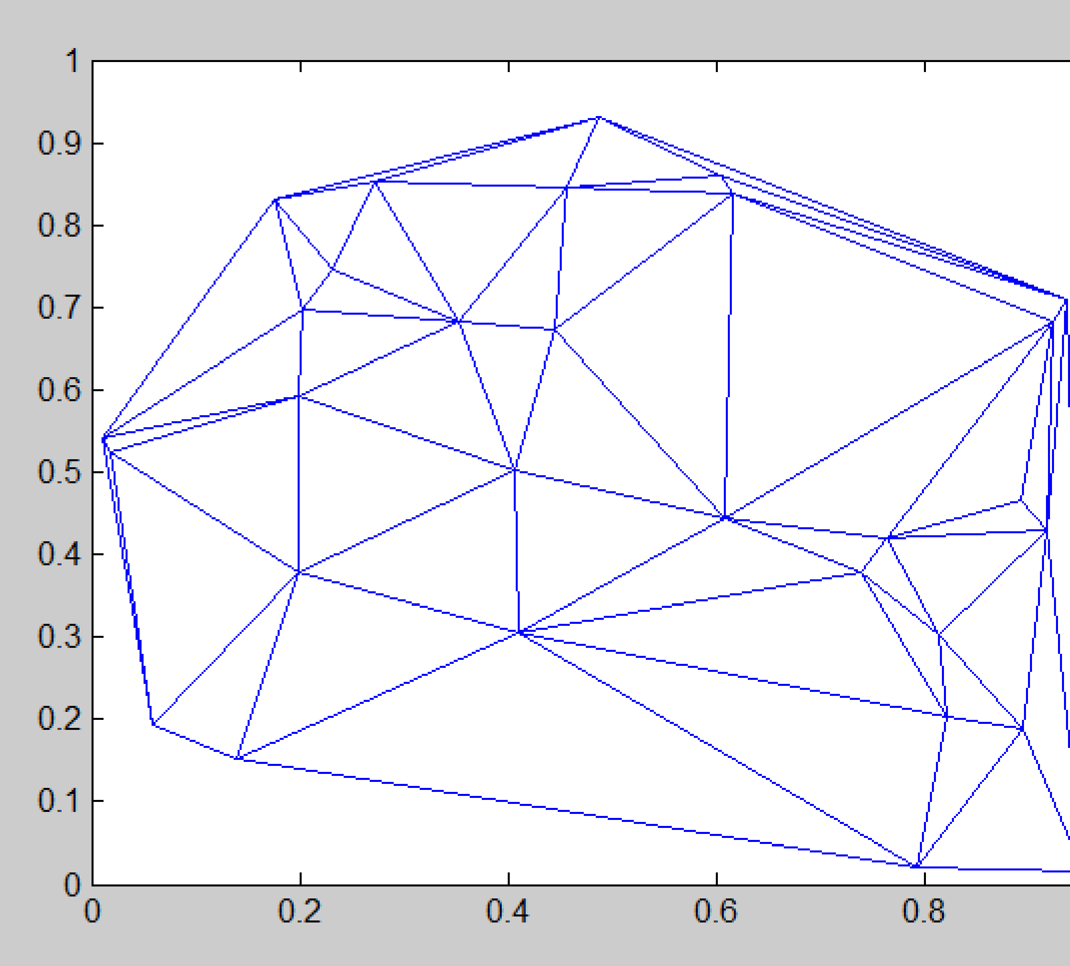
```
DT =

  delaunayTriangulation with properties:

              Points: [30x2 double]
    ConnectivityList: [50x3 double]
         Constraints: []
```

Plot the triangulation.

```
figure
triplot(DT)
```



3-D Delaunay Triangulation

Create a 3-D `delaunayTriangulation` for 30 random points.

```
x = gallery('uniformdata',[30 1],0);
y = gallery('uniformdata',[30 1],1);
z = gallery('uniformdata',[30 1],2);
```

```
DT = delaunayTriangulation(x,y,z)

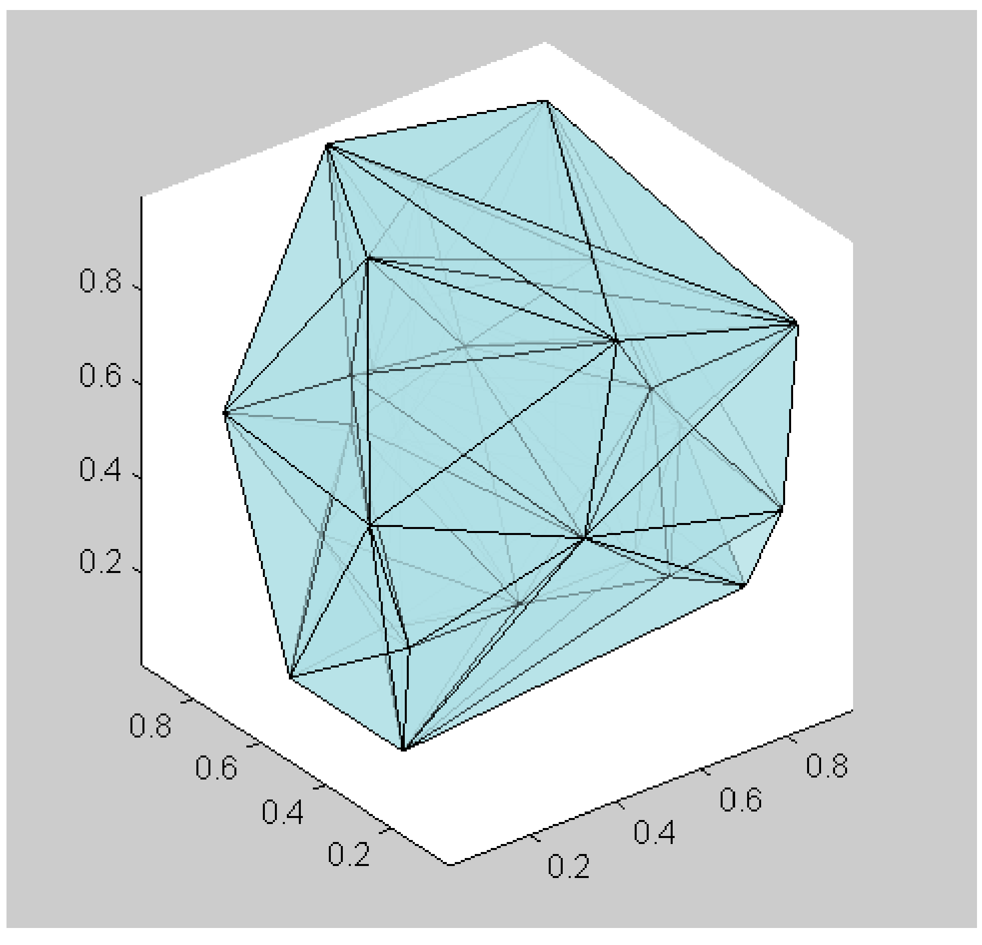
DT = 

  delaunayTriangulation with properties:

              Points: [30x3 double]
    ConnectivityList: [111x4 double]
         Constraints: []
```

Plot the triangulation at 30% opacity with a light blue face color.

```
faceColor  = [0.6875 0.8750 0.8984];
figure
tetramesh(DT,'FaceColor',faceColor,'FaceAlpha',0.3);
```



See Also

`triangulation` | `delaunay` | `delaunayn`

Purpose

Convex hull

Syntax

```
K = convexHull(DT)
[K,v] = convexHull(DT)
```

Description

`K = convexHull(DT)` returns the vertices of the convex hull.

`[K,v] = convexHull(DT)` also returns the area or volume bounded by the convex hull.

Input Arguments

DT

A Delaunay triangulation, see `delaunayTriangulation`.

Output Arguments

K

Convex hull vertices, returned as a matrix of vertex IDs. The shape of `K` depends on whether your triangulation is 2-D or 3-D:

- When `DT` is 2-D, `K` is a column vector containing the sequence of vertex IDs around the convex hull.
- When `DT` is 3-D, `K` is a triangulation connectivity list containing the triangles on the convex hull.

v

Area or volume bounded by the convex hull, returned as a scalar value.

Definitions

Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Convex Hull in 2-D Space

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[10,1],0);
y = gallery('uniformdata',[10,1],1);
DT = delaunayTriangulation(x,y);
```

Calculate the convex hull.

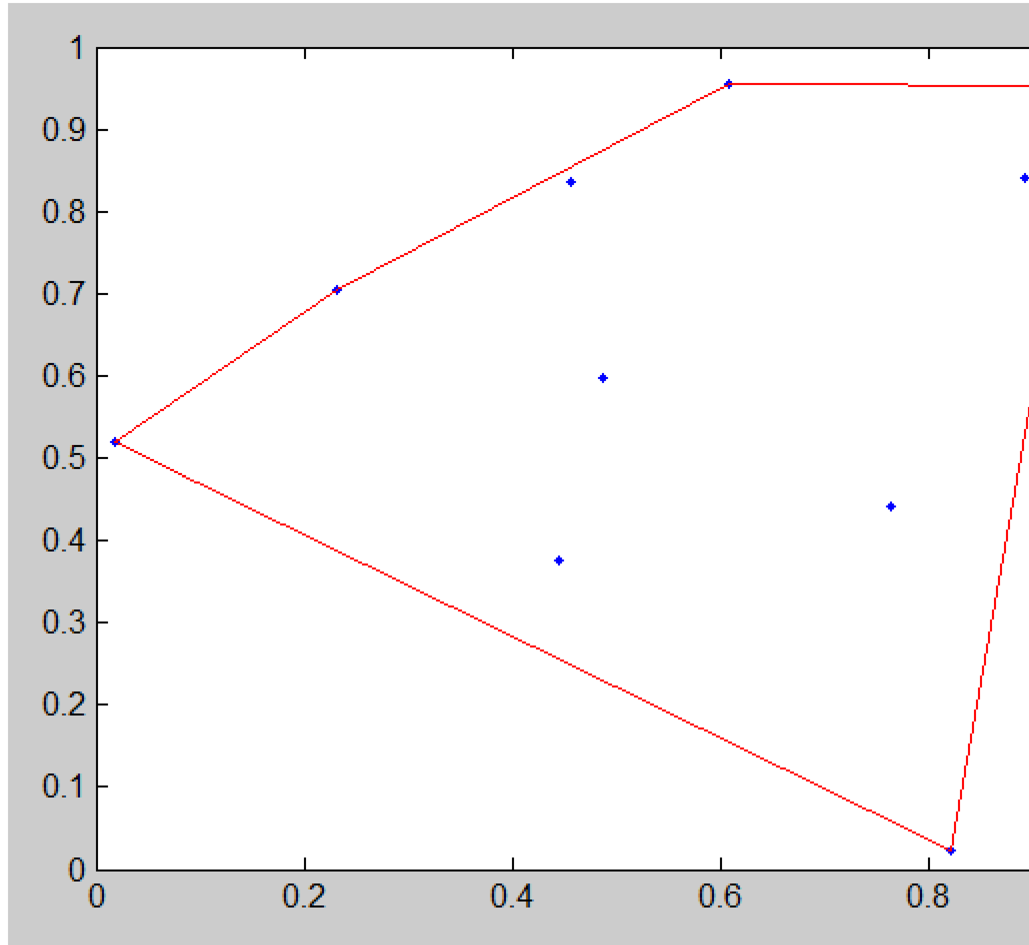
```
k = convexHull(DT)
```

```
k =

     1
     3
     2
     8
     9
     1
```

Plot the points and highlight the convex hull in red.

```
plot(DT.Points(:,1),DT.Points(:,2), '.','markersize',10);
hold on;
plot(DT.Points(k,1),DT.Points(k,2),'r');
hold off;
```



Convex Hull in 3-D Space

Use `convexHull` to calculate the convex hull of a set of random points within a unit cube.

Create a Delaunay triangulation from a set of random points.

```
P = gallery('uniformdata',[25,3],1);
```

```
DT = delaunayTriangulation(P);
```

Calculate the convex hull and the volume bounded by the convex hull.

```
[K,v] = convexHull(DT);
```

Examine the volume.

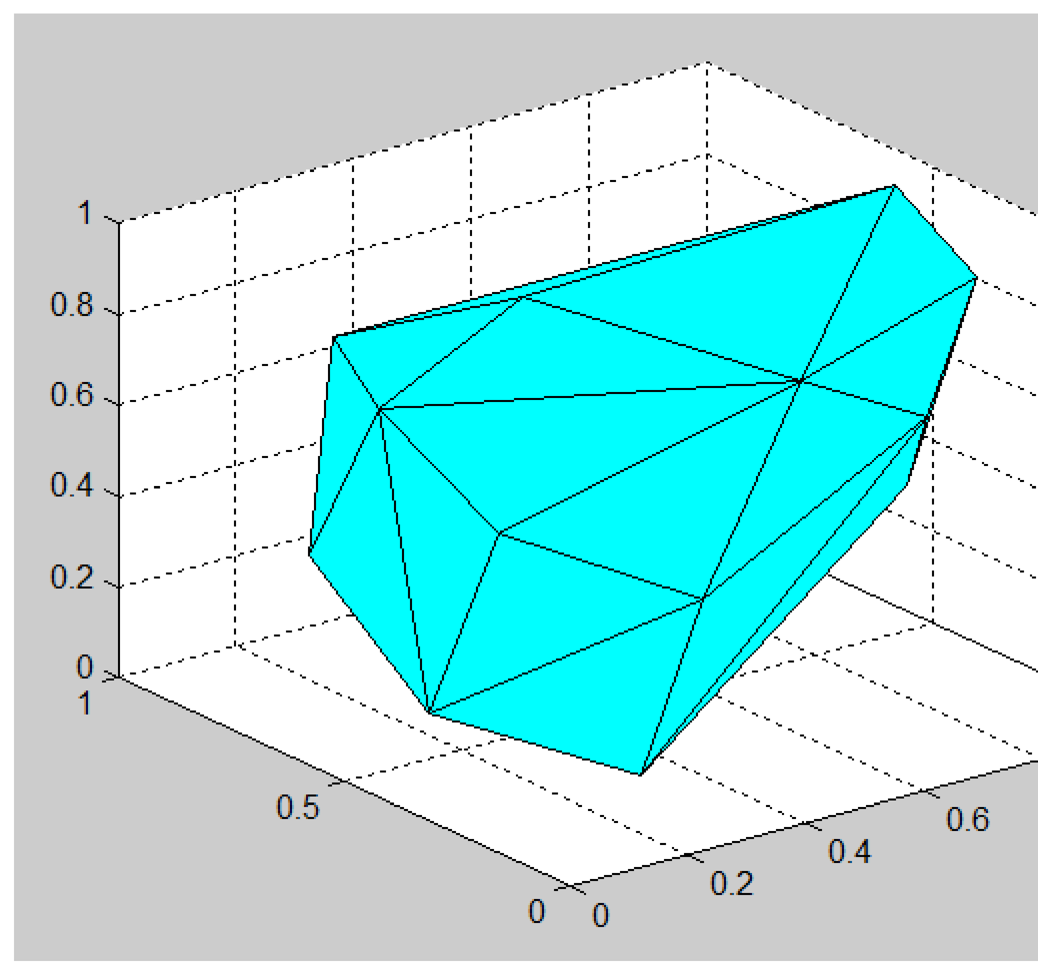
```
v
```

```
v =

    0.3561
```

Plot the convex hull.

```
trisurf(K,DT.Points(:,1),DT.Points(:,2),DT.Points(:,3),...
       'FaceColor','cyan')
```



See Also

`triangulation` | `convhulln` | `convhullvoronoiDiagram` |

delaunayTriangulation.isInterior

Purpose

Test if triangle is in interior of 2-D constrained Delaunay triangulation

Syntax

`tf = isInterior(DT)`

Description

`tf = isInterior(DT)` returns an array of logical values that indicate whether the triangles in a constrained Delaunay triangulation are inside the bounded geometric domain. A triangle, `DT.ConnectivityList(j,:)`, is classified as inside the domain when `tf(j)` is `true`. Otherwise, the triangle outside the domain.

Input Arguments

DT

A 2-D `delaunayTriangulation` that has a set of constrained edges that define a bounded geometric domain.

Output Arguments

tf

Logical values, returned as a column vector. Element `tf(j)` is `true` when the triangle whose ID is `j` is inside the domain of `DT`.

Definitions

Triangle ID

A row number of the matrix, `DT.ConnectivityList`. You use this ID to refer a specific triangle.

Examples

Find and Plot Triangles within a Boundary

Create a geometric domain whose shape is a square frame.

```
outerprofile = [-5 -5; -3 -5; -1 -5;  1 -5;
                 3 -5;  5 -5;  5 -3;  5 -1;
                 5  1;  5  3;  5  5;  3  5;
                 1  5; -1  5; -3  5; -5  5;
                -5  3; -5  1; -5 -1; -5 -3];

innerprofile = outerprofile.*0.5;
profile = [outerprofile; innerprofile];
```

Define the edge constraints.

```
outercons = [(1:19)' (2:20)'; 20 1;];
innercons = [(21:39)' (22:40)'; 40 21];
C = [outercons; innercons];
```

Create the constrained Delaunay triangulation.

```
DT = delaunayTriangulation(profile,C);
```

Plot the triangulation.

```
subplot(1,2,1);
triplot(DT);
```

Highlight the inner square in red.

```
hold on;
plot(DT.Points(innercons',1),DT.Points(innercons',2),...
     '-r','LineWidth',2);
```

Highlight the outer square in red and resize the *x* and *y* axes to make the plot square.

```
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...
     '-r','LineWidth', 2);
axis equal;
```

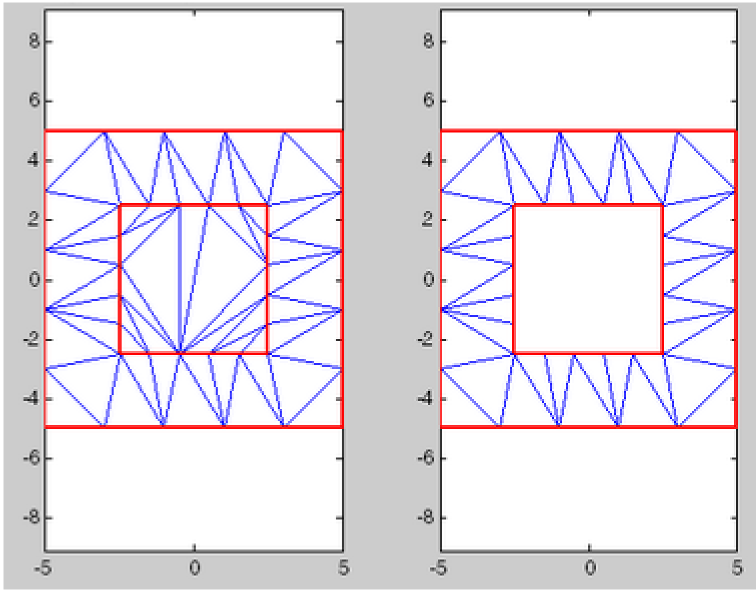
Plot only the triangles that lie inside of the domain.

```
hold off;
subplot(1,2,2);
inside = isInterior(DT);
triplot(DT.ConnectivityList(inside, :),DT.Points(:,1),DT.Points(:,2));
```

Highlight the inner and outer squares in red.

```
hold on;
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...
```

```
     '-r','LineWidth', 2);
plot(DT.Points(innercons',1),DT.Points(innercons',2), ...
     '-r','LineWidth', 2);
axis equal;
hold off;
```



See Also `triangulation` |

Purpose

Vertex closest to specified location

Syntax

```
vi = nearestNeighbor(DT,QP)
vi = nearestNeighbor(DT,qx,qy)
vi = nearestNeighbor(DT,qx,qy,qz)
[vi,d] = nearestNeighbor( ___ )
```

Description

`vi = nearestNeighbor(DT,QP)` returns the IDs of the vertices closest to the query points in `QP`. Each row in matrix `QP` contains the *x*, *y*, (and possibly *z*) coordinates of a query point.

`vi = nearestNeighbor(DT,qx,qy)` specifies the *x* and *y* coordinates of the query points in 2-D as separate column vectors.

`vi = nearestNeighbor(DT,qx,qy,qz)` specifies the *x*, *y*, and *z* coordinates of the query points in 3-D as separate column vectors.

`[vi,d] = nearestNeighbor( ___ )` also returns the Euclidean distance between each query point and its nearest neighbor. You can specify both output arguments with any of the previous syntaxes.

`nearestNeighbor` does not support constrained Delaunay triangulations.

Input Arguments

DT

A Delaunay triangulation, see `delaunayTriangulation`.

QP

Query points, specified as a matrix whose columns are the *x*, *y*, (and possibly *z*) coordinates of the points to query.

qx

Query *x*-coordinates, specified as a column vector containing the *x*-coordinates of the points to query.

qy

Query *y*-coordinates, specified as a column vector containing the *y*-coordinates of the points to query.

qz

Query *z*-coordinates, specified as a column vector containing the *z*-coordinates of the points to query.

Output Arguments

vi

Vertex IDs of nearest neighbor, returned as a column vector. `vi(j)` is the "Vertex ID" on page 1-1322 of the nearest neighbor to the query point `QP(j)`.

d

Distance to nearest neighbor, returned as a column vector the same length as `vi`. Each value in `d` is the Euclidean distance between a query point and its nearest neighbor.

Definitions

Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Nearest Neighbors of Query Points in 2-D

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);
y = gallery('uniformdata',[20 1],1);
DT = delaunayTriangulation(x,y);
```

Define two query points.

```
QP = [0.25 0.25; 0.5 0.5];
```

Find the nearest neighbors to the query points and the distances between them.

```
[vi,d] = nearestNeighbor(DT,QP);
```

Examine the vertex IDs of the nearest neighbors.

```
vi
```

```
vi =

    10
     4
```

Examine the coordinates of the nearest neighbors.

```
DT.Points(vi,:)
```

```
ans =

    0.4447    0.3759
    0.4860    0.5982
```

Examine the Euclidean distance between each query point and its nearest neighbor.

```
d
```

```
d =

    0.2319
    0.0992
```

See Also

triangulation | pointLocation |

delaunayTriangulation.pointLocation

Purpose

Triangle or tetrahedron containing specified location

Syntax

```
ti = pointLocation(DT,QP)
ti = pointLocation(DT,qx,qy)
ti = pointLocation(DT,qx,qy,qz)
[ti,B] = pointLocation( ___ )
```

Description

`ti = pointLocation(DT,QP)` returns the enclosing triangles or tetrahedra for each query point in `QP`. Each row in matrix `QP` contains the *x*, *y*, (and possibly *z*) coordinates of a query point.

`ti = pointLocation(DT,qx,qy)` specifies the *x* and *y* coordinates of the query points in 2-D as separate column vectors.

`ti = pointLocation(DT,qx,qy,qz)` specifies the *x*, *y*, *z* coordinates of the query points in 3-D as separate column vectors.

`[ti,B] = pointLocation( ___ )` also returns the barycentric coordinates of each query point with respect to its enclosing triangle or tetrahedron. You can specify both output arguments with any of the previous syntaxes.

Input Arguments

DT

A Delaunay triangulation, see `delaunayTriangulation`.

QP

Query points, specified as a matrix whose columns are the *x*, *y*, (and possibly *z*) coordinates of the points to query.

qx

Query *x*-coordinates, specified as a column vector containing the *x*-coordinates of the points to query.

qy

Query *y*-coordinates, specified as a column vector containing the *y*-coordinates of the points to query.

qz

Query *z*-coordinates, specified as a column vector containing the *z*-coordinates of the points to query.

Output Arguments

ti

IDs of enclosing triangles or tetrahedra, returned as a column vector. Each element in `ti` is the ID of a triangle or tetrahedron that encloses a query point. `ti(k)` encloses the `k`th query point.

`pointLocation` returns `NaN` values for any points outside the convex hull.

B

Barycentric coordinates, returned as matrix. The values at `B(j,:)` are the barycentric coordinates of the `j`th query point with respect to `ti(j)`.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `DT.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

Find Enclosing Triangles in 2-D

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);
y = gallery('uniformdata',[20 1],1);
DT = delaunayTriangulation(x,y);
```

Define two query points.

```
QP = [0.25 0.25; 0.5 0.5];
```

Find the IDs of the enclosing triangles for each query point.

```
ti = pointLocation(DT,QP)
```

```
ti =
```

```
     8
     7
```

Examine the connectivity of the enclosing triangles.

```
DT.ConnectivityList(ti,:)

ans =

    19    15     8
     4    10     6
```

Find Enclosing Tetrahera and Barycentric Coordinates in 3-D

Create a 3-D Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);
y = gallery('uniformdata',[20 1],1);
z = gallery('uniformdata',[20 1],2);
DT = delaunayTriangulation(x,y,z);
```

Find the tetrahedra that enclose the query points and calculate the barycentric coordinates of the query points.

```
QP = [0.7 0.6 0.3; 0.5 0.5 0.5];
[ti,B] = pointLocation(DT,QP)

ti =

    57
    56

B =

    0.2796    0.0184    0.5286    0.1734
    0.3687    0.0149    0.5343    0.0821
```

`triangulation` | `nearestNeighbor` |

delaunayTriangulation.voronoiDiagram

Purpose

Voronoi diagram

Syntax

`[V,R] = voronoiDiagram(DT)`

Description

`[V,R] = voronoiDiagram(DT)` returns the Voronoi vertices, `V`, and the Voronoi regions, `R`, of the points, `DT.Points`.

The *Voronoi diagram* of a set of points, such as `DT.Points`, decomposes the space around each point, `DT.Points(j,:)`, into a region of influence, `R{j}`. Locations within the region, `R{j}`, are closer to point `j` than any other point in `DT.Points`. The region of influence is called the *Voronoi region*. The collection of all the Voronoi regions is the Voronoi diagram.

The Voronoi regions associated with points that lie on the convex hull of `DT.Points` are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in `V`.

Input Arguments

DT

A Delaunay triangulation, see `delaunayTriangulation`.

Output Arguments

V

Voronoi vertices, returned as a matrix. Each row of `V` contains the coordinates of a Voronoi vertex.

R

Voronoi regions, returned as a vector cell array the same length as `DT.Points`. The elements of `R` are row numbers of `V`. The coordinates of the Voronoi vertices bounding a region are `V(R{j},:)`. The Voronoi region associated with the point `DT.Points(j)` is `R{j}`.

Examples

Compute the Voronoi Diagram of a 2-D Triangulation

Create a Delaunay triangulation from a set of points.

```
P = [ 0.5    0
      0      0.5
```

```
     -0.5   -0.5
     -0.2   -0.1
     -0.1    0.1
      0.1   -0.1
      0.1    0.1 ];
DT = delaunayTriangulation(P);
```

Calculate the Voronoi vertices and regions.

```
[V,R] = voronoiDiagram(DT);
```

Examine the connectivity of the Voronoi region associated with the third point in the triangulation.

```
R{3}

ans =

     1    10     7     4
```

Examine the coordinates of the Voronoi vertices bounding the region.

```
V(R{3},:)

ans =

       Inf       Inf
    0.7000   -1.6500
   -0.0500   -0.5250
   -1.7500    0.7500
```

The `Inf` values indicate that the region contains points on the convex hull.

`triangulation` | `convexHull` | `voronoi` | `voronoin`

Purpose

Remove files or graphics objects

Alternatives

As an alternative to the `delete` function, use the Current Folder browser.

Syntax

```
delete('fileName1', 'filename2', ...)
delete(h)
delete(handle_array)
delete fileName
```

Description

`delete('fileName1', 'filename2', ...)` deletes the files `fileName1`, `fileName2`, and so on, from the disk. `fileName` is a string and can be an absolute path or a path relative to the current folder. `fileName` also can include wildcards (*).

`delete(h)` deletes the graphics object with handle `h`. `h` can also be a vector or matrix of handles. Delete multiple objects by appending their handles as additional arguments, separated by commas. The function deletes objects without requesting verification, even if when they are windows.

`delete(handle_array)` is a method of the `handle` class. It removes from memory the handle objects referenced by `handle_array`.

When deleted, any references to the objects in `handle_array` become invalid. To remove the handle variables, use the `clear` function.

`delete fileName` is the command syntax. Delete multiple files by appending filenames, separated by spaces. When filenames contain space characters, you must use the functional form.

As `delete` does not ask for confirmation, to avoid accidentally losing files or graphics objects, make sure to specify accurately the items to delete. To move files to a different location when running `delete`, use the **General** preference for **Deleting files**, or the `recycle` function.

The `delete` function deletes files and graphics objects only. To delete folders, use `rmdir`.

Examples

Delete all files with a `.mat` extension in the `../mytests/` folder:

```
delete('../mytests/*.mat')
```

Create a figure and an axes, and then delete the axes:

```
hf = figure, ha = axes

hf =
     1
ha =
  170.0332

delete(ha)
```

The axes is deleted, but the figure remain. The axes handle `ha` remains in the workspace but no longer points to an object.

See Also

`dir` | `recycle` | `rmdir`

How To

- "Deleting Files and Folders Using Functions"
- "Path Names in MATLAB"

delete (COM)

Purpose

Remove COM control or server

Syntax

```
h.delete
delete(h)
```

Description

`h.delete` releases all interfaces derived from the specified COM server or control, and then deletes the server or control itself. This is different from releasing an interface, which releases and invalidates only that interface.

`delete(h)` is an alternate syntax.

Tips

COM functions are available on Microsoft Windows systems only.

See Also

`release` | `save (COM)` | `load (COM)` | `actxcontrol` | `actxserver`

Purpose

Remove file on FTP server

Syntax

```
delete(ftpobj,filename)
```

Description

`delete(ftpobj,filename)` removes the specified file from the current folder on the FTP server associated with `ftpobj`.

Input Arguments

ftpobj

FTP object created by `ftp`.

filename

String enclosed in single quotation marks that specifies the name of the file to delete.

Examples

Suppose that a hypothetical host, `ftp.testsite.com`, contains `myfile.m`. Connect to the server and delete the file:

```
test=ftp('ftp.testsite.com');
delete(test,'myfile.m');
```

See Also

`rmdir` | `ftp`

delete (handle)

Purpose Handle object destructor

Syntax

```
delete(h)
```

Description

`delete(h)` deletes a handle object, but does not clear the handle variable from the workspace. The handle variable is not valid once the handle object has been deleted.

A subclass of `handle` can implement a method named `delete` to perform cleanup tasks just before MATLAB destroys the handle object. MATLAB calls the `delete` method of any handle object (if it exists) when the object is destroyed. `h` is a scalar handle object.

A `delete` method should not generate errors or create new handles to the object being destroyed. If the `delete` method has a different signature (having output arguments or more than one input argument) it is not called when the handle objects is destroyed. See "Handle Class Destructor" information on defining destructors for `handle` subclasses.

See Also

`handle` | `(handle) isvalid`

Purpose

Remove serial port object from memory

Syntax

```
delete(obj)
```

Description

`delete(obj)` removes `obj` from memory, where `obj` is a serial port object or an array of serial port objects.

Tips

When you delete `obj`, it becomes an *invalid* object. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command. If multiple references to `obj` exist in the workspace, then deleting one reference invalidates the remaining references.

If `obj` is connected to the device, it has a `Status` property value of `open`. If you issue `delete` while `obj` is connected, then the connection is automatically broken. You can also disconnect `obj` from the device with the `fclose` function.

If you use the `help` command to display help for `delete`, then you need to supply the pathname shown below.

```
help serial/delete
```

Examples

This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, disconnects `s` from the device, removes `s` from memory using `delete`, and then removes `s` from the workspace using `clear`.

```
s = serial('COM1');
fopen(s)
fprintf(s,'*IDN?')
idn = fscanf(s);
fclose(s)
delete(s)
clear s
```

See Also

`clear` | `fclose` | `isvalid` | `Status`

delete (timer)

Purpose Remove timer object from memory

Syntax

```
delete(obj)
```

Description

`delete(obj)` removes the timer object, `obj`, from memory. If `obj` is an array of timer objects, `delete` removes all the objects from memory.

When you delete a timer object, it becomes invalid and cannot be reused. Use the `clear` command to remove invalid timer objects from the workspace.

If multiple references to a timer object exist in the workspace, deleting the timer object invalidates the remaining references. Use the `clear` command to remove the remaining references to the object from the workspace.

See Also

`clear` | `isvalid(timer)` | `timer`

Purpose

Remove custom property from COM object

Syntax

```
h.deleteproperty('propertyname')
deleteproperty(h,'propertyname')
```

Description

`h.deleteproperty('propertyname')` deletes the property specified in the string `propertyname` from the custom properties belonging to object or interface `h`.

`deleteproperty(h,'propertyname')` is an alternate syntax.

You can only delete properties created with the `addproperty` function.

COM functions are available on Microsoft Windows systems only.

Examples

Remove a custom property from an instance of the MATLAB sample control:

1. Create an instance of the control:

   ```
   f = figure('position', [100 200 200 200]);
   h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);
   h.get
   ```

   MATLAB displays its properties:

   ```
        Label: 'Label'
       Radius: 20
   ```

2. Add a custom property named `Position` and assign a value:

   ```
   h.addproperty('Position');
   h.Position = [200 120];
   h.get
   ```

   MATLAB displays (in part):

   ```
          Label: 'Label'
         Radius: 20
   ```

```
    Position: [200 120]
```

3 Delete the custom property `Position`:

```
h.deleteproperty('Position');
h.get
```

MATLAB displays the original list of properties:

```
     Label: 'Label'
    Radius: 20
```

See Also

`addproperty` | `get (COM)` | `set (COM)` | `inspect`

Purpose

Remove `tsdata.event` objects from `timeseries` object

Syntax

```
ts = delevent(ts,event)
ts = delevent(ts,events)
ts = delevent(ts,event,n)
```

Description

`ts = delevent(ts,event)` removes the `tsdata.event` object from the `ts.events` property, where `event` is an event name string.

`ts = delevent(ts,events)` removes the `tsdata.event` object from the `ts.events` property, where `events` is a cell array of event name strings.

`ts = delevent(ts,event,n)` removes the `nth` `tsdata.event` object from the `ts.events` property. `event` is the name of the `tsdata.event` object.

Examples

The following example shows how to remove an event from a `timeseries` object:

1. Create a time series.

   ```
   ts = timeseries(rand(5,4))
   ```

2. Create an event object called `'test'` such that the event occurs at time `3`.

   ```
   e = tsdata.event('test',3)
   ```

3. Add the event object to the time series `ts`.

   ```
   ts = addevent(ts,e)
   ```

4. Remove the event object from the time series `ts`.

   ```
   ts = delevent(ts,'test')
   ```

See Also

`addevent` | `timeseries` | `tsdata.event`

delsamplefromcollection

Purpose

Remove sample from `tscollection` object

Syntax

```
tsc = delsamplefromcollection(tsc,'Index',N)
tsc = delsamplefromcollection(tsc,'Value',Time)
```

Description

`tsc = delsamplefromcollection(tsc,'Index',N)` deletes samples from the `tscollection` object tsc. N specifies the indices of the tsc time vector that correspond to the samples you want to delete.

`tsc = delsamplefromcollection(tsc,'Value',Time)` deletes samples from the `tscollection` object tsc. Time specifies the time values that correspond to the samples you want to delete.

See Also

`addsampletocollection` | `tscollection`

Purpose

Access product examples in Help browser

Syntax

```
demo
demo type
demo type name
```

Description

`demo` displays the list of MATLAB examples in the Help browser.

`demo type` lists the examples for the specified product. Valid values for `type` are `matlab` or `simulink`.

`demo type name` lists the examples for products other than MATLAB or Simulink. Valid values for `type` include `matlab`, `simulink`, `toolbox`, or `blockset`.

Input Arguments

type - Product name or type

`matlab` (default) | `simulink` | `toolbox` | `blockset`

Product name or type, specified as one of these strings: `matlab`, `simulink`, `toolbox`, or `blockset`. For products other than MATLAB or Simulink, you must also specify a `name` input that corresponds to the product name.

name - Product name other than MATLAB or Simulink

string

Product name other than MATLAB or Simulink, specified as a string. If `name` requires multiple words, enclose it in single quotes.

On non-English systems, `name` sometimes uses the localized language.

Examples

MATLAB Examples

```
demo matlab
```

Statistics Toolbox™ Examples

```
demo toolbox statistics
```

Communications System Toolbox™ Examples

```
demo toolbox 'communications system'
```

Simulink Control Design™ Examples

```
demo simulink 'simulink control design'
```

Tips

- To access third-party and custom examples without using the `demo` command, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

`echodemo` | `grabcode` | `help` | `doc`

Purpose

List dependent folders for function or P-file

Syntax

```
list = depdir('file_name')
[list, prob_files, prob_sym,
   prob_strings] = depdir('file_name')
[...] = depdir('file_name1', 'file_name2',...)
```

Description

The `depdir` function lists the folders of all the functions that a specified function or P-file needs to operate. This function is useful for finding all the folders that need to be included with a run-time application and for determining the run-time path.

`list = depdir('file_name')` creates a cell array of strings containing the folders of all the function and P-files that `file_name.m` or `file_name.p` uses. This includes the second-level files that are called directly by `file_name`, as well as the third-level files that are called by the second-level files, and so on.

`[list, prob_files, prob_sym, prob_strings] = depdir('file_name')` creates three additional cell arrays containing information about any problems with the `depdir` search. `prob_files` contains filenames that `depdir` was unable to parse. `prob_sym` contains symbols that `depdir` was unable to find. `prob_strings` contains callback strings that `depdir` was unable to parse.

`[...]  = depdir('file_name1', 'file_name2',...)` performs the same operation for multiple files. The dependent folders of all files are listed together in the output cell arrays.

Examples

```
list = depdir('mesh')
```

See Also

`depfun`

depfun

Purpose

List dependencies of function or P-file

Syntax

```
list = depfun(fun)
[list,builtins] = depfun(fun)
[list,builtins,classes] = depfun(fun)
[list,builtins,classes,prob_files] = depfun(fun)
[list,builtins,classes,prob_files,~,
   eval_strings] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,
   called_from] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,called_from,
   opaque_classes] = depfun(fun)

___ = depfun(fun1,...,funN)

___ = depfun(___,option1,...,optionM)
```

Description

`list = depfun(fun)` returns the paths of MATLAB program files that `fun` requires to run, where `fun` is a function, a P-file, or a figure file for a user interface. The output list includes second-level functions that `fun` calls directly, functions that the second-level functions call, and so on. The `depfun` function also displays a report in the Command Window.

Note

- `depfun` does not always list all dependent files. For example, `depfun` does not list files hidden in callbacks or files whose names are constructed dynamically for evaluation.
- The output list often includes extra files that are not called when the function is actually evaluated.
- If `depfun` returns a parse error for any of the required functions, then the rest of the output of `depfun` might be incomplete. Correct the problematic files and invoke `depfun` again.

`[list,builtins] = depfun(fun)` returns the built-in functions that `fun` requires.

`[list,builtins,classes] = depfun(fun)` returns the MATLAB classes that `fun` requires.

`[list,builtins,classes,prob_files] = depfun(fun)` returns the files that `depfun` cannot parse, find, or access. If there are problematic files (that is, if `prob_files` is not empty), then the rest of the output of `depfun` might be incomplete. Correct the problematic files, and then invoke `depfun` again.

`[list,builtins,classes,prob_files,~,eval_strings] = depfun(fun)` returns a list of files that contain calls to `eval` or related functions (`evalin`, `feval`, or `evalc`). These calls potentially use functions that are not in `list`.

The fifth output argument for `depfun` is not implemented, and returns an empty structure array. To request arguments later in the list, use the tilde symbol (~) as a placeholder. The tilde suppresses the creation of an extra, empty variable.

`[list,builtins,classes,prob_files,~,eval_strings,called_from] = depfun(fun)` returns a cell array of indices that maps each function in `list` to the set of functions that call it. That is, `list{called_from{k}}` returns the paths to the functions that call the function in `list{k}`.

`[list,builtins,classes,prob_files,~,eval_strings,called_from,opaque_cl = depfun(fun)` returns the opaque classes that `fun` requires, such as Java or COM classes.

___ = depfun(fun1,...,funN) returns the functions required for multiple functions fun1,...,funN. You can request any of the outputs from the previous syntaxes.

___ = depfun(___,option1,...,optionM) modifies the output as described by the specified options. For example, specify '-toponly' to list only the functions that fun calls directly. You can precede the options with one or more function names.

Input Arguments

fun - Function name

string | cell array of strings

Function name, specified as a string or a cell array of strings.

fun must be on the MATLAB path, as determined by the which function. If the path contains any relative folders, then files in those folders also will have a relative path in the output.

Example: 'plot.m'

Example: 'plot.m','mesh.m'

Example: {'plot.m','mesh.m'}

Data Types
char | cell

option - Reporting option

'-toponly' | '-verbose' | '-quiet' | '-print'

Reporting option, specified as one of the following strings.

Option	Description
'-toponly'	Identify only the files used directly by the specified function(s), fun.
'-verbose'	Display additional internal messages.
'-quiet'	Display only error and warning messages, and not a summary report.

Option	Description
`'-print',filename`	Print a full report to the specified file.
`'-all'`	Display all outputs in the report, but return only the specified output arguments.
`'-expand'`	Include both indices and full paths in an exported report for the `call` or `called_from` list. Requires the `'-print'` option. This information does not appear in the Command Window report.
`'-calltree'`	Replaces the `called_from` list with a list of functions that each file calls, as derived from the `called_from` list.

Example: `'-print','myreport.txt'`

Data Types
`char`

Output Arguments

list - Paths to required files
cell array of strings

Paths to required files, returned as a cell array of strings.

builtins - Required MATLAB built-in functions
cell array of strings

Required MATLAB built-in functions, returned as a cell array of strings.

classes - Required MATLAB classes
cell array of strings

Required MATLAB classes, returned as a cell array of strings.

prob_files - Files that `depfun` cannot parse or access
structure

Files that `depfun` cannot parse or access, returned as a structure with these fields:

- `name` — Path to the file
- `listindex` — Index of the file in `list`
- `errmsg` — Error message that describes the problem
- `errid` — Error identifier, if present

eval_strings - Files that call evaluation functions
cell array of strings

Files that call evaluation functions, returned as a cell array of strings.

called_from - Indices to files that call each function in `list`
cell array

Indices to files that call each function in `list`, returned as a cell array. Each element of the cell array is a numeric array of indices that correspond to elements in `list`. The `list` and `called_from` outputs have the same length.

opaque_classes - Paths to opaque classes
cell array of strings

Paths to opaque classes, such as Java or COM classes, returned as a cell array of strings.

Examples

Identify Required Functions

Identify the MATLAB program files that `strtok.m` requires to run.

```
fun = 'strtok.m';
list = depfun(fun);
```

MATLAB displays a summary report in the Command Window and stores the list of files in variable `list`.

Identify Top-Level Dependencies Only

List only the program files that `strtok.m` calls directly.

```
fun = 'strtok.m';
list = depfun(fun,'-toponly')
```

```
==========================================================
depfun report summary:(top only)
----------------------------------------------------------
-> trace list:           2 files  (total)
                         1 files  (total arguments)
                         0 files  (arguments off MATLABPATH)
                         0 files  (argument duplicates on MATLABPATH)
----------------------------------------------------------
Notes: 1. Use argument  '-quiet' to not print this summary.
       2. Use arguments '-print','file' to produce a full
          report in file.
       3. Use argument  '-all' to display all possible
          left hand side arguments in the report(s).
==========================================================

list =

    'matlabroot\toolbox\matlab\strfun\strtok.m'
    'matlabroot\toolbox\matlab\strfun\@cell\strtok.m'
```

Determine Which File Invokes Each Function

One of the functions that `strtok.m` depends upon is `num2cell`. Determine which file in the dependency list calls `num2cell`.

Identify the functions that `strtok.m` requires (`list`) and the files that invoke each of those functions (`called_from`).

```
fun = 'strtok.m';
[list,builtins,classes,prob_files,~,eval_strings,called_from] = depfun
```

Find the index for `num2cell` within the dependency list.

```
num2cell_path = which('num2cell');
num2cell_index = find(ismember(list,num2cell_path))
```

```
num2cell_index =
     5
```

Identify the file that calls `num2cell`.

```
calls_num2cell = list{called_from{num2cell_index}}
```

```
calls_num2cell =
     matlabroot\toolbox\matlab\elmat\repmat.m
```

See Also

`depdir`

Concepts

- "Identify Program Dependencies"

Purpose

Matrix determinant

Syntax

```
d = det(X)
```

Description

`d = det(X)` returns the determinant of the square matrix `X`.

Tips

Testing singularity using `abs(det(X)) <= tolerance` is not recommended as it is difficult to choose the correct tolerance. The function `cond(X)` can check for singular and nearly singular matrices.

Algorithms

The determinant is computed from the triangular factors obtained by Gaussian elimination

```
[L,U] = lu(A)
s =  det(L)        % This is always +1 or -1
det(A) = s*prod(diag(U))
```

Examples

The statement `A = [1 2 3; 4 5 6; 7 8 9]`

produces

```
A =
     1     2     3
     4     5     6
     7     8     9
```

This happens to be a singular matrix, so `det(A)` produces a very small number. Changing `A(3,3)` with `A(3,3) = 0` turns `A` into a nonsingular matrix. Now `d = det(A)` produces `d = 27`.

See Also

`cond` | `condest` | `inv` | `lu` | `rref` | `mldivide` | `Arithmetic Operators \,/`

detrend

Purpose

Remove linear trends

Syntax

```
y = detrend(x)
y = detrend(x,'constant')
y = detrend(x,'linear',bp)
```

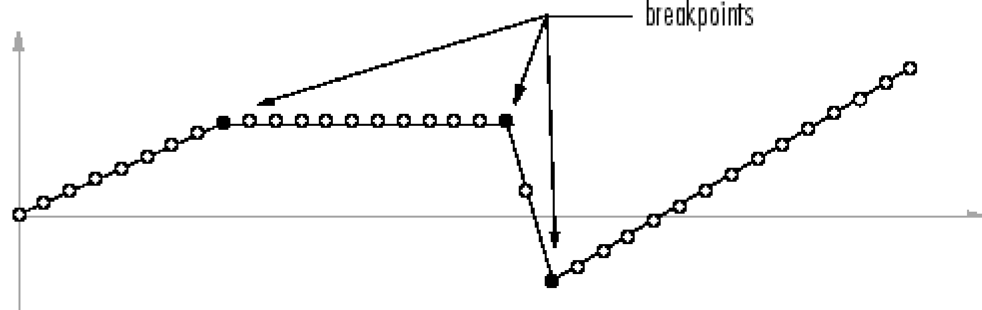
Description

`detrend` removes the mean value or linear trend from a vector or matrix, usually for FFT processing.

`y = detrend(x)` removes the best straight-line fit from vector `x` and returns it in `y`. If `x` is a matrix, `detrend` removes the trend from each column.

`y = detrend(x,'constant')` removes the mean value from vector `x` or, if `x` is a matrix, from each column of the matrix.

`y = detrend(x,'linear',bp)` removes a continuous, piecewise linear trend from vector `x` or, if `x` is a matrix, from each column of the matrix. Vector `bp` contains the indices of the breakpoints between adjacent linear segments. The breakpoint between two segments is defined as the data point that the two segments share.



`detrend(x,'linear')`, with no breakpoint vector specified, is the same as `detrend(x)`.

Examples

```
sig = [0 1 -2 1 0 1 -2 1 0];      % signal with no linear trend
trend = [0 1 2 3 4 3 2 1 0];      % two-segment linear trend
```

```
x = sig+trend;                      % signal with added trend
y = detrend(x,'linear',5)           % breakpoint at 5th element

y =

   -0.0000
    1.0000
   -2.0000
    1.0000
    0.0000
    1.0000
   -2.0000
    1.0000
   -0.0000
```

Note that the breakpoint is specified to be the fifth element, which is the data point shared by the two segments.

Algorithms

`detrend` computes the least-squares fit of a straight line (or composite line for piecewise linear trends) to the data and subtracts the resulting function from the data. To obtain the equation of the straight-line fit, use `polyfit`.

See Also

`polyfit`

deval

Purpose

Evaluate solution of differential equation problem

Syntax

```
sxint = deval(sol,xint)
sxint = deval(xint,sol)
sxint = deval(sol,xint,idx)
sxint = deval(xint,sol,idx)
[sxint, spxint] = deval(...)
```

Description

`sxint = deval(sol,xint)` and `sxint = deval(xint,sol)` evaluate the solution of a differential equation problem. `sol` is a structure returned by one of these solvers:

- An initial value problem solver (`ode45`, `ode23`, `ode113`, `ode15s`, `ode23s`, `ode23t`, `ode23tb`, `ode15i`)
- A delay differential equations solver (`dde23`, `ddesd`, or `ddensd`),
- A boundary value problem solver (`bvp4c` or `bvp5c`).

`xint` is a point or a vector of points at which you want the solution. The elements of `xint` must be in the interval `[sol.x(1),sol.x(end)]`. For each `i`, `sxint(:,i)` is the solution at `xint(i)`.

`sxint = deval(sol,xint,idx)` and `sxint = deval(xint,sol,idx)` evaluate as above but return only the solution components with indices listed in the vector `idx`.

`[sxint, spxint] = deval(...)` also returns `spxint`, the value of the first derivative of the polynomial interpolating the solution.

Note For multipoint boundary value problems, the solution obtained by `bvp4c` or `bvp5c` might be discontinuous at the interfaces. For an interface point `xc`, `deval` returns the average of the limits from the left and right of `xc`. To get the limit values, set the `xint` argument of `deval` to be slightly smaller or slightly larger than `xc`.

Examples

This example solves the system $y' = \text{vdp1}(t,y)$ using `ode45`, and evaluates and plots the first component of the solution at 100 points in the interval `[0,20]`.

```
sol = ode45(@vdp1,[0 20],[2 0]);
x = linspace(0,20,100);
y = deval(sol,x,1);
plot(x,y);
```

diag

Purpose

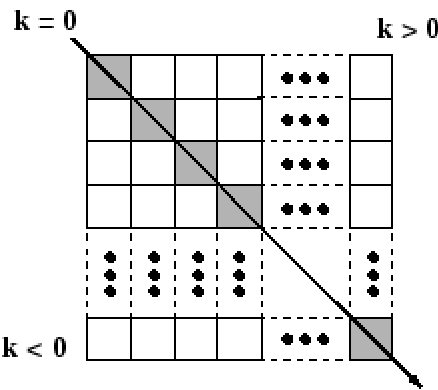
Diagonal matrices and diagonals of matrix

Syntax

```
X = diag(v,k)
X = diag(v)
v = diag(X,k)
v = diag(X)
```

Description

`X = diag(v,k)` when `v` is a vector of `n` components, returns a square matrix `X` of order `n+abs(k)`, with the elements of `v` on the `k`th diagonal. `k = 0` represents the main diagonal, `k > 0` above the main diagonal, and `k < 0` below the main diagonal.



`X = diag(v)` puts `v` on the main diagonal, same as above with `k = 0`.

`v = diag(X,k)` for matrix `X`, returns a column vector `v` formed from the elements of the `k`th diagonal of `X`.

`v = diag(X)` returns the main diagonal of `X`, same as above with `k = 0`.

Tips

`diag(diag(X))` is a diagonal matrix.

`sum(diag(X))` is the trace of `X`.

`diag([])` generates an empty matrix, (`[]`).

`diag(m-by-1,k)` generates a matrix of size `m+abs(k)`-by-`m+abs(k)`.

`diag(1-by-n,k)` generates a matrix of size `n+abs(k)`-by-`n+abs(k)`.

Examples

The statement

```
diag(-m:m)+diag(ones(2*m,1),1)+diag(ones(2*m,1),-1)
```

produces a tridiagonal matrix of order `2*m+1`.

See Also

`spdiags` | `tril` | `triu` | `blkdiag`

dialog

Purpose

Create and display empty dialog box

Syntax

```
h = dialog('PropertyName',PropertyValue,...)
```

Description

`h = dialog('PropertyName',PropertyValue,...)` returns a handle to a dialog box. The dialog box is a figure graphics object with properties recommended for dialog boxes. You can specify any valid figure property value except `DockControls`, which is always `off`.

The properties that `dialog` sets and their values are

Property	Value
'ButtonDownFcn'	'if isempty(allchild(gcbf)), close(gcbf), end'
'Colormap'	[]
'Color'	DefaultUicontrolBackgroundColor
'DockControls'	'off'
'HandleVisibility'	'callback'
'IntegerHandle'	'off'
'InvertHardcopy'	'off'
'MenuBar'	'none'
'NumberTitle'	'off'
'PaperPositionMode'	'auto'
'Resize'	'off'
'Visible'	'on'
'WindowStyle'	'modal'

Note By default, the dialog box is modal. A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

The default `ButtonDownFcn`, `if isempty(allchild(gcbf)), close(gcbf), end`, causes the dialog to terminate itself when clicked as long as it contains no child objects. Replace it with another callback or an empty callback if you do not want this behavior. You can do this only from a script or function if the dialog is modal (the default `WindowStyle`).

Any property you can specify for the `figure` function is valid for this function.

Examples

Create a default modal dialog box:

```
out = dialog;
```

Create a nonmodal dialog box with a name on its title bar:

```
out = dialog('WindowStyle', 'normal', 'Name', 'My Dialog');
```

See Also

`errordlg` | `helpdlg` | `inputdlg` | `listdlg` | `msgbox` | `questdlg` | `warndlg` | `figure` | `uiwait` | `uiresume`

diary

Purpose

Save Command Window text to file

Syntax

```
diary
diary('filename')
diary off
diary on
diary filename
```

Description

The `diary` function creates a log of keyboard input and the resulting text output, with some exceptions (see "Tips" on page 1-1360 for details). The output of `diary` is an ASCII file, suitable for searching in, printing, inclusion in most reports and other documents. If you do not specify `filename`, the MATLAB software creates a file named `diary` in the current folder.

`diary` toggles `diary` mode on and off. To see the status of `diary`, type `get(0,'Diary')`. MATLAB returns either `on` or `off` indicating the `diary` status.

`diary('filename')` writes a copy of all subsequent keyboard input and the resulting output (except it does not include graphics) to the named file, where `filename` is the full pathname or `filename` is in the current MATLAB folder. If the file already exists, output is appended to the end of the file. You cannot use a `filename` called `off` or `on`. To see the name of the `diary` file, use `get(0,'DiaryFile')`.

`diary off` suspends the diary.

`diary on` resumes diary mode using the current filename, or the default filename `diary` if none has yet been specified.

`diary filename` is the unquoted form of the syntax.

Tips

Because the output of `diary` is plain text, the file does not exactly mirror input and output from the Command Window:

- Output does not include graphics (figure windows).
- Syntax highlighting and font preferences are not preserved.

- Hidden components of Command Window output such as hyperlink information generated with `matlab:` are shown in plain text. For example, if you enter the following statement

  ```
  str = sprintf('%s%s', ...
     '<a href="matlab:magic(4)">', ...
     'Generate magic square</a>');
  disp(str)
  ```

  MATLAB displays

  Generate magic square

  However, the diary file, when viewed in a text editor, shows

  ```
  str = sprintf('%s%s', ...
     '<a href="matlab:magic(4)">', ...
     'Generate magic square</a>');
  disp(str)
  <a href="matlab:magic(4)">Generate magic square</a>
  ```

  If you view the output of diary in the Command Window, the Command Window interprets the `<a href ...>` statement and displays it as a hyperlink.

- Viewing the output of `diary` in a console window might produce different results compared to viewing `diary` output in the desktop Command Window. One example is using the `\r` option for the `fprintf` function; using the `\n` option might alleviate that problem.

See Also

`evalc`

How To

- "Command History"

Purpose

Differences and approximate derivatives

Syntax

```
Y = diff(X)
Y = diff(X,n)
Y = diff(X,n,dim)
```

Description

`Y = diff(X)` calculates differences between adjacent elements of `X`.

If `X` is a vector, then `diff(X)` returns a vector, one element shorter than `X`, of differences between adjacent elements:

```
[X(2)-X(1) X(3)-X(2) ... X(n)-X(n-1)]
```

If `X` is a matrix, then `diff(X)` returns a matrix of row differences:

```
[X(2:m,:)-X(1:m-1,:)]
```

In general, `diff(X)` returns the differences calculated along the first non-singleton (`size(X,dim) > 1`) dimension of `X`.

`Y = diff(X,n)` applies `diff` recursively `n` times, resulting in the nth difference. Thus, `diff(X,2)` is the same as `diff(diff(X))`.

`Y = diff(X,n,dim)` is the nth difference function calculated along the dimension specified by scalar `dim`. If order `n` equals or exceeds the length of dimension `dim`, `diff` returns an empty array.

Tips

Since each iteration of `diff` reduces the length of `X` along dimension `dim`, it is possible to specify an order `n` sufficiently high to reduce `dim` to a singleton (`size(X,dim) = 1`) dimension. When this happens, `diff` continues calculating along the next nonsingleton dimension.

Examples

The quantity `diff(y)./diff(x)` is an approximate derivative.

```
x = [1 2 3 4 5];
y = diff(x)
y =
     1     1     1     1
```

```
z = diff(x,2)
z =
     0     0     0
```

Given,

```
A = rand(1,3,2,4);
```

`diff(A)` is the first-order difference along dimension 2.

`diff(A,3,4)` is the third-order difference along dimension 4.

See Also

`gradient` | `prod` | `cumsum` | `sum`

diffuse

Purpose

Calculate diffuse reflectance

Syntax

`R = diffuse(Nx,Ny,Nz,S)`

Description

`R = diffuse(Nx,Ny,Nz,S)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` specifies the direction to the light source. You can specify these directions as three vectors`[x,y,z]` or two vectors `[Theta Phi` (in spherical coordinates).

Lambert's Law: `R = cos(PSI)` where `PSI` is the angle between the surface normal and light source.

See Also

`specular` | `surfnorm` | `surfl`

How To

- "Lighting Overview"

Purpose

List folder contents

Syntax

```
dir
dir name
listing = dir(name)
```

Description

`dir` lists the files and folders in the MATLAB current folder. Results appear in the order returned by the operating system.

`dir name` lists the files and folders that match the string `name`. When name is a folder, `dir` lists the contents of the folder. Specify `name` using absolute or relative path names. You can use wildcards (*).

`listing = dir(name)` returns attributes about `name`.

Tips

- To obtain a list of available drives on Microsoft Windows platforms:

  Use the DOS `net use` command in the Command Window:

  ```
  dos('net use')
  ```

  Or

  ```
  [s,r] = dos('net use')
  ```

  MATLAB returns the results to the character array `r`.

- Short DOS file name support

  The MATLAB `dir` function is consistent with the Microsoft Windows operating system `dir` command in that both support short file names generated by DOS.

- Structure Results for Nonexistent Files

  When you run `dir` with an output argument and the results include a nonexistent file or a file that `dir` cannot query for some other reason, then `dir` returns the following default values:

  ```
  date: ''
  bytes: []
  ```

```
  isdir: 0
  datenum: []
```

The most common occurrence is on UNIX[1] platforms when `dir` queries a file that is a symbolic link, which points to a nonexistent target. A nonexistent target is a target that was moved, removed, or renamed. For example, if `my_file` in `my_dir` is a symbolic link to another file that was deleted, then running

```
r = dir('my_dir')
```

includes this result for `my_file`:

```
r(n) =
  name: 'my_file'
  date: ''
  bytes: []
  isdir: 0
  datenum: []
```

where *n* is the index for `my_file`, found by searching `r` by the `name` field.

Input Arguments

name

A string value specifying a file or folder name.

Output Arguments

listing

Field Name	Description	Class
`name`	File or folder name	char array
`date`	Modification date timestamp	char array

1. UNIX is a registered trademark of The Open Group in the United States and other countries.

Field Name	Description	Class
`bytes`	Size of the file in bytes	double
`isdir`	`1` if name is a folder; `0` if not	logical
`datenum`	Modification date as serial date number. The value is locale-dependent.	double

Examples

View the Contents of a Folder

View the contents of the `matlab/audiovideo` folder:

```
dir(fullfile(matlabroot, 'toolbox/matlab/audiovideo'))
```

Find Information in the Return Structure

Return the folder listing, restricted to files with a `.m` extension, to the variable `av_files`:

```
av_files = dir(fullfile(matlabroot, ...
               'toolbox/matlab/audiovideo/*.m'))
```

MATLAB returns the information in a structure array:

```
av_files =
25x1 struct array with fields:
    name
    date
    bytes
    isdir
    datenum
```

Index into the structure to access a particular item:

```
av_files(3).name
ans =
   audioplayerreg.m
```

– Use the Wildcard Character to Find Multiple Files

View the MAT-files in the current folder that include the term `my_data` by using the wildcard character:

```
dir *my_data*.mat
```

MATLAB returns all file names that match this specification. For instance, it returns the following if they are in the current folder:

```
old_my_data.mat  my_data_final.mat  my_data_test.mat
```

– Exclude Certain Files from the Output

Return the list of files in the current folder, excluding those files that `dir` cannot query:

```
 y = dir;
 y = y(find(~cellfun(@isempty,{y(:).date})));
```

– Find the Date a File Was Modified

To get the serial date number for the date and time a file was last modified, use the `datenum` field of the structure returned by the `dir` command:

```
DirInfo = dir('startup.m');
filedate = DirInfo.datenum
```

Using the `datenum` function to convert the string returned in the `date` field of the structure is not recommended as this can behave differently in different locales.

```
filedate = datenum(DirInfo.date)
```

Alternatives

Use the Current Folder browser to view the list of files in a folder.

How To

- “Working with Files and Folders”

- “Path Names in MATLAB”

FTP.dir

Purpose

View contents of folder on FTP server

Syntax

```
dir(ftpobj)
dir(ftpobj,folder)
details = dir(ftpobj,folder)
```

Description

`dir(ftpobj)` lists the files in current folder on the FTP server associated with `ftpobj`.

`dir(ftpobj,folder)` lists the files in the specified folder.

`details = dir(ftpobj,folder)` returns the results in a structure array that contains the name, modification date, and size of each file.

Input Arguments

ftpobj

FTP object created by `ftp`.

folder

String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use `'..'`.

Output Arguments

details

`m`-by-1 structure array, where `m` is the number of files in the folder. Each element of the structure array contains the following fields:

Field Name	Description	Data Type
`name`	File name	`char`
`date`	Modification date timestamp	`char`
`bytes`	Number of bytes allocated to the file	`double`

Field Name	Description	Data Type
isdir	If a folder, isdir = 1, otherwise isdir = 0	logical
datenum	Modification date as serial date number	char

Examples

Connect to the MathWorks FTP server and view the contents:

```
mw=ftp('ftp.mathworks.com');
dir(mw)
```

This code returns:

```
README    incoming  matlab    outgoing  pub       pubs
```

Continuing the previous example, save the folder contents to the structure m, close the connection, and view details about the pub subfolder:

```
m=dir(mw);
close(mw);

m(5)
```

This code returns:

```
ans =
       name: 'pub'
       date: '13-Aug-2008 00:00:00'
      bytes: 512
      isdir: 1
    datenum: 733633
```

See Also

cd | ftp | mkdir | rmdir

disp

Purpose Display text or array

Syntax

```
disp(X)
```

Description

`disp(X)` displays the contents of `X` without printing the variable name. `disp` does not display empty variables.

Input Arguments

X - Variable to display

variable name

Variable to display, specified by the variable name.

Examples

Display Matrix with Column Labels

```
X = gallery('uniformdata',[5 3],0);
disp('     Corn      Oats      Hay')
disp(X)
```

```
     Corn      Oats      Hay
    0.9501    0.7621    0.6154
    0.2311    0.4565    0.7919
    0.6068    0.0185    0.9218
    0.4860    0.8214    0.7382
    0.8913    0.4447    0.1763
```

Display Hyperlink in Command Window

Include the full hypertext string on a single line as input to `disp`.

```
X = '<a href = "http://www.mathworks.com">MathWorks Web Site</a>';
disp(X)
```

```
MathWorks Web Site
```

The `disp` function generates a hyperlink in the Command Window. Click the link to display the MathWorks home page in a MATLAB Web browser.

Display Multiple Items on Same Line

Concatenate strings together using the [] operator. Convert any numeric values to characters using the num2str function.

```
name = 'Alice';   age = 12;
X = [name, ' will be ', num2str(age), ' this year.'];
```

Display the string.

```
disp(X)
```

```
Alice will be 12 this year.
```

You also can use sprintf to create a string. Terminate the command with a semicolon to prevent "str = " from being displayed. Then, use disp to display the string.

```
name = 'Alice';   age = 12;
X = sprintf('%s will be %d this year.', name, age);
disp(X)
```

```
Alice will be 12 this year.
```

Alternatively, use fprintf to create and display the string. Unlike the sprintf function, fprintf does not display the "str = " text. However, you need to end the string with the newline (\n) metacharacter to terminate its display properly.

```
name = 'Alice';   age = 12;
str = fprintf('%s will be %d this year.\n', name, age);
```

```
Alice will be 12 this year.
```

Tips

- The disp function accepts only one input. To display more than one array or string, you can use concatenation or the sprintf or fprintf functions as shown in the Example, “Display Multiple Items on Same Line” on page 1-1373.

See Also

`format` | `int2str` | `num2str` | `rats` | `sprintf` | `fprintf` | `colon (:)`

disp (memmapfile)

Purpose

Information about memmapfile object

Syntax

```
disp(obj)
```

Description

`disp(obj)` displays all properties and their values for `memmapfile` object `obj`.

The MATLAB software also displays this information when you construct a `memmapfile` object or set any of the object's property values, provided you do not terminate the command to do so with a semicolon.

Examples

Construct an object `m` of class `memmapfile`:

```
m = memmapfile('records.dat',                        ...
               'Offset', 2048,                       ...
               'Format', {                           ...
                  'int16'  [2 2] 'model';            ...
                  'uint32' [1 1] 'serialno';         ...
                  'single' [1 3] 'expenses'});
```

Use `disp` to display all the object's current properties:

```
disp(m)
    Filename: 'd:\matlab\records.dat'
    Writable: false
      Offset: 2048
      Format: {'int16' [2 2] 'model'
               'uint32' [1 1] 'serialno'
               'single' [1 3] 'expenses'}
      Repeat: Inf
        Data: 753x1 struct array with fields:
            model
         serialno
         expenses
```

See Also

`memmapfile` | `get (memmapfile)`

disp (MException)

Purpose

Display MException object

Syntax

```
disp(exception)
disp(exception.property)
```

Description

disp(exception) displays all properties (fields) of MException object exception.

disp(exception.property) displays the specified property of MException object exception.

Examples

Using the surf command without input arguments throws an exception. Use disp to display the identifier, message, stack, and cause properties of the MException object:

```
try
   surf
catch exception
   disp(exception)
end

 MException object with properties:

    identifier: 'MATLAB:narginchk:notEnoughInputs'
       message: 'Not enough input arguments.'
         cause: {}
         stack: [1x1 struct]
```

Display only the stack property:

```
disp(exception.stack)
    file: 'C:\Program Files\MATLAB\toolbox\matlab\graph3d\surf.m'
graph3d\surf.m'
    name: 'surf'
    line: 54
```

See Also

`try` | `catch` | `error` | `assert` | `MException` | `getReport(MException)` | `throw(MException)` | `rethrow(MException)` | `throwAsCaller(MException)` | `addCause(MException)` | `isequal(MException)` | `eq(MException)` | `ne(MException)` | `last(MException)`

disp (serial)

Purpose

Serial port object summary information

Syntax

```
obj
disp(obj)
```

Description

`obj` or `disp(obj)` displays summary information for `obj`, a serial port object or an array of serial port objects.

Tips

In addition to the syntax shown above, you can display summary information for `obj` by excluding the semicolon when:

- Creating a serial port object
- Configuring property values using the dot notation

Use the display summary to quickly view the communication settings, communication state information, and information associated with read and write operations.

Examples

The following commands display summary information for the serial port object `s.` on a Windows platform

```
s = serial('COM1')
s.BaudRate = 300
s
```

Purpose

Information about timer object

Syntax

```
disp(obj)
obj
```

Description

`disp(obj)` displays summary information for the timer object, `obj`.

If `obj` is an array of timer objects, `disp` outputs a table of summary information about the timer objects in the array.

`obj`, that is, typing the object name alone, does the same as `disp(obj)`

In addition to the syntax shown above, you can display summary information for `obj` by excluding the semicolon when

- Creating a timer object, using the `timer` function
- Configuring property values using the dot notation

Examples

The following commands display summary information for timer object `t`.

```
t = timer

Timer Object: timer-1

   Timer Settings
      ExecutionMode: singleShot
             Period: 1
           BusyMode: drop
            Running: off

   Callbacks
           TimerFcn: []
           ErrorFcn: []
           StartFcn: []
            StopFcn: []
```

This example shows the format of summary information displayed for an array of timer objects.

```
t2 = timer;
disp(timerfind)

Timer Object Array
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:     Name:
   1       singleShot      1        ''            timer-1
   2       singleShot      1        ''            timer-2
```

See Also

`timer` | `get(timer)`

Purpose

Display text and numeric expressions

Syntax

```
display(X)
```

Description

`display(X)` prints the value of `X`. MATLAB implicitly calls `display` after any variable or expression that is not terminated by a semicolon.

To customize the display of objects, overload the `disp` function instead of the `display` function. `display` calls `disp`.

Examples

Display a Matrix

```
X = magic(3);
display(X)
```

```
X =

     8     1     6
     3     5     7
     4     9     2
```

Input Arguments

X - Input value

variable | expression

Input value, specified as a variable or expression.

See Also

`disp` | `ans` | `sprintf`

Concepts

- "Implement disp Or disp and display"
- "Overloading Functions for Your Class"
- "Relationship Between disp and display"

dither

Purpose

Convert image, increasing apparent color resolution by dithering

Syntax

```
X = dither(RGB, map)
X = dither(RGB, map, Qm, Qe)
BW = dither(I)
```

Description

`X = dither(RGB, map)` creates an indexed image approximation of the RGB image in the array `RGB` by dithering the colors in the colormap `map`. The colormap cannot have more than 65,536 colors.

`X = dither(RGB, map, Qm, Qe)` creates an indexed image from `RGB`, where `Qm` specifies the number of quantization bits to use along each color axis for the inverse color map, and `Qe` specifies the number of quantization bits to use for the color space error calculations. If `Qe < Qm`, dithering cannot be performed, and an undithered indexed image is returned in `X`. If you omit these parameters, `dither` uses the default values `Qm = 5`, `Qe = 8`.

`BW = dither(I)` converts the grayscale image in the matrix `I` to the binary (black and white) image `BW` by dithering.

Class Support

`RGB` can be `uint8`, `uint16`, `single`, or `double`. `I` can be `uint8`, `uint16`, `int16`, `single`, or `double`. All other input arguments must be `double`. `BW` is `logical`. `X` is `uint8`, if it is an indexed image with 256 or fewer colors; otherwise, it is `uint16`.

Algorithms

`dither` increases the apparent color resolution of an image by applying Floyd-Steinberg's error diffusion dither algorithm.

Examples

Read and display the `cameraman` image. Display the image as a gray scale image using `imagesc`.

```
I = imread('cameraman.tif');
figure; imagesc(I);
colormap(gray);
```

Apply dithering to get an indexed image as,

```
BW = dither(I);
figure; imagesc(BW);
colormap(gray);
```

`rgb2ind`

Purpose

Compute divergence of vector field

Syntax

```
div = divergence(X,Y,Z,U,V,W)
div = divergence(U,V,W)
div = divergence(X,Y,U,V)
div = divergence(U,V)
```

Description

`div = divergence(X,Y,Z,U,V,W)` computes the divergence of a 3-D vector field `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`div = divergence(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`div = divergence(X,Y,U,V)` computes the divergence of a 2-D vector field `U`, `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`div = divergence(U,V)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[m,n] = size(U)`.

Examples

This example displays the divergence of vector volume data as slice planes, using color to indicate divergence.

```
load wind
div = divergence(x,y,z,u,v,w);
```

```
h = slice(x,y,z,div,[90 134],59,0);
shading interp
daspect([1 1 1])
axis tight
camlight
set([h(1),h(2)],'ambientstrength',.6)
```

How To

- "Displaying Divergence with Stream Tubes"

Purpose

Read ASCII-delimited file of numeric data into matrix

Syntax

```
M = dlmread(filename)
M = dlmread(filename, delimiter)
M = dlmread(filename, delimiter, R, C)
M = dlmread(filename, delimiter, range)
```

Description

`M = dlmread(filename)` reads the ASCII-delimited numeric data file `filename`, and returns the data in output matrix `M`. The `filename` input is a string enclosed in single quotes. `dlmread` infers the delimiter from the formatting of the file.

`M = dlmread(filename, delimiter)` reads data from the file, using the specified `delimiter`. Use `'\t'` to specify a tab delimiter.

`M = dlmread(filename, delimiter, R, C)` reads data whose upper left corner is at row `R` and column `C` in the file. Values `R` and `C` are zero-based, so that `R=0`, `C=0` specifies the first value in the file.

`M = dlmread(filename, delimiter, range)` reads the range specified by `range = [R1 C1 R2 C2]` where `(R1,C1)` is the upper left corner of the data to read and `(R2,C2)` is the lower right corner. You can also specify the range using spreadsheet notation, such as `range = 'A1..B7'`.

Tips

- All data in the input file must be numeric. `dlmread` does not read files that contain nonnumeric data, even if the specified rows and columns contain only numeric data.
- When `dlmread` infers the delimiter from the formatting of the file, it treats repeated white spaces as a single delimiter. By contrast, if you specify a delimiter, `dlmread` treats any repeated delimiter character as a separate delimiter.
- If you want to specify an `R`, `C`, or `range` input, but not a `delimiter`, set the `delimiter` argument to the empty string, (two consecutive single quotes with no spaces in between, `''`). For example,

  ```
  M = dlmread('myfile.dat', '', 5, 2)
  ```

In this case, `dlmread` treats repeated white spaces as a single delimiter.

- `dlmread` fills empty delimited fields with zero. If each line ends with a nonspace delimiter, such as a semicolon, the output matrix contains an additional last column of zeros.
- `dlmread` imports any complex number as a whole into a complex numeric field. Valid forms for a complex number are

`—<real>—<imag>i|j`	Example: `5.7-3.1i`
`—<imag>i|j`	Example: `-7j`

Embedded white-space in a complex number is invalid and is regarded as a field delimiter.

Examples

Example 1

Export a 5-by-8 test matrix `M` to a file, and read it with `dlmread`, first with no arguments other than the filename:

```
M = gallery('integerdata', 100, [5 8], 0);
dlmwrite('myfile.txt', M, 'delimiter', '\t')

dlmread('myfile.txt')
ans =
    96    77    62    41     6    21     2    42
    24    46    80    94    36    20    75    85
    61     2    93    92    82    61    45    53
    49    83    74    42     1    28    94    21
    90    45    18    90    14    20    47    68
```

Now read a portion of the matrix by specifying the row and column of the upper left corner:

```
dlmread('myfile.txt', '\t', 2, 3)
ans =
    92    82    61    45    53
```

```
    42     1    28    94    21
    90    14    20    47    68
```

This time, read a different part of the matrix using a range specifier:

```
dlmread('myfile.txt', '\t', 'C1..G4')
ans =
    62    41     6    21     2
    80    94    36    20    75
    93    92    82    61    45
    74    42     1    28    94
```

Example 2

Export matrix `M` to a file, and then append an additional matrix to the file that is offset one row below the first:

```
M = magic(3);
dlmwrite('myfile.txt', [M*5 M/5], ' ')

dlmwrite('myfile.txt', [M/3], '-append', ...
   'roffset', 1, 'delimiter', ' ')

type myfile.txt

40 5 30 1.6 0.2 1.2
15 25 35 0.6 1 1.4
20 45 10 0.8 1.8 0.4

2.6667 0.33333 2
1 1.6667 2.3333
1.3333 3 0.66667
```

When `dlmread` imports these two matrices from the file, it pads the smaller matrix with zeros:

```
dlmread('myfile.txt')
   40.0000    5.0000   30.0000    1.6000    0.2000    1.2000
```

```
   15.0000   25.0000   35.0000    0.6000    1.0000    1.4000
   20.0000   45.0000   10.0000    0.8000    1.8000    0.4000
    2.6667    0.3333    2.0000         0         0         0
    1.0000    1.6667    2.3333         0         0         0
    1.3333    3.0000    0.6667         0         0         0
```

dlmwrite | textscan

Purpose

Write matrix to ASCII-delimited file

Syntax

```
dlmwrite(filename, M)
dlmwrite(filename, M, 'D')
dlmwrite(filename, M, 'D', R, C)
dlmwrite(filename, M, 'attrib1', value1, 'attrib2', value2,
   ...)
dlmwrite(filename, M, '-append')
dlmwrite(filename, M, '-append', attribute-value list)
```

Description

`dlmwrite(filename, M)` writes matrix `M` into an ASCII format file using the default delimiter (,) to separate matrix elements. The data is written starting at the first column of the first row in the destination file, `filename`. The `filename` input is a string enclosed in single quotes.

`dlmwrite(filename, M, 'D')` writes matrix `M` into an ASCII format file, using delimiter `D` to separate matrix elements. The data is written starting at the first column of the first row in the destination file, `filename`. A comma (,) is the default delimiter. Use `\t` to produce tab-delimited files.

`dlmwrite(filename, M, 'D', R, C)` writes matrix `M` into an ASCII format file, using delimiter `D` to separate matrix elements. The data is written starting at row `R` and column `C` in the destination file, `filename`. `R` and `C` are zero based, so that `R=0`, `C=0` specifies the first value in the file, which is the upper left corner.

`dlmwrite(filename, M, 'attrib1', value1, 'attrib2', value2, ...)` is an alternate syntax to those shown above, in which you specify any number of attribute-value pairs in any order in the argument list. Each attribute must be immediately followed by a corresponding value (see the table below).

Attribute	Value
delimiter	Delimiter string to be used in separating matrix elements
newline	Character(s) to use in terminating each line (see table below)
roffset	Offset, in rows, from the top of the destination file to where matrix data is to be written. Offset is zero based.
coffset	Offset, in columns, from the left side of the destination file to where matrix data is to be written. Offset is zero based.
precision	Numeric precision to use in writing data to the file. Specify the number of significant digits or a C-style format string starting in `%`, such as `'%10.5f'`.

This table shows which values you can use when setting the **newline** attribute.

Line Terminator	Description
'pc'	PC terminator (implies carriage return/line feed (`CR`/`LF`))
'unix'	UNIX terminator (implies line feed (`LF`))

`dlmwrite(filename, M, '-append')` appends the matrix to the end of the file. If you do not specify `'-append'`, `dlmwrite` overwrites any existing data in the file.

`dlmwrite(filename, M, '-append', attribute-value list)` accepts a list of `attribute-value` pairs. If you specify `'-append'` and row or column offsets, `dlmwrite` calculates the offset from the end of the original contents of the file.

Tips

The resulting file is readable by spreadsheet programs. Alternatively, if your system has Excel for Windows installed, you can create a spreadsheet using `xlswrite`.

The `dlmwrite` function does not accept cell arrays for the input matrix `M`. To export a cell array that contains only numeric data, use `cell2mat` to convert the cell array to a numeric matrix before calling `dlmwrite`. For other cases, use low-level export functions. For more information, see "Exporting a Cell Array to a Text File" in the MATLAB Data Import and Export documentation.

Examples

Example 1

Export matrix `M` to a file delimited by the tab character and using a precision of six significant digits:

```
dlmwrite('myfile.txt', M, 'delimiter', '\t', ...
         'precision', 6)
type myfile.txt

0.893898      0.284409      0.582792      0.432907
0.199138      0.469224      0.423496      0.22595
0.298723      0.0647811     0.515512      0.579807
0.661443      0.988335      0.333951      0.760365
```

Example 2

Export matrix `M` to a file using a precision of six decimal places and the conventional line terminator for the PC platform:

```
dlmwrite('myfile.txt', m, 'precision', '%.6f', ...
         'newline', 'pc')
type myfile.txt

16.000000,2.000000,3.000000,13.000000
5.000000,11.000000,10.000000,8.000000
9.000000,7.000000,6.000000,12.000000
4.000000,14.000000,15.000000,1.000000
```

Example 3

Export matrix `M` to a file, and then append an additional matrix to the file that is offset one row below the first:

```
M = magic(3);
dlmwrite('myfile.txt', [M*5 M/5], ' ')

dlmwrite('myfile.txt', rand(3), '-append', ...
   'roffset', 1, 'delimiter', ' ')

type myfile.txt

40 5 30 1.6 0.2 1.2
15 25 35 0.6 1 1.4
20 45 10 0.8 1.8 0.4

0.81472 0.91338 0.2785
0.90579 0.63236 0.54688
0.12699 0.09754 0.95751
```

When `dlmread` imports these two matrices from the file, it pads the smaller matrix with zeros:

```
dlmread('myfile.txt')
   40.0000    5.0000   30.0000   1.6000   0.2000   1.2000
   15.0000   25.0000   35.0000   0.6000   1.0000   1.4000
   20.0000   45.0000   10.0000   0.8000   1.8000   0.4000
    0.8147    0.9134    0.2785   0        0        0
    0.9058    0.6324    0.5469   0        0        0
    0.1270    0.0975    0.9575   0        0        0
```

See Also

`dlmread` | `xlswrite`

Purpose

Dulmage-Mendelsohn decomposition

Syntax

```
p = dmperm(A)
[p,q,r,s,cc,rr] = dmperm(A)
```

Description

`p = dmperm(A)` finds a vector `p` such that `p(j) = i` if column `j` is matched to row `i`, or zero if column `j` is unmatched. If `A` is a square matrix with full structural rank, `p` is a maximum matching row permutation and `A(p,:)` has a zero-free diagonal. The structural rank of `A` is `sprank(A) = sum(p>0)`.

`[p,q,r,s,cc,rr] = dmperm(A)` where `A` need not be square or full structural rank, finds the Dulmage-Mendelsohn decomposition of `A`. `p` and `q` are row and column permutation vectors, respectively, such that `A(p,q)` has a block upper triangular form. `r` and `s` are index vectors indicating the block boundaries for the fine decomposition. `cc` and `rr` are vectors of length five indicating the block boundaries of the coarse decomposition.

`C = A(p,q)` is split into a 4-by-4 set of coarse blocks:

```
A11  A12  A13  A14
0      0  A23  A24
0      0    0  A34
0      0    0  A44
```

where `A12`, `A23`, and `A34` are square with zero-free diagonals. The columns of `A11` are the unmatched columns, and the rows of `A44` are the unmatched rows. Any of these blocks can be empty. In the coarse decomposition, the `(i,j)th` block is `C(rr(i):rr(i+1)-1,cc(j):cc(j+1)-1)`. For a linear system,

- `[A11 A12]` is the underdetermined part of the system—it is always rectangular and with more columns and rows, or `0`-by-`0`,
- `A23` is the well-determined part of the system—it is always square, and

- `[A34 ; A44]` is the overdetermined part of the system—it is always rectangular with more rows than columns, or `0`-by-`0`.

The structural rank of `A` is `sprank(A) = rr(4)-1`, which is an upper bound on the numerical rank of `A`. `sprank(A) = rank(full(sprand(A)))` with probability 1 in exact arithmetic.

The `A23` submatrix is further subdivided into block upper triangular form via the fine decomposition (the strongly connected components of `A23`). If `A` is square and structurally nonsingular, `A23` is the entire matrix.

`C(r(i):r(i+1)-1,s(j):s(j+1)-1)` is the `(i,j)`th block of the fine decomposition. The `(1,1)` block is the rectangular block `[A11 A12]`, unless this block is `0`-by-`0`. The `(b,b)` block is the rectangular block `[A34 ; A44]`, unless this block is `0`-by-`0`, where `b = length(r)-1`. All other blocks of the form `C(r(i):r(i+1)-1,s(i):s(i+1)-1)` are diagonal blocks of `A23`, and are square with a zero-free diagonal.

Tips

If `A` is a reducible matrix, the linear system $Ax=b$ can be solved by permuting `A` to a block upper triangular form, with irreducible diagonal blocks, and then performing block backsubstitution. Only the diagonal blocks of the permuted matrix need to be factored, saving fill and arithmetic in the blocks above the diagonal.

In graph theoretic terms, `dmperm` finds a maximum-size matching in the bipartite graph of `A`, and the diagonal blocks of `A(p,q)` correspond to the strong Hall components of that graph. The output of `dmperm` can also be used to find the connected or strongly connected components of an undirected or directed graph. For more information see Pothen and Fan [1].

`sprank`

Purpose

Reference page in Help browser

Syntax

```
doc
doc name
```

Description

`doc` opens the Help browser. If the Help browser is already open, but not visible, then `doc` brings it to the foreground and opens a new tab.

`doc name` displays documentation for the functionality specified by `name`, such as a function, class, block, or product.

- If there is a MathWorks reference page or product page corresponding to `name`, then `doc` displays the page in the Help browser. The `doc` command does not display third-party or custom HTML documentation.
- If there is no reference or product page corresponding to `name`, then `doc` searches for help text in a file named *`name`*`.m`. When help text is available, `doc` displays it in a Web browser.
- If there is no reference or product page and no help text associated with `name`, then `doc` searches the documentation for `name` and displays the search results in the Help browser.

When the browser is already open, the page displays in the most recently used tab.

Input Arguments

name - Name of function, class, block, product folder, or other functionality

string

Name of a function, class, block, product folder, or other functionality, specified as a string. Alternatively, an operator symbol.

Some classes require that you specify the package name. Events, properties, and some methods require that you specify the class name. Separate the components of the name with periods, using one of the following forms:

```
doc className.name
doc packageName.className
doc packageName.className.name
```

Methods for some classes are not accessible using the `doc` command; instead, use links on the class reference page.

If `name` is overloaded (that is, appears in multiple folders on the search path), then include a partial path to display the correct reference page, such as

```
doc folderName/name
```

Examples

Function Reference Pages

Display the reference page for the `abs` function.

```
doc abs
```

Several products include different versions of `abs`. If your Help preferences support displaying documentation for those products, then the Help browser displays the MATLAB `abs` reference page and a message with links to other versions of `abs`. This message appears at the top of the page.

Display the reference page for the `abs` function in the Fixed-Point Designer™ product by specifying the partial path.

```
doc fixedpoint/abs
```

Class and Method Reference Pages

Display the reference page for the `handle` class.

```
doc handle
```

Display the reference page for the `findobj` method in the `handle` class.

```
doc handle.findobj
```

Display the reference page for the `Map` class in the `containers` package.

```
doc containers.Map
```

Custom Class Pages

Display formatted help text for a custom class.

MATLAB includes a set of example files that show how to create a class, including a class file named `sads.m`. Add the example folder to the path, and request documentation for `sads`.

```
addpath(...
   fullfile(matlabroot,'help','techdoc','matlab_env','examples'))
doc sads
```

Display the help for the `steer` method of the `sads` class.

```
doc sads.steer
```

Because the help text follows MATLAB conventions, MATLAB formats the display in the Web browser.

Product Documentation

Display the main documentation page for a toolbox by specifying the toolbox folder name.

Identify the folder name for a product by calling `which`, using the name of a function unique to that product. For example, `ttest` is unique to the Statistics Toolbox product.

```
which ttest
```

```
matlabroot\toolbox\stats\stats\ttest.m
```

The value of `matlabroot` depends on your system. However, the product folder name always appears immediately after `toolbox` in the path.

Display the main page for the Statistics Toolbox.

```
doc stats
```

Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

Concepts

- “Ways to Get Function Help”
- “Add Help for Your Program”
- “Display Custom Documentation”

Purpose

Help browser search

Syntax

```
docsearch
docsearch expression
```

Description

`docsearch` opens the Help browser and displays the documentation home page. If the Help browser is already open, but not visible, then `docsearch` brings it to the foreground.

`docsearch expression` searches MathWorks documentation for pages with words that match the specified expression. The `docsearch` command does not search third-party or custom documentation.

Input Arguments

expression - Expression that defines search terms

string

Expression that defines search terms, specified as a string. Expressions can include:

- Quotation marks to specify exact phrases, such as `"plot tools"`.
- Boolean operator keywords in uppercase (listed here in order of precedence): `NOT`, `OR`, `AND`.
- Asterisk (`*`) wildcard characters, except at the beginning of a word or in an exact phrase. Searches require that at least two characters in the expression are *not* wildcard characters.

Examples

Single Words

Find all documentation pages that contain the word *plot*.

```
docsearch plot
```

Multiple Words

Find documentation pages with the words *plot* and *tools*.

```
docsearch plot tools
```

Expand the search to include variations of the word *plot*, such as *plotting* or *plots*, using a wildcard character.

```
docsearch plot* tools
```

Narrow the search to pages that include an exact phrase by enclosing the phrase in quotation marks.

```
docsearch "plot tools"
```

Find pages with either word, but not necessarily both words, using the `OR` operator.

```
docsearch plot OR tools
```

Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

Concepts

- "Search Syntax and Tips"

Purpose

Execute DOS command and return output

Syntax

```
status = dos(command)
[status,cmdout] = dos(command)
[status,cmdout] = dos(command,'-echo')
```

Description

`status = dos(command)` executes the specified DOS command for Windows platforms, and waits for the command to finish execution before returning the exit status to the `status` variable.

`[status,cmdout] = dos(command)` additionally returns the output of the DOS command to `cmdout`. This syntax is most useful for DOS console commands that do not require user input, such as `dir`.

`[status,cmdout] = dos(command,'-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for DOS console commands that require user input and that run correctly in the MATLAB Command Window, such as `comp`.

Input Arguments

command - MS-DOS® command

string

MS-DOS command, specified as a string. The command can be a Windows UI program that opens a graphical user interface, or a DOS console command that you typically run in a DOS command window. The command executes in a DOS shell, which might not be the shell from which you launched MATLAB.

Example: `'dir'`

Output Arguments

status - Command exit status

0 | nonzero integer

Command exit status, returned as either `0` or a nonzero integer. When the command is successful, `status` is `0`. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (`&`), then `status` is the exit status upon command launch.
- If `command` does not include the ampersand character (`&`), then `status` is the exit status upon command completion.

cmdout - Output of operating system command

string

Output of the operating system command, returned as a string.

Limitations

- DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `dos` with a DOS `command` that relies on the current folder fails. MATLAB returns this error:

  ```
  Error using dos
  DOS commands may not be executed when the current directory is a UNC pa
  ```

  To work around this limitation, change the folder to a mapped drive before running `dos` or a function that calls `dos`.

Examples

Save DOS Command Exit Status

Issue a DOS command to create a new folder named `mynew` and save the exit status to a variable.

```
command = 'mkdir mynew';
status = dos(command)

status =

     0
```

The `status` of zero indicates that the `mynew` folder was created successfully.

Open and Run a Windows UI Command

Open Notepad and immediately return the exit status to MATLAB by appending an ampersand (`&`) to the `notepad` command.

```
status = dos('notepad &')

status =

     0
```

The status of zero indicates that Notepad successfully started.

Save Successful DOS Command Status and Output

When you issue a valid DOS command, status indicates success and cmdout contains the command output.

```
[status,cmdout] = dos('dir');
status

status =

     0

cmdout

cmdout =

 Volume in drive C is OSDisk

```

Save Unsuccessful DOS Command Status and Output

When you issue an invalid DOS command, `status` indicates failure and `results` contains the DOS error message.

```
[status,results] = dos('foo');
status

status =

     1

results =

'foo' is not recognized as an internal or external command,
operable program or batch file.

results

results =

'foo' is not recognized as an internal or external command,
operable program or batch file.

>>
```

Display DOS Command Output in MATLAB Command Window

Display command output and prompts in the Command Window as the command executes, and also assign the command output to the `results` variable.

```
[status,results] = dos('comp', '-echo');

Name of first file to compare: collatz.m
collatz.m
```

```
Name of second file to compare: collatz.asv
collatz.asv
Option: /A
/A
Option:

Comparing collatz.m and collatz.asv...
Files compare OK

Compare more files (Y/N) ? N
N
>>
```

Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the `command` argument (for example, `'notepad &'`). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

  Note If `command` includes the trailing `&` character, `cmdout` is empty.

See Also

`computer` | `perl` | `system` | `unix!` (exclamation point) |

Purpose

Vector dot product

Syntax

```
C = dot(A,B)
C = dot(A,B,dim)
```

Description

`C = dot(A,B)` returns the scalar product of the vectors `A` and `B`. `A` and `B` must be vectors of the same length. When `A` and `B` are both column vectors, `dot(A,B)` is the same as `A'*B`.

For multidimensional arrays `A` and `B`, `dot` returns the scalar product along the first non-singleton dimension of `A` and `B`. `A` and `B` must have the same size.

`C = dot(A,B,dim)` returns the scalar product of `A` and `B` in the dimension `dim`.

Examples

The dot product of two vectors is calculated as shown:

```
a = [1 2 3]; b = [4 5 6];
c = dot(a,b)

c =
      32
```

See Also

`cross`

Purpose

Convert to double precision

Syntax

```
double(x)
```

Description

`double(x)` returns the double-precision value for `X`. If `X` is already a double-precision array, `double` has no effect.

Tips

The `double` function should be overloaded for any object when it makes sense to convert it to a double-precision value.

dragrect

Purpose

Drag rectangles with mouse

Syntax

```
[finalrect] = dragrect(initialrect)
[finalrect] = dragrect(initialrect,stepsize)
```

Description

`[finalrect] = dragrect(initialrect)` tracks one or more rectangles anywhere on the screen. The n-by-4 matrix `initialrect` defines the rectangles. Each row of `initialrect` must contain the initial rectangle position as `[left bottom width height]` values. `dragrect` returns the final position of the rectangles in `finalrect`.

`[finalrect] = dragrect(initialrect,stepsize)` moves the rectangles in increments of `stepsize`. The lower left corner of the first rectangle is constrained to a grid of size equal to `stepsize` starting at the lower left corner of the figure, and all other rectangles maintain their original offset from the first rectangle.

`[finalrect] = dragrect(...)` returns the final positions of the rectangles when the mouse button is released. The default step size is `1`.

Tips

`dragrect` returns immediately if a mouse button is not currently pressed. Use `dragrect` in a `ButtonDownFcn`, or from the command line in conjunction with `waitforbuttonpress`, to ensure that the mouse button is down when `dragrect` is called. `dragrect` returns when you release the mouse button.

If the drag ends over a figure window, the positions of the rectangles are returned in that figure's coordinate system. If the drag ends over a part of the screen not contained within a figure window, the rectangles are returned in the coordinate system of the figure over which the drag began.

Note You cannot use normalized figure units with `dragrect`.

Examples

Drag a rectangle that is 50 pixels wide and 100 pixels in height.

```
waitforbuttonpress
point1 = get(gcf,'CurrentPoint') % button down detected
rect = [point1(1,1) point1(1,2) 50 100]
[r2] = dragrect(rect)
```

See Also

rbbox | waitforbuttonpress

drawnow

Purpose

Flush event queue and update figure window

Syntax

```
drawnow
drawnow expose
drawnow update
```

Description

`drawnow` causes figure windows and their children to update, and flushes the system event queue. Any callbacks generated by incoming events (e.g., mouse or key events) are dispatched before `drawnow` returns.

`drawnow expose` causes only graphics objects to refresh, if needed. It does not allow callbacks to execute and does not process other events in the queue.

`drawnow update` causes only non graphics objects to refresh, if needed. It does not allow callbacks to execute and does not process other events in the queue.

You can combine the `expose` and `update` options to obtain both effects:

```
drawnow expose update
```

Other Events That Cause Event Queue Processing

Other events that cause the MATLAB software to flush the event queue and draw the figure include:

- Returning to the MATLAB prompt
- Executing the following functions:
  - `figure`
  - `getframe`
  - `input`
  - `keyboard`
- Functions that wait for user input (i.e., `waitforbuttonpress`, `waitfor`, `ginput`)

- Any code that causes one of the above functions to execute. For example, suppose `h` is the handle of an axes. Calling `axes(h)` causes its parent figure to be made the current figure and brought to the front of all displayed figures, which results in the event queue being flushed.

Examples

Using `drawnow` in a loop causes the display to update while the loop executes:

```
t = 0:pi/20:2*pi;
y = exp(sin(t));
h = plot(t,y,'YDataSource','y');
for k = 1:.1:10
 y = exp(sin(t.*k));
 refreshdata(h,'caller') % Evaluate y in the function workspace
 drawnow; pause(.1)
end
```

`snapnow` | `waitfor` | `waitforbuttonpress`

dsearchn

Purpose

N-D nearest point search

Syntax

```
k = dsearchn(X,T,XI)
k = dsearchn(X,T,XI,outval)
k = dsearchn(X,XI)
[k,d] = dsearchn(X,...)
```

Description

`k = dsearchn(X,T,XI)` returns the indices `k` of the closest points in `X` for each point in `XI`. `X` is an `m`-by-`n` matrix representing `m` points in n-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in n-dimensional space. `T` is a `numt`-by-`n+1` matrix, a triangulation of the data `X` generated by `delaunayn`. The output `k` is a column vector of length `p`.

`k = dsearchn(X,T,XI,outval)` returns the indices `k` of the closest points in `X` for each point in `XI`, unless a point is outside the convex hull. If `XI(J,:)` is outside the convex hull, then `K(J)` is assigned `outval`, a scalar double. `Inf` is often used for `outval`. If `outval` is `[]`, then `k` is the same as in the case `k = dsearchn(X,T,XI)`.

`k = dsearchn(X,XI)` performs the search without using a triangulation. With large `X` and small `XI`, this approach is faster and uses much less memory.

`[k,d] = dsearchn(X,...)` also returns the distances `d` to the closest points. `d` is a column vector of length `p`.

Algorithms

`dsearchn` is based on Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

`delaunayTriangulation`

Purpose

Abstract class used to derive handle class with dynamic properties

Syntax

`classdef myclass < dynamicprops`

Description

`classdef myclass < dynamicprops` makes *`myclass`* a subclass of the `dynamicprops` class, which is a subclass of the `handle` class.

Use the `dynamicprops` class to derive classes that can define dynamic properties (instance properties), which are associated with a specific objects, but have no effect on the objects class definition. Dynamic properties are useful for attaching temporary data to one or more objects.

dynamicprops Methods

This class defines one method `addprop` and, as a subclass of the `handle` class, inherits all the `handle` class methods.

- `addprop` — adds the named property to the specified handle objects. See “Dynamic Properties — Adding Properties to an Instance” for more information.

See Also

`handle`

echo

Purpose

Display statements during function execution

Syntax

```
echo on
echo off
echo
echo fcnname on
echo fcnname off
echo fcnname
echo on all
echo off all
```

Description

The `echo` command controls the display (or *echoing*) of statements in a function during their execution. Normally, statements in a function file are not displayed on the screen during execution. Command echoing is useful for debugging or for demonstrations, allowing the commands to be viewed as they execute.

The `echo` command behaves in a slightly different manner for script files and function files. For script files, the use of `echo` is simple; echoing can be either `on` or `off`, in which case any script used is affected.

`echo on`	Turns on the echoing of commands in all script files
`echo off`	Turns off the echoing of commands in all script files
`echo`	Toggles the echo state

With function files, the use of `echo` is more complicated. If `echo` is enabled on a function file, the file is interpreted, rather than compiled. Each input line is then displayed as it is executed. Since this results in inefficient execution, use `echo` only for debugging.

`echo` *`fcnname`* `on`	Turns on echoing of the named function file
`echo` *`fcnname`* `off`	Turns off echoing of the named function file

`echo` *`fcnname`*	Toggles the echo state of the named function file
`echo on all`	Sets echoing on for all function files
`echo off all`	Sets echoing off for all function files

Tips

- To avoid confusing syntax, do not use `on` or `off` as a function name.

See Also

`function`

Purpose

Run example script step-by-step in Command Window

Syntax

```
echodemo filename
echodemo(filename,index)
```

Description

`echodemo filename` runs the script specified by `filename` step-by-step in the Command Window. The file must contain sections defined with two percent signs (`%%`) to enable pausing after each step. At each step, you can click links in the Command Window to proceed or stop. If the Command Window is not large enough to show the links, scroll up to see them.

`echodemo(filename,index)` starts with the section number specified by `index`. If the example relies on results of previous steps, using this syntax can produce errors or unexpected results.

Caution

If variables in your base workspace have the same name as variables that the example file creates, the example could overwrite your data. Preserve your data by saving it to a MAT-file before running the example.

Input Arguments

filename - Script file name
string

Script file name, specified as a string.

When you use the function syntax for `echodemo` and specify its inputs within parentheses, enclose the `filename` input in single quotes.

index - Section index
scalar integer

Section index, specified as a scalar integer.

The link text in the Command Window shows the current section number, `n`, and the total number of sections, `m`, as `n/m`.

Examples

Run Example Script in Command Window

Run the Loma Prieta Earthquake example.

```
echodemo quake
```

Start Script from Specified Section

Start the Loma Prieta Earthquake example from the third section.

```
filename = 'quake';
index = 3;
echodemo(filename,index)
```

This code errors because the example requires variables created in earlier sections.

Tips

- Only use `echodemo` to display scripts, not functions. `echodemo` can run any script that you can execute, but only scripts with sections pause between steps.

TriRep.edgeAttachments

Purpose

(Will be removed) Simplices attached to specified edges

Note `edgeAttachments(TriRep)` will be removed in a future release. Use `edgeAttachments(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
SI = edgeAttachments(TR, V1, V2)
SI = edgeAttachments(TR, EDGE)
```

Description

`SI = edgeAttachments(TR, V1, V2)` returns the simplices `SI` attached to the edges specified by `(V1, V2)`. `(V1, V2)` represents the start and end vertices of the edges to be queried.

`SI = edgeAttachments(TR, EDGE)` specifies edges in matrix format.

Input Arguments

`TR`	Triangulation representation.
`V1,V2`	Column vectors of vertex indices into the array of points representing the vertex coordinates.
`EDGE`	Matrix specifying edge start and end points. `EDGE` is of size `m`-by-2, `m` being the number of edges to query.

Output Arguments

`SI`	Vector cell array of indices into the triangulation matrix. `SI` is a cell array because the number of simplices associated with each edge can vary.

Definitions

A simplex is a triangle/tetrahedron or higher dimensional equivalent.

Examples

Example 1

Load a 3-D triangulation to compute the tetrahedra attached to an edge.

```
load tetmesh
trep = TriRep(tet, X);
v1 = [15 21]';
v2 = [936 716]';
t1 = edgeAttachments(trep, v1, v2);
```

You can also specify the input as edges.

```
e = [v1 v2];
t2 = edgeAttachments(trep, e);
isequal(t1,t2);
```

Example 2

Create a triangulation with `DelaunayTri`.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
dt = DelaunayTri(x,y);
```

Query the triangles attached to edge (1,5).

```
t = edgeAttachments(dt, 1,5);
t{:};
```

See Also

`edges` | `triangulation` | `delaunayTriangulation`

TriRep.edges

Purpose

(Will be removed) Triangulation edges

Note `edges(TriRep)` will be removed in a future release. Use `edges(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
E = edges(TR)
```

Description

`E = edges(TR)` returns the edges in the triangulation in an `n`-by-2 matrix. `n` is the number of edges. The vertices of the edges index into `TR.X`, the array of points representing the vertex coordinates.

Input Arguments

`TR`	Triangulation representation.

Output Arguments

`E`	Edge matrix.

Examples

Example 1

Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y);
```

Return all edges.

```
e = edges(trep);
```

Example 2

Query a 2-D `DelaunayTri`-generated triangulation.

```
X = rand(10,2);
```

```
dt = DelaunayTri(X);
e = edges(dt);
```

See Also

edgeAttachments | triangulation | delaunayTriangulation

Purpose

Edit or create file

Syntax

```
edit
edit file
edit file1 ... fileN
```

Description

`edit` opens a new file called `Untitled` in the Editor. MATLAB does not automatically save `Untitled`.

`edit file` opens the specified file in the Editor. If `file` does not already exist, MATLAB asks if you want to create it. `file` can include a partial path, complete path, relative path, or no path. You must have write permission to the path to create `file`, otherwise, MATLAB ignores the argument.

You must specify the extension to open `.mat` and `.mdl` files. MATLAB cannot directly edit binary files, such as `.p` and `.mex` files.

`edit file1 ... fileN` opens each file, `file1 ... fileN`, in the Editor.

Examples

Open a New File

```
edit
```

A new file titled `Untitled` opens in the MATLAB Editor (or default editor). `Untitled` does not appear in your Current Folder.

Create a New File

```
mkdir tests
edit tests/new_script.m
```

A dialog box appears, asking if you want to create `new_script.m`. If you select **Yes**, MATLAB creates and opens `tests/new_script.m`.

Open Files

```
edit file1 file2 file3 file4
```

MATLAB sequentially creates and opens the files: `file1`, `file2`, `file3`, and `file4` in sequence.

Input Arguments

file - Name of file

string

Name of file, specified as a string. If `file` specifies a path that contains a nonexistent folder, MATLAB throws an error.

Data Types

`char`

file1 ... fileN - Names of files

strings

Names of files, specified as strings. You can specify `file1 ... fileN` as a mixture of partial paths, complete paths, relative paths, or no paths.

Data Types

`char`

See Also

`open | type`

Concepts

- "Change Default Editor"

Purpose

Eigenvalues and eigenvectors

Syntax

```
d = eig(A)
d = eig(A,B)
[V,D] = eig(A)
[V,D] = eig(A,'nobalance')
[V,D] = eig(A,B)
[V,D] = eig(A,B,flag)
```

Description

`d = eig(A)` returns a vector of the eigenvalues of matrix `A`.

`d = eig(A,B)` returns a vector containing the generalized eigenvalues, if `A` and `B` are square matrices.

Note If `S` is sparse and symmetric, you can use `d = eig(S)` to return the eigenvalues of `S`. If `S` is sparse but not symmetric, or if you want to return the eigenvectors of `S`, use the function `eigs` instead of `eig`.

`[V,D] = eig(A)` produces matrices of eigenvalues (`D`) and eigenvectors (`V`) of matrix `A`, so that `A*V = V*D`. Matrix `D` is the *canonical form* of `A` — a diagonal matrix with `A`'s eigenvalues on the main diagonal. Matrix `V` is the *modal matrix* — its columns are the eigenvectors of `A`.

`[V,D] = eig(A,'nobalance')` finds eigenvalues and eigenvectors without a preliminary balancing step. This may give more accurate results for certain problems with unusual scaling. Ordinarily, balancing improves the conditioning of the input matrix, enabling more accurate computation of the eigenvectors and eigenvalues. However, if a matrix contains small elements that are really due to roundoff error, balancing may scale them up to make them as significant as the other elements of the original matrix, leading to incorrect eigenvectors. Use the `nobalance` option in this event. See the `balance` function for more details.

`[V,D] = eig(A,B)` produces a diagonal matrix `D` of generalized eigenvalues and a full matrix `V` whose columns are the corresponding eigenvectors so that `A*V = B*V*D`.

`[V,D] = eig(A,B,flag)` specifies the algorithm used to compute eigenvalues and eigenvectors. *`flag`* can be:

`'chol'`	Computes the generalized eigenvalues of `A` and `B` using the Cholesky factorization of `B`. This is the default for symmetric (Hermitian) `A` and symmetric (Hermitian) positive definite `B`.
`'qz'`	Ignores the symmetry, if any, and uses the QZ algorithm as it would for nonsymmetric (non-Hermitian) `A` and `B`.

Note For `eig(A)`, the eigenvectors are scaled so that the norm of each is 1.0. For `eig(A,B)`, `eig(A,'nobalance')`, and `eig(A,B,flag)`, the eigenvectors are not normalized.

Also note that if `A` is symmetric, `eig(A,'nobalance')` ignores the `nobalance` option since `A` is already balanced.

Tips

The eigenvalue problem is to determine the nontrivial solutions of the equation $Ax = \lambda x$

where A is an n-by-n matrix, x is a length n column vector, and λ is a scalar. The n values of λ that satisfy the equation are the *eigenvalues*, and the corresponding values of x are the *right eigenvectors*. The MATLAB function `eig` solves for the eigenvalues λ, and optionally the eigenvectors x.

The *generalized* eigenvalue problem is to determine the nontrivial solutions of the equation $Ax = \lambda Bx$

where both A and B are n-by-n matrices and λ is a scalar. The values of λ that satisfy the equation are the *generalized eigenvalues* and the corresponding values of x are the *generalized right eigenvectors*.

If B is nonsingular, the problem could be solved by reducing it to a standard eigenvalue problem $B^{-1}Ax = \lambda x$

Because B can be singular, an alternative algorithm, called the QZ method, is necessary.

When a matrix has no repeated eigenvalues, the eigenvectors are always independent and the eigenvector matrix V *diagonalizes* the original matrix A if applied as a similarity transformation. However, if a matrix has repeated eigenvalues, it is not similar to a diagonal matrix unless it has a full (independent) set of eigenvectors. If the eigenvectors are not independent then the original matrix is said to be *defective*. Even if a matrix is defective, the solution from eig satisfies A*X = X*D.

Examples

The matrix

```
B = [ 3     -2      -.9    2*eps
     -2      4       1    -eps
     -eps/4  eps/2  -1     0
     -.5    -.5      .1    1   ];
```

has elements on the order of roundoff error. It is an example for which the nobalance option is necessary to compute the eigenvectors correctly. Try the statements

```
[VB,DB] = eig(B)
B*VB - VB*DB
[VN,DN] = eig(B,'nobalance')
B*VN - VN*DN
```

See Also

balance | condeig | eigs | hess | qz | schur

Purpose

Largest eigenvalues and eigenvectors of matrix

Syntax

```
d = eigs(A)
[V,D] = eigs(A)
[V,D,flag] = eigs(A)
eigs(A,B)
eigs(A,k)
eigs(A,B,k)
eigs(A,k,sigma)
eigs(A,B,k,sigma)
eigs(A,K,sigma,opts)
eigs(A,B,k,sigma,opts)
eigs(Afun,n,...)
```

Description

`d = eigs(A)` returns a vector of `A`'s six largest magnitude eigenvalues. `A` must be a square matrix. `A` should be large and sparse, though `eigs` will work on full matrices as well. See "Tips" below.

`[V,D] = eigs(A)` returns a diagonal matrix `D` of `A`'s six largest magnitude eigenvalues and a matrix `V` whose columns are the corresponding eigenvectors.

`[V,D,flag] = eigs(A)` also returns a convergence flag. If `flag` is `0` then all the eigenvalues converged; otherwise not all converged.

`eigs(A,B)` solves the generalized eigenvalue problem `A*V == B*V*D`. `B` must be the same size as `A`. `eigs(A,[],...)` indicates the standard eigenvalue problem `A*V == V*D`.

`eigs(A,k)` and `eigs(A,B,k)` return the `k` largest magnitude eigenvalues.

`eigs(A,k,`*`sigma`*`)` and `eigs(A,B,k,`*`sigma`*`)` return `k` eigenvalues based on *`sigma`*, which can take any of the following values:

scalar (real or complex, including 0)	The eigenvalues closest to `sigma`. If `A` is a function, `Afun` must return `Y = (A-sigma*B)\x` (i.e., `Y = A\x` when `sigma = 0`).
'lm'	Largest magnitude (default).
'sm'	Smallest magnitude. Same as `sigma = 0`. If `A` is a function, `Afun` must return `Y = A\x`.

For real symmetric problems, the following are also options:

'la'	Largest algebraic ('lr')
'sa'	Smallest algebraic ('sr')
'be'	Both ends (one more from high end if `k` is odd)

For nonsymmetric and complex problems, the following are also options:

'lr'	Largest real part
'sr'	Smallest real part
'li'	Largest imaginary part
'si'	Smallest imaginary part

Note The syntax `eigs(A,k,...)` is not valid when `A` is scalar. To pass a value for `k`, you must specify `B` as the second argument and `k` as the third (`eigs(A,B,k,...)`). If necessary, you can set `B` equal to `[]`, the default.

`eigs(A,K,sigma,opts)` and `eigs(A,B,k,sigma,opts)` specify an options structure. Default values are shown in brackets (`{}`).

Parameter	Description	Values
opts.issym	1 if A or A-*sigma**B represented by Afun is symmetric, 0 otherwise.	[{0}	1]
opts.isreal	1 if A or A-*sigma**B represented by Afun is real, 0 otherwise.	[0	{1}]
opts.tol	Convergence: Ritz estimate residual <= tol*norm(A).	[scalar	{eps}]
opts.maxit	Maximum number of iterations.	[integer	{300}]
opts.p	Number of Lanczos basis vectors. p >= 2k (p >= 2k+1 real nonsymmetric) advised. p must satisfy k < p <= n for real symmetric, k+1 < p <= n otherwise. Note: If you do not specify a p value, the default algorithm uses at least 20 Lanczos vectors.	[integer	{2*k}]
opts.v0	Starting vector.	[n-by-1 vector	{randomly generated by rand}]
opts.disp	Diagnostic information display level.	[{0}	1	2]
opts.cholB	1 if B is really its Cholesky factor chol(B), 0 otherwise.	[{0}	1]
opts.permB	Permutation vector permB if sparse B is really chol(B(permB,permB)).	[permB	{1:n}]

`eigs(Afun,n,...)` accepts a function handle, `Afun`, instead of the matrix `A`.

`y = Afun(x)` should return:

`A*x`	if *sigma* is not specified, or is a string other than `'sm'`
`A\x`	if *sigma* is `0` or `'sm'`
`(A-sigma*I)\x`	if *sigma* is a nonzero scalar (standard eigenvalue problem). `I` is an identity matrix of the same size as `A`.
`(A-sigma*B)\x`	if *sigma* is a nonzero scalar (generalized eigenvalue problem)

"Parameterizing Functions" explains how to provide additional parameters to the function `Afun`, if necessary.

The matrix `A`, `A-sigma*I` or `A-sigma*B` represented by `Afun` is assumed to be real and nonsymmetric unless specified otherwise by `opts.isreal` and `opts.issym`. In all the `eigs` syntaxes, `eigs(A,...)` can be replaced by `eigs(Afun,n,...)`.

Tips

`d = eigs(A,k)` is not a substitute for

```
d = eig(full(A))
d = sort(d)
d = d(end-k+1:end)
```

but is most appropriate for large sparse matrices. If the problem fits into memory, it may be quicker to use `eig(full(A))`.

Unless you provide a start vector with `opts.v0`, the default start vector is generated by `rand`, possibly leading to different iterations each run, and perhaps even different convergence behavior. In order to control this, specify your start vector via `opts.v0`.

Examples

Example 1

```
A = delsq(numgrid('C',15));
d1 = eigs(A,5,'sm')
```

returns

```
d1 =
    0.5520
    0.4787
    0.3469
    0.2676
    0.1334
```

Example 2

This example replaces the matrix `A` in example 1 with a handle to a function `dnRk`. The example is contained in file `run_eigs` that

- Calls `eigs` with the function handle `@dnRk` as its first argument.
- Contains `dnRk` as a nested function, so that all variables in `run_eigs` are available to `dnRk`.

The following shows the code for `run_eigs`:

```
function d2 = run_eigs
n = 139;
opts.issym = 1;
R = 'C';
k = 15;
d2 = eigs(@dnRk,n,5,'sm',opts);

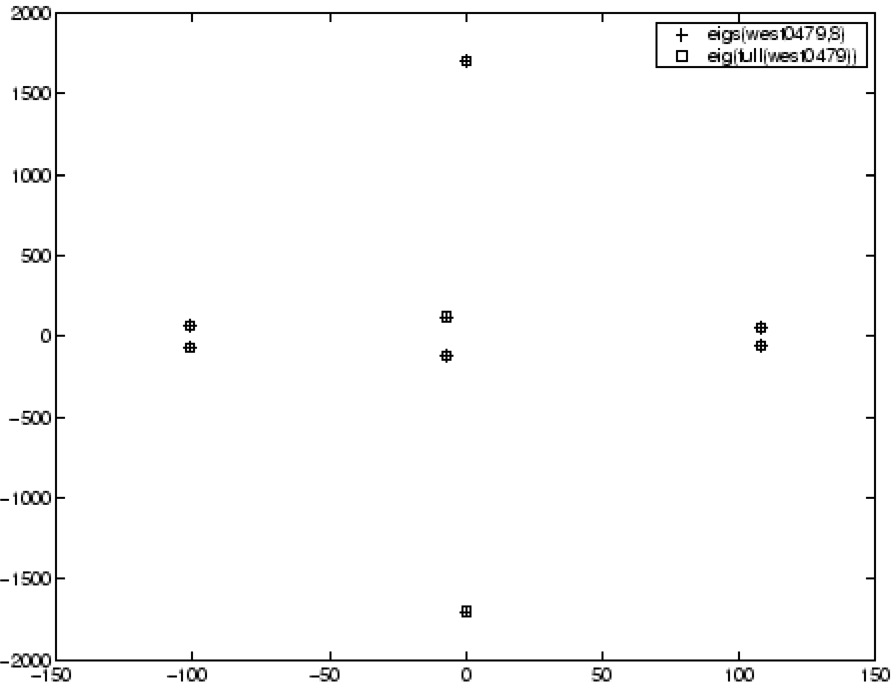
    function y = dnRk(x)
        y = (delsq(numgrid(R,k))) \ x;
    end
end
```

Example 3

west0479 is a real 479-by-479 sparse matrix with both real and pairs of complex conjugate eigenvalues. eig computes all 479 eigenvalues. eigs easily picks out the largest magnitude eigenvalues.

This plot shows the 8 largest magnitude eigenvalues of west0479 as computed by eig and eigs.

```
load west0479
d = eig(full(west0479))
dlm = eigs(west0479,8)
[dum,ind] = sort(abs(d));
plot(dlm,'k+')
hold on
plot(d(ind(end-7:end)),'ks')
hold off
legend('eigs(west0479,8)','eig(full(west0479))')
```



Example 4

A = delsq(numgrid('C',30)) is a symmetric positive definite matrix of size 632 with eigenvalues reasonably well-distributed in the interval (0 8), but with 18 eigenvalues repeated at 4. The eig function computes all 632 eigenvalues. It computes and plots the six largest and smallest magnitude eigenvalues of A successfully with:

```
A = delsq(numgrid('C',30));
d = eig(full(A));
[dum,ind] = sort(abs(d));
dlm = eigs(A);
dsm = eigs(A,6,'sm');

subplot(2,1,1)
plot(dlm,'k+')
```

```
hold on
plot(d(ind(end:-1:end-5)),'ks')
hold off
legend('eigs(A)','eig(full(A))',3)
set(gca,'XLim',[0.5 6.5])

subplot(2,1,2)
plot(dsm,'k+')
hold on
plot(d(ind(1:6)),'ks')
hold off
legend('eigs(A,6,''sm'')','eig(full(A))',2)
set(gca,'XLim',[0.5 6.5])
```

However, the repeated eigenvalue at 4 must be handled more carefully. The call `eigs(A,18,4.0)` to compute 18 eigenvalues near 4.0 tries to find eigenvalues of `A - 4.0*I`. This involves divisions of the form `1/(lambda - 4.0)`, where `lambda` is an estimate of an eigenvalue of `A`. As `lambda` gets closer to 4.0, `eigs` fails. We must use `sigma` near but not equal to 4 to find those 18 eigenvalues.

```
sigma = 4 - 1e-6
[V,D] = eigs(A,18,sigma)
```

The plot shows the 20 eigenvalues closest to 4 that were computed by `eig`, along with the 18 eigenvalues closest to `4 - 1e-6` that were computed by `eigs`.

`eig` | `svds` | `function_handle`

Purpose

Jacobi elliptic functions

Syntax

```
[SN,CN,DN] = ellipj(U,M)
[SN,CN,DN] = ellipj(U,M,tol)
```

Definitions

The Jacobi elliptic functions are defined in terms of the integral:

$$u = \int_0^{\phi} \frac{d\theta}{\sqrt{1 - m\sin^2\theta}}.$$

Then

$$sn(u) = \sin\phi,\ cn(u) = \cos\phi,\ dn(u) = \sqrt{1 - m\sin^2\phi}.$$

Some definitions of the elliptic functions use the modulus k instead of the parameter m. They are related by

$$k^2 = m = \sin^2 a,$$

where a is the modular angle.

The Jacobi elliptic functions obey many mathematical identities; for a good sample, see [1].

Description

`[SN,CN,DN] = ellipj(U,M)` returns the Jacobi elliptic functions `SN`, `CN`, and `DN`, evaluated for corresponding elements of argument `U` and parameter `M`. Inputs `U` and `M` must be the same size (or either can be scalar).

`[SN,CN,DN] = ellipj(U,M,tol)` computes the Jacobi elliptic functions to accuracy `tol`. The default is `eps`; increase this for a less accurate but more quickly computed answer.

Algorithms

`ellipj` computes the Jacobi elliptic functions using the method of the arithmetic-geometric mean [1]. It starts with the triplet of numbers:

$$a_0 = 1,\ b_0 = \sqrt{1-m},\ c_0 = \sqrt{m}$$

`ellipj` computes successive iterates with

$$a_i = \frac{1}{2}(a_{i-1} + b_{i-1})$$
$$b_i = (a_{i-1}b_{i-1})^{\frac{1}{2}}$$
$$c_i = \frac{1}{2}(a_{i-1} - b_{i-1})$$

Next, it calculates the amplitudes in radians using:

$$\sin(2\phi_{n-1} - \phi_n) = \frac{c_n}{a_n}\sin(\phi_n)$$

being careful to unwrap the phases correctly. The Jacobian elliptic functions are then simply:

$$sn(u) = \sin\phi_0$$
$$cn(u) = \cos\phi_0$$
$$dn(u) = \sqrt{1 - m \cdot sn(u)^2}$$

Limitations

The `ellipj` function is limited to the input domain $0 \le m \le 1$. Map other values of `M` into this range using the transformations described in [1], equations 16.10 and 16.11. `U` is limited to real values.

See Also

`ellipke`

Purpose

Complete elliptic integrals of first and second kind

Syntax

```
K = ellipke(M)
[K,E] = ellipke(M)
[K,E] = ellipke(M,tol)
```

Description

`K = ellipke(M)` returns the complete elliptic integral of the first kind for the each element in `M`.

`[K,E] = ellipke(M)` returns the complete elliptic integral of the first and second kinds.

`[K,E] = ellipke(M,tol)` computes the complete elliptic integral to accuracy `tol`. The default is `eps(class(M))`; increase the tolerance for a less accurate but more quickly computed answer.

Limitations

`ellipke` is limited to the input domain $0 \le m \le 1$.

Definitions

The *complete* elliptic integral of the first kind is

$$[K(m)] = \int_0^1 [(1-t^2)(1-mt^2)]^{-\frac{1}{2}} dt.$$

where m is the first argument of `ellipke`.

The complete elliptic integral of the second kind is

$$E(m) = \int_0^1 (1-t^2)^{-\frac{1}{2}} (1-mt^2)^{\frac{1}{2}} dt.$$

Some definitions of `K` and `E` use the elliptical modulus k instead of the parameter m. They are related as

$$k^2 = m = \sin^2 \alpha.$$

References

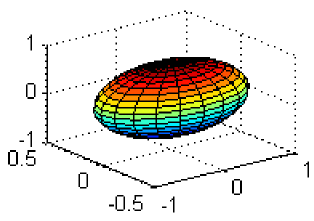
[1] Abramowitz, M., and I.A. Stegun. *Handbook of Mathematical Functions*. Dover Publications, 1965.

See Also

`ellipj`

Purpose

Generate ellipsoid



Syntax

```
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)
ellipsoid(axes_handle,...)
ellipsoid(...)
```

Description

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)` generates a surface mesh described by three `n+1`-by-`n+1` matrices, enabling `surf(x,y,z)` to plot an ellipsoid with center `(xc,yc,zc)` and semi-axis lengths `(xr,yr,zr)`.

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)` uses `n = 20`.

`ellipsoid(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`ellipsoid(...)` with no output arguments plots the ellipsoid as a surface.

Algorithms

`ellipsoid` generates the data using the following equation:

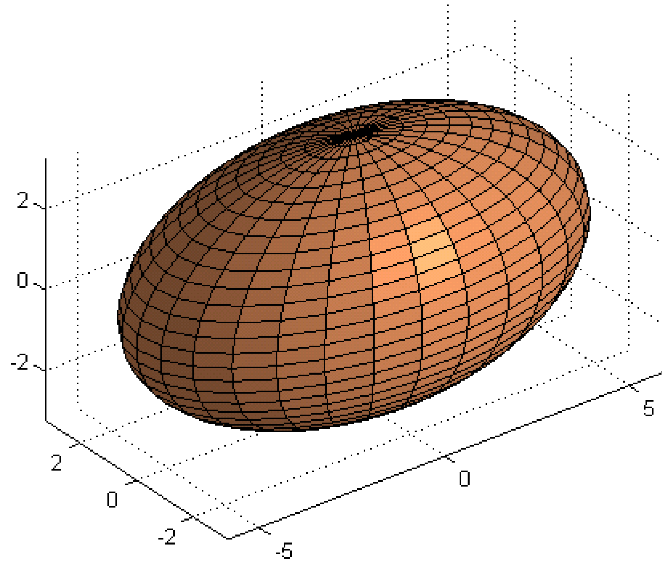
$$\frac{(x-xc)^2}{xr^2}+\frac{(y-yc)^2}{yr^2}+\frac{(z-zc)^2}{zr^2}$$

Note that `ellipsoid(0,0,0, .5,.5,.5)` is equivalent to a unit sphere.

Examples

Generate ellipsoid with size and proportions of a standard U.S. football:

```
[x, y, z] = ellipsoid(0,0,0,5.9,3.25,3.25,30);
surfl(x, y, z)
colormap copper
axis equal
```



See Also

cylinder | sphere | surf

Purpose

Optional keyword within an if statement

Syntax

```
if expression
   statements
elseif expression
   statements
else
   statements
end
```

Description

An `if` statement evaluates an expression, and executes a group of statements when the expression is true.

`elseif` and `else` are optional, and execute only when previous expressions in the `if` statement are false.

For more information about valid expressions and when they are true, see the `if` reference page.

Examples

Find the indices of values in a vector that are greater than a specified limit:

```
A = rand(1,10);
limit = .75;

B = (A > limit);   % B is a vector of logical values
if any(B)
  fprintf('Indices of values > %4.2f: \n', limit);
  disp(find(B))
else
  disp('All values are below the limit.')
end
```

See Also

`if` | `end` | `for` | `while` | `switch`

elseif

Purpose

Optional keyword within an if statement

Syntax

```
if expression
   statements
elseif expression
   statements
else
   statements
end
```

Description

An `if` statement evaluates an expression, and executes a group of statements when the expression is true.

`elseif` and `else` are optional, and execute only when previous expressions in the `if` statement are false.

For more information about valid expressions and when they are true, see the `if` reference page.

Tips

- Avoid adding a space within the `elseif` keyword (`else if`). The space creates a nested `if` statement that requires its own `end` keyword.

Examples

Assign to a matrix values that depend on their indices:

```
% Preallocate a matrix
nrows = 10;
ncols = 10;
myData = ones(nrows, ncols);

% Loop through the matrix
for r = 1:nrows
   for c = 1:ncols

      if r == c
         myData(r,c) = 2;
      elseif abs(r - c) == 1
```

```
            myData(r,c) = -1;
         else
            myData(r,c) = 0;
         end

      end
   end
```

See Also

if | end | for | while | switch

empty

Purpose

Create empty array

Syntax

```
A = ClassName.empty
A = ClassName.empty(n,m,p,...)
A = ClassName.empty([n,m,p,...])
```

Description

Use `empty` to create empty arrays of the specified class, *`ClassName`*. Specify at lease one dimension of the array as 0. MATLAB treats negative values as 0.

`A = ClassName.empty` returns an empty 0-by-0 array of the class of *`ClassName`*.

`A = ClassName.empty(n,m,p,...)` returns an empty rectangular array with the specified dimensions. At least one of the dimensions must be 0.

`A = ClassName.empty([n,m,p,...])` returns an empty rectangular array with the specified dimensions. At least one of the dimensions must be 0. This syntax is useful when using the values returned by the `size` function to define an empty array that is the same size as an existing empty array:

```
A = ClassName.empty(size(otherEmptyArray));
```

Input Arguments

n,m,p,...

Dimensions of the empty array. At least one of the specified dimensions must be 0.

Output Arguments

A

An empty array of the specified dimensions and of the class used in the method invocation.

Attributes

`empty` is a hidden, public, static method of all nonabstract MATLAB classes.

Access	Public
Hidden	true
Static	true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Use `empty` to create a rectangular empty array of class `int16`:

```
A = int16.empty(5,0);
whos
  Name      Size            Bytes  Class    Attributes

  A         5x0                 0  int16
```

Using the `empty` method of the `int16` class to produce an empty array in which some dimensions are not zero is simpler than using conversion and reshape operations:

```
A = int16([]);
A = reshape(A,5,0);
whos
  Name      Size            Bytes  Class    Attributes

  A         5x0                 0  int16
```

Given the following definition for a class,

```
classdef ExEmpty
   properties
      Color = [1,0,0];
   end
   methods
      function obj = ExEmpty(c)
         if nargin > 0
            obj.Color = c;
         end
```

```
      end
   end
end
```

Create an empty array of class `ExEmpty`:

```
A = ExEmpty.empty;
 whos
  Name          Size              Bytes  Class          Attributes

  A             0x0               104  ExEmpty
```

One dimension of an empty array must be zero:

```
A5 = ExEmpty.empty(0,5);
 whos
  Name          Size              Bytes  Class          Attributes

  A5             0x5               104  ExEmpty
```

Empty object arrays follow array concatenation behavior:

```
B = [A,A5]
B =

  0x5 ExEmpty array with properties:

    Color
```

You cannot index into an empty array:

```
A5(1)
Index exceeds matrix dimensions.
```

You can use the `isempty`, `size`, and `length` functions to identify empty object arrays:

```
isempty(A5)
```

```
ans =

     1
size(A5)

ans =

     0     5
length(A5)

ans =

     0
```

Class of Empty Object Array

The `empty` method enables you to initialize arrays of a specific class:

```
C = char.empty(0,7)

C =

   Empty string: 0-by-7

class(C)
ans =

char
```

Initializing an array with empty brackets (`[]`):

```
a = [];
```

produces an array of class `double`:

```
class(a)
ans =
```

`double`

`| isempty | size | length`

Tutorials

- "Creating Empty Arrays"
- "Empty Matrices, Scalars, and Vectors"

Purpose

Enable access to .NET commands from network drive

Syntax

```
enableNETfromNetworkDrive
```

Description

`enableNETfromNetworkDrive` adds an entry for the MATLAB interface to .NET module to the security policy on your machine. You must have administrative privileges to make changes to your configuration.

Compatibility

Use `enableNETfromNetworkDrive` for MATLAB releases R2012b or earlier, which support installed versions 2.0, 3.0, and 3.5 of the Microsoft .NET Framework.

How To

- "Troubleshooting Security Policy Settings From Network Drives"

enableservice

Purpose

Enable, disable, or report status of MATLAB Automation server

Syntax

```
state = enableservice('AutomationServer',enable)
state = enableservice('AutomationServer')
```

Description

`state = enableservice('AutomationServer',enable)` enables or disables the MATLAB Automation server. If `enable` is `true` (logical `1`), `enableservice` converts an existing MATLAB session into an Automation server. If `enable` is `false` (logical `0`), `enableservice` disables the MATLAB Automation server. `state` indicates the previous state of the Automation server. If `state` = `1`, MATLAB was an Automation server. If `state` = `0`, MATLAB was not an Automation server.

`state = enableservice('AutomationServer')` returns the current state of the Automation server. If `state` is logical `1` (`true`), MATLAB is an Automation server.

COM functions are available on Microsoft Windows systems only.

Examples

Enable the Automation server in the current MATLAB session:

```
state = enableservice('AutomationServer',true);
```

Show the current state of the MATLAB session. MATLAB displays `true`:

```
state = enableservice('AutomationServer')
```

Enable the Automation server and show the previous state. MATLAB displays `true`. The previous state can be the same as the current state:

```
state = enableservice('AutomationServer',true)
```

See Also

`actxserver`

How To

- “MATLAB COM Automation Server Interface”

Purpose

Terminate block of code, or indicate last array index

Syntax

```
end
```

Description

`end` terminates `for`, `while`, `switch`, `try`, `if`, and `parfor` statements. Without an `end` statement, `for`, `while`, `switch`, `try`, `if`, and `parfor` wait for further input. Each `end` is paired with the closest previous unpaired `for`, `while`, `switch`, `try`, `if`, or `parfor` and serves to delimit its scope.

`end` also marks the termination of a function, although in many cases it is optional. If your function contains one or more nested functions, then you must terminate every function in the file, whether nested or not, with `end`. This includes primary, nested, private, and local functions.

The `end` function also serves as the last index in an indexing expression. In that context, `end = (size(x,k))` when used as part of the `k`th index. Examples of this use are `X(3:end)` and `X(1,1:2:end-1)`. When using `end` to grow an array, as in `X(end+1)=5`, make sure `X` exists first.

You can overload the `end` statement for a user object by defining an `end` method for the object. The `end` method should have the calling sequence `end(obj,k,n)`, where `obj` is the user object, `k` is the index in the expression where the `end` syntax is used, and `n` is the total number of indices in the expression. For example, consider the expression

```
A(end-1,:)
```

The MATLAB software calls the `end` method defined for `A` using the syntax

```
end(A,1,2)
```

Examples

This example shows `end` used with the `for` and `if` statements.

```
for k = 1:n
 if a(k) == 0
  a(k) = a(k) + 2;
    end
end
```

In this example, `end` is used in an indexing expression.

```
A = magic(5)

A =

    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9

B = A(end,2:end)

B =

    18    25     2     9
```

See Also

`break` | `for` | `if` | `return` | `switch` | `try` | `while` | `parfor`

EndInvoke

Purpose

Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method

Syntax

```
result = EndInvoke(asyncResult)
[res0,...,resN] = EndInvoke(res0,...,resN,asyncResult)
```

Description

`result = EndInvoke(asyncResult)` retrieves result of asynchronous call initiated by `BeginInvoke` method.

`[res0,...,resN] = EndInvoke(res0,...,resN,asyncResult)` for methods with `out` and/or `ref` parameters.

Tips

- If the delegate contains `out` or `ref` parameters, the signature for the `EndInvoke` method follows the MATLAB mapping rules. For information, see “Call Delegates With out and ref Type Arguments”.

Input Arguments

asyncResult

.NET System.IAsyncResult object returned by `BeginInvoke`.

res0,...,resN

For methods with `out` and/or `ref` parameters, results of the asynchronous call. The number of arguments is the sum of:

- Number of return values (`0` or `1`).
- Number of `out` and `ref` arguments.

Output Arguments

result

Results of the asynchronous call.

res0,...,resN

For methods with `out` and/or `ref` parameters, results of the asynchronous call,

Examples

The following examples show how to call delegates with various input and output arguments. Each example contains:

1. The C# delegate signature. In order to execute the MATLAB code, you must build the delegate code into an assembly named `SignatureExamples` and load it into MATLAB. For information, see “Building a .NET Application for MATLAB Examples”.
2. An example MATLAB function to use with the delegate, which must exist on your path.
3. The `BeginInvoke` and `EndInvoke` signatures MATLAB creates. To display the signatures, create a delegate instance, `myDel`, and call the `methodsview` function.
4. Simple MATLAB example.

This examples shows how to use a delegate that has no return value.

1. C# delegate:

   ```
   public delegate void delint(Int32 arg);
   ```

2. MATLAB function to call:

   ```
   %Display input argument
   function dispfnc(A)
   %A = number
   ['Input is ' num2str(A)]
   end
   ```

3. MATLAB creates the following signatures. For `BeginInvoke`:

   ```
   System.IAsyncResult RetVal
       BeginInvoke (
           SignatureExamples.delint this,
           int32 scalar arg,
   ```

```
        System.AsyncCallback callback,
        System.Object object)
```

The `EndInvoke` signature:

```
    EndInvoke (
        SignatureExamples.delint this,
        System.IAsyncResult result)
```

4 Call `dispfnc`:

```
myDel = SignatureExamples.delint(@dispfnc);
asyncRes = myDel.BeginInvoke(6, [], []);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
myDel.EndInvoke(asyncRes)
```

MATLAB displays:

```
Input is 6
```

This example shows how to use a delegate with a return value. The delegate does not have `out` or `ref` parameters.

1 C# delegate:

```
public delegate Int32 del2int(Int32 arg1, Int32 arg2);
```

2 MATLAB function to call:

```
%Add input arguments
function res = addfnc(A, B)
%A and B are numbers
res = A + B;
end
```

3 MATLAB creates the following signatures. For `BeginInvoke`:

```
System.IAsyncResult RetVal
    BeginInvoke (
        SignatureExamples.del2int this,
        int32 scalar arg1,
        int32 scalar arg2,
        System.AsyncCallback callback,
        System.Object object)
```

The `EndInvoke` signature:

```
int32 scalar RetVal
    EndInvoke (
        SignatureExamples.del2int this,
        System.IAsyncResult result)
```

4 Call `addfnc`:

```
myDel = SignatureExamples.del2int(@addfnc);
asyncRes = myDel.BeginInvoke(6,8,[],[]);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
result = myDel.EndInvoke(asyncRes)
```

MATLAB displays:

```
result =
          14
```

This example shows how to use a delegate with a `ref` parameter, `refArg`, and no return value.

1 C# delegate:

```
public delegate void delrefvoid(ref Double refArg);
```

2 MATLAB maps the `ref` argument as both RHS and LHS arguments. MATLAB function to call:

```
%Increment input argument
function res = incfnc(A)
%A = number
res = A + 1;
end
```

3 MATLAB creates the following signatures. For `BeginInvoke`:

```
[System.IAsyncResult RetVal,
double scalar refArg]
    BeginInvoke (
        SignatureExamples.delrefvoid this,
        double scalar refArg,
        System.AsyncCallback callback,
        System.Object object)
```

The `EndInvoke` signature:

```
double scalar refArg
    EndInvoke (
        SignatureExamples.delrefvoid this,
        double scalar refArg,
        System.IAsyncResult result)
```

4 Call `incfnc`:

```
x = 6;
myDel = SignatureExamples.delrefvoid(@incfnc);
asyncRes = myDel.BeginInvoke(x,[],[]);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
myRef = 0;
result = myDel.EndInvoke(myRef,asyncRes);
```

```
disp(['Increment of ' num2str(x) ' = ' num2str(result)]);
```

MATLAB displays:

```
Increment of 6 = 7
```

This example shows how to use a delegate with an `out` parameter, `argOut`, and one return value.

1 C# delegate:

```
public delegate Single deloutsingle(Single argIn, out Single argOut
```

2 MATLAB maps the `out` argument as a return value for a total of two return values. MATLAB function to call:

```
%Double input argument
function [res1 res2] = times2fnc(A)
res1 = A*2;
res2 = res1;
end
```

3 MATLAB creates the following signatures. For `BeginInvoke`:

```
[System.IAsyncResult RetVal,
single scalar argOut]
    BeginInvoke (
        SignatureExamples.deloutsingle this,
        single scalar argIn,
        System.AsyncCallback callback,
        System.Object object)
```

The `EndInvoke` signature:

```
[single scalar RetVal,
single scalar argOut]
    EndInvoke (
```

```
        SignatureExamples.deloutsingle this,
        System.IAsyncResult result)
```

4 Call `times2fnc`:

```
myDel = SignatureExamples.deloutsingle(@times2fnc);
asyncRes = myDel.BeginInvoke(6,[],[]);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
[a1 a2] = myDel.EndInvoke(asyncRes);
a1
```

MATLAB displays:

```
a1 =
    12
```

`BeginInvoke`

How To

- "Calling .NET Methods Asynchronously"

Related Links

- MSDN Calling Synchronous Methods Asynchronously

Purpose

Last day of month

Syntax

```
E = eomday(Y, M)
```

Description

`E = eomday(Y, M)` returns the last day of the year and month given by corresponding elements of arrays `Y` and `M`.

Examples

Show the end of month for January through September for the year 1900:

```
eomday(1900, 1:9)
ans =
    31    28    31    30    31    30    31    31    30
```

Find the number of days during that period:

```
sum(eomday(1900, 1:9))
ans =
   273
```

Because 1996 is a leap year, the statement `eomday(1996,2)` returns `29`. To show all the leap years in the twentieth century, try:

```
y = 1900:1999;
E = eomday(y, 2);
y(find(E == 29))

ans =
  Columns 1 through 6

See Also

datenum | datevec | weekday

Purpose

Display class enumeration members and names

Syntax

```
enumeration ClassName
enumeration(obj)
m = enumeration(ClassName)
m = enumeration(obj)
[m,s] = enumeration(ClassName)
[m,s] = enumeration(obj)
```

Description

`enumeration ClassName` displays the names of the enumeration members for the MATLAB class with the name `ClassName`.

`enumeration(obj)` displays the names of the enumeration members for the class of `obj`.

`m = enumeration(ClassName)` returns the enumeration members for the class in the column vector `m` of objects.

`m = enumeration(obj)` returns the enumeration members for the class of object, `obj`, in the column vector `m` of objects.

`[m,s] = enumeration(ClassName)` returns the names of the enumeration members in the cell array of strings `s`. The names in `s` correspond element-wise to the enumeration members in `m`.

`[m,s] = enumeration(obj)` returns the enumeration members for the class of object, `obj`, in the column vector `m` of objects.

Tips

- An enumeration class that derives from a built-in class can specify more than one name for a given enumeration member.
- When you call the `enumeration` function with no output arguments, MATLAB displays only the first name for each enumeration member (as specified in the class definition). To see all available enumeration members and their names, use the two output arguments (for example, `[m, s] = enumeration(obj);`).

Input Arguments

ClassName

The name of the enumeration class, in single quotes.

obj

A instance of an enumeration class.

Output Arguments

m

Column vector of enumeration members.

s

Cell array of strings containing the enumeration names.

Examples

All examples use the following enumeration class.

```
classdef Boolean < logical
   enumeration
      No  (0)
      Yes (1)
      Off (0)
      On  (1)
   end
end
```

Display the names of the enumeration members for class `Boolean`:

```
enumeration Boolean
Enumerations for class Boolean:

    No
    Yes
```

Get the enumeration members for class `Boolean` in a column vector of objects:

```
members = enumeration('Boolean')
members =
```

```
    No
    Yes
```

Get all available enumeration members and their names:

```
[members, names] = enumeration('Boolean')
members =

    No
    Yes
    No
    Yes

names =

    'No'
    'Yes'
    'Off'
    'On'
```

eps

Purpose

Floating-point relative accuracy

Syntax

```
eps
d = eps(X)
eps('double')
eps('single')
```

Description

`eps` returns the distance from 1.0 to the next largest double-precision number, that is `eps = 2^(-52)`.

`d = eps(X)` is the positive distance from `abs(X)` to the next larger in magnitude floating point number of the same precision as `X`. `X` may be either double precision or single precision. For all `X`,

```
eps(X) = eps(-X) = eps(abs(X))
```

`eps('double')` is the same as `eps` or `eps(1.0)`.

`eps('single')` is the same as `eps(single(1.0))` or `single(2^-23)`.

Except for numbers whose absolute value is smaller than `realmin` , if `2^E <= abs(X) < 2^(E+1)`, then

```
eps(X) = 2^(E-23) if isa(X,'single')
eps(X) = 2^(E-52) if isa(X,'double')
```

For all `X` of class double such that `abs(X) <= realmin`, `eps(X) = 2^(-1074)`. Similarly, for all `X` of class single such that `abs(X) <= realmin('single')`, `eps(X) = 2^(-149)`.

Replace expressions of the form:

```
if Y < eps * ABS(X)
```

with

```
if Y < eps(X)
```

Examples

```
double precision
eps(1/2) = 2^(-53)
```

```
eps(1) = 2^(-52)
eps(2) = 2^(-51)
eps(realmax) = 2^971
eps(0) = 2^(-1074)

if(abs(x)) <= realmin, eps(x) = 2^(-1074)
eps(realmin/2) = 2^(-1074)
eps(realmin/16) = 2^(-1074)
eps(Inf) = NaN
eps(NaN) = NaN

single precision
eps(single(1/2)) = 2^(-24)
eps(single(1)) = 2^(-23)
eps(single(2)) = 2^(-22)
eps(realmax('single')) = 2^104
eps(single(0)) = 2^(-149)
eps(realmin('single')/2) = 2^(-149)
eps(realmin('single')/16) = 2^(-149)
if(abs(x)) <= realmin('single'), eps(x) = 2^(-149)
eps(single(Inf)) = single(NaN)
eps(single(NaN)) = single(NaN)
```

See Also

Purpose

Test for equality

Syntax

```
A == B
eq(A, B)
```

Description

`A == B` compares each element of array `A` for equality with the corresponding element of array `B`, and returns an array with elements set to logical 1 (`true`) where `A` and `B` are equal, or logical 0 (`false`) where they are not equal. Each input of the expression can be an array or a scalar value.

If both `A` and `B` are scalar (i.e., 1-by-1 matrices), then the MATLAB software returns a scalar value.

If both `A` and `B` are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as `A` and `B`.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input `A` is the number 100, and `B` is a 3-by-5 matrix, then `A` is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

When comparing handle objects, use `eq` or the == operator to test whether objects are the same handle. Use `isequal` to test if objects have equal property values, even if those objects are different handles.

`eq(A, B)` is called for the syntax `A == B` when either `A` or `B` is an object.

Examples

Create two 6-by-6 matrices, `A` and `B`, and locate those elements of `A` that are equal to the corresponding elements of `B`:

```
A = magic(6);
B = repmat(magic(3), 2, 2);

A == B
ans =
```

```
     0     1     1     0     0     0
     1     0     1     0     0     0
     0     1     1     0     0     0
     1     0     0     0     0     0
     0     1     0     0     0     0
     1     0     0     0     0     0
```

`ne` | `le` | `ge` | `lt` | `gt` | relational operators

eq (MException)

Purpose

Compare scalar `MException` objects for equality

Syntax

```
eObj1 == eObj2
```

Description

`eObj1 == eObj2` tests scalar `MException` objects `eObj1` and `eObj2` for equality, returning logical 1 (`true`) if the two objects are identical, otherwise returning logical 0 (`false`).

See Also

`try` | `catch` | `error` | `assert` | `MException` | `isequal(MException)` | `ne(MException)` | `getReport(MException)` | `disp(MException)` | `throw(MException)` | `rethrow(MException)` | `throwAsCaller(MException)` | `addCause(MException)` | | `last(MException)`

Purpose

Error function

Syntax

```
Y = erf(X)
```

Definitions

The error function `erf(X)` is twice the integral of the Gaussian distribution with 0 mean and variance of 1/2.

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2}\, dt$$

Description

`Y = erf(X)` returns the value of the error function for each element of real array `X`.

See Also

`erfc` | `erfcinv` | `erfcx` | `erfinv`

Purpose Complementary error function

Syntax

```
Y = erfc(X)
```

Definitions The complementary error function `erfc(X)` is defined as

$$\begin{aligned}\operatorname{erfc}(x) &= \frac{2}{\sqrt{\pi}}\int_x^{\infty} e^{-t^2}\,dt \\ &= 1 - \operatorname{erf}(x)\end{aligned}$$

Description `Y = erfc(X)` computes the value of the complementary error function.

Tips The relationship between the complementary error function `erfc` and the standard normal probability distribution returned by the Statistics Toolbox function `normcdf` is

$$\operatorname{normcdf}(x) = \left(\frac{1}{2}\right) \times \operatorname{erfc}\left(\frac{-x}{\sqrt{2}}\right)$$

See Also `erf` | `erfcinv` | `erfcx` | `erfinv`

Purpose

Inverse complementary error function

Syntax

```
X = erfcinv(Y)
```

Description

`X = erfcinv(Y)` returns the value of the inverse of the complementary error function for each element of `Y`. Elements of `Y` must be in the interval `[0 2]`. The function `erfcinv` satisfies $y = \mathrm{erfc}(x)$ for $2 \geq y \geq 0$ and $-\infty \geq x \geq \infty$.

Tips

The relationship between the inverse complementary error function `erfcinv` and the inverse standard normal probability distribution returned by the Statistics Toolbox function `norminv` is:

$$\mathrm{norminv}(p) = \left(-\sqrt{2}\right) \times \mathrm{erfcinv}(2p).$$

See Also

`erf` | `erfc` | `erfcx` | `erfinv`

Purpose

Scaled complementary error function

Syntax

```
Y = erfcx(X)
```

Definitions

The scaled complementary error function `erfcx(X)` is defined as

$$\mathrm{erfcx}(x) = e^{x^2}\,\mathrm{erfc}(x)$$

For large `X`, `erfcx(X)` is approximately $\left(\frac{1}{\sqrt{\pi}}\right)\frac{1}{x}$

Description

`Y = erfcx(X)` computes the value of the scaled complementary error function.

See Also

`erf` | `erfcinv` | `erfc` | `erfinv`

Purpose

Inverse error function

Syntax

```
X = erfinv(Y)
```

Description

`X = erfinv(Y)` returns the value of the inverse error function for each element of `Y`. Elements of `Y` should be in the interval `[-1 1]` or the function will return NaN. The function `erfinv` satisfies $y = \mathrm{erf}(x)$ for $-1 \le y \le 1$ and $-\infty \le x \le \infty$.

Examples

`erfinv(1)` is `Inf`

`erfinv(-1)` is `-Inf`.

See Also

`erf` | `erfcinv` | `erfcx` | `erfc`

error

Purpose

Display message and abort function

Syntax

```
error('msgIdent', 'msgString', v1, v2, ..., vN)
error('msgString', v1, v2, ...)
error('msgString')
error(msgStruct)
```

Description

`error('msgIdent', 'msgString', v1, v2, ..., vN)` generates an exception if the currently-running function tests for and confirms a faulty or unexpected condition. Depending on how the program has been designed to respond to the error, MATLAB either enters a `catch` block to handle the error condition, or exits the program.

The *`msgIdent`* argument is a unique *message identifier* string that MATLAB attaches to the error message when it throws the error. A message identifier has the format `component:mnemonic`. Its purpose is to better identify the source of the error (see Message Identifiers for more information).

The *`msgString`* argument is a character string that informs the user about the cause of the error and can also suggest how to correct the faulty condition. The *`msgString`* string can include escape sequences such as `\t` or `\n`, as well as any of the format specifiers supported by the `sprintf` function (such as `%s` or `%d`). Additional arguments *`v1`*, *`v2`*, `...`, *`vN`* provide values that correspond to and replace the conversion specifiers.

For example, if *`msgString`* is "Error on line `%d`, command `%s`", then *`v1`* is the line number at which the error was detected, and *`v2`* is the command that failed. See "Formatting Strings" for more detailed information on using string formatting commands.

All string input arguments must be enclosed in single quotation marks. If *`msgString`* is an empty string, the `error` command has no effect.

`error('msgString', v1, v2, ...)`reports an error without including a message identifier in the error report. Although including a message identifier in an error report is recommended, it is not required.

`error('msgString')` is the same as the above syntax, except that the *msgString* string contains no conversion specifiers, no escape sequences, and no substitution value (*v1*, *v2*, ...) arguments. All characters in *msgString* are interpreted exactly as they appear in the *msgString* argument. MATLAB displays the `\t` in `'C:\testFolder'` for example, as a backslash character followed by the letter `t`, and not as a horizontal tab.

`error(msgStruct)` accepts a scalar error structure input *msgStruct* with at least one of the fields `message`, `identifier`, and `stack`. When the *msgStruct* input includes a `stack` field, the `stack` field of the error will be set according to the contents of the `stack` input. When specifying a `stack` input, use the absolute file name and the entire sequence of functions that nests the function in the stack frame. This is the same as the string returned by `dbstack('-completenames')`. If *msgStruct* is an empty structure, no action is taken and `error` returns without exiting the function.

Tips

The `error` function captures what information it can about the error that occurred and stores it in a data structure that is an object of the `MException` class. This *error record* contains the error message string, message identifier, the error stack, and optionally an array of other exception objects that are intended to provide information as to the cause of the exception. See "Capture Information About Exceptions" for more information on how to access and use an exception object.

You can access information in the exception object using the `catch` function as documented in the `catch` reference page. If your program terminates because of an exception and returns control to the Command Prompt, you can access the exception object using the `MException.last` command.

The `error` function also determines where the error occurred and provides this information in the `stack` field of the `MException` object. This field contains a structure array that has the same format as the output of the `dbstack` function. This stack points to the line where the `error` function was called.

The following table shows the MATLAB functions that can be useful for throwing an exception:

Function	Description
error	Throw exception with specified error message.
assert	Evaluate given expression and throw exception if false.
throw	Throw exception based on specified MException object.
throwAsCaller	Throw exception that appears to have been thrown by the calling function.
rethrow	Reissue previously caught exception.

Examples

Example 1 — Simple Error Message

Write a short function errtest1 that throws an error when called with an incorrect number of input arguments. Include a message identifier 'myApp:argChk' and error message:

```
function errtest1(x, y)
if nargin ~= 2
    error('myApp:argChk', 'Wrong number of input arguments')
end
```

Call the function with an incorrect number of inputs. The call to nargin, a function that checks the number of inputs, fails and the program calls error:

```
errtest1(pi)

Error using errtest1 (line 3)
Wrong number of input arguments
```

If you run this function from the Command Window, you can use the MException.last method to view the exception object:

```
err = MException.last
err =
  MException

  Properties:
    identifier: 'myApp:argChk'
       message: 'Wrong number of input arguments'
         cause: {}
         stack: [1x1 struct]
  Methods

err.stack
ans =
    file: 'c:\work\errtest1.m'
    name: 'errtest1'
    line: 3
```

Example 2 — Special Characters

MATLAB converts special characters (like `\n` and `%d`) in the error message string only when you specify more than one input argument with `error`. In the single-argument case shown below, `\n` is taken to mean `backslash-n`. It is not converted to a newline character:

```
error('In this case, the newline \n is not converted.')

In this case, the newline \n is not converted.
```

But, when more than one argument is specified, MATLAB does convert special characters. This holds true regardless of whether the additional argument supplies conversion values or is a message identifier:

```
error('ErrorTests:convertTest', ...
      'In this case, the newline \n is converted.')

In this case, the newline
 is converted.
```

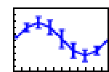
assert | try | dbstop | errordlg | warning | warndlg | MException | throw(MException) | rethrow(MException) | throwAsCaller(MException) | addCause(MException) | getReport(MException) | last(MException)

Purpose

Plot error bars along curve



Syntax

```
errorbar(Y,E)
errorbar(X,Y,E)
errorbar(X,Y,L,U)
errorbar(...,LineSpec)
h = errorbar(...)
```

Description

Error bars show the confidence intervals of data or the deviation along a curve.

`errorbar(Y,E)` plots `Y` and draws an error bar at each element of `Y`. The error bar is a distance of `E(i)` above and below the curve so that each bar is symmetric and `2*E(i)` long.

`errorbar(X,Y,E)` plots `Y` versus `X` with symmetric error bars `2*E(i)` long. `X`, `Y`, `E` must be the same size. When they are vectors, each error bar is a distance of `E(i)` above and below the point defined by `(X(i),Y(i))`. When they are matrices, each error bar is a distance of `E(i,j)` above and below the point defined by `(X(i,j),Y(i,j))`.

`errorbar(X,Y,L,U)` plots `X` versus `Y` with error bars `L(i)+U(i)` long specifying the lower and upper error bars. `X`, `Y`, `L`, and `U` must be the same size. When they are vectors, each error bar is a distance of `L(i)` below and `U(i)` above the point defined by `(X(i),Y(i))`. When they are matrices, each error bar is a distance of `L(i,j)` below and `U(i,j)` above the point defined by `(X(i,j),Y(i,j))`.

`errorbar(...,LineSpec)` uses the color and line style specified by the string `'LineSpec'`. The color is applied to the data line and error bars. The linestyle and marker are applied to the data line only. See `linespec` for examples of styles.

`h = errorbar(...)` returns handles to the errorbarseries objects created. `errorbar` creates one object for vector input arguments and

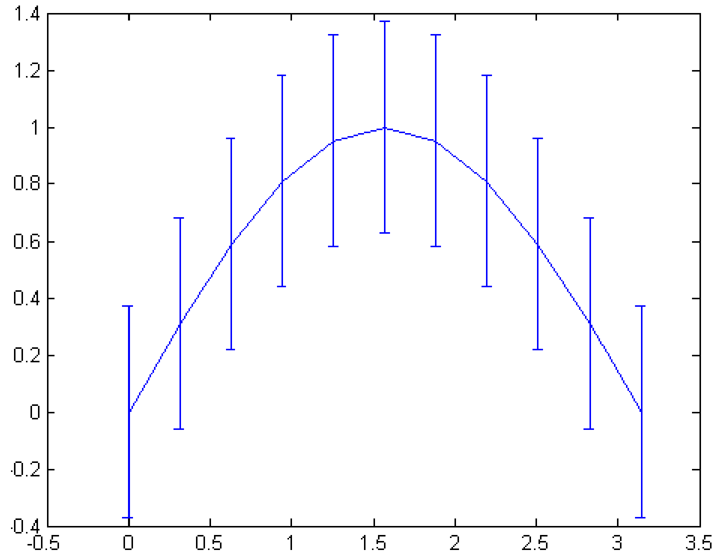
one object per column for matrix input arguments. See `errorbarseries properties` for more information.

When the arguments are all matrices, `errorbar` draws one line per matrix column. If `X` and `Y` are vectors, they specify one curve.

Examples

Draw symmetric error bars that are two standard deviation units in length:

```
X = 0:pi/10:pi;
Y = sin(X);
E = std(Y)*ones(size(X));
errorbar(X,Y,E)
```



Plot the computed average traffic volume and computed standard deviations for three street locations over the course of a day using red 'x' markers:

```
load count.dat;
y = mean(count,2);
```

```
e = std(count,1,2);
figure
errorbar(y,e,'xr')
```

How To

- ConfidenceBounds

Errorbarseries Properties

Purpose

Description of errorbarseries properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property editor (`propertyeditor`).

Note that you cannot define default property values for errorbarseries objects. See "Plot Objects" for more information on errorbarseries objects.

Errorbarseries Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Annotation`

`hg.Annotation` object (read-only)

Control the display of errorbarseries objects in legends. Specifies whether this errorbarseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the errorbarseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
`on`	Include the errorbarseries object in a legend as one entry, but not its children objects
`off`	Do not include the errorbarseries or its children in a legend (default)
`children`	Include only the children of the errorbarseries as separate entries in the legend

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation,'LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the IconDisplayStyle Property

See "Controlling Legends" for more information and examples.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to

perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`Children`
array of graphics object handles

Children of the errorbarseries object. An array containing the handles of all line objects parented to the errorbarseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`
`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`Color`
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is `[0 0 0]` (`black`).

See the `ColorSpec` reference page for more information on specifying color. See "Adding Arrows and Lines to Graphs".

`CreateFcn`
string | function handle

Not available on errorbarseries objects.

`DeleteFcn`
function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`
string

String used by legend. The `legend` function uses the `DisplayName` property to label the errorbarseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more information and examples.

`EraseMode`

`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`
`{on} | off`

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the curve or error bars that compose the graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`
`on | {off}`

Select the object by clicking lines or area of extent. Select plot objects by:

- Clicking curve or error bars (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the curve or error bars to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the lines).

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the`ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see "Control Callback Execution and Interruption".

`LData`
array equal in size to `XData` and `YData`

Errorbar length below data point. The `errorbar` function uses this data to determine the length of the errorbar below each data point. Specify these values in data units. See also `UData`.

`LDataSource`
string (MATLAB variable)

Link `LData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `LData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `LData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

`LineStyle`
`{-} | -- | : | -. | none`

Line style of errorbarseries object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle` `none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $^1/_{72}$ inch. The default is `0.5` points.

`Marker`
character (see table)

Marker symbol. Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle

Specifier	Marker Type
’*’	Asterisk
’.’	Point
’x’	Cross
’square’ or ’s’	Square
’diamond’ or ’d’	Diamond
’^’	Upward-pointing triangle
’v’	Downward-pointing triangle
’>’	Right-pointing triangle
’<’	Left-pointing triangle
’pentagram’ or ’p’	Five-pointed star (pentagram)
’hexagram’ or ’h''’	Six-pointed star (hexagram)
’none’	No marker (default)

MarkerEdgeColor
    ColorSpec | none | {auto}

Marker edge color. The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `Color` property.

MarkerFaceColor
    ColorSpec | {none} | auto

Fill color for closed-shape markers. The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`
scalar

Marker size. Size of the marker in points. The default value is `6`.

Note MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

`Parent`
handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Object selection state. When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this

property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing selection handles on the curve and error bars. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`Tag`
string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an errorbarseries object and set the `Tag` property:

```
t = errorbar(Y,E,'Tag','errorbar1')
```

To access the errorbarseries object, use `findobj` to find the errorbarseries object's handle.

The following statement changes the `MarkerFaceColor` property of the object whose `Tag` is `errorbar1`.

```
set(findobj('Tag','errorbar1'),'MarkerFaceColor','red')
```

`Type`
string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For errorbarseries objects, `Type` is '`hggroup`'. The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UData`

array equal in size to `XData` and `YData`

Errorbar length above data point. The `errorbar` function uses this data to determine the length of the errorbar above each data point. Specify these values in data units.

`UDataSource`

MATLAB variable, as a string

Link `UData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `UData`. The default value is an empty array.

```
set(h,'UDataSource','UDatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `UDataSource` does not change the object's `UData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

`UIContextMenu`

handle of uicontextmenu object

Associate a context menu with the errorbarseries object. Assign this property the handle of a uicontextmenu object created in the errorbarseries object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the

context menu whenever you right-click over the errorbarseries object.

`UserData`
array

User-specified data. Data you want to associate with the errorbarseries object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Visibility of errorbarseries object and its children. By default, errorbarseries object visibility is `on`. This means all children of the errorbarseries object are visible unless the child object's `Visible` property is `off`. Setting an errorbarseries object's `Visible` property to `off` also makes its children invisible.

`XData`
array

X-coordinates of the curve. The `errorbar` function plots a curve using the *x*-axis coordinates in the `XData` array. `XData` must be the same size as `YData`.

If you do not specify `XData` (which is the input argument `X`), the `errorbar` function uses the indices of `YData` to create the curve. See the `XDataMode` property for related information.

`XDataMode`
`{auto} | manual`

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the input argument `x`), the `errorbar` function sets this property to `manual`.

If you set XDataMode to auto after having specified XData, the errorbar function resets the *x* tick-mark labels to the indices of the YData.

XDataSource
string (MATLAB variable)

Link XData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change XData.

You can use the refreshdata function to force an update of the object's data. refreshdata also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call refreshdata. See the refreshdata reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

YData
scalar | vector | matrix

Data defining curve. YData contains the data defining the curve. If YData is a matrix, the errorbar function displays a curve with error bars for each column in the matrix.

The input argument Y in the errorbar function calling syntax assigns values to YData.

`YDataSource`

string (MATLAB variable)

Link `YData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `YData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Purpose

Create and open error dialog box

Syntax

```
h = errordlg
h = errordlg(errorstring)
h = errordlg(errorstring,dlgname)
h = errordlg(errorstring,dlgname,createmode)
```

Description

`h = errordlg` creates and displays a dialog box with title `Error Dialog` that contains the string `This is the default error string.` The `errordlg` function returns the handle of the dialog box in `h`.

`h = errordlg(errorstring)` displays a dialog box with title `Error Dialog` that contains the string `errorstring`.

`h = errordlg(errorstring,dlgname)` displays a dialog box with title`dlgname` that contains the string `errorstring`.

`h = errordlg(errorstring,dlgname,`*`createmode`*`)` specifies whether the error dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `errorstring` and `dlgname`. The *`createmode`* argument can be a string or a structure.

If *`createmode`* is a string, it must be one of the values shown in the following table.

createmode Value	Description
`modal`	Replaces the error dialog box having the specified `Title`, that was last created or clicked on, with a modal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.
`non-modal` (default)	Creates a new nonmodal error dialog box with the specified parameters. Existing

createmode Value	Description
	error dialog boxes with the same title are not deleted.
replace	Replaces the error dialog box having the specified Title, that was last created or clicked on, with a nonmodal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

Note A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the uiwait function.

If you open a dialog with errordlg, msgbox, or warndlg using 'CreateMode','modal' and a non-modal dialog created with any of these functions is already present and *has the same name as the modal dialog*, the non-modal dialog closes when the modal one opens.

For more information about modal dialog boxes, see WindowStyle in the Figure Properties.

If CreateMode is a structure, it can have fields WindowStyle and Interpreter. WindowStyle must be one of the options shown in the table above. Interpreter is one of the strings 'tex' or 'none'. The default value for Interpreter is 'none'.

Tips

MATLAB sizes the dialog box to fit the string 'errorstring'. The error dialog box has an **OK** push button and remains on the screen until you press the **OK** button or the **Return** key. After pressing the button, the error dialog box disappears.

The appearance of the dialog box depends on the platform you use.

Examples

The function

```
errordlg('File not found','File Error');
```

displays this dialog box:

etime

Purpose

Time elapsed between date vectors

Syntax

```
e = etime(t2,t1)
```

Description

`e = etime(t2,t1)` returns the number of seconds between two date vectors or matrices of date vectors, `t1` and `t2`.

Input Arguments

t2,t1 - Date vectors

1-by-6 vector | m-by-6 matrix

Date vectors, specified as 1-by-6 vectors or `m`-by-6 matrices containing `m` full date vectors in the format:

```
[Year Month Day Hour Minute Second]
```

Example: `[2012 03 27 11 50 01]`

Data Types

`double`

Examples

Compute Elapsed Time

Compute the time elapsed between a specific time and the current time, to 0.01-second accuracy.

Define the initial date and time and convert to date vector form.

```
format shortg
str = 'March 28, 2012 11:51:00';
t1 = datevec(str,'mmmm dd, yyyy HH:MM:SS')
```

```
t1 =
        2012           3          28          11          51           0
```

Determine the current date and time.

```
t2 = clock
```

```
t2 =
```

```
        2012           3          28          11          52
```

The `clock` function returns the current date and time as a date vector.

Use `etime` to compute the number of seconds between `t1` and `t2`.

```
e = etime(t2,t1)

e =

       62.357
```

Tips

- To time the duration of an event, use the `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.

Algorithms

`etime` does not account for the following:

- Leap seconds.
- Daylight savings time adjustments.
- Differences in time zones.

See Also

`tic` | `toc` | `cputime` | `clock` | `now`

Purpose

Elimination tree

Syntax

```
p = etree(A)
p = etree(A,'col')
p = etree(A,'sym')
[p,q] = etree(...)
```

Description

`p = etree(A)` returns an elimination tree for the square symmetric matrix whose upper triangle is that of `A`. `p(j)` is the parent of column `j` in the tree, or `0` if `j` is a root.

`p = etree(A,'col')` returns the elimination tree of `A'*A`.

`p = etree(A,'sym')` is the same as `p = etree(A)`.

`[p,q] = etree(...)` also returns a postorder permutation `q` of the tree.

See Also

`treelayout` | `treeplot` | `etreeplot`

Purpose

Plot elimination tree

Syntax

```
etreeplot(A)
etreeplot(A,nodeSpec,edgeSpec)
```

Description

`etreeplot(A)` plots the elimination tree of `A` (or `A+A'`, if non-symmetric).

`etreeplot(A,nodeSpec,edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `''` to omit one or both.

See Also

`etree` | `treeplot` | `treelayout`

eval

Purpose

Execute MATLAB expression in text string

Syntax

```
eval(expression)
[output1,...,outputN] = eval(expression)
```

Description

`eval(expression)` evaluates the MATLAB code in the string `expression`. If you use `eval` within an anonymous function, nested function, or function that contains a nested function, the evaluated `expression` cannot create a variable.

`[output1,...,outputN] = eval(expression)` stores output from `expression` in the specified variables.

Tips

- Many common uses of the `eval` function are less efficient and are more difficult to read and debug than other MATLAB functions and language constructs. For more information, see "Alternatives to the eval Function".
- Whenever possible, do not include output arguments within the input to the `eval` function, such as `eval(['output = ',expression])`. The preferred syntax,

  ```
  output = eval(expression)
  ```

  allows the MATLAB parser to perform stricter checks on your code, preventing untrapped errors and other unexpected behavior.

Input Arguments

expression

String that contains a valid MATLAB expression.

To include a numeric value in the expression, convert it to a string with `int2str`, `num2str`, or `sprintf`.

Output Arguments

output1,...,outputN

Outputs from the evaluated `expression`.

Examples

Variable Name Evaluation

Select a matrix to plot at runtime.

This example requires that you have a matrix in the current workspace. For example:

```
aMatrix = magic(5);
```

Interactively request the name of a matrix to plot, and call `eval` to use its value.

```
expression = input('Enter the name of a matrix: ','s');
if (exist(expression,'var'))
    mesh(eval(expression))
end
```

If you type `aMatrix` at the input prompt, this code creates a mesh plot of `magic(5)`.

See Also

`assignin` | `evalc` | `evalin` | `feval` | `try`

Tutorials

- “Alternatives to the eval Function”
- “Variables in Nested and Anonymous Functions”

Purpose

Evaluate MATLAB expression with capture

Syntax

```
T = evalc(S)
[T, X, Y, Z, ...] = evalc(S)
```

Description

`T = evalc(S)` is the same as `eval(S)` except that anything that would normally be written to the command window, except for error messages, is captured and returned in the character array `T` (lines in `T` are separated by `\n` characters).

`[T, X, Y, Z, ...] = evalc(S)` is the same as `[X, Y, Z, ...] = eval(S)` except that any output is captured into `T`.

Tips

When you are using `evalc`, functions `diary`, `more`, and `input` are disabled.

See Also

`eval` | `evalin` | `assignin` | `feval` | `diary` | `input` | `more`

Purpose

Execute MATLAB expression in specified workspace

Syntax

```
evalin(ws, expression)
[a1, a2, a3, ...] = evalin(ws, expression)
```

Description

`evalin(ws, expression)` executes *`expression`*, a string containing any valid MATLAB expression, in the context of the workspace `ws`. `ws` can have a value of `'base'` or `'caller'` to denote the MATLAB base workspace or the workspace of the caller function. You can construct *`expression`* by concatenating substrings and variables inside square brackets:

```
expression = [string1, int2str(var), string2,...]
```

`[a1, a2, a3, ...] = evalin(ws, expression)` executes *`expression`* and returns the results in the specified output variables. Using the `evalin` output argument list is recommended over including the output arguments in the expression string:

```
evalin(ws,'[a1, a2, a3, ...] = function(var)')
```

The above syntax avoids strict checking by the MATLAB parser and can produce untrapped errors and other unexpected behavior.

Tips

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line.

`evalin('caller', expression)` finds only *variables* in the caller's workspace; it does not find *functions* in the caller. For this reason, you cannot use `evalin` to construct a handle to a function that is defined in the caller.

If you use `evalin('caller', expression)` in the MATLAB debugger after having changed your local workspace context with `dbup` or `dbdown`,

MATLAB evaluates the expression in the context of the function that is one level up in the stack from your current workspace context.

Examples

This example extracts the value of the variable `var` in the MATLAB base workspace and captures the value in the local variable `v`:

```
v = evalin('base', 'var');
```

Limitation

`evalin` cannot be used recursively to evaluate an expression. For example, a sequence of the form `evalin('caller', 'evalin(''caller'', ''x'')')` doesn't work.

See Also

`assignin` | `eval` | `evalc` | `feval` | `catch` | `try`

Purpose

Base class for all data objects passed to event listeners

Description

The `event` package contains the `event.EventData` class, which defines the data objects passed to event listeners. If you want to provide additional information to event listeners, you can do so by subclassing `event.EventData`. See "Defining Event-Specific Data" for more information.

Properties

The `event.EventData` class defines two properties and no methods:

- `EventName` — The name of the event described by this data object.
- `Source` — The source object whose class defines the event described by the data object.

See Also

`event.PropertyEvent`

How To

- "Learning to Use Events and Listeners"

event.listener

Purpose

Class defining listener objects

Syntax

`lh = event.listener(Hobj,'EventName',@CallbackFunction)`

Description

The `event.listener` class defines listener objects. Listener objects respond to the specified event and identify the callback function to invoke when the event is triggered.

`lh = event.listener(Hobj,'EventName',@CallbackFunction)` creates an `event.listener` object, `lh`, for the event named in *`EventName`*, on the specified object, `Hobj`.

If `Hobj` is an array of object handles, the listener responds to the named event on any of the objects referenced in the array.

The listener callback function must accept at least two input arguments. For example,

```
function CallbackFunction(source,eventData)
   ...
end
```

where `source` is the object that is the source of the event and `eventData` is an `event.EventData` object.

The `event.listener` class is a `handle` class.

Limiting Listener Lifecycle

Generally, you create a listener object using `addlistener`. However, you can call the `event.listener` constructor directly to create a listener. When you use the `event.listener` constructor, the listener's lifecycle is not tied to the object(s) being listened to—once the listener object goes out of scope, the listener no longer exists. See "Ways to Create Listeners" for more information on creating listener objects.

Removing a Listener

If you call `delete(lh)` on the listener object, the listener ceases to exist, which means the event no longer causes the listener callback function to execute.

Disabling a Listener

You can enable or disable a listener by setting the value of the listener's `Enabled` property (see Properties table below).

More Information on Events and Listeners

See "Events" for more information and examples of how to use events and listeners.

Properties

Property	Purpose
`Source`	Cell array of source objects
`EventName`	Name of the event
`Callback`	Function to execute when the event is triggered and the `Enabled` property is set to `true`
`Enabled`	The callback executes when the event occurs if and only if `Enabled` is set to `true` (the default).
`Recursive`	When `false` (the default), this listener does not execute recursively. Therefore, if the callback triggers its own event, the listener does not execute again. When `true`, the listener callback can cause the same event that triggered the callback. This scheme can lead to infinite recursion, which ends when the MATLAB recursion limit eventually triggers an error.

See Also

`addlistener` | `delete` | `event.proplistener`

event.PropertyEvent

Purpose

Data for property events

Description

The `event.PropertyEvent` class defines the data objects passed to listeners of the `meta.property` events:

- `PreGet`
- `PostGet`
- `PreSet`
- `PostSet`

`event.PropertyEvent` is a sealed subclass of `event.EventData` (i.e., you cannot subclass `event.PropertyEvent`).

Properties

`event.PropertyEvent` inherits the first two properties from the `event.EventData`, and defines one new property:

- `EventName` — One of the four event names listed in the Description section
- `Source` — `meta.property` object that triggers the event
- `AffectedObject` — The object whose property is affected.

See Also

`event.EventData` | `meta.property`

How To

- “Listen for Changes to Property Values”

Purpose

Define listener object for property events

Syntax

```
lh = event.proplistener(Hobj,Properties,'PropEvent',
   @CallbackFunction)
```

Description

`lh = event.proplistener(Hobj,Properties,'PropEvent',@CallbackFunction)` creates a property listener object for one or more properties on the specified object.

- `Hobj` — handle of object whose property or properties are to be listened to. If `Hobj` is an array, the listener responds to the named event on all objects in the array.
- `Properties` — an object array or a cell array of `meta.property` object handles representing the properties to which you want to listen.
- `PropEvent` — must be one of the strings: `PreSet`, `PostSet`, `PreGet`, `PostGet`
- `@CallbackFunction` — function handle to the callback function that executes when the event occurs.

The `event.proplistener` class defines property event listener objects. It is a subclass of the `event.listener` class and adds one property to those defined by `event.listener`:

- `Object` — Cell array of objects whose property events are being listened to.

You can call the `event.proplistener` constructor instead of calling `addlistener` to create a property listener. However, when you do not use `addlistener`, the listener's lifecycle is not tied to the object(s) being listened to.

See "Listen for Changes to Property Values".

See "Getting Information About Properties" for more information on using `meta.property` objects.

See Also

`event.listener` | `addlistener`

eventlisteners

Purpose

List event handler functions associated with COM object events

Syntax

```
info = h.eventlisteners
info = eventlisteners(h)
```

Description

`info = h.eventlisteners` lists the events and their event handler routines registered with COM object `h`. The function returns a cell array of strings `info`, with each row containing the name of a registered event and the handler routine for that event. If the object has no registered events, `eventlisteners` returns an empty cell array. You can register events either when you create the control, using `actxcontrol`, or at any time afterwards, using `registerevent`.

`info = eventlisteners(h)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

Examples

Manage events for an instance of the MATLAB control `mwsamp`:

```
f = figure('position', [100 200 200 200]);
%Create an mwsamp control and
%register the Click event
h = actxcontrol('mwsamp.mwsampctrl.2', ...
    [0 0 200 200], f, ...
    {'Click' 'myclick'});
h.eventlisteners
```

MATLAB displays the event name and its event handler, `myclick`:

```
ans =
    'Click'    'myclick'
```

Register two more events, `DblClick` and `MouseDown`:

```
h.registerevent({'DblClick', 'my2click'; 'MouseDown' 'mymoused'});
h.eventlisteners
```

MATLAB displays all event names and handlers:

```
ans =
    'Click'         'myclick'
    'Dblclick'      'my2click'
    'Mousedown'     'mymoused'
```

Unregister all events for the control:

```
h.unregisterallevents
h.eventlisteners
```

MATLAB displays an empty cell array, indicating the control has no registered events:

```
ans =
     {}
```

See Also

events (COM) | registerevent | unregisterevent | unregisterallevents | isevent | actxcontrol

events

Purpose

Event names

Syntax

```
events('classname')
events(obj)
e = events(...)
```

Description

`events('classname')` displays the names of the public events for the MATLAB class *`classname`*, including events inherited from superclasses.

`events(obj)` `obj` is a scalar or array of objects of a MATLAB class.

`e = events(...)` returns the event names in a cell array of strings.

An event is public when the value of its `ListenAccess` attribute is `public` and its `Hidden` attribute value is `false` (default values for both attributes). See "Event Attributes" for a complete list of attributes.

`events` is also a MATLAB class-definition keyword. See `classdef` for more information on class definition keywords.

Examples

Get the names of the public events for the `handle` class:

```
events('handle')
Events for class handle:

    ObjectBeingDestroyed
```

See Also

`properties` | `methods`

Tutorials

- "Events"

Purpose

List of events COM object can trigger

Syntax

```
S = h.events
S = events(h)
```

Description

`S = h.events` returns structure array `S` containing all events, both registered and unregistered, known to the COM object, and the function prototype used when calling the event handler routine. For each array element, the structure field is the event name and the contents of that field is the function prototype for that event's handler.

`S = events(h)` is an alternate syntax.

Tips

COM functions are available on Microsoft Windows systems only.

Examples

List Control Events Example

Create an `mwsamp` control and list all events:

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.events
```

MATLAB software displays information similar to:

```
Click = void Click()
DblClick = void DblClick()
MouseDown = void MouseDown(int16 Button, int16 Shift,
  Variant x, Variant y)
Event_Args = void Event_Args(int16 typeshort, int32 typelong,
  double typedouble, string typestring, bool typebool)
```

Assign the output to a variable and get one field of the returned structure:

```
ev = h.events;
ev.MouseDown
```

MATLAB displays:

```
ans =
  void MouseDown(int16 Button, int16 Shift, Variant x, Variant y)
```

List Workbook Events Example

Open a Microsoft Excel application and list all events for a `Workbook` object:

```
myApp = actxserver('Excel.Application');
wbs = myApp.Workbooks;
wb = wbs.Add;
wb.events
```

The MATLAB software displays all events supported by the `Workbook` object.

```
 Open = void Open()
 Activate = void Activate()
 Deactivate = void Deactivate()
 BeforeClose = void BeforeClose(bool Cancel)
                 .
                 .
```

See Also

`isevent` | `eventlisteners` | `registerevent` | `unregisterevent` | `unregisterallevents`

Purpose

Execute MATLAB command in Automation server

Syntax

MATLAB Client

```
result = h.Execute('command')
result = Execute(h, 'command')
result = invoke(h, 'Execute', 'command')
```

IDL Method Signature

```
BSTR Execute([in] BSTR command)
```

Microsoft Visual Basic® Client

```
Execute(command As String) As String
```

Description

The `Execute` function executes the MATLAB statement specified by the string `command` in the MATLAB Automation server attached to handle `h`.

The server returns output from the command in the string, `result`. The `result` string also contains any warning or error messages that might have been issued by MATLAB software as a result of the command.

Note that if you terminate the MATLAB command string with a semicolon and there are no warnings or error messages, `result` might be returned empty.

Tips

If you want to be able to display output from `Execute` in the client window, you must specify an output variable (i.e., `result` in the above syntax statements).

Server function names, like `Execute`, are case sensitive when used with dot notation (the first syntax shown).

All three versions of the MATLAB client syntax perform the same operation.

If there is an error, the `Execute` function returns the MATLAB error message with the characters `???` prepended to the text.

COM functions are available on Microsoft Windows systems only.

Examples

Execute the MATLAB `version` function in the server and return the output to the MATLAB client.

MATLAB Client

```
h = actxserver('matlab.application');
server_version = h.Execute('version')
server_version =
ans =
   6.5.0.180913a (R13)
```

Visual Basic .NET Client

```
Dim Matlab As Object
Dim server_version As String
Matlab = CreateObject("matlab.application")
server_version = Matlab.Execute("version")
```

exifread

Purpose

Read EXIF information from JPEG and TIFF image files

Syntax

Note `exifread` will be removed in a future release. Use `imfinfo` instead.

```
output = exifread(filename)
```

Description

`output = exifread(filename)` reads the Exchangeable Image File Format (EXIF) data from the file specified by the string `filename`. `filename` must specify a JPEG or TIFF image file. `output` is a structure containing metadata values about the image or images in `imagefile`.

Note `exifread` returns all EXIF tags and does not process them in any way.

EXIF is a standard used by digital camera manufacturers to store information in the image file, such as, the make and model of a camera, the time the picture was taken and digitized, the resolution of the image, exposure time, and focal length. For more information about EXIF and the meaning of metadata attributes, see `http://www.exif.org/`.

See Also

`imfinfo` | `imread`

exist

Purpose

Check existence of variable, function, folder, or class

Syntax

```
exist name
exist name kind
A = exist('name','kind')
```

Description

`exist name` returns the status of `name`:

0	`name` does not exist.
1	`name` is a variable in the workspace.
2	One of the following is true: • `name` exists on your MATLAB search path as a file with extension `.m`. • `name` is the name of an ordinary file on your MATLAB search path. • `name` is the full pathname to any file.
3	`name` exists as a MEX- or DLL-file on your MATLAB search path.
4	`name` exists as a Simulink model or library file on your MATLAB search path.
5	`name` is a built-in MATLAB function.
6	`name` is a P-file on your MATLAB search path.
7	`name` is a folder.
8	`name` is a class. (`exist` returns 0 for Java classes if you start MATLAB with the `-nojvm` option.)

If `name` is a class, then `exist('name')` returns an `8`. However, if `name` is a class file, then `exist('name')` returns a `2`.

If a file or folder is not on the search path, then `name` must specify either a full pathname, a partial pathname relative to `MATLABPATH`, a partial

pathname relative to your current folder, or the file or folder must reside in your current working folder.

If `name` specifies a filename, that filename may include an extension to preclude conflicting with other similar filenames. For example, `exist('file.ext')`.

`exist name` *`kind`* returns the status of `name` for the specified *`kind`*. If `name` of type *`kind`* does not exist, it returns `0`. The *`kind`* argument may be one of the following:

`builtin`	Checks only for built-in functions.
`class`	Checks only for classes.
`dir`	Checks only for folders.
`file`	Checks only for files or folders.
`var`	Checks only for variables.

If you do not specify a *`kind`* argument, and `name` belongs to more than one of these categories, `exist` returns one value according to the order of evaluation shown in the table below. For example, if `name` matches both a folder and a file that defines a MATLAB function, `exist` returns `7`, identifying it as a folder.

Order of Evaluation	Return Value	Type of Entity
1	1	Variable
2	5	Built-in
3	7	Folder
4	3	MEX or DLL-file
5	4	MDL-file
6	6	P-file

Order of Evaluation	Return Value	Type of Entity
7	2	MATLAB function
8	8	Class

`A = exist('name','kind')` is the function form of the syntax.

Tips

If `name` specifies a filename, MATLAB attempts to locate the file, examines the filename extension, and determines the value to return based on the extension alone. MATLAB does not examine the contents or internal structure of the file.

You can specify a partial path to a folder or file. A partial pathname is a pathname relative to the MATLAB path that contains only the trailing one or more components of the full pathname. For example, both of the following commands return `2`, identifying `mkdir.m` as a MATLAB function. The first uses a partial pathname:

```
exist('matlab/general/mkdir.m')
exist([matlabroot '/toolbox/matlab/general/mkdir.m'])
```

To check for the existence of more than one variable, use the `ismember` function. For example,

```
a = 5.83;
c = 'teststring';
ismember({'a','b','c'},who)

ans =

     1     0     1
```

Examples

This example uses `exist` to check whether a MATLAB function is a built-in function or a file:

```
type = exist('plot')
type =
```

```
     5
```

This indicates that `plot` is a built-in function.

Run `exist` on a class folder and then on the constructor within that folder:

```
exist('@portfolio')
ans =
     7               % @portfolio is a folder

exist('@portfolio\portfolio')
ans =
     2               % portfolio is a MATLAB  function
```

The following example indicates that `testresults` is both a variable in the workspace and a folder on the search path:

```
exist('testresults','var')
ans =
     1
exist('testresults','dir')
ans =
     7
```

exit

Purpose

Terminate MATLAB program (same as `quit`)

Alternatives

As an alternative to the `exit` function, click the Close box in the MATLAB desktop.

Syntax

```
exit
exit(code)
```

Description

`exit` terminates the current session of MATLAB after running `finish.m`, if the file `finish.m` exists. It performs the same as `quit` and takes the same termination options, such as **`force`**.

`exit(code)` returns exit code when calling a MATLAB command from the system command line.

See Also

`quit` | `finish`

Purpose

Exponential

Syntax

```
Y = exp(X)
```

Description

`Y = exp(X)` returns the exponential for each element of `X`. `exp` operates element-wise on arrays. For complex $x + i * y$, `exp` returns the complex exponential $e^z = e^x(\cos y + i \sin y)$. Use `expm` for matrix exponentials.

Examples

Find the value of $e^{i\pi}$:

```
y=exp(i*pi)
```

returns

```
y =

  -1.0000 + 0.0000i
```

See Also

`expm` | `log`

expint

Purpose

Exponential integral

Syntax

```
Y = expint(X)
```

Definitions

The exponential integral computed by this function is defined as

$$E_1(x) = \int_x^{\infty} e^{-t} / t \, dt$$

Another common definition of the exponential integral function is the Cauchy principal value integral

$$\mathrm{Ei}(x) = \int_{-\infty}^{x} e^{t} / t \, dt$$

which, for real positive x, is related to `expint` as

$$E_1(-x) = -\mathrm{Ei}(x) - i\pi$$

Description

`Y = expint(X)` evaluates the exponential integral for each element of `X`.

References

[1] Abramowitz, M. and I. A. Stegun. *Handbook of Mathematical Functions*. Chapter 5, New York: Dover Publications, 1965.

Purpose

Matrix exponential

Syntax

```
Y = expm(X)
```

Description

`Y = expm(X)` computes the matrix exponential of `X`.

Although it is not computed this way, if `X` has a full set of eigenvectors `V` with corresponding eigenvalues `D`, then

```
[V,D] = EIG(X) and EXPM(X) = V*diag(exp(diag(D)))/V
```

Use `exp` for the element-by-element exponential.

Algorithms

`expm` uses the Padé approximation with scaling and squaring. See reference [3], below.

Note The files, `expmdemo1.m`, `expmdemo2.m`, and `expmdemo3.m` illustrate the use of Padé approximation, Taylor series approximation, and eigenvalues and eigenvectors, respectively, to compute the matrix exponential. References [1] and [2] describe and compare many algorithms for computing a matrix exponential.

Examples

This example computes and compares the matrix exponential of `A` and the exponential of `A`.

```
A = [1         1         0
     0         0         2
     0         0        -1 ];

expm(A)
ans =
    2.7183   1.7183        1.0862
    0        1.0000        1.2642
    0             0        0.3679
```

```
exp(A)
ans =
    2.7183    2.7183    1.0000
    1.0000    1.0000    7.3891
    1.0000    1.0000    0.3679
```

Notice that the diagonal elements of the two results are equal. This would be true for any triangular matrix. But the off-diagonal elements, including those below the diagonal, are different.

See Also

`exp` | `expm1` | `funm` | `logm` | `eig` | `sqrtm`

Purpose

Compute exp(x)-1 accurately for small values of x

Syntax

```
y = expm1(x)
```

Description

`y = expm1(x)` computes `exp(x)-1`, compensating for the roundoff in `exp(x)`.

For small `x`, `expm1(x)` is approximately `x`, whereas `exp(x)-1` can be zero.

See Also

`exp` | `expm` | `log1p`

export2wsdlg

Purpose

Export variables to workspace

Syntax

```
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title,selected)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title,selected,helpfunction)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title,selected,helpfunction,functionlist)
hdialog = export2wsdlg(...)
[hdialog,ok_pressed] = export2wsdlg(...)
```

Description

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport)` creates a dialog with a series of check boxes and edit fields. `checkboxlabels` is a cell array of labels for the check boxes. `defaultvariablenames` is a cell array of strings that serve as a basis for variable names that appear in the edit fields. `itemstoexport` is a cell array of the values to be stored in the variables. If there is only one item to export, `export2wsdlg` creates a text control instead of a check box.

Note By default, the dialog box is modal. A modal dialog box prevents the user from interacting with other windows before responding.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title)` creates the dialog with `title` as its title.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected)` creates the dialog allowing the user to control which check boxes are checked. `selected` is a logical array whose length is the same as `checkboxlabels`. True indicates that the check box should initially be checked, false unchecked.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected,helpfunction)` creates the dialog with a help button. `helpfunction` is a callback that displays help.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected,helpfunction,functionlist)` creates a dialog that enables the user to pass in `functionlist`, a cell array of functions and optional arguments that calculate, then return the value to export. `functionlist` should be the same length as `checkboxlabels`.

`hdialog = export2wsdlg(...)` returns the handle of the dialog.

`[hdialog,ok_pressed] = export2wsdlg(...)` sets `ok_pressed` to true if the OK button is pressed, or false otherwise. If two return arguments are requested, `hdialog` is `[]` and the function does not return until the dialog is closed.

The user can edit the text fields to modify the default variable names. If the same name appears in multiple edit fields, `export2wsdlg` creates a structure using that name. It then uses the `defaultvariablenames` as fieldnames for that structure.

The lengths of `checkboxlabels`, `defaultvariablenames`, `itemstoexport` and `selected` must all be equal.

The strings in `defaultvariablenames` must be unique.

Examples

This example creates a dialog box that enables the user to save the variables `sumA` and/or `meanA` to the workspace. The dialog box title is Save Sums to Workspace.

```
A = randn(10,1);
checkLabels = {'Save sum of A to variable named:' ...
               'Save mean of A to variable named:'};
varNames = {'sumA','meanA'};
items = {sum(A),mean(A)};
export2wsdlg(checkLabels,varNames,items,...
             'Save Sums to Workspace');
```

Purpose

Identity matrix

Syntax

```
I = eye
I = eye(n)
I = eye(n,m)
I = eye(sz)

I = eye(classname)
I = eye(n,classname)
I = eye(n,m,classname)
I = eye(sz,classname)

I = eye('like',p)
I = eye(n,'like',p)
I = eye(n,m,'like',p)
I = eye(sz,'like',p)
```

Description

`I = eye` returns the scalar, `1`.

`I = eye(n)` returns an `n`-by-`n` identity matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(n,m)` returns an `n`-by-`m` matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(sz)` returns an array with ones on the main diagonal and zeros elsewhere. The size vector, `sz`, defines `size(I)`. For example, `eye([2,3])` returns a 2-by-3 array with ones on the main diagonal and zeros elsewhere.

`I = eye(classname)` returns a scalar, `1`, where the string, `classname`, specifies the data type. For example, `eye('int8')` returns a scalar, 8-bit integer.

`I = eye(n,classname)` returns an `n`-by-`n` identity matrix of data type `classname`.

`I = eye(n,m,classname)` returns an `n`-by-`m` matrix of data type `classname` with ones on the main diagonal and zeros elsewhere.

`I = eye(sz,classname)` returns a matrix with ones on the main diagonal and zeros elsewhere. The size vector, `sz`, defines `size(I)` and `classname` defines `class(I)`.

`I = eye('like',p)` returns a scalar, `1`, with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`I = eye(n,'like',p)` returns an `n`-by-`n` identity matrix like `p`.

`I = eye(n,m,'like',p)` returns an `n`-by-`m` matrix like `p`.

`I = eye(sz,'like',p)` returns a matrix like `p` where the size vector, `sz`, defines `size(I)`.

Input Arguments

n - Size of first dimension of `I`

integer value

Size of first dimension of `I`, specified as an integer value.

- If `n` is the only integer input argument, then `I` is a square n-by-n identity matrix.
- If `n` is `0`, then `I` is an empty matrix.
- If `n` is negative, then it is treated as `0`.

Data Types

`double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

m - Size of second dimension of I

integer value

Size of second dimension of I, specified as an integer value.

- If m is 0, then I is an empty matrix.
- If m is negative, then it is treated as 0.

Data Types

double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

sz - Size of I

row vector of no more than two integer values

Size of I, specified as a row vector of no more than two integer values.

- If an element of sz is 0, then I is an empty matrix.
- If an element of sz is negative, then the element is treated as 0.

Example: sz = [2,3] defines I as a 2-by-3 matrix.

Data Types

double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

classname - Output class

'double' (default) | 'single' | 'int8' | 'uint8'

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

Data Types

char

p - Prototype

numeric variable

Prototype, specified as a numeric variable.

Data Types
`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

Examples

Square Identity Matrix

Create a 4-by-4 identity matrix.

```
I = eye(4)

I =

     1     0     0     0
     0     1     0     0
     0     0     1     0
     0     0     0     1
```

Rectangular Matrix

Create a 2-by-3 identity matrix.

```
I = eye(2,3)

I =

     1     0     0
     0     1     0
```

Identity Vector

Create a 3-by-1 identity vector.

```
sz = [3,1];
I = eye(sz)

I =

     1
     0
```

```
     0
```

Nondefault Numeric Data Type

Create a 3-by-3 identity matrix whose elements are 32-bit unsigned integers.

```
I = eye(3,'uint32'),
class(I)
```

```
I =

           1           0           0
           0           1           0
           0           0           1

ans =

uint32
```

Complex Identity Matrix

Create a 2-by-2 identity matrix that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create an identity matrix that is complex like `p`.

```
I = eye(2,'like',p)
```

```
I =

   1.0000 + 0.0000i   0.0000 + 0.0000i
   0.0000 + 0.0000i   1.0000 + 0.0000i
```

Sparse Identity Matrix

Define a 5-by-5 sparse matrix.

```
p = sparse(5,5,pi);
```

Create a 5-by-5 identity matrix that is sparse like P.

```
I = eye(5,'like',p)
```

```
I =

   (1,1)        1
   (2,2)        1
   (3,3)        1
   (4,4)        1
   (5,5)        1
```

Size and Numeric Data Type Defined by Existing Array

Define a 2-by-2 matrix of single precision.

```
p = single([1 3 ; 2 4]);
```

Create an identity matrix that is the same size and data type as P.

```
I = eye(size(p),'like',p),
class(I)
```

```
I =

     1     0
     0     1

ans =

single
```

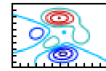
See Also

`speye` | `ones` | `zeros`

Concepts

Purpose

Easy-to-use contour plotter



Syntax

```
ezcontour(fun)
ezcontour(fun,domain)
ezcontour(...,n)
ezcontour(axes_handle,...)
h = ezcontour(...)
```

Description

`ezcontour(fun)` plots the contour lines of `fun(x,y)` using the `contour` function. `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle for a MATLAB file function or an anonymous function (see `function handle` and "Anonymous Functions") or a string (see Tips).

`ezcontour(fun,domain)` plots `fun(x,y)` over the specified `domain`. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where `min` < x < `max`, `min` < y < `max`).

`ezcontour(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontour(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezcontour(...)` returns the handles to contour objects in `h`.

`ezcontour` automatically adds a title and axis labels.

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontour`. For example, the MATLAB syntax for a contour plot of the expression

```
sqrt(x.^2 + y.^2)
```

is written as

```
ezcontour('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezcontour`.

If the function to be plotted is a function of the variables u and v (rather than x and y), the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontour('u^2 - v^3',[0,1],[3,6])` plots the contour lines for $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontour`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontour(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezcontour` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then use an anonymous function to specify that parameter:

```
ezcontour(@(x,y)myfun(x,y,2))
```

Examples

The following mathematical expression defines a function of two variables, x and y.

$$f(x,y) = 3(1-x)^2 e^{-x^2-(y+1)^2} - 10\left(\frac{x}{5} - x^3 - y^5\right)e^{-x^2-y^2} - \frac{1}{3}e^{-(x+1)^2-y^2}$$

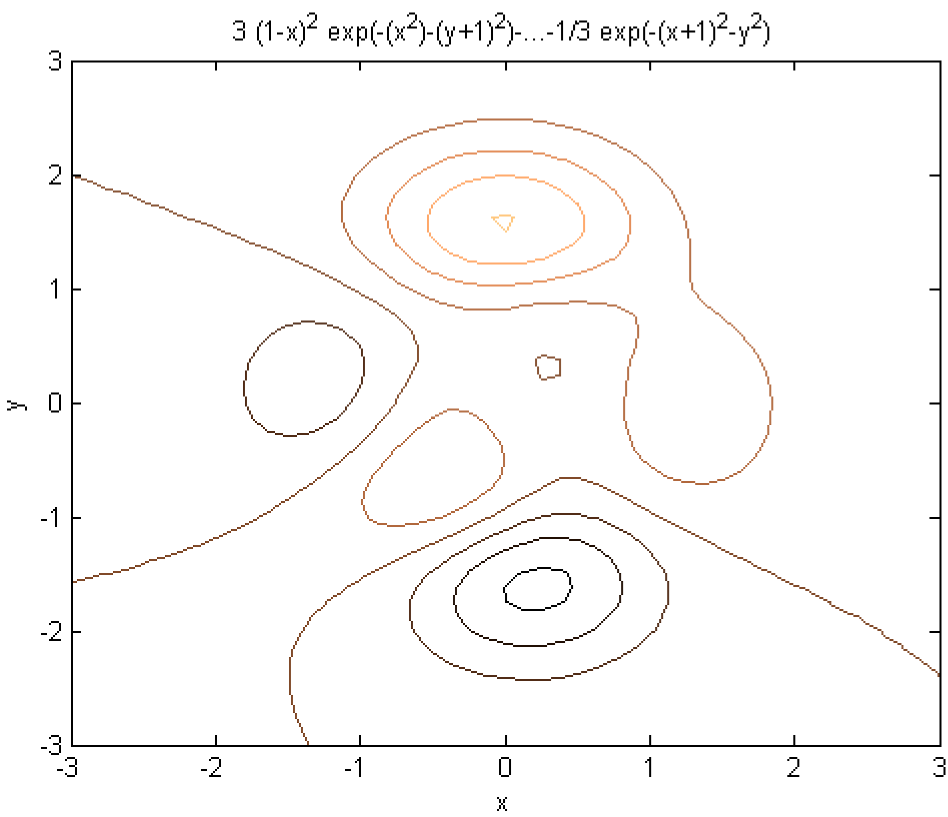
ezcontour requires a function handle argument that expresses this function using MATLAB syntax. This example uses an anonymous function, which you can define in the command window without creating a separate file.

```
f=@(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
   - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
   - 1/3*exp(-(x+1).^2 - y.^2);
```

For convenience, this function is written on three lines. The MATLAB peaks function evaluates this expression for different sizes of grids.

Pass the function handle f to ezcontour along with a domain ranging from -3 to 3 in both *x* and *y* and specify a computational grid of 49-by-49:

```
ezcontour(f,[-3,3],49)
```



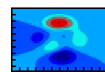
In this particular case, the title is too long to fit at the top of the graph, so MATLAB abbreviates the string.

See Also

`contour` | `ezcontourf` | `ezmesh` | `ezmeshc` | `ezplot` | `ezplot3` | `ezpolar` | `ezsurf` | `ezsurfc` | `function_handle`

Purpose

Easy-to-use filled contour plotter



Syntax

```
ezcontourf(fun)
ezcontourf(fun,domain)
ezcontourf(...,n)
ezcontourf(axes_handle,...)
h = ezcontourf(...)
```

Description

`ezcontourf(fun)` plots the contour lines of `fun(x,y)`using the `contourf` function. `fun` is plotted over the default domain: -2π < `x` < 2π, -2π < `y` < 2π.

`fun` can be a function handle or a string (see Tips).

`ezcontourf(fun,domain)` plots `fun(x,y)` over the specified `domain`. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]`, where `min` < *x* < `max`, `min` < *y* < `max`).

`ezcontourf(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontourf(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = ezcontourf(...)` returns the handles to contour objects in `h`.

`ezcontourf` automatically adds a title and axis labels.

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontourf`. For example, the MATLAB syntax for a filled contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezcontourf('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezcontourf`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontourf('u^2 - v^3',[0,1],[3,6])` plots the contour lines for $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontourf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontourf(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezcontourf` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezcontourf(@(x,y)myfun(x,y,2))
```

Examples

The following mathematical expression defines a function of two variables, x and y.

$$f(x, y) = 3(1-x)^2 e^{-x^2-(y+1)^2} - 10\left(\frac{x}{5} - x^3 - y^5\right)e^{-x^2-y^2} - \frac{1}{3}e^{-(x+1)^2-y^2}$$

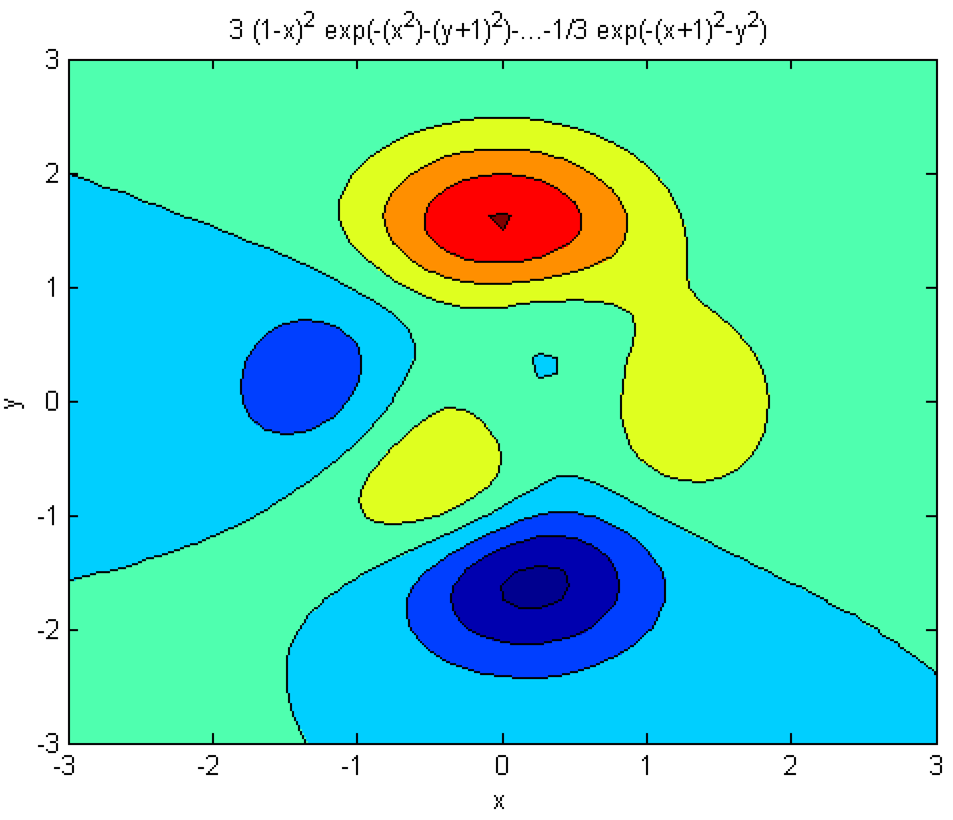
`ezcontourf` requires a string argument that expresses this function using MATLAB syntax to represent exponents, natural logs, etc. This function is represented by the string

```
f = @(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
        - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
        - 1/3*exp(-(x+1).^2 - y.^2);
```

For convenience, this string is written on three lines and concatenated into one string using square brackets.

Pass the string variable `f` to `ezcontourf` along with a domain ranging from -3 to 3 and specify a grid of 49-by-49:

```
ezcontourf(f,[-3,3],49)
```



In this particular case, the title is too long to fit at the top of the graph, so MATLAB abbreviates the string.

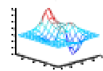
How To

- Anonymous Functions

Purpose

Easy-to-use 3-D mesh plotter



Syntax

```
ezmesh(fun)
ezmesh(fun,domain)
ezmesh(funx,funy,funz)
ezmesh(funx,funy,funz,[smin,smax,tmin,tmax])
ezmesh(funx,funy,funz,[min,max])
ezmesh(...,n)
ezmesh(...,'circ')
ezmesh(axes_handle,...)
h = ezmesh(...)
```

Description

`ezmesh(fun)` creates a graph of `fun(x,y)` using the `mesh` function. `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle or a string (see the Tips section).

`ezmesh(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where `min` < `x` < `max`, `min` < `y` < `max`).

`ezmesh(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: -2π < `s` < 2π, -2π < `t` < 2π.

`ezmesh(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezmesh(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezmesh(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezmesh(...,'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmesh(...)` returns the handle to a surface object in `h`.

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmesh`. For example, the MATLAB syntax for a mesh plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmesh('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezmesh`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmesh('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmesh`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmesh(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezmesh` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmesh(@(x,y)myfun(x,y,2))
```

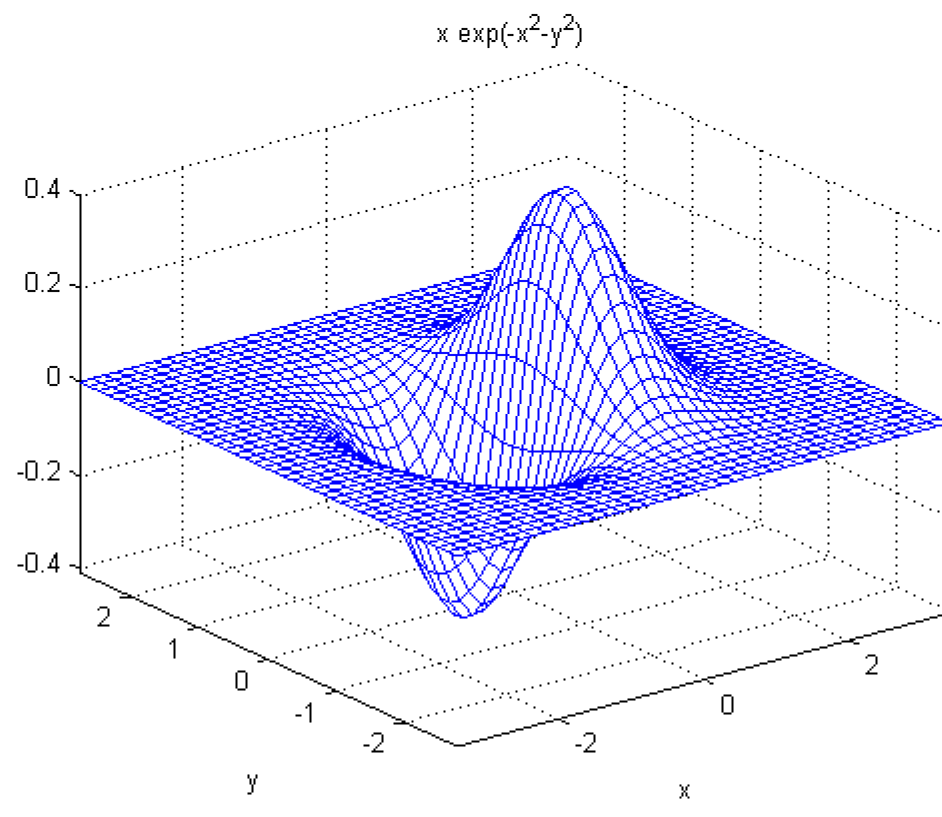
Examples

This example visualizes the function

$$f(x,y) = ex^{-x^2-y^2}$$

with a mesh plot drawn on a 40-by-40 grid. The mesh lines are set to a uniform blue color by setting the colormap to a single color:

```
fh = @(x,y) x.*exp(-x.^2-y.^2);
ezmesh(fh,40)
colormap([0 0 1])
```



See Also

`ezmeshc` | `function_handle` | `mesh`

How To

- Anonymous Functions

Purpose

Easy-to-use combination mesh/contour plotter

Syntax

```
ezmeshc(fun)
ezmeshc(fun,domain)
ezmeshc(funx,funy,funz)
ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])
ezmeshc(funx,funy,funz,[min,max])
ezmeshc(...,n)
ezmeshc(...,'circ')
ezmesh(axes_handle,...)
h = ezmeshc(...)
```

Description

`ezmeshc(fun)` creates a graph of `fun(x,y)` using the `meshc` function. `fun` is plotted over the default domain $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle or a string (see the Tips section).

`ezmeshc(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where `min` < x < `max`, `min` < y < `max`).

`ezmeshc(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: -2π < `s` < 2π, -2π < `t` < 2π.

`ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezmeshc(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezmeshc(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezmeshc(...,'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmeshc(...)` returns the handle to a surface object in `h`.

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmeshc`. For example, the MATLAB syntax for a mesh/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmeshc('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezmeshc`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmeshc('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmeshc`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmeshc(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezmeshc` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmeshc(@(x,y)myfun(x,y,2))
```

Examples

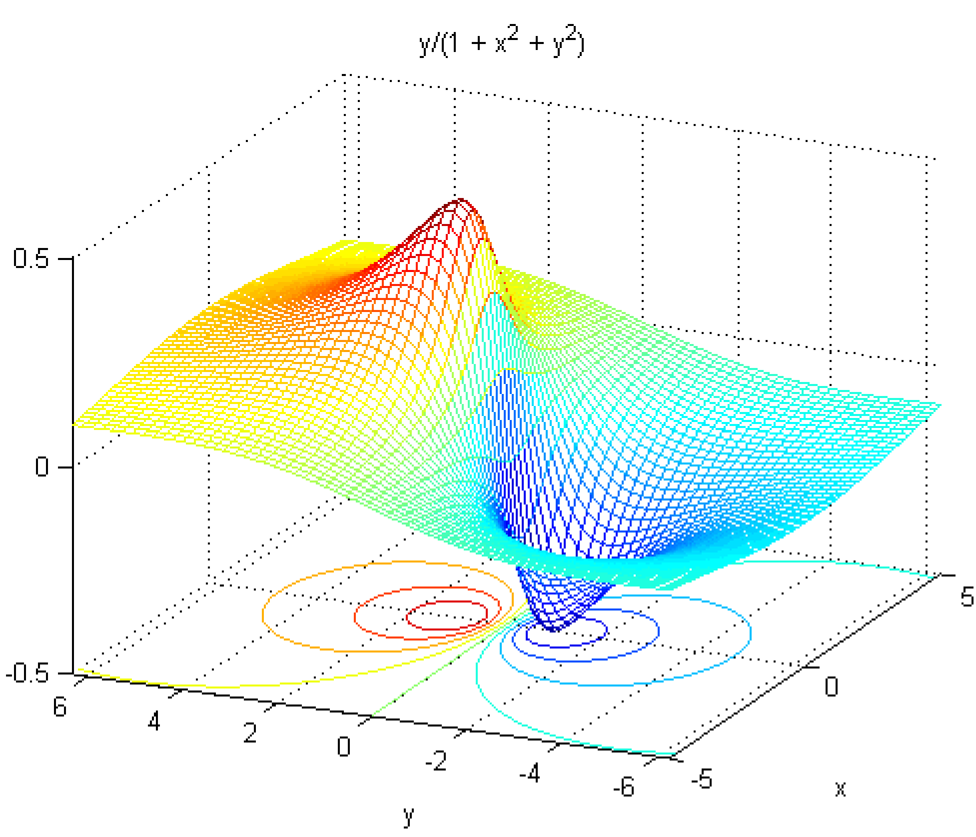
Create a mesh/contour graph of the expression

$$f(x,y) = \frac{y}{1 + x^2 + y^2}$$

over the domain $-5 < x < 5$, $-2*pi < y < 2*pi$:

```
ezmeshc('y/(1 + x^2 + y^2)',[-5,5,-2*pi,2*pi])
view(-65.5,26)
```

Use the mouse to rotate the axes to better observe the contour lines (this picture uses a view of azimuth = -65.5 and elevation = 26)



See Also

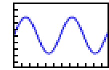
`ezmesh` | `ezsurfc` | `function_handle` | `meshc`

How To

- Anonymous Functions

Purpose

Easy-to-use function plotter



Syntax

```
ezplot(fun)
ezplot(fun,[xmin,xmax])
ezplot(fun2)
ezplot(fun2,[xymin,xymax])
ezplot(fun2,[xmin,xmax,ymin,ymax])
ezplot(funx,funy)
ezplot(funx,funy,[tmin,tmax])
ezplot(...,figure_handle)
ezplot(axes_handle,...)
h = ezplot(...)
```

Description

`ezplot(fun)` plots the expression `fun(x)` over the default domain $-2\pi < x < 2\pi$, where `fun(x)` is an explicit function of only x.

`fun` can be a function handle or a string.

`ezplot(fun,[xmin,xmax])` plots `fun(x)` over the domain: `xmin` < x < `xmax`.

For an implicit function, `fun2(x,y)`:

`ezplot(fun2)` plots `fun2(x,y) = 0` over the default domain $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`ezplot(fun2,[xymin,xymax])` plots `fun2(x,y) = 0` over `xymin` < `x` < `xymax` and `xymin` < `y` < `xymax`.

`ezplot(fun2,[xmin,xmax,ymin,ymax])` plots `fun2(x,y) = 0` over `xmin` < `x` < `xmax` and `ymin` < `y` < `ymax`.

`ezplot(funx,funy)` plots the parametrically defined planar curve `funx(t)` and `funy(t)` over the default domain 0 < `t` < 2π.

`ezplot(funx,funy,[tmin,tmax])` plots `funx(t)` and `funy(t)` over `tmin` < `t` < `tmax`.

`ezplot(...,figure_handle)` plots the given function over the specified domain in the figure window identified by the handle `figure`.

`ezplot(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot(...)` returns the handle to all the plot objects in h.

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot`. For example, the MATLAB syntax for a plot of the expression

```
x.^2 - y.^2
```

which represents an implicitly defined function, is written as

```
ezplot('x^2 - y^2')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezplot`.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot`,

```
fh = @(x,y) sqrt(x.^2 + y.^2 - 1);
ezplot(fh)
axis equal
```

which plots a circle. Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezplot` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
```

```
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezplot(@(x,y)myfun(x,y,2))
```

Controlling Line Color

`ezplot` colors lines according to the type of graphics object it chooses to plot the input function.

- For an implicit function, ezplot uses a `LineSeries` object to generate the graph. To change the color, you should set the `Color` property.
- For an explicit function, the graph generated is a `Hggroup` object. So, to change the color, you should set the `LineColor` property.

Example

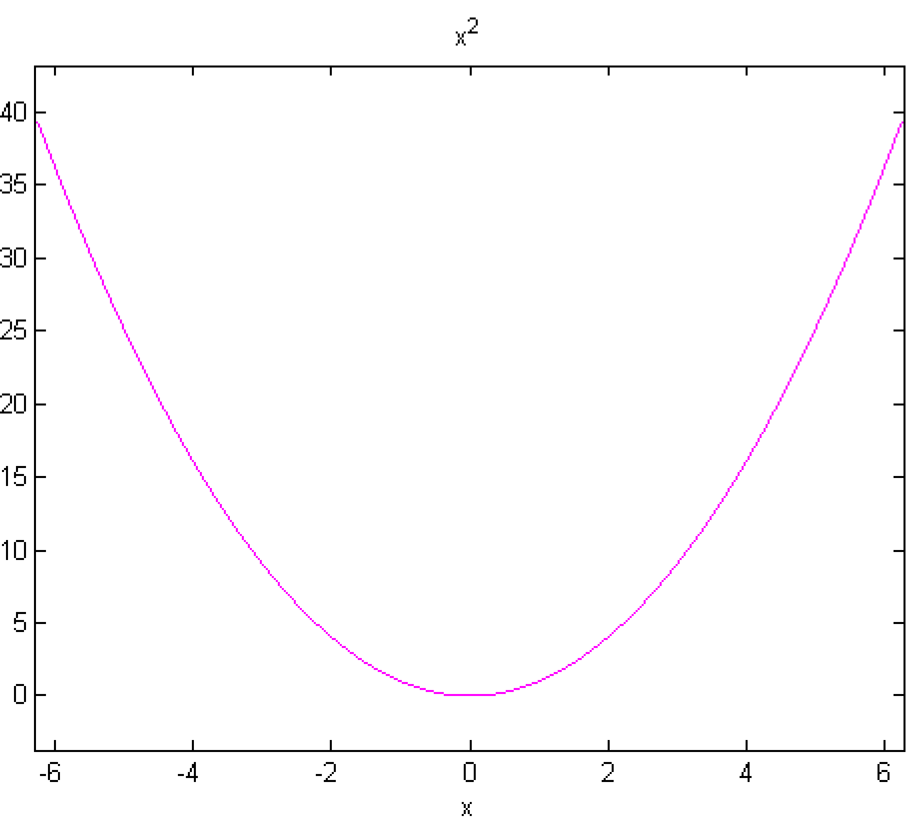
Plotting an Explicit Function

This example plots an explicit function:

x^2

over the domain [-2π, 2π].

```
h = ezplot('x^2')
set(h, 'Color', 'm');   % Make the line magenta
```



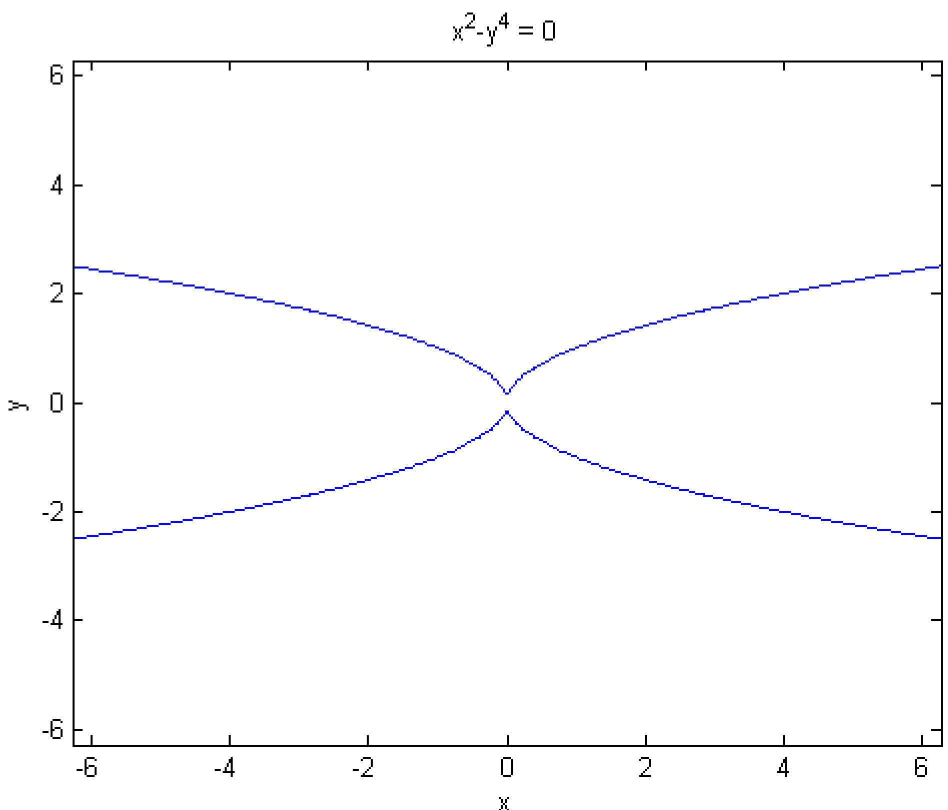
Plotting an Implicit Function

This example plots the implicitly defined function

$x^2 - y^4 = 0$

over the domain [-2π, 2π].

```
ezplot('x^2-y^4')
colormap([0 0 1])   % Make the line blue
```



See Also

`ezplot3` | `ezpolar` | `function_handle` | `plot`

How To

- Anonymous Functions

ezplot3

Purpose

Easy-to-use 3-D parametric curve plotter

Syntax

```
ezplot3(funx,funy,funz)
ezplot3(funx,funy,funz,[tmin,tmax])
ezplot3(...,'animate')
ezplot3(axes_handle,...)
h = ezplot3(...)
```

Description

`ezplot3(funx,funy,funz)` plots the spatial curve `funx(t)`, `funy(t)`, and `funz(t)` over the default domain 0 < `t` < 2π.

`funx`, `funy`, and `funz` can be function handles or strings (see the Tips section).

`ezplot3(funx,funy,funz,[tmin,tmax])` plots the curve `funx(t)`, `funy(t)`, and `funz(t)` over the domain `tmin` < `t` < `tmax`.

`ezplot3(...,'animate')` produces an animated trace of the spatial curve.

`ezplot3(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot3(...)` returns the handle to the plotted objects in `h`.

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot3`. For example, the MATLAB syntax for a plot of the expression

```
x = s./2, y = 2.*s, z = s.^2;
```

which represents a parametric function, is written as

```
ezplot3('s/2','2*s','s^2')
```

That is, `s/2` is interpreted as `s./2` in the string you pass to `ezplot3`.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot3`.

```
fh1 = @(s) s./2; fh2 = @(s) 2.*s; fh3 = @(s) s.^2;
ezplot3(fh1,fh2,fh3)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezplot` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfuntk`:

```
function s = myfuntk(t,k)
s = t.^k.*sin(t);
```

then you can use an anonymous function to specify that parameter:

```
ezplot3(@cos,@(t)myfuntk(t,1),@sqrt)
```

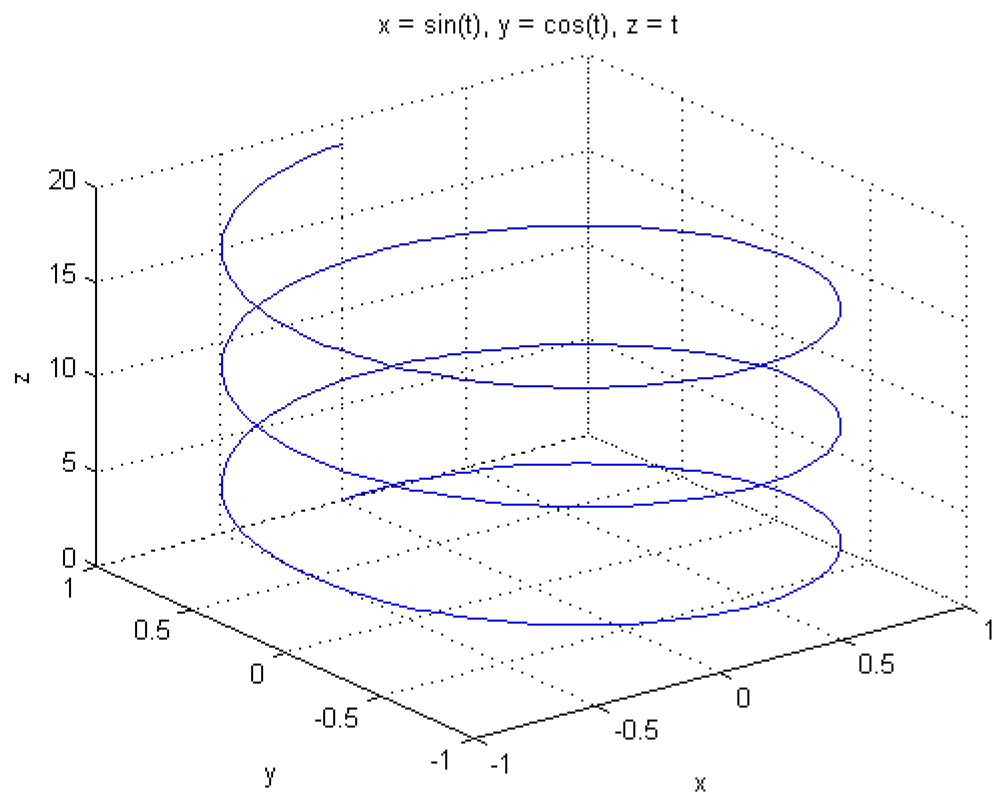
Examples

This example plots the parametric curve

$$x = \sin t, \quad y = \cos t, \quad z = t$$

over the domain [0,6π]:

```
ezplot3('sin(t)','cos(t)','t',[0,6*pi])
```



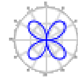
See Also `ezplot` | `ezpolar` | `function_handle` | `plot3`

How To

- Anonymous Functions

Purpose

Easy-to-use polar coordinate plotter



Syntax

```
ezpolar(fun)
ezpolar(fun,[a,b])
ezpolar(axes_handle,...)
h = ezpolar(...)
```

Description

`ezpolar(fun)` plots the polar curve `rho = fun(theta)` over the default domain 0 < `theta` < 2π.

`fun` can be a function handle or a string (see the Tips section).

`ezpolar(fun,[a,b])` plots `fun` for `a` < `theta` < `b`.

`ezpolar(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezpolar(...)` returns the handle to a line object in `h`.

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezpolar`. For example, the MATLAB syntax for a plot of the expression

```
t.^2.*cos(t)
```

which represents an implicitly defined function, is written as

```
ezpolar('t^2*cos(t)')
```

That is, `t^2` is interpreted as `t.^2` in the string you pass to `ezpolar`.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezpolar`.

```
fh = @(t) t.^2.*cos(t);
ezpolar(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezpolar` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k1` and `k2` in `myfun`:

```
function s = myfun(t,k1,k2)
s = sin(k1*t).*cos(k2*t);
```

then you can use an anonymous function to specify the parameters:

```
ezpolar(@(t)myfun(t,2,3))
```

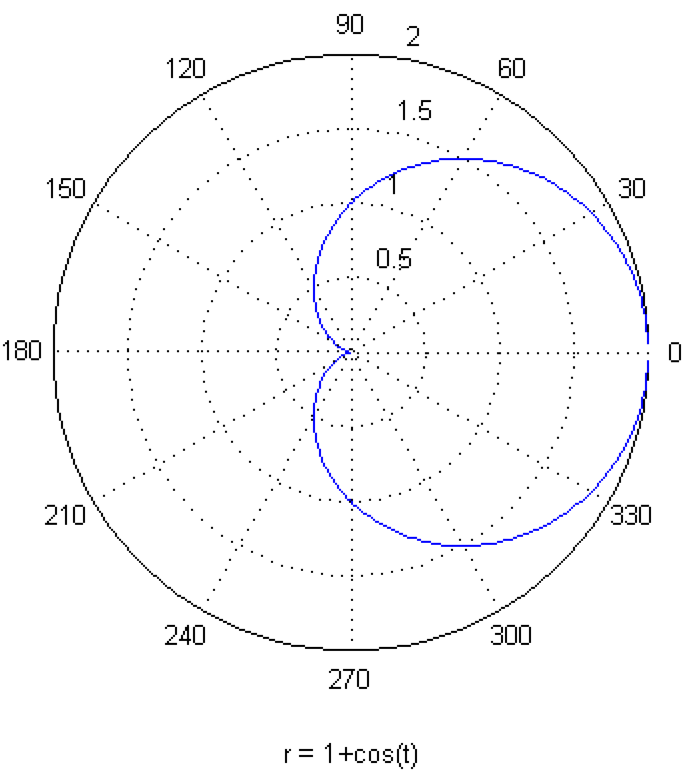
Examples

This example creates a polar plot of the function

$1 + cos(t)$

over the domain $[0, 2\pi]$:

```
ezpolar('1+cos(t)')
```



See Also

`ezplot` | `ezplot3` | `function_handle` | `plot` | `plot3` | `polar`

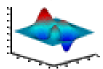
How To

- Anonymous Functions

ezsurf

Purpose

Easy-to-use 3-D colored surface plotter



Syntax

```
ezsurf(fun)
ezsurf(fun,domain)
ezsurf(funx,funy,funz)
ezsurf(funx,funy,funz,[smin,smax,tmin,tmax])
ezsurf(funx,funy,funz,[min,max])
ezsurf(...,n)
ezsurf(...,'circ')
ezsurf(axes_handle,...)
h = ezsurf(...)
```

Description

`ezsurf(fun)` creates a graph of `fun(x,y)` using the `surf` function. `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle or a string (see the Tips section).

`ezsurf(fun,domain)` plots `fun` over the specified `domain`. `domain` must be a vector. See the “Algorithms” on page 1-1582 section for details on vector inputs vs axes limit outputs.

`ezsurf(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

`ezsurf(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezsurf(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezsurf(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezsurf(...,'circ')` plots `fun` over a disk centered on the domain.

`ezsurf(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurf(...)` returns the handle to a surface object in `h`.

Tips

`ezsurf` and `ezsurfc` do not accept complex inputs.

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezmesh`. For example, the MATLAB syntax for a surface plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurf('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezsurf`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurf('u^2 - v^3',[0,1],[3,6])` plots u^2 - v^3 over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezsurf` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurf(@(x,y)myfun(x,y,2,2,4))
```

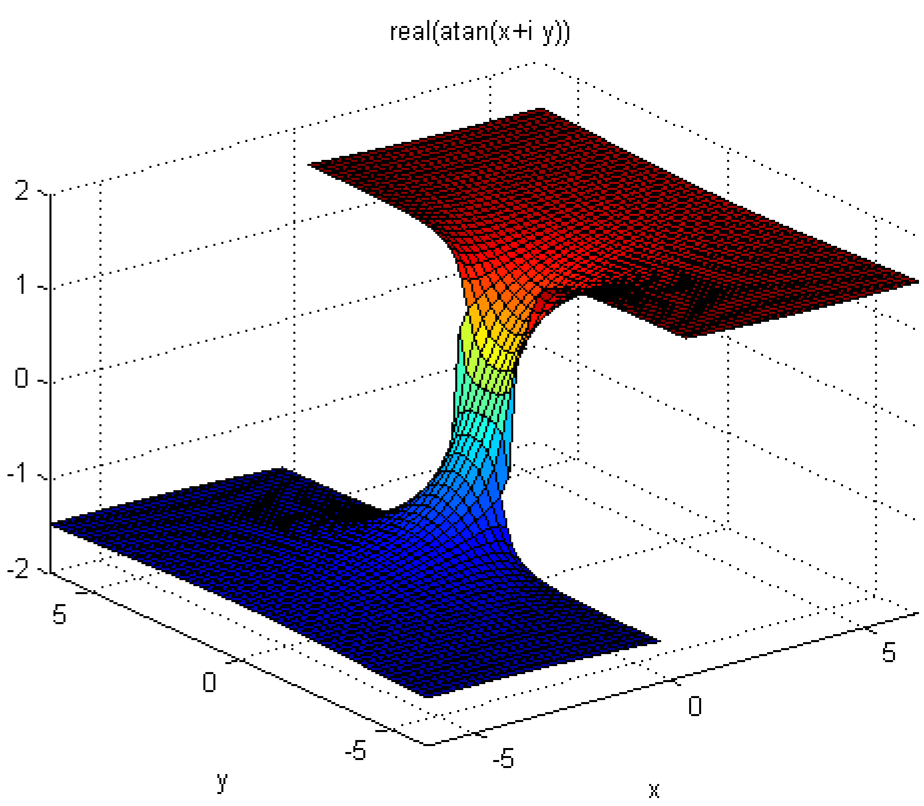
Examples

ezsurf does not graph points where the mathematical function is not defined (these data points are set to NaNs, which do not plot). This example illustrates this filtering of singularities/discontinuous points by graphing the function

$$f(x,y) = real\left(a\tan\left(x+iy\right)\right)$$

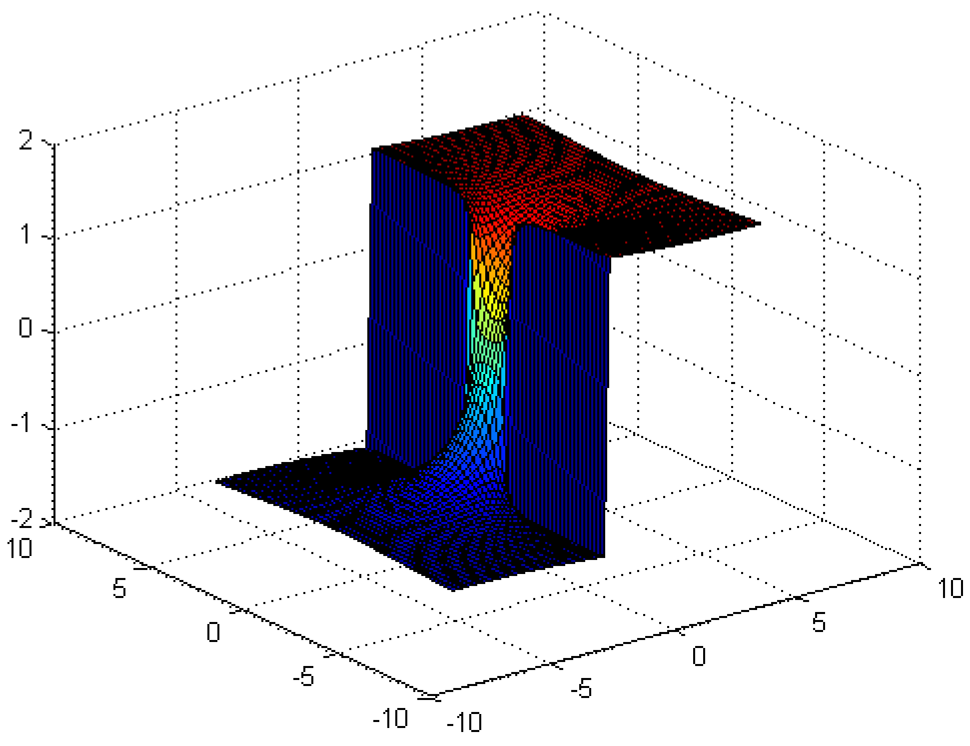
over the default domain $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$:

```
ezsurf('real(atan(x+i*y))')
```



Using `surf` to plot the same data produces a graph without filtering of discontinuities (as well as requiring more steps):

```
[x,y] = meshgrid(linspace(-2*pi,2*pi,60));
z = real(atan(x+1i.*y));
surf(x,y,z)
```



Note also that `ezsurf` creates graphs that have axis labels, a title, and extend to the axis limits.

Algorithms

`ezsurf` determines the *x*- and *y-axes* limits in different ways depending on how you input the domain (if at all). In the following table, `R` is the vector [`xmin`, `xmax`, `ymin`, `ymax`] and `v` is the manually entered domain vector.

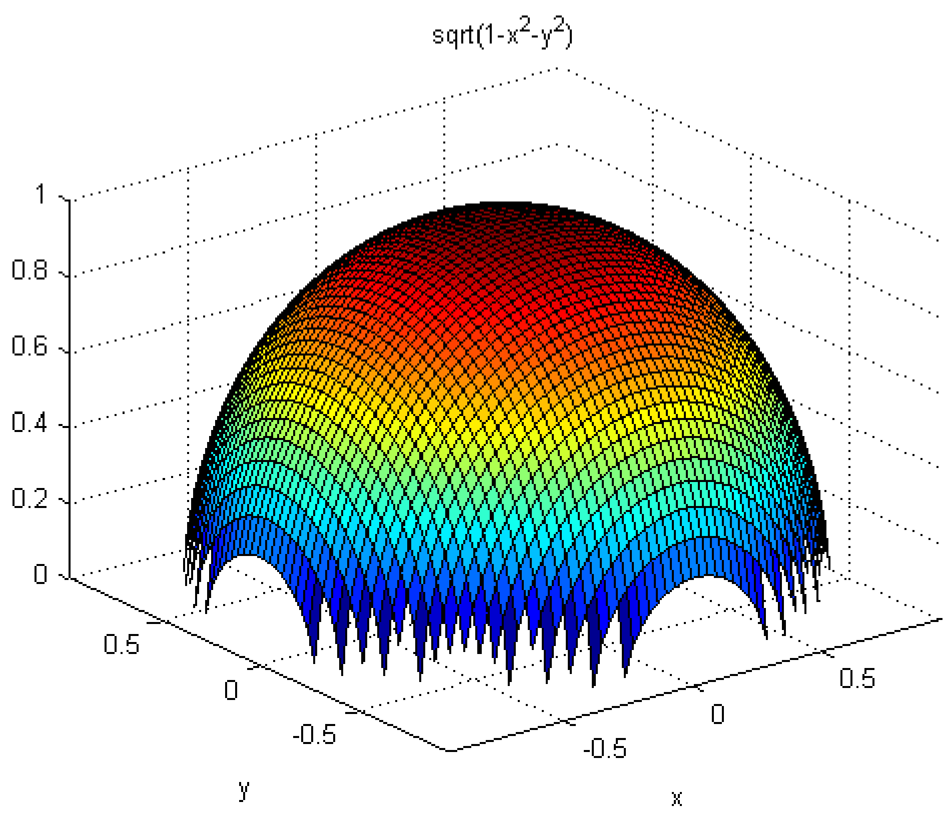
Number of domain values specified:	Resulting domain vector:
`v = [ ];`	`R = [-2*pi, 2*pi, -2*pi, 2*pi];`
`v = [ v(1) ];`	`R = double([-abs(v),abs(v),-abs(v),abs(v)]);`
`v = [ v(1) v(2) ];`	`R = double([v(1),v(2),v(1),v(2)]);`
`v = [ v(1) v(2) v(3) ];`	`R = double([-v(1),v(2),-abs(v(3)),abs(v(3))]);`
`v = [ v(1) v(2) v(3) v(4) ];`	`R = double(v);`
`v = [ v(1)..v(n) ]; n>4`	`R = double([-abs(v(1)), abs(v(1)), -abs(v(1)), abs(`

If you specify a single number in non-vector format (without square brackets, [ ]), `ezsurf` interprets it as the `n`, the number of points desired between the axes `max` and `min` values.

By default, `ezsurf` uses 60 points between the `max` and `min` values of an axes. When the `min` and `max` values are the default values (`R = [-2*pi, 2*pi, -2*pi, 2*pi];`), `ezsurf` ensures the 60 points fall within the non-complex range of the specified equation. For example,

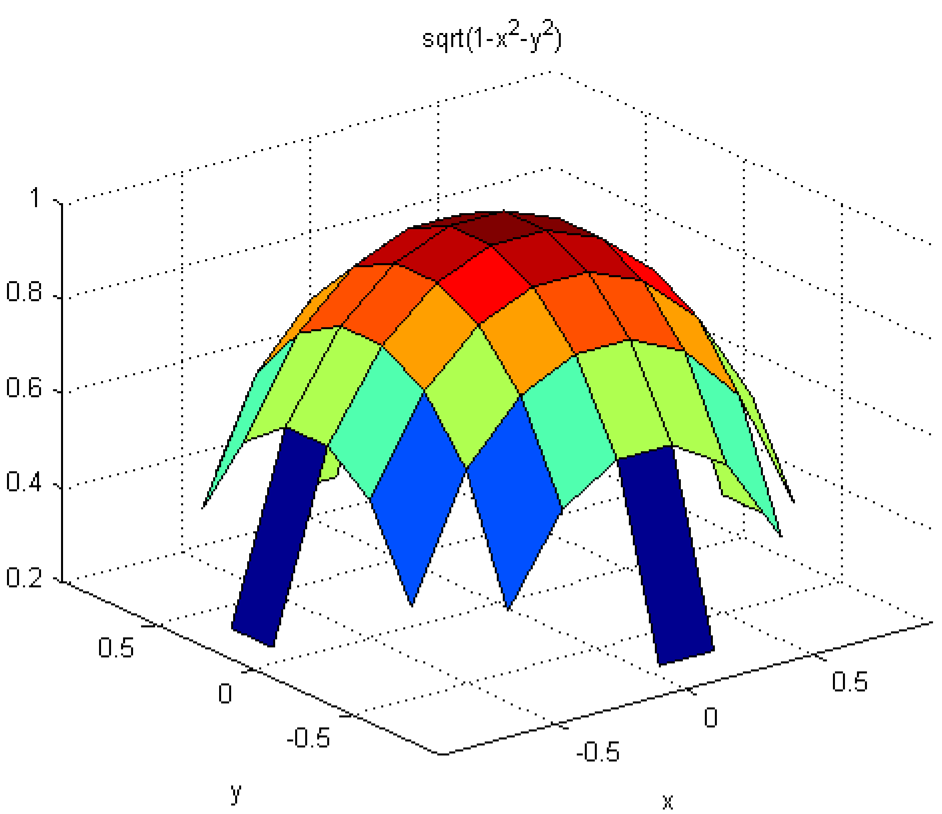
$\sqrt{1-x^2-y^2}$ is only real when $x^2-y^2 \le 1$. The default graph of this function looks like this:

```
ezsurf('sqrt(1 x^2 y^2)')
```



You can see that there are 60 points between the minimum and maximum values for which $\sqrt{1-x^2-y^2}$ has real values. However, when you specify the domain values to be the same as the default (`R = [-2*pi, 2*pi, -2*pi, 2*pi];`), a different result appears:

```
ezsurf('sqrt(1 x^2 y^2)',[-2*pi 2*pi])
```



In this case, the graphic limits are the same, but `ezsurf` used 60 points between the user-defined limits instead of checking to see if all those points would have real answers.

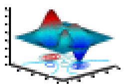
`ezmesh` | `ezsurfc` | `function_handle` | `surf`

How To

- Anonymous Functions

Purpose

Easy-to-use combination surface/contour plotter



Syntax

```
ezsurfc(fun)
ezsurfc(fun,domain)
ezsurfc(funx,funy,funz)
ezsurfc(funx,funy,funz,[smin,smax,tmin,tmax])
ezsurfc(funx,funy,funz,[min,max])
ezsurfc(...,n)
ezsurfc(...,'circ')
ezsurfc(axes_handle,...)
h = ezsurfc(...)
```

Description

`ezsurfc(fun)` creates a graph of `fun(x,y)` using the `surfc` function. The function `fun` is plotted over the default domain: -2π < `x` < 2π, -2π < `y` < 2π.

`fun` can be a function handle or a string (see the Tips section).

`ezsurfc(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where `min` < `x` < `max`, `min` < `y` < `max`).

`ezsurfc(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: -2π < `s` < 2π, -2π < `t` < 2π.

`ezsurfc(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezsurfc(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezsurfc(...,n)` plots *f* over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezsurfc(...,'circ')` plots *f* over a disk centered on the domain.

`ezsurfc(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurfc(...)` returns the handles to the graphics objects in `h`.

Tips

`ezsurf` and `ezsurfc` do not accept complex inputs.

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezsurfc`. For example, the MATLAB syntax for a surface/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurfc('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezsurfc`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurfc('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurfc`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezsurfc` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurfc(@(x,y)myfun(x,y,2,2,4))
```

Examples

Create a surface/contour plot of the expression

$$f(x,y) = \frac{y}{1 + x^2 + y^2}$$

over the domain -5 < x < 5, -2*pi < y < 2*pi, with a computational grid of size 35-by-35:

```
ezsurfc('y/(1 + x^2 + y^2)',[-5,5,-2*pi,2*pi],35)
```

Put the plot in `rotate3d` mode to use the mouse to rotate the axes to better observe the contour lines (this picture uses a view of azimuth = -65.5 and elevation = 26).

How To

- Anonymous Functions

TriRep.faceNormals

Purpose

(Will be removed) Unit normals to specified triangles

Note `faceNormals(TriRep)` will be removed in a future release. Use `faceNormal(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
FN = faceNormals(TR, TI)
```

Description

`FN = faceNormals(TR, TI)` returns the unit normal vector to each of the specified triangles TI.

Note This query is only applicable to triangular surface meshes.

Input Arguments

`TR`	Triangulation representation.
`TI`	Column vector of indices that index into the triangulation matrix `TR.Triangulation`.

Output Arguments

`FN` m-by-3 matrix. `m = length(TI)`, the number of triangles to be queried. Each row `FN(i,:)` represents the unit normal vector to triangle `TI(i)`.

If TI is not specified the unit normal information for the entire triangulation is returned, where the normal associated with triangle i is the `i`'th row of `FN`.

Examples

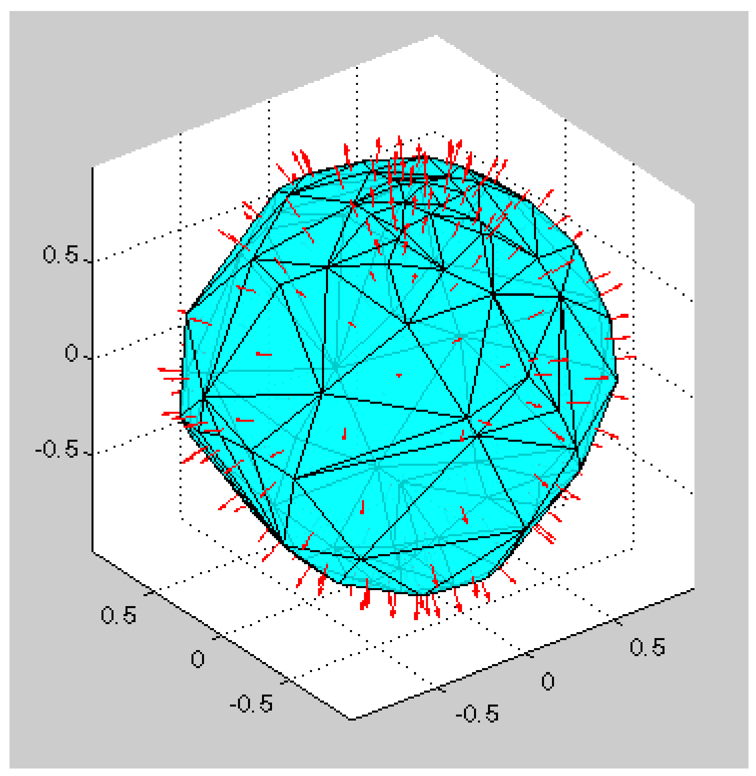
Triangulate a sample of random points on the surface of a sphere and use the `TriRep` to compute the normal to each triangle:

```
numpts = 100;
```

```
thetha = rand(numpts,1)*2*pi;
phi = rand(numpts,1)*pi;
x = cos(thetha).*sin(phi);
y = sin(thetha).*sin(phi);
z = cos(phi);
dt = DelaunayTri(x,y,z);
[tri Xb] = freeBoundary(dt);
tr = TriRep(tri, Xb);
P = incenters(tr);
fn = faceNormals(tr);
trisurf(tri,Xb(:,1),Xb(:,2),Xb(:,3), ...
     'FaceColor', 'cyan', 'faceAlpha', 0.8);
axis equal;
hold on;
```

Display the result using a quiver plot:

```
quiver3(P(:,1),P(:,2),P(:,3), ...
     fn(:,1),fn(:,2),fn(:,3),0.5, 'color','r');
hold off;
```



See Also `freeBoundary` | `delaunayTriangulation` | `triangulation`

Purpose

Prime factors

Syntax

```
f = factor(n)
```

Description

`f = factor(n)` returns a row vector containing the prime factors of `n`. Vector `f` is of the same data type as `n`.

Input Arguments

n - Input values

scalar, real, nonnegative integer values

Input values, specified as scalars that are real, nonnegative, and integer-valued.

Example: `10`

Example: `int16(64)`

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Examples

Prime Factors of Double Integer Value

```
f = factor(200)
```

```
f =

     2     2     2     5     5
```

Multiply the elements of `f` to reproduce the input value.

```
prod(f)
```

```
ans =

   200
```

Prime Factors of Unsigned Integer Value

```
n = uint16(138);
```

```
f = factor(n)
```

```
f =

     2     3    23
```

Multiply the elements of `f` to reproduce `n`.

```
prod(f)
```

```
ans =

   138
```

See Also `isprime` | `primes`

Purpose

Factorial of input

Syntax

```
f = factorial(n)
```

Description

`f = factorial(n)` returns the product of all positive integers less than or equal to `n`, where `n` is a nonnegative integer value. If `n` is an array, then `f` contains the factorial of each value of `n`. The data type and size of `f` is the same as that of `n`.

Input Arguments

n - Input values
scalar, vector, or array of real, nonnegative integer values

Input values, specified as a scalar, vector, or array of real, nonnegative integers.

Example: `5`

Example: `[0 1 2 3 4]`

Example: `int16([10 15 20])`

Data Types
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Limitations

- The result is only accurate for double-precision values of `n` that are less than or equal to `21`. A larger value of `n` produces a result that has the correct order of magnitude and is accurate for the first 15 digits. This is because double-precision numbers are only accurate up to 15 digits.
- For single-precision input, the result is only accurate for values of `n` that are less than or equal to `13`. A larger value of `n` produces a result that has the correct order of magnitude and is accurate for the first 8 digits. This is because single-precision numbers are only accurate up to 8 digits.

Examples

10!

```
f = factorial(10)
```

```
f =

     3628800
```

22!

```
format long
f = factorial(22)
```

```
f =

     1.124000727777608e+21
```

In this case, `f` is accurate up to 15 digits, `1.12400072777760e+21`, because double-precision numbers are only accurate up to 15 digits.

Reset the output format to the default.

```
format
```

Factorial of Array Elements

```
n = [0 1 2; 3 4 5];
f = factorial(n)
```

```
f =

     1     1     2
     6    24   120
```

Factorial of Unsigned Integer Values

```
n = uint64([5 10 15 20]);
f = factorial(n)
```

```
f =

    120      3628800      1307674368000      2432902008176640000
```

See Also `prod`

false

Purpose

Logical 0 (false)

Syntax

```
false
false(n)
false(m, n)
false(m, n, p, ...)
false(size(A))
false(...,'like',p)
```

Description

`false` is shorthand for `logical(0)`.

`false(n)` is an `n`-by-`n` matrix of logical zeros.

`false(m, n)` or `false([m, n])` is an `m`-by-`n` matrix of logical zeros.

`false(m, n, p, ...)` or `false([m n p ...])` is an `m`-by-`n`-by-`p`-by-`...` array of logical zeros.

Note The size inputs `m`, `n`, `p`, `...` should be nonnegative integers. Negative integers are treated as 0.

`false(size(A))` is an array of logical zeros that is the same size as array `A`.

`false(...,'like',p)` is an array of logical zeros of the same data type and sparsity as the logical array `p`.

Tips

`false(n)` is much faster and more memory efficient than `logical(zeros(n))`.

See Also

`true` | `logical`

Purpose

Close one or all open files

Syntax

```
fclose(fileID)
fclose('all')
status = fclose(...)
```

Description

`fclose(fileID)` closes an open file. *`fileID`* is an integer file identifier obtained from `fopen`.

`fclose('all')` closes all open files.

`status` `= fclose(...)` returns a *`status`* of `0` when the close operation is successful. Otherwise, it returns `-1`.

See Also

`ferror` | `fopen` | `frewind` | `fseek` | `ftell` | `feof` | `fscanf` | `fprintf` | `fread` | `fwrite`

fclose (serial)

Purpose

Disconnect serial port object from device

Syntax

```
fclose(obj)
```

Description

`fclose(obj)` disconnects `obj` from the device, where `obj` is a serial port object or an array of serial port objects.

Tips

If `obj` was successfully disconnected, then the `Status` property is configured to `closed` and the `RecordStatus` property is configured to `off`. You can reconnect `obj` to the device using the `fopen` function.

An error is returned if you issue `fclose` while data is being written asynchronously. In this case, you should abort the write operation with the `stopasync` function, or wait for the write operation to complete.

If you use the `help` command to display help for `fclose`, then you need to supply the pathname shown below.

```
help serial/fclose
```

Examples

This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, and then disconnects `s` from the device using `fclose`.

```
s = serial('COM1');
fopen(s)
fprintf(s, '*IDN?')
idn = fscanf(s);
fclose(s)
```

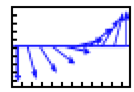
At this point, the device is available to be connected to a serial port object. If you no longer need `s`, you should remove from memory with the `delete` function, and remove it from the workspace with the `clear` command.

See Also

`clear` | `delete` | `fopen` | `stopasync` | `RecordStatus` | `Status`

Purpose

Plot velocity vectors



Syntax

```
feather(U,V)
feather(Z)
feather(...,LineSpec)
feather(axes_handle,...)
h = feather(...)
```

Description

A feather plot displays vectors emanating from equally spaced points along a horizontal axis. You express the vector components relative to the origin of the respective vector.

`feather(U,V)` displays the vectors specified by `U` and `V`, where `U` contains the *x* components as relative coordinates, and `V` contains the *y* components as relative coordinates.

`feather(Z)` displays the vectors specified by the complex numbers in `Z`. This is equivalent to `feather(real(Z),imag(Z))`.

`feather(...,LineSpec)` draws a feather plot using the line type, marker symbol, and color specified by `LineSpec`.

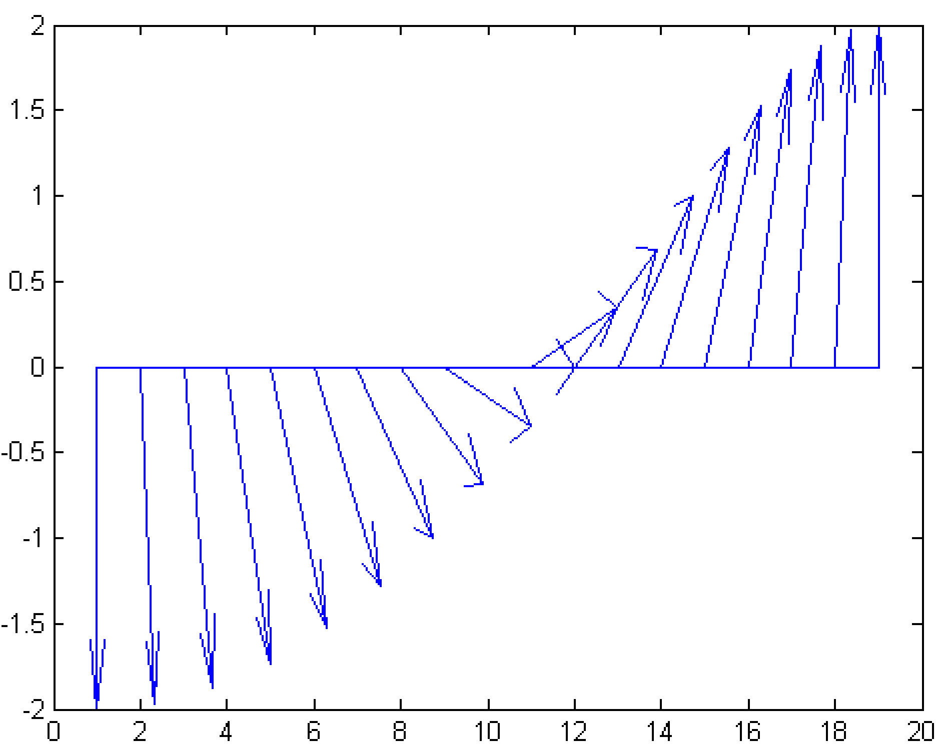
`feather(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = feather(...)` returns the handles to line objects in `h`.

Examples

Create a feather plot showing the direction of `theta`.

```
theta = (-90:10:90)*pi/180;
r = 2*ones(size(theta));
[u,v] = pol2cart(theta,r);
feather(u,v);
```



See Also

`compass` | `LineSpec` | `rose`

Purpose

(Will be removed) Sharp edges of surface triangulation

Note `featureEdges(TriRep)` will be removed in a future release. Use `featureEdges(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
FE = featureEdges(TR, filterangle)
```

Description

`FE = featureEdges(TR, filterangle)` returns an edge matrix `FE`. This method is typically used to extract the sharp edges in the surface mesh for the purpose of display. Edges that are shared by only one triangle and edges that are shared by more than two triangles are considered to be feature edges by default.

Note This query is only applicable to triangular surface meshes.

Input Arguments

`TR`	Triangulation representation.
`filterangle`	The threshold angle in radians. Must be in the range $(0, \pi)$. `featureEdges` will return adjacent triangles that have a dihedral angle that deviates from π by an angle greater than `filterangle`.

Output Arguments

`FE`	Edges of the triangulation. `FE` is of size `m`-by-2 where `m` is the number of computed feature edges in the mesh. The vertices of the edges index into the array of points representing the vertex coordinates, `TR.X`.

Examples

Create a surface triangulation:

```
x = [0 0 0 0 0 3 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
dt = DelaunayTri(x,y);
tri = dt(:,:);
```

Elevate the 2-D mesh to create a surface:

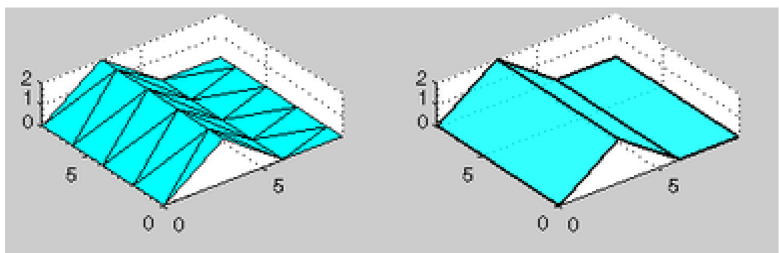
```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(tri,x,y,z, 'FaceColor', 'cyan');
axis equal;
% TRISURF display of surface mesh
% showing mesh edges
```

Compute the feature edges using a filter angle of `pi/6`:

```
tr = TriRep(tri, x,y,z);
fe = featureEdges(tr,pi/6)';
subplot(1,2,2);
trisurf(tr, 'FaceColor', 'cyan', 'EdgeColor','none', ...
     'FaceAlpha', 0.8); axis equal;
```

Add the feature edges to the plot:

```
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth',1.5);
hold off;
% TRISURF display of surface mesh
% suppressing mesh edges
% and showing feature edges
```



See Also

`edges` | `delaunayTriangulation` | `triangulation`

feof

Purpose

Test for end-of-file

Syntax

`status = feof(fileID)`

Description

`status` `= feof(`*`fileID`*`)` returns `1` if a previous operation set the end-of-file indicator for the specified file. Otherwise, `feof` returns `0`. *`fileID`* is an integer file identifier obtained from `fopen`.

Opening an empty file does *not* set the end-of-file indicator. Read operations, and the `fseek` and `frewind` functions, move the file position indicator.

Examples

Read `bench.dat`, which contains MATLAB benchmark data, one character at a time:

```
fid = fopen('bench.dat');

k = 0;
while ~feof(fid)
    curr = fscanf(fid,'%c',1);
    if ~isempty(curr)
       k = k+1;
       benchstr(k) = curr;
    end
end

fclose(fid);
```

See Also

`fclose` | `ferror` | `fopen` | `frewind` | `fseek` | `ftell`

How To

- “Testing for End of File (EOF)”

Purpose

Information about file I/O errors

Syntax

```
message = ferror(fileID)
[message, errnum] = ferror(fileID)
[...] = ferror(fileID, 'clear')
```

Description

`message = ferror(fileID)` returns the error message for the most recent file I/O operation on the specified file. If the operation was successful, *message* is an empty string. *fileID* is an integer file identifier obtained from `fopen`, or an identifier reserved for standard input (0), standard output (1), or standard error (2).

`[message, errnum] = ferror(fileID)` returns the error number. If the most recent file I/O operation was successful, *errnum* is 0. Negative error numbers correspond to MATLAB error messages. Positive error numbers correspond to C library error messages for your system.

`[...] = ferror(fileID, 'clear')` clears the error indicator for the specified file.

See Also

`fclose` | `fopen` | `fseek` | `ftell` | `feof` | `fscanf` | `fprintf` | `fread` | `fwrite`

feval

Purpose

Evaluate function

Syntax

```
[y1, y2, ...] = feval(fhandle, x1, ..., xn)
[y1, y2, ...] = feval(fname, x1, ..., xn)
```

Description

`[y1, y2, ...] = feval(fhandle, x1, ..., xn)` evaluates the function handle, `fhandle`, using arguments `x1` through `xn`. If the function handle is bound to more than one built-in or `.m` function, (that is, it represents a set of overloaded functions), then the data type of the arguments `x1` through `xn` determines which function is dispatched to.

Note It is not necessary to use `feval` to call a function by means of a function handle. This is explained in "Calling a Function Using Its Handle" in the MATLAB Programming Fundamentals documentation.

`[y1, y2, ...] = feval(fname, x1, ..., xn)`. If `fname` is a quoted string containing the name of a function (usually defined within file having a .m file extension), then `feval(fname, x1, ..., xn)` evaluates that function at the given arguments. The `fname` parameter must be a simple function name; it cannot contain path information.

Tips

The following two statements are equivalent.

```
[V,D] = eig(A)
[V,D] = feval(@eig, A)
```

Nested functions are not accessible to `feval`. To call a nested function, you must either call it directly by name, or construct a function handle for it using the `@` operator.

Examples

The following example passes a function handle, `fhandle`, in a call to `fminbnd`. The `fhandle` argument is a handle to the `humps` function.

```
fhandle = @humps;
x = fminbnd(fhandle, 0.3, 1);
```

The `fminbnd` function uses `feval` to evaluate the function handle that was passed in.

```
function [xf, fval, exitflag, output] = ...
    fminbnd(funfcn, ax, bx, options, varargin)
            .
            .
            .
fx = feval(funfcn, x, varargin{:});
```

See Also

`assignin` | `function_handle` | `functions` | `builtin` | `eval` | `evalin`

Feval (COM)

Purpose

Evaluate MATLAB function in Automation server

Syntax

MATLAB Client

```
result = h.Feval('functionname',numout,arg1,arg2,...)
result = Feval(h,'functionname',numout,arg1,arg2,...)
result = invoke(h,'Feval','functionname',numout,...
arg1,arg2,...)
```

IDL Method Signature

```
HRESULT Feval([in] BSTR functionname, [in] long nargout,
[out] VARIANT* result, [in, optional] VARIANT arg1, arg2, ...)
```

Microsoft Visual Basic Client

```
Feval(String functionname, long numout,
arg1, arg2, ...) As Object
```

Description

`Feval` executes the MATLAB function specified by the string `functionname` in the Automation server attached to handle `h`.

Indicate the number of outputs to be returned by the function in a `1`-by-`1` `double` array, `numout`. The server returns output from the function in the cell array, `result`.

You can specify as many as 32 input arguments to be passed to the function. These arguments follow `numout` in the `Feval` argument list. The following table shows ways to pass an argument.

Passing Mechanism	Description
Pass the value itself	To pass any numeric or string value, specify the value in the `Feval` argument list: `a = h.Feval('sin', 1, -pi:0.01:pi);`
Pass a client variable	To pass an argument assigned to a variable in the client, specify the variable name alone: `x = -pi:0.01:pi;`

Passing Mechanism	Description
	`a = h.Feval('sin', 1, x);`

Reference a server variable	To reference a variable defined in the server, specify the variable name followed by an equals (=) sign:
	
	`h.PutWorkspaceData('x', 'base', -pi:0.01:pi);`
	`a = h.Feval('sin', 1, 'x=');`
	
	MATLAB does not reassign the server variable.

Tips

To display the output from `Feval` in the client window, assign a return value.

Server function names, like `Feval`, are case sensitive when using the first two syntaxes shown in the Syntax section.

COM functions are available on Microsoft Windows systems only.

Examples

Passing Arguments — MATLAB Client

This section contains a number of examples showing how to use `Feval` to execute MATLAB commands on a MATLAB Automation server.

- Concatenate two strings in the server by passing the input strings in a call to `strcat` through `Feval` (`strcat` deletes trailing spaces; use leading spaces):

  ```
  h = actxserver('matlab.application');
  a = h.Feval('strcat', 1, 'hello', ' world')
  ```

  MATLAB displays:

  ```
  a =
      'hello world'
  ```

- Perform the same concatenation, passing a string and a local variable `clistr` that contains the second string:

```
clistr = ' world';
a = h.Feval('strcat', 1, 'hello', clistr)
```

MATLAB displays:

```
a =
    'hello world'
```

- In this example, the variable `srvstr` is defined in the server, not the client. Putting an equals sign after a variable name (for example, `srvstr=`) indicates it is a server variable, and the variable is not defined in the client:

```
% Define the variable srvstr on the server.
h.PutCharArray('srvstr', 'base', ' world')

% Pass the name of the server variable using 'name=' syntax
a = h.Feval('strcat', 1, 'hello', 'srvstr=')
```

MATLAB displays:

```
a =
    'hello world'
```

Visual Basic .NET Client

Here are the same examples shown above, but written for a Visual Basic .NET client. These examples return the same strings as shown above.

- Pass the two strings to the MATLAB function `strcat` on the server:

```
Dim Matlab As Object
Dim out As Object
out = Nothing
Matlab = CreateObject("matlab.application")
Matlab.Feval("strcat", 1, out, "hello", " world")
```

- Define `clistr` locally and pass this variable:

```
Dim clistr As String
```

```
clistr = " world"
Matlab.Feval("strcat", 1, out, "hello", clistr)
```

- Pass the name of a variable defined on the server:

```
Matlab.PutCharArray("srvstr", "base", " world")
Matlab.Feval("strcat", 1, out, "hello", "srvstr=")
```

Feval Return Values — MATLAB Client. `Feval` returns data from the evaluated function in a cell array. The cell array has one row for every return value. You control the number of return values using the `numout` argument.

The `numout` argument in the following example specifies that `Feval` return three outputs from the `fileparts` function.

```
a = h.Feval('fileparts', 3, 'd:\work\ConsoleApp.cpp')
```

MATLAB displays:

```
a =
    'd:\work'
    'ConsoleApp'
    '.cpp'
```

Convert the returned values from the cell array `a` to char arrays:

```
a{:}
```

MATLAB displays:

```
ans =
d:\work

ans =
ConsoleApp

ans =
.cpp
```

Feval Return Values — Visual Basic .NET Client

Here is the same example, but coded in Visual Basic. Define the argument returned by `Feval` as an `Object`.

```
Dim Matlab As Object
Dim out As Object
Matlab = CreateObject("matlab.application")
Matlab.Feval("fileparts", 3, out, "d:\work\ConsoleApp.cpp")
```

Purpose

Fast Fourier transform

Syntax

```
Y = fft(x)
Y = fft(X,n)
Y = fft(X,[],dim)
Y = fft(X,n,dim)
```

Definitions

The functions `Y = fft(x)` and `y = ifft(X)` implement the transform and inverse transform pair given for vectors of length N by:

$$X(k) = \sum_{j=1}^{N} x(j)\omega_N^{(j-1)(k-1)}$$

$$x(j) = (1/N)\sum_{k=1}^{N} X(k)\omega_N^{-(j-1)(k-1)}$$

where

$$\omega_N = e^{(-2\pi i)/N}$$

is an Nth root of unity.

Description

`Y = fft(x)` returns the discrete Fourier transform (DFT) of vector `x`, computed with a fast Fourier transform (FFT) algorithm.

If the input `X` is a matrix, `Y = fft(X)` returns the Fourier transform of each column of the matrix.

If the input `X` is a multidimensional array, `fft` operates on the first nonsingleton dimension.

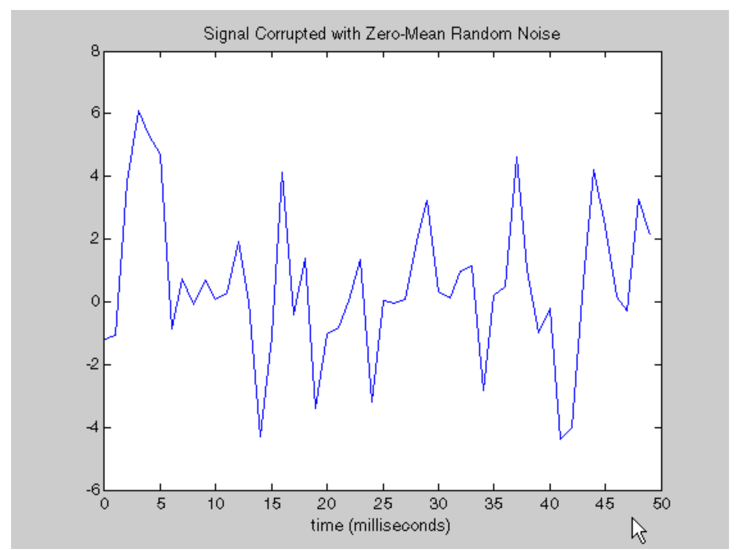
`Y = fft(X,n)` returns the `n`-point DFT. `fft(X)` is equivalent to `fft(X, n)` where `n` is the size of `X` in the first nonsingleton dimension. If the length of `X` is less than `n`, `X` is padded with trailing zeros to length `n`. If the length of `X` is greater than `n`, the sequence `X` is truncated. When `X` is a matrix, the length of the columns are adjusted in the same manner.

`Y = fft(X,[],dim)` and `Y = fft(X,n,dim)` applies the FFT operation across the dimension `dim`.

Examples

A common use of Fourier transforms is to find the frequency components of a signal buried in a noisy time domain signal. Consider data sampled at 1000 Hz. Form a signal containing a 50 Hz sinusoid of amplitude 0.7 and 120 Hz sinusoid of amplitude 1 and corrupt it with some zero-mean random noise:

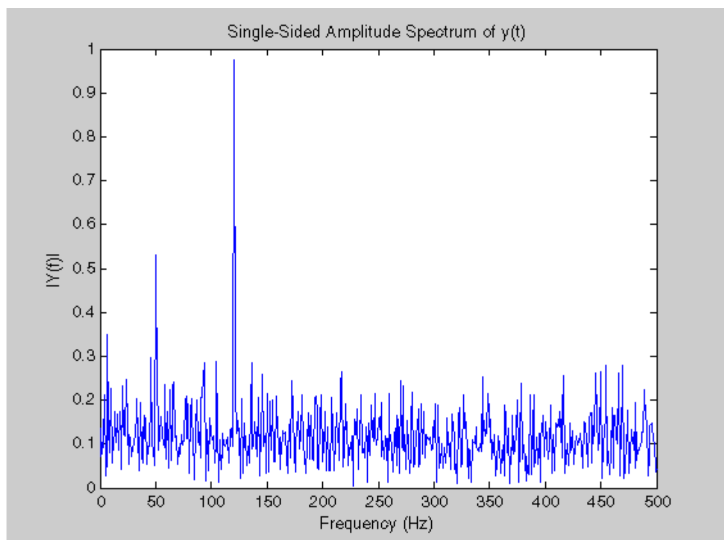
```
Fs = 1000;                    % Sampling frequency
T = 1/Fs;                     % Sample time
L = 1000;                     % Length of signal
t = (0:L-1)*T;                % Time vector
% Sum of a 50 Hz sinusoid and a 120 Hz sinusoid
x = 0.7*sin(2*pi*50*t) + sin(2*pi*120*t);
y = x + 2*randn(size(t));     % Sinusoids plus noise
plot(Fs*t(1:50),y(1:50))
title('Signal Corrupted with Zero-Mean Random Noise')
xlabel('time (milliseconds)')
```



It is difficult to identify the frequency components by looking at the original signal. Converting to the frequency domain, the discrete Fourier transform of the noisy signal `y` is found by taking the fast Fourier transform (FFT):

```
NFFT = 2^nextpow2(L); % Next power of 2 from length of y
Y = fft(y,NFFT)/L;
f = Fs/2*linspace(0,1,NFFT/2+1);

% Plot single-sided amplitude spectrum.
plot(f,2*abs(Y(1:NFFT/2+1)))
title('Single-Sided Amplitude Spectrum of y(t)')
xlabel('Frequency (Hz)')
ylabel('|Y(f)|')
```



The main reason the amplitudes are not exactly at 0.7 and 1 is because of the noise. Several executions of this code (including recomputation of `y`) will produce different approximations to 0.7 and 1. The other reason is that you have a finite length signal. Increasing `L` from 1000 to

10000 in the example above will produce much better approximations on average.

Algorithms

The FFT functions (`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, `ifftn`) are based on a library called FFTW [3],[4]. To compute an N-point DFT when N is composite (that is, when $N = N_1N_2$), the FFTW library decomposes the problem using the Cooley-Tukey algorithm [1], which first computes N_1 transforms of size N_2, and then computes N_2 transforms of size N_1. The decomposition is applied recursively to both the N_1- and N_2-point DFTs until the problem can be solved using one of several machine-generated fixed-size "codelets." The codelets in turn use several algorithms in combination, including a variation of Cooley-Tukey [5], a prime factor algorithm [6], and a split-radix algorithm [2]. The particular factorization of N is chosen heuristically.

When N is a prime number, the FFTW library first decomposes an N-point problem into three $(N - 1)$-point problems using Rader's algorithm [7]. It then uses the Cooley-Tukey decomposition described above to compute the $(N - 1)$-point DFTs.

For most N, real-input DFTs require roughly half the computation time of complex-input DFTs. However, when N has large prime factors, there is little or no speed difference.

The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `fft` using the utility function `fftw`, which controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

Data Type Support

`fft` supports inputs of data types `double` and `single`. If you call `fft` with the syntax `y = fft(X, ...)`, the output `y` has the same data type as the input `X`.

Purpose

2-D fast Fourier transform

Syntax

```
Y = fft2(X)
Y = fft2(X,m,n)
```

Description

`Y = fft2(X)` returns the two-dimensional discrete Fourier transform (DFT) of `X`. The DFT is computed with a fast Fourier transform (FFT) algorithm. The result, `Y`, is the same size as `X`.

If the dimensionality of `X` is greater than `2`, the `fft2` function returns the 2-D DFT for each higher dimensional slice of `X`. For example, if `size(X) = [100 100 3]`, then `fft2` computes the DFT of `X(:,:,1)`, `X(:,:,2)` and `X(:,:,3)`.

`Y = fft2(X,m,n)` truncates `X`, or pads `X` with zeros to create an `m`-by-`n` array before doing the transform. The result is `m`-by-`n`.

Algorithms

`fft2(X)` can be simply computed as

```
fft(fft(X).').'
```

This computes the one-dimensional DFT of each column `X`, then of each row of the result. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `fft2` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

Data Type Support

`fft2` supports inputs of data types `double` and `single`. If you call `fft2` with the syntax `y = fft2(X, ...)`, the output `y` has the same data type as the input `X`.

fft | fftn | fftw | fftshift | ifft2

fftn

Purpose

N-D fast Fourier transform

Syntax

```
Y = fftn(X)
Y = fftn(X,siz)
```

Description

`Y = fftn(X)` returns the discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`Y = fftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the transform. The size of the result `Y` is `siz`.

Algorithms

`fftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
    Y = fft(Y,[],p);
end
```

This computes in-place the one-dimensional fast Fourier transform along each dimension of `X`. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `fftn` using the utility function `fftw`, which controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

Data Type Support

`fftn` supports inputs of data types `double` and `single`. If you call `fftn` with the syntax `y = fftn(X, ...)`, the output `y` has the same data type as the input `X`.

`fft` | `fft2` | `fftn` | `fftw` | `ifftn`

fftshift

Purpose

Shift zero-frequency component to center of spectrum

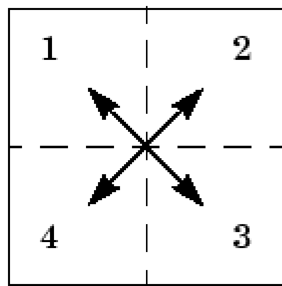
Syntax

```
Y = fftshift(X)
Y = fftshift(X,dim)
```

Description

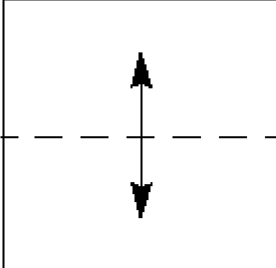
`Y = fftshift(X)` rearranges the outputs of `fft`, `fft2`, and `fftn` by moving the zero-frequency component to the center of the array. It is useful for visualizing a Fourier transform with the zero-frequency component in the middle of the spectrum.

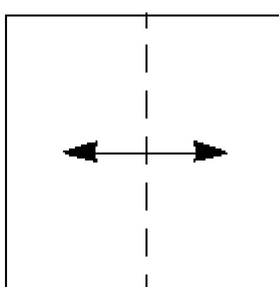
For vectors, `fftshift(X)` swaps the left and right halves of `X`. For matrices, `fftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth.



For higher-dimensional arrays, `fftshift(X)` swaps “half-spaces” of `X` along each dimension.

`Y = fftshift(X,dim)` applies the `fftshift` operation along the dimension `dim`.





Note `ifftshift` will undo the results of `fftshift`. If the matrix `X` contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original `X`. Simply performing `fftshift(X)` twice will not produce `X`.

Examples

For any matrix `X`

```
Y = fft2(X)
```

has `Y(1,1) = sum(sum(X))`; the zero-frequency component of the signal is in the upper-left corner of the two-dimensional FFT. For

```
Z = fftshift(Y)
```

this zero-frequency component is near the center of the matrix.

The difference between `fftshift` and `ifftshift` is important for input sequences of odd-length.

```
N = 5;
X = 0:N-1;
Y = fftshift(fftshift(X));
Z = ifftshift(fftshift(X));
```

Notice that `Z` is a correct replica of `X`, but `Y` is not.

```
isequal(X,Y),isequal(X,Z)

ans =

     0

ans =

     1

Purpose

Interface to FFTW library run-time algorithm tuning control

Syntax

```
fftw('planner', method)
method = fftw('planner')
str = fftw('dwisdom')
str = fftw('swisdom')
fftw('dwisdom', str)
fftw('swisdom', str)
```

Description

`fftw` enables you to optimize the speed of the MATLAB FFT functions `fft`, `ifft`, `fft2`, `ifft2`, `fftn`, and `ifftn`. You can use `fftw` to set options for a tuning algorithm that experimentally determines the fastest algorithm for computing an FFT of a particular size and dimension at run time. MATLAB software records the optimal algorithm in an internal data base and uses it to compute FFTs of the same size throughout the current session. The tuning algorithm is part of the FFTW library that MATLAB software uses to compute FFTs.

`fftw('planner', method)` sets the method by which the tuning algorithm searches for a good FFT algorithm when the dimension of the FFT is not a power of 2. You can specify `method` to be one of the following. The default method is `estimate`:

- `'estimate'`
- `'measure'`
- `'patient'`
- `'exhaustive'`
- `'hybrid'`

When you call `fftw('planner', method)`, the next time you call one of the FFT functions, such as `fft`, the tuning algorithm uses the specified method to optimize the FFT computation. Because the tuning involves trying different algorithms, the first time you call an FFT function, it might run more slowly than if you did not call `fftw`. However, subsequent calls to any of the FFT functions, for a problem of the same size, often run more quickly than they would without using `fftw`.

Note The FFT functions only use the optimal FFT algorithm during the current MATLAB session. "Reusing Optimal FFT Algorithms" on page 1-1630 explains how to reuse the optimal algorithm in a future MATLAB session.

If you set the method to `'estimate'`, the FFTW library does not use run-time tuning to select the algorithms. The resulting algorithms might not be optimal.

If you set the method to `'measure'`, the FFTW library experiments with many different algorithms to compute an FFT of a given size and chooses the fastest. Setting the method to `'patient'` or `'exhaustive'` has a similar result, but the library experiments with even more algorithms so that the tuning takes longer the first time you call an FFT function. However, subsequent calls to FFT functions are faster than with `'measure'`.

If you set `'planner'` to `'hybrid'`, MATLAB software

- Sets method to `'measure'` method for FFT dimensions 8192 or smaller.
- Sets method to `'estimate'` for FFT dimensions greater than 8192.

`method = fftw('planner')` returns the current planner method.

`str = fftw('dwisdom')` returns the information in the FFTW library's internal double-precision database as a string. The string can be saved and then later reused in a subsequent MATLAB session using the next syntax.

`str = fftw('swisdom')` returns the information in the FFTW library's internal single-precision database as a string.

`fftw('dwisdom', str)` loads `fftw` wisdom represented by the string `str` into the FFTW library's internal double-precision wisdom database. `fftw('dwisdom','')` or `fftw('dwisdom',[])` clears the internal wisdom database.

`fftw('swisdom', str)` loads `fftw` wisdom represented by the string `str` into the FFTW library's internal single-precision wisdom database. `fftw('swisdom','')` or `fftw('swisdom',[])` clears the internal wisdom database.

Note on large powers of 2 For FFT dimensions that are powers of 2, between 2^{14} and 2^{22}, MATLAB software uses special preloaded information in its internal database to optimize the FFT computation. No tuning is performed when the dimension of the FTT is a power of 2, unless you clear the database using the command `fftw('wisdom', [])`.

For more information about the FFTW library, see `http://www.fftw.org`.

Examples

Comparison of Speed for Different Planner Methods

The following example illustrates the run times for different settings of `planner`. The example first creates some data and applies `fft` to it using the default method, `estimate`.

```
t=0:.001:5;
x = sin(2*pi*50*t)+sin(2*pi*120*t);
y = x + 2*randn(size(t));

tic; Y = fft(y,1458); toc
Elapsed time is 0.000521 seconds.
```

If you execute the commands

```
tic; Y = fft(y,1458); toc
Elapsed time is 0.000151 seconds.
```

a second time, MATLAB software reports the elapsed time as essentially 0. To measure the elapsed time more accurately, you can execute the command `Y = fft(y,1458)` 1000 times in a loop.

```
tic; for k=1:1000
Y = fft(y,1458);
end; toc
Elapsed time is 0.056532 seconds.
```

This tells you that it takes on order of 1/10000 of a second to execute `fft(y, 1458)` a single time.

For comparison, set `planner` to `patient`. Since this `planner` explores possible algorithms more thoroughly than `hybrid`, the first time you run `fft`, it takes longer to compute the results.

```
fftw('planner','patient')
tic;Y = fft(y,1458);toc
Elapsed time is 0.100637 seconds.
```

However, the next time you call `fft`, it runs at approximately the same speed as before you ran the method `patient`.

```
tic;for k=1:1000
Y=fft(y,1458);
end;toc
Elapsed time is 0.057209 seconds.
```

Reusing Optimal FFT Algorithms

In order to use the optimized FFT algorithm in a future MATLAB session, first save the “wisdom” using the command

```
str = fftw('wisdom')
```

You can save `str` for a future session using the command

```
save str
```

The next time you open a MATLAB session, load `str` using the command

```
load str
```

and then reload the "wisdom" into the FFTW database using the command

```
fftw('wisdom', str)
```

`fft` | `fft2` | `fftn` | `ifft` | `ifft2` | `ifftn` | `fftshift`

Purpose

Read line from file, removing newline characters

Syntax

`tline` `= fgetl(`*`fileID`*`)`

Description

`tline` `= fgetl(`*`fileID`*`)` returns the next line of the specified file, removing the newline characters. *`fileID`* is an integer file identifier obtained from `fopen`. *`tline`* is a text string unless the line contains only the end-of-file marker. In this case, *`tline`* is the numeric value `-1`.

`fgetl` reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use `fopen`.

Examples

Read and display the file `fgetl.m` one line at a time:

```
fid = fopen('fgetl.m');

tline = fgetl(fid);
while ischar(tline)
    disp(tline)
    tline = fgetl(fid);
end

fclose(fid);
```

Compare these results to the `fgets` example, which replaces the calls to `fgetl` with `fgets`.

`fclose` | `feof` | `ferror` | `fgets` | `fopen` | `fprintf` | `fread` | `fscanf` | `fwrite`

How To

- "Testing for EOF with fgetl and fgets"

Purpose

Read line of text from device and discard terminator

Syntax

```
tline = fgetl(obj)
[tline,count] = fgetl(obj)
[tline,count,msg] = fgetl(obj)
```

Description

`tline = fgetl(obj)` reads one line of text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data does not include the terminator with the text line. To include the terminator, use `fgets`.

`[tline,count] = fgetl(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgetl(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

Tips

Before you can read text from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgetl` is issued.

If you use the `help` command to display help for `fgetl`, then you need to supply the pathname shown below.

```
help serial/fgetl
```

Rules for Completing a Read Operation with fgetl

A read operation with `fgetl` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.

- The time specified by the `Timeout` property passes.
- The input buffer is filled.

Examples

On a Windows platform, create the serial port object `s`, connect `s` to a Tektronix® TDS 210 oscilloscope, and write the `RS232?` command with the `fprintf` function. `RS232?` instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s,'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is automatically returned to the input buffer.

```
s.BytesAvailable
ans =
    17
```

Use `fgetl` to read the data returned from the previous write operation, and discard the terminator.

```
settings = fgetl(s)
settings =
9600;0;0;NONE;LF
length(settings)
ans =
    16
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

See Also

`fgets` | `fopen` | `BytesAvailable` | `InputBufferSize` | `ReadAsyncMode` | `Status` | `Terminator` | `Timeout` | `ValuesReceived`

fgets

Purpose

Read line from file, keeping newline characters

Syntax

```
tline = fgets(fileID)
tline = fgets(fileID, nchar)
```

Description

tline = fgets(*fileID*) reads the next line of the specified file, including the newline characters. *fileID* is an integer file identifier obtained from fopen. *tline* is a text string unless the line contains only the end-of-file marker. In this case, *tline* is the numeric value -1. fgets reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use fopen.

tline = fgets(*fileID*, *nchar*) returns at most *nchar* characters of the next line. *tline* does not include any characters after the newline characters or the end-of-file marker.

Examples

Read and display the file fgets.m. Because fgets keeps newline characters and disp adds a newline character, this code displays the file with double-spacing:

```
fid = fopen('fgets.m');

tline = fgets(fid);
while ischar(tline)
    disp(tline)
    tline = fgets(fid);
end

fclose(fid);
```

Compare these results to the fgetl example, which replaces the calls to fgets with fgetl.

How To

- "Testing for EOF with fgetl and fgets"

Purpose

Read line of text from device and include terminator

Syntax

```
tline = fgets(obj)
[tline,count] = fgets(obj)
[tline,count,msg] = fgets(obj)
```

Description

`tline = fgets(obj)` reads one line of text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data includes the terminator with the text line. To exclude the terminator, use `fgetl`.

`[tline,count] = fgets(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgets(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

Tips

Before you can read text from the device, it must be connected to `obj` with the `fopen`function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgets` is issued.

If you use the `help` command to display help for `fgets`, then you need to supply the pathname shown below.

```
help serial/fgets
```

Rules for Completing a Read Operation with fgets

A read operation with `fgets` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.

- The time specified by the `Timeout` property passes.
- The input buffer is filled.

Examples

Create the serial port object `s`, connect `s` to a Tektronix TDS 210 oscilloscope, and write the `RS232?` command with the `fprintf` function. `RS232?` instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s,'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is automatically returned to the input buffer.

```
s.BytesAvailable
ans =
    17
```

Use `fgets` to read the data returned from the previous write operation, and include the terminator.

```
settings = fgets(s)
settings =
9600;0;0;NONE;LF
length(settings)
ans =
    17
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

See Also

fieldnames

Purpose

Field names of structure, or public fields of object

Syntax

```
names = fieldnames(s)
names = fieldnames(obj)
names = fieldnames(obj,'-full')
```

Description

`names = fieldnames(s)` returns a cell array of strings containing the names of the fields in structure `s`.

`names = fieldnames(obj)` returns a cell array of strings containing the names of the public properties of `obj`. MATLAB objects can overload `fieldnames` and define their own behavior.

`names = fieldnames(obj,'-full')` returns a cell array of strings containing the name, type, attributes, and inheritance of the properties of `obj`. Only supported for COM or Java objects.

Examples

Structure Fields

Create a structure array and view its fields.

```
s(1,1).name = 'alice';
s(1,1).ID = 0;
s(2,1).name = 'gertrude';
s(2,1).ID = 1;

names = fieldnames(s)
```

```
names =
    'name'
    'ID'
```

Java Object Properties

Create a Java object and view its public properties.

```
obj = java.lang.Integer(0);
names = fieldnames(obj)
```

```
names =
    'MIN_VALUE'
    'MAX_VALUE'
    'TYPE'
    'SIZE'
```

How To

- “Generate Field Names from Variables”

figure

Purpose

Create figure graphics object

Syntax

```
figure
figure('PropertyName',propertyvalue,...)
figure(h)
h = figure(...)
```

Properties

For a list of properties, see `Figure Properties`.

Description

`figure` creates figure graphics objects. Figure objects are the individual windows on the screen in which the MATLAB software displays graphical output.

`figure` creates a new figure object using default property values. This automatically becomes the current figure and raises it above all other figures on the screen until a new figure is either created or called.

`figure('PropertyName',propertyvalue,...)` creates a new figure object using the values of the properties specified. For a description of the properties, see `Figure Properties`. MATLAB uses default values for any properties that you do not explicitly define as arguments.

`figure(h)` does one of two things, depending on whether or not a figure with handle `h` exists. If `h` is the handle to an existing figure, `figure(h)` makes the figure identified by `h` the current figure, makes it visible, and raises it above all other figures on the screen. The current figure is the target for graphics output. If `h` is not the handle to an existing figure, but is an integer, `figure(h)` creates a figure and assigns it the handle `h`. `figure(h)` where `h` is not the handle to a figure, and is not an integer, is an error.

`h = figure(...)` returns the handle to the figure object.

Tips

To create a figure object, MATLAB creates a new window whose characteristics are controlled by default figure properties (both factory installed and user defined) and properties specified as arguments. See `Figure Properties` for a description of these properties.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

Use `set` to modify the properties of an existing figure or `get` to query the current values of figure properties.

The `gcf` command returns the handle to the current figure and is useful as an argument to the `set` and `get` commands.

Figures can be docked in the desktop. The `DockControls` property determines whether you can dock the figure.

Making a Figure Current

The current figure is the target for graphics output. There are two ways to make a figure `h` the current figure.

- Make the figure `h` current, visible, and displayed on top of other figures:

  ```
  figure(h)
  ```

- Make the figure h current, but do not change its visibility or stacking with respect to other figures:

  ```
  set(0,'CurrentFigure',h)
  ```

Examples

Specifying Figure Size and Screen Location

To create a figure window that is one quarter the size of your screen and is positioned in the upper left corner, use the root object's `ScreenSize` property to determine the size. `ScreenSize` is a four-element vector: `[left, bottom, width, height]`:

```
scrsz = get(0,'ScreenSize');
figure('Position',[1 scrsz(4)/2 scrsz(3)/2 scrsz(4)/2])
```

To position the full figure window including the menu bar, title bar, tool bars, and outer edges, use the `OuterPosition` property in the same manner.

Specifying the Figure Window Title

You can add your own title to a figure by setting the `Name` property and you can turn off the figure number with the `NumberTitle` property:

```
figure('Name','Simulation Plot Window','NumberTitle','off')
```

See `Figure Properties` for a description of all properties.

Setting Default Properties

You can set default figure properties only on the `root object` level.

```
set(0,'DefaultFigureProperty',PropertyValue...)
```

where *`Property`* is the name of the figure property and `PropertyValue` is the value you are specifying. Use `set` and `get` to access figure properties.

See "Setting Default Property Values" for more information.

Figure Properties

Purpose

Define figure properties

Creating Figure Objects

Use `figure` to create figure objects.

Modifying Properties

You can set and query graphics object properties in two ways:

- "The Property Editor" is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of Handle Graphics properties.

To change the default values of properties, see "Setting Default Property Values" in the Handle Graphics Objects documentation.

Figure Property Descriptions

This section provides a description of properties. Curly braces `{ }` enclose default values.

`Alphamap`

`m-by-1` matrix of alpha values

Figure alphamap. An array of non-NaN alpha values. MATLAB accesses alpha values by their row number. For example, an index of `1` specifies the first alpha value, an index of `2` specifies the second alpha value, and so on. Alphamaps can be any length. The default alphamap contains 64 values that progress linearly from `0` to `1`.

Alphamaps affect the rendering of surface, image, and patch objects, but do not affect other graphics objects.

`BeingDeleted`

`on | {off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted`

property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

See the `close` and `delete` function reference pages for related information.

`BusyAction`

`cancel | {queue}`

Callback function interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callback functions. If there is a callback function executing, callback functions invoked subsequently always attempt to interrupt it. If the `Interruptible` property of the object whose callback is executing is `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback function.
- `queue` — Queue the event that attempted to execute a second callback function until the current callback finishes.

`ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Button press callback function. Executes whenever you press a mouse button while the pointer is in the figure window, but not over a child object (i.e., uicontrol, uipanel, axes, or axes child).

Define the `ButtonDownFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with the mouse button press and an empty event structure).

See the figure's `SelectionType` property to determine whether modifier keys were also pressed.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

Using the ButtonDownFcn

This example creates a figure and defines a function handle callback for the `ButtonDownFcn` property. When the user **Ctrl-**clicks the figure, the callback creates a new figure having the same callback.

Click to view in editor — This link opens the MATLAB Editor with the following example.

Click to run example — **Ctrl-**click the figure to create a new figure.

```
fh_cb = @newfig; % Create function handle for newfig function
figure('ButtonDownFcn',fh_cb);

function newfig(src,evnt)
   if strcmp(get(src,'SelectionType'),'alt')
      figure('ButtonDownFcn',fh_cb)
   else
      disp('Use control-click to create a new figure')
   end
end
```

`Children`
vector of handles

Children of the figure. A vector containing the handles of all axes, user-interface objects displayed within the figure. You can change the order of the handles and thereby change the stacking of the objects on the display.

When an object's `HandleVisibility` property is `off`, it is not listed in its parent's `Children` property. See `HandleVisibility` for more information.

`Clipping`

`{on} | off`

Clipping mode. This property has no effect on figures.

`CloseRequestFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Function executed on figure close. Executes whenever you issue the `close` command (either a `close(figure_handle)` or a `close all`), when you close a figure window from the computer's window manager menu, or when you quit MATLAB.

The `CloseRequestFcn` provides a mechanism to intervene in the closing of a figure. It allows you to, for example, display a dialog box to ask a user to confirm or cancel the close operation or to prevent users from closing a figure that contains a GUI.

The basic mechanism is:

1. A user issues the `close` command from the command line, by closing the window from the computer's window manager menu, or by quitting MATLAB.
2. The close operation executes the function defined by the figure `CloseRequestFcn`. The default function is `closereq`.

   `closereq` unconditionally deletes the current figure, destroying the window. `closereq` takes advantage of the fact that the

`close` command makes each figure specified as arguments the current figure before calling its respective close request function.

Note that `closereq` honors the `ShowHiddenHandles` setting during figure deletion and will not delete hidden figures.

Redefining the CloseRequestFcn

Define the `CloseRequestFcn` as a function handle. For example:

```
set(gcf,'CloseRequestFcn',@my_closefcn)
```

Where `@my_closefcn` is a function handle referencing function `my_closefcn`.

Unless the close request function calls `delete` or `close`, MATLAB never closes the figure. (Note that you can always call `delete(`*`figure_handle`*`)` from the command line if you have created a window with a nondestructive close request function.)

A useful application of the close request function is to display a question dialog box asking the user to confirm the close operation. The following function illustrates how to do this.

Click to view in editor — This link opens the MATLAB editor with the following example.

Click to run example — **Ctrl-**click the figure to create a new figure.

```
function my_closereq(src,evnt)
% User-defined close request function
% to display a question dialog box
   selection = questdlg('Close This Figure?',...
      'Close Request Function',...
      'Yes','No','Yes');
   switch selection,
```

```
      case 'Yes',
         delete(gcf)
      case 'No'
      return
   end
end
```

Now create a figure using the `CloseRequestFcn`:

```
figure('CloseRequestFcn',@my_closereq)
```

To make this function your default close request function, set a default value on the root level.

```
set(0,'DefaultFigureCloseRequestFcn',@my_closereq)
```

MATLAB then uses this setting for the `CloseRequestFcn` of all subsequently created figures.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`Color`
: `ColorSpec`

Background color. Controls the figure window background color. You can specify a color using a three-element vector of RGB values or one of the MATLAB predefined names. See `ColorSpec` for more information.

`Colormap`
: `m`-by-`3` matrix of RGB values

Figure colormap. An array of red, green, and blue (RGB) intensity values that define `m` individual colors. MATLAB accesses colors by their row number. For example, an index of `1` specifies the first RGB triplet, an index of `2` specifies the second RGB triplet, and so on.

Number of Colors Allowed

Colormaps can be any length, but must be three columns wide. The default figure colormap contains 64 predefined colors.

Objects That Use Colormaps

Colormaps affect the rendering of `surface`, image, and `patch` objects, but generally do not affect other graphics objects. See `colormap` and `ColorSpec` for more information.

`CreateFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during figure creation. Executes when MATLAB creates a figure object. You must define this property as a default value on the root level. For example, the statement:

```
set(0,'DefaultFigureCreateFcn',@fig_create)
```

defines a default value on the root level that causes all figures created to execute the setup function `fig_create`, which is defined below:

```
function fig_create(src,evnt)
set(src,'Color',[.2 .1 .5],...
   'IntegerHandle','off',...
   'MenuBar','none',...
   'ToolBar','none')
end
```

MATLAB executes the create function after setting all properties for the figure. Setting this property on an existing figure object has no effect.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo` or the handle of the object generating the callback (the source of the event). For example, this,

```
f = figure('CreateFcn',@(o,e) keyboard)
K>> gcbo
```

and this each return 1:

```
f = figure('CreateFcn',@(o,e) keyboard)
K>> o
```

`CurrentAxes`
handle of current axes

Target axes in this figure. MATLAB sets this property to the handle of the figure's current axes (the handle returned by the `gca` command when this figure is the current figure). In all figures for which axes children exist, there is always a current axes. The current axes does not have to be the topmost axes, and setting an axes to be the `CurrentAxes` does not restack it above all other axes.

You can make an axes current using the `axes` and `set` commands. For example, `axes(`*`axes_handle`*`)` and `set(gcf,'CurrentAxes',`*`axes_handle`*`)` both make the axes identified by the handle *`axes_handle`* the current axes. In addition, `axes(`*`axes_handle`*`)` restacks the axes above all other axes in the figure.

If a figure contains no axes, `get(gcf,'CurrentAxes')` returns the empty matrix. Note that the `gca` function actually creates an axes if one does not exist.

`CurrentCharacter`
single character

Last key pressed. MATLAB sets this property to the last key pressed in the figure window. Use `CurrentCharacter` to obtain user input.

`CurrentObject`
object handle

Handle of current object. MATLAB sets this property to the handle of the last object clicked on by the mouse. This object is the frontmost object in the view. You can use this property to determine which object a user has selected. The function `gco` provides a convenient way to retrieve the `CurrentObject` of the `CurrentFigure`.

Note that the `HitTest` property controls whether an object can become the `CurrentObject`.

Hidden Handle Objects

Clicking an object whose `HandleVisibility` property is `off` (such as axis labels and title) causes the `CurrentObject` property to be set to empty `[]`. To avoid returning an empty value when users click hidden objects, set the hidden object's `HitTest` property to `off`.

Mouse Over

Note that cursor motion over objects does not update the `CurrentObject`; you must click objects to update this property. See the `CurrentPoint` property for related information.

`CurrentPoint`
two-element vector: [*x*-coordinate, *y*-coordinate]

Location of last button click in this figure. MATLAB sets this property to the location of the pointer at the time of the most recent mouse button press. MATLAB updates this property

whenever you press the mouse button while the pointer is in the figure window.

Note that if you select a point in the figure and then use the values returned by the CurrentPoint property to plot that point, there can be differences in the position due to round-off errors.

CurrentPoint and Cursor Motion

In addition to the behavior described above, MATLAB updates CurrentPoint before executing callback routines defined for the figure WindowButtonMotionFcn and WindowButtonUpFcn properties. This enables you to query CurrentPoint from these callback routines. It behaves like this:

- If there is no callback routine defined for the WindowButtonMotionFcn or the WindowButtonUpFcn, then MATLAB updates the CurrentPoint only when the mouse button is pressed down within the figure window.
- If there is a callback routine defined for the WindowButtonMotionFcn, then MATLAB updates the CurrentPoint just before executing the callback. Note that the WindowButtonMotionFcn executes only within the figure window unless the mouse button is pressed down within the window and then held down while the pointer is moved around the screen. In this case, the routine executes (and the CurrentPoint is updated) anywhere on the screen until the mouse button is released.
- If there is a callback routine defined for the WindowButtonUpFcn, MATLAB updates the CurrentPoint just before executing the callback. Note that the WindowButtonUpFcn executes only while the pointer is within the figure window unless the mouse button is pressed down initially within the window. In this case, releasing the button anywhere on the screen triggers callback execution, which is preceded by an update of the CurrentPoint.

The figure `CurrentPoint` is updated only when certain events occur, as previously described. In some situations (such as when the `WindowButtonMotionFcn` takes a long time to execute and the pointer is moved very rapidly), the `CurrentPoint` might not reflect the actual location of the pointer, but rather the location at the time when the `WindowButtonMotionFcn` began execution.

The `CurrentPoint` is measured from the lower-left corner of the figure window, in units determined by the `Units` property.

The root `PointerLocation` property contains the location of the pointer updated synchronously with pointer movement. However, the location is measured with respect to the screen, not a figure window.

See `uicontrol` for information on how this property is set when you click a uicontrol object.

`DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Delete figure callback function. Executes when the figure object is deleted (for example, when you issue a `delete` or a `close` command). MATLAB executes the function before destroying the object's properties so these values are available to the callback routine.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

The handle of the object whose `DeleteFcn` is being executed is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See also the figure `CloseRequestFcn` property

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`DockControls`
`{on} | off`

Displays controls used to dock figure. Determines whether the figure enables the **Desktop** menu item and the dock figure button in the title bar that allow you to dock the figure into the MATLAB desktop.

- `on` — Figure docking controls are visible.
- `off` — The **Desktop** menu item that enables you to dock the figure is disabled and the figure dock button is not displayed.

See the `WindowStyle` property for more information on docking figure.

`DoubleBuffer`
`{on} | off`

Note This property is now obsolete and has no effect. It was provided for older computer systems to produce flash-free animations.

Flash-free rendering for simple animations. Double buffering is the process of drawing to an off-screen pixel buffer and then printing the buffer contents to the screen once the drawing is complete. Double buffering generally produces flash-free rendering for simple animations (such as those involving lines, as opposed to objects containing large numbers of polygons). Use double buffering with the animated objects' `EraseMode` property set to `normal`. Use the `set` command to disable double buffering.

```
set(figure_handle,'DoubleBuffer','off')
```

Double buffering works only when the figure `Renderer` property is `painters`.

`FileName`
String

GUI FIG-file name. GUIDE stores the name of the FIG-file used to save the GUI layout in this property. In non-GUIDE GUIs, by default `FileName` is empty. You can `set` the `FileName` property in non-GUIDE GUIs as well, and `get` it to verify what GUI is running or whether it has been previously saved.

`FixedColors`
`m`-by-`3` matrix of RGB values (read-only)

Noncolormap colors. Fixed colors define all colors appearing in a figure window that are not from the figure colormap. These colors include axis lines and labels, the colors of `line`, `text`, `uicontrol`, and `uimenu`, and `text` objects, and any colors explicitly defined, for example, with a statement like:

```
set(gcf,'Color',[0.3,0.7,0.9])
```

Fixed color definitions reside in the system color table and do not appear in the figure colormap. For this reason, fixed colors can limit the number of simultaneously displayed colors if the number of fixed colors plus the number of entries in the figure colormap exceed your system's maximum number of colors.

(See the root `ScreenDepth` property for information on determining the total number of colors supported on your system. See the `MinColorMap` property for information on how MATLAB shares colors between applications.)

Note The `FixedColors` property is being deprecated and will be removed in a future release

---

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

Handles are always visible when `HandleVisibility` is `on`.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Visibility and Handles Returned by Other Functions

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure`property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Making All Handles Visible

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Validity of Hidden Handles

Handles that are hidden are still valid. If you know an object's handle, you can pass it to any function that operates on handles, and set and get its properties.

`HitTest`
`{on} | off`

Selectable by mouse click. Determines if the figure can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the figure. If `HitTest` is `off`, clicking the figure sets the `CurrentObject` to the empty matrix.

`IntegerHandle`
`{on} | off`

Figure handle mode. Figure object handles are integers by default. When creating a new figure, MATLAB uses the lowest integer that is not used by an existing figure. If you delete a figure, its integer handle can be reused.

If you set this property to `off`, MATLAB assigns nonreusable real-number handles (for example, `67.0001221`) instead of integers. This feature is designed for dialog boxes where removing the handle from integer values reduces the likelihood of inadvertently drawing into the dialog box.

`Interruptible`
`{on} | off`

Callback routine interruption mode. Controls whether a figure callback function can be interrupted by subsequently invoked callbacks.

How Callbacks Are Interrupted

MATLAB checks for queued events that can interrupt a callback function only when it encounters a call to `drawnow`, `figure`, `getframe`, or `pause` in the executing callback function. When executing one of these functions, MATLAB processes all pending events, including executing all waiting callback functions. The interrupted callback then resumes execution.

What Property Callbacks Are Interruptible

The `Interruptible` property only affects callback functions defined for the `ButtonDownFcn`, `KeyPressFcn`, `KeyReleaseFcn`, `WindowButtonDownFcn`, `WindowButtonMotionFcn`, `WindowButtonUpFcn`, `WindowKeyPressFcn`, `WindowKeyReleaseFcn`, and `WindowScrollWheelFcn`.

See the `BusyAction` property for related information.

`InvertHardcopy`
`{on} | off`

Change hardcopy to black objects on white background. Affects only printed output. Printing a figure having a background color (`Color` property) that is not white results in poor contrast between graphics objects and the figure background and also consumes a lot of printer toner.

When `InvertHardCopy` is `on`, MATLAB eliminates this effect by changing the color of the figure and axes to white and the axis lines, tick marks, axis labels, etc., to black. `lines`, `text`, and the edges of `patch`es and `surface`s might be changed, depending on the `print` command options specified.

If you set `InvertHardCopy` to `off`, the printed output matches the colors displayed on the screen.

See `print` for more information on printing MATLAB figures.

`KeyPressFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Key press callback function. Callback function invoked by a key press that occurs while the figure window has focus. Define the `KeyPressFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key press and an event structure).

See Function Handle Callbacks for information on how to use function handles to define the callback function.

When no callback is specified for this property (which is the default state), MATLAB passes any key presses to the Command Window. However, when you define a callback for this property, the figure retains focus with each key press and executes the specified callback with each key press.

KeyPressFcn Event Structure

When you specify the callback as a function handle, MATLAB passes to it a structure to containing the following fields.

Field	Contents
`Character`	The character displayed as a result of the pressing the key(s), which can be empty or unprintable
`Key`	The key being pressed, identified by the lowercase label on key or a descriptive string
`Modifier`	A cell array containing the names of one or more modifier keys being pressed (i.e., **control**, **alt**, **shift**). On Macintosh computers, it contains `'command'` when pressing the **command** modifier key

Explore KeyPressFcn Behavior

To view the values of the event data fields for any key or key combination, run the following code:

```
figure('NumberTitle','off','Menubar','none',...
       'Name','Press keys to put event data in Command Window',...
       'Position',[560 728 560 200],...
       'KeyPressFcn',@(obj,evt)disp(evt));
```

Each time you press a key, the `KeyPressFcn` uses `disp` to display the event data in the Command Window.

You can also view and run an example GUI, `ex_KeyPressFcn.m`, which displays keystroke event data in the figure window, and provides an option to write the event data structure to your workspace.

- Click here to view the example in the MATLAB editor
- Click here to add the example to the MATLAB path
- Click to run the example — Press and release various key combinations while the figure has focus. The callback displays event data in text fields in the figure window. The **Char**

Code data is the `Character` field displayed as a number, not a separate event data field.

Event data passed to a `KeyPressFcn` and `KeyReleaseFcn` callbacks have the following characteristics:

- The `Key` field is always in lower case (contains the non-shifted symbol).
- Modifier keys (**Alt**, **Ctrl**, **Shift**,) return data when pressed alone as well as when pressed in combination with other keys.
- `Modifier` fields contain a cell array with zero or more strings.
- Modifier keys can affect the `Character` field, but do not change the `Key` field.
- Certain keys, plus keys modified with **Ctrl**, put unprintable characters in the `Character` field.
- **Ctrl**, **Alt**, **Shift**, function and several other keys generate no `Character` field data.

Using the KeyPressFcn

This example creates a figure and defines a function handle callback for the `KeyPressFcn` property. When you press the **p** key, the callback exports the figure as a PNG image file. When you press **Ctrl+p**, the callback exports the figure as a PDF file.

```
function figure_keypress
    figure('KeyPressFcn',@printfig);
    surf(peaks)

    function printfig(src,event)
    % Callback to parse keypress event data to print a figure
        if event.Character == 'p'
            % On some systems you must send the file to a printer manually
            if length(event.Modifier) == 1 && ...
                strcmp(event.Modifier{:},'control')
```

```
                % Create PDF file of figure when Ctrl key is down
                print ('-dpdf',['-f' num2str(src)])
            elseif isempty(event.Modifier)
                % Print PNG image of figure when Ctrl is not pressed
                print ('-dpng','-r200',['-f' num2str(src)])
            end
        end
    end
end
```

`KeyReleaseFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Key release callback function. Callback function invoked by a key release that occurs while the figure window has focus. Define the `KeyReleaseFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

See Function Handle Callbacks for information on how to use function handles to define the callback function.

KeyReleaseFcn Event Structure

When the callback is a function handle, MATLAB passes a structure as the second argument to the callback function that contains the following fields.

Field	Contents
`Character`	The character displayed as a result of the releasing the key(s), which can be empty or unprintable
`Key`	The key being released, identified by the lowercase label on key or a descriptive string
`Modifier`	A cell array containing the names of one or more modifier keys being released (i.e., **control**, **alt**, **shift**). On Macintosh computers, it contains `'command'` when releasing the **command** modifier key

Properties Affected by the KeyReleaseFcn

When a callback is defined for the `KeyReleaseFcn` property, MATLAB updates the `CurrentCharacter` figure property just before executing the callback.

Multiple-Key Press Events and a Single-Key Release Event

Consider a figure having callbacks defined for both the `KeyPressFcn` and `KeyReleaseFcn`. In the case where you press multiple keys at close to the same time, MATLAB generates repeated `KeyPressFcn` events only for the last key pressed.

For example, suppose you press and hold down the **a** key, then press and hold down the **s** key. MATLAB generates repeated `KeyPressFcn` events for the **a** key until you press the **s** key, at which point MATLAB generates repeated `KeyPressFcn` events for the **s** key. If you then release the **s** key, MATLAB generates a `KeyReleaseFcn` event for the **s** key, but no new `KeyPressFcn` events for the **a** key. When you then release the **a** key, the `KeyReleaseFcn` again executes. The `KeyReleaseFcn` executes its callback every time you release a key while the figure is in focus, regardless of what any `KeyPressFcn` does.

Event structures passed to a `KeyPressFcn` and `KeyReleaseFcn` callbacks have the following characteristics:

- The `Key` field is always in lower case (contains the non-shifted symbol).
- Modifier keys (**Alt**, **Ctrl**, **Shift**,) return data when pressed alone as well as when pressed in combination with other keys.
- `Modifier` fields contain a cell array with zero or more strings.
- Modifier keys can affect the `Character` field, but do not change the `Key` field.
- Certain keys, plus keys modified with **Ctrl**, put unprintable characters in the `Character` field.
- **Ctrl**, **Alt**, **Shift**, function and several other keys generate no `Character` field data.

Modifier Keys

When you press and release a key and a modifier key, the modifier key is returned in the event structure `Modifier` field. If you press and release a modifier key only, its name is not returned in the event structure of the `KeyReleaseFcn`, but is returned in the event structure of the `KeyPressFcn`.

Explore KeyReleaseFcn Behavior

The following code example creates a figure and defines a function handle callback for the `KeyReleaseFcn` property which reports the event data that the callback receives.

- Click here to view the example in the MATLAB editor
- Click here to add the example to the MATLAB path
- Click to run the example — Press and release various key combinations while the figure has focus. The callback displays event data in the Command Window.

```
function key_releaseFcn
   figure('KeyReleaseFcn',@cb)
      function cb(src,evnt)
      if ~isempty(evnt.Modifier)
         for ii = 1:length(evnt.Modifier)
            out = sprintf('Character: %c\nModifier: %s\nKey: %s\n',...
     evnt.Character,evnt.Modifier{ii},evnt.Key);
            disp(out)
         end
      else
         out = sprintf('Character: %c\nModifier: %s\nKey: %s\n',...
    evnt.Character,'No modifier key',evnt.Key);
         disp(out)
      end
   end
end
```

`MenuBar`

`none | {figure}`

Enable-disable figure menu bar. Enables you to display or hide the menu bar that MATLAB places at the top of a figure window. The default (`figure`) is to display the menu bar.

This property affects only built-in menus. This property does not affect menus defined with the `uimenu` command.

Changing the `WindowStyle` of a window to `'modal'` hides both its toolbar and menu bar, if they exist. Changing `WindowStyle` from `'modal'` to `'normal'` or `'docked'` displays any toolbar or menu bar a figure has.

`MinColormap`

scalar (default = `64`)

Minimum number of color table entries used. Specifies the minimum number of system color table entries used by MATLAB to store the colormap defined for the figure (see the `Colormap`

property). In certain situations, you might need to increase this value to ensure proper use of colors.

For example, suppose you run color-intensive applications in addition to MATLAB and have defined a large figure colormap (for example, 150 to 200 colors). MATLAB might select colors that are close but not exact from the existing colors in the system color table because there are not enough slots available to define all the colors you specified.

To ensure that MATLAB uses exactly the colors you define in the figure colormap, set `MinColormap` equal to the length of the colormap.

```
set(gcf,'MinColormap',length(get(gcf,'ColorMap')))
```

Note that the larger the value of `MinColormap`, the greater the likelihood that other windows (including other MATLAB figure windows) will be displayed in false colors.

Note The `MinColormap` property is being deprecated and will be removed in a future release

---

`Name`
: `string`

Figure window title. Specifies the title displayed in the figure window. By default, `Name` is empty and the figure title is displayed as `Figure 1`, `Figure 2`, and so on. When you set this parameter to a string, the figure title becomes `Figure 1: <string>`. See the `NumberTitle` property.

`NextPlot`
: `new | {add} | replace | replacechildren`

How to add next plot. Determines which figure MATLAB uses to display graphics output. If the value of the current figure is:

- `new` — Create a new figure to display graphics (unless an existing parent is specified in the graphing function as a property/value pair).
- `add` — Use the current figure to display graphics (the default).
- `replace` — Reset all figure properties except `Position` to their defaults and delete all figure children before displaying graphics (equivalent to `clf reset`).
- `replacechildren` — Remove all child objects, but do not reset figure properties (equivalent to `clf`).

The `newplot` function provides an easy way to handle the `NextPlot` property. For more information, see the axes `NextPlot` property and "Controlling Graphics Output".

`NumberTitle`
`{on} | off` (GUIDE default `off`)

Figure window title number. Determines whether the string `Figure No.  N` (where `N` is the figure number) is prefixed to the figure window title. See the `Name` property.

`OuterPosition`
four-element vector

Figure position including title bar, menu bar, tool bars, and outer edges. Specifies the size and location on the screen of the full figure window including the title bar, menu bar, tool bars, and outer edges. Specify the position rectangle with a four-element vector of the form:

```
rect = [left, bottom, width, height]
```

where `left` and `bottom` define the distance from the lower-left corner of the screen to the lower-left corner of the full figure

window. `width` and `height` define the dimensions of the window. See the `Units` property for information on the units used in this specification. The `left` and `bottom` elements can be negative on systems that have more than one monitor.

Position of Docked Figures

If the figure is docked in the MATLAB desktop, then the `OuterPosition` property is specified with respect to the figure group container instead of the screen.

Moving and Resizing Figures

Use the `get` function to obtain this property and determine the position of the figure. Use the `set` function to resize and move the figure to a new location. You cannot set the figure `OuterPosition` when it is docked.

Note On Microsoft Windows systems, figure windows cannot be less than `104` pixels wide, regardless of the value of the `OuterPosition` property.

`PaperOrientation`
`{portrait} | landscape`

Horizontal or vertical paper orientation. Determines how to orient printed figures on the page.

- `portrait` — Orients the longest page dimension vertically.
- `landscape` — Orients the longest page dimension horizontally.

See the `orient` command for more information.

`PaperPosition`
four-element rect vector

Location on printed page. A rectangle that determines the location of the figure on the printed page. Specify this rectangle with a vector of the form:

```
rect = [left, bottom, width, height]
```

where `left` specifies the distance from the left side of the paper to the left side of the rectangle and `bottom` specifies the distance from the bottom of the page to the bottom of the rectangle. Together these distances define the lower-left corner of the rectangle. `width` and `height` define the dimensions of the rectangle. The `PaperUnits` property specifies the units used to define this rectangle.

`PaperPositionMode`
`auto | {manual}`

WYSIWYG printing of figure.

- `manual` — MATLAB honors the value specified by the `PaperPosition` property.
- `auto` — MATLAB prints the figure the same size as it appears on the computer screen, centered on the page.

`PaperSize`
`[width height]`

Paper size. Size of the current `PaperType`, measured in `PaperUnits`. See `PaperType` to select standard paper sizes.

`PaperType`
Select a value from the following table.

Selection of standard paper size. Sets the `PaperSize` to one of the following standard sizes.

Paper Sizes Table

Property Value	Size (Width x Height)
usletter (default)	8.5-by-11 inches
uslegal	8.5-by-14 inches
tabloid	11-by-17 inches
A0	841-by-1189 mm
A1	594-by-841 mm
A2	420-by-594 mm
A3	297-by-420 mm
A4	210-by-297 mm
A5	148-by-210 mm
B0	1029-by-1456 mm
B1	728-by-1028 mm
B2	514-by-728 mm
B3	364-by-514 mm
B4	257-by-364 mm
B5	182-by-257 mm
arch-A	9-by-12 inches
arch-B	12-by-18 inches
arch-C	18-by-24 inches
arch-D	24-by-36 inches
arch-E	36-by-48 inches
A	8.5-by-11 inches
B	11-by-17 inches
C	17-by-22 inches

Property Value	Size (Width x Height)
`D`	22-by-34 inches
`E`	34-by-43 inches

Note that you might need to change the `PaperPosition` property in order to position the printed figure on the new paper size. One solution is to use `normalized` `PaperUnits`, which enables MATLAB to automatically size the figure to occupy the same relative amount of the printed page, regardless of the paper size.

`PaperUnits`
`normalized | {inches} | centimeters | points`

Hardcopy measurement units. Specifies the units used to define the `PaperPosition` and `PaperSize` properties. MATLAB measures all units from the lower-left corner of the page. `normalized` units map the lower-left corner of the page to (0, 0) and the upper-right corner to (1.0, 1.0). `inches`, `centimeters`, and `points` are absolute units (one point equals 1/72 of an inch).

If you change the value of `PaperUnits`, it is good practice to return the property to its default value after completing your computation so as not to affect other functions that assume `PaperUnits` is set to the default value.

`Parent`
`handle`

Handle of figure's parent. The parent of a figure object is the `root object` object. The handle to the root is always 0.

`Pointer`

```
crosshair | {arrow} | watch | topl |
topr | botl | botr | circle | cross |
fleur | left | right | top | bottom |
fullcrosshair | ibeam | custom | hand
```

Pointer symbol selection. Determines the symbol used to indicate the pointer (cursor) position in the figure window. Setting `Pointer` to `custom` allows you to define your own pointer symbol. See the `PointerShapeCData` property and "Specifying the Figure Pointer" for more information.

`PointerShapeCData`
16-by-16 matrix

User-defined pointer. Defines the pointer used when you set the `Pointer` property to `custom`. It is a 16-by-16 element matrix defining the 16-by-16 pixel pointer using the following values:

- `1` — Color pixel black.
- `2` — Color pixel white.
- `NaN` — Make pixel transparent (underlying screen shows through).

Element `(1,1)` of the `PointerShapeCData` matrix corresponds to the upper-left corner of the pointer. Setting the `Pointer` property to one of the predefined pointer symbols does not change the value of the `PointerShapeCData`. Computer systems supporting 32-by-32 pixel pointers fill only one quarter of the available pixmap.

`PointerShapeHotSpot`
two-element vector

Pointer active area. Specifies the row and column indices in the `PointerShapeCData` matrix defining the pixel indicating the pointer location. The location is contained in the `CurrentPoint` property and the root object's `PointerLocation` property. The default value is element `(1,1)`, which is the upper-left corner.

`Position`
four-element vector

Figure position. Specifies the size and location on the screen of the figure window, not including title bar, menu bar, tool bars, and outer edges. Specify the position rectangle with a four-element vector of the form:

```
rect = [left, bottom, width, height]
```

where `left` and `bottom` define the distance from the lower-left corner of the screen to the lower-left corner of the figure window. `width` and `height` define the dimensions of the window. See the `Units` property for information on the units used in this specification. The `left` and `bottom` elements can be negative on systems that have more than one monitor.

Position of Docked Figures

If the figure is docked in the MATLAB desktop, then the `Position` property is specified with respect to the figure group container instead of the screen.

Moving and Resizing Figures

You can use the `get` function to obtain this property and determine the position of the figure and you can use the `set` function to resize and move the figure to a new location. You cannot set the figure `Position` when it is docked.

Note On Windows systems, figure windows cannot be less than 104 pixels wide, regardless of the value of the `Position` property.

Also, the figure window includes the area to which MATLAB can draw; it does not include the title bar, menu bar, tool bars, and outer edges. To place the full window, use the `OuterPosition` property.

`Renderer`

`painters | zbuffer | OpenGL`

Rendering method used for screen and printing. Selects the method used to render MATLAB graphics. The choices are:

- `painters` — The original rendering method used by MATLAB is faster when the figure contains only simple or small graphics objects.
- `zbuffer` — MATLAB draws graphics objects faster and more accurately because it colors objects on a per-pixel basis and MATLAB renders only those pixels that are visible in the scene (thus eliminating front-to-back sorting errors). Note that this method can consume a lot of system memory if MATLAB is displaying a complex scene.
- `OpenGL` — OpenGL is a renderer that is available on many computer systems. This renderer is generally faster than `painters` or `zbuffer` and in some cases enables MATLAB to access graphics hardware that is available on some systems.

Hardware vs. Software OpenGL Implementations

There are two kinds of OpenGL implementations — hardware and software.

The hardware implementation uses special graphics hardware to increase performance and is therefore significantly faster than the software version. Many computers have this special hardware available as an option or might come with this hardware right out of the box.

Software implementations of OpenGL are much like the ZBuffer renderer that is available on MATLAB Version 5.0 and later; however, OpenGL generally provides superior performance to ZBuffer.

OpenGL Availability

OpenGL is available on all computers that run MATLAB. MATLAB automatically finds hardware-accelerated versions of OpenGL if such versions are available. If the hardware-accelerated version is not available, then MATLAB uses the software version (except on Macintosh systems, which do not support software OpenGL).

The following software versions are available:

- On UNIX systems, MATLAB uses the software version of OpenGL that is included in the MATLAB distribution.
- On Windows, OpenGL is available as part of the operating system. If you experience problems with OpenGL, contact your graphics driver vendor to obtain the latest qualified version of OpenGL.
- On Macintosh systems, software OpenGL is not available.

MATLAB issues a warning if it cannot find a usable OpenGL library.

Selecting Hardware-Accelerated or Software OpenGL

MATLAB enables you to switch between hardware-accelerated and software OpenGL. However, Windows and UNIX systems behave differently:

- On Windows systems, you can toggle between software and hardware versions any time during the MATLAB session.
- On UNIX systems, you must set the OpenGL version before MATLAB initializes OpenGL. Therefore, you cannot issue the `opengl info` command or create graphs before you call `opengl software`. To reenable hardware accelerated OpenGL, you must restart MATLAB.
- On Macintosh systems, software OpenGL is not available.

If you do not want to use hardware OpenGL, but do want to use object transparency, you can issue the following command.

```
opengl software
```

This command forces MATLAB to use software OpenGL. Software OpenGL is useful if your hardware-accelerated version of OpenGL does not function correctly and you want to use image, patch, or surface transparency, which requires the OpenGL renderer. To reenable hardware OpenGL, use the command:

```
opengl hardware
```

on Windows systems or restart MATLAB on UNIX systems.

By default, MATLAB uses hardware-accelerated OpenGL.

See the `opengl` reference page for additional information

Determining the OpenGL Library Version

To determine the version and vendor of the OpenGL library that MATLAB is using on your system, type the following command at the MATLAB prompt:

```
opengl info
```

The returned information contains a line that indicates if MATLAB is using software (`Software = true`) or hardware-accelerated (`Software = false`) OpenGL.

This command also returns a string of extensions to the OpenGL specification that are available with the particular library MATLAB is using. Include this information if you report a bug.

Note that issuing the `opengl info` command causes MATLAB to initialize OpenGL.

OpenGL vs. Other MATLAB Renderers

There are some differences between drawings created with OpenGL and those created with other renderers. The OpenGL specific differences include:

- OpenGL does not do colormap interpolation. If you create a surface or patch using indexed color and interpolated face or edge coloring, OpenGL interpolates the colors through the RGB color cube instead of through the colormap.
- OpenGL does not support the `phong` value for the `FaceLighting` and `EdgeLighting` properties of surfaces and patches.
- OpenGL does not support logarithmic-scale axes.
- OpenGL and Zbuffer renderers display objects sorted in front to back order, as seen on the monitor, and lines always draw in front of faces when at the same location on the plane of the monitor. Painters sorts by child order (order specified).

XServer Connection Lost

When using Linux or Macintosh systems, MATLAB can crash with a segmentation violation if the connection to the XServer is broken. If this occurs, ensure that the system has the latest XServer installed.

You can also try using software OpenGL and upgrade the OpenGL driver on a Linux system.

Try these workarounds:

1. Upgrade you XServer to the latest version
2. Upgrade your OpenGL driver to the latest version
3. Switch to software OpenGL by entering this command:

   ```
   opengl software
   ```

`RendererMode`
`{auto} | manual`

Automatic or user selection of renderer. Specifies whether MATLAB should choose the `Renderer` based on the contents of the figure window, or whether the `Renderer` should remain unchanged.

When the `RendererMode` property is `auto`, MATLAB selects the rendering method for printing as well as for screen display based on the size and complexity of the graphics objects in the figure.

For printing, MATLAB switches to `zbuffer` at a greater scene complexity than for screen rendering because printing from a z-buffered figure can be considerably slower than one using the `painters` rendering method, and can result in large PostScript® files. However, the output does always match what is on the screen. The same holds true for OpenGL: the output is the same as that produced by the `zbuffer` renderer — a bitmap with a resolution determined by the `print` command's `-r` option.

Criteria for Autoselection of the OpenGL Renderer

When the `RendererMode` property is `auto`, MATLAB uses the following criteria to determine whether to select the OpenGL renderer:

If the `opengl` autoselection mode is `autoselect`, MATLAB selects OpenGL if

- The host computer has OpenGL installed and is in True Color mode (OpenGL does not fully support 8-bit color mode).
- The figure contains no logarithmic axes (OpenGL does not support logarithmic axes).
- MATLAB would select `zbuffer` based on figure contents.

- Patch objects' faces have no more than three vertices (some OpenGL implementations of patch tessellation are unstable).
- The figure contains less than 10 uicontrols (OpenGL clipping around uicontrols is slow).
- No line objects use markers (drawing markers is slow).
- You do not specify Phong lighting (OpenGL does not support Phong lighting; if you specify Phong lighting, MATLAB uses the ZBuffer renderer).

  Or

- Figure objects use transparency (OpenGL is the only MATLAB renderer that supports transparency).

When the `RendererMode` property is `manual`, MATLAB does not change the `Renderer`, regardless of changes to the figure contents.

`Resize`
`{on} | off`

Window resize mode. Determines if you can resize the figure window with the mouse. `on` means you can resize the window, `off` means you cannot. When `Resize` is `off`, the figure window does not display any resizing controls (such as boxes at the corners), to indicate that it cannot be resized.

`ResizeFcn`
function handle | cell array containing function handle and additional arguments | string (not recommended)

Window resize callback function. Executes whenever you resize the figure window and also when the figure is created. You can query the figure's `Position` property to determine the new size and position of the figure. During execution of the callback routine, the handle to the figure being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

You can use ResizeFcn to maintain a GUI layout that is not directly supported by the MATLAB Position/Units paradigm.

For example, consider a GUI layout that maintains an object at a constant height in pixels and attached to the top of the figure, but always matches the width of the figure. The following ResizeFcn accomplishes this; it keeps the uicontrol whose Tag is 'StatusBar' 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the Tag property to retrieve the uicontrol handle, and the gcbo function to retrieve the figure handle. Also note the defensive programming regarding figure Units, which the callback requires to be in pixels in order to work correctly, but which the callback also restores to their previous value afterwards.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

You can change the figure Position from within the ResizeFcn callback; however, the ResizeFcn is not called again as a result.

Note that the print command can cause the ResizeFcn to be called if the PaperPositionMode property is manual and you have defined a resize function. If you do not want your resize function called by print, set the PaperPositionMode to auto.

See “Introduction” for an example of how to implement a resize function for a GUI.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`Selected`
`on | off`

Is object selected? This property indicates whether the figure is selected. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

`SelectionHighlight`
`{on} | off`

Figures do not indicate selection.

`SelectionType`
`{normal} | extend | alt | open`

Mouse selection type. MATLAB maintains this property to provide information about the last mouse button press that occurred within the figure window. This information indicates the type of selection made. Selection types are actions that MATLAB generally associates with particular responses from the user interface software (for example, single-clicking a graphics object places it in move or resize mode; double-clicking a file name opens it, etc.).

The physical action required to make these selections varies on different platforms. However, all selection types exist on all platforms.

Selection Type	Microsoft Windows	X-Windows
`Normal`	Click left mouse button.	Click left mouse button.
`Extend`	**Shift** - click left mouse button or click both left and right mouse buttons.	**Shift**-click left mouse button or click middle mouse button.

Selection Type	Microsoft Windows	X-Windows
`Alternate`	**Control** - click left mouse button or click right mouse button.	**Control**-click left mouse button or click right mouse button.
`Open`	Double-click any mouse button.	Double-click any mouse button.

Note For `uicontrols` whose `Enable` property is `on`, a single left-click, **Ctrl**-left click, or **Shift**-left click sets the figure `SelectionType` property to `normal`. For a list box `uicontrol` whose `Enable` property is `on`, the second click of a double-click sets the figure `SelectionType` property to `open`. All clicks on `uicontrols` whose `Enable` property is `inactive` or `off` and all right-clicks on `uicontrols` whose `Enable` property is `on` set the figure `SelectionType` property as specified in the preceding table.

`Tag`

string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, suppose you want to direct all graphics output from a file to a particular figure, regardless of user actions that might have changed the current figure. To do this, identify the figure with a `Tag`.

```
figure('Tag','Plotting Figure')
```

Then make that figure the current figure before drawing by searching for the `Tag` with `findobj`.

```
figure(findobj('Tag','Plotting Figure'))
```

`Toolbar`
`none | {auto} | figure`

Control display of figure toolbar. Control whether MATLAB displays the default figure toolbar on figures. The possible values are:

- `none` — Do not display the figure toolbar.
- `auto` — Display the figure toolbar, but remove it if a uicontrol is added to the figure.
- `figure` — Display the figure toolbar.

Note that this property affects only the figure toolbar; it does not affect other toolbars (for example, the Camera Toolbar or Plot Edit Toolbar). Selecting **Figure Toolbar** from the figure **View** menu sets this property to `figure`.

Changing the `WindowStyle` of a window to `'modal'` hides both its toolbar and menu bar, if they exist. Changing `WindowStyle` from `'modal'` to `'normal'` or `'docked'` displays any toolbar or menu bar a figure has.

`Type`
string (read-only)

Object class. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For figures, `Type` is always '`figure`'.

`UIContextMenu`
handle of uicontextmenu object

Associate a context menu with the figure. Assign this property the handle of a uicontextmenu object created in the figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the figure.

`Units`

`inches | centimeters | normalized | points | {pixels} | characters`

Units of measurement. Specifies the units MATLAB uses to interpret size and location data. All units are measured from the lower-left corner of the window.

- `normalized` — Units map the lower-left corner of the figure window to (0,0) and the upper-right corner to (1.0,1.0).
- `inches`, `centimeters`, and `points` — Absolute units. 1 point = $^1/_{72}$ inch.
- `pixels` — Size depends on screen resolution.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

This property affects the `CurrentPoint` and `Position` properties. If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is the default value.

When specifying the units as property/value pairs during object creation, you must set the `Units` property before specifying the properties that you want to use these units.

`UserData`

matrix

User-specified data. Data you want to associate with the figure object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Object visibility. The `Visible` property determines whether an object is displayed on the screen. If the `Visible` property of a figure is `off`, the entire figure window is invisible.

A Note About Using the Window Button Properties

Your window button callback functions might need to update the display by calling `drawnow` or `pause`, which causes MATLAB to process all events in the queue. Processing the event queue can cause your window button callback functions to be reentered. For example, a `drawnow` in the `WindowButtonDownFcn` might result in the `WindowButtonDownFcn` being called again before the first call has finished. You should design your code to handle reentrancy and you should not depend on global variables that might change state during reentrance.

You can use the `Interruptible` and `BusyAction` figure properties to control how events interact.

`WindowButtonDownFcn`
function handle | cell array containing function handle and additional arguments | string (not recommended)

Button press callback function. Executes whenever you press a mouse button while the pointer is in the figure window. See the `WindowButtonMotionFcn` property for an example.

Note When using a two- or three-button mouse on Macintosh systems, right-button and middle-button presses are not always reported. This happens *only* when a new figure window appears under the mouse cursor and the mouse is clicked without first moving it. In this circumstance, for the `WindowButtonDownFcn` to work, the user needs to do one of the following:

- Move the mouse after the figure is created, then click any mouse button
- Press **Shift** or **Ctrl** while clicking the left mouse button to perform the Extend and Alternate selection types

Pressing the left mouse button (or single mouse button) works without having to take either of the above actions.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`WindowButtonMotionFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Mouse motion callback function. Executes whenever you move the pointer within the figure window. Define the `WindowButtonMotionFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

Example Using All Window Button Properties

Click to view in editor — This example enables you to use mouse motion to draw lines. It uses all three window button functions.

Click to run example — Click the left mouse button in the axes and move the cursor, left-click to define the line end point, right-click to end drawing mode.

Note On some computer systems, the `WindowButtonMotionFcn` is executed when a figure is created even though there has been no mouse motion within the figure.

`WindowButtonUpFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Button release callback function. Executes whenever you release a mouse button. Define the `WindowButtonUpFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

The button up event is associated with the figure window in which the preceding button down event occurred. Therefore, the pointer need not be in the figure window when you release the button to generate the button up event.

If the callback routines defined by `WindowButtonDownFcn` or `WindowButtonMotionFcn` contain `drawnow` commands or call other functions that contain `drawnow` commands and the `Interruptible` property is `off`, the `WindowButtonUpFcn` might not be called. You can prevent this problem by setting `Interruptible` to `on`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`WindowKeyPressFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Key press callback function for the figure window. Executes whenever a key press occurs. This is a callback function invoked by a key press that occurs while either the figure window or any of its children has focus. Define the `WindowKeyPressFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

See Function Handle Callbacks for information on how to use function handles to define the callback function.

When no callback is specified for this property (which is the default state), MATLAB passes any key presses to the Command Window. However, when you define a callback for this property, the figure retains focus with each key press and executes the specified callback with each key press.

WindowKeyPressFcn Event Structure

When you specify the callback as a function handle, MATLAB passes to it a structure to containing the following fields.

Field	Contents
`Character`	The character displayed as a result of the releasing the key(s), which can be empty or unprintable
`Key`	The key being released, identified by the lowercase label on key or a descriptive string
`Modifier`	A cell array containing the names of one or more modifier keys being released (i.e., **control**, **alt**, **shift**). On Macintosh computers, it contains `'command'` when releasing the **command** modifier key

For more information and examples of use, see the `KeyPressFcn` property description.

`WindowKeyReleaseFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Key release callback function for the figure window. Executes whenever a key release occurs. This is a callback function invoked by a key release that occurs while the figure window or any of its children has focus. Define the `WindowKeyReleaseFcn` as a function handle. The function must define at least two input arguments (handle of the figure associated with key release and an event structure).

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

WindowKeyReleaseFcn Event Structure

When you specify the callback as a function handle, MATLAB passes to it a structure to containing the following fields.

Field	Contents
`Character`	The character displayed as a result of the releasing the key(s), which can be empty or unprintable
`Key`	The key being released, identified by the lowercase label on key or a descriptive string
`Modifier`	A cell array containing the names of one or more modifier keys being released (i.e., **control**, **alt**, **shift**). On Macintosh computers, it contains `'command'` when releasing the **command** modifier key

For more information and examples of use, see the `KeyReleaseFcn` property description.

`WindowScrollWheelFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Respond to mouse scroll wheel. Executes when the mouse wheel is scrolled while the figure has focus. MATLAB executes the callback with each single mouse wheel click.

Note that it is possible for another object to capture the event from MATLAB. For example, if the figure contains Java or ActiveX control objects that are listening for mouse scroll wheel events, then these objects can consume the events and prevent the `WindowScrollWheelFcn` from executing.

There is no default callback defined for this property.

WindowScrollWheelFcn Event Structure

When the callback is a function handle, MATLAB passes a structure to the callback function that contains the following fields.

Field	Contents
`VerticalScrollCount`	A positive or negative integer that indicates the number of scroll wheel clicks. Positive values indicate clicks of the wheel scrolled in the down direction. Negative values indicate clicks of the wheel scrolled in the up direction.
`VerticalScrollAmount`	The current system setting for the number of lines that are scrolled for each click of the scroll wheel. If the mouse property setting for scrolling is set to `One screen at a time`, `VerticalScrollAmount` returns a value of 1.

Effects on Other Properties

- `CurrentObject` property — Mouse scrolling does not update this figure property.
- `CurrentPoint` property — If there is no callback defined for the `WindowScrollWheelFcn` property, then MATLAB does not update the `CurrentPoint` property as the scroll wheel is turned. However, if there is a callback defined for the `WindowScrollWheelFcn` property, then MATLAB updates the `CurrentPoint` property just before executing the callback. This enables you to determine the point at which the mouse scrolling occurred.
- `HitTest` property — The `WindowScrollWheelFcn` callback executes regardless of the setting of the figure `HitTest` property.
- `SelectionType` property — The `WindowScrollWheelFcn` callback has no effect on this property.

Values Returned by VerticalScrollCount

When a user moves the mouse scroll wheel by one click, MATLAB increments the count by +/- 1, depending on the direction of the scroll (scroll down being positive). When MATLAB calls the `WindowScrollWheelFcn` callback, the counter is reset. In most cases, this means that the absolute value of the returned value is 1. However, if the `WindowScrollWheelFcn` callback takes a long enough time to return and/or the user spins the scroll wheel very fast, then the returned value can have an absolute value greater than one.

The actual value returned by `VerticalScrollCount` is the algebraic sum of all scroll wheel clicks that occurred since last processed. This enables your callback to respond correctly to the user's action.

Example

Click to view in editor — This example creates a graph of a function and enables you to use the mouse scroll wheel to change the range over which a mathematical function is evaluated and update the graph to reflect the new limits as you turn the scroll wheel.

Click to run example — Mouse over the figure and scroll your mouse wheel.

Related Information

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`WindowStyle`

`{normal} | modal | docked`

Normal, modal, or dockable window behavior. When `WindowStyle` is `modal`:

- The figure window traps all keyboard and mouse events over all MATLAB windows as long as they are visible.
- Windows belonging to applications other than MATLAB are unaffected.
- Modal figures remain stacked above all normal figures and the MATLAB Command Window.
- When multiple modal windows exist, the most recently created window keeps focus and stays above all other windows until it becomes invisible, or is returned to `WindowStyle normal`, or is deleted. At that time, focus reverts to the window that last had focus.

Use modal figures to create dialog boxes that force the user to respond without being able to interact with other windows. Typing **Ctrl+C** while the figure has focus causes all figures with

`WindowStyle modal` to revert to `WindowStyle normal`, allowing you to type at the command line.

Invisible Modal Figures

Figures with `WindowStyle modal` and `Visible` do not behave modally until they are made visible, so it is acceptable to hide a `modal` window for later reuse instead of destroying it.

Stacking Order of Modal Figures

Creating a figure with `WindowStyle modal` stacks it on top of all existing figure windows, making them inaccessible as long as the top figure exists and remains modal. However, any new figures created after a modal figure is displayed (for example, plots created by a modal GUI) stack on top of it and are accessible; they can be modal as well.

Changing Modes

You can change the `WindowStyle` of a figure at any time, including when the figure is visible and contains children. However, on some systems this might cause the figure to flash or disappear and reappear, depending on the windowing system's implementation of normal and modal windows. For best visual results, you should set `WindowStyle` at creation time or when the figure is invisible.

Window Decorations on Modal Figures

Modal figures do not display `uimenu` children, built-in menus, or toolbars but it is not an error to create uimenus in a modal figure or to change `WindowStyle` to `modal` on a figure with uimenu children. The uimenu objects exist and their handles are retained by the figure. If you reset the figure's `WindowStyle` to `normal`, the uimenus are displayed.

Docked WindowStyle

When `WindowStyle` is `docked`, the figure is docked in the desktop or a document window. When you issue the following command:

```
set(figure_handle,'WindowStyle','docked')
```

MATLAB docks the figure identified by *`figure_handle`* and sets the `DockControls` property to `on`, if it was `off`.

Note that if `WindowStyle` is `docked`, you cannot set the `DockControls` property to `off`.

The value of the `WindowStyle` property is not changed by calling `reset` on a figure.

`WVisual`
identifier string (Windows only)

Specify pixel format for figure. MATLAB automatically selects a pixel format for figures based on your current display settings, the graphics hardware available on your system, and the graphical content of the figure.

Usually, MATLAB chooses the best pixel format to use in any given situation. However, in cases where graphics objects are not rendered correctly, you might be able to select a different pixel format and improve results. See "Understanding the WVisual String" for more information.

Querying Available Pixel Formats on Window Systems

You can determine what pixel formats are available on your system for use with MATLAB using the following statement:

```
set(gcf,'WVisual')
```

MATLAB returns a list of the currently available pixel formats for the current figure. For example, the following are the first three entries from a typical list:

01 (RGB 16 bits(05 06 05 00) zdepth 24, Hardware Accelerated, OpenGL, GDI, Window)

02 (RGB 16 bits(05 06 05 00) zdepth 24, Hardware Accelerated, OpenGL, Double Buffered, Window)

03 (RGB 16 bits(05 06 05 00) zdepth 24, Hardware Accelerated, OpenGL, Double Buffered, Window)

Use the number at the beginning of the string to specify which pixel format to use. For example:

```
set(gcf,'WVisual','02')
```

specifies the second pixel format in the list above. Note that pixel formats might differ on your system.

Understanding the WVisual String

The string returned by querying the `WVisual` property provides information on the pixel format. For example:

- `RGB 16 bits(05 06 05 00)` — Indicates true color with 16-bit resolution (5 bits for red, 6 bits for green, 5 bits for blue, and 0 for alpha (transparency). MATLAB requires true color.
- `zdepth 24` — Indicates 24-bit resolution for sorting object's front to back position on the screen. Selecting pixel formats with higher (24 or 32) zdepth might solve sorting problems.
- `Hardware Accelerated` — Some graphics functions might be performed by hardware for increased speed. If there are incompatibilities between your particular graphic hardware and MATLAB, select a pixel format in which the term `Generic` appears instead of `Hardware Accelerated`.
- `Opengl` — Supports OpenGL. See the preceding "Pixel Formats and OpenGL" for more information.
- `GDI` — Supports for Windows 2-D graphics interface.

- `Double Buffered` — Support for double buffering with the OpenGL renderer. Note that the figure `DoubleBuffer` property applies only to the painters renderer.
- `Bitmap` — Support for rendering into a bitmap (as opposed to drawing in the window).
- `Window` — Support for rendering into a window.

Pixel Formats and OpenGL

If you are experiencing problems using hardware OpenGL on your system, you can try using generic OpenGL, which is implemented in software. To do this, first instruct MATLAB to use the software version of OpenGL with the following statement:

```
opengl software
```

Then allow MATLAB to select best pixel format to use.

See the `Renderer` property for more information on how MATLAB uses OpenGL.

`WVisualMode`
`{auto} | manual` (Windows only)

Auto or manual selection of pixel format. `WVisualMode` can take on two values — `auto` (the default) and `manual`. In `auto` mode, MATLAB selects the best pixel format to use based on your computer system and the graphical content of the figure. In `manual` mode, MATLAB does not change the visual from the one currently in use. Setting the `WVisual` property sets this property to `manual`.

`XDisplay`
display identifier (UNIX only)

Contains the display used for MATLAB. You can query this property to determine the name of the display that MATLAB is

using. For example, if MATLAB is running on a system called `mycomputer`, querying `XDisplay` returns a string of the following form:

```
get(gcf,'XDisplay')
ans
mycomputer:0.0
```

Setting XDisplay on Motif

If your computer uses Motif-based figures, you can specify the display MATLAB uses for a figure by setting the value of the figure's `XDisplay` property. For example, to display the current figure on a system called `fred`, use the command:

```
set(gcf,'XDisplay','fred:0.0')
```

`XVisual`
visual identifier (UNIX only)

Select visual used by MATLAB. You can select the visual used by MATLAB by setting the `XVisual` property to the desired visual ID. This can be useful if you want to test your application on an 8-bit or grayscale visual. To see what visuals are available on your system, use the UNIX `xdpyinfo` command. From MATLAB, type:

```
!xdpyinfo
```

The information returned contains a line specifying the visual ID. For example:

```
visual id:    0x23
```

To use this visual with the current figure, set the `XVisual` property to the ID.

```
set(gcf,'XVisual','0x23')
```

To see which of the available visuals MATLAB can use, call `set` on the `XVisual` property:

```
set(gcf,'XVisual')
```

The following typical output shows the visual being used (in curly braces) and other possible visuals. Note that MATLAB requires a TrueColor visual.

```
{ 0x23 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff) }
  0x24 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x25 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x26 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x27 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x28 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x29 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x2a (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
```

You can also use the `glxinfo` UNIX command to see what visuals are available for use with the OpenGL renderer. From MATLAB, type:

```
!glxinfo
```

After providing information about the implementation of OpenGL on your system, `glxinfo` returns a table of visuals. The partial listing below shows typical output:

```
visual  x  bf lv rg d st colorbuffer ax dp st accumbuffer  ms  cav
 id dep cl sp sz l  ci b ro  r  g  b  a bf th cl  r  g  b  a ns b eat
----------------------------------------------------------------
-
0x23 24 tc  0 24  0 r  y  .  8  8  8  8  0  0  0  0  0  0  0  0 0 None
0x24 24 tc  0 24  0 r  .  .  8  8  8  8  0  0  0  0  0  0  0  0 0 None
0x25 24 tc  0 24  0 r  y  .  8  8  8  8  0 24  8  0  0  0  0  0 0 None
0x26 24 tc  0 24  0 r  .  .  8  8  8  8  0 24  8  0  0  0  0  0 0 None
0x27 24 tc  0 24  0 r  y  .  8  8  8  8  0  0  0 16 16 16  0  0 0 Slow
```

The third column is the class of visual. `tc` means a true color visual. Note that some visuals might be labeled `Slow` under the caveat column. Such visuals should be avoided.

To determine which visual MATLAB will use by default with the OpenGL renderer, use the MATLAB `opengl info` command. The returned entry for the visual might look like the following:

```
Visual = 0x23 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
```

Experimenting with a different TrueColor visual might improve certain rendering problems.

`XVisualMode`

`{auto} | manual` (UNIX only)

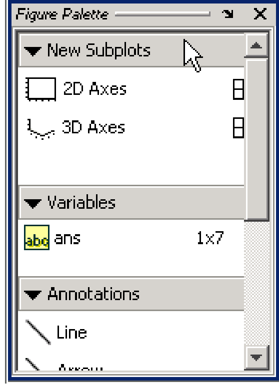
Auto or manual selection of visual. `XVisualMode` can take on two values — `auto` (the default) and `manual`. In `auto` mode, MATLAB selects the best visual to use based on the number of colors, availability of the OpenGL extension, etc. In `manual` mode, MATLAB does not change the visual from the one currently in use. Setting the `XVisual` property sets this property to `manual`.

See Also

`figure`

Purpose

Show or hide **Figure Palette**



Syntax

```
figurepalette('show')
figurepalette('hide')
figurepalette
figurepalette(figure_handle,...)
```

Description

`figurepalette('show')` displays the palette on the current figure.

`figurepalette('hide')` hides the palette on the current figure.

`figurepalette` toggles the visibility of the palette on the current figure. You can also use `figurepalette('toggle')` instead for the same functionality.

`figurepalette(figure_handle,...)` shows or hides the palette on the figure specified by `figure_handle`.

Tips

If you call `figurepalette` in a MATLAB program and subsequent lines depend on the Figure Palette being fully initialized, follow it by `drawnow` to ensure complete initialization.

Alternatives

To collectively enable **Plotting Tools**, use the large Plotting Tool icon on the figure toolbar. To collectively disable the **Plotting Tools**,

use the smaller icon . Open or close the **Figure Palette** tool from the figure's **View** menu.

`plottools` | `plotbrowser` | `propertyeditor`

Purpose

Set or get attributes of file or folder

Syntax

```
fileattrib
fileattrib(name)

fileattrib(name,attribs)
fileattrib(name,attribs,users)
fileattrib(name,attribs,users,'s')

[status,message,messageid] = fileattrib(name,attribs,___)
[status,message] = fileattrib(name)
```

Description

`fileattrib` gets attribute values for the current folder, using the following structure, where `Name` is always a string containing the current folder name. For the other fields, a value of `0` indicates that the attribute is off, `1` indicates that the attribute is on, and `NaN` indicates that the attribute does not apply:

```
Name
archive
system
hidden
directory
UserRead
UserWrite
UserExecute
GroupRead
GroupWrite
GroupExecute
OtherRead
```

`fileattrib(name)` gets the attribute values for the named file or folder.

`fileattrib(name,attribs)` sets the specified attributes for the named file or folder.

`fileattrib(name,attribs,users)` sets the file or folder attributes for the specified subset of users.

`fileattrib(name,attribs,users,'s')` sets the specified attributes for the specified users for the contents of the named folder.

`[status,message,messageid] = fileattrib(name,attribs,___)` sets the specified file attributes and gets the function status:

- If `status` is `0`, then `message` is the error message, and `messageid` is the error message identifier.
- If `status` is `1`, then `message` is a structure containing the attributes of the named file or folder, and `messageid` is an empty string.

`[status,message] = fileattrib(name)` gets `status` and the last *successfully* set attribute structure values for the named file or folder and returns the structure to `message`. (`status` is always `1`.)

Input Arguments

name - File or folder name

The absolute or relative path for a folder or file, specified as a string. To specify all names beginning with certain characters, add the wildcard character, `*`.

Example: `fileattrib('myfile.m')`

attribs - File or folder attribute values

`'a' | 'h' | 's' | 'w' | 'x'`

File or folder attribute values, specified as a space delimited string. Use the plus (+) qualifier before an attribute to set it, and the minus (-) qualifier before an attribute to clear it.

attribvalue	Description
'a'	Archive (Microsoft Windows platform only).
'h'	Hidden file (Windows platform only).
's'	System file (Windows platform only).
'w'	Write access (Windows and UNIX platforms). Results differ by platform and application. For example, even though `fileattrib` disables the "write" privilege for a folder, making it read only, files in the folder could be writable for some platforms or applications.
'x'	Executable (UNIX platform only).

Example: `fileattrib('myfile.m', '+w -h')`

users - Subset of users

`'a' | 'g' | 'o' | 'u' | ''`

Subset of users (on UNIX platforms only), specified as a string. For all platforms other than UNIX, specify the `users` argument as an empty string, `''`. This value is not returned by `fileattrib` get operations.

Value for UNIX Users	Description
'a'	All users on UNIX platforms
'g'	Group of users
'o'	All other users
'u'	Current user

Example: `fileattrib('D:/work/results','-w','a')`

Output Arguments

status - Indication of whether attempt to set attribute was successful

`0 | 1`

If attempt to set attribute was unsuccessful, status is 0. Otherwise, status is 1.

message - Attribute structure or error message

Attribute structure or error message, depending on whether you are setting or getting attributes and status.

Getting or Setting Attributes	Status	Message contents
Setting	0	Error message
Setting	1	Empty string
Getting	1	Structure containing file attributes and values

When you are getting file attributes, the structure contains these fields and possible values.

Field name	Possible Values
Name	String containing name of file or folder
archive	0 (not set), 1 (set), or NaN (not applicable)
system	0, 1, or NaN
hidden	0, 1, or NaN
directory	0, 1, or NaN
UserRead	0, 1, or NaN
UserWrite	0, 1, or NaN
UserExecute	0, 1, or NaN
GroupRead	0, 1, or NaN

Field name	Possible Values
`GroupWrite`	`0`, `1`, or `NaN`
`GroupExecute`	`0`, `1`, or `NaN`
`OtherRead`	`0`, `1`, or `NaN`
`OtherWrite`	`0`, `1`, or `NaN`
`OtherExecute`	`0`, `1`, or `NaN`

messageid - Error message identifier

Error message identifier returned when attempt to set attribute is unsuccessful (`status` is 0). If `status` is 1, `messageid` is an empty string.

Tips

- `fileattrib` is like the DOS `attrib` command, or the UNIX `chmod` command. [2]

Examples

View Current Folder Attributes

View attributes of the current folder, assuming the current folder is `C:\my_MATLAB_files`.

```
fileattrib
```

```
ans = 

            Name: 'C:\my_MATLAB_files'
         archive: 0
          system: 0
          hidden: 0
       directory: 1
        UserRead: 1
       UserWrite: 1
     UserExecute: 1
       GroupRead: NaN
      GroupWrite: NaN
    GroupExecute: NaN
       OtherRead: NaN
      OtherWrite: NaN
    OtherExecute: NaN
```

The attributes indicate that you have read, write, and execute permissions for the current folder.

View File Attributes

View attributes of file `collatz.m`.

```
fileattrib('collatz.m')
```

2. UNIX is a registered trademark of The Open Group in the United States and other countries.

```
ans =

           Name: 'C:\my_MATLAB_files\collatz.m'
        archive: 1
         system: 0
         hidden: 0
      directory: 0
       UserRead: 1
      UserWrite: 0
    UserExecute: 1
      GroupRead: NaN
     GroupWrite: NaN
   GroupExecute: NaN
      OtherRead: NaN
     OtherWrite: NaN
   OtherExecute: NaN
```

The attributes indicate that the specfieid item is a file. You can read and execute the file, but cannot update it. The file is archived.

View Folder Attributes on a Windows System

View attributes for the folder `C:\my_MATLAB_files\doc`.

```
fileattrib('C:\my_MATLAB_files\doc')
```

```
ans =

           Name: 'C:\my_MATLAB_files\doc'
        archive: 0
         system: 0
         hidden: 0
      directory: 1
       UserRead: 1
      UserWrite: 1
    UserExecute: 1
      GroupRead: NaN
     GroupWrite: NaN
```

```
    GroupExecute: NaN
       OtherRead: NaN
      OtherWrite: NaN
    OtherExecute: NaN
```

The attributes indicate that you have read, write, and execute permissions for the specified folder.

View Folder Attributes on a UNIX System

View attributes for the folder `/public` on a UNIX system.

```
fileattrib('/public')
```

```
ans =

            Name: '/public'
         archive: NaN
          system: NaN
          hidden: NaN
       directory: 1
        UserRead: 1
       UserWrite: 1
     UserExecute: 1
       GroupRead: 1
      GroupWrite: 0
    GroupExecute: 1
       OtherRead: 1
      OtherWrite: 0
    OtherExecute: 1
```

The attributes indicate that you have read, write, and execute permissions for the specfied folder. In addition, users in your UNIX group and all others have read and execute permissions for the specified folder, but not write permissions.

Set File Attributes

Make `myfile.m` writeable.

```
fileattrib('myfile.m','+w')
```

Set File Attributes for Specific Users on UNIX

Make the folder `/home/work/results` a read-only folder for *all users* on UNIX platforms.

```
fileattrib('/home/work/results','-w','a')
```

The minus (-) preceding the write attribute, `w`, removes the write status.

Set Attributes for Folder and Its Contents

On Windows platforms, make the folder `D:\work\results` and all its contents read only and hidden.

```
fileattrib('D:\work\results','+h -w','','s')
```

Because a value for the `users` argument is not applicable on Windows systems, the argument is an empty string. The `s` argument applies the hidden and read-only attributes to the contents of the folder.

Get Attributes Structure for a Folder

Get the attributes for the folder `results` and return them to a structure:

```
[stat,struc]=fileattrib('results')

stat =
     1

struc =
            Name: 'D:\work\results'
         archive: 0
          system: 0
          hidden: 0
       directory: 1
        UserRead: 1
       UserWrite: 1
     UserExecute: 1
       GroupRead: NaN
```

```
      GroupWrite: NaN
    GroupExecute: NaN
       OtherRead: NaN
      OtherWrite: NaN
    OtherExecute: NaN
```

The operation is successful as indicated by the status, `stat`, value of 1. The structure, `struc`, contains the file attributes.

Access the name attribute value in the structure. MATLAB returns the path for `results`.

```
struc.Name

ans =
D:\work\results
```

Get Attributes Structure for Multiple Files

Get the attributes for all files in the current folder with names that begin with `new`.

```
[stat,struc]=fileattrib('new*')

stat =
     1

mess =
1x3 struct array with fields:
    Name
    archive
    system
    hidden
    directory
    UserRead
    UserWrite
    UserExecute
    GroupRead
    GroupWrite
```

```
    GroupExecute
    OtherRead
    OtherWrite
    OtherExecute
```

The results indicate there are three matching files.

View the file names.

```
struc.Name
```

```
ans =
D:\work\results\newname.m

ans =
D:\work\results\newone.m

ans =
D:\work\results\newtest.m
```

View just the second file name.

```
struct(2).Name
```

```
ans =
D:\work\results\newname.m
```

Successfully Set Attributes for a File and Get Messages

Show output that results when an attempt to set file attributes is successful.

```
[status, message, messageid] = fileattrib('C:/my_MATLAB_files\doc','+h
```

```
status =

     1

message =
```

```
     ''

messageid =

     ''
```

The `status` value of `1` indicates the set operation was successful; therefore, no error `message` or `messageid` is returned.

Unsuccessfully Set Attributes for a File and Get Messages

Show output that results when an attempt to set file attributes is unsuccessful.

```
[status, message, messageid] = fileattrib('C:/my_MATLAB_files\doc','+h w-
```

```
status =

     0

message =

Illegal file mode characters on the current platform.

messageid =

MATLAB:FILEATTRIB:ModeSyntaxError
```

The `status` value of `0` indicates the set operation was unsuccessful. The minus sign incorrectly appears after `w`, instead of before it.

How To

- "Working with Files and Folders"

filemarker

Purpose

Character to separate file name and internal function name

Syntax

```
M = filemarker
```

Description

`M = filemarker` returns the character that separates a file and a within-file function name.

Examples

On the Microsoft Windows platform, for example, `filemarker` returns the '>' character:

```
filemarker

ans =
   >
```

You can use the following command on any platform to get the help text for the local function `pdeodes` defined in `pdepe.m`:

```
 helptext = help(['imwrite' filemarker 'validateSizes'])

helptext =
  How many bytes does each element occupy in memory?
```

You can use the `filemarker` character to indicate a location within a MATLAB program file where you want to set a breakpoint, for example. On all platforms, if you need to distinguish between two nested functions with the same name, use the forward slash (/) character to indicate the path to a particular instance of a function.

For instance, suppose `myfile.m` contains the following code:

```
function x = A(p1, p2)
...
  function y = B(p3)
    ...
  end
  function m = C(p4)
    ...
```

```
    end
end

function z = C(p5)
...
  function y = D(p6)
    ...
  end
end
```

To indicate that you want to set a breakpoint at `function y` nested within `function x`, use the following command on the Windows platform:

```
dbstop myfile>x/y
```

To indicate that you want to set a breakpoint at `function m` nested within `function x` use the following command on the Windows platform:

```
dbstop myfile>m
```

In the first case, you specify `x/y` because `myfile.m` contains two nested functions named `y`. In the second case, there is no need to specify `x/m` because there is only one function `m` within `myfile.m`.

See Also

`filesep`

fileparts

Purpose

Parts of file name and path

Note The fourth output argument of `fileparts` (file version) is no longer supported and has been removed. Calling the function with more than three output arguments generates an error.

Syntax

```
[pathstr, name, ext] = fileparts(filename)
```

Description

`[pathstr, name, ext] = fileparts(filename)` returns the path name, file name, and extension for the specified file. The file does not have to exist. `filename` is a string enclosed in single quotes. The returned `ext` field contains a dot (`.`) before the file extension.

Tips

- `fileparts` only parses file names. It does not verify that a file or a folder exists.
- You can reconstruct the file from the parts using:

  ```
  fullfile(pathstr,[name ext])
  ```

- On Microsoft Windows systems, you can use either forward (`/`) or back (`\`) slashes as path delimiters, even within the same string. On UNIX and Macintosh systems, use only `/` as a delimiter. You can use the `filesep` function to insert the correct separator character for the platform on which your code executes:

  ```
  sep = filesep;
  file = ['H:' sep 'user4' sep 'matlab' sep 'myfile.txt'];

  file =
  H:\user4\matlab\myfile.txt
  ```

- If the input consists of a folder name only, be sure that the right-most character is a delimiter (`/` or `\`). Otherwise, `fileparts` parses the trailing portion of `filename` as the name of a file and returns it in `name` instead of in `pathstr`.

Input Arguments

filename

String containing a name of a file or folder, which can include a path and file extension. The function interprets all characters following the right-most delimiter as a file name plus extension.

Output Arguments

pathstr

String containing the part of `filename` interpreted as a path name

name

String containing the name of the file without any extension

ext

String containing the file extension only, beginning with a period (`.`)

Definitions

Path Name

The full or partial path to a destination folder location, always the initial portion of the filename string. Path names end with a slash character and, where appropriate, can begin with a drive letter. Windows paths use backward slashes (`\`). UNIX and Macintosh paths use forward slashes (`/`).

Examples

Return the pieces of a file specification string to the separate string outputs `pathstr`, `name`, and `ext`. The full file specification is:

```
file = 'H:\user4\matlab\myfile.txt';
[pathstr, name, ext] = fileparts(file)

pathstr =
H:\user4\matlab

name =
myfile

ext =
```

```
.txt
```

Query parts of a user `.cshrc` file:

```
[p,n,e] = fileparts('/home/jsmith/.cshrc')

pathstr =
/home/jsmith

name =
   Empty string: 1-by-0

ext =
.cshrc
```

`fileparts` interprets the entire file name as an extension because it begins with a period.

Alternatives

Use `uigetfile` to interactively select and return a file name and path, or `uigetdir` to interactively select and return a path name. If you call `fileparts` with the output of `uigetfile`, you can parse out the file name and extension.

`filesep` | `fullfile` | `pathsep` | `uigetdir` | `uigetfile`

Tutorials

- “Path Names in MATLAB”

Purpose

Read contents of file into string

Syntax

```
text = fileread(filename)
```

Description

text = fileread(*filename*) returns the contents of the file *filename* as a MATLAB string.

Examples

Read and search the file Contents.m in the MATLAB iofun directory for the reference to fileread:

```
% find the correct directory and file
io_contents = ...
  fullfile(matlabroot, 'toolbox', 'matlab', 'iofun', 'Contents.m');

% read the file
filetext = fileread(io_contents);

% search for the line of code that includes 'fileread'
% each line is separated by a newline ('\n')

expr = '[^\n]*fileread[^\n]*';
fileread_info = regexp(filetext, expr, 'match');
```

See Also

filesep

Purpose

File separator for current platform

Syntax

```
f = filesep
```

Description

`f = filesep` returns the platform-specific file separator character. The file separator is the character that separates individual folder and file names in a path string.

Examples

Create a path to the `iofun` folder on a Microsoft Windows platform:

```
iofun_dir = ['toolbox' filesep 'matlab' filesep 'iofun']

iofun_dir =
   toolbox\matlab\iofun
```

Create a path to `iofun` on a UNIX[3] platform.

```
iodir = ['toolbox' filesep 'matlab' filesep 'iofun']

iodir =
   toolbox/matlab/iofun
```

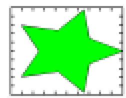
`fullfile` | `fileparts` | `pathsep`

3. UNIX is a registered trademark of The Open Group in the United States and other countries.

Purpose

Filled 2-D polygons



Syntax

```
fill(X,Y,C)
fill(X,Y,ColorSpec)
fill(X1,Y1,C1,X2,Y2,C2,...)
fill(...,'PropertyName',PropertyValue)
h = fill(...)
```

Description

The `fill` function creates colored polygons.

`fill(X,Y,C)` creates filled polygons from the data in `X` and `Y` with vertex color specified by `C`. `C` is a vector or matrix used as an index into the colormap. If `C` is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if `C` is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`. If necessary, `fill` closes the polygon by connecting the last vertex to the first.

`fill(X,Y,`*`ColorSpec`*`)` fills two-dimensional polygons specified by `X` and `Y` with the color specified by `ColorSpec`.

`fill(X1,Y1,C1,X2,Y2,C2,...)` specifies multiple two-dimensional filled areas.

`fill(...,'`*`PropertyName`*`',PropertyValue)` allows you to specify property names and values for a patch graphics object.

`h = fill(...)` returns a vector of handles to patch graphics objects, one handle per patch object.

Tips

If `X` or `Y` is a matrix, and the other is a column vector with the same number of elements as rows in the matrix, `fill` replicates the column vector argument to produce a matrix of the required size. `fill` forms a vertex from corresponding elements in `X` and `Y` and creates one polygon from the data in each column.

The type of color shading depends on how you specify color in the argument list. If you specify color using `ColorSpec`, `fill` generates flat-shaded polygons by setting the patch object's `FaceColor` property to the corresponding RGB triple.

If you specify color using `C`, `fill` scales the elements of `C` by the values specified by the axes property `CLim`. After scaling `C`, `C` indexes the current colormap.

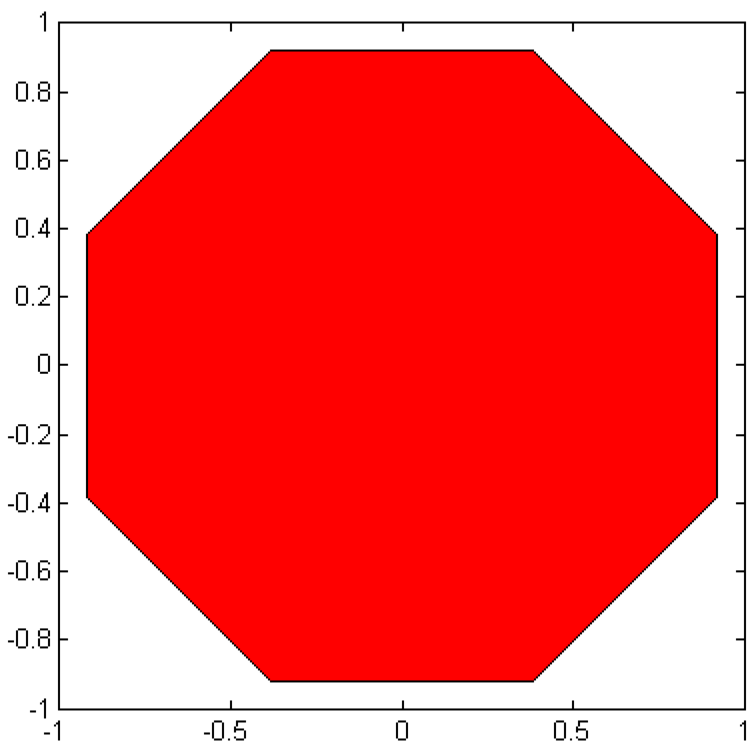
If `C` is a row vector, `fill` generates flat-shaded polygons where each element determines the color of the polygon defined by the respective column of the `X` and `Y` matrices. Each patch object's `FaceColor` property is set to `'flat'`. Each row element becomes the `CData` property value for the `n`th patch object, where *n* is the corresponding column in `X` or `Y`.

If `C` is a column vector or a matrix, `fill` uses a linear interpolation of the vertex colors to generate polygons with interpolated colors. It sets the patch graphics object `FaceColor` property to `'interp'` and the elements in one column become the `CData` property value for the respective patch object. If `C` is a column vector, `fill` replicates the column vector to produce the required sized matrix.

Examples

Create a red octagon.

```
t = (1/16:1/8:1)'*2*pi;
x = sin(t);
y = cos(t);
fill(x,y,'r')
axis square
```



See Also

`axis` | `caxis` | `colormap` | `ColorSpec` | `fill3` | `patch`

Purpose

Filled 3-D polygons

Syntax

```
fill3(X,Y,Z,C)
fill3(X,Y,Z,ColorSpec)
fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)
fill3(...,'PropertyName',PropertyValue)
h = fill3(...)
```

Description

The `fill3` function creates flat-shaded and Gouraud-shaded polygons.

`fill3(X,Y,Z,C)` fills three-dimensional polygons. `X`, `Y`, and `Z` triplets specify the polygon vertices. If `X`, `Y`, or `Z` is a matrix, `fill3` creates *n* polygons, where *n* is the number of columns in the matrix. `fill3` closes the polygons by connecting the last vertex to the first when necessary.

`C` specifies color, where `C` is a vector or matrix of indices into the current colormap. If `C` is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if `C` is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`.

`fill3(X,Y,Z,`*`ColorSpec`*`)` fills three-dimensional polygons defined by `X`, `Y`, and `Z` with color specified by `ColorSpec`.

`fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)` specifies multiple filled three-dimensional areas.

`fill3(...,'`*`PropertyName`*`',PropertyValue)` allows you to set values for specific patch properties.

`h = fill3(...)` returns a vector of handles to patch graphics objects, one handle per patch.

Algorithms

If `X`, `Y`, and `Z` are matrices of the same size, `fill3` forms a vertex from the corresponding elements of `X`, `Y`, and `Z` (all from the same matrix location), and creates one polygon from the data in each column.

If X, Y, or Z is a matrix, fill3 replicates any column vector argument to produce matrices of the required size.

If you specify color using ColorSpec, fill3 generates flat-shaded polygons and sets the patch object FaceColor property to an RGB triple.

If you specify color using C, fill3 scales the elements of C by the axes property CLim, which specifies the color axis scaling parameters, before indexing the current colormap.

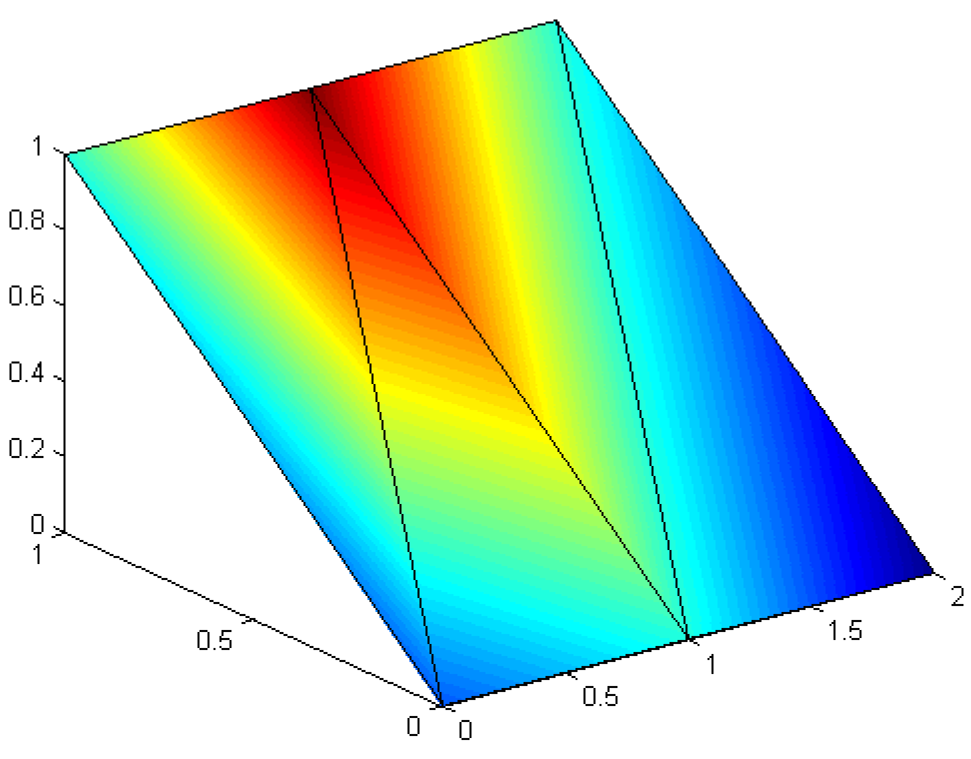
If C is a row vector, fill3 generates flat-shaded polygons and sets the FaceColor property of the patch objects to 'flat'. Each element becomes the CData property value for the respective patch object.

If C is a column vector or a matrix, fill3 generates polygons with interpolated colors and sets the patch object FaceColor property to 'interp'. fill3 uses a linear interpolation of the vertex colormap indices when generating polygons with interpolated colors. The elements in one column become the CData property value for the respective patch object. If C is a column vector, fill3 replicates the column vector to produce the required sized matrix.

Examples

Create four triangles with interpolated colors.

```
X = [0 1 1 2;1 1 2 2;0 0 1 1];
Y = [1 1 1 1;1 0 1 0;0 0 0 0];
Z = [1 1 1 1;1 0 1 0;0 0 0 0];
C = [0.5000 1.0000 1.0000 0.5000;
     1.0000 0.5000 0.5000 0.1667;
     0.3330 0.3330 0.5000 0.5000];
fill3(X,Y,Z,C)
```



See Also

axis | caxis | colormap | ColorSpec | fill | patch

Purpose

1-D digital filter

Syntax

```
y = filter(b,a,X)
[y,zf] = filter(b,a,X)
[y,zf] = filter(b,a,X,zi)
y = filter(b,a,X,zi,dim)
[...] = filter(b,a,X,[],dim)
```

Description

The `filter` function filters a data sequence using a digital filter which works for both real and complex inputs. The filter is a *direct form II transposed* implementation of the standard difference equation (see "Algorithm").

`y = filter(b,a,X)` filters the data in vector `X` with the filter described by numerator coefficient vector `b` and denominator coefficient vector `a`. If `a(1)` is not equal to `1`, `filter` normalizes the filter coefficients by `a(1)`. If `a(1)` equals `0`, `filter` returns an error.

If `X` is a matrix, `filter` operates on the columns of `X`. If `X` is a multidimensional array, `filter` operates on the first nonsingleton dimension.

`[y,zf] = filter(b,a,X)` returns the final conditions, `zf`, of the filter delays. If `X` is a row or column vector, output `zf` is a column vector of `max(length(a),length(b))-1`. If `X` is a matrix, `zf` is an array of such vectors, one for each column of `X`, and similarly for multidimensional arrays.

`[y,zf] = filter(b,a,X,zi)` accepts initial conditions, `zi`, and returns the final conditions, `zf`, of the filter delays. Input `zi` is a vector of length `max(length(a),length(b))-1`, or an array with the leading dimension of size `max(length(a),length(b))-1` and with remaining dimensions matching those of `X`.

`y = filter(b,a,X,zi,dim)` and `[...]  = filter(b,a,X,[],dim)` operate across the dimension `dim`.

Examples

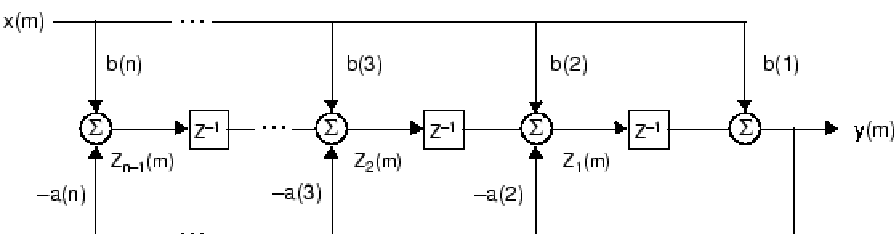
You can use `filter` to find a running average without using a `for` loop. This example finds the running average of a 16-element vector, using a window size of 5.

```
data = [1:0.2:4]';
windowSize = 5;
filter(ones(1,windowSize)/windowSize,1,data)

ans =
    0.2000
    0.4400
    0.7200
    1.0400
    1.4000
    1.6000
    1.8000
    2.0000
    2.2000
    2.4000
    2.6000
    2.8000
    3.0000
    3.2000
    3.4000
    3.6000
```

Algorithms

The `filter` function is implemented as a direct form II transposed structure,



or

```
y(n) = b(1)*x(n) + b(2)*x(n-1) + ... + b(nb+1)*x(n-nb)
                 - a(2)*y(n-1) - ... - a(na+1)*y(n-na)
```

where `n-1` is the filter order, which handles both FIR and IIR filters [1], `na` is the feedback filter order, and `nb` is the feedforward filter order.

The operation of `filter` at sample m is given by the time domain difference equations

$$
\begin{aligned}
y(m) &= b(1)x(m) + z_1(m-1) \\
z_1(m) &= b(2)x(m) + z_2(m-1) - a(2)y(m) \\
\vdots \quad &= \quad \vdots \qquad\qquad \vdots \\
z_{n-2}(m) &= b(n-1)x(m) + z_{n-1}(m-1) - a(n-1)y(m) \\
z_{n-1}(m) &= b(n)x(m) - a(n)y(m)
\end{aligned}
$$

The input-output description of this filtering operation in the z-transform domain is a rational transfer function,

$$
Y(z) = \frac{b(1) + b(2)z^{-1} + \ldots + b(nb+1)z^{-nb}}{1 + a(2)z^{-1} + \ldots + a(na+1)z^{-na}} X(z)
$$

`filter2` | `filtfilt` | `filtic`

filter2

Purpose

2-D digital filter

Syntax

```
Y = filter2(h,X)
Y = filter2(h,X,shape)
```

Description

`Y = filter2(h,X)` filters the data in `X` with the two-dimensional FIR filter in the matrix `h`. It computes the result, `Y`, using two-dimensional correlation, and returns the central part of the correlation that is the same size as `X`.

`Y = filter2(h,X,`*`shape`*`)` returns the part of `Y` specified by the `shape` parameter. *`shape`* is a string with one of these values:

'full'	Returns the full two-dimensional correlation. In this case, `Y` is larger than `X`.
'same'	(default) Returns the central part of the correlation. In this case, `Y` is the same size as `X`.
'valid'	Returns only those parts of the correlation that are computed without zero-padded edges. In this case, `Y` is smaller than `X`.

Tips

Two-dimensional correlation is equivalent to two-dimensional convolution with the filter matrix rotated 180 degrees. See the Algorithm section for more information about how `filter2` performs linear filtering.

Algorithms

Given a matrix `X` and a two-dimensional FIR filter `h`, `filter2` rotates your filter matrix 180 degrees to create a convolution kernel. It then calls `conv2`, the two-dimensional convolution function, to implement the filtering operation.

`filter2` uses `conv2` to compute the full two-dimensional convolution of the FIR filter with the input matrix. By default, `filter2` then extracts the central part of the convolution that is the same size as the input

matrix, and returns this as the result. If the `shape` parameter specifies an alternate part of the convolution for the result, `filter2` returns the appropriate part.

See Also

`conv2` | `filter`

find

Purpose

Find indices and values of nonzero elements

Syntax

```
ind = find(X)
ind = find(X, k)
ind = find(X, k, 'first')
ind = find(X, k, 'last')
[row,col] = find(X, ...)
[row,col,v] = find(X, ...)
```

Description

`ind = find(X)` locates all nonzero elements of array `X`, and returns the linear indices of those elements in vector `ind`. If `X` is a row vector, then `ind` is a row vector; otherwise, `ind` is a column vector. If `X` contains no nonzero elements or is an empty array, then `ind` is an empty array.

`ind = find(X, k)` or `ind = find(X, k, 'first')` returns at most the first `k` indices corresponding to the nonzero entries of `X`. `k` must be a positive integer, but it can be of any numeric data type.

`ind = find(X, k, 'last')` returns at most the last `k` indices corresponding to the nonzero entries of `X`.

`[row,col] = find(X, ...)` returns the row and column indices of the nonzero entries in the matrix `X`. This syntax is especially useful when working with sparse matrices. If `X` is an N-dimensional array with N > 2, `col` contains linear indices for the columns. For example, for a 5-by-7-by-3 array `X` with a nonzero element at `X(4,2,3)`, `find` returns 4 in `row` and 16 in `col`. That is, (7 columns in page 1) + (7 columns in page 2) + (2 columns in page 3) = 16.

`[row,col,v] = find(X, ...)` returns a column or row vector `v` of the nonzero entries in `X`, as well as row and column indices. If `X` is a logical expression, then `v` is a logical array. Output `v` contains the non-zero elements of the logical array obtained by evaluating the expression `X`. For example,

```
A= magic(4)
A =
    16     2     3    13
     5    11    10     8
```

```
     9     7     6    12
     4    14    15     1

[r,c,v]= find(A>10);

r', c', v'
ans =
     1     2     4     4     1     3
ans =
     1     2     2     3     4     4
ans =
     1     1     1     1     1     1
```

Here the returned vector `v` is a logical array that contains the nonzero elements of `N` where

```
N=(A>10)
```

Examples

Example 1

```
X = [1 0 4 -3 0 0 0 8 6];
indices = find(X)
```

returns linear indices for the nonzero entries of `X`.

```
indices =
     1     3     4     8     9
```

Example 2

You can use a logical expression to define `X`. For example,

```
find(X > 2)
```

returns linear indices corresponding to the entries of `X` that are greater than 2.

```
ans =
     3     8     9
```

Example 3

The following `find` command

```
X = [3 2 0; -5 0 7; 0 0 1];
[r,c,v] = find(X)
```

returns a vector of row indices of the nonzero entries of `X`

```
r =
     1
     2
     1
     2
     3
```

a vector of column indices of the nonzero entries of `X`

```
c =
     1
     1
     2
     3
     3
```

and a vector containing the nonzero entries of `X`.

```
v =
     3
    -5
     2
     7
     1
```

Example 4

The expression

```
X = [3 2 0; -5 0 7; 0 0 1];
[r,c,v] = find(X>2)
```

returns a vector of row indices of the nonzero entries of `N` where `N=(X>2)`

```
r =
     1
     2
```

a vector of column indices of the nonzero entries of `N` where `N=(X>2)`

```
c =
     1
     3
```

and a logical array that contains the nonzero elements of `N` where `N=(X>2)`.

```
v =
     1
     1
```

Recall that when you use `find` on a logical expression, the output vector `v` does not contain the nonzero entries of the input array. Instead, it contains the nonzero values returned after evaluating the logical expression.

Example 5

Some operations on a vector

```
x = [11  0  33  0  55]';

find(x)
ans =
     1
     3
     5

find(x == 0)
ans =
     2
```

```
     4

find(0 < x & x < 10*pi)
ans =
     1
```

Example 6

For the matrix

```
M = magic(3)
M =
     8     1     6
     3     5     7
     4     9     2

find(M > 3, 4)
```

returns the indices of the first four entries of `M` that are greater than 3.

```
ans =
     1
     3
     5
     6
```

Example 7

If `X` is a vector of all zeros, `find(X)` returns an empty matrix. For example,

```
indices = find([0;0;0])
indices =
   Empty matrix: 0-by-1
```

See Also

`nonzeros` | `sparse` | `colon` | `ind2sub` | Logical Operators: Elementwise | Logical Operators: Short-circuit | Relational Operators

Purpose

Find all graphics objects

Syntax

```
object_handles = findall(handle_list)
object_handles = findall(handle_list,'property','value',...)
```

Description

`object_handles = findall(handle_list)` returns the handles, including hidden handles, of all objects in the hierarchy under the objects identified in `handle_list`.

`object_handles = findall(handle_list,'property','value',...)` returns the handles of all objects in the hierarchy under the objects identified in `handle_list` that have the specified properties set to the specified values.

Tips

`findall` is similar to `findobj`, except that it finds objects even if their `HandleVisibility` is set to `off`.

Examples

```
plot(1:10)
xlabel xlab
a = findall(gcf)
b = findobj(gcf)
c = findall(b,'Type','text') % return the xlabel handle twice
d = findobj(b,'Type','text') % can't find the xlabel handle
```

See Also

`allchild` | `findobj`

findfigs

Purpose Find visible offscreen figures

Syntax

```
findfigs
```

Description

`findfigs` finds all visible figure windows whose display area is off the screen and positions them on the screen.

A window appears to the MATLAB software to be offscreen when its display area (the area not covered by the window's title bar, menu bar, and toolbar) does not appear on the screen.

This function is useful when you are bringing an application from a larger monitor to a smaller one (or one with lower resolution). Windows visible on the larger monitor may appear offscreen on a smaller monitor. Using `findfigs` ensures that all windows appear on the screen.

Purpose

Locate graphics objects with specific properties

Syntax

```
findobj
h = findobj
h = findobj('PropertyName',PropertyValue,...)
h =
findobj('PropertyName',PropertyValue,'-logicaloperator',
   PropertyName',PropertyValue,...)
h = findobj('-regexp','PropertyName','regexp',...)
h = findobj('-property','PropertyName')
h = findobj(objhandles,...)
h = findobj(objhandles,'-depth',d,...)
h = findobj(objhandles,'flat','PropertyName',PropertyValue,
   ...)
```

Description

`findobj` returns handles of the root object and all its descendants without assigning the result to a variable.

`h = findobj` returns handles of the root object and all its descendants.

`h = findobj('`*`PropertyName`*`',PropertyValue,...)` returns handles of all graphics objects having the property *`PropertyName`*, set to the value `PropertyValue`. You can specify more than one property/value pair, in which case, `findobj` returns only those objects having all specified values.

`h =`
`findobj('`*`PropertyName`*`',PropertyValue,'`*`-logicaloperator`*`',`
`PropertyName``',PropertyValue,...)` applies the logical operator to the property value matching. Possible values for *`-logicaloperator`* are:

- `-and`
- `-or`
- `-xor`
- `-not`

See "Logical Operators" for an explanation of logical operators.

`h = findobj('-regexp','PropertyName','regexp',...)` matches objects using regular expressions as if the value of you passed the property `PropertyName` to the `regexp` function as

```
regexp(PropertyValue,'regexp')
```

If a match occurs, `findobj` returns the object handle. See the `regexp` function for information on how the MATLAB software uses regular expressions.

`h = findobj('-property','PropertyName')` finds all objects having the specified property.

`h = findobj(objhandles,...)` restricts the search to objects listed in `objhandles` and their descendants.

`h = findobj(objhandles,'-depth',d,...)` specifies the depth of the search. The depth argument `d` controls how many levels under the handles in `objhandles` MATLAB traverses. Specify `d` as `inf` to get the default behavior of all levels. Specify `d` as `0` to get the same behavior as using the `flat` argument.

`h = findobj(objhandles,'flat','PropertyName',PropertyValue,...)` restricts the search to those objects listed in `objhandles` and does not search descendants.

`findobj` returns an error if a handle refers to a nonexistent graphics object.

`findobj` correctly matches any legal property value. For example,

```
findobj('Color','r')
```

finds all objects having a `Color` property set to `red`, `r`, or `[1 0 0]`.

When a graphics object is a descendant of more than one object identified in `objhandles`, MATLAB searches the object each time `findobj` encounters its handle. Therefore, implicit references to a graphics object can result in multiple returns of its handle.

To find handle objects that meet specified conditions, use `handle.findobj`.

Examples

Find all line objects in the current axes:

```
h = findobj(gca,'Type','line')
```

Find all objects having a `Label` set to `'foo'` and a `String` set to `'bar'`:

```
h = findobj('Label','foo','-and','String','bar');
```

Find all objects whose `String` is not `'foo'` and is not `'bar'`:

```
h = findobj('-not','String','foo','-not','String','bar');
```

Find all objects having a `String` set to `'foo'` and a `Tag` set to `'button one'` and whose `Color` is not `'red'` or `'blue'`:

```
h = findobj('String','foo','-and','Tag','button one',...
 '-and','-not',{'Color','red','-or','Color','blue'})
```

Find all objects for which you have assigned a value to the `Tag` property (that is, the value is not the empty string `''`):

```
h = findobj('-regexp','Tag','[^'']')
```

Find all children of the current figure that have their `BackgroundColor` property set to a certain shade of gray (`[.7 .7 .7]`). This statement also searches the current figure for the matching property value pair.

```
h = findobj(gcf,'-depth',1,'BackgroundColor',[.7 .7 .7])
```

Tutorials

- "Example — Using Logical Operators and Regular Expression"

Purpose

Find handle objects matching specified conditions

Syntax

```
Hmatch = findobj(Hobj,<conditions>)
Hmatch = findobj(Hobj,'-property','PropertyName')
```

Description

`Hmatch = findobj(Hobj,<conditions>)` finds `handle` class objects that meet the specified conditions. Specify conditions as property name/property value pairs, indicating that the objects you are trying to find have specific property values.

The `Hobj` argument must be an array of `handle` objects. The returned value, `Hmatch` contains an array of object `handles` that match the conditions.

`Hmatch = findobj(Hobj,'-property','PropertyName')` finds all object in `Hobj` having the specified property.

`findobj` has access only to public members of the objects in `Hobj`. `findobj` can find dynamic properties. See "Find Handle Objects" for more information on using `findobj`.

You cannot use regular expression with `handle` class objects.

Examples

Find the object with a specific property value. Given the `handle` class, `BasicHandle`:

```
classdef BasicHandle < handle
   properties
      Prop1
   end
   methods
      function obj = BasicHandle(val)
         if nargin > 0
            obj.Prop1 = val;
         end
      end
   end
end
```

Create an array of BasicHandle objects:

```
h(1) = BasicHandle(7);
h(2) = BasicHandle(11);
h(3) = BasicHandle(27);
```

Find the handle of the object whose Prop1 property has a value of 7:

```
h7 = findobj(h,'Prop1',7);
h7.Prop1

ans =

     7
```

Find the object with a specific dynamic property. Given the button class:

```
classdef button < dynamicprops
   properties
      UiHandle
   end
   methods
      function obj = button(pos)
         if nargin > 0
            if length(pos) == 4
               obj.UiHandle = uicontrol('Position',pos,...
                'Style','pushbutton');
            else
               error('Improper position')
            end
         end
      end
   end
end
```

Create an array of button objects, only one element of which defines a dynamic property. Use `findobj` to get the handle of the object with the dynamic property named `ButtonCoord`:

```
b(1) = button([20 40 80 20]);
b(1).addprop('ButtonCoord');
b(1).ButtonCoord = [2,3];
b(2) = button([120 40 80 20]);
b(3) = button([220 40 80 20]);

h =  findobj(b,'-property','ButtonCoord');
h.ButtonCoord

ans =

     2     3
```

See Also

`findprop` | `handle`

Purpose Find `meta.property` object associated with property name

Syntax

```
p = findprop(h,'Name')
```

Description `p = findprop(h,'Name')` returns the `meta.property` object associated with the property `Name` of the object `h`. `Name` can be a property defined by the class of `h` or a dynamic property defined only for the object `h`.

Examples Use `findprop` to view property attribute settings:

```
findprop(containers.Map,'Count')

ans =

  meta.property handle
  Package: meta

  Properties:
                   Name: 'Count'
            Description: 'Number of pairs in the collection'
    DetailedDescription: ''
              GetAccess: 'public'
              SetAccess: 'private'
              Dependent: 1
               Constant: 0
               Abstract: 0
              Transient: 1
                 Hidden: 0
          GetObservable: 0
          SetObservable: 0
               AbortSet: 0
              GetMethod: []
              SetMethod: []
          DefiningClass: [1x1 meta.class]

  Methods, Events, Superclasses
```

- "Dynamic Properties — Adding Properties to an Instance"

findstr

Purpose

Find string within another, longer string

Note `findstr` is not recommended. Use `strfind` instead.

Syntax

```
k = findstr(str1, str2)
```

Description

`k = findstr(str1, str2)` searches the longer of the two input strings for any occurrences of the shorter string, returning the starting index of each such occurrence in the double array `k`. If no occurrences are found, then `findstr` returns the empty array, `[]`.

The search performed by `findstr` is case sensitive. Any leading and trailing blanks in either input string are explicitly included in the comparison.

Unlike the `strfind` function, the order of the input arguments to `findstr` is not important. This can be useful if you are not certain which of the two input strings is the longer one.

Examples

```
s = 'Find the starting indices of the shorter string.';

findstr(s, 'the')
ans =
     6    30

findstr('the', s)
ans =
     6    30
```

Purpose

Termination file for MATLAB program

Description

When the MATLAB program quits, it runs a script called `finish.m`, if the script exists and is on the search path MATLAB uses or in the current directory. This is a file you create yourself that instructs MATLAB to perform any final tasks just prior to terminating. For example, you might want to save the data in your workspace to a MAT-file before MATLAB exits.

`finish.m` is invoked whenever you do one of the following:

- Click the Close box ☒ in the MATLAB desktop on Microsoft Windows platforms or the equivalent on UNIX[4] platforms
- Type `quit` or `exit` at the Command Window prompt

Tips

When using Handle Graphics features in `finish.m`, use `uiwait`, `waitfor`, or `drawnow` so that figures are visible. See the reference pages for these functions for more information.

Examples

Two sample termination files are provided with MATLAB in *`matlabroot`*`/toolbox/local`.

- `finishsav.m` — Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m` — Displays a dialog allowing you to cancel quitting and saves the workspace. See also the "Confirmation Dialogs Preferences" and the option for exiting MATLAB.

To create a termination file, make a copy of one of these sample files, changing the name to `finish.m`, and add it to the path to use it. You can modify the file to include any operations you want the termination file to perform.

4. UNIX is a registered trademark of The Open Group in the United States and other countries.

Purpose

Display FITS metadata

Syntax

```
fitsdisp(filename)
fitsdisp(filename,Name,Value)
```

Description

`fitsdisp(filename)` displays metadata for all the Header/Data Units (HDUs) found in the FITS file specified by `filename`.

`fitsdisp(filename,Name,Value)` displays metadata for all the Header/Data Units (HDUs) found in the FITS file with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

filename

Text string specifying the name of an existing FITS file.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Index'

Positive scalar value or vector specifying the HDUs.

'Mode'

One of the following strings:

- `standard` – Display standard keywords
- `min` – Display only HDU types and sizes
- `full` – Display all HDU keywords

Default: `standard`

Examples

Display metadata in the 2nd HDU in the FITS file.

```
fitsdisp('tst0012.fits','Index',2);
```

Display the metadata in the 1st, 3rd, and 5th HDUs in a file.

```
fitsdisp('tst0012.fits','Index',[1 3 5]);
```

Display all metadata in the 5th HDU in a file

```
fitsdisp('tst0012.fits','Index',5,'Mode','full');
```

`fitsread` | `fitswrite` | `fitsdisp` | matlab.io.fits

Purpose

Information about FITS file

Syntax

```
info = fitsinfo(filename)
```

Description

`info = fitsinfo(filename)` returns the structure, `info`, with fields that contain information about the contents of a Flexible Image Transport System (FITS) file. `filename` is a string enclosed in single quotes that specifies the name of the FITS file.

The `info` structure contains the following fields, listed in the order they appear in the structure. In addition, the info structure can also contain information about any number of optional file components, called *extensions* in FITS terminology. For more information, see "FITS File Extensions" on page 1-1758.

Field Name	Description	Return Type
`Filename`	Name of the file	String
`FileModDate`	File modification date	String
`FileSize`	Size of the file in bytes	Double
`Contents`	List of extensions in the file in the order that they occur	Cell array of strings
`PrimaryData`	Information about the primary data in the FITS file	Structure array

PrimaryData

The `PrimaryData` field is a structure that describes the primary data in the file. The following table lists the fields in the order they appear in the structure.

Field Name	Description	Return Type
`DataType`	Precision of the data	String
`Size`	Array containing the size of each dimension	Double array

Field Name	Description	Return Type
`DataSize`	Size of the primary data in bytes	Double
`MissingDataValue`	Value used to represent undefined data	Double
`Intercept`	Value, used with `Slope`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value + Intercept`	Double
`Slope`	Value, used with `Intercept`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value + Intercept`	Double
`Offset`	Number of bytes from beginning of the file to the location of the first data value	Double
`Keywords`	A number-of-keywords-by-3 cell array containing keywords, values, and comments of the header in each column	Cell array of strings

FITS File Extensions

A FITS file can also include optional extensions. If the file contains any of these extensions, the `info` structure can contain these additional fields.

- AsciiTable — Numeric information in tabular format, stored as ASCII characters

- BinaryTable — Numeric information in tabular format, stored in binary representation
- Image — A multidimensional array of pixels
- Unknown — Nonstandard extension

AsciiTable Extension

The `AsciiTable` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`Rows`	Number of rows in the table	Double
`RowSize`	Number of characters in each row	Double
`NFields`	Number of fields in each row	Double array
`FieldFormat`	A 1-by-`NFields` cell containing formats in which each field is encoded. The formats are FORTRAN-77 format codes.	Cell array of strings
`FieldPrecision`	A 1-by-`NFields` cell containing precision of the data in each field	Cell array of strings
`FieldWidth`	A 1-by-`NFields` array containing the number of characters in each field	Double array
`FieldPos`	A 1-by-`NFields` array of numbers representing the starting column for each field	Double array
`DataSize`	Size of the data in the table in bytes	Double
`MissingDataValue`	A 1-by-`NFields` array of numbers used to represent undefined data in each field	Cell array of strings

Field Name	Description	Return Type
Intercept	A 1-by-NFields array of numbers used along with Slope to calculate actual data values from the array data values using the equation: actual_value = Slope*array_value+Intercept	Double array
Slope	A 1-by-NFields array of numbers used with Intercept to calculate true data values from the array data values using the equation: actual_value = Slope*array_value+Intercept	Double array
Offset	Number of bytes from beginning of the file to the location of the first data value in the table	Double
Keywords	A number-of-keywords-by-3 cell array containing all the Keywords, Values and Comments in the ASCII table header	Cell array of strings

BinaryTable Extension

The BinaryTable structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
Rows	Number of rows in the table	Double
RowSize	Number of bytes in each row	Double
NFields	Number of fields in each row	Double

Field Name	Description	Return Type
FieldFormat	A 1-by-NFields cell array containing the data type of the data in each field. The data type is represented by a FITS binary table format code.	Cell array of strings
FieldPrecision	A 1-by-NFields cell containing precision of the data in each field	Cell array of strings
FieldSize	A 1-by-NFields array, where each element contains the number of values in the Nth field	Double array
DataSize	Size of the data in the Binary Table, in bytes. Includes any data past the main table.	Double
MissingDataValue	An 1-by-NFields array of numbers used to represent undefined data in each field	Cell array of double
Intercept	A 1-by-NFields array of numbers used along with Slope to calculate actual data values from the array data values using the equation: actual_value = slope*array_value+Intercept	Double array
Slope	A 1-by-NFields array of numbers used with Intercept to calculate true data values from the array data values using the equation: actual_value = Slope*array_value+Intercept	Double array

Field Name	Description	Return Type
`Offset`	Number of bytes from beginning of the file to the location of the first data value	Double
`ExtensionSize`	Size of any data past the main table, in bytes	Double
`ExtensionOffset`	Number of bytes from the beginning of the file to any data past the main table	Double
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

Image Extension

The `Image` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`DataType`	Precision of the data	String
`Size`	Array containing sizes of each dimension	Double array
`DataSize`	Size of the data in the Image extension in bytes	Double
`Offset`	Number of bytes from the beginning of the file to the first data value	Double
`MissingDataValue`	Value used to represent undefined data	Double

Field Name	Description	Return Type
`Intercept`	Value, used with `Slope`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value+Intercept`	Double
`Slope`	Value, used with `Intercept`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value + Intercept`	Double
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

Unknown Structure

The `Unknown` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`DataType`	Precision of the data	String
`Size`	Sizes of each dimension	Double array
`DataSize`	Size of the data in nonstandard extensions, in bytes	Double
`Offset`	Number of bytes from beginning of the file to the first data value	Double

Field Name	Description	Return Type
`MissingDataValue`	Representation of undefined data	Double
`Intercept`	Value, used with `Slope`, to calculate actual data values from the array data values, using the equation: `actual_value = Slope*array_value+Intercept`	Double
`Slope`	Value, used with `Intercept`, to calculate actual data values from the array data values, using the equation: `actual_value = Slope*array_value+Intercept`	Double
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

Examples

Use `fitsinfo` to obtain information about the FITS file `tst0012.fits`. In addition to its primary data, the file also contains an example of the extensions `BinaryTable`, `Unknown`, `Image`, and `AsciiTable`.

```
S = fitsinfo('tst0012.fits');
S =
         Filename: [1x71 char]
      FileModDate: '12-Mar-2001 18:37:46'
         FileSize: 109440
         Contents: {'Primary' 'Binary Table' 'Unknown'
'Image' 'ASCII Table'}
      PrimaryData: [1x1 struct]
      BinaryTable: [1x1 struct]
```

```
         Unknown: [1x1 struct]
           Image: [1x1 struct]
      AsciiTable: [1x1 struct]
```

The `PrimaryData` field describes the data in the file. For example, the `Size` field indicates the data is a 102-by-109 matrix.

```
S.PrimaryData
          DataType: 'single'
              Size: [102 109]
          DataSize: 44472
  MissingDataValue: []
         Intercept: 0
             Slope: 1
            Offset: 2880
          Keywords: {25x3 cell}
```

The `AsciiTable` field describes the `AsciiTable` extension. For example, using the `FieldWidth` and `FieldPos` fields you can determine the length and location of each field within a row.

```
S.AsciiTable
ans =
              Rows: 53
           RowSize: 59
           NFields: 8
       FieldFormat: {'A9' 'F6.2' 'I3' 'E10.4' 'D20.15' 'A5' 'A1' 'I4'}
    FieldPrecision: {1x8 cell}
        FieldWidth: [9 6.2000 3 10.4000 20.1500 5 1 4]
          FieldPos: [1 11 18 22 33 54 54 55]
          DataSize: 3127
  MissingDataValue: {'*' '---.--' '  *' [] '*' '*' '*' ''}
         Intercept: [0 0 -70.2000 0 0 0 0 0]
             Slope: [1 1 2.1000 1 1 1 1 1]
            Offset: 103680
          Keywords: {65x3 cell}
```

fitsread

Purpose

Read data from FITS file

Syntax

```
data = fitsread(filename)
data = fitsread(filename,extname)
data = fitsread(filename,extname,index)
data = fitsread(filename,Name,Value)
```

Description

`data = fitsread(filename)` reads the primary data of the Flexible Image Transport System (FITS) file specified by the text string `filename`. The function replaces undefined data values with `NaN` and scales numeric data by the slope and intercept values, always returning double precision values.

`data = fitsread(filename,extname)` reads data from the FITS file extension specified by `extname`.

`data = fitsread(filename,extname,index)` reads data from the FITS file extension specified by `extname` . If there is more than one of the specified extensions in the file, `index` specifies the one to read.

`data = fitsread(filename,Name,Value)` reads data from the FITS file with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

filename

Text string specifying the name of a FITS file.

extname

One of the following text strings specifying the name of a data array or extension in the FITS file. To determine the contents of a FITS, view the `Contents` field of the structure returned by `fitsinfo`.

Data Arrays or Extensions

Extname	Description
'primary'	Read data from the primary data array.
'asciitable'	Read data from the ASCII Table extension. The return value, data, is a 1-D cell array.
'binarytable'	Read data from the Binary Table extension. The return value, data, is a 1-D cell array.
'image'	Read data from the Image extension.
'unknown'	Read data from the Unknown extension.

index

Numeric value specifying which extension to read, if more than one exists in the file.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'info'

`info` structure returned by `fitsinfo` specifying the location of data to read.

Note Using the `info` structure returned by `fitsinfo` to specify the location of data in a FITS file can significantly improve performance, especially when reading multiple images from the file.

'PixelRegion'

Cell array {rows,cols,...} specifying the boundaries of a subimage region to read from the file. Each dimension (rows, cols) is a vector of 1-based indices given either as START, [START STOP], or [START INCREMENT STOP]. This parameter is valid only for primary or image extensions.

'raw'

Specifies that fitsread should not scale the data read from the file or replace undefined values with NaN. Data read from the file is the same class as it is stored in the file.

'TableColumns'

Vector of 1-based indices specifying the columns to read from the ASCII or Binary table extension. This vector should contain unique and valid indices into the table data specified in increasing order. This parameter is valid only for ASCII or Binary extensions.

'TableRows'

Vector of 1-based indices specifying the rows to read from the ASCII or Binary table extension. This vector should contain unique and valid indices into the table data specified in increasing order. This parameter is valid only for ASCII or Binary extensions.

Output Arguments

data

Data returned from the FITS file.

Definitions

extension

A FITS file contains primary data and can optionally contain any number of optional components, called *extensions* in FITS terminology.

Examples

Read primary data from FITS file

```
data = fitsread('tst0012.fits');
```

```
Name          Size              Bytes  Class     Attributes

data        109x102             88944  double
```

Inspect available extensions, read ’image’ extension using the `extname` option.

```
info = fitsinfo('tst0012.fits');
 % List of contents, includes any extensions if present.
 disp(info.Contents);
 imageData = fitsread('tst0012.fits','image');
```

Subsample the fifth plane of ’image’ extension by 2.

```
info        = fitsinfo('tst0012.fits');
 rowend      = info.Image.Size(1);
 colend      = info.Image.Size(2);
 primaryData = fitsread('tst0012.fits','image',...
                      'Info', info,...
                      'PixelRegion',{[1 2 rowend], [1 2 colend], 5 });
```

Read every other row from an ASCII table.

```
info      = fitsinfo('tst0012.fits');
rowend    = info.AsciiTable.Rows;
tableData = fitsread('tst0012.fits','asciitable',...
                    'Info',info,...
                    'TableRows',[1:2:rowend]);
```

Read all data for the first, second and fifth columns of the Binary table.

```
info      = fitsinfo('tst0012.fits');
```

```
rowend    = info.BinaryTable.Rows;
tableData = fitsread('tst0012.fits','binarytable',...
                     'Info',info,...
                     'TableColumns',[1 2 5]);
```

- “Importing Flexible Image Transport System (FITS) Files”

Purpose

Write image to FITS file

Syntax

```
fitswrite(imagedata,filename)
fitswrite(imagedata,filename,Name,Value)
```

Description

`fitswrite(imagedata,filename)` writes `imagedata` to the FITS file specified by `filename`. If `filename` does not exist, `fitswrite` creates the file as a simple FITS file. If `filename` exists, `fitswrite` overwrites the file or appends the image to the end of the file, depending on the value of the `writemode` argument.

`fitswrite(imagedata,filename,Name,Value)` writes `imagedata` to the FITS file specified by `filename` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

imagedata

Image array.

filename

Text string specifying the name of an existing FITS file or the name you want to assign to a new FITS file.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'WriteMode''

One of these strings:

- `overwrite`
- `append`

Default: `overwrite`

'Compression''

One of these strings:

- `none`
- `gzip`
- `rice`
- `hcompress`
- `plio`

Default: `none`

Examples

Create a FITS file containing the red channel of an RGB image.

```
X = imread('ngc6543a.jpg');
R = X(:,:,1);
fitswrite(R,'myfile.fits');
fitsdisp('myfile.fits');
```

Create a FITS file with three images constructed from the channels of an RGB image.

```
X = imread('ngc6543a.jpg');
R = X(:,:,1);  G = X(:,:,2);  B = X(:,:,3);
fitswrite(R,'myfile.fits');
fitswrite(G,'myfile.fits','writemode','append');
fitswrite(B,'myfile.fits','writemode','append');
fitsdisp('myfile.fits');
```

Purpose Round toward zero

Syntax

```
B = fix(A)
```

Description

`B = fix(A)` rounds the elements of `A` toward zero, resulting in an array of integers. For complex `A`, the imaginary and real parts are rounded independently.

Examples

```
a = [-1.9, -0.2, 3.4, 5.6, 7.0, 2.4+3.6i]

a =
  Columns 1 through 4
  -1.9000        -0.2000        3.4000        5.6000

  Columns 5 through 6
   7.0000        2.4000 + 3.6000i

fix(a)

ans =
  Columns 1 through 4
  -1.0000        0             3.0000        5.0000

  Columns 5 through 6
   7.0000        2.0000 + 3.0000i
```

See Also

`ceil` | `floor` | `round`

flintmax

Purpose

Largest consecutive integer in floating-point format

Syntax

```
f = flintmax
f = flintmax(precision)
```

Description

`f = flintmax` returns the largest consecutive integer in IEEE® double precision, which is `2^53`. Above this value, double-precision format does not have integer precision, and not all integers can be represented exactly.

`f = flintmax(precision)` returns the largest consecutive integer in IEEE single or double precision. `flintmax` returns `single(2^24)` for single precision and `2^53` for double precision.

Input Arguments

precision - Floating-point precision type

`'double'` (default) | `'single'`

Floating-point precision type, specified as `'double'` or `'single'`.

Data Types
`char`

Output Arguments

f - Largest consecutive integer in floating-point format

scalar constant

Largest consecutive integer in floating-point format returned as a scalar constant. This constant is `2^53` for double precision and `single(2^24)` for single precision.

Examples

Double Precision

Return the largest consecutive integer in IEEE double precision.

```
format long e
f = flintmax
```

```
f =
```

```
    9.007199254740992e+15
```

This is `2^53`.

Single Precision

Return the largest consecutive integer in IEEE single precision.

```
f = flintmax('single')

f =

    16777216

class(f)

ans =

single
```

This is `single(2^24)`.

Limit of Integer Single Precision

Above the value returned by `flintmax('single')`, not all integers can be represented exactly with single precision.

Return the largest consecutive integer in IEEE single precision.

```
f = flintmax('single')

f =

    16777216
```

This is `single(2^24).`

Add `1` to the value returned from `flintmax`.

```
f1 = f + 1
```

```
f1 =

    16777216
```

f1 is the same as f.

```
isequal(f,f1)
```

```
ans =

     1
```

Add 2 to the value returned from flintmax.

```
f2 = f + 2
```

```
f2 =

    16777218
```

16777218 is represented exactly in single precision while 16777217 is not.

eps | realmax | intmax | format

Concepts

- “Floating-Point Numbers”

Purpose

Flip array along specified dimension

Syntax

```
B = flipdim(A,dim)
```

Description

`B = flipdim(A,dim)` returns `A` with dimension `dim` flipped.

When the value of `dim` is `1`, the array is flipped row-wise down. When `dim` is `2`, the array is flipped columnwise left to right. `flipdim(A,1)` is the same as `flipud(A)`, and `flipdim(A,2)` is the same as `fliplr(A)`.

Examples

`flipdim(A,1)` where

```
A =

     1     4
     2     5
     3     6
```

produces

```
     3     6
     2     5
     1     4
```

See Also

`fliplr` | `flipud` | `permute` | `rot90`

fliplr

Purpose

Flip matrix left to right

Syntax

```
B = fliplr(A)
```

Description

`B = fliplr(A)` returns `A` with columns flipped in the left-right direction, that is, about a vertical axis.

If `A` is a row vector, then `fliplr(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a column vector, then `fliplr(A)` simply returns `A`.

Examples

If `A` is the 3-by-2 matrix,

```
A =
     1     4
     2     5
     3     6
```

then `fliplr(A)` produces

```
     4     1
     5     2
     6     3
```

If `A` is a row vector,

```
A =
     1     3     5     7     9
```

then `fliplr(A)` produces

```
     9     7     5     3     1
```

Limitations

The array being operated on cannot have more than two dimensions. This limitation exists because the axis upon which to flip a multidimensional array would be undefined.

See Also

`flipdim` | `flipud` | `rot90`

Purpose

Flip matrix up to down

Syntax

```
B = flipud(A)
```

Description

`B = flipud(A)` returns `A` with rows flipped in the up-down direction, that is, about a horizontal axis.

If `A` is a column vector, then `flipud(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a row vector, then `flipud(A)` simply returns `A`.

Examples

If `A` is the 3-by-2 matrix,

```
A =
     1     4
     2     5
     3     6
```

`then flipud(A)` produces

```
     3     6
     2     5
     1     4
```

If `A` is a column vector,

```
A =
     3
     5
     7
```

then `flipud(A)` produces

```
A =
     7
     5
     3
```

Limitations

The array being operated on cannot have more than two dimensions. This limitation exists because the axis upon which to flip a multidimensional array would be undefined.

See Also

`flipdim` | `fliplr` | `rot90`

Purpose

Round toward negative infinity

Syntax

`B = floor(A)`

Description

`B = floor(A)` rounds the elements of `A` to the nearest integers less than or equal to `A`. For complex `A`, the imaginary and real parts are rounded independently.

Examples

```
a = [-1.9  -0.2  3.4  5.6  7.0  2.4+3.6i];

floor(a)

ans =
  -2.0000    -1.0000     3.0000     5.0000     7.0000     2.0000 + 3.0000i
```

`ceil` | `fix` | `round`

flow

Purpose

Simple function of three variables

Syntax

```
v = flow
v = flow(n)
v = flow(x,y,z)
[x,y,z,v] = flow(...)
```

Description

`flow`, a function of three variables, generates fluid-flow data that is useful for demonstrating `slice`, `interp3`, and other functions that visualize scalar volume data.

`v = flow` produces a 50-by-25-by-25 array.

`v = flow(n)` produces a `n`-by-`2n`-by-`n` array.

`v = flow(x,y,z)` evaluates the speed profile at the points `x`, `y`, and `z`.

`[x,y,z,v] = flow(...)` returns the coordinates as well as the volume data.

See Also

`slice` | `interp3`

How To

- "Slicing Fluid Flow Data"

Purpose

Find minimum of single-variable function on fixed interval

Syntax

```
x = fminbnd(fun,x1,x2)
x = fminbnd(fun,x1,x2,options)
[x,fval] = fminbnd(...)
[x,fval,exitflag] = fminbnd(...)
[x,fval,exitflag,output] = fminbnd(...)
```

Description

`fminbnd` finds the minimum of a function of one variable within a fixed interval.

`x = fminbnd(fun,x1,x2)` returns a value `x` that is a local minimizer of the function that is described in `fun` in the interval `x1 < x < x2`. `fun` is a `function_handle`.

"Parameterizing Functions" in the MATLAB Mathematics documentation, explains how to pass additional parameters to your objective function `fun`.

`x = fminbnd(fun,x1,x2,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminbnd` uses these `options` structure fields:

`Display`	Level of display. `'off'` displays no output; `'iter'` displays output at each iteration; `'final'` displays just the final output; `'notify'` (default) displays output only if the function does not converge. See "Iterative Display" in MATLAB Mathematics for more information.
`FunValCheck`	Check whether objective function values are valid. `'on'` displays an error when the objective function returns a value that is `complex` or `NaN`. `'off'` displays no error.
`MaxFunEvals`	Maximum number of function evaluations allowed.
`MaxIter`	Maximum number of iterations allowed.

`OutputFcn`	User-defined function that is called at each iteration. See "Output Functions" in MATLAB Mathematics for more information.
`PlotFcns`	Plots various measures of progress while the algorithm executes, select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none (`[]`). • `@optimplotx` plots the current point • `@optimplotfval` plots the function value • `@optimplotfunccount` plots the function count See "Plot Functions" in MATLAB Mathematics for more information.
`TolX`	Termination tolerance on `x`.

`[x,fval] = fminbnd(...)` returns the value of the objective function computed in `fun` at `x`.

`[x,fval,exitflag] = fminbnd(...)` returns a value `exitflag` that describes the exit condition of `fminbnd`:

`1`	`fminbnd` converged to a solution `x` based on `options.TolX`.
`0`	Maximum number of function evaluations or iterations was reached.
`-1`	Algorithm was terminated by the output function.
`-2`	Bounds are inconsistent (`x1 > x2`).

`[x,fval,exitflag,output] = fminbnd(...)` returns a structure `output` that contains information about the optimization in the following fields:

`algorithm`	Algorithm used
`funcCount`	Number of function evaluations
`iterations`	Number of iterations
`message`	Exit message

Arguments

`fun` is the function to be minimized. `fun` accepts a scalar `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for a function file

```
x = fminbnd(@myfun,x1,x2);
```

where `myfun.m` is a function file such as

```
function f = myfun(x)
f = ...          % Compute function value at x.
```

or as a function handle for an anonymous function:

```
x = fminbnd(@(x) sin(x*x),x1,x2);
```

Other arguments are described in the syntax descriptions above.

Examples

`x = fminbnd(@cos,3,4)` computes π to a few decimal places and gives a message on termination.

```
[x,fval,exitflag] = ...
   fminbnd(@cos,3,4,optimset('TolX',1e-12,'Display','off'))
```

computes π to about 12 decimal places, suppresses output, returns the function value at `x`, and returns an `exitflag` of 1.

The argument `fun` can also be a function handle for an anonymous function. For example, to find the minimum of the function $f(x) = x^3 - 2x - 5$ on the interval `(0,2)`, create an anonymous function `f`

```
f = @(x)x.^3-2*x-5;
```

Then invoke `fminbnd` with

```
x = fminbnd(f, 0, 2)
```

The result is

```
x =
    0.8165
```

The value of the function at the minimum is

```
y = f(x)

y =
    -6.0887
```

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following function file:

```
function f = myfun(x,a)
f = (x - a)^2;
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fminbind`. To optimize for a specific value of `a`, such as `a = 1.5`.

1. Assign the value to `a`.

   ```
   a = 1.5; % define parameter first
   ```

2. Call `fminbnd` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

   ```
   x = fminbnd(@(x) myfun(x,a),0,1)
   ```

Algorithms

`fminbnd` is a function file. Its algorithm is based on golden section search and parabolic interpolation. Unless the left endpoint x_1 is very

close to the right endpoint x_2, `fminbnd` never evaluates `fun` at the endpoints, so `fun` need only be defined for x in the interval $x_1 < x < x_2$.

If the minimum actually occurs at x_1 or x_2, `fminbnd` returns a point `x` in the interior of the interval (x_1,x_2) that is close to the minimizer. In this case, the distance of `x` from the minimizer is no more than `2*(TolX + 3*abs(x)*sqrt(eps))`. See [1] or [2] for details about the algorithm.

Limitations

The function to be minimized must be continuous. `fminbnd` may only give local solutions.

`fminbnd` often exhibits slow convergence when the solution is on a boundary of the interval.

`fminbnd` only handles real variables.

`fminsearch` | `fzero` | `optimset` | `function_handle`

How To

- anonymous function

Purpose

Find minimum of unconstrained multivariable function using derivative-free method

Syntax

```
x = fminsearch(fun,x0)
x = fminsearch(fun,x0,options)
[x,fval] = fminsearch(...)
[x,fval,exitflag] = fminsearch(...)
[x,fval,exitflag,output] = fminsearch(...)
```

Description

`fminsearch` finds the minimum of a scalar function of several variables, starting at an initial estimate. This is generally referred to as *unconstrained nonlinear optimization*.

`x = fminsearch(fun,x0)` starts at the point `x0` and returns a value `x` that is a local minimizer of the function described in `fun`. `x0` can be a scalar, vector, or matrix. `fun` is a `function_handle`.

"Parameterizing Functions" in the MATLAB Mathematics documentation explains how to pass additional parameters to your objective function `fun`. See also "Example 2" on page 1-1791 and "Example 3" on page 1-1791 below.

`x = fminsearch(fun,x0,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminsearch` uses these `options` structure fields:

`Display`	Level of display. `'off'` displays no output; `'iter'` displays output at each iteration; `'final'` displays just the final output; `'notify'` (default) displays output only if the function does not converge. See "Iterative Display" in MATLAB Mathematics for more information.
`FunValCheck`	Check whether objective function values are valid. `'on'` displays an error when the objective function returns a value that is `complex`, `Inf` or `NaN`. `'off'` (the default) displays no error.

MaxFunEvals	Maximum number of function evaluations allowed
MaxIter	Maximum number of iterations allowed
OutputFcn	User-defined function that is called at each iteration. See "Output Functions" in MATLAB Mathematics for more information.
PlotFcns	Plots various measures of progress while the algorithm executes, select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none ([]). • @optimplotx plots the current point • @optimplotfval plots the function value • @optimplotfunccount plots the function count See "Plot Functions" in MATLAB Mathematics for more information.
TolFun	Termination tolerance on the function value
TolX	Termination tolerance on x

[x,fval] = fminsearch(...) returns in fval the value of the objective function fun at the solution x.

[x,fval,exitflag] = fminsearch(...) returns a value exitflag that describes the exit condition of fminsearch:

1	fminsearch converged to a solution x.
0	Maximum number of function evaluations or iterations was reached.
-1	Algorithm was terminated by the output function.

[x,fval,exitflag,output] = fminsearch(...) returns a structure output that contains information about the optimization in the following fields:

`algorithm`	`'Nelder-Mead simplex direct search'`
`funcCount`	Number of function evaluations
`iterations`	Number of iterations
`message`	Exit message

Arguments

`fun` is the function to be minimized. It accepts an input `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for a function file

```
x = fminsearch(@myfun, x0)
```

where `myfun` is a function file such as

```
function f = myfun(x)
f = ...             % Compute function value at x
```

or as a function handle for an anonymous function, such as

```
x = fminsearch(@(x)sin(x^2), x0);
```

Other arguments are described in the syntax descriptions above.

Examples

Example 1

The Rosenbrock banana function is a classic test example for multidimensional minimization:

$$f(x) = 100\left(x_2 - x_1^2\right)^2 + \left(1 - x_1\right)^2.$$

The minimum is at `(1,1)` and has the value `0`. The traditional starting point is `(-1.2,1)`. The anonymous function shown here defines the function and returns a function handle called `banana`:

```
banana = @(x)100*(x(2)-x(1)^2)^2+(1-x(1))^2;
```

Pass the function handle to `fminsearch`:

```
[x,fval] = fminsearch(banana,[-1.2, 1])
```

This produces

```
x =

    1.0000    1.0000

fval =

    8.1777e-010
```

This indicates that the minimizer was found to at least four decimal places with a value near zero.

Example 2

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following function file:

```
function f = myfun(x,a)
f = x(1)^2 + a*x(2)^2;
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fminsearch`. To optimize for a specific value of `a`, such as `a = 1.5`.

1. Assign the value to `a`.

   ```
   a = 1.5; % define parameter first
   ```

2. Call `fminsearch` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

   ```
   x = fminsearch(@(x) myfun(x,a),[0,1])
   ```

Example 3

You can modify the first example by adding a parameter a to the second term of the banana function:

$$f(x) = 100\left(x_2 - x_1^2\right)^2 + \left(a - x_1\right)^2.$$

This changes the location of the minimum to the point [a,a^2]. To minimize this function for a specific value of a, for example a = sqrt(2), create a one-argument anonymous function that captures the value of a.

```
a = sqrt(2);
banana = @(x)100*(x(2)-x(1)^2)^2+(a-x(1))^2;
```

Then the statement

```
[x,fval] = fminsearch(banana, [-1.2, 1], ...
   optimset('TolX',1e-8));
```

seeks the minimum [sqrt(2), 2] to an accuracy higher than the default on x.

Algorithms

fminsearch uses the simplex search method of Lagarias et al. [1]. This is a direct search method that does not use numerical or analytic gradients.

If n is the length of x, a simplex in n-dimensional space is characterized by the n+1 distinct vectors that are its vertices. In two-space, a simplex is a triangle; in three-space, it is a pyramid. At each step of the search, a new point in or near the current simplex is generated. The function value at the new point is compared with the function's values at the vertices of the simplex and, usually, one of the vertices is replaced by the new point, giving a new simplex. This step is repeated until the diameter of the simplex is less than the specified tolerance.

For more information, see "fminsearch Algorithm".

Limitations

fminsearch can often handle discontinuity, particularly if it does not occur near the solution. fminsearch may only give local solutions.

fminsearch only minimizes over the real numbers, that is, x must only consist of real numbers and $f(x)$ must only return real numbers. When x has complex variables, they must be split into real and imaginary parts.

`fminbnd` | `optimset` | `function_handle`

How To

- anonymous function

fopen

Purpose

Open file, or obtain information about open files

Syntax

```
fileID = fopen(filename)
fileID = fopen(filename, permission)
fileID = fopen(filename, permission, machineformat)
fileID = fopen(filename, permission,
machineformat, encoding)
[fileID, message] = fopen(filename, ...)
fIDs = fopen('all')
[filename, permission, machineformat,
   encoding] = fopen(fileID)
```

Description

`fileID = fopen(filename)` opens the file `filename` for read access, and returns an integer file identifier.

`fileID = fopen(filename, permission)` opens the file with the specified `permission`.

`fileID = fopen(filename, permission, machineformat)` specifies the order for reading or writing bytes or bits in the file.

`fileID = fopen(filename, permission, machineformat, encoding)` specifies the character encoding scheme associated with the file.

`[fileID, message] = fopen(filename, ...)` opens a file. If the operation fails, `message` is a system-dependent error message. Otherwise, `message` is an empty string.

`fIDs = fopen('all')` returns a row vector containing the file identifiers of all open files.

`[filename, permission, machineformat, encoding] = fopen(fileID)` returns the file name, permission, machine format, and encoding that a previous call to `fopen` used when it opened the specified file. `fopen` does not read information from the file to determine these output values. An invalid `fileID` returns empty strings for all output arguments.

Input Arguments

filename

String in single quotation marks that specifies the name of the file to open. Can include a full or partial path.

On UNIX systems, if *`filename`* begins with `'~/'` or `'~`*`username`*`/'`, the `fopen` function expands the path to the current or specified user's home directory, respectively.

If you open a file with read access and `fopen` cannot find *`filename`* in the current folder, `fopen` searches along the MATLAB search path. Otherwise, `fopen` creates a file in the current directory.

permission

String that describes the type of access for the file: read, write, append, or update. Also specifies whether to open files in binary or text mode.

To open files in binary mode, specify one of the following:

`'r'`	Open file for reading (default).
`'w'`	Open or create new file for writing. Discard existing contents, if any.
`'a'`	Open or create new file for writing. Append data to the end of the file.
`'r+'`	Open file for reading and writing.
`'w+'`	Open or create new file for reading and writing. Discard existing contents, if any.
`'a+'`	Open or create new file for reading and writing. Append data to the end of the file.
`'A'`	Append without automatic flushing. (Used with tape drives.)
`'W'`	Write without automatic flushing. (Used with tape drives.)

To read and write to the same file:

- Open the file in update mode (with a *permission* that includes a plus sign, '+').
- Call fseek or frewind between read and write operations. For example, do not call fread followed by fwrite, or fwrite followed by fread, unless you call fseek or frewind between them.

To open files in text mode, attach the letter 't' to the *permission*, such as 'rt' or 'wt+'. For better performance, do not use text mode. The following applies on Windows systems, in text mode:

- Read operations that encounter a carriage return followed by a newline character ('\r\n') remove the carriage return from the input.
- Write operations insert a carriage return before any newline character in the output.

This additional processing is unnecessary for most cases. All MATLAB import functions, and most text editors (including Microsoft Word and WordPad), recognize both '\r\n' and '\n' as newline sequences. However, when you create files for use in Microsoft Notepad, end each line with '\r\n'. For an example, see fprintf.

machineformat

String that specifies the order for reading or writing bytes or bits in the file.

Possible values are:

'n' or 'native'	The byte ordering that your system uses (default)
'b' or 'ieee-be'	Big-endian ordering
'l' or 'ieee-le'	Little-endian ordering

`'s'` or `'ieee-be.l64'`	Big-endian ordering, 64-bit long data type
`'a'` or `'ieee-le.l64'`	Little-endian ordering, 64-bit long data type

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big- or little-endian ordering.

encoding

String that specifies the character encoding scheme to use for subsequent read and write operations, including `fscanf`, `fprintf`, `fgetl`, `fgets`, `fread`, and `fwrite`.

Supported values are:

`'Big5'`	`'ISO-8859-1'`	`'windows-932'`
`'EUC-JP'`	`'ISO-8859-2'`	`'windows-936'`
`'GBK'`	`'ISO-8859-3'`	`'windows-949'`
`'Macintosh'`	`'ISO-8859-4'`	`'windows-950'`
`'Shift_JIS'`	`'ISO-8859-9'`	`'windows-1250'`
`'US-ASCII'`	`'ISO-8859-13'`	`'windows-1251'`
`'UTF-8'`	`'ISO-8859-15'`	`'windows-1252'`
		`'windows-1253'`
		`'windows-1254'`
		`'windows-1257'`

For a list of additional encoding character sets, see http://www.iana.org/assignments/character-sets. If you specify a value for encoding that is not in the list of supported values, MATLAB issues a warning. Specifying other encodings sometimes (but not always) produces correct results.

Default: system-dependent

Output Arguments

fileID

An integer that identifies the file for all subsequent low-level file I/O operations. If `fopen` cannot open the file, *`fileID`* is `-1`.

MATLAB reserves file identifiers `0`, `1`, and `2` for standard input, standard output (the screen), and standard error, respectively. When `fopen` successfully opens a file, it returns a file identifier greater than or equal to `3`.

message

A system-dependent error message when `fopen` cannot open the specified file. Otherwise, an empty string.

fIDs

Row vector containing the identifiers for all open files, except the identifiers reserved for standard input, output, and error. The number of elements in the vector is equal to the number of open files.

filename

Name of the file associated with the specified *`fileID`*.

permission

The *`permission`* that `fopen` assigned to the file specified by *`fileID`*.

machineformat

The value of *`machineformat`* that `fopen` used when it opened the file specified by *`fileID`*.

encoding

The character encoding scheme that `fopen` associated with the file specified by *`fileID`*.

The value that `fopen` returns for *`encoding`* is a standard character encoding scheme name. It is not always the same as the *`encoding`* argument that you used in the call to `fopen` to open the file.

Examples

Open a file. Pass the file identifier, `fid`, to other file I/O functions to read data and close the file.

```
fid = fopen('fgetl.m');

tline = fgetl(fid);
while ischar(tline)
    disp(tline);
    tline = fgetl(fid);
end

fclose(fid);
```

Create a prompt to request the name of a file to open. If `fopen` cannot open the file, display the relevant error message.

```
fid = -1;
msg = '';
while fid < 0
   disp(msg);
   filename = input('Open file: ', 's');
   [fid,msg] = fopen(filename);
end
```

Open a file to write Unicode® characters to a file using the Shift-JIS character encoding scheme:

```
fid = fopen('japanese_out.txt', 'w', 'n', 'Shift_JIS');
```

`fclose` | `ferror` | `fseek` | `ftell` | `feof` | `fscanf` | `fprintf` | `fread` | `fwrite`

fopen (serial)

Purpose

Connect serial port object to device

Syntax

```
fopen(obj)
```

Description

`fopen(obj)` connects the serial port object, `obj` to the device.

Tips

Before you can perform a read or write operation, `obj` must be connected to the device with the `fopen` function. When `obj` is connected to the device:

- Data remaining in the input buffer or the output buffer is flushed.
- The `Status` property is set to `open`.
- The `BytesAvailable`, `ValuesReceived`, `ValuesSent`, and `BytesToOutput` properties are set to 0.

An error is returned if you attempt to perform a read or write operation while `obj` is not connected to the device. You can connect only one serial port object to a given device.

Some properties are read-only while the serial port object is open (connected), and must be configured before using `fopen`. Examples include `InputBufferSize` and `OutputBufferSize`. Refer to the property reference pages to determine which properties have this constraint.

The values for some properties are verified only after `obj` is connected to the device. If any of these properties are incorrectly configured, then an error is returned when `fopen` is issued and `obj` is not connected to the device. Properties of this type include `BaudRate`, and are associated with device settings.

If you use the `help` command to display help for `fopen`, then you need to supply the pathname shown below.

```
help serial/fopen
```

Examples

This example creates the serial port object `s`, connects `s` to the device using `fopen`, writes and reads text data, and then disconnects `s` from the device. This example works on a Windows platform.

```
s = serial('COM1');
fopen(s)
fprintf(s,'*IDN?')
idn = fscanf(s);
fclose(s)
```

See Also

fclose | BytesAvailable | BytesToOutput | Status | ValuesReceived | ValuesSent

Purpose

Execute statements specified number of times

Syntax

```
for index = values
   program statements
          :
end
```

Description

`for index=values, program statements, end` repeatedly executes one or more MATLAB statements in a loop. *`values`* has one of the following forms:

`initval``:`*`endval`*	increments the *`index`* variable from *`initval`* to *`endval`* by `1`, and repeats execution of *`program statements`* until *`index`* is greater than *`endval`*.
`initval``:`*`step`*`:`*`endval`*	increments *`index`* by the value *`step`* on each iteration, or decrements when *`step`* is negative.
`valArray`	creates a column vector *`index`* from subsequent columns of array *`valArray`* on each iteration. For example, on the first iteration, *`index`* `=` *`valArray`*`(:,1)`. The loop executes for a maximum of *`n`* times, where *`n`* is the number of columns of *`valArray`*, given by `numel(`*`valArray`*`, 1, :)`. The input *`valArray`* can be of any MATLAB data type, including a string, cell array, or struct.

Tips

- To force an immediate exit of the loop, use a `break` or `return` statement. To skip the rest of the instructions in the loop, increment the loop counter, and begin the next iteration, use a `continue` statement.
- Avoid assigning a value to the *`index`* variable within the body of a loop. The `for` statement overrides any changes made to the *`index`* within the loop.

- To iterate over the values of a single column vector, first transpose it to create a row vector.

Examples

Create a Hilbert matrix using nested `for` loops:

```
k = 10;
hilbert = zeros(k,k);      % Preallocate matrix

for m = 1:k
    for n = 1:k
        hilbert(m,n) = 1/(m+n -1);
    end
end
```

Step by increments of `-0.1`, and display the step values:

```
for s = 1.0: -0.1: 0.0
   disp(s)
end
```

Execute statements for a defined set of index values:

```
for s = [1,5,8,17]
   disp(s)
end
```

Successively set `e` to unit vectors:

```
for e = eye(5)
  disp('Current value of e:')
  disp(e)
end
```

See Also

`end` | `while` | `break` | `continue` | `parfor` | `return` | `if` | `switch` | `colon`

Purpose

Set display format for output

Syntax

```
format
format Style
```

Description

`format` sets the display of floating-point numeric values to the default display format, which is the short fixed decimal format. This format displays 5-digit scaled, fixed-point values.

The `format` function affects only how numbers display in the Command Window, not how MATLAB computes or saves them.

`format Style` changes the display format to the specified `Style`.

Input Arguments

Style - Output display format

`short` (default) | `long` | `shortE` | `longE`

Output display format, specified as one of the strings listed in the tables that follow.

Use these styles to switch between different output display formats for floating-point variables. Styles are case insensitive. You also can insert a space between `short` or `long` and the presentation type, for instance, `format short E`.

Style	Result	Example
`short` (default)	Short fixed decimal format, with 4 digits after the decimal point. If you are displaying a matrix with a wide range of values, consider using `shortG`. See "Display Large Data Range in short and shortg Formats" on page 1-1810	`3.1416`
`long`	Long fixed decimal format, with 15 digits after the decimal point for `double` values, and 7 digits	`3.141592653589793`

Style	Result	Example
	after the decimal point for `single` values.	
`shortE`	Short scientific notation, with 4 digits after the decimal point. Integer-valued floating-point numbers with a maximum of 9 digits do not display in scientific notation.	`3.1416e+00`
`longE`	Long scientific notation, with 15 digits after the decimal point for `double` values, and 7 digits after the decimal point for `single` values. Integer-valued floating-point numbers with a maximum of 9 digits do not display in scientific notation.	`3.141592653589793e+00`
`shortG`	The more compact of short fixed decimal or scientific notation, with 5 digits.	`3.1416`
`longG`	The more compact of long fixed decimal or scientific notation, with 15 digits for `double` values, and 7 digits for `single` values.	`3.14159265358979`
`shortEng`	Short engineering notation, with 4 digits after the decimal point, and an exponent that is a multiple of 3.	`3.1416e+000`
`longEng`	Long engineering notation, with 15 significant digits, and an exponent that is a multiple of 3.	`3.14159265358979e+000`

Use these format styles to switch between different output display formats for all numeric variables.

Style	Result	Example
`+`	Positive/Negative format, with `+`, `-`, and blank characters displayed for positive, negative, and zero elements.	`+`
`bank`	Currency format, with 2 digits after the decimal point.	`3.14`
`hex`	Hexadecimal representation of a binary double-precision number.	`400921fb54442d18`
`rat`	Ratio of small integers.	`355/113`

Use these format styles to affect the spacing in the display of all variables.

DispType	Result	Example

`compact`	Suppresses excess line feeds to show more output in a single screen. Contrast with `loose`.	`theta = pi/2`
		`theta =`
		`1.5708`

`loose`	Adds linefeeds to make output more readable. Contrast with `compact`.	`theta = pi/2`
		
		`theta =`
		
		`1.5708`

Examples

Change and View Current Format

Set the display format to long fixed decimal.

```
format long
```

View the result for the value of `pi`.

```
pi
```

```
ans =

   3.141592653589793
```

View the current format.

```
get(0,'format')
```

```
ans =

long
```

Display Values in Default and Hexadecimal Format

Set the format to its default, and display the maximum values for integers and real numbers in MATLAB.

```
format

intmax('uint64')
```

```
ans =

 18446744073709551615
```

```
realmax
```

```
ans =
  1.7977e+308
```

Change the display format to hexadecimal, and then display the same values.

```
format hex
```

```
intmax('uint64')

ans =

   ffffffffffffffff

realmax

ans =

   7fefffffffffffff
```

The hexadecimal display corresponds to the internal representation of the value. It is not the same as the hexadecimal notation in the C programming language.

View Output in Short and Long Engineering Notation

View the difference between output displayed in the `shortEng` and `longEng` formats.

Set the display format to `shortEng`.

```
format shortEng
```

Create variable `A` and increase its value by a multiple of 10 each time through a `for` loop. Display each value of `A`.

```
A = 5.123456789;
for k=1:10
   disp(A)
   A = A * 10;
end

     5.1235e+000
    51.2346e+000
   512.3457e+000
     5.1235e+003
    51.2346e+003
```

```
   512.3457e+003
     5.1235e+006
    51.2346e+006
   512.3457e+006
     5.1235e+009
```

The values for A display with 4 digits after the decimal point, and an exponent that is a multiple of 3.

Set the display format to longEng and view the same values of A.

```
format longEng

A = 5.123456789;
for k=1:10
   disp(A)
   A = A * 10;
end
```

```
    5.12345678900000e+000
    51.2345678900000e+000
    512.345678900000e+000
    5.12345678900000e+003
    51.2345678900000e+003
    512.345678900000e+003
    5.12345678900000e+006
    51.2345678900000e+006
    512.345678900000e+006
    5.12345678900000e+009
```

The values for A display with 15 digits, and an exponent that is a multiple of 3.

Display Large Data Range in short and shortg Formats

View the difference between the short and shortg formats when the values in a matrix span a wide range.

Define variable x and display the output in the short format.

```
x = [25 56 255 9876899999];
format short
x

x =
   1.0e+09 *
    0.0000    0.0000    0.0000    9.8769
```

The display indicates each value is multiplied by `1.0e+09`.

Set the format to `shortg` and redisplay `x`.

```
format shortg
x

x =
           25            56           255    9.8769e+09
```

Algorithms

MATLAB always displays integer variables to the appropriate number of digits for the class. For example, MATLAB uses 3 digits to display numbers of type `int8` (for example, -128:127). Setting `format` to `short` or `long` does not affect the display of integer variables.

If the largest element of a matrix is larger than 10^3 or smaller than 10^{-3}, then MATLAB applies a common scale factor for the short and long formats.

Tips

- The specified format applies only to the current MATLAB session. To maintain a format across sessions, choose a **Numeric format** or **Numeric display** option in the Command Window Preferences.
- To see which `Style` is currently in use, type

  ```
  get(0,'Format')
  ```

  To see if `compact` or `loose` formatting is currently selected, type

  ```
  get(0,'FormatSpacing')
  ```

Concepts

- "Format Output in Command Window"

Purpose

Plot function between specified limits

Syntax

```
fplot(fun,limits)
fplot(fun,limits,LineSpec)
fplot(fun,limits,tol)
fplot(fun,limits,tol,LineSpec)
fplot(fun,limits,n)
fplot(fun,lims,...)
fplot(axes_handle,...)
[X,Y] = fplot(fun,limits,...)
```

Description

`fplot` plots a function between specified limits. The function must be of the form $y = f(x)$, where x is a vector whose range specifies the limits, and `y` is a vector the same size as `x` and contains the function's value at the points in x (see the first example). If the function returns more than one value for a given x, then y is a matrix whose columns contain each component of $f(x)$ (see the second example).

`fplot(fun,limits)` plots `fun` between the limits specified by `limits`. `limits` is a vector specifying the x-axis limits (`[xmin xmax]`), or the x- and y-axes limits, (`[xmin xmax ymin ymax]`).

`fun` must be

- The name of a function
- A string with variable `x` that may be passed to `eval`, such as `'sin(x)'`, `'diric(x,10)'`, or `'[sin(x),cos(x)]'`
- A function handle

The function $f(x)$ must return a row vector for each element of vector x. For example, if $f(x)$ returns `[f1(x),f2(x),f3(x)]` then for input `[x1;x2]` the function should return the matrix

```
f1(x1) f2(x1) f3(x1)
f1(x2) f2(x2) f3(x2)
```

`fplot(fun,limits,LineSpec)` plots `fun` using the line specification `LineSpec`.

`fplot(fun,limits,tol)` plots `fun` using the relative error tolerance `tol` (the default is `2e-3`, i.e., 0.2 percent accuracy).

`fplot(fun,limits,tol,LineSpec)` plots `fun` using the relative error tolerance `tol` and a line specification that determines line type, marker symbol, and color. See `LineSpec` for more information.

`fplot(fun,limits,n)` with `n >= 1` plots the function with a minimum of `n+1` points. The default `n` is `1`. The maximum step size is restricted to be `(1/n)*(xmax-xmin)`.

`fplot(fun,lims,...)` accepts combinations of the optional arguments `tol`, `n`, and `LineSpec`, in any order.

`fplot(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`[X,Y] = fplot(fun,limits,...)` returns the abscissas and ordinates for `fun` in `X` and `Y`. No plot is drawn on the screen; however, you can plot the function using `plot(X,Y)`.

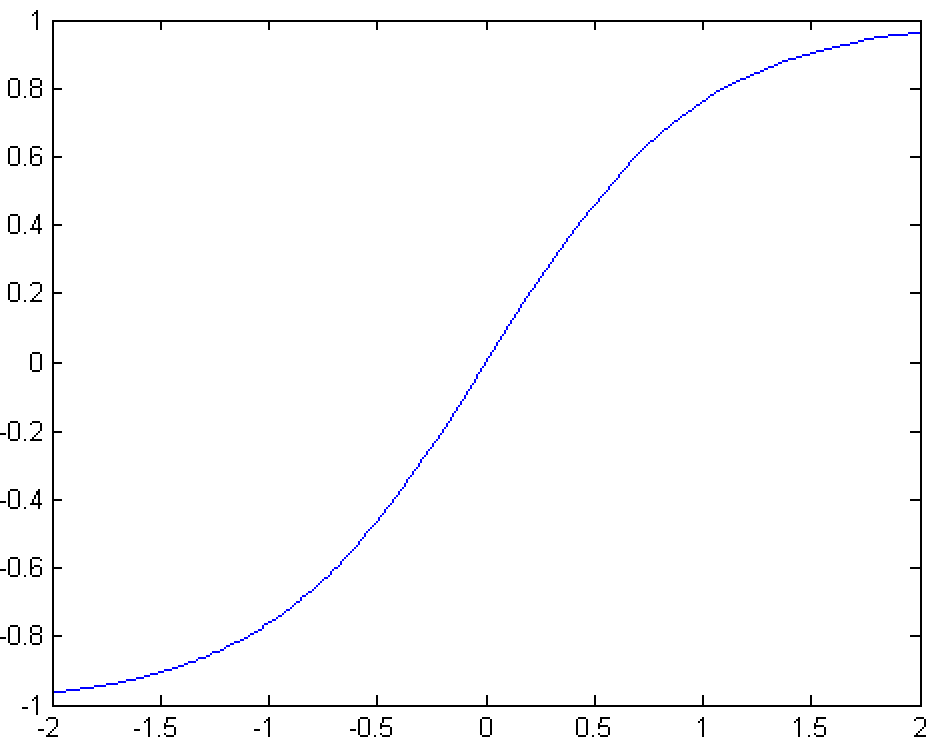
Tips

`fplot` uses adaptive step control to produce a representative graph, concentrating its evaluation in regions where the function's rate of change is the greatest.

Examples

Plot the hyperbolic tangent function from -2 to 2:

```
fnch = @tanh;
fplot(fnch,[-2 2])
```



Create a file, `myfun`, that returns a two-column matrix:

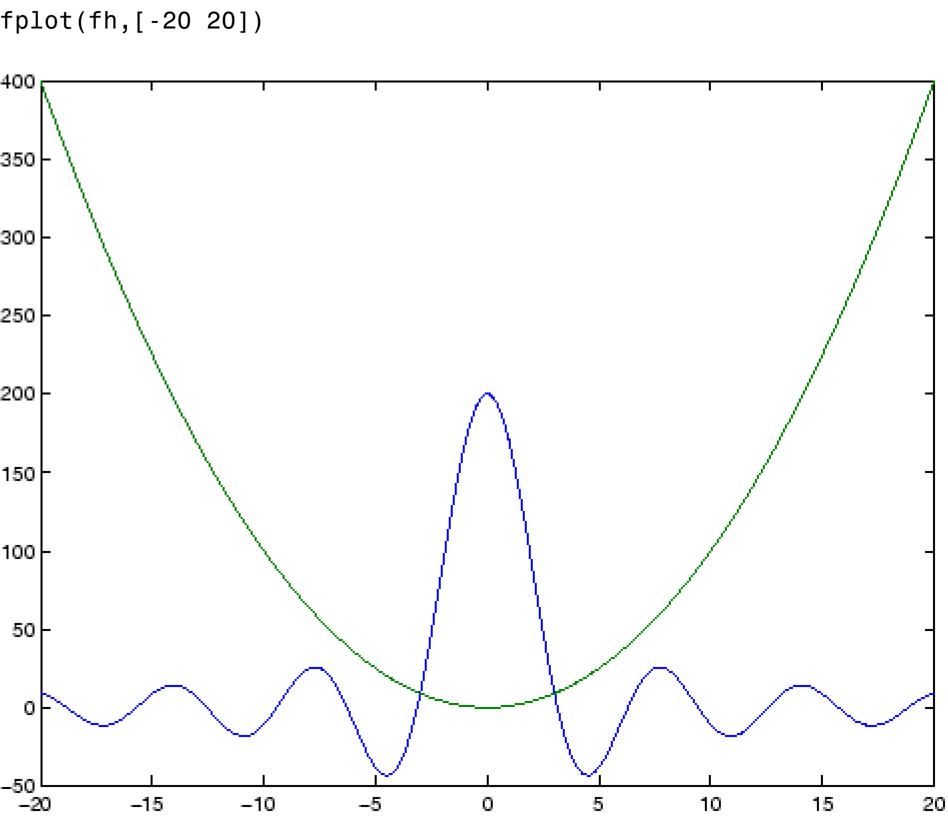
```
function Y = myfun(x)
Y(:,1) = 200*sin(x(:))./x(:);
Y(:,2) = x(:).^2;
```

Create a function handle pointing to `myfun`:

```
fh = @myfun;
```

Plot the function with the statement

```
fplot(fh,[-20 20])
```



Additional Example

This example passes function handles to `fplot`, one created from a MATLAB function and the other created from an anonymous function.

```
hmp = @humps;
subplot(2,1,1);fplot(hmp,[0 1])
sn = @(x) sin(1./x);
subplot(2,1,2);fplot(sn,[.01 .1])
```

How To

- Anonymous Functions

fprintf

Purpose

Write data to text file

Syntax

```
fprintf(fileID,formatSpec,A1,...,An)
nbytes = fprintf(fileID,formatSpec,A1,...,An)

fprintf(formatSpec,A1,...,An)
```

Description

`fprintf(fileID,formatSpec,A1,...,An)` applies the `formatSpec` to all elements of arrays `A1,...An` in column order, and writes the data to a text file. `fprintf` uses the encoding scheme specified in the call to `fopen`.

`nbytes = fprintf(fileID,formatSpec,A1,...,An)` additionally returns the number of bytes that `fprintf` writes.

`fprintf(formatSpec,A1,...,An)` formats data and displays the results on the screen.

Input Arguments

fileID - File identifier

`1` (default) | `2` | scalar

File identifier, specified as one of the following:

- A file identifier obtained from `fopen`.
- `1` for standard output (the screen).
- `2` for standard error.

Data Types

`double`

formatSpec - Format of the output fields

string

Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

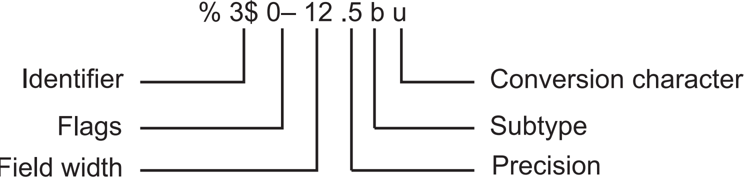
Value Type	Conversion	Details
Integer, signed	`%d` or `%i`	Base 10
Integer, unsigned	`%u`	Base 10
	`%o`	Base 8 (octal)
	`%x`	Base 16 (hexadecimal), lowercase letters `a`–`f`
	`%X`	Same as `%x`, uppercase letters `A`–`F`
Floating-point number	`%f`	Fixed-point notation
	`%e`	Exponential notation, such as `3.141593e+00`
	`%E`	Same as `%e`, but uppercase, such as `3.141593E+00`
	`%g`	The more compact of `%e` or `%f`, with no trailing zeros
	`%G`	The more compact of `%E` or `%f`, with no trailing zeros

	`%bx` or `%bX`
	`%bo`
	`%bu`
		Double-precision hexadecimal, octal, or decimal value
		Example: `%bx` prints `pi` as `400921fb54442d18`

	`%tx` or `%tX`
	`%to`
	`%tu`
		Single-precision hexadecimal, octal, or decimal value
		Example: `%tx` prints `pi` as `40490fdb`

Characters	`%c`	Single character
	`%s`	String of characters

The string can include optional operators, which appear in the following order (includes spaces for clarity):



Optional operators include:

- Identifier

  Order for processing inputs. Use the syntax *n*$, where *n* represents the position of the value in the input list.

  For example, `'%3$s %2$s %1$s %2$s'` prints inputs `'A'`, `'B'`, `'C'` as follows: `C B A B`.

- Flags

`'–'`	Left-justify. Example: `%-5.2f`
`'+'`	Print sign character (+) for positive values. Example: `%+5.2f`
`' '`	Pad to field width with spaces before the value. Example: `% 5.2f`

'0'	Pad to field width with zeros. Example: `%05.2f`
'#'	Modify selected numeric conversions: • For `%o`, `%x`, or `%X`, print `0`, `0x`, or `0X` prefix. • For `%f`, `%e`, or `%E`, print decimal point even when precision is 0. • For `%g` or `%G`, do not remove trailing zeros or decimal point. Example: `%#5.0f`

- Field width

  Minimum number of characters to print. Can be a number, or an asterisk (`*`) to refer to an argument in the input list. For example, the input list `('%12d', intmax)` is equivalent to `('%*d', 12, intmax)`.

- Precision

For `%f`, `%e`, or `%E`:	Number of digits to the right of the decimal point. Example: `'%6.4f'` prints `pi` as `'3.1416'`
For `%g` or `%G`	Number of significant digits. Example: `'%6.4g'` prints `pi` as `' 3.142'`

  Can be a number, or an asterisk (`*`) to refer to an argument in the input list. For example, the input list `('%6.4f', pi)` is equivalent to `('%*.*f', 6, 4, pi)`.

The string can also include combinations of the following:

- Literal text to print. To print a single quotation mark, include `''` in `formatSpec`.
- Control characters, including:

`%%`	Percent character
`\\`	Backslash
`\a`	Alarm
`\b`	Backspace
`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab
`\xN`	Character whose ASCII code is the hexadecimal number, *N*
`\N`	Character whose ASCII code is the octal number, *N*

The following limitations apply to conversions:

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses `%e`.
- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, `'%s'` converts `[65 66 67]` to `ABC`.

A1,...,An - Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

Data Types
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

Examples

Print Literal Text and Array Values

Print multiple numeric values and literal text to the screen.

```
A1 = [9.9, 9900];
A2 = [8.8,  7.7 ; ...
      8800, 7700];
formatSpec = 'X is %4.2f meters or %8.3f mm\n';
fprintf(formatSpec,A1,A2)
```

```
X is 9.90 meters or 9900.000 mm
X is 8.80 meters or 8800.000 mm
X is 7.70 meters or 7700.000 mm
```

Print Double-Precision Values as Integers

Explicitly convert double-precision values with fractions to integer values.

```
a = [1.02, 3.04, 5.06];
fprintf('%d\n',round(a));
```

```
1
3
5
```

Write Table to Text File

Write a short table of the exponential function to a text file called `exp.txt`.

```
x = 0:.1:1;
A = [x; exp(x)];

fileID = fopen('exp.txt','w');
fprintf(fileID,'%6s %12s\n','x','exp(x)');
fprintf(fileID,'%6.2f %12.8f\n',A);
fclose(fileID);
```

The first call to `fprintf` prints header text `x` and `exp(x)`, and the second call prints the values from variable `A`.

If you plan to read the file with Microsoft Notepad, use `'\r\n'` instead of `'\n'` to move to a new line. For example, replace the calls to `fprintf` with the following:

```
fprintf(fileID,'%6s %12s\r\n','x','exp(x)');
fprintf(fileID,'%6.2f %12.8f\r\n',A);
```

MATLAB import functions, all UNIX applications, and Microsoft Word and WordPad recognize `'\n'` as a newline indicator.

View the contents of the file with the `type` command.

```
type exp.txt
```

Display Hyperlinks in Command Window

Display a hyperlink (The MathWorks Web Site) on the screen.

```
site = 'http://www.mathworks.com';
title = 'The MathWorks Web Site';

fprintf('<a href = "%s">%s</a>\n',site,title)
```

Concepts

- “Formatting Strings”

fprintf (serial)

Purpose

Write text to device

Syntax

```
fprintf(obj,'cmd')
fprintf(obj,'format','cmd')
fprintf(obj,'cmd','mode')
fprintf(obj,'format','cmd','mode')
```

Description

`fprintf(obj,'cmd')` writes the string `cmd` to the device connected to the serial port object, `obj`. The default format is `%s\n`. The write operation is synchronous and blocks the command-line until execution completes.

`fprintf(obj,'format','cmd')` writes the string using the format specified by *`format`*.

`fprintf(obj,'cmd','mode')` writes the string with command line access specified by *`mode`*. *`mode`* specifies if `cmd` is written synchronously or asynchronously.

`fprintf(obj,'format','cmd','mode')` writes the string using the specified format. *`format`* is a C language conversion specification.

You need an open connection from the serial port object, `obj`, to the device before performing read or write operations.

Use the `fopen` function to open a connection to the device. When `obj` has an open connection to the device it has a `Status` property value of `open`. Refer to "Troubleshooting Common Errors" for `fprintf` errors.

To understand the use of `fprintf` refer to " Completing a Write Operation with fprintf" and "Rules for Writing the Terminator".

Input Arguments

format

ANSI C conversion specification includes these conversion characters.

Specifier	Description
`%c`	Single character
`%d` or `%i`	Decimal notation (signed)

Specifier	Description
`%e`	Exponential notation (using lowercase `e` as in `3.1415e+00`)
`%E`	Exponential notation (using uppercase `E` as in `3.1415E+00`)
`%f`	Fixed-point notation
`%g`	The more compact of `%e` or `%f`, as defined above. Insignificant zeros do not print.
`%G`	Same as `%g`, but using uppercase `E`
`%o`	Octal notation (unsigned)
`%s`	String of characters
`%u`	Decimal notation (unsigned)
`%x`	Hexadecimal notation (using lowercase letters `a`–`f`)
`%X`	Hexadecimal notation (using uppercase letters `A`–`F`)

mode

Specifies whether the string `cmd` is written synchronously or asynchronously:

- `sync`: `cmd` is written synchronously and the command line is blocked.
- `async`: `cmd` is written asynchronously and the command line is not blocked.

If *`mode`* is not specified, the write operation is synchronous.

If you specify asynchronous *`mode`*, when the write operation occurs:

- The `BytesToOutput` property value continuously updates to reflect the number of bytes in the output buffer.
- The MATLAB file callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

Use the `TransferStatus` property to determine whether an asynchronous write operation is in progress.

For more information on synchronous and asynchronous write operations, see Controlling Access to the MATLAB Command Line.

Examples

Create a serial port object `s` and connect it to a Tektronix TDS 210 oscilloscope. Write the `RS232?` command with `fprintf`. `RS232?` instructs the scope to return serial port communications settings. This example works on a Windows platform.

```
s = serial('COM1');
fopen(s)
fprintf(s,'RS232?')
```

Specify a format for the data that does not include the terminator, or configure the terminator to empty.

```
s = serial('COM1');
fopen(s)
fprintf(s,'%s','RS232?')
```

The default format for `fprintf` is `%s\n`. Therefore, the terminator specified by the `Terminator` property is automatically written. However, in some cases you might want to suppress writing the terminator.

Specify an array of formats and commands:

```
s = serial('COM1');
fopen(s)
fprintf(s,['ch:%d scale:%d'],[1 20e-3],'sync');
```

Tutorials

- Writing and Reading Data
- Controlling Access to the MATLAB Command Line

Purpose

Return image data associated with movie frame

Syntax

```
[X,Map] = frame2im(F)
```

Description

`[X,Map] = frame2im(F)` returns the indexed image `X` and associated colormap `Map` from the single movie frame `F`. If the frame contains true-color data, the m-by-n-3 matrix `Map` is empty. The functions `getframe` and `im2frame` create a movie frame.

Examples

Create and capture an image using `getframe` and `frame2im`:

```
peaks                          %Make figure
f = getframe;                  %Capture screen shot
[im,map] = frame2im(f);        %Return associated image data
if isempty(map)                %Truecolor system
  rgb = im;
else                           %Indexed system
  rgb = ind2rgb(im,map);       %Convert image data
end
```

See Also

`getframe` | `im2frame` | `movie`

fread

Purpose

Read data from binary file

Syntax

```
A = fread(fileID)
A = fread(fileID, sizeA)
A = fread(fileID, sizeA, precision)
A = fread(fileID, sizeA, precision, skip)
A = fread(fileID, sizeA, precision, skip, machineformat)
[A, count] = fread( ___ )
```

Description

`A = fread(fileID)` reads data from a binary file into column vector *A* and positions the file pointer at the end-of-file marker.

`A = fread(fileID, sizeA)` reads *sizeA* elements into *A* and positions the file pointer after the last element read. *sizeA* can be an integer, or can have the form `[m,n]`.

`A = fread(fileID, sizeA, precision)` interprets values in the file according to the form and size described by the *precision*. The *sizeA* parameter is optional.

`A = fread(fileID, sizeA, precision, skip)` skips *skip* bytes after reading each value. If *precision* is `bitn` or `ubitn`, specify *skip* in bits. The *sizeA* parameter is optional.

`A = fread(fileID, sizeA, precision, skip, machineformat)` reads data with the specified *machineformat*. The *sizeA* and *skip* parameters are optional.

`[A, count] = fread( ___ )` returns the number of elements `fread` reads into *A*.

Input Arguments

fileID

An integer file identifier obtained from `fopen`.

sizeA

Dimensions of the output array *A*. Specify in one of the following forms:

`inf`	Column vector with the number of elements in the file. (default)
n	Column vector with *n* elements.
[*m*,*n*]	*m*-by-*n* matrix, filled in column order. *n* can be `inf`, but *m* cannot.

precision

String that specifies the form and size of the values to read. Optionally includes the class for the output matrix *A*.

Use one of the following forms:

'*source*'	Specifies class of input values. Output matrix *A* is class `double`. Example: `'int16'`
'*source*=>*output*'	Specifies classes of input and output. Example: `'int8=>char'`
'**source*'	Output has the same class as input. Example: `'*uint8'` For '`bit`*n*' or '`ubit`*n*' precisions, output has the smallest class that can contain the input. Example: `'*ubit18'` is equivalent to `'ubit18=>uint32'`
'*N***source*' OR '*N***source*=>*output*'	Valid if you specify a *skip* parameter. Read *N* values before each skip. Example: `'4*int8'`

The following table shows possible values for *source* and *output*.

Value Type	Precision	Bits (Bytes)
Integers, unsigned	uint	32 (4)
	uint8	8 (1)
	uint16	16 (2)
	uint32	32 (4)
	uint64	64 (8)
	uchar	8 (1)
	unsigned char	8 (1)
	ushort	16 (2)
	ulong	system-dependent
	ubit*n*	$1 \le n \le 64$
Integers, signed	int	32 (4)
	int8	8 (1)
	int16	16 (2)
	int32	32 (4)
	int64	64 (8)
	integer*1	8 (1)
	integer*2	16 (2)
	integer*4	32 (4)
	integer*8	64 (8)
	schar	8 (1)
	signed char	8 (1)
	short	16 (2)
	long	system-dependent
	bit*n*	$1 \le n \le 64$

Value Type	Precision	Bits (Bytes)
Floating-point numbers	`single`	`32 (4)`
	`double`	`64 (8)`
	`float`	`32 (4)`
	`float32`	`32 (4)`
	`float64`	`64 (8)`
	`real*4`	`32 (4)`
	`real*8`	`64 (8)`
Characters	`char*1`	`8 (1)`
	`char`	Depends on the encoding scheme associated with the file. Set encoding with `fopen`.

On 32-bit systems, `long` and `ulong` are 32 bits. On 64-bit systems, the sizes of `long` and `ulong` correspond to the data model that the C compiler uses: 32 bits on Microsoft Windows systems, 64 bits on other 64-bit systems.

For most *`source`* precisions, if `fread` reaches the end of the file before reading a complete element, `fread` does not return a value for the final element. However, if *`source`* is `bit`*`n`* or `ubit`*`n`*, then `fread` returns a partial result for the final element.

Default: `'uint8=>double'`

skip

Number of bytes to skip after reading each value. If you specify a *`precision`* of `bit`*`n`* or `ubit`*`n`*, specify *`skip`* in bits. Use this parameter to read data from noncontiguous fields in fixed-length records.

Default: 0

machineformat

String that specifies the order for reading bytes within the file. For `bitn` and `ubitn` precisions, specifies the order for reading bits within a byte.

Possible values are:

`'n'` or `'native'`	The byte ordering that your system uses (default)
`'b'` or `'ieee-be'`	Big-endian ordering
`'l'` or `'ieee-le'`	Little-endian ordering
`'s'` or `'ieee-be.l64'`	Big-endian ordering, 64-bit long data type
`'a'` or `'ieee-le.l64'`	Little-endian ordering, 64-bit long data type

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big- or little-endian ordering.

Output Arguments

A

A column vector, unless you specify *sizeA* with the form `[m,n]`. Data in *A* is class `double` unless you specify a different class in the *precision* argument.

count

The number of elements that `fread` successfully reads.

Examples

Read the contents of a file:

```
% Create the file
fid = fopen('magic5.bin', 'w');
fwrite(fid, magic(5));
fclose(fid);

% Read the contents back into an array
```

```
fid = fopen('magic5.bin');
m5 = fread(fid, [5, 5], '*uint8');
fclose(fid);
```

Simulate the `type` function with `fread`, to display the contents of a text file:

```
fid = fopen('fread.m');

% read the entire file as characters
% transpose so that F is a row vector
F = fread(fid, '*char')'

fclose(fid);
```

If you do not specify the precision, `fread` applies the default `uint8=>double`:

```
fid = fopen('fread.m');
F_nums = fread(fid, 6)'  % read the first 6 bytes ('%FREAD')
fclose(fid);
```

This code returns

```
F_nums =
    37    70    82    69    65    68
```

Read selected rows or columns from a file:

```
% Create a file with values from 1 to 9
fid = fopen('nine.bin', 'w');
alldata = reshape([1:9],3,3);
fwrite(fid, alldata);
fclose(fid);
```

```
% Read the first six values into two columns
fid = fopen('nine.bin');
two_cols = fread(fid, [3, 2]);

% Return to the beginning of the file
frewind(fid);

% Read two values at a time, skip one
% Returns six values into two rows
% (first two rows of 'alldata')

two_rows = fread(fid, [2, 3], '2*uint8', 1);

% Close the file
fclose(fid);
```

Specify *machineformat* to read separate digits of binary coded decimal (BCD) values correctly:

```
% Create a file with BCD values
str = ['AB'; 'CD'; 'EF'; 'FA'];

fid = fopen('bcd.bin', 'w');
fwrite(fid, hex2dec(str), 'ubit8');
fclose(fid);

% If you read one byte at a time,
% no need to specify machine format
fid = fopen('bcd.bin');

onebyte = fread(fid, 4, '*ubit8');
disp('Correct data, read with ubit8:')
disp(dec2hex(onebyte))

% However, if you read 4 bits on a little-endian
% system, your results appear in the wrong order
```

```
frewind(fid);     % return to beginning of file

part_err = fread(fid, 8, '*ubit4');
disp('Incorrect data on little-endian systems, ubit4:')
disp(dec2hex(part_err))

% Specify a big-endian format for correct results
frewind(fid);

part_corr = fread(fid, 8, '*ubit4', 'ieee-be');
disp('Correct result, ubit4:')
disp(dec2hex(part_corr))

fclose(fid);
```

How To

- "Reading Portions of a File"
- "Reading Files Created on Other Systems"

fread (serial)

Purpose Read binary data from device

Syntax

```
A = fread(obj)
A = fread(obj,size,'precision')
[A,count] = fread(...)
[A,count,msg] = fread(...)
```

Description

`A = fread(obj)` and A = fread(obj,size) read binary data from the device connected to the serial port object, `obj`, and returns the data to `A`. The maximum number of values to read is specified by `size`. If `size` is not specified, the maximum number of values to read is determined by the object's `InputBufferSize` property. Valid options for `size` are:

`n`	Read at most `n` values into a column vector.
`[m,n]`	Read at most m-by-n values filling an m–by–n matrix in column order.

`size` cannot be `inf`, and an error is returned if the specified number of values cannot be stored in the input buffer. You specify the size, in bytes, of the input buffer with the `InputBufferSize` property. A value is defined as a byte multiplied by the *`precision`* (see below).

`A = fread(obj,`*`size`*`,'`*`precision`*`')` reads binary data with precision specified by *`precision`*.

`precision` controls the number of bits read for each value and the interpretation of those bits as integer, floating-point, or character values. If *`precision`* is not specified, `uchar` (an 8-bit unsigned character) is used. By default, numeric values are returned in double-precision arrays. The supported values for *`precision`* are listed below in Tips.

`[A,count] = fread(...)` returns the number of values read to `count`.

`[A,count,msg] = fread(...)` returns a warning message to `msg` if the read operation was unsuccessful.

Tips

Before you can read data from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read, each time `fread` is issued.

If you use the `help` command to display help for `fread`, then you need to supply the pathname shown below.

```
help serial/fread
```

Rules for Completing a Binary Read Operation

A read operation with `fread` blocks access to the MATLAB command line until:

- The specified number of values are read.
- The time specified by the `Timeout` property passes.

Note The `Terminator` property is not used for binary read operations.

Supported Precisions

The supported values for *`precision`* are listed below.

Data Type	Precision	Interpretation
Character	`uchar`	8-bit unsigned character
	`schar`	8-bit signed character
	`char`	8-bit signed or unsigned character

Data Type	Precision	Interpretation
Integer	int8	8-bit integer
	int16	16-bit integer
	int32	32-bit integer
	uint8	8-bit unsigned integer
	uint16	16-bit unsigned integer
	uint32	32-bit unsigned integer
	short	16-bit integer
	int	32-bit integer
	long	32- or 64-bit integer
	ushort	16-bit unsigned integer
	uint	32-bit unsigned integer
	ulong	32- or 64-bit unsigned integer
Floating-point	single	32-bit floating point
	float32	32-bit floating point
	float	32-bit floating point
	double	64-bit floating point
	float64	64-bit floating point

Purpose

(Will be removed) Facets referenced by only one simplex

Note `freeBoundary(TriRep)` will be removed in a future release. Use `freeBoundary(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
FF = freeBoundary(TR)
[FF XF] = freeBoundary(TR)
```

Description

`FF = freeBoundary(TR)` returns a matrix `FF` that represents the free boundary facets of the triangulation. A facet is on the free boundary if it is referenced by only one simplex (triangle/tetrahedron, etc). `FF` is of size `m`-by-`n`, where `m` is the number of boundary facets and `n` is the number of vertices per facet. The vertices of the facets index into the array of points representing the vertex coordinates `TR.X`. The array `FF` could be empty as in the case of a triangular mesh representing the surface of a sphere.

`[FF XF] = freeBoundary(TR)` returns a matrix of free boundary facets

Input Arguments

`TR`	Triangulation representation.

Output Arguments

`FF`	`FF` that has vertices defined in terms of a compact array of coordinates `XF`.
`XF`	`XF` is of size `m`-by-`ndim` where `m` is the number of free facets, and `ndim` is the dimension of the space where the triangulation resides

Definitions

A *simplex* is a triangle/tetrahedron or higher-dimensional equivalent. A *facet* is an edge of a triangle or a face of a tetrahedron.

Examples

Example 1

Use `TriRep` to compute the boundary triangulation of an imported triangulation.

Load a 3-D triangulation:

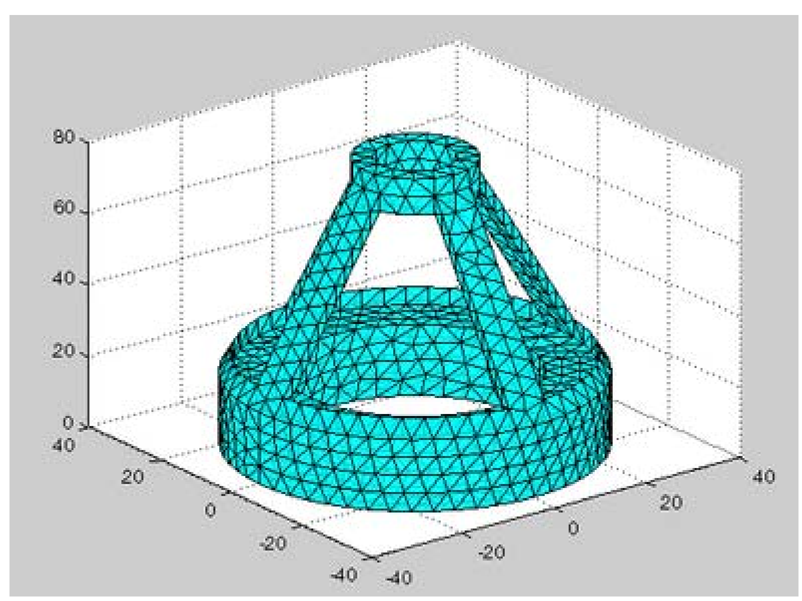
```
load tetmesh;
trep = TriRep(tet, X);
```

Compute the boundary triangulation:

```
 [tri xf] = freeBoundary(trep);
```

Plot the boundary triangulation:

```
trisurf(tri, xf(:,1),xf(:,2),xf(:,3), ...
     'FaceColor','cyan', 'FaceAlpha', 0.8);
```



Example 2

Perform a direct query of a 2-D triangulation created with `DelaunayTri`.

Plot the mesh:

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y);
fe = freeBoundary(dt)';
triplot(dt);
hold on;
```

Display the free boundary edges in red:

```
plot(x(fe), y(fe), '-r', 'LineWidth',2) ;
hold off;
```

In this instance the free edges correspond to the convex hull of `(x, y)`.

delaunayTriangulation | convexHull | featureEdges | faceNormal | triangulation

Purpose

Frequency spacing for frequency response

Syntax

```
[f1,f2] = freqspace(n)
[f1,f2] = freqspace([m n])
[x1,y1] = freqspace(...,'meshgrid')
f = freqspace(N)
f = freqspace(N,'whole')
```

Description

`freqspace` returns the implied frequency range for equally spaced frequency responses. `freqspace` is useful when creating desired frequency responses for various one- and two-dimensional applications.

`[f1,f2] = freqspace(n)` returns the two-dimensional frequency vectors `f1` and `f2` for an `n`-by-`n` matrix.

For `n` odd, both `f1` and `f2` are `[-n+1:2:n-1]/n`.

For `n` even, both `f1` and `f2` are `[-n:2:n-2]/n`.

`[f1,f2] = freqspace([m n])` returns the two-dimensional frequency vectors `f1` and `f2` for an `m`-by-`n` matrix.

`[x1,y1] = freqspace(...,'meshgrid')` is equivalent to

```
[f1,f2] = freqspace(...);
[x1,y1] = meshgrid(f1,f2);
```

`f = freqspace(N)` returns the one-dimensional frequency vector `f` assuming `N` evenly spaced points around the unit circle. For `N` even or odd, `f` is `(0:2/N:1)`. For `N` even, `freqspace` therefore returns `(N+2)/2` points. For `N` odd, it returns `(N+1)/2` points.

`f = freqspace(N,'whole')` returns `N` evenly spaced points around the whole unit circle. In this case, `f` is `0:2/N:2*(N-1)/N`.

See Also

`meshgrid`

frewind

Purpose

Move file position indicator to beginning of open file

Syntax

`frewind(fileID)`

Description

`frewind(fileID)` sets the file position indicator to the beginning of a file. *`fileID`* is an integer file identifier obtained from `fopen`.

If the file is on a tape device and the rewind operation fails, `frewind` does not return an error message.

Alternatives

`frewind(fileID)` is equivalent to:

```
fseek(fileID, 0, 'bof');
```

See Also

`fclose` | `feof` | `ferror` | `fopen` | `fseek` | `ftell` | `fscanf` | `fprintf` | `fread` | `fwrite`

Purpose

Read data from text file

Syntax

```
A = fscanf(fileID, format)
A = fscanf(fileID, format, sizeA)
[A, count] = fscanf(...)
```

Description

`A = fscanf(fileID, format)` reads and converts data from a text file into array *A* in column order. To convert, `fscanf` uses the *format* and the encoding scheme associated with the file. To set the encoding scheme, use `fopen`. The `fscanf` function reapplies the *format* throughout the entire file, and positions the file pointer at the end-of-file marker. If `fscanf` cannot match the *format* to the data, it reads only the portion that matches into *A* and stops processing.

`A = fscanf(fileID, format, sizeA)` reads *sizeA* elements into *A*, and positions the file pointer after the last element read. *sizeA* can be an integer, or can have the form `[m,n]`.

`[A, count] = fscanf(...)` returns the number of elements that `fscanf` successfully reads.

Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

Input Arguments

fileID

Integer file identifier obtained from `fopen`.

format

String enclosed in single quotation marks that describes each type of element (field). Includes one or more of the following specifiers.

Field Type	Specifier	Details
Integer, signed	`%d`	Base 10
	`%i`	Base determined from the values. Defaults to base 10. If initial digits are `0x` or `0X`, it is base 16. If initial digit is `0`, it is base 8.
	`%ld` or `%li`	64-bit values, base 10, 8, or 16
Integer, unsigned	`%u`	Base 10
	`%o`	Base 8 (octal)
	`%x`	Base 16 (hexadecimal)
	`%lu`, `%lo`, `%lx`	64-bit values, base 10, 8, or 16
Floating-point number	`%f`	Floating-point fields can contain any of the following (not case sensitive): `Inf`, `-Inf`, `NaN`, or `-NaN`.
	`%e`	
	`%g`	
Character string	`%s`	Read series of characters, until find white space.
	`%c`	Read any single character, including white space. (To read multiple characters, specify field length.)
	`%[...]`	Read only characters in the brackets, until the first nonmatching character or white space.

Optionally:

- To skip fields, insert an asterisk (`*`) after the percent sign (`%`). For example, to skip integers, specify `%*d`.

- To specify the maximum width of a field, insert a number. For example, `%10c` reads exactly 10 characters at a time, including white space.
- To skip a specific set of characters, insert the literal characters in the *format*. For example, to read only the floating-point number from `'pi=3.14159'`, specify a *format* of `'pi=%f'`.

sizeA

Dimensions of the output array *A*. Specify in one of the following forms:

`inf`	Read to the end of the file. (default)
n	Read at most *n* elements.
[*m*,*n*]	Read at most *m***n* elements in column order. *n* can be `inf`, but *m* cannot.

When the *format* includes `%s`, *A* can contain more than *n* columns. *n* refers to elements, not characters.

Output Arguments

A

An array. If the *format* includes:

- Only numeric specifiers, *A* is numeric. If *format* includes only 64-bit signed integer specifiers, *A* is of class `int64`. Similarly, if *format* includes only 64-bit unsigned integer specifiers, *A* is of class `uint64`. Otherwise, *A* is of class `double`. If *sizeA* is `inf` or *n*, then *A* is a column vector. If the input contains fewer than *sizeA* elements, MATLAB pads *A* with zeros.
- Only character or string specifiers (`%c` or `%s`), *A* is a character array. If *sizeA* is `inf` or *n*, *A* is a row vector. If the input contains fewer than *sizeA* characters, MATLAB pads *A* with `char(0)`.
- A combination of numeric and character specifiers, *A* is numeric, of class `double`. MATLAB converts each character to its numeric equivalent. This conversion occurs even when the *format* explicitly skips all numeric values (for example, a *format* of `'%*d %s'`).

If MATLAB cannot match the input to the *format*, and the *format* contains both numeric and character specifiers, *A* can be numeric or character. The class of *A* depends on the values MATLAB reads before processing stops.

count

The number of elements `fscanf` reads into *A*.

Examples

Read the contents of a file. `fscanf` reuses the *format* throughout the file, so you do not need a control loop:

```
% Create a file with an exponential table
x = 0:.1:1;
y = [x; exp(x)];

fid = fopen('exp.txt', 'w');
fprintf(fid, '%6.2f %12.8f\n', y);
fclose(fid);

% Read the data, filling A in column order
% First line of the file:
%    0.00    1.00000000

fid = fopen('exp.txt');
A = fscanf(fid, '%g %g', [2 inf]);
fclose(fid);

% Transpose so that A matches
% the orientation of the file
A = A';
```

Skip specific characters in a file, and return only numeric values:

```
% Create a file with temperatures
tempstr = '78 F 72 F 64 F 66 F 49 F';
```

```
fid = fopen('temperature.dat', 'w+');
fprintf(fid, '%s', tempstr);

% Return to the beginning of the file
frewind(fid);

% Read the numbers in the file, skipping the units
% num_temps is a numeric column vector

degrees = char(176);
num_temps = fscanf(fid, ['%d' degrees 'F']);

fclose(fid);
```

How To

- “Reading Data in a Formatted Pattern”
- “Opening Files with Different Character Encodings”

fscanf (serial)

Purpose

Read data from device, and format as text

Syntax

```
A = fscanf(obj)
A = fscanf(obj,'format')
A = fscanf(obj,'format',size)
[A,count] = fscanf(...)
[A,count,msg] = fscanf(...)
```

Description

`A = fscanf(obj)` reads data from the device connected to the serial port object, `obj`, and returns it to `A`. The data is converted to text using the `%c` format.

`A = fscanf(obj,'format')` reads data and converts it according to *`format`*. *`format`* is a C language conversion specification. Conversion specifications involve the `%` character and the conversion characters d, i, o, u, x, X, f, e, E, g, G, c, and s. Refer to the `sscanf` file I/O format specifications or a C manual for more information.

`A = fscanf(obj,'format',size)` reads the number of values specified by `size`. Valid options for `size` are:

`n`	Read at most `n` values into a column vector.
`[m,n]`	Read at most m-by-n values filling an m–by–n matrix in column order.

`size` cannot be `inf`, and an error is returned if the specified number of values cannot be stored in the input buffer. If `size` is not of the form `[m,n]`, and a character conversion is specified, then `A` is returned as a row vector. You specify the size, in bytes, of the input buffer with the `InputBufferSize` property. An ASCII value is one byte.

`[A,count] = fscanf(...)` returns the number of values read to `count`.

`[A,count,msg] = fscanf(...)` returns a warning message to `msg` if the read operation did not complete successfully.

Tips

Before you can read data from the device, it must be connected to obj with the fopen function. A connected serial port object has a Status property value of open. An error is returned if you attempt to perform a read operation while obj is not connected to the device.

If msg is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The ValuesReceived property value is increased by the number of values read – including the terminator – each time fscanf is issued.

If you use the help command to display help for fscanf, then you need to supply the pathname shown below.

```
help serial/fscanf
```

Rules for Completing a Read Operation with fscanf

A read operation with fscanf blocks access to the MATLAB command line until:

- The terminator specified by the Terminator property is read.
- The time specified by the Timeout property passes.
- The number of values specified by size is read.
- The input buffer is filled (unless size is specified)

Examples

Create the serial port object s and connect s to a Tektronix TDS 210 oscilloscope, which is displaying sine wave. This example works on a Windows platform.

```
s = serial('COM1');
fopen(s)
```

Use the fprintf function to configure the scope to measure the peak-to-peak voltage of the sine wave, return the measurement type, and return the peak-to-peak voltage.

```
fprintf(s,'MEASUREMENT:IMMED:TYPE PK2PK')
```

```
fprintf(s,'MEASUREMENT:IMMED:TYPE?')
fprintf(s,'MEASUREMENT:IMMED:VALUE?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data associated with the two query commands is automatically returned to the input buffer.

```
s.BytesAvailable
ans =
    21
```

Use `fscanf` to read the measurement type. The operation will complete when the first terminator is read.

```
meas = fscanf(s)
meas =
PK2PK
```

Use `fscanf` to read the peak-to-peak voltage as a floating-point number, and exclude the terminator.

```
pk2pk = fscanf(s,'%e',14)
pk2pk =
    2.0200
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

See Also

`fgetl` | `fgets` | `fopen` | `fread` | `textscan` | `BytesAvailable` | `BytesAvailableFcn` | `InputBufferSize` | `Status` | `Terminator` | `Timeout`

Purpose

Move to specified position in file

Syntax

```
fseek(fileID, offset, origin)
status = fseek(fileID, offset, origin)
```

Description

`fseek(fileID, offset, origin)` sets the file position indicator *`offset`* bytes from *`origin`* in the specified file.

`status = fseek(fileID, offset, origin)` returns `0` when the operation is successful. Otherwise, it returns `-1`.

Input Arguments

fileID

Integer file identifier obtained from `fopen`.

offset

Number of bytes to move from `origin`. Can be positive, negative, or zero. The *n* bytes of a given file are in positions `0` through *n*`-1`.

origin

Starting location in the file:

`'bof'` or `-1`	Beginning of file
`'cof'` or `0`	Current position in file
`'eof'` or `1`	End of file

Examples

Copy 5 bytes from the file `test1.dat`, starting at the tenth byte, and append to the end of `test2.dat`:

```
% Create files test1.dat and test2.dat
% Each character uses 8 bits (1 byte)

fid1 = fopen('test1.dat', 'w+');
fwrite(fid1, 'ABCDEFGHIJKLMNOPQRSTUVWXYZ');
```

```
fid2 = fopen('test2.dat', 'w+');
fwrite(fid2, 'Second File');

% Seek to the 10th byte ('J'), read 5
fseek(fid1, 9, 'bof');
A = fread(fid1, 5, 'uint8=>char');
fclose(fid1);

% Append to test2.dat
fseek(fid2, 0, 'eof');
fwrite(fid2, A);
fclose(fid2);
```

Alternatives

To move to the beginning of a file, call

```
frewind(fileID)
```

This call is identical to

```
fseek(fileID, 0, 'bof')
```

How To

- “Reading Portions of a File”

Purpose

Position in open file

Syntax

`position = ftell(fileID)`

Description

position = ftell(*fileID*) returns the current position in the specified file. *position* is a zero-based integer that indicates the number of bytes from the beginning of the file. If the query is unsuccessful, *position* is -1. *fileID* is an integer file identifier obtained from fopen.

See Also

fclose | feof | ferror | fopen | frewind | fseek | fscanf | fprintf | fread | fwrite

Purpose

Connect to FTP server

Description

Connect to an FTP server by calling the `ftp` function, which creates an FTP object. Perform file operations using methods on the FTP object, such as `mput` and `mget`. When you finish accessing the server, call the `close` method to close the connection.

Construction

`f = ftp(host,username,password)` connects to the FTP server `host` and creates FTP object `f`. If the host supports anonymous connections, you can use the `host` argument alone. To specify an alternate port, separate it from `host` with a colon (`:`).

Input Arguments

host

String enclosed in single quotation marks that specifies the FTP server.

username

String enclosed in single quotation marks that specifies your user name for the FTP server.

password

String enclosed in single quotation marks that specifies your password for the FTP server. Because FTP is not a secure protocol, others can see your user name and password.

Methods

ascii	Set FTP transfer type to ASCII
binary	Set FTP transfer type to binary
cd	Change or view current folder on FTP server
close	Close connection to FTP server
delete	Remove file on FTP server

dir	View contents of folder on FTP server
mget	Download files from FTP server
mkdir	Create folder on FTP server
mput	Upload file or folder to FTP server
rename	Rename file on FTP server
rmdir	Remove folder on FTP server

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Connect to the MathWorks FTP server, and display the FTP object:

```
mw=ftp('ftp.mathworks.com');
disp(mw)
```

MATLAB returns:

```
FTP Object
  host: ftp.mathworks.com
  user: anonymous
   dir: /
  mode: binary
```

Connect to port 34 (not supported at `ftp.mathworks.com`, so this code returns an error):

```
mw=ftp('ftp.mathworks.com:34')
```

Modify the following code to connect to a host that requires a password:

```
test=ftp('ftp.testsite.com','myname','mypassword')
```

Algorithms

The `ftp` function is based on code from the Apache Jakarta Project.

`urlwrite`

How To

- "Specify Proxy Server Settings for Connecting to the Internet"

Purpose

Convert sparse matrix to full matrix

Syntax

```
A = full(S)
```

Description

`A = full(S)` converts a sparse matrix `S` to full storage organization. If `S` is a full matrix, it is left unchanged. If `A` is full, `issparse(A)` is `0`.

Tips

If `X` is an `m`-by-`n` matrix with `nz` nonzero elements then `full(X)` requires space to store `m*n` elements. On the other hand, `sparse(X)` requires space to store `nz` elements and `(nz+n+1)` integers.

The density of a matrix (`nnz(X)/numel(X)`) determines whether or not it is more efficient to store the matrix as sparse or full. The exact crossover point depends on the matrix class as well as the platform. For example, in 32-bit MATLAB, a double sparse matrix with less than about 2/3 density will require less space than the same matrix in full storage. In 64-bit MATLAB, however, double matrices with less than half of their elements nonzero are more efficient to store as sparse matrices.

Examples

Here is an example of a sparse matrix with a density of about two-thirds. `sparse(S)` and `full(S)` require about the same number of bytes of storage.

```
S = sparse(+(rand(200,200) < 2/3));
A = full(S);
whos
Name    Size    Bytes     Class
  A    200X200 320000 double array
  S    200X200 318432 double array (sparse)
```

See Also

`issparse` | `sparse`

fullfile

Purpose

Build full file name from parts

Syntax

```
f = fullfile(filepart1,...,filepartN)
```

Description

`f = fullfile(filepart1,...,filepartN)` builds a full file specification, `f`, from the folders and file names specified. `fullfile` inserts platform-dependent file separators where necessary, and does not add a trailing file separator. The output of `fullfile` is conceptually equivalent to

```
f = [filepart1 filesep filepart2 filesep ... filesep filepartN]
```

Input Arguments

filepart1,...,filepartN - Folder and file names

strings | cell arrays of strings

Folder and file names, specified as strings and cell arrays of strings. Any nonscalar cell arrays must be of the same size.

Example: `'folder1','folder2','myfile.m'`

Example:
`{'folder1';'folder2'},{'subfolder1';'subfolder2'},'myfile.m'`

Examples

Create a Full File Name

```
f = fullfile('myfolder','mysubfolder','myfile.m')
```

```
f =
myfolder\mysubfolder\myfile.m
```

`fullfile` returns a string containing the full path to the file. On Windows platforms, the file separator character is a backslash, `\`. On other platforms, the file separator might be a different character.

Create Paths to Multiple Files

```
f = fullfile(toolboxdir('matlab'),'iofun',{'filesep.m';'fullfile.m'});
```

`fullfile` returns a cell array containing a path to the file `filesep.m`, and a path to the file `fullfile.m`.

Create a Path to a Folder

```
f = fullfile(matlabroot,'toolbox','matlab',filesep);
```

`fullfile` does not trim a leading or trailing `filesep`.

See Also

`fileparts` | `filesep` | `path` | `pathsep` | `genpath`

Purpose

Construct function name string from function handle

Syntax

```
func2str(fhandle)
```

Description

`func2str(fhandle)` constructs a string `s` that holds the name of the function to which the function handle `fhandle` belongs.

When you need to perform a string operation, such as compare or display, on a function handle, you can use `func2str` to construct a string bearing the function name.

The `func2str` command does not operate on nonscalar function handles. Passing a nonscalar function handle to `func2str` results in an error.

Tips

Any variables and their values originally stored in a function handle when it was created are lost if you convert the function handle to a string and back again using the `func2str` and `str2func` functions.

Examples

Example 1

Convert a `sin` function handle to a string:

```
fhandle = @sin;

func2str(fhandle)
ans =
    sin
```

Example 2

The `catcherr` function shown here accepts function handle and data arguments and attempts to evaluate the function through its handle. If the function fails to execute, `catcherr` uses `sprintf` to display an error message giving the name of the failing function. The function name must be a string for `sprintf` to display it. The code derives the function name from the function handle using `func2str`:

```
function catcherr(func, data)
try
```

```
    ans = func(data);
    disp('Answer is:');
    ans
catch
    disp(sprintf('Error executing function ''%s''\n', ...
        func2str(func)))
end
```

The first call to `catcherr` passes a handle to the `round` function and a valid data argument. This call succeeds and returns the expected answer. The second call passes the same function handle and an improper data type (a MATLAB structure). This time, `round` fails, causing `catcherr` to display an error message that includes the failing function name:

```
catcherr(@round, 5.432)
ans =
Answer is 5

xstruct.value = 5.432;
catcherr(@round, xstruct)
Error executing function "round"
```

See Also

`function_handle` | `str2func` | `functions`

function

Purpose

Declare function name, inputs, and outputs

Syntax

```
function [y1,...,yN] = myfun(x1,...,xM)
```

Description

`function [y1,...,yN] = myfun(x1,...,xM)` declares a function named `myfun` that accepts inputs `x1,...,xM` and returns outputs `y1,...,yN`. This declaration statement must be the first executable line of the function.

Save the function code in a text file with a `.m` extension. The name of the file should match the name of the first function in the file. Valid function names begin with an alphabetic character, and can contain letters, numbers, or underscores.

You can declare multiple local functions within the same file, or nest functions. If any function in a file contains a nested function, all functions in the file must use the `end` keyword to indicate the end of the function. Otherwise, the `end` keyword is optional.

Examples

Function with One Output

Define a function in a file named `average.m` that accepts an input vector, calculates the average of the values, and returns a single result.

```
function y = average(x)
if ~isvector(x)
    error('Input must be a vector')
end
y = sum(x)/length(x);
```

Call the function from the command line.

```
z = 1:99;
average(z)
```

```
ans =
    50
```

Function with Multiple Outputs

Define a function in a file named `stat.m` that returns the mean and standard deviation of an input vector.

```
function [m,s] = stat(x)
n = length(x);
m = sum(x)/n;
s = sqrt(sum((x-m).^2/n));
```

Call the function from the command line.

```
values = [12.7, 45.4, 98.9, 26.6, 53.1];
[ave,stdev] = stat(values)
```

```
ave =
   47.3400
stdev =
   29.4124
```

Multiple Functions in a File

Define two functions in a file named `stat2.m`, where the first function calls the second.

```
function [m,s] = stat2(x)
n = length(x);
m = avg(x,n);
s = sqrt(sum((x-m).^2/n));
end

function m = avg(x,n)
m = sum(x)/n;
end
```

Function `avg` is a *local function*. Local functions are only available to other functions within the same file.

Call function `stat2` from the command line.

```
values = [12.7, 45.4, 98.9, 26.6, 53.1];
[ave,stdev] = stat2(values)

ave =
   47.3400
stdev =
   29.4124
```

Purpose

Handle used in calling functions indirectly

Syntax

```
handle = @functionname
handle = @(arglist)anonymous_function
```

Description

`handle = @functionname` returns a handle to the specified MATLAB function.

A function handle is a MATLAB value that provides a means of calling a function indirectly. You can pass function handles in calls to other functions (often called *function functions*). You can also store function handles in data structures for later use (for example, as Handle Graphics callbacks). A function handle is one of the standard MATLAB data types.

At the time you create a function handle, the function you specify must be on the MATLAB path and in the current scope of the code creating the handle. For example, you can create a handle to a local function as long as you do so from within the file that defines that local function. This condition does not apply when you evaluate the function handle. You can, for example, execute a local function from a separate (out-of-scope) file using a function handle. This requires that the handle was created by the local function (in-scope).

`handle = @(arglist)anonymous_function` constructs an anonymous function and returns a `handle` to that function. The body of the function, to the right of the parentheses, is a single MATLAB statement or command. `arglist` is a comma-separated list of input arguments. Execute the function by calling it by means of the function handle, `handle`.

Tips

The function handle is a standard MATLAB data type. As such, you can manipulate and operate on function handles in the same manner as on other MATLAB data types. This includes using function handles in structures and cell arrays:

```
S.a = @sin;  S.b = @cos;  S.c = @tan;
C = {@sin, @cos, @tan};
```

However, standard matrices or arrays of function handles are not supported:

```
A = [@sin, @cos, @tan];        % This is not supported
```

For nonoverloaded functions, local functions, and private functions, a function handle references just the one function specified in the `@functionname` syntax. When you evaluate an overloaded function by means of its handle, the arguments the handle is evaluated with determine the actual function that MATLAB dispatches to.

Use `isa(h, 'function_handle')` to see if variable `h` is a function handle.

Examples

Example 1 — Constructing a Handle to a Named Function

The following example creates a function handle for the `humps` function and assigns it to the variable `fhandle`.

```
fhandle = @humps;
```

Pass the handle to another function in the same way you would pass any argument. This example passes the function handle just created to `fminbnd`, which then minimizes over the interval `[0.3, 1]`.

```
x = fminbnd(fhandle, 0.3, 1)
x =
    0.6370
```

The `fminbnd` function evaluates the `@humps` function handle. A small portion of the `fminbnd` file is shown below. In line 1, the `funfcn` input parameter receives the function handle `@humps` that was passed in. The statement, in line 113, evaluates the handle.

```
1    function [xf,fval,exitflag,output] = ...
         fminbnd(funfcn,ax,bx,options,varargin)
             .
             .
             .
```

```
113  fx = funfcn(x,varargin{:});
```

Example 2 — Constructing a Handle to an Anonymous Function

The statement below creates an anonymous function that finds the square of a number. When you call this function, MATLAB assigns the value you pass in to variable `x`, and then uses `x` in the equation `x.^2`:

```
sqr = @(x) x.^2;
```

The `@` operator constructs a function handle for this function, and assigns the handle to the output variable `sqr`. As with any function handle, you execute the function associated with it by specifying the variable that contains the handle, followed by a comma-separated argument list in parentheses. The syntax is

```
fhandle(arg1, arg2, ..., argN)
```

To execute the `sqr` function defined above, type

```
a = sqr(5)
a =
   25
```

Because `sqr` is a function handle, you can pass it in an argument list to other functions. The code shown here passes the `sqr` anonymous function to the MATLAB `integral` function to compute its integral from zero to one:

```
integral(sqr, 0, 1)
ans =
   0.3333
```

Example 3 — Using an Array of Function Handles

This example creates a structure array of function handles `S` and then applies each handle in the array to the output of a `linspace` calculation in one operation using `structfun`:

```
S.a = @sin;  S.b = @cos;  S.c = @tan;
```

```
structfun(@(x)x(linspace(1,4,3)), S, 'UniformOutput', false)
ans =
    a: [0.8415 0.5985 -0.7568]
    b: [0.5403 -0.8011 -0.6536]
    c: [1.5574 -0.7470 1.1578]
```

See Also

str2func | func2str | functions | isa

Purpose

Information about function handle

Syntax

```
S = functions(funhandle)
```

Description

`S = functions(funhandle)` returns, in MATLAB structure `S`, the function name, type, filename, and other information for the function handle stored in the variable `funhandle`.

`functions` does not operate on nonscalar function handles. Passing a nonscalar function handle to `functions` results in an error.

Caution The `functions` function is provided for querying and debugging purposes. Because its behavior may change in subsequent releases, you should not rely upon it for programming purposes.

This table lists the standard fields of the return structure.

Field Name	Field Description
`function`	Function name
`type`	Function type (e.g., simple, overloaded)
`file`	The file to be executed when the function handle is evaluated with a nonoverloaded data type

Examples

Example 1

To obtain information on a function handle for the `poly` function, type

```
f = functions(@poly)
f =
    function: 'poly'
        type: 'simple'
        file:  '$matlabroot\toolbox\matlab\polyfun\poly.m'
```

(The term `$matlabroot` used in this example stands for the file specification of the directory in which MATLAB software is installed for your system. Your output will display this file specification.)

Access individual fields of the returned structure using dot selection notation:

```
f.type
ans =
   simple
```

Example 2

The function `get_handles` returns function handles for a local function and private function in output arguments `l` and `p` respectively:

```
function [l, p] = get_handles
l = @mylocfun;
p = @myprivatefun;
%
function mylocfun
disp 'Executing local function mylocfun'
```

Call `get_handles` to obtain the two function handles, and then pass each to the `functions` function. MATLAB returns information in a structure having the fields `function`, `type`, `file`, and `parentage`. The `file` field contains the file specification for the local or private function:

```
[floc fprv] = get_handles;

functions(floc)
ans =
     function: 'mylocfun'
         type: 'scopedfunction'
         file: 'c:\matlab\get_handles.m'
    parentage: {'mylocfun'  'get_handles'}

functions(fprv)
ans =
```

```
     function: 'myprivatefun'
         type: 'scopedfunction'
         file: 'c:\matlab\private\myprivatefun.m'
    parentage: {'myprivatefun'}
```

Example 3

In this example, the function `get_handles_nested.m` contains a nested function `nestfun`. This function has a single output which is a function handle to the nested function:

```
function handle = get_handles_nested(A)
nestfun(A);

   function y = nestfun(x)
   y = x + 1;
   end

handle = @nestfun;
end
```

Call this function to get the handle to the nested function. Use this handle as the input to `functions` to return the information shown here. Note that the `function` field of the return structure contains the names of the nested function and the function in which it is nested in the format. Also note that `functions` returns a `workspace` field containing the variables that are in context at the time you call this function by its handle:

```
fh = get_handles_nested(5);

fhinfo = functions(fh)
fhinfo =
     function: 'get_handles_nested/nestfun'
         type: 'nested'
         file: 'c:\matlab\get_handles_nested.m'
    workspace: [1x1 struct]

fhinfo.workspace
```

```
ans =
    handle: @get_handles_nested/nestfun
         A: 5
```

See Also function_handle

Purpose

Evaluate general matrix function

Syntax

```
F = funm(A,fun)
F = funm(A,fun,options)
F = funm(A,fun,options,p1,p2,...)
[F,exitflag] = funm(...)
[F,exitflag,output] = funm(...)
```

Description

`F = funm(A,fun)` evaluates the user-defined function `fun` at the square matrix argument `A`. `F = fun(x,k)` must accept a vector `x` and an integer `k`, and return a vector `f` of the same size of `x`, where `f(i)` is the `k`th derivative of the function `fun` evaluated at `x(i)`. The function represented by fun must have a Taylor series with an infinite radius of convergence, except for `fun = @log`, which is treated as a special case.

You can also use `funm` to evaluate the special functions listed in the following table at the matrix `A`.

Function	Syntax for Evaluating Function at Matrix A
`exp`	`funm(A, @exp)`
`log`	`funm(A, @log)`
`sin`	`funm(A, @sin)`
`cos`	`funm(A, @cos)`
`sinh`	`funm(A, @sinh)`
`cosh`	`funm(A, @cosh)`

For matrix square roots, use `sqrtm(A)` instead. For matrix exponentials, which of `expm(A)` or `funm(A, @exp)` is the more accurate depends on the matrix `A`.

The function represented by `fun` must have a Taylor series with an infinite radius of convergence. The exception is `@log`, which is treated as a special case. “Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`F = funm(A,fun,options)` sets the algorithm's parameters to the values in the structure `options`.

The following table lists the fields of `options`.

Field	Description	Values
`options.Display`	Level of display	`'off'` (default), `'on'`, `'verbose'`
`options.TolBlk`	Tolerance for blocking Schur form	Positive scalar. The default is `0.1`.
`options.TolTay`	Termination tolerance for evaluating the Taylor series of diagonal blocks	Positive scalar. The default is `eps`.
`options.MaxTerms`	Maximum number of Taylor series terms	Positive integer. The default is `250`.
`options.MaxSqrt`	When computing a logarithm, maximum number of square roots computed in inverse scaling and squaring method.	Positive integer. The default is `100`.
`options.Ord`	Specifies the ordering of the Schur form `T`.	A vector of length `length(A)`. `options.Ord(i)` is the index of the block into which `T(i,i)` is placed. The default is `[]`.

`F = funm(A,fun,options,p1,p2,...)` passes extra inputs `p1,p2,...` to the function.

`[F,exitflag] = funm(...)` returns a scalar `exitflag` that describes the exit condition of `funm`. `exitflag` can have the following values:

- `0` — The algorithm was successful.

- `1` — One or more Taylor series evaluations did not converge, or, in the case of a logarithm, too many square roots are needed. However, the computed value of `F` might still be accurate.

`[F,exitflag,output] = funm(...)` returns a structure `output` with the following fields:

Field	Description
`output.terms`	Vector for which `output.terms(i)` is the number of Taylor series terms used when evaluating the *i*th block, or, in the case of the logarithm, the number of square roots of matrices of dimension greater than 2.
`output.ind`	Cell array for which the `(i,j)` block of the reordered Schur factor `T` is `T(output.ind{i}, output.ind{j})`.
`output.ord`	Ordering of the Schur form, as passed to `ordschur`
`output.T`	Reordered Schur form

If the Schur form is diagonal then `output = struct('terms',ones(n,1),'ind',{1:n})`.

Examples

Example 1

The following command computes the matrix sine of the 3-by-3 magic matrix.

```
F=funm(magic(3), @sin)

F =

   -0.3850    1.0191    0.0162
    0.6179    0.2168   -0.1844
    0.4173   -0.5856    0.8185
```

Example 2

The statements

```
S = funm(X,@sin);
C = funm(X,@cos);
```

produce the same results to within roundoff error as

```
E = expm(i*X);
C = real(E);
S = imag(E);
```

In either case, the results satisfy `S*S+C*C = I`, where `I = eye(size(X))`.

Example 3

To compute the function `exp(x) + cos(x)` at `A` with one call to `funm`, use

```
F = funm(A,@fun_expcos)
```

where `fun_expcos` is the following function.

```
function f = fun_expcos(x, k)
% Return kth derivative of exp + cos at X.
        g = mod(ceil(k/2),2);
        if mod(k,2)
           f = exp(x) + sin(x)*(-1)^g;
        else
           f = exp(x) + cos(x)*(-1)^g;
        end
```

Algorithms

The algorithm `funm` uses is described in [1].

`expm` | `logm` | `sqrtm` | `function_handle`

Purpose

Write data to binary file

Syntax

```
fwrite(fileID, A)
fwrite(fileID, A, precision)
fwrite(fileID, A, precision, skip)
fwrite(fileID, A, precision, skip, machineformat)
count = fwrite(...)
```

Description

`fwrite(fileID, A)` writes the elements of array *A* to a binary file in column order.

`fwrite(fileID, A, precision)` translates the values of *A* according to the form and size described by the *precision*.

`fwrite(fileID, A, precision, skip)` skips *skip* bytes before writing each value. If *precision* is `bitn` or `ubitn`, specify *skip* in bits.

`fwrite(fileID, A, precision, skip, machineformat)` writes data with the specified *machineformat*. The *skip* parameter is optional.

`count = fwrite(...)` returns the number of elements of *A* that `fwrite` successfully writes to the file.

Input Arguments

fileID

File identifier, specified as one of the following:

- A file identifier obtained from `fopen`.
- `1` for standard output (the screen).
- `2` for standard error.

A

Numeric or character array.

precision

String in single quotation marks that controls the form and size of the output. The following table shows possible values for *precision*.

Value Type	Precision	Bits (Bytes)
Integers, unsigned	uint	32 (4)
	uint8	8 (1)
	uint16	16 (2)
	uint32	32 (4)
	uint64	64 (8)
	uchar	8 (1)
	unsigned char	8 (1)
	ushort	16 (2)
	ulong	system-dependent
	ubit*n*	$1 \leq n \leq 64$
Integers, signed	int	32 (4)
	int8	8 (1)
	int16	16 (2)
	int32	32 (4)
	int64	64 (8)
	integer*1	8 (1)
	integer*2	16 (2)
	integer*4	32 (4)
	integer*8	64 (8)
	schar	8 (1)
	signed char	8 (1)
	short	16 (2)
	long	system-dependent
	bit*n*	$1 \leq n \leq 64$

Value Type	Precision	Bits (Bytes)
Floating-point numbers	`single`	`32 (4)`
	`double`	`64 (8)`
	`float`	`32 (4)`
	`float32`	`32 (4)`
	`float64`	`64 (8)`
	`real*4`	`32 (4)`
	`real*8`	`64 (8)`
Characters	`char*1`	`8 (1)`
	`char`	Depends on the encoding scheme associated with the file. Set encoding with `fopen`.

On 32-bit systems, `long` and `ulong` are 32 bits. On 64-bit systems, the sizes of `long` and `ulong` correspond to the data model that the C compiler uses: 32 bits on Microsoft Windows systems, 64 bits on other 64-bit systems.

If you specify a precision of `bit`*n* or `ubit`*n*, and a value is out of range, `fwrite` sets all bits for that value.

Default: `uint8`

skip

Number of bytes to skip before writing each value. If you specify a *`precision`* of `bit`*n* or `ubit`*n*, specify *`skip`* in bits. Use this parameter to insert data into noncontiguous fields in fixed-length records.

Default: `0`

machineformat

String that specifies the order for writing bytes within the file. For `bitn` and `ubitn` precisions, specifies the order for writing bits within a byte.

Possible values are:

`'n'` or `'native'`	The byte ordering that your system uses (default)
`'b'` or `'ieee-be'`	Big-endian ordering
`'l'` or `'ieee-le'`	Little-endian ordering
`'s'` or `'ieee-be.l64'`	Big-endian ordering, 64-bit long data type
`'a'` or `'ieee-le.l64'`	Little-endian ordering, 64-bit long data type

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big- or little-endian ordering.

Examples

Create a 100-byte binary file containing the 25 elements of the 5-by-5 magic square, stored as 4-byte integers:

```
fid = fopen('magic5.bin', 'w');
fwrite(fid, magic(5), 'integer*4');
fclose(fid);
```

How To

- “Overwriting or Appending to an Existing File”
- “Creating a File for Use on a Different System”
- “Writing and Reading Complex Numbers”

fwrite (serial)

Purpose

Write binary data to device

Syntax

```
fwrite(obj,A)
fwrite(obj,A,'precision')
fwrite(obj,A,'mode')
fwrite(obj,A,'precision','mode')
```

Description

`fwrite(obj,A)` writes the binary data `A` to the device connected to the serial port object, `obj`.

`fwrite(obj,A,'precision')` writes binary data with precision specified by *`precision`*.

`precision` controls the number of bits written for each value and the interpretation of those bits as integer, floating-point, or character values. If *`precision`* is not specified, `uchar` (an 8-bit unsigned character) is used. The supported values for *`precision`* are listed below in Tips.

`fwrite(obj,A,'mode')` writes binary data with command line access specified by *`mode`*. If *`mode`* is `sync`, `A` is written synchronously and the command line is blocked. If *`mode`* is `async`, `A` is written asynchronously and the command line is not blocked. If *`mode`* is not specified, the write operation is synchronous.

`fwrite(obj,A,'precision','mode')` writes binary data with precision specified by *`precision`* and command line access specified by *`mode`*.

Tips

Before you can write data to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a write operation while `obj` is not connected to the device.

The `ValuesSent` property value is increased by the number of values written each time `fwrite` is issued.

An error occurs if the output buffer cannot hold all the data to be written. You can specify the size of the output buffer with the `OutputBufferSize` property.

If you use the `help` command to display help for `fwrite`, then you need to supply the pathname shown below.

```
help serial/fwrite
```

`fwrite` will return an error message if you set the `FlowControl` property to `hardware` on a serial object, and a hardware connection is not detected. This occurs if a device is not connected, or a connected device is not asserting that is ready to receive data. Check you remote device's status and flow control settings to see if hardware flow control is causing errors in MATLAB.

Note If you want to check to see if the device is asserting that it is ready to receive data, set the `FlowControl` to `none`. Once you connect to the device check the `PinStatus` structure for `ClearToSend`. If `ClearToSend` is `off`, there is a problem on the remote device side. If `ClearToSend` is `on`, there is a hardware `FlowControl` device prepared to receive data and you can execute `fwrite`.

Synchronous Versus Asynchronous Write Operations

By default, data is written to the device synchronously and the command line is blocked until the operation completes. You can perform an asynchronous write by configuring the *`mode`* input argument to be `async`. For asynchronous writes:

- The `BytesToOutput` property value is continuously updated to reflect the number of bytes in the output buffer.
- The callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

You can determine whether an asynchronous write operation is in progress with the `TransferStatus` property.

Synchronous and asynchronous write operations are discussed in more detail in Writing Data.

Rules for Completing a Write Operation with fwrite

A binary write operation using `fwrite` completes when:

- The specified data is written.
- The time specified by the `Timeout` property passes.

> **Note** The `Terminator` property is not used with binary write operations.

Supported Precisions

The supported values for *`precision`* are listed below.

Data Type	Precision	Interpretation
Character	`uchar`	8-bit unsigned character
	`schar`	8-bit signed character
	`char`	8-bit signed or unsigned character
Integer	`int8`	8-bit integer
	`int16`	16-bit integer
	`int32`	32-bit integer
	`uint8`	8-bit unsigned integer
	`uint16`	16-bit unsigned integer
	`uint32`	32-bit unsigned integer
	`short`	16-bit integer
	`int`	32-bit integer
	`long`	32- or 64-bit integer
	`ushort`	16-bit unsigned integer
	`uint`	32-bit unsigned integer

Data Type	Precision	Interpretation
	ulong	32- or 64-bit unsigned integer
Floating-point	single	32-bit floating point
	float32	32-bit floating point
	float	32-bit floating point
	double	64-bit floating point
	float64	64-bit floating point

fzero

Purpose

Root of nonlinear function

Syntax

```
x = fzero(fun,x0)
x = fzero(fun,x0,options)

x = fzero(problem)

[x,fval,exitflag,output] = fzero( ___ )
```

Description

`x = fzero(fun,x0)` tries to find a point `x` where `fun(x) = 0`. This solution is where `fun(x)` changes sign—`fzero` cannot find a root of a function such as `x^2`.

`x = fzero(fun,x0,options)` uses `options` to modify the solution process.

`x = fzero(problem)` solves a root-finding problem specified by `problem`.

`[x,fval,exitflag,output] = fzero( ___ )` returns `fun(x)` in the `fval` output, `exitflag` encoding the reason `fzero` stopped, and an output structure containing information on the solution process.

Input Arguments

fun - Function to solve

function handle

Function to solve, specified as a handle to a scalar-valued function. `fun` accepts a scalar `x` and returns a scalar `fun(x)`.

`fzero` solves `fun(x) = 0`. To solve an equation `fun(x) = c(x)`, instead solve `fun2(x) = fun(x) - c(x) = 0`.

To include extra parameters in your function, see the example "Root of Function with Extra Parameter" on page 1-1895 and the section "Parameterizing Functions".

Example: `@sin`

Example: `@myFunction`

Example: `@(x)(x-a)^5 - 3*x + a - 1`

Data Types
`function_handle`

x0 - Initial value

scalar | 2-element vector

Initial value, specified as a real scalar or a 2-element real vector.

- Scalar — `fzero` begins at `x0` and tries to locate a point `x1` where `fun(x1)` has the opposite sign of `fun(x0)`. Then `fzero` iteratively shrinks the interval where `fun` changes sign to reach a solution.
- 2-element vector — `fzero` checks that `fun(x0(1))` and `fun(x0(2))` have opposite signs, and errors if they do not. It then iteratively shrinks the interval where `fun` changes sign to reach a solution. An interval `x0` must be finite; it cannot contain ±`Inf`.

Tip Calling `fzero` with an interval (`x0` with two elements) is often faster than calling it with a scalar `x0`.

Example: 3

Example: [2,17]

Data Types
`double`

options - Options for solution process

Options for solution process, specified as a structure. Create or modify the `options` structure using `optimset`. `fzero` uses these `options` structure fields.

`Display`	Level of display: • `'off'` displays no output. • `'iter'` displays output at each iteration. • `'final'` displays just the final output. • `'notify'` (default) displays output only if the function does not converge.
`FunValCheck`	Check whether objective function values are valid. • `'on'` displays an error when the objective function returns a value that is `complex`, `Inf`, or `NaN`. • The default, `'off'`, displays no error.
`OutputFcn`	Specify one or more user-defined functions that an optimization function calls at each iteration, either as a function handle or as a cell array of function handles. The default is none (`[]`). See "Output Functions".
`PlotFcns`	Plot various measures of progress while the algorithm executes. Select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none (`[]`). • `@optimplotx` plots the current point. • `@optimplotfval` plots the function value. For information on writing a custom plot function, see "Plot Functions".
`TolX`	Termination tolerance on `x`, a positive scalar. The default is `eps`, 2.2204e–16.

Example: `options = optimset('FunValCheck','on')`

Data Types
`struct`

problem - Root-finding problem

Root-finding problem, specified as a structure with all of the following fields.

`objective`	Objective function
`x0`	Initial point for `x`, real scalar or 2-element vector
`solver`	`'fzero'`
`options`	Options structure created with `optimset`

For an example, see "Solve Problem Structure" on page 1-1897.

Data Types
`struct`

Output Arguments

x - Location of root or sign change

Real scalar

Location of root or sign change, returned as a scalar.

fval - Function value at `x`

Real scalar

Function value at `x`, returned as a scalar.

exitflag - Integer encoding the exit condition

Integer encoding the exit condition, meaning the reason `fsolve` stopped its iterations.

`1`	Function converged to a solution `x`.
`-1`	Algorithm was terminated by the output function or plot function.
`-3`	`NaN` or `Inf` function value was encountered while searching for an interval containing a sign change.

`-4`	Complex function value was encountered while searching for an interval containing a sign change.
`-5`	Algorithm might have converged to a singular point.
`-6`	`fzero` did not detect a sign change.

output - Information about root-finding process

Information about root-finding process, returned as a structure. The fields of the structure are:

`intervaliterations`	Number of iterations taken to find an interval containing a root
`iterations`	Number of zero-finding iterations
`funcCount`	Number of function evaluations
`algorithm`	`'bisection, interpolation'`
`message`	Exit message

Examples

Root Starting From One Point

Calculate π by finding the zero of the sine function near 3.

```
fun = @sin; % function
x0 = 3; % initial point
x = fzero(fun,x0)
```

```
x =
    3.1416
```

Root Starting From an Interval

Find the zero of cosine between 1 and 2.

```
fun = @cos; % function
x = [1 2]; % initial interval
x = fzero(fun,x0)
```

```
x =
   1.5708
```

Note that `cos(1)` and `cos(2)` differ in sign.

Root of a Function Defined by a File

Find a zero of the function

$$f(x) = x^3 - 2x - 5.$$

First, write a file called `f.m`.

```
function y = f(x)
y = x.^3-2*x-5;
```

Save `f.m` on your MATLAB path.

Find the zero of $f(x)$ near `2`.

```
fun = @f; % function
x0 = 2; % initial point
z = fzero(fun,x0)

z =
    2.0946
```

Since `f(x)` is a polynomial, you can find the same real zero, and a complex conjugate pair of zeros, using the `roots` command.

```
roots([1 0 -2 -5])

   ans =
   2.0946
  -1.0473 + 1.1359i
  -1.0473 - 1.1359i
```

Root of Function with Extra Parameter

Find the root of a function that has an extra parameter.

```
myfun = @(x,c) cos(c*x);  % parameterized function
c = 2;                    % parameter
fun = @(x) myfun(x,c);    % function of x alone
x = fzero(fun,0.1)

x =

    0.7854
```

Nondefault Options

Plot the solution process by setting some plot functions.

Define the function and initial point.

```
fun = @(x)sin(cosh(x));
x0 = 1;
```

Examine the solution process by setting options that include plot functions.

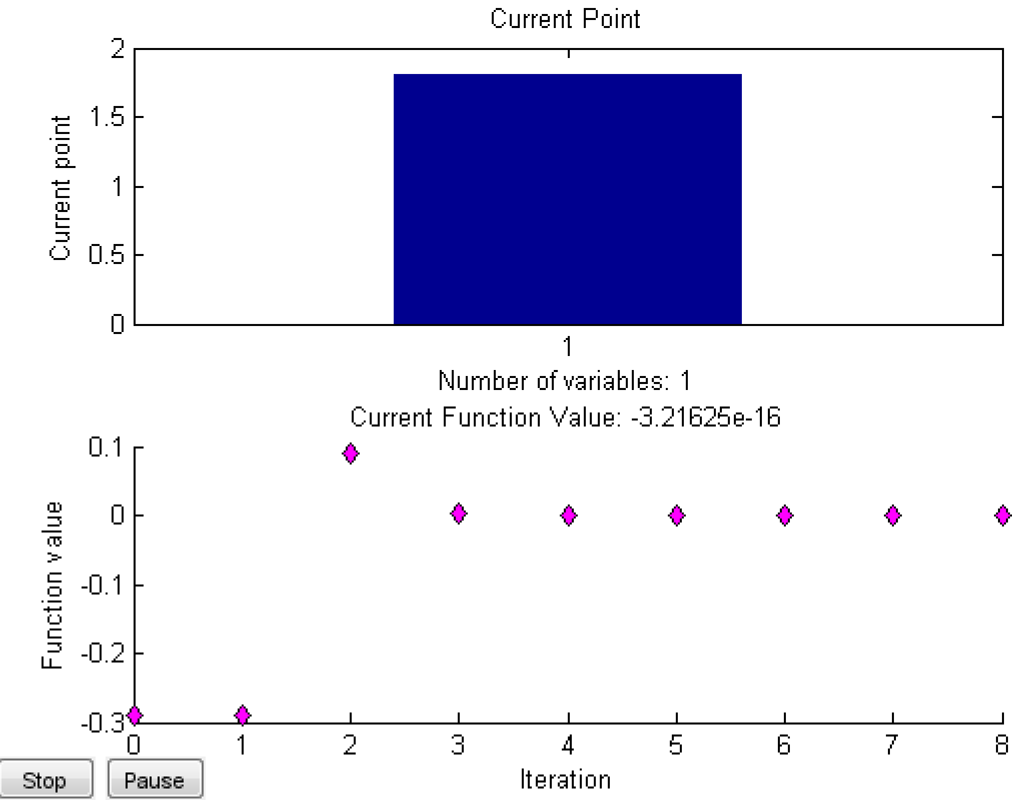
```
options = optimset('PlotFcns',{@optimplotx,@optimplotfval});
```

Run `fzero` including the options.

```
x = fzero(fun,x0,options)

x =

    1.8115
```



Solve Problem Structure

Solve a problem that is defined by a problem structure.

Define a structure that encodes a root-finding problem.

```
problem.objective = @(x)sin(cosh(x));
problem.x0 = 1;
problem.solver = 'fzero'; % a required part of the structure
problem.options = optimset(@fzero); % default options
```

Solve the problem.

```
x = fzero(problem)

x =

    1.8115
```

More Information from Solution

Find the point where `exp(-exp(-x)) = x`, and display information about the solution process.

```
fun = @(x) exp(-exp(-x)) - x; % function
x0 = [0 1]; % initial interval
options = optimset('Display','iter'); % show iterations
[x fval exitflag output] = fzero(fun,x0,options)
```

```
 Func-count    x          f(x)             Procedure
    2               1     -0.307799        initial
    3        0.544459     0.0153522        interpolation
    4        0.566101    0.00070708        interpolation
    5        0.567143  -1.40255e-08        interpolation
    6        0.567143   1.50013e-12        interpolation
    7        0.567143             0        interpolation

Zero found in the interval [0, 1]
x =
    0.5671
fval =
     0
exitflag =
     1
output =
    intervaliterations: 0
            iterations: 5
             funcCount: 7
             algorithm: 'bisection, interpolation'
               message: 'Zero found in the interval [0, 1]'
```

`fval` = 0 means `fun(x) = 0`, as desired.

Algorithms

The `fzero` command is a function file. The algorithm, created by T. Dekker, uses a combination of bisection, secant, and inverse quadratic interpolation methods. An Algol 60 version, with some improvements, is given in [1]. A Fortran version, upon which `fzero` is based, is in [2].

gallery

Purpose

Test matrices

Syntax

```
[A,B,C,...] = gallery(matname,P1,P2,...)
[A,B,C,...] = gallery(matname,P1,P2,...,classname)
gallery(3)
gallery(5)
```

Description

`[A,B,C,...] = gallery(matname,P1,P2,...)` returns the test matrices specified by the quoted string `matname`. The `matname` input is the name of a matrix family selected from the table below. `P1,P2,...` are input parameters required by the individual matrix family. The number of optional parameters `P1,P2,...` used in the calling syntax varies from matrix to matrix. The exact calling syntaxes are detailed in the individual matrix descriptions below.

`[A,B,C,...] = gallery(matname,P1,P2,...,classname)` produces a matrix of class `classname`. The `classname` input is a quoted string that must be either `'single'` or `'double'` (unless `matname` is `'integerdata'`, in which case `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, and `'uint32'` are also allowed). If `classname` is not specified, then the class of the matrix is determined from those arguments among `P1,P2,...` that do not specify dimensions or select an option. If any of these arguments is of class `single` then the matrix is `single`; otherwise the matrix is `double`.

`gallery(3)` is a badly conditioned 3-by-3 matrix and `gallery(5)` is an interesting eigenvalue problem.

The gallery holds over fifty different test matrix functions useful for testing algorithms and other purposes.

binomial — Multiple of involutory matrix

`A = gallery('binomial',n)` returns an `n`-by-`n` matrix,with integer entries such that `A^2 = 2^(n-1)*eye(n)`.

Thus, `B = A*2^((1-n)/2)` is involutory, that is, `B^2 = eye(n)`.

cauchy — Cauchy matrix

`C = gallery('cauchy',x,y)` returns an `n`-by-`n` matrix, `C(i,j) = 1/(x(i)+y(j))`. Arguments `x` and `y` are vectors of length `n`. If you pass in scalars for `x` and `y`, they are interpreted as vectors `1:x` and `1:y`.

`C = gallery('cauchy',x)` returns the same as above with `y = x`. That is, the command returns `C(i,j) = 1/(x(i)+x(j))`.

Explicit formulas are known for the inverse and determinant of a Cauchy matrix. The determinant `det(C)` is nonzero if `x` and `y` both have distinct elements. `C` is totally positive if `0 < x(1) <...  < x(n)` and `0 < y(1) < ...  < y(n)`.

chebspec — Chebyshev spectral differentiation matrix

`C = gallery('chebspec',n,switch)` returns a Chebyshev spectral differentiation matrix of order `n`. Argument `switch` is a variable that determines the character of the output matrix. By default, `switch` = `0`.

For `switch` = `0` (“no boundary conditions”), `C` is nilpotent (`C^n = 0`) and has the null vector `ones(n,1)`. The matrix `C` is similar to a Jordan block of size `n` with eigenvalue zero.

For `switch` = `1`, `C` is nonsingular and well-conditioned, and its eigenvalues have negative real parts.

The eigenvector matrix of the Chebyshev spectral differentiation matrix is ill-conditioned.

chebvand — Vandermonde-like matrix for the Chebyshev polynomials

`C = gallery('chebvand',p)` produces the (primal) Chebyshev Vandermonde matrix based on the vector of points `p`, which define where the Chebyshev polynomial is calculated.

`C = gallery('chebvand',m,p)` where `m` is scalar, produces a rectangular version of the above, with `m` rows.

If `p` is a vector, then $C(i,j) = T_{i-1}(p(j))$ where T_{i-1} is the Chebyshev polynomial of degree $i - 1$. If `p` is a scalar, then `p` equally spaced points on the interval `[0,1]` are used to calculate `C`.

chow — Singular Toeplitz lower Hessenberg matrix

`A = gallery('chow',n,alpha,delta)` returns `A` such that `A = H(alpha) + delta*eye(n)`, where $H_{i,j}(\alpha) = \alpha^{(i-j+1)}$ and argument `n` is the order of the Chow matrix. Default value for scalars `alpha` and `delta` are `1` and `0`, respectively.

`H(alpha)` has `p = floor(n/2)` eigenvalues that are equal to zero. The rest of the eigenvalues are equal to `4*alpha*cos(k*pi/(n+2))^2, k=1:n-p`.

circul — Circulant matrix

`C = gallery('circul',v)` returns the circulant matrix whose first row is the vector `v`.

A circulant matrix has the property that each row is obtained from the previous one by cyclically permuting the entries one step forward. It is a special Toeplitz matrix in which the diagonals “wrap around.”

If `v` is a scalar, then `C = gallery('circul',1:v)`.

The eigensystem of `C` (`n`-by-`n`) is known explicitly: If `t` is an `n`th root of unity, then the inner product of `v` and $w = [1\ t\ t^2\ \ldots\ t^{(n-1)}]$ is an eigenvalue of `C` and `w(n:-1:1)` is an eigenvector.

clement — Tridiagonal matrix with zero diagonal entries

`A = gallery('clement',n,k)` returns an `n`-by-`n` tridiagonal matrix with zeros on its main diagonal and known eigenvalues. It is singular if `n` is odd. About 64 percent of the entries of the inverse are zero. The eigenvalues include plus and minus the numbers `n-1`, `n-3`, `n-5`, `...`, (1 or 0).

For `k=0` (the default), `A` is nonsymmetric. For `k=1`, `A` is symmetric.

`gallery('clement',n,1)` is diagonally similar to `gallery('clement',n)`.

For odd `N = 2*M+1, M+1` of the singular values are the integers `sqrt((2*M+1)^2 - (2*K+1).^2), K = 0:M`.

Note Similar properties hold for `gallery('tridiag',x,y,z)` where `y = zeros(n,1)`. The eigenvalues still come in plus/minus pairs but they are not known explicitly.

---

compar — Comparison matrices

`A = gallery('compar',A,1)` returns `A` with each diagonal element replaced by its absolute value, and each off-diagonal element replaced by minus the absolute value of the largest element in absolute value in its row. However, if `A` is triangular `compar(A,1)` is too.

`gallery('compar',A)` is `diag(B) - tril(B,-1) - triu(B,1)`, where `B = abs(A)`. `compar(A)` is often denoted by M(*A*) in the literature.

`gallery('compar',A,0)` is the same as `gallery('compar',A)`.

condex — Counter-examples to matrix condition number estimators

`A = gallery('condex',n,k,theta)` returns a “counter-example” matrix to a condition estimator. It has order `n` and scalar parameter `theta` (default 100).

The matrix, its natural size, and the estimator to which it applies are specified by `k`:

`k = 1`	4-by-4	LINPACK
`k = 2`	3-by-3	LINPACK
`k = 3`	arbitrary	LINPACK (`rcond`) (independent of `theta`)
`k = 4`	`n >= 4`	LAPACK (RCOND) (default). It is the inverse of this matrix that is a counter-example.

If `n` is not equal to the natural size of the matrix, then the matrix is padded out with an identity matrix to order `n`.

cycol — Matrix whose columns repeat cyclically

`A = gallery('cycol',[m n],k)` returns an `m`-by-`n` matrix with cyclically repeating columns, where one "cycle" consists of `randn(m,k)`. Thus, the rank of matrix `A` cannot exceed `k`, and `k` must be a scalar.

Argument `k` defaults to `round(n/4)`, and need not evenly divide `n`.

`A = gallery('cycol',n,k)`, where `n` is a scalar, is the same as `gallery('cycol',[n n],k)`.

dorr — Diagonally dominant, ill-conditioned, tridiagonal matrix

`[c,d,e] = gallery('dorr',n,theta)` returns the vectors defining an `n`-by-`n`, row diagonally dominant, tridiagonal matrix that is ill-conditioned for small nonnegative values of `theta`. The default value of `theta` is `0.01`. The Dorr matrix itself is the same as `gallery('tridiag',c,d,e)`.

`A = gallery('dorr',n,theta)` returns the matrix itself, rather than the defining vectors.

dramadah — Matrix of zeros and ones whose inverse has large integer entries

`A = gallery('dramadah',n,k)` returns an `n`-by-`n` matrix of `0`'s and `1`'s for which `mu(A) = norm(inv(A),'fro')` is relatively large, although not necessarily maximal. An anti-Hadamard matrix `A` is a matrix with elements `0` or `1` for which `mu(A)` is maximal.

`n` and `k` must both be scalars. Argument `k` determines the character of the output matrix:

k = 1	Default. `A` is Toeplitz, with `abs(det(A)) = 1`, and `mu(A) > c(1.75)^n`, where `c` is a constant. The inverse of `A` has integer entries.
k = 2	`A` is upper triangular and Toeplitz. The inverse of `A` has integer entries.
k = 3	`A` has maximal determinant among lower Hessenberg (0,1) matrices. `det(A)` = the `n`th Fibonacci number. `A` is Toeplitz. The eigenvalues have an interesting distribution in the complex plane.

fiedler — Symmetric matrix

`A = gallery('fiedler',c)`, where `c` is a length `n` vector, returns the `n`-by-`n` symmetric matrix with elements `abs(n(i)-n(j))`. For scalar `c`, `A = gallery('fiedler',1:c)`.

Matrix `A` has a dominant positive eigenvalue and all the other eigenvalues are negative.

Explicit formulas for `inv(A)` and `det(A)` are given in [Todd, J., *Basic Numerical Mathematics*, Vol. 2: Numerical Algebra, Birkhauser, Basel, and Academic Press, New York, 1977, p. 159] and attributed to Fiedler. These indicate that `inv(A)` is tridiagonal except for nonzero `(1,n)` and `(n,1)` elements.

forsythe — Perturbed Jordan block

`A = gallery('forsythe',n,alpha,lambda)` returns the `n`-by-`n` matrix equal to the Jordan block with eigenvalue `lambda`, excepting that

A(n,1) = alpha. The default values of scalars alpha and lambda are sqrt(eps) and 0, respectively.

The characteristic polynomial of A is given by:

```
det(A-t*I) = (lambda-t)^N - alpha*(-1)^n.
```

frank — Matrix with ill-conditioned eigenvalues

F = gallery('frank',n,k) returns the Frank matrix of order n. It is upper Hessenberg with determinant 1. If k = 1, the elements are reflected about the anti-diagonal (1,n) — (n,1). The eigenvalues of F may be obtained in terms of the zeros of the Hermite polynomials. They are positive and occur in reciprocal pairs; thus if n is odd, 1 is an eigenvalue. F has floor(n/2) ill-conditioned eigenvalues — the smaller ones.

gcdmat — Greatest common divisor matrix

A = gallery('gcdmat',n) returns the n-by-n matrix with (i,j) entry gcd(i,j). MatrixA is symmetric positive definite, and A.^r is symmetric positive semidefinite for all nonnegative r.

gearmat — Gear matrix

A = gallery('gearmat',n,i,j) returns the n-by-n matrix with ones on the sub- and super-diagonals, sign(i) in the (1,abs(i)) position, sign(j) in the (n,n+1-abs(j)) position, and zeros everywhere else. Arguments i and j default to n and -n, respectively.

Matrix A is singular, can have double and triple eigenvalues, and can be defective.

All eigenvalues are of the form 2*cos(a) and the eigenvectors are of the form [sin(w+a), sin(w+2*a), ..., sin(w+n*a)], where a and w are given in Gear, C. W., "A Simple Set of Test Matrices for Eigenvalue Programs," *Math. Comp.*, Vol. 23 (1969), pp. 119-125.

grcar — Toeplitz matrix with sensitive eigenvalues

A = gallery('grcar',n,k) returns an n-by-n Toeplitz matrix with -1s on the subdiagonal, 1s on the diagonal, and k superdiagonals of 1s. The default is k = 3. The eigenvalues are sensitive.

hanowa — Matrix whose eigenvalues lie on a vertical line in the complex plane

`A = gallery('hanowa',n,d)` returns an `n`-by-`n` block `2`-by-`2` matrix of the form:

```
[d*eye(m) -diag(1:m)
diag(1:m) d*eye(m)]
```

Argument `n` is an even integer `n=2*m`. Matrix `A` has complex eigenvalues of the form `d` ± `k*i`, for `1 <= k <= m`. The default value of `d` is `-1`.

house — Householder matrix

`[v,beta,s] = gallery('house',x,k)` takes `x`, an `n`-element column vector, and returns `V` and `beta` such that `H*x = s*e1`. In this expression, `e1` is the first column of `eye(n)`, `abs(s) = norm(x)`, and `H = eye(n) - beta*V*V'` is a Householder matrix.

`k` determines the sign of `s`:

`k = 0`	`sign(s) = -sign(x(1))` (default)
`k = 1`	`sign(s) = sign(x(1))`
`k = 2`	`sign(s) = 1` (`x` must be real)

If `x` is complex, then `sign(x) = x./abs(x)` when `x` is nonzero.

If `x = 0`, or if `x = alpha*e1` (`alpha >= 0`) and either `k = 1` or `k = 2`, then `V = 0`, `beta = 1`, and `s = x(1)`. In this case, `H` is the identity matrix, which is not strictly a Householder matrix.

`[v, beta] = gallery('house',x)` takes `x`, a scalar or `n`-element column vector, and returns `v` and `beta` such that `eye(n,n) - beta*v*v'` is a Householder matrix. A Householder matrix `H` satisfies the relationship

```
H*x = -sign(x(1))*norm(x)*e1
```

where `e1` is the first column of `eye(n,n)`. Note that if `x` is complex, then `sign(x) exp(i*arg(x))` (which equals `x./abs(x)` when `x` is nonzero).

If `x = 0`, then `v = 0` and `beta = 1`.

integerdata — Array of arbitrary data from uniform distribution on specified range of integers

`A = gallery('integerdata',imax,[m,n,...],j)` returns an `m`-by-`n`-by-... array `A` whose values are a sample from the uniform distribution on the integers `1:imax`. `j` must be an integer value in the interval `[0, 2^32-1]`. Calling `gallery('integerdata', ...)` with different values of `J` will return different arrays. Repeated calls to `gallery('integerdata',...)` with the same `imax`, size vector and `j` inputs will always return the same array.

In any call to `gallery('integerdata', ...)` you can substitute individual inputs `m`,`n`,... for the size vector input `[m,n,...]`. For example, `gallery('integerdata',7,[1,2,3,4],5)` is equivalent to `gallery('integerdata',7,1,2,3,4,5)`.

`A = gallery('integerdata',[imin imax],[m,n,...],j)` returns an `m`-by-`n`-by-... array `A` whose values are a sample from the uniform distribution on the integers `imin:imax`.

`[A,B,...]  = gallery('integerdata',[imin imax],[m,n,...],j)` returns multiple `m`-by-`n`-by-... arrays `A`, `B`, ..., containing different values.

`A = gallery('integerdata',[imin imax],[m,n,...],j,classname)` produces an array of class `classname`. `classname` must be `'uint8'`, `'uint16'`, `'uint32'`, `'int8'`, `'int16'`, `int32'`, `'single'` or `'double'`.

invhess — Inverse of an upper Hessenberg matrix

`A = gallery('invhess',x,y)`, where `x` is a length `n` vector and `y` is a length `n-1` vector, returns the matrix whose lower triangle agrees with that of `ones(n,1)*x'` and whose strict upper triangle agrees with that of `[1 y]*ones(1,n)`.

The matrix is nonsingular if `x(1) ~= 0` and `x(i+1) ~= y(i)` for all `i`, and its inverse is an upper Hessenberg matrix. Argument `y` defaults to `-x(1:n-1)`.

If `x` is a scalar, `invhess(x)` is the same as `invhess(1:x)`.

invol — Involutory matrix

`A = gallery('invol',n)` returns an `n`-by-`n` involutory (`A*A = eye(n)`) and ill-conditioned matrix. It is a diagonally scaled version of `hilb(n)`.

`B = (eye(n)-A)/2` and `B = (eye(n)+A)/2` are idempotent (`B*B = B`).

ipjfact — Hankel matrix with factorial elements

`[A,d] = gallery('ipjfact',n,k)` returns `A`, an `n`-by-`n` Hankel matrix, and `d`, the determinant of `A`, which is known explicitly. If `k = 0` (the default), then the elements of `A` are `A(i,j) = (i+j)!` If `k = 1`, then the elements of `A` are `A(i,j) 1/(i+j)`.

Note that the inverse of `A` is also known explicitly.

jordbloc — Jordan block

`A = gallery('jordbloc',n,lambda)` returns the `n`-by-`n` Jordan block with eigenvalue `lambda`. The default value for `lambda` is `1`.

kahan — Upper trapezoidal matrix

`A = gallery('kahan',n,theta,pert)` returns an upper trapezoidal matrix that has interesting properties regarding estimation of condition and rank.

If `n` is a two-element vector, then `A` is `n(1)`-by-`n(2)`; otherwise, `A` is `n`-by-`n`. The useful range of `theta` is `0 < theta < pi`, with a default value of `1.2`.

To ensure that the QR factorization with column pivoting does not interchange columns in the presence of rounding errors, the diagonal is perturbed by `pert*eps*diag([n:-1:1])`. The default `pert` is `25`, which ensures no interchanges for `gallery('kahan',n)` up to at least `n = 90` in IEEE arithmetic.

kms — Kac-Murdock-Szego Toeplitz matrix

`A = gallery('kms',n,rho)` returns the `n`-by-`n` Kac-Murdock-Szego Toeplitz matrix such that `A(i,j) = rho^(abs(i-j))`, for real `rho`.

For complex `rho`, the same formula holds except that elements below the diagonal are conjugated. `rho` defaults to 0.5.

The KMS matrix `A` has these properties:

- An LDL' factorization with `L inv(gallery('triw',n,-rho,1))'`, and `D(i,i) (1-abs(rho)^2)*eye(n)`, except `D(1,1) = 1`.
- Positive definite if and only if `0 < abs(rho) < 1`.
- The inverse `inv(A)` is tridiagonal.

krylov — Krylov matrix

`B = gallery('krylov',A,x,j)` returns the Krylov matrix

```
[x, Ax, A^2x, ..., A^(j-1)x]
```

where `A` is an `n`-by-`n` matrix and `x` is a length `n` vector. The defaults are `x ones(n,1)`, and `j = n`.

`B = gallery('krylov',n)` is the same as `gallery('krylov',(randn(n))`.

lauchli — Rectangular matrix

`A = gallery('lauchli',n,mu)` returns the `(n+1)`-by-`n` matrix

```
[ones(1,n); mu*eye(n)]
```

The Lauchli matrix is a well-known example in least squares and other problems that indicates the dangers of forming `A'*A`. Argument `mu` defaults to `sqrt(eps)`.

lehmer — Symmetric positive definite matrix

`A = gallery('lehmer',n)` returns the symmetric positive definite `n`-by-`n` matrix such that `A(i,j) = i/j` for `j >= i`.

The Lehmer matrix `A` has these properties:

- A is totally nonnegative.
- The inverse inv(A) is tridiagonal and explicitly known.
- The order n <= cond(A) <= 4*n*n.

leslie — Matrix of birth numbers and survival rates

L = gallery('leslie',a,b) is the n-by-n matrix from the Leslie population model with average birth numbers a(1:n) and survival rates b(1:n-1). It is zero, apart from the first row (which contains the a(i)) and the first subdiagonal (which contains the b(i)). For a valid model, the a(i) are nonnegative and the b(i) are positive and bounded by 1, i.e., 0 < b(i) <= 1.

L = gallery('leslie',n) generates the Leslie matrix with a = ones(n,1), b = ones(n-1,1).

lesp — Tridiagonal matrix with real, sensitive eigenvalues

A = gallery('lesp',n) returns an n-by-n matrix whose eigenvalues are real and smoothly distributed in the interval approximately [-2*N-3.5, -4.5].

The sensitivities of the eigenvalues increase exponentially as the eigenvalues grow more negative. The matrix is similar to the symmetric tridiagonal matrix with the same diagonal entries and with off-diagonal entries 1, via a similarity transformation with D = diag(1!,2!,...,n!).

lotkin — Lotkin matrix

A = gallery('lotkin',n) returns the Hilbert matrix with its first row altered to all ones. The Lotkin matrix A is nonsymmetric, ill-conditioned, and has many negative eigenvalues of small magnitude. Its inverse has integer entries and is known explicitly.

minij — Symmetric positive definite matrix

A = gallery('minij',n) returns the n-by-n symmetric positive definite matrix with A(i,j) = min(i,j).

The minij matrix has these properties:

- The inverse `inv(A)` is tridiagonal and equal to `-1` times the second difference matrix, except its `(n,n)` element is `1`.
- Givens' matrix, `2*A-ones(size(A))`, has tridiagonal inverse and eigenvalues `0.5*sec((2*r-1)*pi/(4*n))^2`, where `r=1:n`.
- `(n+1)*ones(size(A))-A` has elements that are `max(i,j)` and a tridiagonal inverse.

moler — Symmetric positive definite matrix

`A = gallery('moler',n,alpha)` returns the symmetric positive definite `n`-by-`n` matrix `U'*U`, where `U = gallery('triw',n,alpha)`.

For the default `alpha` = `-1`, `A(i,j) = min(i,j)-2`, and `A(i,i) = i`. One of the eigenvalues of `A` is small.

neumann — Singular matrix from the discrete Neumann problem (sparse)

`C = gallery('neumann',n)` returns the sparse `n`-by-`n` singular, row diagonally dominant matrix resulting from discretizing the Neumann problem with the usual five-point operator on a regular mesh. Argument `n` is a perfect square integer $n = m^2$ or a two-element vector. `C` is sparse and has a one-dimensional null space with null vector `ones(n,1)`.

normaldata — Array of arbitrary data from standard normal distribution

`A = gallery('normaldata',[m,n,...],j)` returns an `m`-by-`n`-by-... array `A`. The values of `A` are a random sample from the standard normal distribution. `j` must be an integer value in the interval `[0, 2^32-1]`. Calling `gallery('normaldata', ...)` with different values of `j` will return different arrays. Repeated calls to `gallery('normaldata',...)` with the same size vector and `j` inputs will always return the same array.

In any call to `gallery('normaldata', ...)` you can substitute individual inputs `m`,`n`,... for the size vector input `[m,n,...]`. For example, `gallery('normaldata',[1,2,3,4],5)` is equivalent to `gallery('normaldata',1,2,3,4,5)`.

`[A,B,...] = gallery('normaldata',[m,n,...],j)` returns multiple `m`-by-`n`-by-... arrays `A`, `B`, ..., containing different values.

`A = gallery('normaldata',[m,n,...],j, classname)` produces a matrix of class `classname`. `classname` must be either `'single'` or `'double'`.

Generate the arbitrary 6-by-4 matrix of data from the standard normal distribution `N(0, 1)` corresponding to `j = 2`:.

```
x = gallery('normaldata', [6, 4], 2);
```

Generate the arbitrary 1-by-2-by-3 single array of data from the standard normal distribution `N(0, 1)` corresponding to `j = 17`:.

```
y = gallery('normaldata', 1, 2, 3, 17, 'single');
```

orthog — Orthogonal and nearly orthogonal matrices

`Q = gallery('orthog',n,k)` returns the kth type of matrix of order `n`, where `k > 0` selects exactly orthogonal matrices, and `k < 0` selects diagonal scalings of orthogonal matrices. Available types are:

`k = 1`	`Q(i,j) = sqrt(2/(n+1)) * sin(i*j*pi/(n+1))` Symmetric eigenvector matrix for second difference matrix. This is the default.
`k = 2`	`Q(i,j) = 2/(sqrt(2*n+1)) * sin(2*i*j*pi/(2*n+1))` Symmetric.
`k = 3`	`Q(r,s) = exp(2*pi*i*(r-1)*(s-1)/n) / sqrt(n)` Unitary, the Fourier matrix. Q^4 is the identity. This is essentially the same matrix as `fft(eye(n))/sqrt(n)`!
`k = 4`	Helmert matrix: a permutation of a lower Hessenberg matrix, whose first row is `ones(1:n)/sqrt(n)`.

`k = 5`	`Q(i,j) = sin(2*pi*(i-1)*(j-1)/n) + cos(2*pi*(i-1)*(j-1)/n)` Symmetric matrix arising in the Hartley transform.
`k = 6`	`Q(i,j) = sqrt(2/n)*cos((i-1/2)*(j-1/2)*pi/n)` Symmetric matrix arising as a discrete cosine transform.
`k = -1`	`Q(i,j) = cos((i-1)*(j-1)*pi/(n-1))` Chebyshev Vandermonde-like matrix, based on extrema of `T(n-1)`.
`k = -2`	`Q(i,j) = cos((i-1)*(j-1/2)*pi/n))` Chebyshev Vandermonde-like matrix, based on zeros of `T(n)`.

parter — Toeplitz matrix with singular values near pi

`C = gallery('parter',n)` returns the matrix `C` such that `C(i,j) = 1/(i-j+0.5)`.

`C` is a Cauchy matrix and a Toeplitz matrix. Most of the singular values of `C` are very close to `pi`.

pei — Pei matrix

`A = gallery('pei',n,alpha)`, where `alpha` is a scalar, returns the symmetric matrix `alpha*eye(n) + ones(n)`. The default for `alpha` is 1. The matrix is singular for `alpha` equal to either `0` or `-n`.

poisson — Block tridiagonal matrix from Poisson's equation (sparse)

`A = gallery('poisson',n)` returns the block tridiagonal (sparse) matrix of order `n^2` resulting from discretizing Poisson's equation with the 5-point operator on an `n`-by-`n` mesh.

prolate — Symmetric, ill-conditioned Toeplitz matrix

`A = gallery('prolate',n,w)` returns the `n`-by-`n` prolate matrix with parameter `w`. It is a symmetric Toeplitz matrix.

If `0 < w < 0.5` then A is positive definite

- The eigenvalues of A are distinct, lie in `(0,1)`, and tend to cluster around 0 and 1.
- The default value of w is 0.25.

randcolu — Random matrix with normalized cols and specified singular values

`A = gallery('randcolu',n)` is a random n-by-n matrix with columns of unit 2-norm, with random singular values whose squares are from a uniform distribution.

`A'*A` is a correlation matrix of the form produced by `gallery('randcorr',n)`.

`gallery('randcolu',x)` where x is an n-vector (n > 1), produces a random n-by-n matrix having singular values given by the vector x. The vector x must have nonnegative elements whose sum of squares is n.

`gallery('randcolu',x,m)` where `m >= n`, produces an m-by-n matrix.

`gallery('randcolu',x,m,k)` provides a further option:

`k = 0`	`diag(x)` is initially subjected to a random two-sided orthogonal transformation, and then a sequence of Givens rotations is applied (default).
`k = 1`	The initial transformation is omitted. This is much faster, but the resulting matrix may have zero entries.

For more information, see:

References

[1] Davies, P. I. and N. J. Higham, "Numerically Stable Generation of Correlation Matrices and Their Factors," *BIT*, Vol. 40, 2000, pp. 640-651.

randcorr — Random correlation matrix with specified eigenvalues

`gallery('randcorr',n)` is a random `n`-by-`n` correlation matrix with random eigenvalues from a uniform distribution. A correlation matrix is a symmetric positive semidefinite matrix with `1`s on the diagonal (see `corrcoef`).

`gallery('randcorr',x)` produces a random correlation matrix having eigenvalues given by the vector `x`, where `length(x) > 1`. The vector `x` must have nonnegative elements summing to `length(x)`.

`gallery('randcorr',x,k)` provides a further option:

`k = 0`	The diagonal matrix of eigenvalues is initially subjected to a random orthogonal similarity transformation, and then a sequence of Givens rotations is applied (default).
`k = 1`	The initial transformation is omitted. This is much faster, but the resulting matrix may have some zero entries.

For more information, see:

[2] Davies, P. I. and N. J. Higham, "Numerically Stable Generation of Correlation Matrices and Their Factors," *BIT*, Vol. 40, 2000, pp. 640-651.

randhess — Random, orthogonal upper Hessenberg matrix

`H = gallery('randhess',n)` returns an `n`-by-`n` real, random, orthogonal upper Hessenberg matrix.

`H = gallery('randhess',x)` if `x` is an arbitrary, real, length `n` vector with `n > 1`, constructs `H` nonrandomly using the elements of `x` as parameters.

Matrix `H` is constructed via a product of `n-1` Givens rotations.

randjorth — Random J-orthogonal matrix

`A = gallery('randjorth', n)`, for a positive integer `n`, produces a random `n`-by-`n` `J`-orthogonal matrix `A`, where

- `J = blkdiag(eye(ceil(n/2)),-eye(floor(n/2)))`
- `cond(A) = sqrt(1/eps)`

`J`-orthogonality means that A'*J*A = J. Such matrices are sometimes called *hyperbolic*.

`A = gallery('randjorth', n, m)`, for positive integers `n` and `m`, produces a random (`n+m`)-by-(`n+m`) `J`-orthogonal matrix `A`, where

- `J = blkdiag(eye(n),-eye(m))`
- `cond(A) = sqrt(1/eps)`

```
A = gallery('randjorth',n,m,c,symm,method)
```

uses the following optional input arguments:

- `c` — Specifies `cond(A)` to be the scalar `c`.
- `symm` — Enforces symmetry if the scalar `symm` is nonzero.
- `method` — calls `qr` to perform the underlying orthogonal transformations if the scalar `method` is nonzero. A call to `qr` is much faster than the default method for large dimensions

rando — Random matrix composed of elements -1, 0 or 1

`A = gallery('rando',n,k)` returns a random `n`-by-`n` matrix with elements from one of the following discrete distributions:

`k = 1`	`A(i,j)` = `0` or `1` with equal probability (default).
`k = 2`	`A(i,j)` = `-1` or `1` with equal probability.
`k = 3`	`A(i,j)` = `-1`, `0` or `1` with equal probability.

Argument `n` may be a two-element vector, in which case the matrix is `n(1)`-by-`n(2)`.

randsvd — Random matrix with preassigned singular values

`A = gallery('randsvd',n,kappa,mode,kl,ku)` returns a banded (multidiagonal) random matrix of order `n` with `cond(A) = kappa` and singular values from the distribution mode. If `n` is a two-element vector, `A` is `n(1)`-by-`n(2)`.

Arguments `kl` and `ku` specify the number of lower and upper off-diagonals, respectively, in `A`. If they are omitted, a full matrix is produced. If only `kl` is present, `ku` defaults to `kl`.

Distribution `mode` can be:

`1`	One large singular value.
`2`	One small singular value.
`3`	Geometrically distributed singular values (default).
`4`	Arithmetically distributed singular values.
`5`	Random singular values with uniformly distributed logarithm.
`< 0`	If `mode` is `-1`, `-2`, `-3`, `-4`, or `-5`, then `randsvd` treats `mode` as `abs(mode)`, except that in the original matrix of singular values the order of the diagonal entries is reversed: small to large instead of large to small.

Condition number `kappa` defaults to `sqrt(1/eps)`. In the special case where `kappa < 0`, `A` is a random, full, symmetric, positive definite matrix with `cond(A) = -kappa` and eigenvalues distributed according to `mode`. Arguments `kl` and `ku`, if present, are ignored.

`A = gallery('randsvd',n,kappa,mode,kl,ku,method)` specifies how the computations are carried out. `method = 0` is the default, while `method = 1` uses an alternative method that is much faster for large dimensions, even though it uses more flops.

redheff — Redheffer's matrix of 1s and 0s

`A = gallery('redheff',n)` returns an `n`-by-`n` matrix of `0`'s and `1`'s defined by `A(i,j) = 1`, if `j = 1` or if `i` divides `j`, and `A(i,j) = 0` otherwise.

The Redheffer matrix has these properties:

- `(n-floor(log2(n)))-1` eigenvalues equal to `1`
- A real eigenvalue (the spectral radius) approximately `sqrt(n)`
- A negative eigenvalue approximately `-sqrt(n)`
- The remaining eigenvalues are provably "small."
- The Riemann hypothesis is true if and only if $\det(A) = O(n^{1/2+\varepsilon})$ for every ε `> 0`.

Barrett and Jarvis conjecture that "the small eigenvalues all lie inside the unit circle `abs(Z) = 1`," and a proof of this conjecture, together with a proof that some eigenvalue tends to zero as `n` tends to infinity, would yield a new proof of the prime number theorem.

riemann — Matrix associated with the Riemann hypothesis

`A = gallery('riemann',n)` returns an `n`-by-`n` matrix for which the Riemann hypothesis is true if and only if

$$\det(A) = O(n!n^{-1/2+\varepsilon})$$

for every $\varepsilon > 0$.

The Riemann matrix is defined by:

```
A = B(2:n+1,2:n+1)
```

where `B(i,j) = i-1` if `i` divides `j`, and `B(i,j) = -1` otherwise.

The Riemann matrix has these properties:

- Each eigenvalue `e(i)` satisfies `abs(e(i)) <= m-1/m`, where `m = n+1`.
- `i <= e(i) <= i+1` with at most `m-sqrt(m)` exceptions.
- All integers in the interval `(m/3, m/2]` are eigenvalues.

ris — Symmetric Hankel matrix

`A = gallery('ris',n)` returns a symmetric `n`-by-`n` Hankel matrix with elements

```
A(i,j) = 0.5/(n-i-j+1.5)
```

The eigenvalues of `A` cluster around $\pi/2$ and $-\pi/2$. This matrix was invented by F.N. Ris.

sampling — Nonsymmetric matrix with ill-conditioned integer eigenvalues.

`A = gallery('sampling',x)`, where `x` is an `n`-vector, is the `n`-by-`n` matrix with `A(i,j) = X(i)/(X(i)-X(j))` for `i ~= j` and `A(j,j)` the sum of the off-diagonal elements in column `j`. A has eigenvalues `0:n-1`. For the eigenvalues 0 and `n`–1, corresponding eigenvectors are `X` and `ones(n,1)`, respectively.

The eigenvalues are ill-conditioned. `A` has the property that `A(i,j) + A(j,i) = 1` for `i ~= j`.

Explicit formulas are available for the left eigenvectors of `A`. For scalar `n`, `sampling(n)` is the same as `sampling(1:n)`. A special case of this matrix arises in sampling theory.

smoke — Complex matrix with a 'smoke ring' pseudospectrum

`A = gallery('smoke',n)` returns an `n`-by-`n` matrix with 1's on the superdiagonal, 1 in the `(n,1)` position, and powers of roots of unity along the diagonal.

`A = gallery('smoke',n,1)` returns the same except that element `A(n,1)` is zero.

The eigenvalues of `gallery('smoke',n,1)` are the `n`th roots of unity; those of `gallery('smoke',n)` are the `n`th roots of unity times `2^(1/n)`.

toeppd — Symmetric positive definite Toeplitz matrix

`A = gallery('toeppd',n,m,w,theta)` returns an `n`-by-`n` symmetric, positive semi-definite (SPD) Toeplitz matrix composed of the sum of `m` rank 2 (or, for certain `theta`, rank 1) SPD Toeplitz matrices. Specifically,

```
T = w(1)*T(theta(1)) + ... + w(m)*T(theta(m))
```

where `T(theta(k))` has `(i,j)` element `cos(2*pi*theta(k)*(i-j))`.

By default: `m = n`, `w = rand(m,1)`, and `theta = rand(m,1)`.

toeppen — Pentadiagonal Toeplitz matrix (sparse)

`P = gallery('toeppen',n,a,b,c,d,e)` returns the `n`-by-`n` sparse, pentadiagonal Toeplitz matrix with the diagonals: `P(3,1) = a`, `P(2,1) = b`, `P(1,1) = c`, `P(1,2) = d`, and `P(1,3) = e`, where `a`, `b`, `c`, `d`, and `e` are scalars.

By default, `(a,b,c,d,e) = (1,-10,0,10,1)`, yielding a matrix of Rutishauser. This matrix has eigenvalues lying approximately on the line segment `2*cos(2*t) + 20*i*sin(t)`.

tridiag — Tridiagonal matrix (sparse)

`A = gallery('tridiag',c,d,e)` returns the tridiagonal matrix with subdiagonal `c`, diagonal `d`, and superdiagonal `e`. Vectors `c` and `e` must have `length(d)-1`.

A = gallery('tridiag',n,c,d,e), where c, d, and e are all scalars, yields the Toeplitz tridiagonal matrix of order n with subdiagonal elements c, diagonal elements d, and superdiagonal elements e. This matrix has eigenvalues

```
d + 2*sqrt(c*e)*cos(k*pi/(n+1))
```

where k = 1:n. (see [1].)

A = gallery('tridiag',n) is the same as A = gallery('tridiag',n,-1,2,-1), which is a symmetric positive definite M-matrix (the negative of the second difference matrix).

triw — Upper triangular matrix discussed by Wilkinson and others

A = gallery('triw',n,alpha,k) returns the upper triangular matrix with ones on the diagonal and alphas on the first k >= 0 superdiagonals.

Order n may be a 2-element vector, in which case the matrix is n(1)-by-n(2) and upper trapezoidal.

Ostrowski ["On the Spectrum of a One-parametric Family of Matrices," *J. Reine Angew. Math.,* 1954] shows that

```
cond(gallery('triw',n,2)) = cot(pi/(4*n))^2,
```

and, for large abs(alpha), cond(gallery('triw',n,alpha)) is approximately abs(alpha)^n*sin(pi/(4*n-2)).

Adding -2^(2-n) to the (n,1) element makes triw(n) singular, as does adding -2^(1-n) to all the elements in the first column.

uniformdata — Array of arbitrary data from standard uniform distribution

A = gallery('uniformdata',[m,n,...],j) returns an m-by-n-by-... array A. The values of A are a random sample from the standard uniform distribution. j must be an integer value in the interval [0, 2^32-1]. Calling gallery('uniformdata', ...) with different values of j will return different arrays. Repeated calls to

gallery('uniformdata',...) with the same size vector and j inputs will always return the same array.

In any call to gallery('uniformdata', ...) you can substitute individual inputs m,n,... for the size vector input [m,n,...]. For example, gallery('uniformdata',[1,2,3,4],5) is equivalent to gallery('uniformdata',1,2,3,4,5).

[A,B,...] = gallery('uniformdata',[m,n,...],j) returns multiple m-by-n-by-... arrays A, B, ..., containing different values.

A = gallery('uniformdata',[m,n,...],j, classname) produces a matrix of class classname. classname must be either 'single' or 'double'.

Generate the arbitrary 6-by-4 matrix of data from the uniform distribution on [0, 1] corresponding to j = 2.

```
x = gallery('uniformdata', [6, 4], 2);
```

Generate the arbitrary 1-by-2-by-3 single array of data from the uniform distribution on [0, 1] corresponding to j = 17.

```
y = gallery('uniformdata', 1, 2, 3, 17, 'single');
```

wathen — Finite element matrix (sparse, random entries)

A = gallery('wathen',nx,ny) returns a sparse, random, n-by-n finite element matrix where n = 3*nx*ny + 2*nx + 2*ny + 1.

Matrix A is precisely the "consistent mass matrix" for a regular nx-by-ny grid of 8-node (serendipity) elements in two dimensions. A is symmetric, positive definite for any (positive) values of the "density," rho(nx,ny), which is chosen randomly in this routine.

A = gallery('wathen',nx,ny,1) returns a diagonally scaled matrix such that

```
0.25 <= eig(inv(D)*A) <= 4.5
```

where D = diag(diag(A)) for any positive integers nx and ny and any densities rho(nx,ny).

wilk — Various matrices devised or discussed by Wilkinson

`gallery('wilk',n)` returns a different matrix or linear system depending on the value of `n`.

`n = 3`	Upper triangular system `Ux=b` illustrating inaccurate solution.
`n = 4`	Lower triangular system `Lx=b`, ill-conditioned.
`n = 5`	`hilb(6)(1:5,2:6)*1.8144`. A symmetric positive definite matrix.
`n = 21`	`W21+`, a tridiagonal matrix. eigenvalue problem. For more detail, see [2].

`hadamard` | `hilb` | `invhilb` | `magic` | `wilkinson`

Purpose Gamma function

Syntax

```
Y = gamma(X)
```

Definitions The `gamma` function is defined by the integral:

$$\Gamma(x) = \int_0^\infty e^{-t} t^{x-1} dt$$

The `gamma` function interpolates the `factorial` function. For integer `n`:

```
gamma(n+1) = n! = prod(1:n)
```

Description `Y = gamma(X)` returns the `gamma` function at the elements of `X`. `X` must be real.

Algorithms The computation of `gamma` is based on algorithms outlined in [1]. Several different minimax rational approximations are used depending upon the value of `A`.

gammainc

Purpose

Incomplete gamma function

Syntax

```
Y = gammainc(X,A)
Y = gammainc(X,A,tail)
Y = gammainc(X,A,'scaledlower')
Y = gammainc(X,A,'scaledupper')
```

Definitions

The incomplete `gamma` function is:

$$P(a,x) = \frac{1}{\Gamma(a)} \int_0^x e^{-t} t^{a-1} dt$$

For any `A` ≥ 0, `gammainc(X,A)` approaches 1 as `X` approaches `infinity`. For small `X` and `A`, `gammainc(X,A)` is approximately equal to `X^A`, so `gammainc(0,0) = 1`.

Description

`Y = gammainc(X,A)` returns the incomplete `gamma` function of corresponding elements of `X` and `A`. The elements of `A` must be nonnegative. Furthermore, `X` and `A` must be real and the same size (or either can be scalar).

`Y = gammainc(X,A,tail)` specifies the tail of the incomplete `gamma` function. The choices for `tail` are `'lower'` (the default) and `'upper'`. The upper incomplete `gamma` function is defined as:

$$Q(a,x) = \frac{1}{\Gamma(a)} \int_x^{\infty} e^{-t} t^{a-1} dt = 1 - P(a,x).$$

When the upper tail value is close to 0, the `'upper'` option provides a way to compute that value more accurately than by subtracting the lower tail value from 1.

`Y = gammainc(X,A,'scaledlower')` and `Y = gammainc(X,A,'scaledupper')` return the incomplete gamma function, scaled by

$$\Gamma(a+1)\left(\frac{e^x}{x^a}\right).$$

These functions are unbounded above, but are useful for values of `X` and `A` where `gammainc(X,A,'lower')` or `gammainc(X,A,'upper')` underflow to zero.

Note When `X` is negative, `Y` can be inaccurate for `abs(X)>A+1`. This applies to all syntaxes.

`gamma` | `gammaincinv` | `gammaln` | `psi`

gammaincinv

Purpose

Inverse incomplete gamma function

Syntax

```
x = gammaincinv(y,a)
y = gammaincinv(x,a,tail)
```

Description

`x = gammaincinv(y,a)` evaluates the inverse incomplete gamma function for corresponding elements of `y` and `a`, such that `y = gammainc(x,a)`. The elements of `y` must be in the closed interval `[0,1]`, and those of `a` must be nonnegative. `y` and `a` must be real and the same size (or either can be a scalar).

`y = gammaincinv(x,a,tail)` specifies the tail of the incomplete gamma function. Choices are `lower` (the default) to use the integral from 0 to `x`, or `upper` to use the integral from `x` to infinity.

These two choices are related as:

`gammaincinv(y,a,'upper') = gammaincinv(1-y,a,'lower')`.

When `y` is close to 0, the `upper` option provides a way to compute `x` more accurately than by subtracting `y` from 1.

Definitions

The lower incomplete gamma function is defined as:

$$\mathrm{gammainc}(x,a) = \frac{1}{\Gamma(a)}\int_0^x e^{-t} t^{(a-1)} dt$$

The upper incomplete gamma function is defined as:

$$\mathrm{gammainc}(x,a) = \frac{1}{\Gamma(a)}\int_x^\infty e^{-t} t^{(a-1)} dt$$

`gammaincinv` computes the inverse of the incomplete gamma function with respect to the integration limit `x` using Newton's method.

For any `a>0`, as `y` approaches 1, `gammaincinv(y,a)` approaches infinity.

For small `x` and `a`, `gammainc(x,a)` $\cong x^a$, so `gammaincinv(1,0) = 0`.

`gamma` | `gammainc` | `gammaln` | `psi`

gammaln

Purpose Logarithm of gamma function

Syntax

```
Y = gammaln(A)
```

Description `Y = gammaln(A)` returns the logarithm of the `gamma` function, `gammaln(A) = log(gamma(A))`. The `gammaln` command avoids the underflow and overflow that may occur if it is computed directly using `log(gamma(A))`.

See Also `gammainc` | `gammaincinv` | `gamma` | `psi`

Purpose

Current axes handle

Syntax

```
h = gca
```

Description

`h = gca` returns the handle to the current axes for the current figure. If no axes exists, the MATLAB software creates one and returns its handle. You can use the statement

```
get(gcf,'CurrentAxes')
```

if you do not want MATLAB to create an axes if one does not already exist.

Current Axes

The current axes is the target for graphics output when you create axes children. The current axes is typically the last axes used for plotting or the last axes clicked on by the mouse. Graphics commands such as `plot`, `text`, and `surf` draw their results in the current axes. Changing the current figure also changes the current axes.

`axes` | `cla` | `gcf` | `findobj` | `CurrentAxes`

gcbf

Purpose

Handle of figure containing object whose callback is executing

Syntax

```
fig = gcbf
```

Description

`fig = gcbf` returns the handle of the figure that contains the object whose callback is currently executing. This object can be the figure itself, in which case, `gcbf` returns the figure's handle.

When no callback is executing, `gcbf` returns the empty matrix, `[]`.

The value returned by `gcbf` is identical to the `figure` output argument returned by `gcbo`.

See Also

`gcbo` | `gco` | `gcf` | `gca`

Purpose

Handle of object whose callback is executing

Syntax

```
h = gcbo
[h,figure] = gcbo
```

Description

`h = gcbo` returns the handle of the graphics object whose callback is executing.

`[h,figure] = gcbo` returns the handle of the current callback object and the handle of the figure containing this object.

Tips

The MATLAB software stores the handle of the object whose callback is executing in the root `CallbackObject` property. If a callback interrupts another callback, MATLAB replaces the `CallbackObject` value with the handle of the object whose callback is interrupting. When that callback completes, MATLAB restores the handle of the object whose callback was interrupted.

The root `CallbackObject` property is read only, so its value is always valid at any time during callback execution. The root `CurrentFigure` property, and the figure `CurrentAxes` and `CurrentObject` properties (returned by `gcf`, `gca`, and `gco`, respectively) are user settable, so they can change during the execution of a callback, especially if that callback is interrupted by another callback. Therefore, those functions are not reliable indicators of which object's callback is executing.

When you write callback routines for the `CreateFcn` and `DeleteFcn` of any object and the figure `ResizeFcn`, you must use `gcbo` since those callbacks do not update the root's `CurrentFigure` property, or the figure's `CurrentObject` or `CurrentAxes` properties; they only update the root's `CurrentFigure` property.

When no callbacks are executing, `gcbo` returns `[]` (an empty matrix).

`gca` | `gcf` | `gco` | `rootobject`

gcd

Purpose

Greatest common divisor

Syntax

```
G = gcd(A,B)
[G,U,V] = gcd(A,B)
```

Description

`G = gcd(A,B)` returns the greatest common divisors of the elements of `A` and `B`. The elements in `G` are always nonnegative, and `gcd(0,0)` returns `0`. This syntax supports inputs of any numeric type.

`[G,U,V] = gcd(A,B)` also returns the Bézout coefficients, `U` and `V`, which satisfy: `A.*U + B.*V = G`. The Bézout coefficients are useful for solving Diophantine equations. This syntax supports double, single, and signed integer inputs.

Input Arguments

A,B - Input values

scalars, vectors, or arrays of real integer values

Input values, specified as scalars, vectors, or arrays of real integer values. `A` and `B` can be any numeric type, and they can be of different types within certain limitations:

- If `A` or `B` is of type `single`, then the other can be of type `single` or `double`.
- If `A` or `B` belongs to an integer class, then the other must belong to the same class or it must be a `double` scalar value.

`A` and `B` must be the same size or one must be a scalar.

Example: `[20 -3 13],[10 6 7]`

Example: `int16([100 -30 200]),int16([20 15 9])`

Example: `int16([100 -30 200]),20`

Data Types
`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

Output Arguments

G - Greatest common divisor
real, nonnegative integer values

Greatest common divisor, returned as an array of real nonnegative integer values. `G` is the same size as `A` and `B`, and the values in `G` are always real and nonnegative. `G` is returned as the same type as `A` and `B`. If `A` and `B` are of different types, then `G` is returned as the nondouble type.

U,V - Bézout coefficients
real integer values

Bézout coefficients, returned as arrays of real integer values that satisfy the equation, `A.*U + B.*V = G`. The data type of `U` and `V` is the same type as that of `A` and `B`. If `A` and `B` are of different types, then `U` and `V` are returned as the nondouble type.

Algorithms

`g = gcd(A,B)` is calculated using the Euclidian algorithm.[1]

`[g,u,v] = gcd(A,B)` is calculated using the extended Euclidian algorithm.[1]

Examples

Greatest Common Divisors of Double Values

```
A = [-5 17; 10 0];
B = [-15 3; 100 0];
G = gcd(A,B)
```

```
G =

     5     1
    10     0
```

`gcd` returns positive values, even when the inputs are negative.

Greatest Common Divisors of Unsigned Integers

```
A = uint16([255 511 15]);
B = uint16([15 127 1023]);
```

```
G = gcd(A,B)

G =

    15     1     3
```

Solution to Diophantine Equation

Solve the Diophantine equation, $30x + 56y = 8$ for x and y.

Find the greatest common divisor and a pair of Bézout coefficients for `30` and `56`.

```
[g,u,v] = gcd(30,56)

g =

     2

u =

   -13

v =

     7
```

`u` and `v` satisfy the Bézout's identity, `(30*u) + (56*v) = g`.

Rewrite Bézout's identity so that it looks more like the original equation. Do this by multiplying by `4`. Use == to verify that both sides of the equation are equal.

```
(30*u*4) + (56*v*4) == g*4

ans =

   1
```

Calculate the values of *x* and *y* that solve the problem.

```
x = u*4
y = v*4

x =

   -52

y =

    28
```

`lcm`

gcf

Purpose

Current figure handle

Syntax

```
h = gcf
```

Description

`h = gcf` returns the handle of the current figure. The current figure is the figure window in which graphics commands such as `plot`, `title`, and `surf` draw their results. If no figure exists, the MATLAB software creates one and returns its handle. You can use the statement

```
get(0,'CurrentFigure')
```

if you do not want MATLAB to create a figure if one does not already exist.

See Also

`clf` | `figure` | `gca` | `CurrentFigure`

Purpose

Handle of current object

Syntax

```
h = gco
h = gco(figure_handle)
```

Description

`h = gco` returns the handle of the current object.

`h = gco(figure_handle)` returns the handle of the current object in the figure specified by `figure_handle`.

Tips

The current object is the last object clicked on, excluding `uimenus`. If the mouse click did not occur over a figure child object, the figure becomes the current object. The MATLAB software stores the handle of the current object in the figure's `CurrentObject` property.

The `CurrentObject` of the `CurrentFigure` does not always indicate the object whose callback is being executed. Interruptions of callbacks by other callbacks can change the `CurrentObject` or even the `CurrentFigure`. Some callbacks, such as `CreateFcn` and `DeleteFcn`, and uimenu `Callback`, intentionally do not update `CurrentFigure` or `CurrentObject`.

`gcbo` provides the only completely reliable way to retrieve the handle to the object whose callback is executing, at any point in the `callback` function, regardless of the type of callback or of any previous interruptions.

See Also

`gca` | `gcbo` | `gcf`

ge

Purpose

Test for greater than or equal to

Syntax

```
A >= B
ge(A, B)
```

Description

`A >= B` compares each element of array `A` with the corresponding element of array `B`, and returns an array with elements set to logical 1 (`true`) where `A` is greater than or equal to `B`, or set to logical 0 (`false`) where `A` is less than `B`. Each input of the expression can be an array or a scalar value.

If both `A` and `B` are scalar (i.e., 1-by-1 matrices), then the MATLAB software returns a scalar value.

If both `A` and `B` are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as `A` and `B`.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input `A` is the number 100, and `B` is a 3-by-5 matrix, then `A` is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

`ge(A, B)` is called for the syntax `A >= B` when either `A` or `B` is an object.

Examples

Create two 6-by-6 matrices, `A` and `B`, and locate those elements of `A` that are greater than or equal to the corresponding elements of `B`:

```
A = magic(6);
B = repmat(3*magic(3), 2, 2);

A >= B
ans =
     1     0     0     1     1     1
     0     1     0     1     1     1
     1     0     0     1     1     1
     0     1     1     0     1     0
```

```
     1     0     1     1     0     0
     0     1     1     1     0     1
```

How To

- "Relational Operators"

genpath

Purpose

Generate path string

Syntax

```
p = genpath
p = genpath(folderName)
```

Description

`p = genpath` returns a path string, `p`, that includes all the folders and subfolders below *`matlabroot`*`/toolbox`, including empty subfolders.

`p = genpath(folderName)` returns a path string that includes `folderName` and multiple levels of subfolders below `folderName`. The path string does not include folders named `private`, folders that begin with the `@` character (class folders), folders that begin with the `+` character (package folders), or subfolders within any of these.

Input Arguments

folderName - Folder name

string

Folder name, specified as a string.

Example: `'c:/matlab/myfiles'`

Examples

Add Folder and Subfolders to Search Path

Use `genpath` in conjunction with `addpath` to add a folder and its subfolders to the search path.

Generate a path that includes *`matlabroot`*`/toolbox/images/colorspaces` and all folders below it.

```
folderName = fullfile(matlabroot,'toolbox','images','colorspaces');
p = genpath(folderName);
```

Add the folder and its subfolders to the search path.

```
addpath(p)
```

See Also

`addpath` | `path` | `rmpath`

Concepts

- "What Is the MATLAB Search Path?"

genvarname

Purpose

Construct valid variable name from string

Syntax

```
varname = genvarname(str)
varname = genvarname(str, exclusions)
```

Description

`varname = genvarname(str)` constructs a string `varname` that is similar to or the same as the `str` input, and can be used as a valid variable name. `str` can be a single character array or a cell array of strings. If `str` is a cell array of strings, `genvarname` returns a cell array of strings in `varname`. The strings in a cell array returned by `genvarname` are guaranteed to be different from each other.

`varname = genvarname(str, exclusions)` returns a valid variable name that is different from any name listed in the `exclusions` input. The `exclusions` input can be a single character array or a cell array of strings. Specify the function `who` in the `exclusions` character array to create a variable name that will be unique in the current MATLAB workspace (see "Example 4" on page 1-1948, below).

Note `genvarname` returns a string that can be used as a variable name. It does not create a variable in the MATLAB workspace. You cannot, therefore, assign a value to the output of `genvarname`.

Tips

A valid MATLAB variable name is a character string of letters, digits, and underscores, such that the first character is a letter, and the length of the string is less than or equal to the value returned by the `namelengthmax` function. Any string that exceeds `namelengthmax` is truncated in the `varname` output. See "Example 6" on page 1-1949, below.

The variable name returned by `genvarname` is not guaranteed to be different from other variable names currently in the MATLAB workspace unless you use the `exclusions` input in the manner shown in "Example 4" on page 1-1948, below.

If you use `genvarname` to generate a field name for a structure, MATLAB does create a variable for the structure and field in the MATLAB workspace. See "Example 3" on page 1-1947, below.

If the `str` input contains any whitespace characters, `genvarname` removes then and capitalizes the next alphabetic character in `str`. If `str` contains any nonalphanumeric characters, `genvarname` translates these characters into their hexadecimal value.

Examples

Example 1

Create four similar variable name strings that do not conflict with each other:

```
v = genvarname({'A', 'A', 'A', 'A'})
v =
    'A'    'A1'    'A2'    'A3'
```

Example 2

Read a column header `hdr` from worksheet `trial2` in Excel spreadsheet myproj_apr23:

```
[data hdr] = xlsread('myproj_apr23.xls', 'trial2');
```

Make a variable name from the text of the column header that will not conflict with other names:

```
v = genvarname(['Column ' hdr{1,3}]);
```

Assign data taken from the spreadsheet to the variable in the MATLAB workspace:

```
eval([v '= data(1:7, 3);']);
```

Example 3

Collect readings from an instrument once every minute over the period of an hour into different fields of a structure. `genvarname` not only generates unique fieldname strings, but also creates the structure and fields in the MATLAB workspace:

```
for k = 1:60
record.(genvarname(['reading' datestr(clock, 'HHMMSS')])) = takeReading;
pause(60)
end
```

After the program ends, display the recorded data from the workspace:

```
record
record =
    reading090446: 27.3960
    reading090546: 23.4890
    reading090646: 21.1140
    reading090746: 23.0730
    reading090846: 28.5650
          .
          .
          .
```

Example 4

Generate variable names that are unique in the MATLAB workspace by putting the output from the `who` function in the `exclusions` list.

```
for k = 1:5
   t = clock;
   pause(uint8(rand * 10));
   v = genvarname('time_elapsed', who);
   eval([v ' = etime(clock,t)'])
   end
```

As this code runs, you can see that the variables created by `genvarname` are unique in the workspace:

```
time_elapsed =
    5.0070
time_elapsed1 =
    2.0030
time_elapsed2 =
    7.0010
```

```
time_elapsed3 =
    8.0010
time_elapsed4 =
    3.0040
```

After the program completes, use the `who` function to view the workspace variables:

```
who

k            time_elapsed   time_elapsed2  time_elapsed4
t            time_elapsed1  time_elapsed3  v
```

Example 5

If you try to make a variable name from a MATLAB keyword, `genvarname` creates a variable name string that capitalizes the keyword and precedes it with the letter `x`:

```
v = genvarname('global')
v =
   xGlobal
```

Example 6

If you enter a string that is longer than the value returned by the `namelengthmax` function, `genvarname` truncates the resulting variable name string:

```
namelengthmax
ans =
    63

vstr = genvarname(sprintf('%s%s', ...
   'This name truncates because it contains ', ...
   'more than the maximum number of characters'))
vstr =
ThisNameTruncatesBecauseItContainsMoreThanTheMaximumNumberOfCha
```

Purpose Query Handle Graphics object properties

Syntax

```
get(h)
get(h,'PropertyName')
<m-by-n value cell array> = get(H,pn)
a = get(h)
a = get(0)
a = get(0,'Factory')
a = get(0,'FactoryObjectTypePropertyName')
a = get(h,'Default')
a = get(h,'DefaultObjectTypePropertyName')
```

Description

Note Do not use the `get` function on Java objects as it will cause a memory leak. For more information, see "Accessing Private and Public Data"

`get(h)` returns all properties of the graphics object identified by the handle `h` and their current values. For this syntax, `h` must be a scalar.

`get(h,'PropertyName')` returns the value of the property `'PropertyName'` of the graphics object identified by `h`.

`<m-by-n value cell array> = get(H,pn)` returns *n* property values for *m* graphics objects in the *m*-by-*n* cell array, where `m = length(H)` and *n* is equal to the number of property names contained in `pn`.

`a = get(h)` returns a structure whose field names are the object's property names and whose values are the current values of the corresponding properties. If you do not specify an output argument, MATLAB displays the information on the screen. For this syntax, `h` may be a scalar or a `m`-by-`n` array of handles. If `h` is a vector, `a` will be a `(m*n)`-by-1 struct array.

`a = get(0)` returns the current values of all user-settable properties. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties.

If you do not specify an output argument, MATLAB displays the information on the screen.

`a = get(0,'Factory')` returns the factory-defined values of all user-settable properties. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties. If you do not specify an output argument, MATLAB displays the information on the screen.

`a = get(0,'FactoryObjectTypePropertyName')` returns the factory-defined value of the named property for the specified object type. The argument *FactoryObjectTypePropertyName* is the word `Factory` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`)`FactoryFigureColor`.

`a = get(h,'Default')` returns all default values currently defined on object `h`. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties. If you do not specify an output argument, MATLAB displays the information on the screen.

`a = get(h,'DefaultObjectTypePropertyName')` returns the factory-defined value of the named property for the specified object type. The argument *DefaultObjectTypePropertyName* is the word `Default` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`).

```
DefaultFigureColor
```

Examples

You can obtain the default value of the `LineWidth` property for line graphics objects defined on the root level with the statement

```
get(0,'DefaultLineLineWidth')
ans =
      0.5000
```

To query a set of properties on all axes children, define a cell array of property names:

```
props = {'HandleVisibility', 'Interruptible';
```

```
   'SelectionHighlight', 'Type'};
output = get(get(gca,'Children'),props);
```

The variable `output` is a cell array of dimension `length(get(gca,'Children')`-by-4.

For example, type

```
patch;surface;text;line
output = get(get(gca,'Children'),props)
output =
 'on'    'on'    'on'    'line'
 'on'    'off'   'on'    'text'
 'on'    'on'    'on'    'surface'
 'on'    'on'    'on'    'patch'
```

See Also

`findobj` | `gca` | `gcf` | `gco` | `set`

Purpose

Query property values for `audioplayer` object

Syntax

```
Value = get(obj,Name)
Values = get(obj,{Name1,...,NameN})
Values = get(obj)
get(obj)
```

Description

`Value = get(obj,Name)` returns the value of the specified property for object `obj`.

`Values = get(obj,{Name1,...,NameN})` returns the values of the specified properties in a 1-by-`N` cell array.

`Values = get(obj)` returns a scalar structure that contains the values of all properties of `obj`. Each field name corresponds to a property name.

`get(obj)` displays all property names and their current values.

Examples

Create an `audioplayer` object from the example file `handel.mat` and query the object properties:

```
load handel.mat;
handelObj = audioplayer(y, Fs);

% Display all properties.
get(handelObj)

% Display only the SampleRate property.
get(handelObj, 'SampleRate')

% Create a cell array that contains
% values for two properties.
info = get(handelObj, {'BitsPerSample', 'NumberOfChannels'});
```

Alternatives

To access a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, find the value of the `TotalSamples` property for an object named `handelObj` (as created in the Example):

```
numSamples = handelObj.TotalSamples;
```

This command is exactly equivalent to:

```
numSamples = get(handelObj, 'TotalSamples');
```

See Also

audioplayer | set

Purpose

Query property values for `audiorecorder` object

Syntax

```
Value = get(obj,Name)
Values = get(obj,{Name1,...,NameN})
Values = get(obj)
get(obj)
```

Description

`Value = get(obj,Name)` returns the value of the specified property for object *obj*.

`Values = get(obj,{Name1,...,NameN})` returns the values of the specified properties in a 1-by-*N* cell array.

`Values = get(obj)` returns a scalar structure that contains the values of all properties of *obj*. Each field name corresponds to a property name.

`get(obj)` displays all property names and their current values.

Examples

Create an `audiorecorder` object and query the object properties:

```
recorderObj = audiorecorder;

% Display all properties.
get(recorderObj)

% Display only the SampleRate property.
get(recorderObj, 'SampleRate')

% Create a cell array that contains
% values for two properties.
info = get(recorderObj, {'BitsPerSample', 'NumberOfChannels'});
```

Alternatives

To access a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, find the value of the `TotalSamples` property for an object named `recorderObj` (as created in the Example):

```
numSamples = recorderObj.TotalSamples;
```

This command is exactly equivalent to:

```
numSamples = get(recorderObj, 'TotalSamples');
```

See Also

`audiorecorder` | `set`

Purpose

Get property value from interface, or display properties

Syntax

```
V = h.get
V = h.get('propertyname')
V = get(h,...)
```

Description

`V = h.get` returns a list of all properties and their values for the object or interface, `h`.

If `V` is empty, either there are no properties in the object, or the MATLAB software cannot read the object's type library. Refer to the COM vendor's documentation. For Automation objects, if the vendor provides documentation for a specific property, use the `V = get(h,...)` syntax to call it.

`V = h.get('propertyname')` returns the value of the property specified in the string, `propertyname`.

`V = get(h,...)` is an alternate syntax for the same operation.

Tips

The meaning and type of the return value is dependent upon the specific property being retrieved. The object's documentation should describe the specific meaning of the return value. MATLAB may convert the data type of the return value. For a description of how MATLAB converts COM data types, see "Handling COM Data in MATLAB Software".

COM functions are available on Microsoft Windows systems only.

Examples

Create a COM server running Microsoft Excel software:

```
e = actxserver ('Excel.Application');
```

Retrieve a single property value:

```
e.Path
```

Depending on your spreadsheet program, MATLAB software displays:

```
ans =
```

```
C:\Program Files\MSOffice\OFFICE11
```

Retrieve a list of all properties for the `CommandBars` interface:

```
c = e.CommandBars.get
```

MATLAB displays information similar to the following:

```
c =
                   Application: [1x1
Interface.Microsoft_Excel_11.0_Object_Library._Application]
                       Creator: 1.4808e+009
                 ActionControl: []
                 ActiveMenuBar: [1x1
Interface.Microsoft_Office_12.0_Object_Library.CommandBar]
                         Count: 129
               DisplayTooltips: 1
         DisplayKeysInTooltips: 0
                  LargeButtons: 0
            MenuAnimationStyle: 'msoMenuAnimationNone'
                        Parent: [1x1
Interface.Microsoft_Excel_11.0_Object_Library._Application]
                 AdaptiveMenus: 0
                  DisplayFonts: 1
              DisableCustomize: 0
    DisableAskAQuestionDropdown: 0
```

See Also

`set (COM)` | `inspect` | `isprop` | `addproperty` | `deleteproperty`

Purpose

Query property values of handle objects derived from `hgsetget` class

Syntax

```
CV = get(H,'PropertyName')
SV = get(h)
get(h)
```

Description

`CV = get(H,'PropertyName')` returns the value of the named property from the objects in the handle array `H`. If `H` is scalar, `get` returns a single value; if `H` is an array, `get` returns a cell array of property values. If you specify a cell array of property names, then `get` returns a cell array of values, where each row in the cell corresponds to an element in `H` and each column in the cell corresponds to an element in the property name cell array.

If `H` is nonscalar and `PropertyName` is the name of a dynamic property, `get` returns a value only if the property exists in all objects referenced in `H`.

`SV = get(h)` returns a `struct` array in which the field names are the object's property names and the values are the current values of the corresponding properties. If `h` is an array, then `SV` is a `numel(h)`-by-`1` array of `struct`s.

`get(h)` displays all property names and their current values for the MATLAB objects with handle `h`.

Your subclass can override the `hgsetget` `getdisp` method to control how MATLAB displays this information.

See Also

`get` | `handle` | `hgsetget` | `set (hgsetget)`

How To

- "Implementing a Set/Get Interface for Properties"

get (memmapfile)

Purpose

Memmapfile object properties

Syntax

```
s = get(obj)
val = get(obj, prop)
```

Description

`s = get(obj)` returns the values of all properties of the `memmapfile` object `obj` in structure array `s`. Each property retrieved from the object is represented by a field in the output structure. The name and contents of each field are the same as the name and value of the property it represents.

Note Although property names of a `memmapfile` object are not case sensitive, field names of the output structure returned by `get` (named the same as the properties they represent) are case sensitive.

`val = get(obj, prop)` returns the value(s) of one or more properties specified by `prop`. The `prop` input can be a quoted string or a cell array of quoted strings, each containing a property name. If the latter is true, `get` returns the property values in a cell array.

Examples

You can use the `get` method of the `memmapfile` class to return information on any or all of the object's properties. Specify one or more property names to get the values of specific properties.

This example returns the values of the `Offset`, `Repeat`, and `Format` properties for a `memmapfile` object. Start by constructing the object:

```
m = memmapfile('records.dat',                    ...
               'Offset', 2048,                   ...
               'Format', {                       ...
                  'int16'  [2 2] 'model';        ...
                  'uint32' [1 1] 'serialno';     ...
                  'single' [1 3] 'expenses'});
```

Use the get method to return the specified property values in a 1-by-3 cell array m_props:

```
m_props = get(m, {'Offset', 'Repeat', 'Format'})
m_props =
    [2048]    [Inf]    {3x3 cell}

m_props{3}
ans =
    'int16'     [1x2 double]    'model'
    'uint32'    [1x2 double]    'serialno'
    'single'    [1x2 double]    'expenses'
```

Another way to return the same information is to use the objname.property syntax:

```
m_props = {m.Offset, m.Repeat, m.Format}
m_props =
    [2048]    [Inf]    {3x3 cell}
```

To return the values for all properties with get, pass just the object name:

```
s = get(m)
    Filename: 'd:\matlab\records.dat'
    Writable: 0
      Offset: 2048
      Format: {3x3 cell}
      Repeat: Inf
        Data: [753 1]
```

To see just the Format field of the returned structure, type

```
s.Format
ans =
    'int16'     [1x2 double]    'model'
    'uint32'    [1x2 double]    'serialno'
    'single'    [1x2 double]    'expenses'
```

See Also

memmapfile | disp (memmapfile)

Purpose

Query property values for video reader object

Syntax

```
Value = get(obj,Name)
Values = get(obj,{Name1,...,NameN})
allValues = get(obj)
get(obj)
```

Description

`Value = get(obj,Name)` returns the value of the property with the specified `Name` for object `obj`.

`Values = get(obj,{Name1,...,NameN})` returns the values of the specified properties in a 1-by-`N` cell array.

`allValues = get(obj)` returns a scalar structure that contains the values of all properties of `obj`. Each field name corresponds to a property name.

`get(obj)` displays all property names and their current values.

Input Arguments

obj

`VideoReader` object created by the `VideoReader` function.

Name

String enclosed in single quotation marks that specifies a `VideoReader` property.

Output Arguments

Value

String containing the value associated with the specified `VideoReader` property.

Values

Cell array containing the values associated with the specified `VideoReader` properties. Values is a row vector, with one column for each property.

allValues

Scalar (1-by-1) structure array that contains the values of all properties of `VideoReader` object `obj`.

Examples

Display all properties of an object associated with the example file `xylophone.mpg`:

```
xyloObj = VideoReader('xylophone.mpg');
get(xyloObj)
```

Create a 1-by-3 cell array that contains the values of the `Height`, `Width`, and `NumberOfFrames` properties of an object associated with `xylophone.mpg`:

```
xyloObj = VideoReader('xylophone.mpg');
xyloSize = get(xyloObj, {'Height', 'Width', 'NumberOfFrames'})
```

Alternatives

To access a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, find the value of the `NumberOfFrames` property for object `xyloObj` (as created in the Examples):

```
numFrames = xyloObj.NumberOfFrames;
```

This command is exactly equivalent to:

```
numFrames = get(xyloObj, 'NumberOfFrames');
```

See Also

`VideoReader` | `set`

Purpose Random stream properties

Class `@RandStream`

Syntax

```
get(s)
P = get(s)
P = get(s,'PropertyName')
```

Description

`get(s)` prints the list of properties for the random stream `s`.

`P = get(s)` returns all properties of `s` in a scalar structure.

`P = get(s,'PropertyName')` returns the property `'PropertyName'`.

See Also `RandStream` | `set (RandStream)`

get (serial)

Purpose

Serial port object properties

Syntax

```
get(obj)
out = get(obj)
out = get(obj,'PropertyName')
```

Description

`get(obj)` returns all property names and their current values to the command line for the serial port object, `obj`.

`out = get(obj)` returns the structure `out` where each field name is the name of a property of `obj`, and each field contains the value of that property.

`out = get(obj,'PropertyName')` returns the value `out` of the property specified by *`PropertyName`* for `obj`. If *`PropertyName`* is replaced by a 1-by-n or n-by-1 cell array of strings containing property names, then `get` returns a 1-by-n cell array of values to `out`. If `obj` is an array of serial port objects, then `out` will be a m-by-n cell array of property values where m is equal to the length of `obj` and n is equal to the number of properties specified.

Tips

Refer to Displaying Property Names and Property Values for a list of serial port object properties that you can return with `get`.

When you specify a property name, you can do so without regard to case, and you can make use of property name completion. For example, if `s` is a serial port object, then these commands are all valid.

```
out = get(s,'BaudRate');
out = get(s,'baudrate');
out = get(s,'BAUD');
```

If you use the `help` command to display help for `get`, then you need to supply the pathname shown below.

```
help serial/get
```

Examples

This example illustrates some of the ways you can use `get` to return property values for the serial port object `s` on a Windows platform.

```
s = serial('COM1');
out1 = get(s);
out2 = get(s,{'BaudRate','DataBits'});
get(s,'Parity')
ans =
none
```

See Also

`set`

get (timer)

Purpose

Timer object properties

Syntax

```
get(obj)
V = get(obj)
V = get(obj,'PropertyName')
```

Description

`get(obj)` displays all property names and their current values for the timer object `obj`. `obj` must be a single timer object.

`V = get(obj)` returns a structure, `V`, where each field name is the name of a property of `obj` and each field contains the value of that property. If `obj` is an M-by-1 vector of timer objects, V is an M-by-1 array of structures.

`V = get(obj,'PropertyName')` returns the value, `V`, of the timer object property specified in *`PropertyName`*.

If *`PropertyName`* is a 1-by-N or N-by-1 cell array of strings containing property names, `V` is a 1-by-N cell array of values. If `obj` is a vector of timer objects, `V` is an M-by-N cell array of property values where M is equal to the length of `obj` and N is equal to the number of properties specified.

Examples

```
t = timer;
get(t)
       AveragePeriod: NaN
            BusyMode: 'drop'
            ErrorFcn: ''
       ExecutionMode: 'singleShot'
       InstantPeriod: NaN
                Name: 'timer-1'
    ObjectVisibility: 'on'
              Period: 1
             Running: 'off'
          StartDelay: 1
            StartFcn: ''
             StopFcn: ''
                 Tag: ''
```

```
        TasksExecuted: 0
       TasksToExecute: Inf
             TimerFcn: ''
                 Type: 'timer'
             UserData: []
get(t, {'StartDelay','Period'})
ans =

    [0]    [1]
```

See Also

`timer` | `set(timer)`

get (tscollection)

Purpose

Query `tscollection` object property values

Syntax

```
value = get(tsc,'PropertyName')
```

Description

`value = get(tsc,'PropertyName')` returns the value of the specified property of the `tscollection` object tsc. The following syntax is equivalent:

```
value = tsc.PropertyName
```

`get(tsc)` displays all properties and values of the `tscollection` object tsc.

See Also

`set (tscollection)` | `timeseries`

Purpose

Extract date-string time vector into cell array

Syntax

```
getabstime(tsc)
```

Description

`getabstime(tsc)` extracts the time vector from the `tscollection` object tsc as a cell array of date strings. To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the time-series collection. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

Examples

1 Create a `tscollection` object.

```
tsc = tscollection(timeseries([3 6 8 0 10]));
```

2 Set the `StartDate` property.

```
tsc.TimeInfo.StartDate = '10/27/2005 07:05:36';
```

3 Extract a vector of absolute time values.

```
getabstime(tsc)

ans =

    '27-Oct-2005 07:05:36'
    '27-Oct-2005 07:05:37'
    '27-Oct-2005 07:05:38'
    '27-Oct-2005 07:05:39'
    '27-Oct-2005 07:05:40'
```

4 Change the date-string format of the time vector.

```
tsc.TimeInfo.Format = 'mm/dd/yy';
```

5 Extract the time vector with the new date-string format.

```
getabstime(tsc)
```

```
ans =

    '10/27/05'
    '10/27/05'
    '10/27/05'
    '10/27/05'
    '10/27/05'
```

See Also

datestr | tscollection | setabstime (tscollection)

Purpose

Value of application-defined data

Syntax

```
value = getappdata(h,'name')
values = getappdata(h)
```

Description

`value = getappdata(h,'name')` gets the value of the application-defined data with the name specified by `name`, in the object with handle `h`. If the application-defined data does not exist, the MATLAB software returns an empty matrix in `value`.

`values = getappdata(h)` returns all application-defined data for the object with handle `h`.

Tips

Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

See Also

`setappdata` | `rmappdata` | `isappdata`

audiorecorder.getaudiodata

Purpose

Store recorded audio signal in numeric array

Syntax

```
y = getaudiodata(recorder)
y = getaudiodata(recorder, dataType)
```

Description

`y = getaudiodata(recorder)` returns recorded audio data associated with `audiorecorder` object *recorder* to `double` array *y*.

`y = getaudiodata(recorder, dataType)` converts the signal data to the specified data type: `'double'`, `'single'`, `'int16'`, `'int8'`, or `'uint8'`.

Output Arguments

y

Audio signal data *y* contains the same number of columns as the number of channels in the recording: one for mono, two for stereo. The range of values depends on the data type, as shown in the following table.

Data Type	Sample Value Range
`int8`	-128 to 127
`uint8`	0 to 255
`int16`	-32768 to 32767
`single`	-1 to 1
`double`	-1 to 1

Examples

Collect a sample of your speech with a microphone, and plot the signal data:

```
% Record your voice for 5 seconds.
recObj = audiorecorder;
disp('Start speaking.')
recordblocking(recObj, 5);
disp('End of Recording.');
```

```
% Play back the recording.
play(recObj);

% Store data in double-precision array.
myRecording = getaudiodata(recObj);

% Plot the waveform.
plot(myRecording);
```

GetCharArray

Purpose

Character array from Automation server

Syntax

MATLAB Client

```
str = h.GetCharArray('varname', 'workspace')
str = GetCharArray(h, 'varname', 'workspace')
```

IDL Method Signature

```
HRESULT GetCharArray([in] BSTR varName, [in] BSTR Workspace,  [out, retva
```

Microsoft Visual Basic Client

```
GetCharArray(varname As String, workspace As String) As String
```

Description

`str = h.GetCharArray('varname', 'workspace')` gets the character array stored in `varname` from the specified `workspace` of the server attached to handle `h` and returns it in `str`. The values for *workspace* arebase or `global`.

`str = GetCharArray(h, 'varname', 'workspace')` is an alternate syntax.

Examples

This example uses a MATLAB client.

```
h = actxserver('matlab.application');
%Assign a string to variable 'str' in the base workspace of the server
h.PutCharArray('str', 'base', ...
    'He jests at scars that never felt a wound.');
%Read 'str' back in the client
S = h.GetCharArray('str', 'base')
```

This example uses a Visual Basic .NET client.

1. Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application.

   ```
   Dim Matlab As Object
   Dim S As String
   ```

```
Matlab = CreateObject("matlab.application")
MsgBox("In MATLAB, type" & vbCrLf _
    & "str='new string';")
```

2. Open the MATLAB window, then type:

```
str='new string';
```

3. Click **Ok**.

```
Try
    S = Matlab.GetCharArray("str", "base")
    MsgBox("str = " & S)
Catch ex As Exception
    MsgBox("You did not set 'str' in MATLAB")
End Try
```

The Visual Basic `MsgBox` displays what you typed in MATLAB.

See Also

`PutCharArray` | `GetWorkspaceData` | `GetVariable`

RandStream.getDefaultStream

Purpose

Random number stream

Note `RandStream.getDefaultStream` will be removed in a future version. Use `RandStream.getGlobalStream` instead. The shared global stream used by `rand`, `randi`, and `randn`, referred to in former versions of MATLAB as the *default stream* is now referred to as the *global stream*.

Class

`RandStream`

Syntax

```
stream = RandStream.getDefaultStream
```

Description

`stream = RandStream.getDefaultStream` returns the global random number stream. The MATLAB functions `rand`, `randi`, and `randn` use the global stream to generate values.

Purpose Override to change command window display

Syntax

```
getdisp(H)
```

Description `getdisp(H)` called by `get` when `get` is called with no output arguments and a single input argument that is a handle array. Override this `hgsetget` class method in a subclass to change how property information is displayed in the command window.

See Also `hgsetget` | `get (hgsetget)`

How To

- “Implementing a Set/Get Interface for Properties”

getenv

Purpose

Environment variable

Syntax

```
getenv 'name'
N = getenv('name')
```

Description

`getenv 'name'` searches the underlying operating system's environment list for a string of the form `name=value`, where `name` is the input string. If found, the MATLAB software returns the string `value`. If the specified name cannot be found, an empty matrix is returned.

`N = getenv('name')` returns `value` to the variable `N`.

Examples

```
os = getenv('OS')

os =
Windows_NT
```

See Also

`setenv` | `computer` | `pwd` | `ver` | `path`

Purpose

Field of structure array

Syntax

```
value = getfield(struct, 'field')
value =
getfield(struct,{sIndx1,...,sIndxM},'field',{fIndx1,
   ...,fIndxN})
```

Description

`value = getfield(struct, 'field')`, where `struct` is a 1-by-1 structure, returns the contents of the specified field, equivalent to `value = struct.field`. Pass field references as strings.

`value = getfield(struct,{sIndx1,...,sIndxM},'field',{fIndx1,...,fIndxN})` returns the contents of the specified field, equivalent to `value = struct(sIndx1,...,sIndxM).field(fIndx1,...,fIndxN)`. The `getfield` function supports multiple sets of `field` and `fIndx` inputs, and all `Indx` inputs are optional. If structure `struct` or any of the fields is a nonscalar structure, and you do not specify an `Indx`, the `getfield` function returns the values associated with the first index. If you specify a single colon operator for an `fIndx` input, enclose it in single quotation marks: `':'`.

Tips

- For most cases, retrieve data from a structure array by indexing rather than using the `getfield` function. For more information, see "Access Data in a Structure Array" and "Generate Field Names from Variables".
- Call `getfield` to simplify references to structure arrays with nested fields, or to avoid creating unnecessary temporary variables, as shown in the Examples section.

Examples

The `what` function returns a structure array that describes the MATLAB files in the current folder. Find the files with the `.m` extension:

```
files = getfield(what, 'm');
```

To perform the same task by indexing requires that you create a temporary variable:

```
templist = what;
files = templist.m;
```

Find values within a structure that contains nested fields:

```
level = 5;
semester = 'Fall';
subject = 'Math';
student = 'John_Doe';
fieldnames = {semester subject student};

% Add data to a structure named grades.
grades(level).(semester).(subject).(student)(10,21:30) = ...
             [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];

% Retrieve the data added.
getfield(grades, {level}, fieldnames{:}, {10,21:30})
```

Using the structure defined in the previous example, find all values in the tenth row of the specified field:

```
getfield(grades, {level}, fieldnames{:}, {10,':'})
```

`setfield` | `fieldnames` | `isfield` | `orderfields` | `rmfield`

How To

- "Generate Field Names from Variables"
- "Access Data in a Structure Array"

Purpose

File formats that `VideoReader` supports

Syntax

```
formats = VideoReader.getFileFormats()
```

Description

`formats = VideoReader.getFileFormats()` returns an array of `audiovideo.FileFormatInfo` objects that indicate which formats `VideoReader` can read on the current system. Each object has the following properties: `Extension`, `Description`, `ContainsVideo`, and `ContainsAudio`.

Tips

- On Windows and UNIX systems, the list of file formats does not always contain all the formats that `VideoReader` can read on your system. `getFileFormats` returns a platform-dependent, static list of formats that `VideoReader` can read on most systems.
- On all systems, `VideoReader` cannot always read a particular video file even if `getFileFormats` lists its format. For more information, see Supported Video File Formats.

Output Arguments

formats

Array of `audiovideo.FileFormatInfo` objects, which have the following properties:

`Extension`	File extension.
`Description`	Text description of the file format.
`ContainsVideo`	Whether `VideoReader` can read video from this format.
`ContainsAudio`	Whether `VideoReader` can read audio from this format.

To convert this array to a filter list for dialog boxes generated with `uigetfile`, use the `getFilterSpec` method with the following syntax:

```
filterSpec = getFilterSpec(formats)
```

The filter list includes `'All Video Files'` in the first row of the cell array, and `'All Files (*.*)'` in the last row.

Examples

View the list of file formats that `VideoReader` supports on your system:

```
VideoReader.getFileFormats()
```

On a Windows system, this list appears as follows:

```
Video File Formats:
    .asf - ASF File
    .asx - ASX File
    .avi - AVI File
    .mj2 - Motion JPEG2000
    .mpg - MPEG-1
    .wmv - Windows Media Video
```

Create a dialog box to select a video file:

```
% Get the supported file formats.
formats = VideoReader.getFileFormats();

% Convert to a filter list.
filterSpec = getFilterSpec(formats);

% Create the dialog box.
[filename, pathname] = uigetfile(filterSpec);
```

Check whether `VideoReader` can read an `.avi` file on the current system:

```
fmtList = VideoReader.getFileFormats();
```

```
if any(ismember({fmtList.Extension},'avi'))
     disp('VideoReader can read AVI files on this system.');
else
     disp('VideoReader cannot read AVI files on this system.');
end
```

See Also

VideoReader

getframe

Purpose

Capture movie frame

Syntax

```
getframe
F = getframe
F = getframe(h)
F = getframe(h,rect)
```

Description

`getframe` returns a movie frame. The frame is a snapshot (pixmap) of the current axes or figure.

`F = getframe` gets a frame from the current axes.

`F = getframe(h)` gets a frame from the figure or axes identified by handle `h`.

`F = getframe(h,rect)` specifies a rectangular area from which to copy the pixmap. `rect` is relative to the lower left corner of the figure or axes `h`, in pixel units. `rect` is a four-element vector in the form `[left bottom width height]`, where `width` and `height` define the dimensions of the rectangle.

`getframe` returns a movie frame, which is a structure having two fields:

- `cdata` — The image data stored as a matrix of `uint8` values. The dimensions of `F.cdata` are height-by-width-by-3.
- `colormap` — The colormap stored as an n-by-3 matrix of doubles. `F.colormap` is empty on true color systems.

To capture an image, use this approach:

```
F = getframe(gcf);
image(F.cdata)
colormap(F.colormap)
```

Tips

`getframe` is usually used in a `for` loop to assemble an array of movie frames for playback using `movie`. For example,

```
for j = 1:n
   plotting commands
   F(j) = getframe;
```

```
end
movie(F)
```

If you are capturing frames of a plot that takes a long time to generate or are repeatedly calling `getframe` in a loop, make sure that your computer's screen saver does not activate and that your monitor does not turn off for the duration of the capture; otherwise one or more of the captured frames can contain graphics from your screen saver or nothing at all.

Note In situations where MATLAB software is running on a virtual desktop that is not currently visible on your monitor, calls to `getframe` will complete, but will capture a region on your monitor that corresponds to the position occupied by the figure or axes on the hidden desktop. Therefore, make sure that the window to be captured by `getframe` exists on the currently active desktop.

Capture Regions

`F = getframe` returns the contents of the current axes, exclusive of the axis labels, title, or tick labels.

`F = getframe(gcf)` captures the entire interior of the current figure window.

To capture the figure window menu, use `F = getframe(h,rect)` with a rectangle sized to include the menu.

Resolution of Captured Frames

The resolution of the framed image depends on the size of the axes in pixels when `getframe` is called. As the `getframe` command takes a snapshot of the screen, if the axes is small in size (e.g., because you have restricted the view to a window within the axes), `getframe` captures fewer screen pixels, and the captured image might have poor resolution if enlarged for display.

Capturing UIControls

To capture uicontrols along with the axes and any annotations displayed on the plot, specify the figure handle:

```
F = getframe(figure_handle);
```

To exclude uicontrols outside of the current axes, do not specify the figure handle:

```
F = getframe;
```

Limitations with Renderer on Windows Systems

Setting the figure `Renderer` property to `zbuffer` or `painters` works around limitations of using `getframe` with the `OpenGL` renderer on some Windows systems.

Examples

Make the `peaks` function vibrate.

```
Z = peaks;
figure('Renderer','zbuffer');
surf(Z);
axis tight;
set(gca,'NextPlot','replaceChildren');
for j = 1:20
    surf(sin(2*pi*j/20)*Z,Z)
    F(j) = getframe;
end
movie(F,20) % Play the movie twenty times
```

The fifth frame of the sequence looks like this.

`axis` | `frame2im` | `gcf` | `image` | `im2frame` | `movie`

GetFullMatrix

Purpose

Matrix from Automation server workspace

Syntax

MATLAB Client

```
[xreal ximag] =
h.GetFullMatrix('varname','workspace',zreal,
   zimag)
[xreal ximag] =
GetFullMatrix(h,'varname','workspace',zreal,
   zimag)
```

IDL Method Signature

```
GetFullMatrix([in] BSTR varname, [in] BSTR
workspace, [in, out] SAFEARRAY(double) *pr, [in,
out] SAFEARRAY(double) *pi)
```

Microsoft Visual Basic Client

```
GetFullMatrix(varname As String, workspace As String,
[out] XReal As Double, [out] XImag As Double
```

Description

`[xreal ximag] = h.GetFullMatrix('varname','`*`workspace`*`',zreal,zimag)` gets matrix stored in variable `varname` from the specified `workspace` of the server attached to handle `h`. The function returns the real part in `xreal` and the imaginary part in `ximag`. The values for *`workspace`* are `base` or `global`.

`[xreal ximag] = GetFullMatrix(h,'varname','`*`workspace`*`',zreal,zimag)` is an alternate syntax.

The `zreal` and `zimag` arguments are matrices of the same size as the real and imaginary matrices (`xreal` and `ximag`) returned from the server. The `zreal` and `zimag` matrices are commonly set to zero.

Use `GetFullMatrix` for values of type `double` only. Use `GetVariable` or `GetWorkspaceData` for other types.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the `variant` data type instead of the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`. VBScript does not support `safearray`.

Examples

This example uses a MATLAB client to read data from a MATLAB Automation server:

```
%Create the MATLAB server
h = actxserver('matlab.application');
%Create variable M in the base workspace of the server
h.PutFullMatrix('M','base',rand(5),zeros(5));
MReal = h.GetFullMatrix('M','base',zeros(5),zeros(5))
```

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

1. Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application.

```
Dim MatLab As Object
Dim Result As String
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim i, j As Integer

MatLab = CreateObject("matlab.application")
Result = MatLab.Execute("M = rand(5);")
MsgBox("In MATLAB, type" & vbCrLf _
    & "M(3,4)")
```

2. Open the MATLAB window and type:

```
M(3,4)
```

3. Click **Ok**.

4. In the Visual Basic application:

```
MatLab.GetFullMatrix("M", "base", XReal, XImag)
i = 2   %0-based array
j = 3

MsgBox("XReal(" & i + 1 & "," & j + 1 & ")" & _
    " = " & XReal(i, j))
```

5. Click **Ok** to close and terminate MATLAB.

`PutFullMatrix` | `GetVariable` | `GetWorkspaceData` | `Execute`

How To

- “Exchanging Data with the Server”
- “MATLAB COM Automation Server Interface”

getpixelposition

Purpose

Get component position in pixels

Syntax

```
position = getpixelposition(handle)
position = getpixelposition(handle,recursive)
```

Description

`position = getpixelposition(handle)` gets the position, in pixel units, of the component with handle `handle`. The `position` is returned as a four-element vector that specifies the location and size of the component: [distance from left, distance from bottom, width, height].

`position = getpixelposition(handle,recursive)` gets the position as above. If `recursive` is true, the returned position is relative to the parent figure of `handle`.

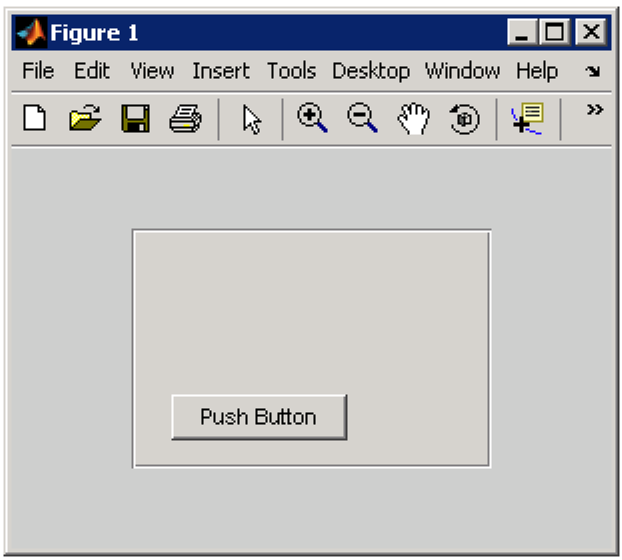
Use the `getpixelposition` function only to obtain coordinates for children of figures and container components (uipanels, or uibuttongroups). Results are not reliable for children of axes or other Handle Graphics objects.

Examples

This example creates a push button within a panel, and then retrieves its position, in pixels, relative to the panel.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton','Units','Normalized',...
               'String','Push Button','Position',[.1 .1 .5 .2]);
pos1 = getpixelposition(h1)

pos1 =
     18.6000   12.6000   88.0000   23.2000
```



The following statement retrieves the position of the push button, in pixels, relative to the figure.

```
pos1 = getpixelposition(h1,true)

pos1 =
      79.6000   53.6000   88.0000   23.2000
```

See Also

`setpixelposition` | `uicontrol` | `uipanel`

Purpose

Preference

Syntax

```
getpref('group','pref')
getpref('group','pref',default)
getpref('group',{'pref1','pref2',...'prefn'})
getpref('group',{'pref1',...'prefn'},{default1,...defaultn})
getpref('group')
getpref
```

Description

`getpref('group','pref')` returns the value for the preference specified by `group` and `pref`. It is an error to get a preference that does not exist.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. `'ApplicationOnePrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`getpref('group','pref',default)` returns the current value if the preference specified by `group` and `pref` exists. Otherwise creates the preference with the specified default value and returns that value.

`getpref('group',{'pref1','pref2',...'prefn'})` returns a cell array containing the values for the preferences specified by `group` and the cell array of preference names. The return value is the same size as the input cell array. It is an error if any of the preferences do not exist.

`getpref('group',{'pref1',...'prefn'},{default1,...defaultn})` returns a cell array with the current values of the preferences specified by `group` and the cell array of preference names. Any preference that does not exist is created with the specified default value and returned.

`getpref('group')` returns the names and values of all preferences in the `group` as a structure.

`getpref` returns all groups and preferences as a structure.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

Example 1

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')

ans =
     1.0
```

Example 2

```
rmpref('mytoolbox','version')
getpref('mytoolbox','version','1.0');
getpref('mytoolbox','version')

ans =
     1.0
```

See Also

addpref | ispref | rmpref | setpref | uigetpref | uisetpref

Purpose

List profiles and file formats supported by `VideoWriter`

Syntax

```
profiles = VideoWriter.getProfiles()
```

Description

`profiles = VideoWriter.getProfiles()` returns an array of `audiovideo.writer.ProfileInfo` objects that indicate the types of files `VideoWriter` can create.

Output Arguments

profiles

An array of `audiovideo.writer.ProfileInfo` objects, which have the following read-only properties:

`Name`	String profile name, such as `'Uncompressed AVI'`.
`Description`	String description of the profile.
`FileExtensions`	Cell array of strings containing file extensions supported by the file format.
`ColorChannels`	Number of color channels in each output video frame.
`CompressionRatio`	Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. Only applies to objects associated with Motion JPEG 2000 files. Default: `10`.
`FrameRate`	Rate of playback for the video in frames per second. Default: `30`.

LosslessCompression	Boolean value (logical `true` or `false`) that specifies whether to use reversible mode, so that the decompressed data is identical to the input data. When `true`, `VideoWriter` ignores values for `CompressionRatio`. Only applies to objects associated with Motion JPEG 2000 files.
MJ2BitDepth	Number of least significant bits in the input image data, from 1 to 16. Only applies to objects associated with Motion JPEG 2000 files.
Quality	Number from 0 through 100. Higher values correspond to higher quality video and larger files. Only applies to objects associated with the `MPEG-4` or `Motion JPEG AVI` profile. Default: `75`.
VideoBitsPerPixel	Number of bits per pixel in each output video frame.
VideoCompressionMethod	String indicating the type of video compression, such as `'None'` or `'Motion JPEG'`.
VideoFormat	String indicating the MATLAB representation of the video format, such as `'RGB24'`.

Examples

Profile Information

View the list of available profiles and specific information about the `'Uncompressed AVI'` profile.

```
profiles = VideoWriter.getProfiles()

uncompAVI = find(ismember({profiles.Name},'Uncompressed AVI'));
profiles(uncompAVI)
```

```
profiles(uncompAVI).FileExtensions
```

See Also

`VideoWriter`

getReport (MException)

Purpose

Get error message for exception

Syntax

```
msgString = getReport(exception)
msgString = getReport(exception, type)
msgString = getReport(exception, type, 'hyperlinks', value)
```

Description

msgString = getReport(*exception*) returns a formatted message string, *msgString*, from an exception. This exception is represented by the *exception* input which is a scalar object of the MException class. The message string returned by getReport is the same as the error message displayed by MATLAB when it throws this exception.

msgString = getReport(*exception*, *type*) returns a message string that either describes just the error (**basic** type), or shows the error and the stack as well (**extended** type). The *type* argument, when used, must be the second argument in the input argument list. See "Examples" on page 1-2001 , below.

type Option	Displayed Text
'extended'	Display line number, error message, and cause and stack summary (default)
'basic'	Display line number and error message

msgString = getReport(*exception*, *type*, '**hyperlinks**', *value*) returns a message string that either does or does not include active hyperlinks to the failing lines in the code. See the table below for the valid choices for *value*. The **hyperlinks** and *value* arguments, when used, must be the third and fourth arguments in the input argument list.

`value` Option	Action
'on'	Display hyperlinks to failing lines (default)
'off'	Do not display hyperlinks to failing lines
'default'	Use the default for the Command Window to determine whether or not to use hyperlinks in the error message

Examples

This function attempts to read from a file that does not exist. When you call it, pass either `basic' or `extended' to specify the type of report you want to see displayed:

```
function line = test_getreport(file, rpttype)
try
    line = read_file(file);
catch exc
    getReport(exc, rpttype)
end

function line = read_file(file)
    fid = fopen(file, 'r');
    line = fread(fid);
```

The basic option displays only the error message:

```
test_getreport('filethatdoesnotexist.txt', 'basic')
ans =

Error using fread

Invalid file identifier.  Use fopen to generate a valid file identifie
```

The extended option displays the error message and error call stack:

```
test_getreport('filethatdoesnotexist.txt', 'extended')
ans =
```

```
Error using fread

Invalid file identifier.  Use fopen to generate a valid file identifier.

Error in test_getreport>read_file (line 10)

    line = fread(fid);

Error in test_getreport (line 3)

    line = read_file(file);
```

Purpose Extract data samples into new `tscollection` object

Syntax

```
tsc2 = getsampleusingtime(tsc1,Time)
tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)
```

Description `tsc2 = getsampleusingtime(tsc1,Time)` returns a new `tscollection` tsc2 with a single sample corresponding to Time in tsc1.

`tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)` returns a new `tscollection` tsc2 with samples between the times StartTime and EndTime in tsc1.

Tips When the time vector in ts1 is numeric, `StartTime` and `EndTime` must also be numeric. When the times in ts1 are date strings and the `StartTime` and `EndTime` values are numeric, then the `StartTime` and `EndTime` values are treated as `datenum` values.

See Also `tscollection`

Tiff.getTag

Purpose

Value of specified tag

Syntax

```
tagValue = getTag(tagId)
```

Description

`tagValue = getTag(tagId)` retrieves the value of the TIFF tag specified by `tagId`. You can specify `tagId` as a character string (`'ImageWidth'`) or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

Examples

Open a `Tiff` object, and get the value of a tag. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path:

```
t = Tiff('myfile.tif', 'r');
% Specify tag by name.
tagval = t.getTag('ImageWidth');
%
% Specify tag by numeric identifier.
tagval1 = t.getTag(256);
%
% Specify tag by name.
tagval2 = t.getTag('t.TagID.ImageWidth');
```

References

This method corresponds to the `TIFFGetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTiff - TIFF Library and Utilities`.

Purpose List of recognized TIFF tags

Syntax

```
tagNames = Tiff.getTagNames()
```

Description `tagNames = Tiff.getTagNames()` returns a cell array of TIFF tags recognized by the `Tiff` object.

Examples Retrieve a list of TIFF tags recognized by the `Tiff` object.

```
Tiff.getTagNames

ans =

    'SubFileType'
    'ImageWidth'
    'ImageLength'
    'BitsPerSample'
    'Compression'
    'Photometric'
    'Thresholding'
    'FillOrder'
    'DocumentName'
    'ImageDescription'
     .
     .
     .
```

gettimeseriesnames

Purpose

Cell array of names of `timeseries` objects in `tscollection` object

Syntax

```
names = gettimeseriesnames(tsc)
```

Description

`names = gettimeseriesnames(tsc)` returns `names` of `timeseries` objects in a `tscollection` object `tsc`. `names` is a cell array of strings.

Examples

1 Create `timeseries` objects `a` and `b`.

```
a = timeseries(rand(1000,1),'name','position');
b = timeseries(rand(1000,1),'name','response');
```

2 Create a `tscollection` object that includes these two time series.

```
tsc = tscollection({a,b});
```

3 Get the names of the `timeseries` objects in `tsc`.

```
names = gettimeseriesnames(tsc)

names =

    'position'    'response'
```

See Also

`timeseries` | `tscollection`

Purpose

New `timeseries` object with samples occurring at or after event

Syntax

```
ts1 = gettsafteratevent(ts,event)
ts1 = gettsafteratevent(ts,event,n)
```

Description

`ts1 = gettsafteratevent(ts,event)` returns a new `timeseries` object ts1 with samples occurring at and after an event in ts, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of the time series ts that matches the event name specifies the time.

`ts1 = gettsafteratevent(ts,event,n)` returns a new `timeseries` object ts1 with samples at and after an event in ts, where n is the number of the event occurrence with a matching event name.

Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

See Also

`gettsafterevent` | `gettsbeforeevent` | `gettsbetweenevents` | `tsdata.event` | `timeseries`

gettsafterevent

Purpose

New `timeseries` object with samples occurring after event

Syntax

```
ts1 = gettsafterevent(ts,event)
ts1 = ttsafterevent(ts,event,n)
```

Description

`ts1 = gettsafterevent(ts,event)` returns a new `timeseries` object ts1 with samples occurring after an event in ts, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = ttsafterevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring after an event in time series `ts`, where n is the number of the event occurrence with a matching event name.

Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

Purpose

New `timeseries` object with samples occurring at event

Syntax

```
ts1 = gettsatevent(ts,event)
ts1 = gettsatevent(ts,event,n)
```

Description

`ts1 = gettsatevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at an event in `ts`, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsatevent(ts,event,n)` returns a new time series `ts1` with samples occurring at an event in time series `ts`, where n is the number of the event occurrence with a matching event name.

Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in the `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

gettsbeforeatevent

Purpose

New `timeseries` object with samples occurring before or at event

Syntax

```
ts1 = gettsbeforeatevent(ts,event)
ts1 = gettsbeforeatevent(ts,event,n)
```

Description

`ts1 = gettsbeforeatevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in `ts`, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeatevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in time series `ts`, where n is the number of the event occurrence with a matching event name.

Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

gettsbeforeevent

Purpose

New `timeseries` object with samples occurring before event

Syntax

```
ts1 = gettsbeforeevent(ts,event)
ts1 = gettsbeforeevent(ts,event,n)
```

Description

`ts1 = gettsbeforeevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where n is the number of the event occurrence with a matching event name.

Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

See Also

gettsbetweenevents

Purpose

New `timeseries` object with samples occurring between events

Syntax

```
ts1 = gettsbetweenevents(ts,event1,event2)
ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)
```

Description

`ts1 = gettsbetweenevents(ts,event1,event2)` returns a new `timeseries` object ts1 with samples occurring between events in `ts`, where `event1` and `event2` can be either a `tsdata.event` object or a string. When `event1` and `event2` are `tsdata.event` objects, the time defined by the events is used. When `event1` and `event2` are strings, the first `tsdata.event` object in the `Events` property of `ts` that matches the event names specifies the time.

`ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)` returns a new `timeseries` object ts1 with samples occurring between events in `ts`, where `n1` and `n2` are the `n`th occurrences of the events with matching event names.

Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

`gettsafterevent` | `gettsbeforeevent` | `tsdata.event`

Purpose

Data from variable in Automation server workspace

Syntax

MATLAB Client

```
D = h.GetVariable('varname','workspace')
D = GetVariable(h,'varname','workspace')
```

IDL Method Signature

```
HRESULT GetVariable([in] BSTR varname, [in] BSTR
workspace, [out, retval] VARIANT* pdata)
```

Microsoft Visual Basic Client

```
GetVariable(varname As String, workspace As
String) As Object
```

Description

`D = h.GetVariable('varname','workspace')` gets data stored in variable `varname` from the specified `workspace` of the server attached to handle `h` and returns it in output argument `D`. The values for *`workspace`* are `base` or `global`.

`D = GetVariable(h,'varname','workspace')` is an alternate syntax.

Do *not* use `GetVariable` on sparse arrays, structures, or function handles.

If your scripting language requires a result be returned explicitly, use the `GetVariable` function in place of `GetWorkspaceData`, `GetFullMatrix` or `GetCharArray`.

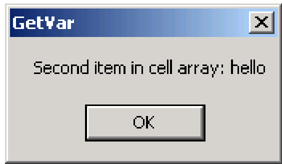
Examples

This example uses a MATLAB client to read data from a MATLAB Automation server:

```
%Create the MATLAB server
h = actxserver('matlab.application');
%Create variable C1 in the base workspace of the server
h.PutWorkspaceData('C1', 'base', {25.72, 'hello', rand(4)});
%The client reads the data
C2 = h.GetVariable('C1','base')
```

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object
Dim Result As String
Dim C2 As Variant
Matlab = CreateObject("matlab.application")
Result = Matlab.Execute("C1 = {25.72, 'hello', rand(4)};")
C2 = Matlab.GetVariable("C1", "base")
MsgBox("Second item in cell array: " & C2(0, 1))
```



See Also

`GetWorkspaceData` | `GetFullMatrix` | `GetCharArray` | `Execute`

How To

- “MATLAB COM Automation Server Interface”
- “Exchanging Data with the Server”

Purpose

LibTIFF library version

Syntax

```
versionString = Tiff.getVersion()
```

Description

`versionString = Tiff.getVersion()` returns the version number and other information about the LibTIFF library.

Examples

Display version of LibTIFF library:

```
Tiff.getVersion

ans =

LIBTIFF, Version 3.9.5
Copyright (c) 1988-1996 Sam Leffler
Copyright (c) 1991-1996 Silicon Graphics, Inc.
```

References

This method corresponds to the `TIFFGetVersion` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTIFF - TIFF Library and Utilities`.

GetWorkspaceData

Purpose

Data from Automation server workspace

Syntax

MATLAB Client

```
D = h.GetWorkspaceData('varname','workspace')
D = GetWorkspaceData(h,'varname','workspace')
```

IDL Method Signature

```
HRESULT GetWorkspaceData([in] BSTR varname, [in] BSTR
workspace, [out] VARIANT* pdata)
```

Microsoft Visual Basic Client

```
GetWorkspaceData(varname As String, workspace
As String) As Object
```

Description

`D = h.GetWorkspaceData('varname','workspace')` gets data stored in variable `varname` from the specified `workspace` of the server attached to handle `h` and returns it in output argument `D`. The values for *`workspace`* are `base` or `global`.

`D = GetWorkspaceData(h,'varname','workspace')` is an alternate syntax.

Use `GetWorkspaceData` instead of `GetFullMatrix` and `GetCharArray` to get numeric and character array data, respectively. Do *not* use `GetWorkspaceData` on sparse arrays, structures, or function handles.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the `variant` data type instead of the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`. VBScript does not support `safearray`.

Examples

This example uses a MATLAB client to read data from a MATLAB Automation server:

```
%Create the MATLAB server
h = actxserver('matlab.application');
%Create cell array C1 in the base workspace of the server
```

```
h.PutWorkspaceData('C1', 'base', ...
    {25.72, 'hello', rand(4)});
C2 = h.GetWorkspaceData('C1', 'base')
```

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object
Dim C2 As Variant
Dim Result As String
Matlab = CreateObject("matlab.application")
Result = MatLab.Execute("C1 = {25.72, 'hello', rand(4)};")
MsgBox("In MATLAB, type" & vbCrLf & "C1")
Matlab.GetWorkspaceData("C1", "base", C2)
MsgBox("second value of C1 = " & C2(0, 1))
```

ginput

Purpose

Graphical input from mouse or cursor

Syntax

```
[x,y] = ginput(n)
[x,y] = ginput
[x,y,button] = ginput(...)
```

Description

`ginput` raises crosshairs in the current axes to for you to identify points in the figure, positioning the cursor with the mouse. The figure must have focus before `ginput` can receive input. If it has no axes, one is created upon the first click or keypress.

`[x,y] = ginput(n)` enables you to identify `n` points from the current axes and returns their *x*- and *y*-coordinates in the `x` and `y` column vectors. Press the **Return** key to terminate the input before entering `n` points.

`[x,y] = ginput` gathers an unlimited number of points until you press the **Return** key.

`[x,y,button] = ginput(...)` returns the *x*-coordinates, the *y*-coordinates, and the button or key designation. `button` is a vector of integers indicating which mouse buttons you pressed (1 for left, 2 for middle, 3 for right), or ASCII numbers indicating which keys on the keyboard you pressed.

Clicking an axes makes that axes the current axes. Even if you set the current axes before calling `ginput`, whichever axes you click becomes the current axes and `ginput` returns points relative to that axes. If you select points from multiple axes, the results returned are relative to the coordinate system of the axes they come from.

Note MATLAB returns errors such as the following if you start MATLAB with the `noFigureWindows` or `nodisplay` flag and then run `ginput`:

```
Error using ginput (line 31)
Terminal mode is no longer supported
```

Definitions

Coordinates returned by `ginput` are scaled to the `XLim` and `YLim` bounds of the axes you click (data units). Setting the axes or figure `Units` property has no effect on the output from `ginput`. You can click anywhere within the figure canvas to obtain coordinates. If you click outside the axes limits, `ginput` extrapolates coordinate values so they are still relative to the axes origin.

The figure `CurrentPoint` property, by contrast, is always returned in figure Units, irrespective of axes Units or limits.

Examples

Pick 4 two-dimensional points from the figure window.

```
[x,y] = ginput(4)
```

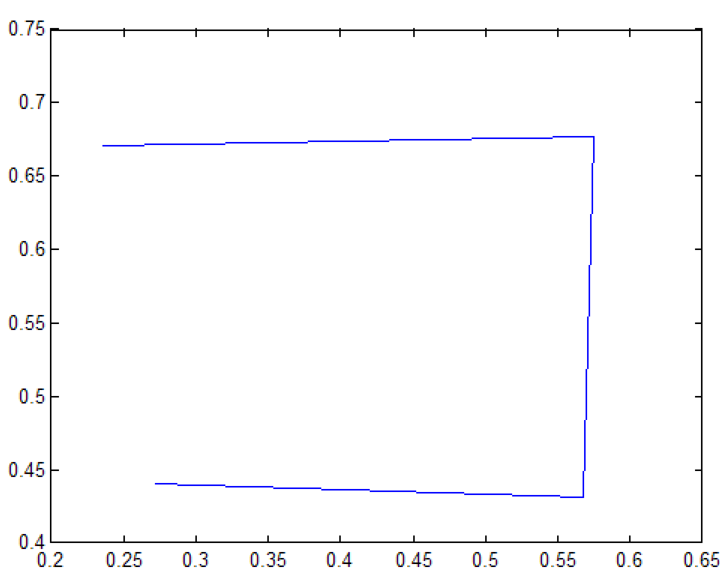
Position the cursor with the mouse. Enter data points by pressing a mouse button or a key on the keyboard. To terminate input before entering 4 points, press the **Return** key.

```
x =
    0.2362
    0.5749
    0.5680
    0.2707

y =
    0.6711
    0.6769
    0.4313
```

```
    0.4401

plot(x,y)
```



In this example, `plot` rescaled the axes *x*-limits and *y*-limits from `[0 1]` and `[0 1]` to `[0.20 0.65]` and `[0.40 0.75]`. The rescaling occurred because the axes `XLimMode` and `YLimMode` are set to `'auto'` (the default). Consider setting `XLimMode` and `YLimMode` to `'manual'` if you want to maintain consistency when you gather results from `ginput` and plot them together.

- "Subsetting a Graphics Image (Cropping)"

Purpose

Declare global variables

Syntax

`global X Y Z`

Description

`global X Y Z` defines `X`, `Y`, and `Z` as global in scope.

Ordinarily, each MATLAB function has its own local variables, which are separate from those of other functions, and from those of the base workspace. However, if several functions, and possibly the base workspace, all declare a particular name as global, they all share a single copy of that variable. Any assignment to that variable, in any function, is available to all the functions declaring it global.

If the global variable does not exist the first time you issue the `global` statement, it is initialized to the empty matrix.

If a variable with the same name as the global variable already exists in the current workspace, MATLAB issues a warning and changes the value of that variable to match the global.

Tips

Use `clear global` *`variable`* to clear a global variable from the global workspace. Use `clear` *`variable`* to clear the global link from the current workspace without affecting the value of the global.

To use a global within a callback, declare the global, use it, then clear the global link from the workspace. This avoids declaring the global after it has been referenced. For example,

```
cbstr = sprintf('%s, %s, %s, %s, %s', ...
   'global MY_GLOBAL',                 ...
   'MY_GLOBAL = 100',                  ...
   'disp(MY_GLOBAL)',                  ...
   'MY_GLOBAL = MY_GLOBAL+1',          ...
   'clear MY_GLOBAL');

uicontrol('style', 'pushbutton', 'CallBack', cbstr, ...
   'string', 'count')
```

There is no function form of the global command (i.e., you cannot use parentheses and quote the variable names).

Examples

Example 1

Type `edit global_demo1` at the command line and enter the following function definition in a new file named `global_demo1.m`.

```
function global_demo1(num)
global globalvar

if nargin > 0
    globalvar = num;
end

fprintf('Global variable in function %s is %d\n', ...
    mfilename, globalvar);
```

This function declares a global variable named `globalvar`. If you pass a value when calling the function, the function stores the value in `globalvar` and then displays it. If you call the function with no arguments, the function just displays the value last written to the global workspace.

Create another function `global_demo2` just like it. These two functions have separate function workspaces, but share a common global workspace:

```
copyfile global_demo1.m global_demo2.m
```

Call `global_demo1`, passing a numeric value. Then call `global_demo2` with no value. You can see that the latter function has global access to the value that was passed to `global_demo1`.

```
global_demo1(1357);
Global variable in function global_demo1 is 1357

global_demo2
Global variable in function global_demo2 is 1357
```

Now set the value in `global_demo2` and read it in `global_demo1`:

```
global_demo2(2468)
Global variable in function global_demo2 is 2468

global_demo1
Global variable in function global_demo1 is 2468
```

Example 2

Call the function `global_demo1` that was defined in the previous example to assign a value to variable `globalvar` in the global workspace. Even though the variable is global, it is not accessible outside of the function workspace:

```
clear all
global_demo1(1357);
Global variable in function global_demo1 is 1357

if exist('globalvar', 'var')
    fprintf('Global variable is set to %d\n', globalvar);
else
    fprintf('Global variable is not available at the command line.\n')
end

Global variable is not available at the command line.
```

Now declare `globalvar` as a global variable at the MATLAB command line. Run the same statements to display the variable and this time you can see that the value assigned by the function is also available as a global variable in the base workspace:

```
global globalvar

if exist('globalvar', 'var')
    fprintf('Global variable is set to %d\n', globalvar);
else
```

```
    fprintf('Global variable is not available at the command line.\n');
end

Global variable is set to 1357
```

Example 3

Here is the code for the functions `tic` and `toc` (some comments abridged). These functions manipulate a stopwatch-like timer. The global variable `TICTOC` is shared by the two functions, but it is invisible in the base workspace or in any other functions that do not declare it.

```
function tic
%    TIC Start a stopwatch timer.
%        TIC; any stuff; TOC
%    prints the time required.
%    See also: TOC, CLOCK.
global TICTOC
TICTOC = clock;

function t = toc
%    TOC Read the stopwatch timer.
%    TOC prints the elapsed time since TIC was used.
%    t = TOC; saves elapsed time in t, does not print.
%    See also: TIC, ETIME.
global TICTOC
if nargout < 1
    elapsed_time = etime(clock, TICTOC)
else
    t = etime(clock, TICTOC);
end
```

`clear` | `isglobal` | `who`

Purpose

Generalized minimum residual method (with restarts)

Syntax

```
x = gmres(A,b)
gmres(A,b,restart)
gmres(A,b,restart,tol)
gmres(A,b,restart,tol,maxit)
gmres(A,b,restart,tol,maxit,M)
gmres(A,b,restart,tol,maxit,M1,M2)
gmres(A,b,restart,tol,maxit,M1,M2,x0)
[x,flag] = gmres(A,b,...)
[x,flag,relres] = gmres(A,b,...)
[x,flag,relres,iter] = gmres(A,b,...)
[x,flag,relres,iter,resvec] = gmres(A,b,...)
```

Description

`x = gmres(A,b)` attempts to solve the system of linear equations `A*x = b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle, `afun`, such that `afun(x)` returns `A*x`. For this syntax, `gmres` does not restart; the maximum number of iterations is `min(n,10)`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `gmres` converges, a message to that effect is displayed. If `gmres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`gmres(A,b,restart)` restarts the method every `restart` inner iterations. The maximum number of outer iterations is `min(n/restart,10)`. The maximum number of total iterations is `restart*min(n/restart,10)`. If `restart` is `n` or `[]`, then `gmres` does not restart and the maximum number of total iterations is `min(n,10)`.

`gmres(A,b,restart,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `gmres` uses the default, `1e-6`.

`gmres(A,b,restart,tol,maxit)` specifies the maximum number of outer iterations, i.e., the total number of iterations does not exceed `restart*maxit`. If `maxit` is `[]` then `gmres` uses the default, `min(n/restart,10)`. If `restart` is `n` or `[]`, then the maximum number of total iterations is `maxit` (instead of `restart*maxit`).

`gmres(A,b,restart,tol,maxit,M)` and `gmres(A,b,restart,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `gmres` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`gmres(A,b,restart,tol,maxit,M1,M2,x0)` specifies the first initial guess. If `x0` is `[]`, then `gmres` uses the default, an all-zero vector.

`[x,flag] = gmres(A,b,...)` also returns a convergence flag:

`flag = 0`	`gmres` converged to the desired tolerance `tol` within `maxit` outer iterations.
`flag = 1`	`gmres` iterated `maxit` times but did not converge.
`flag = 2`	Preconditioner `M` was ill-conditioned.
`flag = 3`	`gmres` stagnated. (Two consecutive iterates were the same.)

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = gmres(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`. The third output, `relres`, is the relative residual of the preconditioned system.

`[x,flag,relres,iter] = gmres(A,b,...)` also returns both the outer and inner iteration numbers at which `x` was computed, where `0 <= iter(1) <= maxit` and `0 <= iter(2) <= restart`.

`[x,flag,relres,iter,resvec] = gmres(A,b,...)` also returns a vector of the residual norms at each inner iteration. These are the residual norms for the preconditioned system.

Examples

Using gmres with a Matrix Input

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = gmres(A,b,10,tol,maxit,M1);
```

displays the following message:

```
gmres(10) converged at outer iteration 2 (inner iteration 9) to
a solution with relative residual 3.3e-013
```

Using gmres with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in a function `run_gmres` that

- Calls `gmres` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_gmres` are available to `afun` and `mfun`.

The following shows the code for `run_gmres`:

```
function x1 = run_gmres
n = 21;
b = afun(ones(n,1));
tol = 1e-12;  maxit = 15;
x1 = gmres(@afun,b,10,tol,maxit,@mfun);

    function y = afun(x)
        y = [0; x(1:n-1)] + ...
              [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
              [x(2:n); 0];
    end
```

```
    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
end
```

When you enter

```
x1 = run_gmres;
```

MATLAB software displays the message

```
gmres(10) converged at outer iteration 2 (inner iteration 10)
to a solution with relative residual 1.1e-013.
```

Using a Preconditioner without Restart

This example demonstrates the use of a preconditioner without restarting `gmres`.

1

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

2

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

3

Define `b` so that the true solution is a vector of all ones.

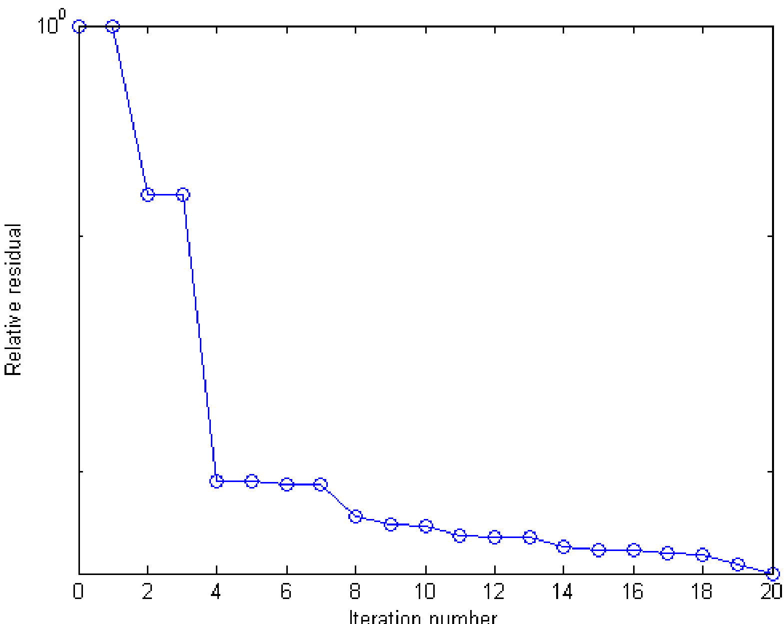
```
b = full(sum(A,2));
[x0,fl0,rr0,it0,rv0] = gmres(A,b,[],tol,maxit);
```

`fl0` is 1 because `gmres` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The best approximate solution that `gmres` returns is the last one (as indicated by `it0(2) = 20`). MATLAB stores the residual history in `rv0`.

4

Plot the behavior of `gmres`:

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution converges slowly. A preconditioner may improve the outcome.

5

Use `ilu` to form the preconditioner, since `A` is nonsymmetric :

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
Error using ilu
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

Note MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

6

As indicated by the error message, try again with a reduced drop tolerance:

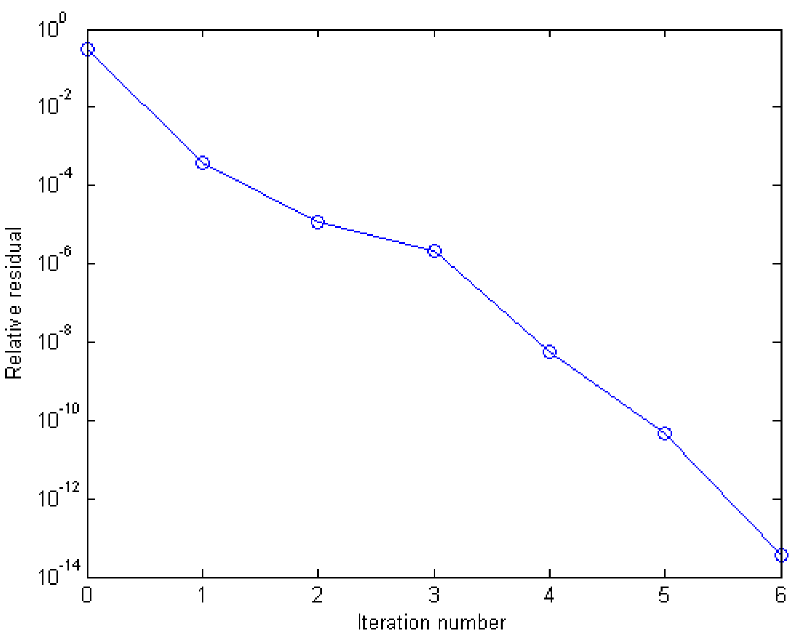
```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = gmres(A,b,[],tol,maxit,L,U);
```

`fl1` is 0 because `gmres` drives the relative residual to `9.5436e-14` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the sixth iteration (the value of `it1(2)`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output, `rv1(1)`, is `norm(M\b)`, where `M = L*U`. The output, `rv1(7)`, is `norm(U\(L\(b-A*x1)))`.

7

Follow the progress of `gmres` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1(2),rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



Using a Preconditioner with Restart

This example demonstrates the use of a preconditioner with restarted `gmres`.

1

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

2

Define `b` so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

3

Construct an incomplete LU preconditioner as in the previous example:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
```

The benefit to using restarted `gmres` is to limit the amount of memory required to execute the method. Without restart, `gmres` requires `maxit` vectors of storage to keep the basis of the Krylov subspace. Also, `gmres` must orthogonalize against all of the previous vectors at each step. Restarting limits the amount of workspace used and the amount of work done per outer iteration. Note that even though preconditioned `gmres` converged in six iterations above, the algorithm allowed for as many as twenty basis vectors and therefore, allocated all of that space up front.

4

Execute `gmres(3)`, `gmres(4)`, and `gmres(5)`:

```
tol = 1e-12; maxit = 20;
re3 = 3;
[x3,fl3,rr3,it3,rv3] = gmres(A,b,re3,tol,maxit,L,U);
re4 = 4;
[x4,fl4,rr4,it4,rv4] = gmres(A,b,re4,tol,maxit,L,U);
re5 = 5;
[x5,fl5,rr5,it5,rv5] = gmres(A,b,re5,tol,maxit,L,U);
```

`fl3`, `fl4`, and `fl5` are all 0 because in each case restarted `gmres` drives the relative residual to less than the prescribed tolerance of `1e-12`. The following plots show the convergence histories of each restarted `gmres` method. `gmres(3)` converges at outer iteration 5, inner iteration 3 (`it3 = [5, 3]`) which would be the same as outer iteration 6, inner iteration 0, hence the marking of 6 on the final tick mark.

gobjects

Purpose

Create array of graphics handles

Syntax

```
H = gobjects(n)
H = gobjects(s1,...,sn)
H = gobjects(v)

H = gobjects
H = gobjects(0)
```

Description

`H = gobjects(n)` returns an `n`-by-`n` array of graphics handles. Use the `gobjects` function instead of the `ones` or `zeros` functions to preallocate an array to store graphics handles.

`H = gobjects(s1,...,sn)` returns an `s1`-by-...-by-`sn` array of graphics handles, where the list of integers `s1,...,sn` defines the dimensions of the array. For example, `gobjects(2,3)` returns a 2-by-3 array.

`H = gobjects(v)` returns an array of graphics handles where the elements of the row vector, `v`, define the dimensions of the array. For example, `gobjects([2,3,4])` returns a 2-by-3-by-4 array.

`H = gobjects` returns a 1-by-1 graphics handle array.

`H = gobjects(0)` returns empty.

Input Arguments

n - Size of square matrix

integer value

Size of the square matrix, specified as an integer value. Negative integers are treated as 0. The square matrix has dimensions `n`-by-`n`.

Data Types

`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

s1,...,sn - Size of each array dimension

two or more integer values

Size of each array dimension, specified as a list of two or more integer values. Negative integers are treated as 0.

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

v - Size of each array dimension

row vector of integer values

Size of each array dimension, specified as a row vector of integer values. Negative integers are treated as 0.

Example: [2,4,6,7]

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Examples

Specifying Array Dimensions

Preallocate a 4-by-1 array to store graphics handles.

```
H = gobjects(4,1);
```

You can assign axes handles to the array elements.

```
for k = 1:4
    H(k) = subplot(2,2,k);
end
```

Specifying Array Dimensions with Size of Existing Array

Create an array to store graphics handles using the size of an existing array.

Define `A` as a 3-by-4 array.

```
A = [1,2,3,2; 4,5,6,6; 7,8,9,7];
```

Create an array of graphics handles using the size of A.

```
v = size(A);
H = gobjects(v);
```

The dimensions of the graphics handle array are the same as the dimensions of A.

```
isequal(size(H),size(A))
```

```
ans =

     1
```

Returning Empty Handle Array

Use the `gobjects` function to return an empty array.

```
H = gobjects(0)
```

```
H =

     []
```

Purpose

Plot nodes and links representing adjacency matrix

Syntax

```
gplot(A,Coordinates)
gplot(A,Coordinates,LineSpec)
```

Description

The `gplot` function graphs a set of coordinates using an adjacency matrix.

`gplot(A,Coordinates)` plots a graph of the nodes defined in `Coordinates` according to the *n*-by-*n* adjacency matrix `A`, where *n* is the number of nodes. `Coordinates` is an *n*-by-2 matrix, where *n* is the number of nodes and each coordinate pair represents one node.

`gplot(A,Coordinates,`*`LineSpec`*`)` plots the nodes using the line type, marker symbol, and color specified by *`LineSpec`*.

Tips

For two-dimensional data, `Coordinates(i,:) = [x(i) y(i)]` denotes node `i`, and `Coordinates(j,:) = [x(j)y(j)]` denotes node `j`. If node `i` and node `j` are connected, `A(i,j)` or `A(j,i)` is nonzero; otherwise, `A(i,j)` and `A(j,i)` are zero.

Examples

Plot half of a “Bucky ball” carbon molecule, placing asterisks at each node:

```
k = 1:30;
[B,XY] = bucky;
gplot(B(k,k),XY(k,:),'-*')
axis square
```

`LineSpec` | `sparse` | `spy`

Purpose

Extract MATLAB code from file published to HTML

Syntax

```
grabcode('name.html')
grabcode('urlname')
codeString = grabcode('name.html')
```

Description

`grabcode('name.html')` copies MATLAB code from the file `name.html` and pastes it into an untitled document in the Editor. Use `grabcode` to get MATLAB code from published files when the source code is not readily available. The file `name.html` was created by publishing `name.m`, a MATLAB code file containing cells. The MATLAB code from `name.m` is included at the end of `name.html` as HTML comments.

`grabcode('urlname')` copies MATLAB code from the `urlname` location and pastes it into an untitled document in the Editor.

`codeString = grabcode('name.html')` gets MATLAB code from the file `name.html` and assigns it the variable `codeString`.

Examples

This example illustrates how to use `grabcode` to get MATLAB code from an existing HTML file:

```
% Copy sine_wave_f.html and the images it includes
% from the MATLAB examples directory to your
% current folder:

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
 'examples','sine_wave_f.html'), 'my_sine_wave.html')

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
 'examples','sine_wave_f_01.png'), 'sine_wave_f_01.png')

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
 'examples','sine_wave_f_02.png'), 'sine_wave_f_02.png')

% If you want to view the file, double-click my_sine_wave.html
5 in your current folder.
```

```
% Extract the MATLAB code from sine_wave_f.html:
code = grabcode('my_sine_wave.html')
```

MATLAB returns:

```
code =

%% Plot Sine Wave
% Calculate and plot a sine wave.

%% Calculate and Plot Sine Wave
% Calculate and plot |y = sin(x)|.

function sine_wave_f(x)

y = sin(x);
plot(x,y)

%% Modify Plot Properties

title('Sine Wave', 'FontWeight','bold')
xlabel('x')
ylabel('sin(x)')
set(gca, 'Color', 'w')
set(gcf, 'MenuBar', 'none')

publish
```

Purpose

Numerical gradient

Syntax

```
FX = gradient(F)
[FX,FY] = gradient(F)
[FX,FY,FZ,...] = gradient(F)
[...] = gradient(F,h)
[...] = gradient(F,h1,h2,...)
```

Definitions

The *gradient* of a function of two variables, $F(x,y)$, is defined as

$$\nabla F = \frac{\partial F}{\partial x}\hat{i} + \frac{\partial F}{\partial y}\hat{j}$$

and can be thought of as a collection of vectors pointing in the direction of increasing values of F. In MATLAB software, numerical gradients (differences) can be computed for functions with any number of variables. For a function of N variables, $F(x,y,z, ...)$,

$$\nabla F = \frac{\partial F}{\partial x}\hat{i} + \frac{\partial F}{\partial y}\hat{j} + \frac{\partial F}{\partial z}\hat{k} + \ldots$$

Description

`FX = gradient(F)` where `F` is a vector returns the one-dimensional numerical gradient of `F`. `FX` corresponds to $\partial F/\partial x$, the differences in x (horizontal) direction.

`[FX,FY] = gradient(F)` where `F` is a matrix returns the x and y components of the two-dimensional numerical gradient. `FX` corresponds to $\partial F/\partial x$, the differences in x (horizontal) direction. `FY` corresponds to $\partial F/\partial y$, the differences in the y (vertical) direction. The spacing between points in each direction is assumed to be one.

`[FX,FY,FZ,...]  = gradient(F)` where `F` has `N dimensions` returns the `N` components of the gradient of `F`. There are two ways to control the spacing between values in `F`:

- A single spacing value, `h`, specifies the spacing between points in every direction.

- N spacing values (h1,h2,...) specifies the spacing for each dimension of F. Scalar spacing parameters specify a constant spacing for each dimension. Vector parameters specify the coordinates of the values along corresponding dimensions of F. In this case, the length of the vector must match the size of the corresponding dimension.

Note The first output FX is always the gradient along the 2nd dimension of F, going across columns. The second output FY is always the gradient along the 1st dimension of F, going across rows. For the third output FZ and the outputs that follow, the Nth output is the gradient along the Nth dimension of F.

[...] = gradient(F,h) where h is a scalar uses h as the spacing between points in each direction.

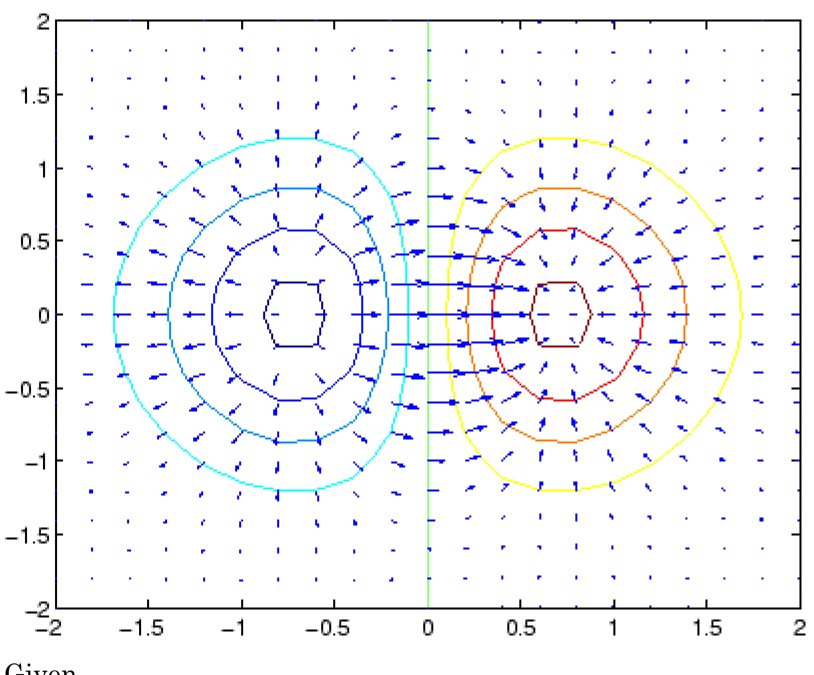
[...] = gradient(F,h1,h2,...) with N spacing parameters specifies the spacing for each dimension of F.

Examples

The statements

```
v = -2:0.2:2;
[x,y] = meshgrid(v);
z = x .* exp(-x.^2 - y.^2);
[px,py] = gradient(z,.2,.2);
contour(v,v,z), hold on, quiver(v,v,px,py), hold off
```

produce



Given,

```
F(:,:,1) = magic(3); F(:,:,2) = pascal(3);
gradient(F)
```

takes `dx = dy = dz = 1`.

```
[PX,PY,PZ] = gradient(F,0.2,0.1,0.2)
```

takes `dx = 0.2`, `dy = 0.1`, and `dz = 0.2`.

`del2` | `diff`

graymon

Purpose

Set default figure properties for grayscale monitors

Syntax

```
graymon
```

Description

`graymon` sets defaults for graphics properties to produce more legible displays for grayscale monitors.

See Also

`axes` | `figure`

Purpose

Grid lines for 2-D and 3-D plots

Syntax

```
grid on
grid off
grid minor
grid
grid(axes_handle,...)
grid minor
```

Description

`grid on` adds major grid lines to the current axes.

`grid off` removes major and minor grid lines from the current axes.

`grid minor` toggles the visibility of minor grid lines of the current axes.

`grid` toggles the major grid visibility state.

`grid(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

Algorithms

`grid` sets the `XGrid`, `YGrid`, and `ZGrid` properties of the axes.

`grid minor` sets the `XMinorGrid`, `YMinorGrid`, and `ZMinorGrid` properties of the axes. Reissuing `grid minor` toggles minor grid visibility.

You can set the grid lines for just one axis using the `set` command and the individual property. For example,

```
set(axes_handle,'XGrid','on')
```

turns on only *x*-axis grid lines.

You can set grid line width with the axes `LineWidth` property.

By default, the number of grid lines changes when you resize a figure. To prevent this and keep grids the same at any size, set the `XTickMode` or `YTickMode` axes properties to `'manual'`:

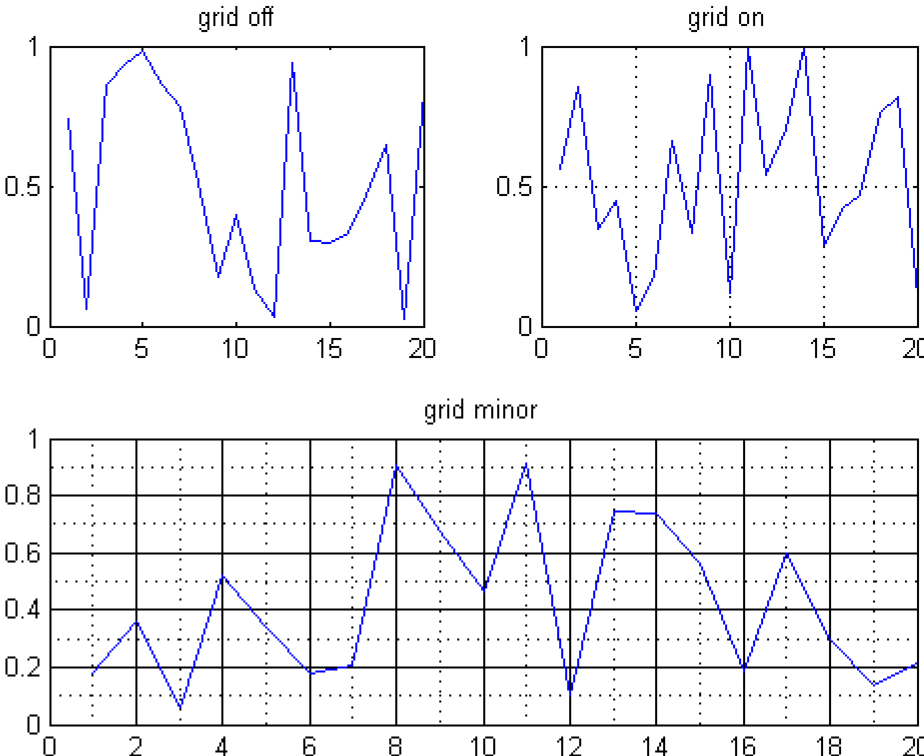
```
set(axes_handle,'XTickMode','manual')
set(axes_handle,'YTickMode','manual')
```

To customize the locations of ticks along an axis, set the axes XTick, YTick, and ZTick properties. For minor ticks, use the XMinorTick, YMinorTick, and ZTick properties.

Examples

Create multiple plots within a single figure and manipulate their grid visibility using the grid function:

```
figure
subplot(2,2,1)
plot(rand(1,20))
title('grid off')
subplot(2,2,2)
plot(rand(1,20))
grid on
title('grid on')
subplot(2,2,[3 4])
plot(rand(1,20))
grid on
set(gca, 'GridLineStyle', '-');
grid(gca,'minor')
title('grid minor')
```



You can also use the following code to control grids on a per-axis basis:

```
set(axh,'XGrid','on','YGrid','on','ZGrid','on')
```

Alternatives

To control the presence and appearance of grid lines on a graph, use the Property Editor, one of the plotting tools. For details, see The Property Editor.

box | axes | set

griddata

Purpose

Interpolate scattered data

Note Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `griddata`.

In a future release, the following syntaxes will be removed:

```
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq)
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq, method)
```

In addition, `griddata` will not accept any input vectors of mixed orientation in a future release. To specify a grid of query points, construct a full grid with `ndgrid` or `meshgrid` before calling `griddata`.

Syntax

```
vq = griddata(x,y,v,xq,yq)
vq = griddata(x,y,z,v,xq,yq,zq)
vq = griddata(..., method)
```

Description

`vq = griddata(x,y,v,xq,yq)` fits a surface of the form $v = f(x,y)$ to the scattered data in the vectors `(x,y,v)`. The `griddata` function interpolates the surface at the query points specified by `(xq,yq)` and returns the interpolated values, `vq`. The surface always passes through the data points defined by `x` and `y`.

`vq = griddata(x,y,z,v,xq,yq,zq)` fits a hypersurface of the form $v = f(x,y,z)$.

`vq = griddata(..., method)` uses a specified interpolation method to compute `vq`.

Input Arguments

x

Vector specifying the *x*- coordinates of the sample points.

y

Vector specifying the *y*- coordinates of the sample points.

z

Vector specifying the *z*- coordinates of the sample points.

v

Vector of sample values that correspond to the sample coordinates `x`, `y` (and `z` for 3-D interpolation).

xq

Vector or array that specifies *x*- coordinates of the query points to be evaluated. `xq` must be the same size as `yq` (and `zq` for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

yq

Vector or array that specifies *y*- coordinates of the query points to be evaluated. `yq` must be the same size as `xq` (and `zq` for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

zq

Vector or array that specifies *z*- coordinates of the query points to be evaluated. `zq` must be the same size as `xq` and `yq`.

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

method

Keyword that specifies the interpolation method. Use one of the following:

`'linear'`	Linear interpolation (default)
`'cubic'`	Cubic interpolation
`'natural'`	Natural neighbor interpolation
`'nearest'`	Nearest neighbor interpolation
`'v4'`	MATLAB 4 `griddata` method

Output Arguments

vq

The interpolated values at the query points.

- For 2-D interpolation, where `xq` and `yq` specify an `m`-by-`n` grid of query points, `vq` is an `m`-by-`n` array.
- For 3-D interpolation, where `xq`, `yq`, and `zq` specify an `m`-by-`n`-by-`p` grid of query points, `vq` is an `m`-by-`n`-by-`p` array.
- If `xq`, `yq`, (and `zq` for 3-D interpolation) are vectors that specify scattered points, `vq` is a vector of the same length.

Examples

Interpolate Scattered Data Over a Uniform Grid

Sample a function at 200 random points between `-2.5` and `2.5`.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);
x = xy(:,1); y = xy(:,2);
v = x.*exp(-x.^2-y.^2);
```

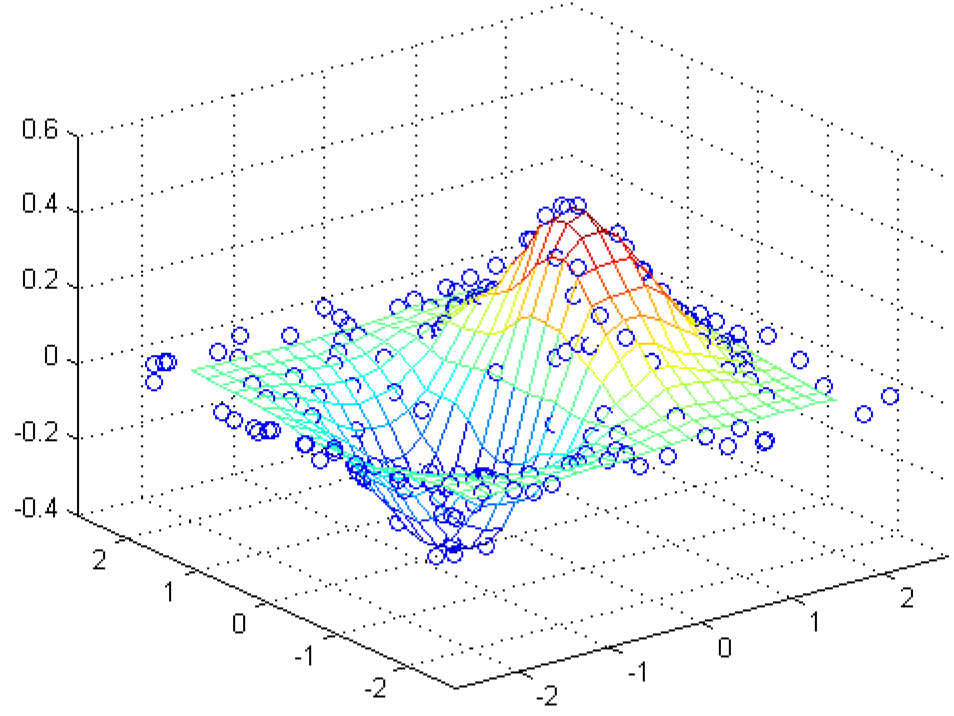
`x`, `y`, and `v` are vectors containing scattered (nonuniform) sample points and data.

Define a regular grid and interpolate the scattered data over the grid.

```
[xq,yq] = meshgrid(-2:.2:2, -2:.2:2);
vq = griddata(x,y,v,xq,yq);
```

Plot the gridded data as a mesh and the scattered data as dots.

```
figure
mesh(xq,yq,vq);
hold on
plot3(x,y,v,'o');
h = gca;
set(h,'XLim',[-2.7 2.7]);
set(h,'YLim',[-2.7 2.7]);
```



Interpolate 3-D Data Set Over a Grid in the x-y Plane

Sample a function at 5000 random points between -1 and 1.

```
rng(0,'twister')
x = 2*rand(5000,1)-1;
y = 2*rand(5000,1)-1;
z = 2*rand(5000,1)-1;
v = x.^2 + y.^2 + z.^2;
```

x, y, and z are now vectors containing nonuniformly sampled data. Define a regular grid with points in the range [-0.8, 0.8].

```
d = -0.8:0.05:0.8;
[xq,yq,zq] = meshgrid(d,d,0);
```

Interpolate the scattered data over a rectangular region at z=0. Then, plot the results.

```
vq = griddata(x,y,z,v,xq,yq,zq);
surf(xq,yq,vq);
set(gca,'XTick',[-1 -0.5 0 0.5 1]);
set(gca,'YTick',[-1 -0.5 0 0.5 1]);
```

griddatan

Purpose

Data gridding and hypersurface fitting (dimension ≥ 2)

Syntax

```
yi = griddatan(x,y,xi)
yi = griddatan(x,y,xi,method)
yi = griddatan(x,y,xi,method,options)
```

Description

`yi = griddatan(x,y,xi)` fits a hyper-surface of the form *y = f(x)* to the data in the (usually) nonuniformly-spaced vectors (`x`, `y`). `griddatan` interpolates this hyper-surface at the points specified by `xi` to produce `yi`. `xi` can be nonuniform.

`X` is of dimension `m`-by-`n`, representing `m` points in n-dimensional space. `y` is of dimension `m`-by-`1`, representing `m` values of the hyper-surface *f*(`X`). `xi` is a vector of size `p`-by-`n`, representing `p` points in the n-dimensional space whose surface value is to be fitted. `yi` is a vector of length `p` approximating the values *f*(`xi`). The hypersurface always goes through the data points (`X`,`y`). `xi` is usually a uniform grid (as produced by `meshgrid`).

`yi = griddatan(x,y,xi,method)` defines the type of surface fit to the data, where `'method'` is one of:

'linear'	Triangulation-based linear interpolation (default)
'nearest'	Nearest neighbor interpolation

All the methods are based on a Delaunay triangulation of the data.

If `method` is `[]`, the default `'linear'` method is used.

`yi = griddatan(x,y,xi,method,options)` specifies a cell array of strings `options` to be used in Qhull via `delaunayn`.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options are used, not even the default.

Examples

```
X=2*gallery('uniformdata',[5000 3],0)-1;;
Y = sum(X.^2,2);
d = -0.8:0.05:0.8;
```

```
[y0,x0,z0] = ndgrid(d,d,d);
XI = [x0(:) y0(:) z0(:)];
YI = griddatan(X,Y,XI);
```

Since it is difficult to visualize 4-D data sets, use isosurface at 0.8:

```
YI = reshape(YI, size(x0));
p = patch(isosurface(x0,y0,z0,YI,0.8));
isonormals(x0,y0,z0,YI,p);
set(p,'FaceColor','blue','EdgeColor','none');
view(3), axis equal, axis off, camlight, lighting phong
```

griddedInterpolant

Purpose

Gridded data interpolation

Note The behavior of `griddedInterpolant` has changed. All interpolation methods now support extrapolation by default. Set `F.ExtrapolationMethod` to `'none'` to preserve the pre-R2013a behavior when `F.Method` is `'linear'`, `'cubic'` or `'nearest'`. Before R2013a, evaluation returned `NaN` values at query points outside the domain when `F.Method` was set to `'linear'`, `'cubic'` or `'nearest'`.

Description

Use `griddedInterpolant` to perform interpolation on a 1-D, 2-D, 3-D, or N-D "Gridded Data" on page 1-2062 set. For example, you can pass a set of `(x,y)` points and values, `v`, to `griddedInterpolant`, and it returns a surface of the form $v = F(x, y)$. This surface always passes through the sample values at the point locations. You can evaluate this surface at any query point, `(xq,yq)`, to produce an interpolated value, `vq`.

Use `griddedInterpolant` to create the "Interpolant" on page 1-2062, `F`. Then you can evaluate `F` at specific points using any of the following syntaxes:

- `Vq = F(Xq)` evaluates `F` at a set of query points in matrix `Xq`. The points in `Xq` are scattered, and each row of `Xq` contains the coordinates of a query point.
- `Vq = F(xq1,xq2,...,xqn)` specifies the query locations, `xq1,xq2,...,xqn`, as column vectors of length `m` representing `m` points scattered in `n`-dimensional space.
- `Vq = F(Xq1,Xq2,...,Xqn)` specifies the query locations as `n` `n`-dimensional arrays, `Xq1,Xq2,...,Xqn`, of equal size which define a "Full Grid" on page 1-2062 of points.
- `Vq = F({xgq1,xgq2,...,xgqn})` specifies the query locations as "Grid Vectors" on page 1-2062 . Use this syntax to conserve memory when you want to query a large grid of points.

Construction

`F = griddedInterpolant(x,v)` creates a 1-D interpolant from a vector of sample points, `x`, and corresponding values, `v`.

`F = griddedInterpolant(X1,X2,...,Xn,V)` creates a 2-D, 3-D, or N-D interpolant using a "Full Grid" on page 1-2062 of sample points passed as a set of `n`-dimensional arrays, `X1,X2,...,Xn`. The V array contains the sample values associated with the point locations in `X1,X2,...,Xn`. Each of the arrays, `X1,X2,...,Xn` must be the same size as `V`.

`F = griddedInterpolant(V)` uses the default grid to create the interpolant. When you use this syntax, `griddedInterpolant` defines the grid as set of points whose spacing is `1` and range is [`1`, `size(V,i)`] in the `i`th dimension. Use this syntax to when you want to conserve memory and are not concerned about the relative distances between points.

`F = griddedInterpolant({xg1,xg2,...,xgn},V)` specifies `n` "Grid Vectors" on page 1-2062 to describe an `n`-dimensional grid of sample points. Use this syntax when you want to use a specific grid and also conserve memory.

`F = griddedInterpolant( ___ ,Method)` specifies any of five strings that describe an interpolation method: `'nearest'`, `'linear'`, `'spline'`, `'pchip'`, or `'cubic'`. You can specify `Method` as the last input argument in any of the first four syntaxes.

`F = griddedInterpolant( ___ ,Method,ExtrapolationMethod)` specifies both the interpolation and extrapolation methods as strings. `griddedInterpolant` uses `ExtrapolationMethod` to estimate the value when your query points fall outside the domain of your sample points. Specify `Method` and `ExtrapolationMethod` together as the last two input arguments in any of the first four syntaxes.

Input Arguments

x

Sample points vector, specified as a vector of input coordinates the same size as `v`.

v

Sample values vector, specified as a vector of input values the same size as x.

X1,X2,...,Xn

Sample points in "Full Grid" on page 1-2062 form, specified as a set of n-dimensional arrays. You can create the arrays, X1,X2,...,Xn, using the ndgrid function. These arrays are all the same size, and each one is the same size as V.

{xg1,xg2,...,xgn}

Sample points in grid vector form, specified as a cell array of grid vectors. These vectors must specify a grid that is the same size as V. In other words, size(V) = [length(xg1) length(xg2),...,length(xgn)]. Use this form as an alternative to the full grid to save memory when your grid is very large.

V

Sample values, specified as an array. The elements of V are the values that correspond to the sample points. The size of V must be the size of the full grid of sample points.

- If you specify the sample points as a full grid consisting of N-D arrays, then V must be the same size as any one of: X1,X2,...,Xn.
- If you specify the sample points as grid vectors, then size(V) = [length(xg1) length(xg2) ... length(xgn)].

Method

Interpolation method, specified as a string from the table below.

Method String	Description
'linear' (default)	Linear interpolation of the values at neighboring grid points in each respective dimension.
'nearest'	Nearest neighbor interpolation.

Method String	Description
'spline'	Spline interpolation.
'pchip'	Shape-preserving piecewise cubic interpolation (1-D only).
'cubic'	Cubic interpolation of the values at neighboring grid points in each respective dimension. This method supports only uniformly spaced data.

ExtrapolationMethod

Extrapolation method, specified as any of the `Method` choices: `'linear'`, `'nearest'`, `'spline'`, `'pchip'`, or `'cubic'`. In addition, you can specify `'none'` if you want queries outside the domain of your grid return `NaN` values.

If you omit `ExtrapolationMethod`, the default value is the string you specify for `Method`. If you omit both the `Method` and `ExtrapolationMethod` arguments, both default to `'linear'`.

Properties

GridVectors

Cell array containing grid vectors, `{xg1,xg2,...,xgn}`. These vectors specify the grid points (locations) for the values in `F.Values`.

Values

Array of values associated with the grid points in `F.GridVectors`.

Method

A string specifying the name of a method used to interpolate the data. `Method` is one of five strings: `'nearest'`, `'linear'`, `'spline'`, `'pchip'`, or `'cubic'`. The default value is `'linear'`.

ExtrapolationMethod

A string specifying the name of a method used to extrapolate the data. `ExtrapolationMethod` is one of six strings: `'nearest'`,

`'linear'`, `'spline'`, `'pchip'`, `'cubic'`, or `'none'`. A value of `'none'` indicates that extrapolation is disabled. The default value is the value of `F.Method`.

Definitions

Interpolant

Interpolating function that you can evaluate at query locations.

Gridded Data

A set of points that are axis-aligned and ordered.

Scattered Data

A set of points that have no structure among their relative locations.

Full Grid

A grid represented as a set of arrays. For example, you can create a full grid using `ndgrid`.

Grid Vectors

A set of vectors that serve as a compact representation of a grid in `ndgrid` format. For example, `[X,Y] = ndgrid(xg,yg)` returns a full grid in the matrices `X` and `Y`. You can represent the same grid using the grid vectors, `xg` and `yg`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Indexing

Index-based editing of the properties of `F` are not supported. Instead, wholly replace the `GridVectors` or `Values` arrays as necessary. See "Interpolation with the griddedInterpolant Class" in the MATLAB Mathematics documentation for more information.

Examples

2-D Interpolation Over Finer Grid

Interpolate coarsely sampled data using a full grid with spacing of `0.5`.

Define the sample points as a full grid with range [1, 10] in both dimensions.

```
[X,Y] = ndgrid(1:10,1:10);
```

Sample $f(x,y) = x^2+y^2$ at the grid points.

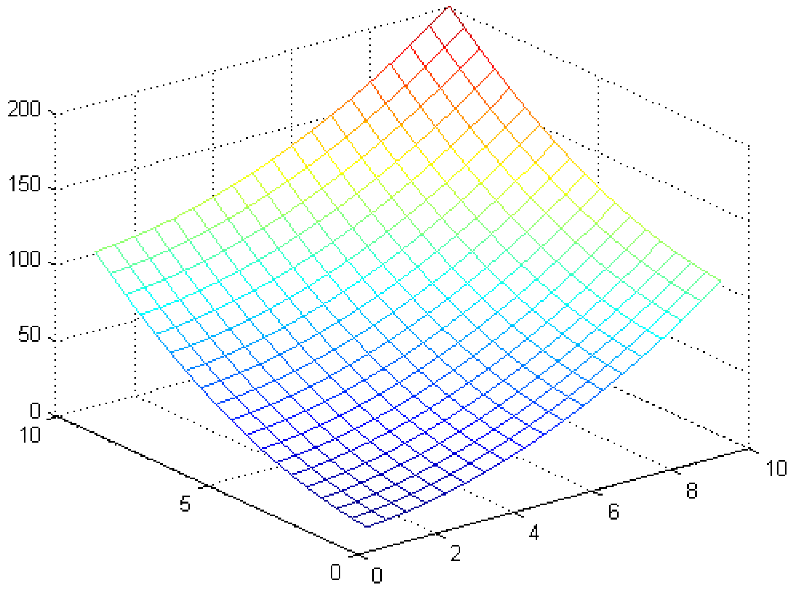
```
V = X.^2 + Y.^2;
```

Create the interpolant, specifying cubic interpolation.

```
F = griddedInterpolant(X,Y,V,'cubic');
```

Define a full grid of query points with `0.5` spacing and evaluate the interpolant at those points. Then plot the result.

```
[Xq,Yq] = ndgrid(1:0.5:10,1:0.5:10);
Vq = F(Xq,Yq);
mesh(Xq,Yq,Vq);
```



1-D Extrapolation

Compare results of querying the interpolant outside the domain of `F` using the `'pchip'` and `'nearest'` extrapolation methods.

Create the interpolant and specify `'pchip'` as the interpolation method.

```
x = [1 2 3 4 5];
v = [12 16 31 10 6];
F = griddedInterpolant(x,v,'pchip')
```

```
F =

  griddedInterpolant with properties:

            GridVectors: {[1 2 3 4 5]}
                 Values: [12 16 31 10 6]
                 Method: 'pchip'
```

```
    ExtrapolationMethod: 'pchip'
```

Query the interpolant, and include points outside the domain of `F`.

```
xq = 0:0.1:6;
vq = F(xq);
figure
plot(x,v,'o',xq,vq,'-b');
legend ('v','vq')
```

Query the interpolant at the same points again, using the nearest neighbor extrapolation method.

```
F.ExtrapolationMethod = 'nearest';
figure
vq = F(xq);
plot(x,v,'o',xq,vq,'-b');
legend ('v','vq')
```

- Property Attributes
- "Interpolating Gridded Data"

gsvd

Purpose

Generalized singular value decomposition

Syntax

```
[U,V,X,C,S] = gsvd(A,B)
sigma = gsvd(A,B)
```

Description

`[U,V,X,C,S] = gsvd(A,B)` returns unitary matrices `U` and `V`, a (usually) square matrix `X`, and nonnegative diagonal matrices `C` and `S` so that

```
A = U*C*X'
B = V*S*X'
C'*C + S'*S = I
```

`A` and `B` must have the same number of columns, but may have different numbers of rows. If `A` is `m`-by-`p` and `B` is `n`-by-`p`, then `U` is `m`-by-`m`, `V` is `n`-by-`n` and `X` is `p`-by-`q` where `q = min(m+n,p)`.

`sigma = gsvd(A,B)` returns the vector of generalized singular values, `sqrt(diag(C'*C)./diag(S'*S))`.

The nonzero elements of `S` are always on its main diagonal. If `m >= p` the nonzero elements of `C` are also on its main diagonal. But if `m < p`, the nonzero diagonal of `C` is `diag(C,p-m)`. This allows the diagonal elements to be ordered so that the generalized singular values are nondecreasing.

`gsvd(A,B,0)`, with three input arguments and either `m` or `n >= p`, produces the "economy-sized"decomposition where the resulting `U` and `V` have at most `p` columns, and `C` and `S` have at most `p` rows. The generalized singular values are `diag(C)./diag(S)`.

When `B` is square and nonsingular, the generalized singular values, `gsvd(A,B)`, are equal to the ordinary singular values, `svd(A/B)`, but they are sorted in the opposite order. Their reciprocals are `gsvd(B,A)`.

In this formulation of the `gsvd`, no assumptions are made about the individual ranks of `A` or `B`. The matrix `X` has full rank if and only if the matrix `[A;B]` has full rank. In fact, `svd(X)` and `cond(X)` are equal to `svd([A;B])` and `cond([A;B])`. Other formulations, eg. G. Golub and

C. Van Loan [1], require that `null(A)` and `null(B)` do not overlap and replace `X` by `inv(X)` or `inv(X')`.

Note, however, that when `null(A)` and `null(B)` do overlap, the nonzero elements of `C` and `S` are not uniquely determined.

Examples

Example 1

The matrices have at least as many rows as columns.

```
A = reshape(1:15,5,3)
B = magic(3)
A =
          1     6    11
          2     7    12
          3     8    13
          4     9    14
          5    10    15
B =
          8     1     6
          3     5     7
          4     9     2
```

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 5-by-5 orthogonal `U`, a 3-by-3 orthogonal `V`, a 3-by-3 nonsingular `X`,

```
X =
        2.8284   -9.3761   -6.9346
       -5.6569   -8.3071  -18.3301
        2.8284   -7.2381  -29.7256
```

and

```
C =
        0.0000         0         0
```

```
              0    0.3155         0
              0         0    0.9807
              0         0         0
              0         0         0
S =
         1.0000         0         0
              0    0.9489         0
              0         0    0.1957
```

Since `A` is rank deficient, the first diagonal element of `C` is zero.

The economy sized decomposition,

```
[U,V,X,C,S] = gsvd(A,B,0)
```

produces a 5-by-3 matrix `U` and a 3-by-3 matrix `C`.

```
U =
         0.5700   -0.6457   -0.4279
        -0.7455   -0.3296   -0.4375
        -0.1702   -0.0135   -0.4470
         0.2966    0.3026   -0.4566
         0.0490    0.6187   -0.4661

C =
         0.0000         0         0
              0    0.3155         0
              0         0    0.9807
```

The other three matrices, `V`, `X`, and `S` are the same as those obtained with the full decomposition.

The generalized singular values are the ratios of the diagonal elements of `C` and `S`.

```
sigma = gsvd(A,B)
sigma =
         0.0000
         0.3325
```

```
        5.0123
```

These values are a reordering of the ordinary singular values

```
svd(A/B)
ans =
        5.0123
        0.3325
        0.0000
```

Example 2

The matrices have at least as many columns as rows.

```
A = reshape(1:15,3,5)
B = magic(5)
A =

     1     4     7    10    13
         2     5     8    11    14
         3     6     9    12    15
B =
    17    24     1     8    15
        23     5     7    14    16
         4     6    13    20    22
        10    12    19    21     3
        11    18    25     2     9
```

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 3-by-3 orthogonal `U`, a 5-by-5 orthogonal `V`, a 5-by-5 nonsingular `X` and

```
C =
             0          0     0.0000          0          0
             0          0          0     0.0439          0
             0          0          0          0     0.7432
```

```
S =
       1.0000         0         0         0         0
            0    1.0000         0         0         0
            0         0    1.0000         0         0
            0         0         0    0.9990         0
            0         0         0         0    0.6690
```

In this situation, the nonzero diagonal of `C` is `diag(C,2)`. The generalized singular values include three zeros.

```
sigma = gsvd(A,B)
sigma =
            0
            0
       0.0000
       0.0439
       1.1109
```

Reversing the roles of `A` and `B` reciprocates these values, producing two infinities.

```
gsvd(B,A)
ans =
      1.0e+016 *

       0.0000
       0.0000
       4.4126
          Inf
          Inf
```

Algorithms

The generalized singular value decomposition uses the C-S decomposition described in [1], as well as the built-in `svd` and `qr` functions. The C-S decomposition is implemented in a local function in the `gsvd` program file.

Diagnostics

The only warning or error message produced by `gsvd` itself occurs when the two input arguments do not have the same number of columns.

`qr` | `svd`

Purpose

Test for greater than

Syntax

```
A > B
gt(A, B)
```

Description

`A > B` compares each element of array `A` with the corresponding element of array `B`, and returns an array with elements set to logical 1 (`true`) where `A` is greater than `B`, or set to logical 0 (`false`) where `A` is less than or equal to `B`. Each input of the expression can be an array or a scalar value.

If both `A` and `B` are scalar (i.e., 1-by-1 matrices), then the MATLAB software returns a scalar value.

If both `A` and `B` are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as `A` and `B`.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input `A` is the number 100, and `B` is a 3-by-5 matrix, then `A` is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

`gt(A, B)` is called for the syntax `A>B` when either `A` or `B` is an object.

Examples

Create two 6-by-6 matrices, `A` and `B`, and locate those elements of `A` that are greater than the corresponding elements of `B`:

```
A = magic(6);
B = repmat(3*magic(3), 2, 2);

A > B
ans =
     1     0     0     1     1     1
     0     1     0     1     1     1
     1     0     0     1     0     1
     0     1     1     0     1     0
```

```
     1     0     1     1     0     0
     0     1     1     1     0     1
```

How To

- "Relational Operators"

gtext

Purpose

Mouse placement of text in 2-D view

Syntax

```
gtext('string')
gtext({'string1','string2','string3',...})
gtext({'string1';'string2';'string3';...})
gtext(...,'PropertyName',PropertyValue,...)
h = gtext(...)
```

Description

`gtext` displays a text string in the current figure window after you select a location with the mouse.

`gtext('`*`string`*`')` waits for you to press a mouse button or keyboard key while the pointer is within a figure window. Pressing a mouse button or any key places `'`*`string`*`'` on the plot at the selected location.

`gtext({'string1','string2','string3',...})` places all strings with one click, each on a separate line.

`gtext({'string1';'string2';'string3';...})` places one string per click, in the sequence specified.

`gtext(...,'PropertyName',PropertyValue,...)` sets the values of the specified text properties. For a list of properties, see `Text Properties`.

`h = gtext(...)` returns the handle to a text graphics object that is placed on the plot at the location you select.

Tips

As you move the pointer into a figure window, the pointer becomes crosshairs to indicate that `gtext` is waiting for you to select a location. `gtext` uses the functions `ginput` and `text`.

Examples

Place a label on the current plot:

```
gtext('Note this divergence!')
```

See Also

`ginput` | `text`

Purpose

Store or retrieve GUI data

Syntax

```
guidata(object_handle,data)
data = guidata(object_handle)
```

Description

`guidata(object_handle,data)` stores the variable `data` as GUI data. If `object_handle` is not a figure handle, then the object's parent figure is used. `data` can be any MATLAB variable, but is typically a structure, which enables you to add new fields as required.

`guidata` can manage only one variable at any time. Subsequent calls to `guidata(object_handle,data)` overwrite the previously created version of GUI `data`.

GUIDE Uses guidata

GUIDE uses `guidata` to store and maintain the `handles` structure. In a GUIDE GUI code file, do not overwrite the `handles` structure or your GUI will no longer work. If you need to store data other than handles for your GUI, you can add new fields to the `handles` structure and safely place your data there. See GUI Data in the MATLAB documentation.

`data = guidata(object_handle)` returns previously stored data, or an empty matrix if nothing is stored.

To change the data managed by `guidata`:

1. Get a copy of the data with the command `data = guidata(object_handle)`.
2. Make the desired changes to `data`.
3. Save the changed version of `data` with the command `guidata(object_handle,data)`.

guidata provides application developers with a convenient interface to a figure's application data:

- You do not need to create and maintain a hard-coded property name for the application data throughout your source code.
- You can access the data from within a local function callback routine using the component's handle (which is returned by gcbo), without needing to find the figure's handle.

If you are not using GUIDE, guidata is particularly useful in conjunction with guihandles, which creates a structure containing the handles of all the components in a GUI.

Examples

This example calls guidata to save a structure containing a GUI figure's application data from within the initialization section of the application code file. The first section shows how to do this within a GUI you create manually. The second section shows how the code differs when you use GUIDE to create a template code file. GUIDE provides a handles structure as an argument to all local function callbacks, so you do not need to call guidata to obtain it. You do, however, need to call guidata to save changes you make to the structure.

Using guidata in a Programmed GUI

Calling the guihandles function creates the structure into which your code places additional data. It contains all handles used by the figure at the time it is called, generating field names based on each object's Tag property.

```
% Create figure to use as GUI in your main function or a local function
figure_handle = figure('Toolbar','none');
% create structure of handles
myhandles = guihandles(figure_handle);
% Add some additional data as a new field called numberOfErrors
myhandles.numberOfErrors = 0;
% Save the structure
guidata(figure_handle,myhandles)
```

You can recall the data from within a local callback function, modify it, and then replace the structure in the figure:

```
function My_Callback()
% ...
% Get the structure using guidata in the local function
myhandles = guidata(gcbo);
% Modify the value of your counter
myhandles.numberOfErrors = myhandles.numberOfErrors + 1;
% Save the change you made to the structure
guidata(gcbo,myhandles)
```

Using guidata in a GUIDE GUI

If you use GUIDE, you do not need to call `guihandles` to create a structure, because GUIDE generates a `handles` structure that contains the GUI's handles. You can add your own data to it, for example from within the `OpeningFcn` template that GUIDE creates:

```
% --- Executes just before simple_gui_tab is made visible.
function my_GUIDE_GUI_OpeningFcn(hObject, eventdata, handles, varargin)
% This function has no output args, see OutputFcn.
% hObject    handle to figure
% eventdata  reserved - to be defined in a future version of MATLAB
% handles    structure with handles and user data (see GUIDATA)
% varargin   command line arguments to simple_gui_tab (see VARARGIN)
% ...

% add some additional data as a new field called numberOfErrors
handles.numberOfErrors = 0;
% Save the change you made to the structure
guidata(hObject,handles)
```

Notice that you use the input argument `hObject` in place of `gcbo` to refer to the object whose callback is executing.

Suppose you needed to access the `numberOfErrors` field in a push button callback. Your callback code now looks something like this:

```
% --- Executes on button press in pushbutton1.
function my_GUIDE_GUI_pushbutton1_Callback(hObject, eventdata, handles)
% hObject    handle to pushbutton1 (see GCBO)
% eventdata  reserved - to be defined in a future version of MATLAB
% handles    structure with handles and user data (see GUIDATA)
% ...

% No need to call guidata to obtain a structure;
% it is provided by GUIDE via the handles argument
handles.numberOfErrors = handles.numberOfErrors + 1;
% save the changes to the structure
guidata(hObject,handles)
```

guide | guihandles | getappdata | setappdata

Purpose

Open GUI Layout Editor

Syntax

```
guide
guide('filename.fig')
guide('fullpath')
guide(HandleList)
```

Description

`guide` initiates the GUI design environment (GUIDE) tools that allow you to create or edit GUIs interactively.

`guide` opens the GUIDE Quick Start dialog where you can choose to open a previously created GUI or create a new one using one of the provided templates.

`guide('filename.fig')` opens the FIG-file named `filename.fig` for editing if it is on the MATLAB path.

`guide('fullpath')` opens the FIG-file at `fullpath` even if it is not on the MATLAB path.

`guide(HandleList)` opens the content of each of the figures in `HandleList` in a separate copy of the GUIDE design environment.

guihandles

Purpose

Create structure of handles

Syntax

```
handles = guihandles(object_handle)
handles = guihandles
```

Description

`handles = guihandles(object_handle)` returns a structure containing the handles of the objects in a figure, using the value of their `Tag` properties as the fieldnames, with the following caveats:

- Objects are excluded if their `Tag` properties are empty, or are not legal variable names.
- If several objects have the same `Tag`, that field in the structure contains a vector of handles.
- Objects with hidden handles are included in the structure.

`handles = guihandles` returns a structure of handles for the current figure.

Purpose

Uncompress GNU zip files

Syntax

```
gunzip(files)
gunzip(files,outputdir)
gunzip(url, ...)
filenames = gunzip(...)
```

Description

`gunzip(files)` uncompresses GNU zip files from the list of files specified in `files`. Directories recursively `gunzip` all of their content. The output files have the same name, excluding the extension `.gz`, and are written to the same directory as the input files.

`files` is a string or cell array of strings containing a list of files or directories. Individual files that are on the MATLAB path can be specified as partial path names. Otherwise, an individual file can be specified relative to the current directory or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~`*`username`*`/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`gunzip(files,outputdir)` writes the gunzipped file into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`gunzip(url, ...)` extracts the GNU zip contents from an Internet universal resource locator (URL). The URL must include the protocol type (for example, `'http://'`). MATLAB downloads the URL to the temp directory, and then deletes it.

`filenames = gunzip(...)` gunzips the files and returns the relative path names of the gunzipped files in the string cell array `filenames`.

Examples

To `gunzip` all `.gz` files in the current directory, type:

```
gunzip('*.gz');
```

To `gunzip` Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory `ncm`, type:

```
url ='http://www.mathworks.com/moler/ncm.tar.gz';
gunzip(url,'ncm')
untar('ncm/ncm.tar','ncm')
```

See Also

`gzip` | `tar` | `untar` | `unzip` | `zip`

Purpose

Compress files into GNU zip files

Syntax

```
gzip(files)
gzip(files,outputdir)
filenames = gzip(...)
```

Description

`gzip(files)` creates GNU zip files from the list of files specified in `files`. Directories recursively `gzip` all their contents. Each output gzipped file is written to the same directory as the input file and with the file extension `.gz`.

`files` is a string or cell array of strings containing a list of files or directories to `gzip`. Individual files that are on the MATLAB path can be specified as partial path names. Otherwise, an individual file can be specified relative to the current directory or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~`*`username`*`/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`gzip(files,outputdir)` writes the gzipped files into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`filenames = gzip(...)` gzips the files and returns the relative path names of all gzipped files in the string cell array `filenames`.

Examples

To `gzip` all `.m` and `.mat` files in the current directory and store the results in the directory `archive`, type:

```
gzip({'*.m','*.mat'},'archive');
```

h5create

Purpose

Create HDF5 data set

Syntax

```
h5create(filename,datasetname,size,Name,Value)
```

Description

`h5create(filename,datasetname,size,Name,Value)` creates an HDF5 data set in the file specified by `filename`.

Input Arguments

filename

Text string specifying the name of an HDF5 file. If `filename` does not already exist, `h5create` creates it, with additional options specified by one or more `Name,Value` pair arguments.

datasetname

Text string specifying the name of the data set you want to create. If `datasetname` is a full path name, `h5create` creates all intermediate groups, if they don't already exist.

size

Array specifying the extents of the dataset. To specify an unlimited extent, set the corresponding element of `size` to `Inf`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Datatype

Any of the following MATLAB datatypes.

double	uint64	uint32	uint16	uint8
single	int64	int32	int16	int8

Default: `double`

ChunkSize

Defines chunking layout.

Default: Not chunked

Deflate

Defines gzip compression level (0-9).

Default: 0

FillValue

Defines the fill value for numeric data sets.

Fletcher32

Turns on the Fletcher32 checksum filter.

Default: `false`

Shuffle

Turns on the Shuffle filter.

Default: `false`

Examples

Create a fixed-size 100-by-200 data set.

```
h5create('myfile.h5','/myDataset1',[100 200]);
h5disp('myfile.h5');
```

Create a single-precision 1000-by-2000 data set with a chunk size of 50-by-80. Apply the highest level of compression.

```
h5create('myfile.h5','/myDataset2',[1000 2000], 'Datatype','single', ...
         'ChunkSize',[50 80],'Deflate',9);
h5disp('myfile.h5');
```

Create a two-dimensional data set that is unlimited along the second extent.

```
h5create('myfile.h5','/myDataset3',[200 Inf],'ChunkSize',[20 20]);
h5disp('myfile.h5');
```

h5disp

Purpose

Display contents of HDF5 file

Syntax

```
h5disp(filename)
h5disp(filename,location)
h5disp(filename,location,mode)
```

Description

`h5disp(filename)` displays the structure (metadata) of the entire HDF5 file, `filename`.

`h5disp(filename,location)` displays the metadata for the specified location.

`h5disp(filename,location,mode)` displays the file metadata according to the value of `mode`.

Input Arguments

filename

Text string specifying the name of an HDF5 file.

location

Text string specifying the full path to a location in an HDF5 file. To display the metadata for the entire file, specify `'/'` as the value of `location`. If `location` is a group, `h5disp` displays all objects below the group.

mode

Either of the following text strings.

Value	Description
`min`	Minimal, display only group and data set names.
`simple`	Display data set metadata and attribute values, if the attribute is an integer, floating point, or a scalar string.

Default: `simple`

h5disp

Examples

Display the entire contents of an HDF5 file.

```
h5disp('example.h5')
```

Display metadata for one data set in an HDF5 file.

```
h5disp('example.h5','/g4/world');
```

`h5info`

Tutorials

- "Using the High-Level HDF5 Functions to Import Data"

Purpose

Return information about HDF5 file

Syntax

```
info = h5info(filename)
info = h5info(filename,location)
```

Description

`info = h5info(filename)` returns information about the entire HDF5 file, specified by `filename`.

`info = h5info(filename,location)` returns information about the group, data set, or named datatype specified by `location` in the HDF5 file, `filename`.

Input Arguments

filename

Text string specifying the name of an HDF5 file.

location

Text string specifying the location of a group, data set, or named datatype in an HDF5 file.

Output Arguments

info

A structure containing information about the HDF5 file. The set of fields in the structure depends on the `location` parameter. The first field is always `'Filename'`. Other fields that might be present in the `info` structure are as follows.

Location Type	Field	Description
Files and Groups		
	`Name`	Text string specifying name of the group. If you specify only a file name, this value is `'/'`.

Location Type	Field	Description
	`Groups`	Array of structures describing subgroups.
	`Datasets`	Array of structures describing data sets.
	`Datatypes`	Array of structures describing named datatypes.
	`Links`	Array of structures describing soft, external, user-defined, and certain hard links.
	`Attributes`	Array of structures describing group attributes.
Data sets		
	`Name`	Text string specifying the name of the data set.
	`Datatype`	Structure describing the datatype.
	`Dataspace`	Structure describing the size of the dataset.
	`ChunkSize`	Extents of the data set's chunk size, if defined.
	`FillValue`	Data set's fill value, if defined.
	`Filter`	Array of structures describing any defined filters such as compression.
	`Attributes`	Array of structures describing data set attributes.
Named Datatypes		

Location Type	Field	Description
	`Name`	Text string specifying the name of the datatype object.
	`Class`	HDF5 class of the named datatype.
	`Type`	Text string or struct further describing the datatype.
	`Size`	Size of the named datatype in bytes.

Examples

Return all information.

```
info = h5info('example.h5');
```

Return information about a group and all data sets contained within the group.

```
info = h5info('example.h5','/g4');
```

Return information about a specific dataset.

```
info = h5info('example.h5','/g4/time');
```

`h5disp`

Tutorials

- “Using the High-Level HDF5 Functions to Import Data”

h5read

Purpose

Read data from HDF5 data set

Syntax

```
data = h5read(filename,datasetname)
data = h5read(filename,datasetname,start,count)
data = h5read(filename,datasetname,start,count,stride)
```

Description

`data = h5read(filename,datasetname)` retrieves all of the data from the HDF5 data set `datasetname` in the file `filename`.

`data = h5read(filename,datasetname,start,count)` reads a subset of data from the data set `datasetname`. `start` is the one-based index of the first element to be read. `count` defines how many elements to read along each dimension. If a particular element of `count` is `Inf`, `h5read` reads data until the end of the corresponding dimension.

`data = h5read(filename,datasetname,start,count,stride)` reads a subset of data, where `stride` specifies the interelement spacing along each data set extent.

Input Arguments

filename

Text string specifying the name of an HDF5 file.

datasetname

Text string specifying the name of a data set in an HDF5 file.

start

Numeric index value specifying the place to start reading data in the dataset in an HDF5 file. Indices are 1-based.

count

Numeric value specifying the amount of data to read.

stride

Numeric value specifying the intervalue spacing during the read operation. For example, a spacing of 2 indicates reading every other value.

Output Arguments

data

Data read from the data set.

Examples

Read an entire data set.

```
h5disp('example.h5','/g4/lat');
data = h5read('example.h5','/g4/lat');
```

Read the first 5-by-3 subset of a data set.

```
h5disp('example.h5','/g4/world');
data = h5read('example.h5','/g4/world',[1 1],[5 3]);
```

Read a data set of references to other data sets.

```
h5disp('example.h5','/g3/reference');
data = h5read('example.h5','/g3/reference');
```

Tutorials

- "Using the High-Level HDF5 Functions to Import Data"

h5readatt

Purpose

Read attribute from HDF5 file

Syntax

```
attval = h5readatt(filename,location,attr)
```

Description

`attval = h5readatt(filename,location,attr)` retrieves the value for the named attribute `attr` from the given `location` in the HDF5 file `filename`.

Input Arguments

filename

Text string specifying the name of an HDF5 file.

location

Text string specifying the full path of the attribute in an HDF5 file. `location` can refer to either a group or a data set.

attr

Text string specifying the name of an attribute in an HDF5 file.

Output Arguments

attval

Value of the attribute.

Examples

Read a group attribute.

```
attval = h5readatt('example.h5','/','attr2');
```

Read a data set attribute.

```
attval = h5readatt('example.h5','/g4/lon','units');
```

`h5writeatt | h5info`

Tutorials

- “Using the High-Level HDF5 Functions to Import Data”

Purpose

Write to HDF5 data set

Syntax

```
h5write(filename,datasetname,data)
h5write(filename,datasetname,data,start,count)
h5write(filename,datasetname,data,start,count,stride)
```

Description

`h5write(filename,datasetname,data)` writes `data` to an entire data set, `datasetname`, in the HDF5 file, `filename`.

`h5write(filename,datasetname,data,start,count)` writes a subset of the `data` to a data set, `datasetname`, in the HDF5 file, `filename`. `start` is a one-based index value that specifies the first element to be written. `count` specifies the number of elements to write along each dimension. `h5write` extends an extendable data set along any unlimited dimensions, if necessary.

`h5write(filename,datasetname,data,start,count,stride)` writes a hyperslab of data, where `stride` specifies the inter-element spacing along each dimension.

Input Arguments

filename

Text string specifying the name of an HDF5 file.

datasetname

Text string specifying the name of a data set in the HDF5 file.

data

Data to be written to the HDF5 file. You can specify only floating-point and integer data sets.

start

Numeric index value specifying where in the data set to start writing to the file.

count

Numeric value specifying how much data to write to the file.

stride

Numeric value specifying the interelement spacing of data to write to the file.

Default: Vector of ones.

Definitions

Hyperslab

A hyperslab is a collection of points in a data space. The points can be contiguous or form a regular pattern of points or blocks in a data space.

Examples

Write to an entire data set.

```
h5create('myfile.h5','/DS1',[10 20]);
mydata = rand(10,20);
h5write('myfile.h5', '/DS1', mydata);
```

Write a hyperslab of data to the last 5-by-7 block of a data set.

```
 h5create('myfile.h5','/DS2',[10 20]);
        mydata = rand(5,7);
        h5write('myfile.h5','/DS2',mydata,[6 14],[5 7]);
```

Append data to an unlimited data set.

```
h5create('myfile.h5','/DS3',[20 Inf],'ChunkSize',[5 5]);
for j = 1:10
      data = j*ones(20,1);
      start = [1 j];
      count = [20 1];
      h5write('myfile.h5','/DS3',data,start,count);
end
```

```
h5disp('myfile.h5');
```

Limitations

- `h5write` supports only floating point and integer data sets. To write to string data sets, you must use the H5D package.

`h5read` | `h5create` | `h5writeatt` | `h5disp` | `H5D.create` | `H5D.write`

Tutorials

- "Exporting to Hierarchical Data Format (HDF5) Files"

h5writeatt

Purpose

Write HDF5 attribute

Syntax

`h5writeatt(filename,location,attname,attvalue)`

Description

`h5writeatt(filename,location,attname,attvalue)` writes the attribute named `attname` with the value `attvalue` to the HDF5 file `filename`. The parent object `location` can be either a group or variable. `location` is the complete path name of the group or variable to which you want to associate the attribute.

Input Arguments

filename

Text string specifying the name of an HDF5 file.

location

Text string specifying the full path identifying a group or variable in an HDF5 file.

attname

Text string specifying the name of an attribute in an HDF5 file. If the attribute does not exist, `h5writeatt` creates the attribute with the name specified.

If the specified attribute already exists but does not have a datatype or dataspace consistent with `attvalue`, `h5writeatt` deletes the attribute and recreates it. String attributes are created with a scalar dataspace.

attvalue

Value to be written to the attribute in an HDF5 file.

Examples

Create a root group attribute whose value is the current time.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
h5writeatt('myfile.h5','/','creation_date',datestr(now));
```

Create a double-precision data set attribute.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5'
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
attData = [0 1 2 3];
h5writeatt('myfile.h5','/g4/world','attr',attData);
h5disp('myfile.h5','/g4/world');
```

H5.close

Purpose Close HDF5 library

Syntax `H5.close()`

Description `H5.close()` closes the HDF5 library.

See Also `H5.open`

Purpose Free unused memory in HDF5 library

Syntax

```
H5.garbage_collect()
```

Description `H5.garbage_collect()` frees unused memory in the HDF5 library.

H5.get_libversion

Purpose Version of HDF5 library

Syntax

```
[majnum,minnum,relnum] = H5.get_libversion()
```

Description `[majnum,minnum,relnum] = H5.get_libversion()` returns the version of the HDF5 library in use.

Purpose Open HDF5 library

Syntax `H5.open()`

Description `H5.open()` opens the HDF5 library.

See Also `H5.close`

H5.set_free_list_limits

Purpose Set size limits on free lists

Syntax

```
H5.set_free_list_limits(reg_global_lim,reg_list_lim,
   arr_global_lim,arr_list_lim,blk_global_lim,blk_list_lim)
```

Description

`H5.set_free_list_limits(reg_global_lim,reg_list_lim,arr_global_lim,arr_li`
sets size limits on all types of free lists.

Purpose

Close specified attribute

Syntax

```
H5A.close(attr_id)
```

Description

`H5A.close(attr_id)` terminates access to the attribute specified by `attr_id`, releasing the identifier.

See Also

`H5A.open`

H5A.create

Purpose

Create attribute

Syntax

```
attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id)
attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id,
   aapl_id)
```

Description

`attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id)` creates the attribute name that is attached to the object specified by `loc_id`. `loc_id` is a group, dataset, or named datatype identifier. The datatype and dataspace identifiers of the attribute, `type_id` and `space_id`, respectively, are created with the H5T and H5S interfaces. The attribute property list, `acpl_id`, is currently unused and should be set to `'H5P_DEFAULT'`. This interface corresponds to the 1.6.x version of `H5Acreate`.

`attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id,aapl_id)` creates the attribute with the additional attribute access property list identifier `aapl_id`. `aapl_id` should currently be set to `'H5P_DEFAULT'`. This interface corresponds to the 1.8.x version of `H5Acreate`.

Examples

```
acpl_id = H5P.create('H5P_ATTRIBUTE_CREATE');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
space_id = H5S.create('H5S_SCALAR');
fid = H5F.create('myfile.h5');
attr_id = H5A.create(fid,'my_attr',type_id,space_id,acpl_id);
H5A.close(attr_id);
H5F.close(fid);
```

See Also

`H5A.close` | `H5P.create`

Purpose

Delete attribute

Syntax

```
H5A.delete(loc_id,name)
```

Description

`H5A.delete(loc_id,name)` removes the attribute specified by `name` from the dataset, group, or named datatype specified by `loc_id`.

Examples

Delete a root group attribute.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5')
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
gid = H5G.open(fid,'/');
H5A.delete(gid,'attr1');
H5G.close(gid);
H5F.close(fid);
```

H5A.get_info

Purpose

Information about attribute

Syntax

```
info = H5A.get_info(attr_id)
```

Description

`info = H5A.get_info(attr_id)` returns information about an attribute specified by `attr_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/');
attr_id = H5A.open(gid,'attr1');
info = H5A.get_info(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.open`

Purpose

Attribute name

Syntax

```
attr_name = H5A.get_name(attr_id)
```

Description

`attr_name = H5A.get_name(attr_id)` returns the name of the attribute specified by `attr_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.1');
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_INC';
attr_id = H5A.open_by_idx(gid,'dset1.1.1',idx_type,order,0);
name = H5A.get_name(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.open_by_idx`

H5A.get_space

Purpose

Copy of attribute data space

Syntax

```
dspace_id = H5A.get_space(attr_id)
```

Description

`dspace_id = H5A.get_space(attr_id)` returns a copy of the data space for the attribute specified by `attr_id`.

Examples

Retrieve the dimensions of an attribute data space.

```
fid = H5F.open('example.h5');
attr_id = H5A.open(fid,'attr2');
space = H5A.get_space(attr_id);
[~,dims] = H5S.get_simple_extent_dims(space);
H5A.close(attr_id);
H5F.close(fid);
```

See Also

`H5A.open` | `H5S.close`

Purpose

Copy of attribute data type

Syntax

```
type_id = H5A.get_type(attr_id)
```

Description

`type_id = H5A.get_type(attr_id)` returns a copy of the data type for the attribute specified by `attr_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/');
attr_id = H5A.open(gid,'attr1');
type_id = H5A.get_type(attr_id);
H5T.close(type_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.open` | `H5T.close`

H5A.iterate

Purpose

Execute function for attributes attached to object

Syntax

```
[status,idx_stop,cdata_out] = H5A.iterate(obj_id,idx_type,
   order,idx_start,iter_func,cdata_in)
H5A.iterate(loc_id,attr_idx,iterator_func)
```

Description

`[status,idx_stop,cdata_out] = H5A.iterate(obj_id,idx_type,order,idx_start,iter_func,cdata_in)` executes the specified function `iter_func` for each attribute connected to an object. `obj_id` identifies the object to which attributes are attached. `idx_type` is the type of index and valid values include the following.

'H5_INDEX_NAME'	An alpha-numeric index by attribute name
'H5_INDEX_CRT_ORDER'	An index by creation order

`order` specifies the index traversal order. Valid values include the following.

'H5_ITER_INC'	Iteration from beginning to end
'H5_ITER_DEC'	Iteration from end to beginning
'H5_ITER_NATIVE'	Iteration in the fastest available order

`idx_start` specifies the starting point of the iteration. `idx_stop` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed.

The callback function, `iter_func`, must have the following signature:

```
[status,cdata_out] =
iter_func(obj_id,attr_name,info,cdata_in)
```

`cdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `cdata_in` parameter. The `cdata_out` of an iteration step forms the `cdata_in` for the next iteration

step. Then, the final `cdata_out` at the end of the iteration is returned to the caller as `cdata_out`. This form of `H5A.iterate` corresponds to the `H5Aiterate2` function in the HDF5 C API.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

`H5A.iterate(loc_id,attr_idx,iterator_func)` executes the specified function for each attribute of the group, dataset, or named datatype specified by `loc_id`. The `attr_idx` argument specifies where the iteration begins. `iterator_func` must be a function handle.

The iterator function must have the following signature:

```
status = iterator_func(loc_id,attr_name)
```

`loc_id` still specifies the group, dataset, or named data type passed into `H5A.iterate`, and `attr_name` specifies the current attribute. This form of `H5A.iterate` corresponds to `H5Aiterate1` function in the HDF5 C API.

H5A.open

Purpose

Open attribute

Syntax

```
attr_id = H5A.open(obj_id,attr_name)
attr_id = H5A.open(obj_id,attr_name,aapl_id)
```

Description

`attr_id = H5A.open(obj_id,attr_name)` opens an attribute for an object specified by a parent object identifier and attribute name.

`attr_id = H5A.open(obj_id,attr_name,aapl_id)` opens an attribute with an attribute access property list identifier, `aapl_id`. The only currently valid value for `aapl_id` is `'H5P_DEFAULT'`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/');
attr_id = H5A.open(gid,'attr1');
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.close` | `H5A.open_by_name` | `H5A.open_by_idx`

Purpose

Open attribute specified by index

Syntax

```
attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n)
attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n,
   aapl_id,lapl_id)
```

Description

`attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n)` opens an existing attribute at index `n` attached to an object specified by its location, `loc_id`, and name, `obj_name`.

`idx_type` is the type of index and valid values include the following.

'H5_INDEX_NAME'	An alpha-numeric index by attribute name
'H5_INDEX_CRT_ORDER'	An index by creation order

`order` specifies the index traversal order. Valid values include the following.

'H5_ITER_INC'	Iteration from beginning to end
'H5_ITER_DEC'	Iteration from end to beginning
'H5_ITER_NATIVE'	Iteration in the fastest available order

`attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n,aapl_id,lapl_id)` opens an attribute with attribute access property list, `aapl_id`, and link access property list, `lapl_id`. The `aapl_id` argument must currently be specified as `'H5P_DEFAULT'`. Also, `lapl_id` can be specified by `'H5P_DEFAULT'`.

Examples

Loop through a set of dataset attributes in reverse alphabetical order.

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.1');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
```

```
info = H5O.get_info(dset_id);
for idx = 0:info.num_attrs-1
  attr_id =H5A.open_by_idx(gid,'dset1.1.1','H5_INDEX_NAME','H5_ITER_DEC',
  fprintf('attribute name:  %s\n',H5A.get_name(attr_id));
  H5A.close(attr_id);
end
H5G.close(gid);
H5F.close(fid);
```

See Also

H5A.open | H5A.open_by_name | H5A.close

Purpose

Open attribute specified by name

Syntax

```
attr_id = H5A.open_by_name(loc_id,obj_name,attr_name)
attr_id = H5A.open_by_name(loc_id,obj_name,attr_name,aapl_id,
   lapl_id)
```

Description

`attr_id = H5A.open_by_name(loc_id,obj_name,attr_name)` opens an existing attribute `attr_name` attached to an object specified by its location `loc_id` and name `obj_name`.

`attr_id = H5A.open_by_name(loc_id,obj_name,attr_name,aapl_id,lapl_id)` opens an existing attribute with the attribute access property list `aapl_id` and link access property list `lacpl_id`. `aapl_id` must be specified as `'H5P_DEFAULT'`. `lapl_id` may also be specified by `'H5P_DEFAULT'`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.1');
attr_id = H5A.open_by_name(gid,'dset1.1.1','attr1');
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.close` | `H5A.open` | `H5A.open_by_idx`

H5A.read

Purpose

Read attribute

Syntax

```
attr = H5A.read(attr_id)
attr = H5A.read(attr_id, mem_type_id)
```

Description

`attr = H5A.read(attr_id)` reads the attribute specified by `attr_id`. MATLAB will determine the appropriate memory datatype.

`attr = H5A.read(attr_id, mem_type_id)` reads the attribute specified by `attr_id`. `mem_type_id` specifies the attribute's memory datatype and should usually be given as `'H5ML_DEFAULT'`, which specifies that MATLAB will determine the appropriate memory datatype.

Note The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. If the HDF5 library reports the attribute size as 3-by-4-by-5, then the corresponding MATLAB array size is 5-by-4-by-3. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/');
attr_id = H5A.open(gid,'attr1');
data = H5A.read(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.open | H5A.write`

Purpose

Write attribute

Syntax

```
H5A.write(attr_id,type_id,buf)
```

Description

`H5A.write(attr_id,type_id,buf)` writes the data in buf into the attribute specified by `attr_id`. `type_id` specifies the attribute's memory datatype. The memory datatype should be `'H5ML_DEFAULT'`, which specifies that MATLAB should determine the appropriate memory datatype.

Note The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. If the MATLAB array size is 5-by-4-by-3, then the HDF5 library should be reporting the attribute size as 3-by-4-by-5. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Write a scalar double precision attribute.

```
acpl = H5P.create('H5P_ATTRIBUTE_CREATE');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
space_id = H5S.create('H5S_SCALAR');
fid = H5F.create('myfile.h5');
attr_id = H5A.create(fid,'my_attr',type_id,space_id,acpl);
H5A.write(attr_id,'H5ML_DEFAULT',10.0)
H5A.close(attr_id);
H5F.close(fid);
H5T.close(type_id);
```

See Also

`H5A.read`

H5D.close

Purpose

Close dataset

Syntax

`H5D.close(dataset_id)`

Description

`H5D.close(dataset_id)` ends access to a dataset specified by `dataset_id` and releases resources used by it.

See Also

`H5D.create` | `H5D.open`

Purpose

Create new dataset

Syntax

```
dataset_id = H5D.create(loc_id,name,type_id,space_id,
   plist_id)
dataset_id = H5D.create(loc_id,name,type_id,space_id,lcpl_id,
   dcpl_id,dapl_id)
```

Description

`dataset_id = H5D.create(loc_id,name,type_id,space_id,plist_id)` creates the data set specified by `name` in the file or in the group specified by `loc_id`. `type_id` and `space_id` identify the datatype and dataspace, respectively. `plist_id` identifies the dataset creation property list. This interface corresponds to the `H5Dcreate1` function in the HDF5 library C 1.6 API.

`dataset_id = H5D.create(loc_id,name,type_id,space_id,lcpl_id,dcpl_id,dapl_id)` creates the data set with three distinct property lists:

`lcpl_id`	link creation property list
`dcpl_id`	dataset creation property list
`dapl_id`	dataset access property list

This interface corresponds to the `H5Dcreate` function in the HDF5 library C 1.8 API.

Examples

Create a 10x5 double precision dataset with default property list settings.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [10 5];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = 'H5P_DEFAULT';
```

```
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5S.close(space_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
h5disp('myfile.h5');
```

Create a 6x3 fixed length string dataset. Each string will have a length of 4 characters.

```
fid = H5F.create('myfile_strings.h5');
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,4);
dims = [6 3];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = 'H5P_DEFAULT';
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5S.close(space_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
h5disp('myfile_strings.h5');
```

See Also

H5D.close | H5S.create_simple | H5S.close | H5T.copy

Purpose

Copy of dataset access property list

Syntax

```
plist_id = H5D.get_access_plist(dataset_id)
```

Description

`plist_id = H5D.get_access_plist(dataset_id)` returns a copy of the dataset access property list used to open the specified dataset.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
dapl = H5D.get_access_plist(dset_id);
H5P.close(dapl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.get_create_plist` | `H5P.close`

H5D.get_create_plist

Purpose

Copy of dataset creation property list

Syntax

```
plist_id = H5D.get_create_plist(dataset_id)
```

Description

`plist_id = H5D.get_create_plist(dataset_id)` returns the identifier to a copy of the dataset creation property list for the dataset specified by `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
dcpl = H5D.get_create_plist(dset_id);
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.get_access_plist` | `H5P.close`

H5D.get_offset

Purpose Location of dataset in file

Syntax

```
offset = H5D.get_offset(dataset_id)
```

Description

`offset = H5D.get_offset(dataset_id)` returns the location in the file of the dataset specified by `dataset_id`. The location is expressed as an offset, in bytes, from the beginning of the file.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
offset = H5D.get_offset(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

H5D.get_space

Purpose

Copy of dataset data space

Syntax

```
dspace_id = H5D.get_space(dataset_id)
```

Description

`dspace_id = H5D.get_space(dataset_id)` returns an identifier for a copy of the data space for a dataset.

Examples

Retrieve the dimensions of an attribute data space.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
space = H5D.get_space(dset_id);
[~,dims] = H5S.get_simple_extent_dims(space);
H5S.close(space);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.open` | `H5S.close`

Purpose Determine if space is allocated

Syntax

```
status = H5D.get_space_status(dataset_id)
```

Description

`status = H5D.get_space_status(dataset_id)` determines whether space has been allocated for the dataset specified by `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
status = H5D.get_space_status(dset_id);
switch(status)
    case H5ML.get_constant_value('H5D_SPACE_STATUS_NOT_ALLOCATED')
        fprintf('Not allocated.\n');
    case H5ML.get_constant_value('H5D_SPACE_STATUS_ALLOCATED')
        fprintf('Allocated.\n');
    case H5ML.get_constant_value('H5D_SPACE_STATUS_PART_ALLOCATED')
        fprintf('Part allocated.\n');
end
H5D.close(dset_id);
H5F.close(fid);
```

See Also `H5D.get_space`

H5D.get_storage_size

Purpose Determine required storage size

Syntax

```
dataset_size = H5D.get_storage_size(dataset_id)
```

Description

`dataset_size = H5D.get_storage_size(dataset_id)` returns the amount of storage that is required for the dataset specified by `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
dataset_size = H5D.get_storage_size(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

H5D.get_type

Purpose

Copy of datatype

Syntax

```
type_id = H5D.get_type(dataset_id)
```

Description

`type_id = H5D.get_type(dataset_id)` returns an identifier for a copy of the data type for the dataset specified by `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
type_id = H5D.get_type(dset_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

H5T.close

H5D.open

Purpose

Open specified dataset

Syntax

```
dataset_id = H5D.open(loc_id,name)
dataset_id = H5D.open(loc_id,name,dapl_id)
```

Description

`dataset_id = H5D.open(loc_id,name)` opens the dataset specified by `name` in the file or group specified by `loc_id`.

`dataset_id = H5D.open(loc_id,name,dapl_id)` opens the dataset specified by `name` in the file or group specified by `loc_id`. The dataset access property list, `dapl_id`, provides information regarding access to the dataset.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
dset_id = H5D.open(gid,'dset2.2');
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.close`

Purpose

Read data from HDF5 dataset

Syntax

```
data = H5D.read(dataset_id)
data = H5D.read(dataset_id,mem_type_id,mem_space_id,
   file_space_id,dxpl)
```

Description

`data = H5D.read(dataset_id)` reads the entire dataset specified by `dataset_id`.

`data = H5D.read(dataset_id,mem_type_id,mem_space_id,file_space_id,dxpl)` reads the dataset specified by `dataset_id`. The `mem_type_id` input specifies the memory data type and should usually be `'H5ML_DEFAULT'` to allow MATLAB to determine the appropriate value. `mem_space_id` describes how the data is to be arranged in memory and should usually be `'H5S_ALL'`. The `file_space_id` input describes how the data is to be selected from the file. It also can be given as `'H5S_ALL'`, but this results in the entire dataset being read into memory. `dxpl` is the dataset transfer property list identifier and should usually be `'H5P_DEFAULT'`.

Note The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Read an entire dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
data = H5D.read(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

Read the 2x3 hyperslab starting in the 4th row and 5th column of the example dataset.

```
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
dims = fliplr([2 3]);
mem_space_id = H5S.create_simple(2,dims,[]);
file_space_id = H5D.get_space(dset_id);
offset = fliplr([3 4]);
block = fliplr([2 3]);
H5S.select_hyperslab(file_space_id,'H5S_SELECT_SET',offset,[],[],block);
data = H5D.read(dset_id,'H5ML_DEFAULT',mem_space_id,file_space_id,plist);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

H5D.open | H5D.write | H5S.create_simple

Purpose Change size of dataset dimensions

Syntax `H5D.set_extent(dset_id,h5_extents)`

Description `H5D.set_extent(dset_id,h5_extents)` changes the dimensions of the dataset `dset_id` to the sizes specified in `h5_extents`.

Note The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_extents` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples Extend an unlimited one-dimensional dataset from a length of 10 to a length of 20.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5')
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
dset_id = H5D.open(fid,'/g4/time');
H5D.set_extent(dset_id,20);
H5D.close(dset_id);
H5F.close(fid);
```

H5D.vlen_get_buf_size

Purpose

Determine variable length storage requirements

Syntax

```
size = H5D.vlen_get_buf_size(dataset_id,type_id,space_id)
```

Description

`size = H5D.vlen_get_buf_size(dataset_id,type_id,space_id)` determines the number of bytes required to store the VL data from the dataset, using the `space_id` for the selection in the dataset on disk and the `type_id` for the memory representation of the VL data in memory.

Purpose

Write data to HDF5 dataset

Syntax

```
H5D.write(dataset_id,mem_type_id,mem_space_id,file_space_id,
   plist_id,buf)
```

Description

`H5D.write(dataset_id,mem_type_id,mem_space_id,file_space_id,plist_id,b` writes the dataset specified by `dataset_id` from the application memory buffer `buf` into the file. `plist_id` specifies the data transfer properties. `mem_type_id` identifies the memory datatype of the dataset. `mem_space_id` and `file_space_id` define the part of the dataset to write. The memory datatype should usually be `'H5ML_DEFAULT'`, which specifies that MATLAB should determine the appropriate memory datatype.

Note The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Write to the entire 36-by-19 `/g4/world` example dataset.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5')
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
dset_id = H5D.open(fid,'/g4/world');
dims = [36 19];
data = rand(dims);
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',plist,data);
H5D.close(dset_id);
H5F.close(fid);
```

Write to the entire two-element /g3/VLstring dataset.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
h5disp('myfile.h5','/g3/VLstring');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
dset_id = H5D.open(fid,'/g3/VLstring');
data = {'dogs'; 'dogs and cats'};
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',plist,data);
H5D.close(dset_id);
H5F.close(fid);
data_out = h5read('myfile.h5','/g3/VLstring');
```

Write a 10-by-5 block of data to the location starting at row index 15 and column index 5 of the same dataset. Recall that indexing is zero-based.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
dset_id = H5D.open(fid,'/g4/world');
start = [15 5];
h5_start = fliplr(start);
block = [10 5];
h5_block = fliplr(block);
mem_space_id = H5S.create_simple(2,h5_block,[]);
file_space_id = H5D.get_space(dset_id);
H5S.select_hyperslab(file_space_id,'H5S_SELECT_SET',h5_start,[],[],h5_blo
data = rand(block);
H5D.write(dset_id,'H5ML_DEFAULT',mem_space_id,file_space_id,plist,data);
H5D.close(dset_id);
H5F.close(fid);
```

See Also `H5D.read`

H5DS.attach_scale

Purpose

Attach dimension scale to specific dataset dimension

Syntax

```
H5DS.attach_scale(dataset_id,dimscale_id,idx)
```

Description

`H5DS.attach_scale(dataset_id,dimscale_id,idx)` attaches a dimension scale `dimscale_id` to dimension `idx` of the dataset `dataset_id`.

Note The ordering of the dimension scale indices are the same as the HDF5 library C API.

Examples

Add the `'lon'` and `'lat'` dimension scales to the `'world'` dataset.

```
plist = 'H5P_DEFAULT';
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
world_dset_id = H5D.open(fid,'/g4/world',plist);
lat_dset_id = H5D.open(fid,'/g4/lat',plist);
lon_dset_id = H5D.open(fid,'/g4/lon',plist);
H5DS.attach_scale(world_dset_id,lat_dset_id,0);
H5DS.attach_scale(world_dset_id,lon_dset_id,1);
H5D.close(lat_dset_id);
H5D.close(lon_dset_id);
H5D.close(world_dset_id);
H5F.close(fid);
```

See Also

`H5DS.detach_scale`

H5DS.detach_scale

Purpose Detach dimension scale from specific dataset dimension

Syntax

```
H5DS.detach_scale(dataset_id,dimscale_id,idx)
```

Description `H5DS.detach_scale(dataset_id,dimscale_id,idx)` detaches dimension scale `dimscale_id` from dimension `idx` of the dataset `dataset_id`.

Note The ordering of the dimension scale indices are the same as the HDF5 library C API.

See Also `H5DS.attach_scale`

H5DS.get_label

Purpose

Retrieve label from specific dataset dimension

Syntax

```
label = H5DS.get_label(dataset_id,idx)
```

Description

`label = H5DS.get_label(dataset_id,idx)` retrieves the label for dimension `idx` of the dataset `dataset_id`.

Note The ordering of the dimension scale indices are the same as the HDF5 library C API.

Examples

```
fid = H5F.open('example.h5');
world_dset_id = H5D.open(fid,'/g4/world');
label = H5DS.get_label(world_dset_id,0);
H5D.close(world_dset_id);
H5F.close(fid);
```

See Also

`H5DS.set_label`

Purpose Number of scales attached to dataset dimension

Syntax

```
num_scales = H5DS.get_num_scales(dataset_id,idx)
```

Description `num_scales = H5DS.get_num_scales(dataset_id,idx)` determines the number of dimension scales that are attached to dimension `idx` of the dataset `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
world_dset_id = H5D.open(fid,'/g4/world');
num_scales = H5DS.get_num_scales(world_dset_id,0);
H5D.close(world_dset_id);
H5F.close(fid);
```

H5DS.get_scale_name

Purpose Name of dimension scale

Syntax

```
name = H5DS.get_scale_name(dimscale_id)
```

Description `name = H5DS.get_scale_name(dimscale_id)` retrieves the name of the dimension scale `dimscale_id`.

Examples

```
fid = H5F.open('example.h5');
lat_dset_id = H5D.open(fid,'/g4/lat');
scale_name = H5DS.get_scale_name(lat_dset_id);
H5D.close(lat_dset_id);
H5F.close(fid);
```

See Also `H5DS.set_scale`

H5DS.is_scale

Purpose

Determine if dataset is a dimension scale

Syntax

```
bool = H5DS.is_scale(dataset_id)
```

Description

`bool = H5DS.is_scale(dataset_id)` determines whether the dataset `dataset_id` is a dimension scale.

Examples

```
fid = H5F.open('example.h5');
lat_dset_id = H5D.open(fid,'/g4/lat');
if H5DS.is_scale(lat_dset_id)
    fprintf('/g4/lat is a dimension scale.\n');
else
    fprintf('/g4/lat is not a dimension scale.\n');
end
H5D.close(lat_dset_id);
H5F.close(fid);
```

H5DS.iterate_scales

Purpose

Iterate on scales attached to dataset dimension

Syntax

```
[status,idx_out,opdata_out] = H5DS.iterate_scales(dset_id,dim,
   idx_in,iter_func,opdata_in)
```

Description

`[status,idx_out,opdata_out] = H5DS.iterate_scales(dset_id,dim,idx_in,iter_func,opdata_in)` iterates over the scales attached to dimension `dim` of the dataset `dset_id` to perform a common operation whose function handle is `iter_func`.

`idx_in` specifies the starting point of the iteration. `idx_out` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed. If `idx_in` is `[]`, then the iterator starts at the first member.

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] =
iter_func(dset_id,dim,dimscale_id,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`dimscale_id` specifies the current dimension scale dataset identifier and `dim` is the associated dimension.

status value returned by `iter_func` is interpreted as follows:

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

H5DS.set_label

Purpose Set label for dataset dimension

Syntax `H5DS.set_label(dataset_id,idx,label)`

Description `H5DS.set_label(dataset_id,idx,label)` sets a label for dimension `idx` of the dataset `dataset_id`.

Note The ordering of the dimension scale indices are the same as the HDF5 library C API.

Examples

```
plist = 'H5P_DEFAULT';
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
world_dset_id = H5D.open(fid,'/g4/world',plist);
H5DS.set_label(world_dset_id,0,'latitude');
H5DS.set_label(world_dset_id,1,'longitude');
H5D.close(world_dset_id);
H5F.close(fid);
```

See Also `H5DS.get_label`

H5DS.set_scale

Purpose Convert dataset to dimension scale

Syntax `H5DS.set_scale(dataset_id,dim_name)`

Description `H5DS.set_scale(dataset_id,dim_name)` converts the dataset, `dataset_id`, to a dimension scale with name `dim_name`.

Examples Create a dimension scale with name `'xdim'`. The dataset has the name, `'x'`.

```
fid = H5F.create('myfile.h5');
space_id = H5S.create_simple(1,10,10);
dtype = 'H5T_NATIVE_INT';
dcpl = 'H5P_DEFAULT';
dset_id = H5D.create(fid,'x',dtype,space_id,dcpl);
H5DS.set_scale(dset_id,'xdim');
H5S.close(space_id);
H5D.close(dset_id);
H5F.close(fid);
```

See Also `H5DS.get_scale_name`

H5E.clear

Purpose Clear error stack

Syntax

```
H5E.clear()
```

Description `H5E.clear()` clears the error stack for the current thread.

H5E.get_major

Purpose

Description of major error number

Syntax

```
err_string = H5E.get_major(major_number)
```

Description

`err_string = H5E.get_major(major_number)` returns a character string describing an error specified by the major error number, `major_number`.

The HDF5 group has deprecated the use of this function.

See Also

`H5E.get_minor`

H5E.get_minor

Purpose Description of minor error number

Syntax `err_string = H5E.get_minor(minor_number)`

Description `err_string = H5E.get_minor(minor_number)` returns a character string describing an error specified by the minor error number, `minor_number`.

The HDF5 group has deprecated the use of this function.

See Also `H5E.get_major`

Purpose Walk error stack

Syntax

```
H5E.walk(direction,func)
```

Description `H5E.walk(direction,func)` walks the error stack for the current thread and calls the specified function for each error along the way. `func` is a function handle. `direction` specifies how the error stack is traversed and can be given by one of the following strings or the numeric equivalent.

`'H5E_WALK_UPWARD'`

`'H5E_WALK_DOWNWARD'`

The specified function must have the following signature:

```
status = func(n,error_struct)
```

where `n` is the indexed position of the error in the stack and `error_struct` is a structure with the following fields:

`maj_num`	Major error number
`min_num`	Minor error number
`func_name`	Function in which the error occurred
`file_name`	File in which the error occurred
`line`	Line in file where error occurs
`desc`	Optional supplied description

This function corresponds to the `H5Ewalk1` function in the HDF5 library C API.

See Also `H5ML.get_constant_value`

H5F.close

Purpose Close HDF5 file

Syntax `H5F.close(file_id)`

Description `H5F.close(file_id)` terminates access to HDF5 file identified by `file_id`, flushing all data to storage.

See Also `H5F.open`

Purpose

Create HDF5 file

Syntax

```
file_id = H5F.create(filename)
file_id = H5F.create(name,flags,fcpl_id,fapl_id)
```

Description

`file_id = H5F.create(filename)` creates the file specified by `filename` with default library properties if the file does not already exist.

`file_id = H5F.create(name,flags,fcpl_id,fapl_id)` creates the file specified by `name`. `flags` specifies whether to truncate the file, if it already exists, or to fail if the file already exists. `flags` can be specified by one of the following strings or the numeric equivalent:

'H5F_ACC_TRUNC'	overwrite any existing file by the same name
'H5F_ACC_EXCL'	do not overwrite an existing file

`fcpl_id` is the file creation property list identifier. `fapl_id` is the file access property list identifier. A value of `'H5P_DEFAULT'` for either property list indicates that the library should use default values for the appropriate property list.

Examples

Create an HDF5 file called `'myfile.h5'`.

```
fid = H5F.create('myfile.h5');
H5F.close(fid);
```

Create an HDF5 file called `'myfile.h5'`, overwriting any existing file by the same name. Default file access and file creation properties shall apply.

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

`H5F.close` | `H5P.create` | `H5ML.get_constant_value`

Purpose

Flush buffers to disk

Syntax

```
H5F.flush(object_id,scope)
```

Description

`H5F.flush(object_id,scope)` causes all buffers associated with a file to be immediately flushed to disk without removing the data from the cache. `object_id` can be any object associated with the file, including the file itself, a dataset, a group, an attribute, or a named data type. `scope` specifies whether the scope of the flushing action is global or local. `scope` may be one of the following strings:

`'H5F_SCOPE_GLOBAL'`

`'H5F_SCOPE_LOCAL'`

H5F.get_access_plist

Purpose File access property list

Syntax

```
fapl_id = H5F.get_access_plist(file_id)
```

Description `fapl_id = H5F.get_access_plist(file_id)` returns the file access property list identifier of the file specified by `file_id`.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
H5P.close(fapl);
H5F.close(fid);
```

See Also `H5F.get_create_plist`

Purpose

File creation property list

Syntax

```
fcpl_id = H5F.get_create_plist(file_id)
```

Description

`fcpl_id = H5F.get_create_plist(file_id)` returns a file creation property list identifier identifying the creation properties used to create the file specified by `file_id`.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
H5P.close(fcpl);
H5F.close(fid);
```

See Also

`H5F.get_access_plist`

H5F.get_filesize

Purpose

Size of HDF5 file

Syntax

```
size = H5F.get_filesize(file_id)
```

Description

`size = H5F.get_filesize(file_id)` returns the size of the HDF5 file specified by `file_id`.

Purpose

Amount of free space in file

Syntax

```
free_space = H5F.get_freespace(file_id)
```

Description

`free_space = H5F.get_freespace(file_id)` returns the amount of space that is unused by any objects in the file specified by `file_id`.

H5F.get_info

Purpose

Global information about file

Syntax

```
file_info = H5F.get_info(obj_id)
```

Description

`file_info = H5F.get_info(obj_id)` returns global information for the file associated with the object identifier `obj_id`. For details about the fields of the `file_info` structure, please refer to the HDF5 documentation.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'g2');
info = H5F.get_info(gid);
H5G.close(gid);
H5F.close(fid);
```

H5F.get_mdc_config

Purpose

Metadata cache configuration

Syntax

```
config_struct = H5F.get_mdc_config(file_id)
```

Description

`config_struct = H5F.get_mdc_config(file_id)` returns the current metadata cache configuration for the target file.

Examples

```
fid = H5F.open('example.h5');
config = H5F.get_mdc_config(fid);
H5F.close(fid);
```

See Also

`H5F.set_mdc_config`

H5F.get_mdc_hit_rate

Purpose Metadata cache hit-rate

Syntax

```
hitRate = H5F.get_mdc_hit_rate(file_id)
```

Description `hitRate = H5F.get_mdc_hit_rate(file_id)` queries the metadata cache of the target file to obtain its hit-rate since the last time hit-rate statistics were reset. If the cache has not been accessed since the last time the hit-rate statistics were reset, the hit-rate is defined to be 0.0. The hit-rate is calculated as

```
(cache hits / (cache hits + cache misses))
```

Examples

```
fid = H5F.open('example.h5');
hit_rate = H5F.get_mdc_hit_rate(fid);
H5F.close(fid);
```

See Also `H5F.get_mdc_config`

H5F.get_mdc_size

Purpose

Metadata cache size data

Syntax

```
[max_sz,min_clean_sz,cursz,
   num_cur_entries] = H5F.get_mdc_size(fileId)
```

Description

`[max_sz,min_clean_sz,cursz,num_cur_entries] = H5F.get_mdc_size(fileId)` queries the metadata cache of the target file to obtain current metadata cache size information.

Examples

```
fid = H5F.open('example.h5');
[maxsz,minsz,cursz,nent] = H5F.get_mdc_size(fid);
H5F.close(fid);
```

See Also

`H5F.get_mdc_config`

H5F.get_name

Purpose

Name of HDF5 file

Syntax

```
name = H5F.get_name(obj_id)
```

Description

`name = H5F.get_name(obj_id)` returns the name of the file to which the object `obj_id` belongs. The object can be a group, dataset, attribute, or named data type.

Examples

```
fid = H5F.open('example.h5');
name = H5F.get_name(fid);
H5F.close(fid);
```

See Also

`H5A.get_name` | `H5I.get_name`

H5F.get_obj_count

Purpose Number of open objects in HDF5 file

Syntax

```
obj_count = H5F.get_obj_count(file_id,types)
```

Description

`obj_count = H5F.get_obj_count(file_id,types)` returns the number of open object identifiers for the file specified by `file_id` for the specified type. `types` can be one of the following strings.

- 'H5F_OBJ_FILE'
- 'H5F_OBJ_DATASET'
- 'H5F_OBJ_GROUP'
- 'H5F_OBJ_DATATYPE'
- 'H5F_OBJ_ATTR'
- 'H5F_OBJ_ALL'
- 'H5F_OBJ_LOCAL'

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
obj_count = H5F.get_obj_count(fid,'H5F_OBJ_GROUP');
H5G.close(gid);
H5F.close(fid);
```

See Also `H5F.get_obj_ids`

H5F.get_obj_ids

Purpose

List of open HDF5 file objects

Syntax

```
[num_obj_ids,obj_id_list] = H5F.get_obj_ids(file_id,types,
   max_objs)
```

Description

`[num_obj_ids,obj_id_list] = H5F.get_obj_ids(file_id,types,max_objs)` returns a list of all open identifiers for HDF5 objects of the type specified by `types` in the file specified by `file_id`. The `max_objs` input specifies the maximum number of object identifiers to return. `num_obj_ids` is the total number of objects in the list. `types` can be one of the following strings.

'H5F_OBJ_FILE'

'H5F_OBJ_DATASET'

'H5F_OBJ_GROUP'

'H5F_OBJ_DATATYPE'

'H5F_OBJ_ATTR'

'H5F_OBJ_ALL'

'H5F_OBJ_LOCAL'

Examples

```
fid = H5F.open('example.h5');
gid1 = H5G.open(fid,'/g1');
gid2 = H5G.open(fid,'/g2');
gid3 = H5G.open(fid,'/g3');
gid4 = H5G.open(fid,'/g4');
[num_obj_ids,objs] = H5F.get_obj_ids(fid,'H5F_OBJ_GROUP',3);
H5G.close(gid1);
H5G.close(gid2);
H5G.close(gid3);
H5G.close(gid4);
H5F.close(fid);
```

See Also

`H5F.get_obj_count`

H5F.is_hdf5

Purpose

Determine if file is HDF5

Syntax

```
value = H5F.is_hdf5(name)
```

Description

`value = H5F.is_hdf5(name)` returns a positive number if the file specified by `name` is in the HDF5 format, and zero if it is not. A negative return value indicates failure.

Examples

```
value = H5F.is_hdf5('example.tif');
if value > 0
    fprintf('example.tif is an HDF5 file\n');
else
    fprintf('example.tif is not an HDF5 file\n');
end
```

H5F.mount

Purpose

Mount HDF5 file onto specified location

Syntax

```
H5F.mount(loc_id,name,child_id,plist_id)
```

Description

`H5F.mount(loc_id,name,child_id,plist_id)` mounts the file specified by `child_id` onto the group specified by `loc_id` and `name`, using the mount properties specified by `plist_id`.

Examples

Mount one file with a dataset onto a group in a second file and access the dataset via the second file.

```
plist = 'H5P_DEFAULT';
fid2 = H5F.create('file2.h5','H5F_ACC_TRUNC',plist,plist);
gid2 = H5G.create(fid2,'g2',plist,plist,plist);
fid1 = H5F.create('file1.h5','H5F_ACC_TRUNC','H5P_DEFAULT','H5P_DEFAULT')
space_id = H5S.create('H5S_SCALAR');
dset_id = H5D.create(fid1,'DS1','H5T_NATIVE_DOUBLE',space_id,plist);
H5S.close(space_id);
H5D.close(dset_id);
H5F.mount(fid2,'g2',fid1,plist);
dset_id1 = H5D.open(fid1,'/g2/DS1',plist);
H5D.close(dset_id1);
H5F.unmount(fid1,'g2');
H5G.close(gid2);
H5F.close(fid1);
H5F.close(fid2);
```

See Also

`H5F.unmount`

Purpose

Open HDF5 file

Syntax

```
file_id = H5F.open(filename)
file_id = H5F.open(name,flags,fapl_id)
```

Description

`file_id = H5F.open(filename)` opens the file specified by `filename` for read-only access and returns the file identifier, `file_id`.

`file_id = H5F.open(name,flags,fapl_id)` opens the file specified by `name`, returning the file identifier, `file_id`. `flags` specifies file access flags and can be specified by one of the following strings or their numeric equivalents:

'H5F_ACC_RDWR'	read-write mode
'H5F_ACC_RDONLY'	read-only mode

The file access property list, `fapl_id`, may be specified as `'H5P_DEFAULT'`, in which case the default I/O settings are used.

Examples

Open a file in read-only mode with default file access properties.

```
fid = H5F.open('example.h5');
H5F.close(fid);
```

Open a file in read-write mode.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5')
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
H5F.close(fid);
```

See Also

`H5F.close` | `H5ML.get_constant_value`

H5F.reopen

Purpose

Reopen HDF5 file

Syntax

```
new_file_id = H5F.reopen(file_id)
```

Description

`new_file_id = H5F.reopen(file_id)` returns a new file identifier for the already open HDF5 file specified by `file_id`.

See Also

`H5F.open`

H5F.set_mdc_config

Purpose

Configure HDF5 file metadata cache

Syntax

`H5F.set_mdc_config(fileId,config)`

Description

`H5F.set_mdc_config(fileId,config)` attempts to configure the file's metadata cache according to the supplied configuration structure. Before using this function, you should retrieve the current configuration using `H5F.get_mdc_config`.

See Also

`H5F.get_mdc_config`

H5F.unmount

Purpose

Unmount file or group from mount point

Syntax

```
H5F.unmount(loc_id,name)
```

Description

`H5F.unmount(loc_id,name)` dissassociates the file or group specified by `loc_id` from the mount point specified by `name`. `loc_id` can be a file or group identifier.

See Also

`H5F.mount`

Purpose

Close group

Syntax

```
H5G.close(group_id)
```

Description

`H5G.close(group_id)` releases resources used by the group specified by `group_id`. `group_id` was returned by either `H5G.create` or `H5G.open`.

See Also

`H5G.create` | `H5G.open`

H5G.create

Purpose

Create group

Syntax

```
group_id = H5G.create(loc_id,name,size_hint)
group_id = H5G.create(loc_id,name,lcpl_id,gcpl_id,gapl_id)
```

Description

`group_id = H5G.create(loc_id,name,size_hint)` creates a new group with the name specified by `name` at the location specified by `loc_id`. `loc_id` can be a file or group identifier. `size_hint` specifies the number of bytes to reserve for the names that will appear in the group. This interface corresponds to the 1.6 version of `H5Gcreate`.

`group_id = H5G.create(loc_id,name,lcpl_id,gcpl_id,gapl_id)` creates a new group with link creation, group creation, and group access property lists `lcpl_id`, `gcpl_id`, and `gapl_id`. This interface corresponds to the 1.8 version of `H5Gcreate`.

Examples

Create an HDF5 file `'myfile.h5'` with a group `'my_group'` with default property list settings.

```
fid = H5F.create('myfile.h5');
plist = 'H5P_DEFAULT';
gid = H5G.create(fid,'my_group',plist,plist,plist);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5G.open` | `H5G.close`

Purpose

Information about group

Syntax

```
info = H5G.get_info(group_id)
```

Description

`info = H5G.get_info(group_id)` retrieves information about the group specified by `group_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
info = H5G.get_info(gid);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5G.open` | `H5G.create`

H5G.open

Purpose

Open specified group

Syntax

```
group_id = H5G.open(loc_id,name)
group_id = H5G.open(loc_id,name,gapl_id)
```

Description

`group_id = H5G.open(loc_id,name)` opens the group specified by `name` at the location specified by `loc_id`. `loc_id` is a file or group identifier. This interface corresponds to the 1.6 version of `H5Gopen`.

`group_id = H5G.open(loc_id,name,gapl_id)` opens the group with an additional group access property list, `gapl_id`. This interface corresponds to the 1.8 version of `H5Gopen`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
H5G.close(gid);
H5F.close(fid);
```

`H5G.close` | `H5P.create`

H5I.dec_ref

Purpose

Decrement reference count

Syntax

```
ref_count = H5I.dec_ref(obj_id)
```

Description

`ref_count = H5I.dec_ref(obj_id)` decrements the reference count of the object identified by `obj_id` and returns the new count.

See Also

`H5I.get_ref` | `H5I.inc_ref`

H5I.get_file_id

Purpose

File identifier for specified object

Syntax

```
file_id = H5I.get_file_id(obj_id)
```

Description

`file_id = H5I.get_file_id(obj_id)` returns the identifier of the file associated with the object referenced by `obj_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g4');
fid2 = H5I.get_file_id(gid);
name = H5F.get_name(fid2);
fprintf('The filename is %s.\n',name);
H5G.close(gid);
H5F.close(fid);
H5F.close(fid2);
```

Purpose

Name of object

Syntax

```
name = H5I.get_name(obj_id)
```

Description

`name = H5I.get_name(obj_id)` returns the name of the object specified by `obj_id`. If no name is attached to the object, the empty string is returned.

Examples

Display the names of all the objects in the `/g3` group in the example file by alphabetical order.

```
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_INC';
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g3');
info = H5G.get_info(gid);
for j = 1:info.nlinks
    obj_id = H5O.open_by_idx(fid,'g3',idx_type,order,j-1,'H5P_DEFAULT
    name = H5I.get_name(obj_id);
    fprintf('Object %d: ''%s''.\n',j-1,name);
    H5O.close(obj_id);
end
H5G.close(gid);
H5F.close(fid);
```

`H5A.get_name` | `H5F.get_name`

H5I.get_ref

Purpose

Reference count of object

Syntax

```
refcount = H5I.get_ref(obj_id)
```

Description

`refcount = H5I.get_ref(obj_id)` returns the reference count of the object specified by `obj_id`.

See Also

`H5I.dec_ref` | `H5I.inc_ref`

Purpose

Type of object

Syntax

```
obj_type = H5I.get_type(obj_id)
```

Description

`obj_type = H5I.get_type(obj_id)` returns the type of the object specified by `obj_id`. `obj_type` corresponds to one of the following enumerated values.

```
H5I_FILE
H5I_GROUP
H5I_DATATYPE
H5I_DATASPACE
H5I_DATASET
H5I_ATTR
H5I_BADID
```

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g3');
dset_id = H5D.open(fid,'/g4/world');
[~,objs] = H5F.get_obj_ids(fid,'H5F_OBJ_ALL',3);
for j = 1:numel(objs)
    name = H5I.get_name(objs(j));
    fprintf('object ''%s'':  ==> ',name);
    type = H5I.get_type(objs(j));
    switch(type)
        case H5ML.get_constant_value('H5I_FILE')
            fprintf('FILE identifier.\n');
        case H5ML.get_constant_value('H5I_GROUP')
            fprintf('GROUP identifier.\n');
        case H5ML.get_constant_value('H5I_DATASET')
            fprintf('DATASET identifier.\n');
        otherwise
            fprintf('unknown identifier type.\n');
    end
```

```
end
H5G.close(gid);
H5F.close(fid);
```

See Also H5ML.get_constant_value

Purpose Increment reference count of specified object

Syntax

```
ref_count = H5I.inc_ref(obj_id)
```

Description `ref_count = H5I.inc_ref(obj_id)` increments the reference count of the specified by `obj_id` and returns the new count.

See Also `H5I.dec_ref` | `H5I.get_ref`

H5I.is_valid

Purpose

Determine if specified identifier is valid

Syntax

```
tf = H5I.is_valid(obj_id)
```

Description

`tf = H5I.is_valid(obj_id)` determines whether the identifier `obj_id` is valid.

Examples

```
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.close(fapl);
if H5I.is_valid(fapl);
    fprintf('File access property list is valid.\n');
else
    fprintf('File access property list is not valid.\n');
end
```

Purpose

Copy link from source location to destination location

Syntax

```
H5L.copy(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,
   lapl_id)
```

Description

`H5L.copy(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)` copies the link specified by `src_name` from the file or group specified by `src_loc_id` to the destination `dest_loc_id`. The new copy of the link is created with the name `dest_name`.

`dest_loc_id` must refer to either the current file or a group in the current file. If `dest_loc_id` is the file identifier, the copy is placed in the file's root group.

The new link is created with the creation and access property lists specified by `lcpl_id` and `lapl_id`.

Examples

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist_id,plist_id);
g1 = H5G.create(fid,'g1',plist_id);
g2 = H5G.create(fid,'g2',plist_id);
g11 = H5G.create(g1,'g3',plist_id);
H5L.copy(g1,'g3',g2,'g4',plist_id,plist_id);
```

H5L.create_external

Purpose Create soft link to external object

Syntax

```
H5L.create_external(filename,objname,link_loc_id,link_name,
   lcpl_id,lapl_id)
```

Description

`H5L.create_external(filename,objname,link_loc_id,link_name,lcpl_id,lapl_id)` creates a soft link to an object in a different file. `filename` identifies the target file containing the target object. `obj_name` specifies the path to the target object within that file. `obj_name` must start at the target file's root group but is not interpreted until lookup time.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

Examples

```
plist_id = 'H5P_DEFAULT';
fid1 = H5F.create('myfile1.h5');
g1 = H5G.create(fid1,'g1',plist_id,plist_id,plist_id);
H5G.close(g1);
H5F.close(fid1);
fid2 = H5F.create('myfile2.h5');
H5L.create_external('myfile1.h5','g1',fid2,'g2',plist_id,plist_id);
```

H5L.create_hard

Purpose

Create hard link

Syntax

```
H5L.create_hard(obj_loc_id,obj_name,link_loc_id,link_name,
   lcpl_id,lapl_id)
```

Description

`H5L.create_hard(obj_loc_id,obj_name,link_loc_id,link_name,lcpl_id,lapl` creates a new hard link to a pre-existing object in an HDF5 file. The new link may be one of many that point to that object. `obj_loc_id` and `obj_name` specify the location and name, respectively, of the target object, i.e., the object to which the new hard link points.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

Examples

```
fid = H5F.create('myfile.h5');
gid1 = H5G.create(fid,'/g1',0);
gid2 = H5G.create(gid1,'g2',0);
gid3 = H5G.create(gid2,'g3',0);
lcpl = 'H5P_DEFAULT';
lapl = 'H5P_DEFAULT';
H5L.create_hard(gid2,'g3',gid1,'g4',lcpl,lapl);
H5G.close(gid3);
H5G.close(gid2);
H5G.close(gid1);
H5F.close(fid);
```

See Also

`H5L.create_soft`

H5L.create_soft

Purpose

Create soft link

Syntax

```
H5L.create_soft(target_path,link_loc_id,link_name,lcpl_id,
   lapl_id)
```

Description

`H5L.create_soft(target_path,link_loc_id,link_name,lcpl_id,lapl_id)` creates a new soft link to an object in an HDF5 file. The new link may be one of many that point to that object. `target_path` specifies the path to the target object, i.e., the object that the new soft link points to. `target_path` can be anything and is interpreted at lookup time. This `target_path` may be absolute in the file or relative to `link_loc_id`.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

Examples

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5');
gid1 = H5G.create(fid,'/g1',0);
gid3 = H5G.create(gid1,'g3',0);
gid2 = H5G.create(fid,'/g2',0);
lcpl = 'H5P_DEFAULT';
lapl = 'H5P_DEFAULT';
H5L.create_soft('/g1/g3',gid2,'g4',lcpl,lapl);
H5G.close(gid3);
H5G.close(gid2);
H5G.close(gid1);
H5F.close(fid);
```
